#### MALIGNANT DISEASE OF THE SKIN.

The patient was an agricultural labourer, 70 years of age, who had kept at work until three months before his death. At first he noticed an ulcer on the inner side of the right thigh, and soon after enlargement of the glands in the groin. When he came to the Hospital, the whole surface was dotted over with very hard lumps, red on the surface, varying in size from that of a nut to a walnut. There was an epithelial cancer of the glans penis, and almost all the glands in the body were affected. There was a nodule of encephaloid cancer in the heart, spleen, and liver.

Dr. BRISTOWE showed two or three specimens of

#### OLD STANDING CLOTS IN THE HEART CAVITIES,

and brought forward statistics of 42 cases which had come under his observation between November 22, 1855, and October, 1860. He stated that these cases confirmed the views which he had already expressed in a paper published in the *Transactions* of the Society, which were founded on an analysis of 23 or 24 cases. The gist of the views referred to is, that the clots are formed, for the most part, in persons who are dying slowly; that they are formed some time prior to death, and that the softening which takes place in their interior is a process of disintegration, which is common to those with clots in other situations; that they are most frequent in the left ventricle and least frequent in the left auricle; and, further, that age and sex seem to exert little influence upon their production. The following is a tabular analysis of the 42 cases:—29 were males, 13 females—1 occurred between the ages of 10 and 15; 3 between 15 and 20; 4 between 20 and 30; 10 between 30 and 40; 9 between 40 and 50; 11 between 50 and 60; 3 between 60 and 70; and 1 between 70 and 80. In 9 cases the cause of death was phthisis; in 6, bronchitis; in 5, renal disease; in 19, heart disease; in 1, ascites; in 1, tubercular pericarditis; in 1, scarlet fever. In 27 cases they were found in the left ventricle; in 16, in the right ventricle; in 6, in the left auricle; in 19, in the right auricle. In 17 cases they were found in more than one cavity. The clots in the case of scarlet fever were peculiar; they contained fluid in all respects resembling pus, and were associated with sloughing of the tonsils. There was no further evidence of pyæmia in this case, and, unless this is to be regarded as a case of pyæmia, Dr. Bristowe had never met with these clots in cases of that disease.

Mr. MAUNDER exhibited a specimen of

#### WOUND OF THE POPLITEAL ARTERY AND VEIN,

which came into his possession under the following circumstances:—J. M., aged 16, was accidentally wounded in the left thigh with a knife, which entered the limb from before, at the junction of its middle and lower third. Copious hæmorrhage followed, but was readily controlled by a bystander, until the arrival of Mr. Leach, of the Borough, by whom a compress and bandage were applied; bleeding did not recur. The limb below the wound began to swell, and, after forty-eight hours, the bandage was removed. On the seventh day Mr. Maunday saw the case, with Mr. Leach; the limb had become very œdematous and a pulsating tumour, the area of which was extensive and on the increase, existed. A wound, about half an inch in length, through

which a portion of cellular tissue projected, occupied the centre of the swelling; and a little external to the above was a small vesication, caused, probably, by the bandage. The dorsalis pedis artery pulsated; and pressure upon the femoral in the groin checked the pulse both in the above vessel and in the tumour. The posterior tibial artery could not be recognised. The patient was at once removed to the London Hospital, when, after consultation with his colleague, and with Mr. Leach, Mr. Maunder enlarged the wound in the thigh upwards and downwards with a view to find the wounded vessel, and to ligature it above and below the wound. The aneurismal tumour being laid open, its contents, fluid blood, gushed forth, and the forefinger of the left hand quickly inserted, followed the original track of the knife, and entered a wounded vessel, the tip of the finger being then bathed in warmer blood. With great difficulty, by reason of the depth of the wound, and constant oozing of dark blood whenever the finger was moved in the least degree, a ligature was applied to an artery above and below the wound, in it. The finger was now removed, when, quite unexpectedly, dark blood gushed up as before, and, believing that the main vein was also wounded, amputation was at once performed at the seat of injury. The popliteal artery and vein proved to be both wounded—the former to the extent of one-half its circumference; the latter was transfixed and nearly severed. The boy died exhausted on the sixth day.

Mr. GAY then brought forward a specimen from a case of

EXTENSIVE SLOUGHING OF THE SKIN.

A man, 21 years of age. He complained of pain in the region of the liver, which in three weeks was followed by fluctuation. The swelling was punctured on October 11, and some pus evacuated. The wound sloughed, and, after awhile, there was one large ulcer from the umbilicus to the ribs. The principal part of the external oblique had been removed, and the sheath of the rectus opened. He died on January 21. At the time of death, the sloughing had extended, in front, to the umbilicus, and, behind, to within an inch of the vertical column, above to the nipple, below to three inches below the spine of the ilium. It had destroyed a great part of the external oblique, transversalis, internal oblique, and rectus muscles. It had penetrated the abdominal cavity by a large opening just below the borders of the ribs, and there exposed the edge of the liver. At the junction of the ascending with the arch of the colon, the bowel had been perforated, but the peritoneum had become adherent to the opening, and no perforation had taken place. Mr. Savory, who saw the case, thought that the disease commenced by an abscess in the liver.

Mr. HOLMES exhibited a specimen of

CANCER OF THE FEMALE BLADDER.

The patient died of simple atrophic softening of the brain. There was no cancer of the genital organs. This was (Mr. Holmes said) the only case of cancer of the female bladder which had been brought before the Society.

Mr. TEEVAN exhibited a specimen showing

FAT IN THE PLEURA.

The fat was between the pleura costalis and pleura pulmonalis. He believed that the "fringes of fat," described by Sir Astley Cooper as having been found at the autopsy of George IV., were really fat, and not, as Dr. Watson supposed, emphysematous appendices.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, February 19, 1863:—

Frederick Wright, Stamford-bridge, Yorkshire; John Berry Mulock, London; George John Blason, Guy's Hospital; John Robinson, Winterton, Lincolnshire; Arthur Wigglesworth, Liverpool.

The following gentlemen also on the same day passed their First Examination:—

Chauncey Puzey, Guy's Hospital; Edward Ashwell Burnham, Guy's Hospital.

APPOINTMENTS.

BRADSHAW, JOHN T., M.R.C.S. Eng., has been appointed Consulting Surgeon to the Huddersfield Infirmary.  
 CLARKE, WM. FAIRLIE, M.A. (Oxon.), M.R.C.S. Eng., has been appointed Surgical Registrar to King's College Hospital.  
 COLEMAN, ALFRED, M.R.C.S. Eng., has been appointed an Assistant Dental Surgeon to the Dental Hospital, Soho-square.  
 FORSYTH, W. F., L.D.S., R.C.S.E., has been appointed an Assistant Dental Surgeon to the Dental Hospital, Soho-square.  
 GREGSON, D., L.D.S., R.C.S.E., has been appointed an Assistant Dental Surgeon to the Dental Hospital, Soho-square.  
 HAYWARD, HENRY H., M.R.C.S. Eng., has been appointed an Assistant Dental Surgeon to the Dental Hospital, Soho-square.  
 HEATH, CHRISTOPHER, F.R.C.S. Eng., has been elected Surgeon to the West London Hospital and Dispensary, Hammersmith.  
 HILL, A., L.D.S., R.C.S.E., has been appointed an Assistant Dental Surgeon to the Dental Hospital, Soho-square.  
 HUNT, WILLIAM J., L.R.C.P. Edin., has been appointed Medical Superintendent and Manager of the Hoxton House Lunatic Asylum.  
 SIMPSON, THOMAS, M.D. Edin., has been elected Consulting Physician to the York County Hospital.  
 SWAINE, WILLIAM E., F.R.C.P. Lond., has been elected Physician to the York County Hospital.  
 WALKER, J., M.D., has been appointed an Assistant Dental Surgeon to the Dental Hospital, Soho-square.

DEATHS.

ATKIN, JOHN, Surgeon, at Billesdon, Leicester, on January 31.  
 BULL, FRANK, M.D., at Toronto, Upper Canada, on January 20, aged 31.  
 CAMPBELL, ARCHIBALD, M.D. Glasg., at Cawdor-place, Oban, Argyleshire, on February 10, aged 51.  
 DOUGLAS, J. A., at Scawby, Lincolnshire, on January 5, aged 82.  
 JAMES, JOB, J.P., in practice prior to 1815, at Pontmorlais, Merthyr Tydvil, on February 11, aged 75, formerly Surgeon R.N.  
 JONES, WILLIAM HENRY, M.D. Edin., Staff Assistant-Surgeon Army, at 2, Waterloo-cottages, Torquay, on February 11, aged 24.  
 LOVETT, SAMUEL, M.R.C.S. Eng., at 23, Clare-street, Lincoln's-inn-fields, on February 19, aged 58, for twenty-two years one of the Medical Officers to the Strand Union.  
 MARTIN, GEORGE WHITE, L.R.C.P. Ed., at Rochester, Kent, on February 19, aged 26.  
 MONTGOMERY, ANDREW, late Inspector-General of Hospitals, Bombay Army, at 19, Marlborough-buildings, Bath, on February 16, aged 69.

PROFESSOR PURKINYE.—This Nestor of German physiologists, has just celebrated with great *éclat* his seventy-fifth birthday, all the Medical bodies uniting in the ovation.

ROYAL COLLEGE OF SURGEONS.—The introductory portion of the course of lectures now being delivered in the theatre of the above Institution, will be concluded on Tuesday next, when Professor Huxley will give a review of the "Classification of the Mammalia;" on Thursday he will give the "Structure and Development of the Vertebrate Skeleton." The sixth lecture will be given this day (Saturday). Amongst the celebrities who honour the Professor with their company, we observe, on every occasion, Bishop Colenso, who appears to take, with the public generally, a great interest in these lectures.

ST. BARTHOLOMEW'S HOSPITAL.—A large meeting of the governors of this charity took place on Wednesday last, in the great hall, for the purpose of electing a president in the room of Mr. Cubitt, who, it may be remembered, held office, but resigned it when he dissolved his connection with the City, and at the same time intimating that his resignation was owing to the objections started by others, rather than the free exercise of his own will. The Lord Mayor was put in nomination, whereupon Mr. Cubitt was then proposed for re-election, and, on the votes being taken, was declared to be elected by a majority of 87 votes over 44.

LONDON INSTITUTION.—Mr. Carter Blake's lecture on Tuesday last was devoted to the *Aves Altrices*. The order *Insessores* was divided into the *Dentirostres*, *Conirostres*, *Tenni-rostres*, and *Fissirostres*, examples of each order being given. The orders *Volitores* and *Scansores* were likewise described in detail. Examples of the geographical distribution of the Raptorial order were adduced, and the lecturer concluded that portion of his course which relates to the class of birds by a concise summary of the geological facts known, respecting their range in time. The description of the Mammalian class will be commenced on the 4th of March.

ROYAL SOCIETY OF EDINBURGH.—Dr. J. G. Wilson, F.R.C.S.E., of this city, and Dr. Matthews Duncan, F.R.C.P.E., of Edinburgh, were, on Monday last, elected Fellows of the Royal Society of Edinburgh.

**PREVALENCE OF EPIDEMIC PURULENT OPHTHALMIA IN GERMANY.**—For a considerable time past purulent ophthalmia has extensively prevailed at Frankfort and on the Lower Rhine; and while the military have suffered less from this scourge than in former years, schools and various other civil establishments have presented subjects of its attack in large numbers.

**DR. FRIEDRICH JAGER.**—This well-known Vienna oculist has recently celebrated his jubilee consequent upon attaining the fiftieth year of his doctorate, being in excellent health and spirits. All the Medical corporations complimented him, and the College of Doctors presented him with a new diploma, and represented to the Minister of State the desirableness of some recognition of his merits. His influence on the progress of ophthalmic medicine is too well known to require more than adverting to. The most faithful apostle of his master Beer, the founder of ophthalmology in Austria, his reputation has spread throughout Europe as teacher and Practitioner, and foreign orders of merit have been freely accorded to him.

**THE LEVÉE.**—The following members of the Medical Profession attended the levée of H.R.H. the Prince of Wales on Wednesday, viz., Sir Rutherford Alcock, K.C.B., her Majesty's Envoy Extraordinary and Minister Plenipotentiary in Japan; Sir Henry Holland, Physician in Ordinary to the Queen; William Lawrence, Esq., Serjeant Surgeon to the Queen; William Fergusson, Esq., Surgeon Extraordinary to the Queen. Doctors Lavies, Pickford, Dalton, Arthur Farre, Cape, Jeaffreson, J. Stevenson Bushnan, T. De Meschier, E. A. Parkes, G. T. D. Evans, F. G. Read, Breslin, E. Meryon, Robert Ferguson, Farr, Watson, Granville, Ramsbotham, Alexander Bryson, Golden, Smith, Waller Lewis, Forbes Winslow, Gideon Dolmage, T. G. Balfour, Alexander Marsden, McCann, Ashley, Kirkman, Fraser, Routh, Professor Owen, Deputy Inspector-General Thomas Longmore; and Messrs. Wakley, Reeves Traer, White Cooper, R. W. Tamplin, Dendy, W. Sands Cox, Propert, Thomas Fitzgerald, B. E. Brodhurst, S. S. Scriven, G. B. Childs, Erasmus Wilson, R. McCormick, R.N. The presentations will appear next week.

UNIVERSAL distrust and anticipation of evil are the present distinguishing features of the Army Surgeon's physiognomy. We cannot blame them. There are no men to whom the Government owes more—there are none to whom it has paid so little. From the earliest days of British connexion with the affairs of India, her Medical servants have been conspicuous in smoothing the way for the acquisition of permanent rights. At the time when all other Europeans were looked on with suspicion; the skill of the western Physician was a passport to the eastern palace. The gratitude called forth by his efforts was used, not for the furtherance of his own personal avarice, but in securing an advantageous footing for his countrymen in the land now called British India. These services are, however, now forgotten; and, in place of gratitude, the Home Government have, for some time past, being using such endeavours as they could to lower the *status* and ignore the claims of the Army Medical Department.—*The Madras Times*, January 14, 1863.

**THE RIBERI PRIZE.**—Professor Riberi left by his will a valuable bequest to the Turin Royal Academy of Medicine and Surgery, in the foundation of which he took a leading part. It consists in a sufficient sum of money to constitute seven prizes of 20,000 francs each, one to be decreed every third year. The Academy, in fulfilling the wishes of its late President and Professor, has determined that the first period shall comprise from January 1, 1862, to December 31, 1864. All works, whether published or written, upon any subject relating to Medicine or Surgery, will be admitted to the *concours*, the Academy deciding in favour of such of them as exhibit a true and important progress in Medical science. The printed works should be sent in duplicate, and, whether printed or written, they must be in the Italian, Latin, or French language. The author of a manuscript work is at liberty either to make his name known or to send it in a sealed packet. All works must be forwarded free any time before, but not after December 31, 1864. All works sent will be retained by the Academy, but the author of a manuscript can have a copy made at his own expense. It is requested that, in the letters accompanying their works, authors will indicate the most important portions or arguments of these to which they think the attention of the judges should be especially directed.

**LIBEL ON A MEDICAL MAN.**—At the Southwark Police-court, on Monday last, John Finch, a teacher and private tutor, residing at No. 11, Wallgrave-place, Earl's-court-road, Kensington, was summoned before Mr. Burcham for publishing a libel, containing defamatory statements concerning Dr. John Shea, of 84, Blackfriars-road. The evidence completely proved the publication of a series of attacks on the character of the prosecutor and his family of the most atrocious description. Dr. John Shea, the complainant, said he resided at 84, Blackfriars-road. The defendant had been tutor to four of his sons, and left about autumn, 1861. He was always treated kindly and with the greatest respect, and he had very lately recommended him as a tutor to several respectable families. He could not account for his writing and distributing such productions. They had been sent about in all directions. The rector of the parish had received one, and several of his neighbours had been supplied with them. About a year ago the prisoner circulated some scurrilous papers among his friends, but he took no notice of them, thinking that he would discontinue to do so. Mr. Burcham told the prisoner that Dr. Shea had acted with great forbearance in not proceeding against him when he circulated the first libels. He committed him for trial at the next Central Criminal Court sessions, but would accept bail for his appearance, himself in £50 and two sureties in £25 each. Bail not being forthcoming, he was committed to prison.

**THE TWICKENHAM ECONOMIC MUSEUM.**—In a letter to the Rev. J. B. Owen, read at the National Club on January 20, Mr. T. Twining has announced that a collection, in the formation of which he has been for many years engaged, and to which he gives the name of Economic Museum, is now thrown open to the public. This collection contains designs for town and country dwellings for the labouring classes, hospitals, asylums, schools, cooking establishments, baths, and washhouses; models of the most remarkable British and continental designs; specimens of building materials of every description; an assortment of building ironmongery; a collection of British and foreign stoves; estimates, illustrated by specimens, of furniture and clothing required by the poor; popular illustrations of food economy and domestic hygiene; special requirements of cottagers, emigrants, etc.; also indications of every kind for facilitating the formation of museums for the instruction and benefit of the working classes. The use of a collection so valuable is a real boon to those who are devoting time and attention to the subjects of social science, and Mr. Twining, by placing it within their reach, has proved himself a public benefactor. The museum building is very near the Twickenham railway-station, accessible in half an hour by fast trains from the Waterloo terminus, and Mr. Twining's curator is always in attendance to give the required explanations, on Wednesdays and Saturdays, between two and five p.m. In reference to admission, Mr. Twining wishes it to be known that, "as the collection has been formed purely for purposes of social improvement and Christian benevolence, all admissions are gratuitous, and any persons engaged in raising the condition of their poorer brethren will always be welcome visitors. Any number of cards of admission may be obtained at the Society of Arts, together with programmes and other printed information."

**EPDS v. MORRIS.**—COURT OF QUEEN'S BENCH, GUILD-HALL, FEBRUARY 24.—This was an action by a Practitioner of Medicine to recover from the defendant for attendances upon a lady to whom he had been married. The defence was, that at the time he married her she was married to another person then still living, so that her second marriage was bigamous and void. To this it was replied that the defendant had held her out as his wife to the world, and that, therefore, he was as much liable for her necessary debts as if she was really his wife. In 1841, the lady, at the early age of 17, was married to her first husband, from whom, a few years afterwards, she was divorced *à mensâ et thoro*. In 1846 she went through the ceremony of marriage with the defendant, who knew of the fact of the former marriage, but supposed that the divorce dissolved the marriage and made her free to marry again. They lived together as man and wife until the year 1854. They then separated, and she has since lived by herself in lodgings, bearing his name, and having an allowance from him—first of not less than £1000, then of £500, and ultimately of £250 a-year. This money was sent to her down to the present time by the defendant's attorney under the name of Mrs. Morris. The plaintiff's bill was £127 for

attendances during the years 1861 and 1862. The fact that the former, or rather the true, husband was alive at the time of the second marriage was proved. It did not appear that the plaintiff knew of the defendant's marriage with the lady, but he said he knew her as Mrs. Morris. The Lord Chief Justice, in summing up the case to the jury, said the sole question for them was, whether at the time of the attendances the defendant allowed the lady to hold herself out as his wife. No doubt, so long as they were living together, that would be so. But so soon as a man separated himself from a mistress, and ceased to live with her, of course that implied holding her out as his wife was put an end to. The question was whether, when a tradesman or a Medical man found a woman living by herself, and chose to trust her without making any inquiry, he could make liable for her debts any one with whom she had formerly lived as his mistress. It had not appeared that the plaintiff knew, as a fact, the actual marriage between the parties. The jury at once found for the defendant.

**ANTHROPOLOGICAL SOCIETY OF LONDON.**—The first meeting of this Society took place on Tuesday last, when an introductory address was delivered by the President, Dr. Hunt, on the "Study of Anthropology." He observed that his position in the chair had been caused more by the interest he took in the objects of the Society, than by any special qualification for the office he held. He defined Anthropology to mean the science of man and mankind, and said it had no right to be confined within such narrow limits as simply the distinction of man from the inferior animals. Before advance could be made, it was necessary to settle what was the distinction of man from the Mammalia; and man's place in nature was at the very root and foundation of the science of mankind. Man, hitherto, had been looked upon as a link in the chain of creation totally disconnected with every other link, and inquirers had sought for some fresh laws applicable to this isolated being. It was necessary to give up such notions, and study man scientifically; the bugbear to the science of man had been *a priori* assumptions. They must take a lesson from the geologist, and found a science on facts, and there could never be a science of man until they adopted a scientific method of investigation. Nor were they to confine the question to physical Anthropology, which Blumenbach first introduced; but must study the mental and moral characters of mankind generally. The negro differed far more from the European, mentally and morally, than he did physically. The science of Anthropology was not only in its infancy, but, as a science, hardly yet had any existence. There were plenty of good reliable facts respecting every animal but man. No progress had been made for the last fifty years; but the geologists during that time had founded their science on a sure basis. It was necessary for them to begin *de novo*, and widen and deepen their sphere of observation, and collect a wider and more systematic range of facts. They must reform the terms in use, many of which were founded on vague historical statements, and the use of them implied a theory. The hypothesis of unity or plurality of the origins of mankind could not be discussed on scientific grounds at all. Everything relating to mankind seemed to be in a state of chaos, and we ought to confess our ignorance, and say

"All we know is,  
Nothing yet is known,"

either respecting the origin of mankind, or of the laws by which he is governed. Anthropology had wonders as great as any other branch of study to reveal, and what was now wanted were earnest workers and real lovers of truth. The secretary, Mr. Carter Blake, spoke at great length respecting the various subjects which would be brought before the society. A discussion ensued, which was joined in by Messrs. Burke, Blackstone, Chambers, Blake, Mackie, Dr. Gibb, Avery, Bouverie, Pusey, Collingwood, Prideaux, and the President. The next meeting will take place on March 24.

### BOOKS RECEIVED.

Evidence as to Man's Place in Nature. By Thomas Henry Huxley, Fellow of the Royal Society. London and Edinburgh: Williams and Norgate. 1863. Pp. 159.

The Principles and Practice of Obstetrics. By Gunning S. Bedford, A.M., M.D., Professor of Obstetrics in the University of New York, etc., etc. With 4 coloured Lithographic Plates and 99 Wood Engravings. Third Edition, carefully revised and enlarged. New York: William Wood and Co. 1863. Pp. 742.

Stammering and Stuttering: their Nature and Treatment. By James Hunt, Ph.D., F.S.A., etc. Fifth Edition. London: Longmans. 1863.

Researches on the Nature, Pathology, and Treatment of Emphysema of the Lungs, and its Relations with other Diseases of the Chest. By A. T. H. Waters, M.D., Member of the Royal College of Physicians, London, Physician to the Northern Hospital, and Lecturer on Anatomy and Physiology in the Royal Infirmary School of Medicine, Liverpool. London: John Churchill and Sons, New Burlington-street. Liverpool: Adam Holden, Church-street. 1862. Pp. 114.

A Systematic Handbook of Volumetric Analysis; or, the Quantitative Estimation of Chemical Substances by Measure. Adapted to the Requirements of Pure Chemical Research, Pathological Chemistry, Pharmacy, Metallurgy, Manufacturing Chemistry, Photography, etc., and for the Valuation of Substances used in Commerce, Agriculture, and the Arts. By Francis Suttou, F.C.S., Professor of Practical Chemistry, Norwich. London: John Churchill and Sons, New Burlington-street. 1863. Pp. 282.

Anatomy of the Parts concerned in Femoral Rupture. By George W. Callender, Assistant-Surgeon to, and Demonstrator of Anatomy at, St. Bartholomew's Hospital. London: John Churchill and Sons, New Burlington-street. 1863. Pp. 51.

A Manual of Animal Physiology, for the Use of non-Medical Students; with an Appendix of Questions from various Examination Papers, including those for the B.A. Lond. for the last Ten Years. By John Shea, M.D., Bachelor of Arts of the University of London, Member of the Royal College of Surgeons, etc., etc. London: John Churchill and Sons, New Burlington-street. 1863. Pp. 240.

Clinique Chirurgicale. Par J. G. Maisonneuve, Chirurgien, de l'Hotel-Dieu de Paris, Membre Fondateur et Honoraire de la Société de Chirurgie, etc., etc. Tome Premier. Paris: F. Savy, Libraire-Editeur, 24, Rue Hautefeuille. 1863. Pp. 640.

Illustrations of the Surgery of the Female Pelvic Organs, in a Series of Plates taken from Nature; with Physiological and Pathological References. By Henry Savage, M.D. Lond., F.R.C.S., Physician to the Samaritan Hospital for Women. London: Churchill and Sons. 1863. 4to. 12 Plates.

Proceedings of the International Temperance and Prohibition Convention, held in London, September, 1862. London: Job Caudwell. 1862.

### PAMPHLETS.

Contribution to the Normal and Pathological Histology of the Kidneys. By V. Rasmussen, Candidate in Medicine and Surgery. Translated from *Bibliothek for Laeger*, for April, 1862, by William Daniel Moore, M.D., etc.

The Minute Anatomy and Physiology of the Nervous System in the Lobster. By T. S. Clouston, M.D. Reprinted from the *Edinburgh New Philosophical Journal* for January, 1863. Pp. 34.

On Special Hospitals. By Mr. W. Martin, F.R.C.S.

### NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Reports of Dr. Brown-Séguard's and Dr. Pavy's lectures are unavoidably postponed until next week.

*The Midland Society of Chemists and Druggists.*—An association bearing the above name has been formed at Nottingham for the protection of the interests of chemists and druggists, and for the interchange of opinion on matters of trade and chemical science. The president of the society is Mr. Charles V. Wilcockson. Their first annual festival was held on the 12th inst., at the Exchange. Dr. Robertson, in returning thanks for the Medical men of Nottingham, made a racy address, from which we take the following extract:—

"On an occasion like this, compliments were not what were required—they had met to hear the truth. (Hear, hear.) Well then, in former times, a youth, just come from school, was put to the Medical Profession. He was at once appointed to dispense medicine, notwithstanding that he might be doing so in cases involving the life of a father of a family. This was a mistake (hear, hear); and seeing that there was no knowing at the present day what new discoveries in Medicine might be made, he trusted very sincerely that the day was not far distant when dispensing would be totally dissociated from the Medical Profession. (Applause.) He remembered the song that was popular in his younger days—the song of a young student, which exactly described the state of things which might be supposed to exist now:—

"Now endless scrapes Master Harry got in  
By sending out physic in phials unclean;  
He nearly killed a nabob sent home diabetic,  
Through ne'er weighing calomel or tartar emetic.  
But the worst mixture of all was a label one morn  
Prescribing prussic acid for a baby just born.  
Harry swore that the gov'nor the case had mistook—  
He'd be hang'd if *pro re nata* wasn't writ in the book."

(Cheers and laughter.) This (he said) was the sort of thing that was likely to occur. At present they knew that calomel and black draughts were good things; but what they were likely to have neither the Medical men nor the druggists could tell. Not at all unlikely that they would be recommended one of these days to try the saccharated carbonate of quinine lime-treacle, iron, tartaric acid, and tobacco—(loud laughter);—and, under these circumstances, he contended that it was material that the dispensing should be dissociated from the Medical Profession. He was sure that the Medical men and the druggists also would be gainers by the change. He agreed with the programme as read by Mr. Atherton in every thing but that relating to Medicine, and he thought that druggists should not interfere with that, because it belonged exclusively to the Profession, for this reason: if our watch is out of order, we take it to the watchmaker, simply because he understands the internal mechanism. Now, complicated as that machinery was, that of the human frame, internally, was more so. The chemist understood all the external, but he had not been trained to the internal. To give an illustration:—The other day he became acquainted with the case of man who went to a Medical Practitioner and described his ailment. He was prescribed for, paid his fee, put the prescription into one of his breeches' pockets and went away.

He went to another Medical man, told his tale, was examined, prescribed for, paid his fee, and, placing that prescription in his other pocket, went away. He proceeded to a chemist's shop not a hundred miles from Longrow to consult the celebrated proprietor of that establishment. 'I shall be obliged,' said he to the chemist (telling him also his complaint), 'if you can tell me which of these prescriptions is the right one?' (Laughter.) Said the chemist, 'I could not recommend either of them; but I'll tell you what, I'll give you something that will do you more good myself.' (Roars of laughter.) Well now, he submitted there should be some limit to this sort of thing. He could understand a chemist prescribing for a man who should come into his shop suffering from a pain in the stomach; but with such cases he contended the province of chemists should be abridged."

#### QUALIFICATIONS FOR POOR-LAW MEDICAL OFFICERS.

The subjoined replies have been given by the Law Officers of the Crown in Ireland, in answer to queries submitted to them by the Poor-law Commissioners, relative to the interpretation of their recent warrant respecting the qualifications of Medical Officers of workhouses and dispensaries:—

##### ROYAL COLLEGE OF SURGEONS IN IRELAND.

Queries submitted by the Poor-law Commissioners to the Attorney-General and the Solicitor-General for Ireland, with their opinions thereon:—

##### Queries.

1. Whether the Royal College of Surgeons in Ireland has power and is competent to grant letters testimonial and diplomas, testifying that the person to whom same may be granted is qualified to practise Medicine as well as Surgery?

2. Whether, if the General Council of Medical Education shall register, under the provisions of the statute 21 and 22 Vic., cap. 90, the letters testimonial or diploma to practise Medicine, so granted by the College of Surgeons, the person so registered is to be considered in all respects as holding the qualifications required in that behalf by the order of the Commissioners above stated [in the case]; or would it be competent, notwithstanding such registry, for the Commissioners to question the power of the College of Surgeons to grant such diploma in Medicine?

##### Opinions.

1. After perusing and considering the Charters of the College of Surgeons, we are of opinion that it has not power, and is not competent to grant a diploma or degree in Medicine.

2. We do not think that the registration of such letters testimonial or diploma to practise Medicine can be held to qualify the person registered within the meaning of the order of the Poor-law Commissioners. That order requires the possession of a diploma to practise Surgery, granted by a body competent to give it, and a degree in Medicine, granted by a body having power to give it also; and, if we are right in our opinion, that the College of Surgeons is not authorised by its charters to give a degree in Medicine, the giving of such a degree, even though it were subsequently registered by that College, would not supply the necessary qualification.

THOMAS O'HAGAN.  
JAMES A. LAWSON.

December 24, 1862.

##### APOTHECARIES' HALL, IRELAND.

Queries submitted by the Poor-law Commissioners to the Attorney-General and Solicitor-General, with their opinions thereon:—

##### Queries.

1. Whether the Apothecaries' Hall, Ireland, has power and is competent, either under its charter or by usage or any common law, right, or otherwise, to grant a diploma or licence to practise Medicine?

2. Whether, if the General Council of Medical Education shall register under the provisions of the statute 21st and 22nd Vic., cap. 90, the certificate granted by the Apothecaries' Hall, the person holding such certificate, and being so registered, but having no qualification, licence, or diploma from any other body or university competent to grant the same, is to be considered in all respects as holding the several qualifications required in that behalf by the Poor-law Order of October 10, 1862, or can the Commissioners legally object to confirm the appointment of such a person as a Medical Officer under the Poor-law or Medical Charities' Act, and give such general advice for the guidance of querists as you may consider necessary?

—*Dublin Evening Mail.*

##### Opinions.

We think that the Apothecaries' Hall, Ireland, has no power to grant a diploma or licence to practise Medicine.

We are of opinion that he cannot be considered to be qualified within the Order of October 10, 1862.

THOMAS O'HAGAN.  
JAMES A. LAWSON.

February 11, 1863.

#### A FRUIT OF THE FEMALE PHYSICIAN MOVEMENT.

The following paragraph appears in a Nottingham paper. Quackery in crinoline is not new, but the diploma is a novel feature in such a manifesto:—

"*Novelty in English Medical Practice.*—Our friends who reside on the other side of the Atlantic have now for some years availed themselves of the services of female practitioners of medicine, one excellent consequence of which, at least, has been that many of the weaker sex, who would silently have endured years of suffering from a dislike to consult a male practitioner, have unveiled their miseries to one of their own sex, and been spared years of wretchedness by a speedy relief. Female Doctors of Medicine are a great boon to society, and an inestimable safeguard to the feelings of delicacy. In England, we believe, only one female practitioner holding a diploma is at present practising, Mdle. Cavania, Hospital, Lordsmill-street, Chesterfield, and 2, Station-street, Nottingham, and 4, King-street, Derby, who is certainly effecting a revolution in Medical practice, as evinced by the immense number of cures which she has performed in Chesterfield, Nottingham, and the surrounding townships, and the daily increasing number of patients, particularly females, who are wisely availing themselves of her professional knowledge and skill, of which report speaks as being of a very high order. The press bears testimony of her great success in the treatment of disease:—in what town, village,

or hamlet in the Midland Counties has not her fame widely spread? Hundreds of persons have tendered their thanks, and requested their cures to be published in the local newspapers, for the benefit of others. Mdle. Cavania's days of attendance at 2, Station-street, Nottingham, are every Monday, Wednesday, and Saturday."

#### PYTHOGENIC FEVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—On what principle of etymology is this word "pythogenic" formed, and what does it mean? If derived from *πυθος* and *γενικός*, it would signify—"belonging to the race of Pytho"; and this latter word, in combination, might either imply a native of Pytho, or one of the great serpents named after the Pythian one slain by Apollo.

"Genetic" (*γεννητικός*) means—"possessing generative power," while "genic" (*γενικός*) is equivalent to the Latin *genitalis*. Why are we not to rest contented with "enteric,"—a word which everybody who has the slightest knowledge of Greek can understand, instead of coining one so puzzling and uncouth as "pythogenic"? I am, &c.

February 18.

QUERENS.

#### MERCURY IN SYPHILIS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—With reference to Mr. Solly's remark (*Medical Times and Gazette*, February 21, 1863, page 199), will you kindly permit me, through your valuable columns, as an old regimental Surgeon, to say, I never, even as assistant, considered myself restricted to any peculiar mode of treatment in syphilis; that I frequently used mercury; and can bear testimony also to the excellent effects, even in extreme cases of tertiary, of alternating mild mercurial courses judiciously conducted with those of iodide of potass and sarsa, the patients being restricted to the milk diet of the military hospitals? Mr. Solly may have been misled by the lectures of the late Dr. Thomson, of Edinburgh, and the late Mr. Guthrie, both military Surgeons; but there is every variety in the army as well as in civil life, though I am not sure but there was some little restriction or understanding when first I entered the service, thirty-five years ago—at all events, non-mercurial was then in its heyday in the army. I am, &c.

R. H. A. HUNTER, Staff-Surgeon, H.P.

Moffat, February 23.

#### GRADUATION AT ST. ANDREWS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—One of the "individuals" to whom I referred in my note, contained in your Journal of February 14, having kindly come forward as a fellow graduate to disabuse my perturbed mind and allay its excitement, has, I think, conferred a favour, not upon me alone, but upon the graduates of St. Andrews at large.

Your correspondent, "*Δικη*," says:—"If the *Senatus Academicus* have, through force of circumstances, deviated from the usual track, and admitted a select number of gentlemen to examination before the completion of their entire curriculum, I could show your correspondent that such procedure is by no means without precedent with other examining boards, and that, in this case, the *Senatus* have been especially careful in withholding the parchment until such curriculum in its entirety is fulfilled."

Does "*Δικη*," in the face of the published list and calendar of the University, mean to assert that he has not been capped, and that his name is not inserted in the calendar as a Doctor of Medicine? Will he inform your readers upon what conditions men were entitled to gain admission amongst the select number, and how far these conditions were made known to students generally of the British Medical schools?

Your correspondent then condemns my language, and seems to have forewarned that the *Senatus* will severely censure me for my depreciation of the performance of their duty. My reply is, if the *Senatus* is not prepared to give a full explanation, in the *Medical Times and Gazette*, of the performance of so unique a duty, it is little, very little, I shall value any censure they may please to favour me with.

Lastly, "*Δικη*" says, "Perhaps the time is not far distant when, in Medicine as in kindred sciences, a man's attainments will gain the meed of honour, even though the prescribed onerous formulæ of classes should remain unfulfilled." Hitherto, I have had every reason to believe that Medicine has for years past stood far above other sciences. My belief is not in the least degree shaken, and I sincerely hope the time is very far distant when, from lack of a regular and complete academical education, the Medical Profession shall sink below her compeers.

In concluding this note, I cannot pass over Dr. Day's reply to Dr. Kealy without remarking that I am prepared to substantiate, in its main points, the article to which Dr. Day refers as containing mis-statements.

I am, &c.

A MATURE GRADUATE.

[The old theologians, when baptism had been improperly performed, said, *Factum valet; fieri non debet*. With the same words we may wind up the controversy respecting the admission of improper candidates to the highest honours of their Profession at St. Andrews.—ED.]

#### PERVIN v. THE BRIGHTON RAILWAY COMPANY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your editorial remarks of last week upon the above case you do me a great injustice, and I hope, therefore, you will permit me to make a few observations in reply. In the first place, I never stepped out of my Professional *status* in settling with the sufferers. As the Medical adviser of the company, well acquainted with the nature of the injury which the party had sustained, I was better qualified than a lawyer or one of the company's clerks to determine whether the amount of compensation claimed was reasonable and just; and, therefore, when the patient was convalescent, and had arranged with his private Medical attendant what sum to ask from the company, and I was appealed to, I did not hesitate, when the amount was within a certain sum—and, in my judgment, not beyond what the party was entitled to—at once to accede to it; and, in thus acting, I felt that I was the friend of the patient and the protector of the company from imposition.

Where the demands of the injured party were unreasonably or extortionately large, I submitted them to the traffic manager or the directors, with what explanation I deemed called for, and was guided by their decision in the matter.

Surely this was a preferable proceeding, in ninety-nine cases out of a hundred, to allowing the party to fall into the hands of an attorney, whose costs and expenses would have deprived him of a large portion of the compensation money.

If I had time, and you could afford me space in your able Journal, I could relate some of the grossest cases of attempted imposition, arising

out of that melancholy accident, which would go far to alter the public mind, and modify the excessive damages which juries are accustomed to give to sufferers from railway accidents. One fact I may, however, state, that the parties who applied for compensation after the accident in question, exceeded in number the tickets issued for the two trains.

Permit me, in conclusion, to relate the leading points in the case of Pervin—the one which, on trial, called forth the harsh and unjustifiable observations of the judge and your editorial comments. Pervin, after the accident, went to London, returning to his home, in Brighton, the following evening. Within an hour or so of his arrival, the Surgeon of the company, Mr. Verrall, visited him, and, after a careful examination, came to the conclusion that his injuries were very slight. The following day, the father sent for his private Medical attendant, Mr. Taaffe, who continued to visit him until September 9—about a fortnight—when he left him quite convalescent. On September 2, I saw the young man with Mr. Taaffe, examined him very carefully, and arrived at the same conclusion as Mr. Verrall and Mr. Taaffe, viz., that the injuries were very slight. That the father thought so, too, as well as the patient, may be inferred from the fact mentioned by Mr. Taaffe—that they had spoken to him about the compensation some days before I was called in. At this meeting, the amount of compensation was arranged in another room by the father and Mr. Taaffe: the latter submitted it to me, and I agreed to pay it on behalf of the railway company.

The young man soon afterwards went into the country, and neither Mr. Taaffe, I, nor the railway company, heard anything more of him for the period of twelve months, when a London solicitor wrote to the company, demanding the sum of £2000 for compensation for the injuries his client had sustained in the Clayton-tunnel accident. On inquiry we ascertained that in February, 1862, nearly six months after the accident, this young man entered a benefit society, was examined carefully by the Surgeon, and stated, in answer to certain questions, that he was then in excellent health, that he had never been ill nor attended by a Doctor in his life, never had spitting of blood, etc. To these questions and replies he signed his name, and was admitted a member of the society as a sound man.

In the following month (March) he came to the Surgeon with a deep-seated whitlow of the finger, which he refused to have operated on, and the consequence was suppuration and sloughing, followed by a second whitlow and a low, typhoid condition of system, which lasted for more than two months. During the whole of this time he was attended by the club Surgeon, Mr. Passmore, to whom, for many weeks after the commencement of his illness, he never mentioned that he had been in the Clayton-tunnel accident.

In June—still in low health from blood poisoning (?) owing to the sloughing whitlows—he went to London, where he was introduced to Mr. Bridgman, a Surgeon, who, early in the following August, took him to Dr. Hawkesley. This gentleman found evidence of enlarged liver, which, as he was informed of the accident, he concluded arose from concussion in the railway train producing rupture of the liver. He also diagnosed some injury in the region of the right hip and the lower part of the spine.

The trial took place on the 11th inst. On the 9th, four Medical men, including myself, made a most careful examination of the plaintiff, stripped. He stood with his right knee flexed, his heel raised, and the toe pointing inwards. The leg was straightened, and the foot placed level on the ground without any difficulty; the thigh was not shortened, and there was no perceptible swelling about the hip. The calves of the legs were of equal circumference; so were the thighs. The boots which he had used two months were equally worn on the soles and the sides of the heels. The region of the liver was examined, and we could not discover any enlargement. The young man was undersized for his age; had a dyspeptic, unhealthy look, such as you constantly observe in those born (as he was) in the densely-peopled districts of the metropolis, and brought up to the trade of a shoemaker.

Such are, as briefly as I can give them, the leading points in this case, which a jury awarded £500 damages to, though settled eighteen months previously for £15. In my opinion a more unjust verdict was never delivered by a British jury. But it is the usual fate of railway companies when they go into court to resist extortion, and there is no chance of justice being done them except through a jury of competent Medical men as assessors. Apologising for thus intruding on your valuable space,

I am, &c.

ALFRED HALL, M.D.

Brighton, February 23.  
[Our remarks were not directed so much to this individual case as to the principle involved. We need scarcely say that on this our opinion remains unchanged.—Ed.]

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—May I claim a small space in your Journal to correct what I deem an error in your remarks on the "Duty of Medical Men to Railway Companies." Dr. Hall called on me with an official letter from Mr. Hawkins, traffic manager to the company, accrediting him, from which the following is an extract:—

"To put himself in communication with the various Medical men who are attending to cases of injury sustained in the accident at Clayton Tunnel, with a view of rendering any additional professional aid that may be required, and affording, on our behalf, any pecuniary assistance that may be needed."

I accordingly went with Dr. Hall and examined the patient, which we did together. On retiring to consult, we agreed that the case was a trivial one—this was a week after the accident. Dr. Hall requested me to ascertain from the patient and his father what sum of money they deemed to be an adequate compensation. This I consented to do, the father having already some days previously spoken to me on this point, but no sum had been named. I now suggested £10, the father said £15, which sum I named to Dr. Hall, to which he acceded, and immediately wrote a cheque, and received an acknowledgment in full of all demands. The case improved, and a week afterwards, the young man being convalescent, I discontinued my visits. Five months subsequently he was passed by the examining Surgeon of a benefit society, and he himself (the patient) certified to his belief in his own feelings of perfect health.

I stated distinctly in evidence that I was not acting in any way as an agent of or for the railway company, and I believe that this statement bears me out. If acting in any way, it must have been for my patient, being his own private Medical attendant; and any leaning that I might have had would necessarily have been towards him, and not in favour of the railway company, with which I had no communication whatever.

I am, &c.

R. P. B. TAAFFE.

Brighton, February 23.

P.S.—I can see no error in having acted for the patient as I did.

COMMUNICATIONS have been received from—

Mr. R. BRUDENELL CARTER; Mr. J. H. MONKS; Dr. WILDE; Mr. A. Z. LAURENCE; TRAVERS' WEEKLY CIRCULAR; Mr. C. D. ## APPOINTMENTS FOR THE WEEK.

February 28. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.  
ROYAL INSTITUTION, 3 p.m. Professor Max Müller, "On the Science of Language."

March 2. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.  
EPIDEMIOLOGICAL SOCIETY, 8 p.m. Deputy-Inspector Dr. Smart, R.N., "On the Successive Epidemics of Malignant Fever in Bermuda."  
MEDICAL SOCIETY OF LONDON (General Meeting for Election of Officers and Council, 7 p.m.) 8½ p.m., Dr. Routh, "On Some Points in the Treatment of Prolapsus Uteri."  
ODONTOLOGICAL SOCIETY OF LONDON, 8 p.m. Meeting.  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8 p.m. Anniversary.  
ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

3. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.  
ETHNOLOGICAL SOCIETY, 8 p.m. L. J. Beale, Esq., "On the Brain and the Skull in some of the Families of Man."  
PATHOLOGICAL SOCIETY, 8 p.m. Meeting.  
ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Mechanics."

4. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.  
OBSTETRICAL SOCIETY OF LONDON, 8 p.m. Dr. Shortt, "On Woman's Life in Southern India." Dr. Clay, "Observations on Ovariectomy, Statistical and Practical; also, a Successful Case of Entire Removal of the Uterus and Appendages." Dr. Broadbent, "On Displacement of the Bladder as a Cause of Tedious Labour."  
ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 p.m. Croonian Lectures—Dr. Risdon Bennett, "On Some Points Connected with Bronchitis, and its Results."

5. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.  
HARVEIAN SOCIETY, 8 p.m. Clinical Discussion.  
ROYAL INSTITUTION, 3 p.m. Dr. E. Frankland, "On Chemical Affinity."

6. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.  
MEDICAL SOCIETY OF LONDON, 8 p.m. Meeting of Council.  
ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 p.m. Croonian Lectures—Dr. Risdon Bennett, "On Some Points Connected with Bronchitis, and its Results."  
ROYAL INSTITUTION, 8 p.m. Dr. W. A. Miller, "On the most Recent Spectrum Discoveries."  
WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON, 8 p.m. Practical Evening, for the Narration of Cases and the Exhibition of Specimens.

<b>Secretary.</b> JOHN MESSENT, F.S.S.		

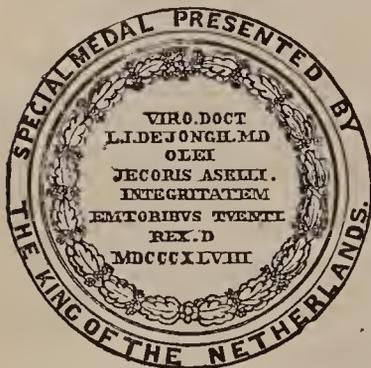

By the peculiarly equitable manner of dividing the profits, the Policies issued by this Association become payable during the lifetime of the person Assured without extra Premium. After having been in force a period of five years, all Policies are absolutely indefeasible and indisputable.

Attention is directed to the facility afforded by this Institution for the assurance of declined or diseased lives. The experience of the large staff of Medical officers connected with this Association has enabled the Directors to prepare a set of tables which they believe place such lives on an equitable footing in relation to other assured Members of the Company.

Qualified Medical Attendants who are named by Proposers to this Association are consulted as the Medical Advisers of the Directors, by whom all Medical Fees are discharged.

Every description of Life Assurance transacted; terms for which, with detailed Prospectuses and every information, may be had on application to  
JOHN MESSENT, F.S.S., *Manager and Secretary.*

*Applications for Agencies are invited.*

## DR. DE JONGH'S (Knight of the Order of Leopold of Belgium) LIGHT-BROWN COD-LIVER OIL.

### SELECT MEDICAL OPINIONS.

Sir HENRY MARSH, Bart., M.D., Physician in Ordinary to the Queen in Ireland:—"I consider Dr. de Jongh's Cod-liver Oil to be a very pure Oil, not likely to create disgust, and a therapeutic agent of great value."

Dr. BARLOW, Senior Physician to Guy's Hospital:—"I have been well satisfied with the effects of Dr. de Jongh's Cod-liver Oil, and believe it to be a very pure Oil, well fitted for those cases in which the use of that substance is indicated."

Dr. LANKESTER, F.R.S., late Lecturer on the Practice of Medicine, St. George's School of Medicine:—"I consider that the purity and genuineness of

this Oil are secured in its preparation by the personal attention of so good a Chemist and intelligent a Physician as Dr. de Jongh, who has also written the best Medical Treatise on the Oil with which I am acquainted. Hence I deem the Cod-liver Oil sold under his guarantee to be preferable to any other kind as regards genuineness and medicinal efficacy."

SOLE CONSIGNEES AND AGENTS,

ANSAR, HARFORD, & CO., 77, Strand, London, W.C.

## WALTERS' INDIA-RUBBER URINALS.

F. WALTERS having originally invented these Urinals, begs to warn the Profession of the many bad and useless imitations which are now sold, and he would advise them, before purchasing, to look that they are stamped with his name; as, unless that be the case, he cannot guarantee them.

These conveniences are made for those who require them only occasionally, during a long journey, as well as for those invalids who use them always. Mr. WALTERS has much improved them by making them of *Ætherised India-Rubber*, which adds very greatly to the strength of the India-Rubber, at the same time that it prevents its sticking together; by this means he is enabled to make them less stiff and harsh than hitherto, and yet to retain all the advantages of that stiffness. There is a patent valve which prevents the return of the fluid; and they may be worn either sitting, walking, or lying, without the slightest inconvenience, and without being perceived by any one.

WALTERS' CONVENIENCES FOR LADIES will be found particularly useful during pregnancy. They are perfectly soft and flexible, and may be worn with perfect comfort.

*All Orders must be accompanied by a Post-office order or reference.—Entrance for Ladies at the private door, where a Female attends.*

MANUFACTURER OF ELASTIC STOCKINGS, BELTS, &c.

16, MOORGATE STREET, NEAR THE BANK, LONDON, E.C.

ORIGINAL LECTURES.

INAUGURAL LECTURE  
ON THE  
SKELETON OF A GLYPTODON,  
RECENTLY PRESENTED  
TO THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS.  
DELIVERED AT  
The Royal College of Surgeons,  
By PROFESSOR HUXLEY.

(Continued from page 207.)

By working in this manner we determine not only that this *Glyptodon* was a placental mammal, but we further establish the fact that it belonged to that great division of the placental Mammalia which is known by the name of the *Edentata* or *Bruta*. If you look at the front part of the snout of this animal you find that there are no median incisor-teeth either in its upper or its lower jaw, which is one of the characteristics of the *Edentata*. If you look again you will observe that the ungual phalanges are much produced, and were sheathed in long claws, like, though proportionally shorter than, those of the armadillo. This is a second characteristic of the *Edentata*. Thirdly, the teeth are all long, with well-defined sockets, but form no root at their base. In man, we all know that, after a tooth has grown for a certain time, it finishes itself off below in one or more fangs. But if you examine one of the teeth of this *Glyptodon*, you find that the straight shaft runs down in it grooved fashion, and ends below as broad as it is at the top, and that the great pulp cavity extends far up into the tooth, which grows continually from below. It has no enamel, but merely consists of dentine and cement. Teeth of this kind, again, are characteristic of the same order; and finding all these characters combined, we may make sure that the *Glyptodon* was one of this great order of *Edentata*, which contains such creatures as the Sloths, the *Manis*, the *Myrmecophaga*, and, among the rest, those singular armadillos, of which several specimens are on the table. Having determined this point, we may next consider the structure of the feet of the *Glyptodon*, as shown in these diagrams, Figs. 2 and 3. When they are contrasted with those of an armadillo, the principle of structure of the two will be found to be similar, though there are some remarkable differences in detail—as in the articulation of the cuneiform of the carpus with the fourth and fifth metacarpals in the *Glyptodon* (Fig. 2). Indeed, Laurillard, many years ago, argued, from this part of its organisation, that the *Glyptodon* must be a close ally of the armadillo. And this conclusion is fully borne out by a comparison of the bony shield which covers some existing armadillos with the carapace of the *Glyptodon*. If I strip off the horny outer covering off this carapace of this armadillo, the pattern of the separate bony elements which it presents is as nearly like that in the *Glyptodon* as possible. There is the central facet and a number of other facets, that form together a sort of rosette in each case. And looking at the carapace as a whole, the differences are merely differences in detail, in arrangement, and in relative mobility of parts, and in no respect is there any difference of principle. So that, at length, we come to the conclusion, that this *Glyptodon* was an animal closely allied to the existing armadillo, though differing from them in certain respects, just as armadillos differ one from another, but differing more largely, and in size vastly surpassing anything we know at present. The extreme length of the specimen, without the tail, is about seven feet, and the height is about four feet.

Thus, by the application of our empirical laws, without the intervention of physiological principles or physiological reasoning in any way, we are enabled to settle and decide the place of this extinct animal in the scale of nature. But I trust you will not imagine from this phraseology that I in any way undervalue the importance of physiological reasoning, or that I suppose it may not be made—when we have once determined the morphological relations of an animal—the instrument of most important researches, explaining what would be otherwise mysteries of structure. Indeed, if I had

been guilty of this assumption, this skeleton alone would be sufficient to confute me, for it contains within itself one of the most singular physiological adaptations in existence. You

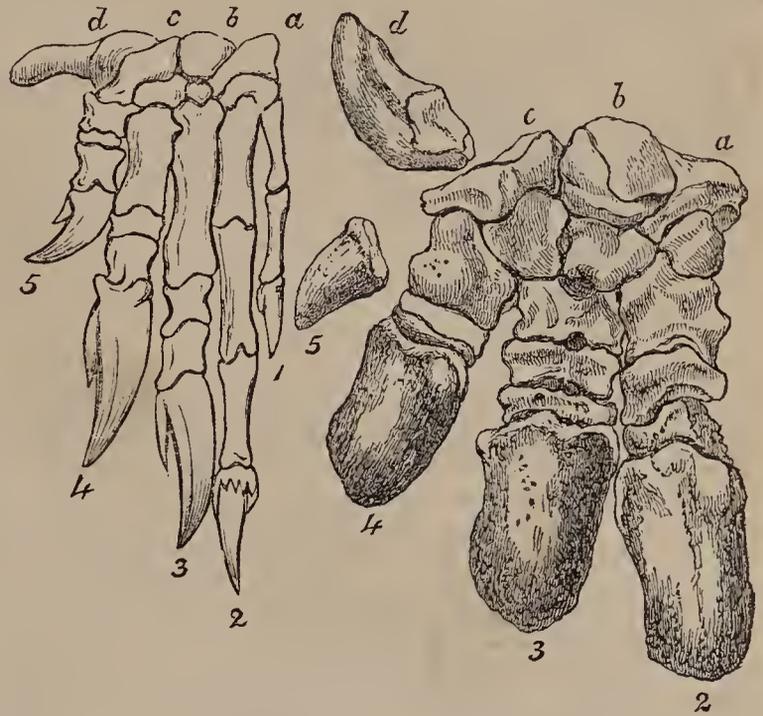

Fig. 2.—Right fore-feet of *Dasypus sexcinctus* and of *Glyptodon*. a, scaphoid; b, semilunare; c, cuneiforme; d, pisiforme. 1, 2, 3, 4, 5, digits.

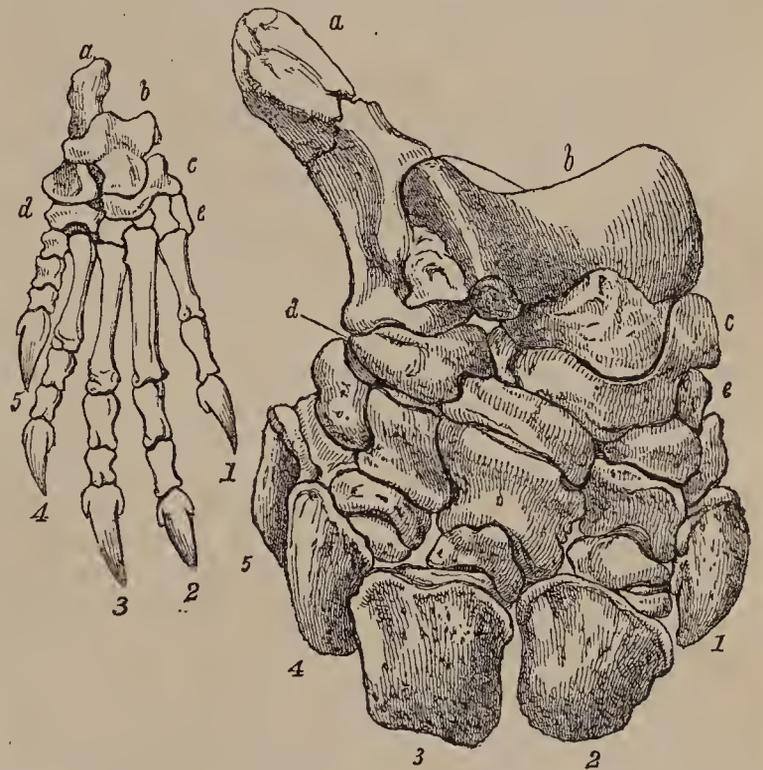

Fig. 3.—Right hind-feet of the same, on a somewhat larger scale. a, calcaneum; b, astragalus; c, scaphoides; d, cuboides; e, cuneiformia. 1, 2, 3, 4, 5, digits.

will observe that the trivertebral bone, which I spoke of just now, is free to move, as I said, on a vertical plane, upon the ankylosed vertebræ which succeed it, and that the whole dorso-lumbar region of the vertebral column is perfectly immovable except in that particular joint (Fig. 4).

On each side of the trivertebral bone are great fossæ of a very irregular shape, into which the heads of the anterior ribs fix themselves, and the fossa for the first rib is of such a form, that it is quite impossible for the head of that rib to rotate; it can neither turn outwards or inwards, or on its axis, or backwards and forwards. Furthermore, the specimen of *Schistopleuron*, an animal closely allied to this, which has been described by M. Nodot in the *Transactions of the Dijon Academy*, fortunately shows that this first rib is fixed to the sides of the sternum. The arrangement of the parts is, therefore, such as is sketched in the following diagram.

Here we have the trivertebral bone (a), with the first rib (c) and sternum (d) immovably fixed to it, and it is obvious that if the trivertebral bone is caused to move upwards and down-

wards between the positions  $a$  and  $a'$ , as it might have been by the muscles attached to its "handle," the first rib and sternum will be compelled to travel between the positions  $c d$  and  $c' d'$ .

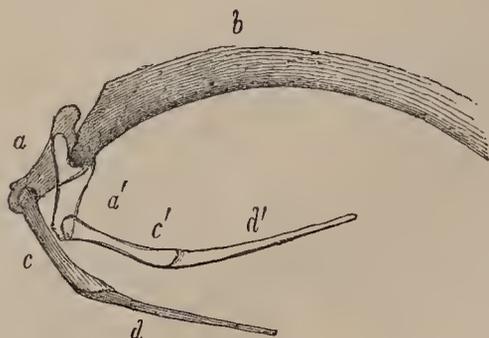

FIG. 4.—Diagram of part of the vertebral column of the *Glyptodon*, designed to show, on an exaggerated scale, the effects of the movements of the trivertebral bone,  $a$ , upon the anchylosed dorso-lumbar column,  $b$ ;  $c$ , first rib;  $d$ , line of the sternum.

I confess, that when the knowledge of this structure first came to my mind, I found it very difficult to believe in it, although it was there before my eyes. I could not conceive what was the object of this joint in the front part of the back, while the other vertebræ were so closely anchylosed. But I bethought me of this question—How did this animal breathe? We know that in the mammalian series respiration is effected by a double mechanism. In the first place, there is the piston-like motion of the diaphragm backwards and forwards, which is amply competent to give rise to a certain amount of working respiration, but apparently not all the change of space that is requisite; so that the motion of the diaphragm in every kind of mammal is accompanied by a certain amount of movement of the ribs, which play backwards and forwards, carrying the sternum with them, and so enlarging and diminishing the cavity of the chest. But this motion by which, in conjunction with the movement of the diaphragm, the dimensions of the thorax are increased in inspiration and diminished in expiration—this movement, so long as the vertebral column is fixed, depends entirely upon the mobility of the ribs, and upon the power of their turning on their heads, as axes. If the ribs were fixed to the sides of the vertebral column, and then again to the sides of the sternum, it is quite obvious that no such motion as this could take place. Having got thus far, I thought I began to see the physiological reason for this joint; for, as costal, as well as diaphragmatic respiration occurs in all the Mammalia, doubtless there is some good reason for it—some necessity deep-seated in the economy; and it was necessary for this mammal, like the rest, to breathe costally as well as diaphragmatically. But, inasmuch as the first rib was fixed in its fossa on the side of the trivertebral bone on the one hand, and to the side of the sternum on the other—if the trivertebral bone had been anchylosed to the rest of the dorsal vertebræ, costal respiration would have been impossible.

Here appeared the significance of the joint. For as the area  $b a' c' d'$  (Fig. 3) is much smaller than the area  $b a c d$ , it is plain that the motion of the trivertebral bone upwards and downwards, through a much smaller arc than that represented in the figure, must have amply sufficed to produce as large an alternate enlargement and diminution of the thoracic cavity as is effected by the costal movements of ordinary Mammalia.

This, indeed, is by no means the only help that physiology will yield in endeavouring to explain some of the peculiar and anomalous points in this animal. But I must pass on to the last question which remains,—to the question of how far this skeleton helps us in any way, to that which I defined as the great object of biological study; how far it helps us to throw light upon the history of the past, and how far it exemplifies or contradicts, some generalisations which have been put forward with respect to the character and nature of the changes through which the varied forms of life, which we know to have succeeded one another through past ages, have undergone.

One law it illustrates with remarkable force, and it is one which is established upon the best possible evidence, apart from any theory or hypothesis whatever. This law, which is one of those which must be taken into account as among the weightiest, whatever view we may be disposed to entertain with respect to the causes of the succession of events on the surface of the globe,—this law, which was first, I believe,

clearly promulgated by Mr. Darwin for South America, is, that in that country—and, indeed, in all countries—the *fauna*, that is to say, the assemblage of animal inhabitants, at the present day, in its great generic and family features, is identical with the *fauna* which existed in the immediately preceding geological epoch; that is to say, taking the mammalia of the fauna of the old world—of Africa and Europe—you find over that geographical area elephants, hyenas, rhinoceroses, hippopotamuses, and creatures of that kind. And going back to the animals immediately preceding that epoch—the post-pliocene—there you find skeletons of elephants, hyenas, rhinoceroses, hippopotamuses, and such like, all specifically different from those which now inhabit those areas,—or, at least, the great majority of them,—but belonging to the same genera and families, so that there is a similarity of character between the fauna which exists now and the fauna which immediately preceded it.

If you extend your researches to Australia, you find there the remains of great kangaroo-like and other Marsupial animals, differing specifically, for the most part, from those which now live there, but having the same great characteristics as the existing *fauna*. If you turn to South America, it exactly bears out the same conclusion, and it is a striking circumstance that you find predominant in the post-pliocene formations there, not rhinoceroses, or hippopotamuses, or kangaroos, but sloth-like creatures and armadillo-like animals, such as the *Glyptodon*; remarkable forms, differing specifically, or generically, from those which constitute the great features of the present fauna.

The other supposed law to which I refer is this, that the animals of the older formations were more embryonic or more generalised in character than those of the same groups which live at the present day.

To this generalisation the skeleton of the *Glyptodon* before us appears to me to give a glaring contradiction. No living armadillo, indeed no known Edentate animal, presents a vertebral column exhibiting more special characters, or one which departs so widely from the embryonic type, as that of the *Glyptodon*.

THE LEVEE.—In addition to those members of the profession who attended the levee last week, at St. James's Palace, a list of which appeared in our last number, we have now to report that the following presentations to His Royal Highness the Prince of Wales took place on that occasion, viz.,—Dr. Butler, Dr. Acland, Dr. Anderson, Dr. T. K. Chambers, Dr. W. Dick, Dr. C. J. Foster, Dr. Gallagher, Dr. Francis Hawkins, Dr. E. Hilditch, Dr. William Jenner, Dr. R. O'Shaughnessy, Dr. G. E. Paget, Dr. E. Phillips, Dr. G. C. Millar, Dr. J. M. Minter, Dr. Sieveking, Dr. G. Sykes, Dr. Forbes Watson, Dr. J. Grant Wilson, Mr. J. Moncrieff Arnott, Assistant-Surgeon Agnis, Surgeon H. Baillie, Mr. William Bowman, Mr. William Coulson, Assistant-Surgeon J. C. Corbyn, Sir Daniel Cooper, Mr. C. F. Du Pasquier, Surgeon W. C. B. Eatwell, Surgeon R. Gilborne, Surgeon-Major E. Grant, Mr. C. H. Hawkins, Surgeon-Major Jee, Mr. James Paget, Mr. George Pollock, Mr. R. Quain, Surgeon H. Martin, Deputy-Inspector-General C. J. Smith, Assistant Surgeon R. Turner, Assistant Surgeon E. J. Vivian, Surgeon Young, and Surgeon-Major Wyatt, making, with the list published last week, the large number of ninety-three loyal members of our profession who paid their respects to His Royal Highness.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the General Monthly Meeting, Monday, March 2, 1863, William Pole, Esq., M.A., F.R.S., treasurer and vice-president, in the chair, Edward Atkinson, Esq., the Rev. Henry Blunt, Col. Craven Hildesley Dickens, Frederick William Gingell, Esq., Ernest Hart, Esq., William Hartree, Esq., John Hogg, Esq., M.A., F.R.S., William Wood Humphry, Esq., William Edward Kilburn, Esq., Henry Lanson, Esq., Thomas Leckie, M.D., James Lees, Esq., William McKeand, Esq., Abraham Pope, Esq., John Rivington, Esq., John Rutherford Russell, M.D., John Benjamin Smith, Esq., M.P., and George S. Trower, Esq., were elected members of the Royal Institution. The thanks of the members were returned to Mr. James Glaisher, Prof. Frankland, the Rev. George Williams, and to Mr. John Lubbock, for their discourses on the evening meetings on Fridays, February 6, 13, 20, and 27. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

## ORIGINAL COMMUNICATIONS.

## CLINICAL MIDWIFERY.

By FRANCIS H. RAMSBOTHAM, M.D.

Physician-Accoucheur to the London Hospital, etc.

(Continued from page 159.)

THE following six cases of cerebral affection in pregnancy or labour occurred in my practice during the last half of 1841, 1842, and the first two months of 1843:—

*Convulsions after Labour, at Six Months.*

*Case 178.*—On May 2, 1841, at 9.30 p.m., I was requested by a Professional friend to see Mrs. N., Bell-lane, Spitalfields, who had been delivered of her second child at six months, at one o'clock on the same morning. She had made no complaint during her pregnancy, went through her labour very well, and neither could she nor her Medical attendant account for its having come on prematurely. At 11 a.m., she was seized with a convulsion fit, without any premonitory symptoms or warning whatever. Before I saw her she had suffered four of a very violent character, and was in a state of profound coma. Some leeches had been applied to the temples without any benefit. I had her bled to twenty ounces immediately, and ordered ten grains of calomel to be placed upon her tongue, and a strong purgative mixture, of which a tablespoonful was to be given as often as she could be made to swallow until motions were obtained. She had no fit after the bleeding. The stupor continued through the night, but gradually diminished; and when I saw her at 1 p.m. on the next day, she was sleepy and dull, although quite sensible when roused, and she answered questions accurately. She recovered quite well, and had a perfect recollection of her labour.

*Blindness coming on Gradually in Pregnancy—Craniotomy.*

*Case 179.*—On June 14, 1842, I saw, in consultation with a Medical friend, Mrs. N., Commercial-road East, in the last month of her first pregnancy. The earlier months had passed over very well, but about six weeks before she began to lose the sight of both eyes simultaneously, and continued to get worse by degrees until my visit, when she was so completely blind that she could only just point out the situation of the window. She had not suffered any pain in the head, nor any unusual drowsiness; her recollection was perfect, and she was quite sensible. The pupils were much dilated, the right more so than the left. The pulse was quick and small. She was cupped, leeches, blistered, and slightly salivated, without relief, and continued getting worse until she could not distinguish the brightest sunshine. On the 23rd she began to feel a tingling and numbness in the right arm and leg without any loss of power, and on the 24th Dr. Blundell met us in consultation. He feared, as I did, that convulsions or apoplexy would occur during her labour. He recommended that more blood should be taken by leeches to the temples, and that the mercury should be continued. She went into labour at midday of the 28th; the membranes broke at 4 p.m., when her general attendant was sent for, and I was summoned to her at 11 p.m. The pains were then strong and frequent; the os uteri dilated to the diameter of half-a-crown and rigid; in two hours more, however, it became relaxed and began to open more kindly, so that I expected the labour would soon be completed. As she appeared comparatively well, with the exception of the blindness, I left her under the care of my friend, and retired to rest. At 7 a.m. I was called to her again, and found the head still above the pelvic brim, although the pains continued powerful and frequent, and the os uteri was almost entirely dilated. The pelvis was below the average size, and as the child was putrid I did not hesitate to perforate the skull. Delivery occupied nearly an hour; the placenta was soon expelled, and I left her much more comfortable than could have been expected. As far as her labour was concerned she went on exceedingly well; but the blindness, numbness, and tingling remained without diminution for ten days. After that she gradually began to mend; in a month she could distinguish objects; in six weeks she told me the hour by my watch, and on the 24th of August she went out of town very weak, but able to stand and walk with assistance, and she had completely recovered her sight. A deep sore formed on the sacrum, but this was healed before she left her home. She

gradually recovered, and I know that she had one child afterwards without any return of the symptoms; but as she left that part of the town I am not aware whether she ever bore another.

*Puerperal Convulsions at Seven and a-Half Months.*

*Case 180.*—On June 25, 1842, at 8 p.m., I was called by a Medical friend to Mrs. L., Blackfriars'-road, in the last month of her seventh pregnancy. She was a delicate woman, nervous and hysterical, and for the last three or four days had complained of intense headache. She had been very sick during the day, and occasionally slightly delirious. She had had three convulsion fits when I arrived, from the last of which she was just recovering, and she was in a state of coma, with stertorous breathing; six leeches had been applied to the temples. I had her bled to twenty ounces, when the pulse began to falter, ordered her hair to be taken off, ten grains of calomel to be put upon her tongue, and a table-spoonful of a strong purgative mixture to be given frequently. At nine o'clock she had another fit; ten ounces more blood were taken, when she fainted. She began now to mutter unintelligibly, and, although she continued quite insensible, she had no more fits. The os uteri was quite close when I first saw her, but it soon began to open; dilatation went on rapidly, and she was delivered of a seven and a-half months' child living at 2 a.m. During her labour she seemed unconscious, except that with each return of uterine contraction she made a piteous outcry. At four o'clock another fit came on, but it was much less severe than any that had preceded it. Twelve leeches were now applied to the head, which bled freely; and the bowels acted copiously. From this time there were no more fits, and she fell into what appeared to be a placid sleep. She awoke at 8 a.m. quite conscious, did not complain of any pain in the head, recovered perfectly well, and nursed her infant satisfactorily.

N.B.—Case 73, already reported, is the history of one of twins complicated with convulsions, in which I extracted both children by the forceps. This occurred on July 31, 1842.

*Puerperal Convulsions—Craniotomy.*

*Case 181.*—On August 12, 1842, at 12 at night, I was sent for by a Medical friend to Mrs. N., Homerton, aged 39, of rather a full habit, in labour of her first child. The membranes broke at 8 a.m. The uterus was acting very strongly, and the head was partially in the pelvis, which was small throughout. The vagina and external structures were very rigid, and there was a very tough frænum at the posterior part of the vagina, greatly narrowing the canal, against which the head was being forcibly protruded. Neither ear was within reach of the finger. Feeling assured that the head would not be expelled for some hours, I went to lie down, leaving her under the care of her own attendant, and was called hurriedly at 3.15. I found her on the floor in a convulsion fit. She had got out of bed to pass water, and was sitting on the night-chair when it came on. Her legs had been œdematous for some weeks; but beyond that there had not been any untoward symptoms, and there was not the slightest premonition of what was about to happen. She was immediately bled to twenty ounces, which produced an approach to syncope; and her hair was cut off. She gradually recovered her consciousness completely. The pains became very forcing, much stronger than they were before the bleeding, but they made no impression on the head whatever. I proposed delivery; and, having emptied the bladder, I applied the long forceps over the child's head diagonally, with tolerable ease. I had a most powerful hold upon the head; but, with all the exertion I dared to use, I could not move it in the least degree. The uterus was acting so violently, that, fearing another fit would come on, I perforated the skull and delivered with considerable difficulty. The placenta came away in fifteen minutes, and the lady, for half an hour after delivery, appeared to be going on well; but as I was sitting by her alone in the room, she suddenly exclaimed—“I can't tell what you say.” Two or three twitches of the facial muscles came on; in about two minutes she went into another fit, and, on its cessation, remained in a state of semi-coma. We immediately took about sixteen ounces more blood, and it flowed very freely. But a condition of deep syncope supervened; for some time there was no pulse to be felt at the wrist, jactitation came on, and she could not swallow; soon, however, we got a little brandy and ammonia down, and remained by her side for three hours, giving her occasion-

ally a small quantity of brandy and gruel. I have seldom seen a longer or more intense degree of faintness recovered from. However, there were no more convulsions. She remained insensible till between 8 and 9 a.m., when she gradually came to herself and went to sleep. In the middle of the day she was comparatively well, and she was restored by degrees to her ordinary health.

*Convulsions before Delivery.*

*Case 182.*—On February 28, 1843, at 2 a.m., I was requested by a Medical friend to see Mrs. P., in the Mile-end-road, about eight months advanced in her first pregnancy. She had complained of pain in the head for a fortnight, and, three or four days before, she had said to her mother-in-law that she was sure she was losing her memory, for she could not remember what her (the mother-in-law's) name was. On the morning of the 27th, her husband went down stairs between seven and eight o'clock, and when he returned to his room he found her in a state of coma, with stertorous breathing. From the disturbed appearance of the bed-clothes, there is no doubt that she had had a fit in his absence. Before her Medical man could arrive she had another fit, and he immediately took twenty ounces of blood from the arm, and had her hair cut off, and cold lotions applied. The bleeding soon restored her to consciousness, and she became quite herself. This gentleman stayed with her until 3 o'clock p.m., and left her apparently greatly relieved; but at 5 p.m. she had another fit, and, for some reason or other, they applied to another Practitioner in the neighbourhood. On his arrival he took twenty ounces more blood, blistered her neck by means of the *Acetum lyttæ*, and applied mustard to the feet and to the pit of the stomach. She had two more fits—five in all—between the first attack and my visit. I found her under deep coma, with stertorous breathing, and both pupils highly contracted. The pulse was full and hard. She was again bled to the amount of sixteen ounces, until, indeed, the lips became pallid and the heart's action faltered. There was no appearance of labour. I left and saw her again at 9.30 a.m., having ordered ten grains of calomel and a purgative mixture, of which a tablespoonful was to be given as often as was possible. She was still insensible, but there had been no fit since the last bleeding. Twelve leeches were ordered to the temples and forehead, and, as nothing had passed from the bowels, she was to go on with the purgative. During the early part of the day the medicine acted copiously, and, after that, she gradually recovered her consciousness. Next day (March 1) she was quite rational; did not recollect anything of her seizure, but remembered having seen me the previous evening. On March 2, she became maniacal, but was not violent; she was then ordered two grains of calomel every four hours. On the 3rd, she was rather better, but still talked incoherently, and the calomel was continued. In the course of that night the maniacal disposition ceased, and at 5 p.m., on March 4, she was delivered of a dead child after a rapid labour, during which she was quite conscious, though she complained much of headache. As this continued two or three days after delivery, twelve more leeches were applied to the head. Her mouth was made sore by the calomel previously taken. She gradually lost the pain in her head after the last leeches, and recovered completely.

8, Portman-square.

(To be continued.)

AN ACCOUNT OF THE  
PHYSIOLOGICAL RESEARCHES OF  
THE REV. PROFESSOR HAUGHTON, M.D.,  
TRINITY COLLEGE, DUBLIN.

(Continued from page 133.)

THE results of the Rev. Professor Haughton's experiments on urea are, that the mean daily excretion of that substance, per vesicam, in well-fed, flesh-eating, wine-drinking men is 576 grains, and in well-fed, water-drinking vegetarians, 394 grains; the range being from 315.00 to 677.25 grains, affording a mean of 493.19 grains, which is almost exactly a mean between the two extremes. These results do not differ very materially from those recorded by Dr. Parkes, principally from German chemists, who fixes the daily excretion of urea at 512.4 grains, adopting the mean of the results of the experiments of twenty-

four observers, including different chemical methods, and persons of different habits, and using different foods, between the ages of 20 and 40; wherefore, grouping together men of every weight, food, occupation, and country, we may set down 500 grains of urea per day as the natural healthy discharge in the urine. Professor Haughton, connecting the quantity of urea in healthy urine with the specific gravity, propounds the following bedside rule, which follows from experiments on the relation between the specific gravity of healthy urine and the quantity of urea contained in it, that "half the excess of the specific gravity of urine (not containing either sugar or albumen) above 1000 is the number of grains of urea per fluid ounce."

Experiments were necessary to establish the important point, that the whole of the nitrogen of the food is accounted for by the nitrogen in the urea and fæces, and for this purpose an analysis of various mixed diets was undertaken. The amount of water in each article of food was determined by drying at 212° F.; the dried product was afterwards analysed for nitrogen by burning in a tube with soda lime, and collecting the ammonia in muriatic acid. The quantity of nitrogen was found by adding bichloride of platinum, and afterwards weighing the double chloride of platinum and ammonium on a weighed filter, or by the weight of platinum after ignition, or by both methods. It was always found that, when the ignition of the double chloride was conducted slowly, the results were identical with those given by the direct weighing of the ammoniaco-platino-chloride. The subjoined table shows the quantity of urea equivalent to the nitrogen contained in various articles of food; and here it may be mentioned that, to find the amount of nitrogen in urea, we have to take  $\frac{1}{3}$ ths of the urea.

*The Urea Equivalents of Several Kinds of Human Food.*

No.	Food.	Quantity.	Urea equivalent.
1.	Lean roasted mutton—leg, near shank-end, contains fat and fascia . . . . .	1 lb.	480 gr.
2.	Lean roasted mutton—leg, near the loin, very little fat or fascia . . . . .	1 ,,	957 ,,
3.	Lean raw mutton—loin . . . . .	1 ,,	544 ,,
4.	Lean roasted beef—sirloin . . . . .	1 ,,	724 ,,
5.	Lean raw beef—sirloin . . . . .	1 ,,	979 ,,
6.	White bread, first quality . . . . .	1 ,,	196 ,,
7.	White bread, second quality . . . . .	1 ,,	203 ,,
8.	Brown bread, wheaten . . . . .	1 ,,	267 ,,
9.	Oatmeal . . . . .	1 ,,	421 ,,
10.	Indian meal . . . . .	1 ,,	150 ,,
11.	Rice . . . . .	1 ,,	245 ,,
12.	Cauliflower, boiled . . . . .	1 ,,	58 ,,
13.	Cabbage, boiled . . . . .	1 ,,	57 ,,
14.	Tea . . . . .	1 ,,	603 ,,
15.	Porter . . . . .	1 qt.	54 ,,
16.	Milk, sp. gr. = 1025 . . . . .	1 ,,	116 ,,
17.	Milk, sp. gr. = 1027 . . . . .	1 ,,	126 ,,
18.	Milk, sp. gr. = 1035 . . . . .	1 ,,	174 ,,

The per-centage of nitrogen which Professor Haughton found in beef and mutton was 12, and goes to confirm the experiments of Schlossberger and Kemp, whose investigations show, that the amount of nitrogen in muscular fibre does not essentially differ throughout the whole animal kingdom, the average per-centage of nitrogen being about 13. Taking one part with another, and disregarding kind, 1 lb. of beef or mutton is equivalent to 737 grains of urea.

An individual [No. 1., Table A., see page 133] is now experimented on thus:—His diet, for some time preceding and during the investigations, is—

Roast beef (cold) . . . . .	8 oz. =	362 grains of urea.
White bread . . . . .	8 oz. =	98 ,,
Boiled cauliflowers . . . . .	10 oz. =	36 ,,
Milk (sp. gr.) 1025 . . . . .	1 pt. =	58 ,,

Total equivalent of urea . . . . . = 554 ,,

The fæces passed per day by the same individual, who was under the same conditions of food and habits prior to and during the experiments, amounted to 5 oz., the analysis of which gave the following results:—

305.45 grains, dried at 212° F., gave 80.05 grains. 28.15 grains of the latter gave of am. plat. chloride 30.75 grains. From these data are found solids = 26.21 per cent. Nitrogen = 6.86 per cent.

From this is obtained by the chain rule the total urea equivalent to the nitrogen thus excreted.

5 oz. faeces.	16
7000 grains.	10,000
2621 grains at 212° F.	10,000
686 grains nitrogen.	28
60 grains urea.	
84.28 grains.	

Now, the urea excreted by this individual, per vesicam, during the experiment was seen in table A to be = 465.09; so that, combining these results, we have,—

1. Urea, excreted per vesicam	. 465.09 grains.
2. Equivalent of urea excreted per anum	84.28 „
Total	. 549.37 „

The close agreement of this result with that obtained from the analysis of the food, entitles the Professor to assume that no nitrogen is excreted *per cutem et halitum*, and this view is supported by the experiments of Bischoff and Voit, which show that in carnivorous animals all their nitrogen is excreted as urea.

We find, therefore, that the nitrogen entering the body as food leaves it by two different channels—per anum (the minor portion), per vesicam (the major portion). It is discharged by both ways as excrementitious, but the nitrogen in the faeces was cast off as surplus and unneeded; it was neither assimilated nor required by the body—it was never used; whereas the nitrogen, now urea, in the urine has done its work; it represents the wear and tear of tissue of every kind, and when fully used up is expelled the system as no longer useful, but actually noxious and dangerous; it is now an unassimilable nitrogenous compound; if administered, it is diuretic and is hurried out of the body,—if retained, it is a fatal poison; it must go to the vegetable kingdom, before it again returns in the protenic compounds as nutritious food.

We are, as yet, unable to reduce to symbols the metamorphoses by which vital chemistry converts the protein compounds into urea, as we are those by which vegetable chemistry re-converts urea into protein; but we know that the excretions are more highly oxidated than the food and drink consumed, and it is from this point of view the Professor proceeds to calculate the amount of work done by the animal body, and attempts the solution of a problem hitherto left unexplained.

(To be continued.)

## PAPERS ON ENGLISH AND CONTINENTAL SPAS.

By JULIUS ALTHAUS, M.D., M.R.C.P. Lond.

### I. PROLEGOMENA.

As little attention has of late been paid to the nature and action of mineral waters, and, therefore, much misconception exists in the Professional mind concerning their therapeutical powers, I hope that the following communications on this important subject may prove acceptable to the readers of the *Medical Times and Gazette*.

It may be laid down as a general rule that Spas are only suitable for patients suffering from chronic diseases, and in these only, so long as the composition of the blood has not become too much altered, and in the absence of considerable structural changes of important organs.

The therapeutical action of the Spas depends chiefly upon their chemical composition and temperature. Each mineral water which possesses curative powers is, by virtue of its peculiar composition and temperature, as it were, an individual remedy which, although it may greatly resemble others of the same class, is not absolutely identical with any other, neither in a chemical nor in a pharmacological point of view. For this reason it is especially suitable for certain diseases in which other Spas, however similar to the former, are either less or not at all fit. It is therefore the duty of Physicians to make themselves thoroughly acquainted with the individual action of the several Spas, in order to be able to distinguish which one of them is most likely to prove successful in a given case.

Independently of the chemical composition and the temperature of mineral waters, there is a variety of other circumstances which have an important bearing upon the result of the treatment. Amongst these may be mentioned the situation of the place, its climate and neighbourhood, the formation of the soil, the character of the vegetation, the presence or absence of flowing and stagnant waters, barometric pressure, the mean annual temperature and the mean temperature of the summer months, the variations of temperature occurring during the twenty-four hours, and from one month to the other, as well as the amount of moisture contained in the air. The pleasant neighbourhood and sublime scenery which surrounds many Spas greatly aid the curative effects of the waters; while the gloomy and wild aspect of others may, at least in a certain number of cases, retard the benefit which would otherwise result from the peculiar virtues of the springs. The health of patients is much influenced according as the Spa is at a low level or in an Alpine neighbourhood, in broad and open places, or in narrow valleys surrounded by steep mountains. In places which are at a high elevation above the sea, the air itself is, by its greater purity and keenness, and also by its diminished density, an agent powerful for good and, it may be, for evil. Thus, persons suffering from abdominal plethora, torpidity of the nervous system, atonic hœmorrhœa of the respiratory organs, hysteria and hypochondriasis, are frequently much improved by being transferred to a high and airy mountainous health-resort; while such as suffer from an irritable condition of the lungs, with tendency to bronchitis and hæmoptœ, are better in places at a lower level, with a mild and moist climate, and where there is sufficient protection against winds. Thus, for instance, it is easy to understand why the acidulous chalybeates of St. Moritz, in the Upper Engadin, which is 5464 feet above the sea, and where the mean temperature of the summer months is 51°, should have different effects from those of Pyrmont, which is only 704 feet above the sea, and where the mean annual temperature is 42°.5. The same may be said of the alkaline saline springs of Tarasp, in the Lower Engadin, which are at 4300 feet, and where the mean temperature of July is 51°.8; of Marienbad, in Bohemia, which is at 1932 feet, and has a mean annual temperature of 45°.5; of the indifferent thermals of Gastein, at 2939 feet, and with a mean summer temperature of 55°; of Pfäfers, at 2130 feet, and with a mean summer temperature of 56°; of Wildbad, at 1322 feet, and with a mean summer temperature of 61°; of Plombières, at 1272 feet; of Warmbrunn, at 1164 feet; of Schlangenbad, at 900 feet; of Teplitz, at 628 feet, and with a mean annual temperature of 50°.

The best time for commencing a mineral water cure is, in the majority of cases, the months of June, July, and August. For patients who suffer from great irritability and rheumatic affections, May and September are, however, frequently more advisable. The quality of whey is best in May; while sea-baths prove most useful in the later part of the summer. Certain mineral waters, as, for instance, those of St. Moritz, can only be used in July and August, as before and after that time the climate is too rough. The state of the weather in the several summer months is also of importance; thus, in Gastein May is very pleasant, June extremely changeable, July hot and stormy, while August and September are again pleasant. It may, therefore, happen that if patients are sent to Gastein for the months of June and July, they derive little benefit from the waters, while they might have been greatly improved or cured had they been advised to resort to that Spa for August and September.

It was formerly believed that mineral waters should on no account be used during winter. As far as the physical and chemical properties of the springs are concerned, this opinion is, for the large majority of cases, untenable; and experience has shown that, even during severe winters, they may be employed with the utmost advantage. There are many diseases for which a mineral water cure proves more successful than any other treatment, and where it would be wrong to delay at all the use of the waters, as in the mean time the complaint would probably be aggravated, and the chances of a cure be thus lessened. In winter it is generally advisable to prescribe artificial or imported natural mineral waters; but if it should seem desirable to send patients to the Spas themselves, we must take care to choose such only as are protected against cutting north and east winds; where no sudden changes of temperature occur; where the mean winter temperature is comparatively high, and where all comforts, doubly necessary at that inclement season, are easily obtainable.

The mode of using mineral waters is now widely different from what it was in former times. The principle that the benefit is more considerable, the more water is drunk, and that "crises" and "critical excretions" are necessary if the treatment is to be successful, is now rejected by all enlightened members of the Medical Profession. Many cases have occurred in which large quantities of water, drunk in rapid succession, have not only greatly disturbed digestion, but have caused dropsy and general prostration, and a moderate use of the springs is, at the present day, justly believed to be the only safe plan.

The rules to be observed for the use of mineral waters have also been greatly changed. We no longer advise "preparatory cures," "great cures," "little cures," "prophylactic cures," and "after-cures;" but the mode of treatment is made to suit the requirements of each individual case.

Waters which contain much carbonic acid and few salines agree better with the stomach than such as are rich in solid constituents and poor in carbonic acid. These latter are, however, more easily borne if they have a somewhat high temperature. If the water, on issuing from the earth, is very hot, it is better to let it cool before taking it; water which is very cold must, on the other hand, be heated. If the quantity of carbonic acid contained in the water is very large, this should be allowed to stand for some time before being drunk, or flatulency might be caused; and if the quantity of salines contained in a spring is very considerable, it is better to dilute it with some fresh water. Moreover, in persons who have a weak and irritable stomach, milk or whey is frequently added, whereby the water is rendered more easily digestible.

In most cases early rising during a mineral water cure is advisable. The water should be drunk before breakfast, at intervals of about one-quarter of an hour between each tumbler, moderate exercise being taken at the same time. It is on this account of great importance, that porticoes, covered walks, benches, etc., should be in the immediate neighbourhood of the springs, so that exercise may be taken regardless of the state of the weather. Persons who become exhausted by exercise before breakfast, or who perspire freely in the morning, may take the water while in bed. Breakfast should not be taken immediately after the last tumblerful, but an interval of half an hour or an hour should be left. A second dose in the evening is in many cases advisable.

If patients cannot travel to Spas, much benefit may be obtained by prescribing mineral waters to be taken at home. Such was not the opinion of Hufeland, who, when speaking on this subject, says:—"Doubtless the use of mineral waters immediately from the spring,—that is, from the living hand of Nature herself,—is the only true method to obtain them in all their power and integrity. The slightest separation from the common mass, any deviation from their usual temperature, the mere removal from their subterranean laboratories to the contact of air and light, must produce a very considerable decomposition of their more delicate ingredients; so that we should, in fact, drink them with our lips immediately applied to the spring itself, and when that is not possible, carry the cup to the mouth as quickly as possible; for it is certain that every moment's delay is accompanied with a loss of curative powers." Although there is much force in this argument, experience has shown that mineral waters may, when drunk at a distance from the place where they issue, exercise a most beneficial action upon certain diseases. No doubt the probability of a cure is greater if the patient is able to travel to the Spa. In certain cases, the journey and the change of air and of the mode of living prove of great benefit; the mixture may be taken in its integrity; besides which, baths of the most various kinds, douches, inhalations, and other allied remedies, may be used with greater ease than is possible at home. On the other hand, the patient who remains at home has the advantage that the cure may be commenced at once, without loss of time, money, and trouble; he is not dependent upon the weather; and his Medical attendants, familiar with his condition, may regulate the treatment as it proceeds.

If it has been decided that a patient is to drink mineral waters at home, we have then to choose between the imported natural and the artificially-prepared waters. The former would be altogether preferable if it were possible to avoid their decomposition after being bottled; but this is, unfortunately, only too apt to occur if mineral waters have been kept for some time, however carefully the vessels in which they are placed may have been closed. The waters specially liable to

decomposition are the acidulous chalybeates and those containing sulphates. The former, after being bottled, lose the carbonic acid which keeps the iron in solution; bicarbonate of iron is then changed into carbonate, which is insoluble and precipitated at the bottom, whereby the mineral water becomes useless. In mineral waters containing sulphates, decomposition frequently takes place, if bits of organic matter, straw, cork, etc., have been accidentally enclosed with the water. The sulphates are then decomposed, and sulphuretted hydrogen is formed. Waters containing sulphuretted hydrogen and sulphurets of metals are also liable to be decomposed by the oxygen contained in the bottle previous to being filled. In order to avoid the injurious effects of oxygen upon the waters, and also to prevent the escape of carbonic acid, M. Hecht has introduced the method of filling the bottles with carbonic acid before the water is let in; but, although this proceeding is very judicious, the escape of carbonic acid cannot be entirely prevented by it, and it is therefore not advisable to use natural imported chalybeates and sulphurous waters; while those containing sulphates and others may be useful if sufficient care has been taken to prevent impurities from being mixed up with them.

M. Constantin James (a) has lately stigmatised, in strong terms, the various *artificial mineral waters*, which are employed as substitutes for the Spas themselves. He contends that these imitations are of no value whatever, save as mere refreshing table-drinks or purgatives; while when ordered for baths the most varied compositions are employed, and nothing analogous to the natural waters is obtained. No doubt most artificial mineral waters offered for sale richly deserve this censure; but the same cannot be said of Struve's imitations, which closely resemble the natural waters. In consequence of the great success of Struve's establishments, a large number of other manufacturers have invested their capital in the same trade, and most of these produce very inferior fabrications. The very cheapness of these imitations suggests the suspicion that they cannot have been carefully prepared. It is notorious that in some of these establishments the bitter water of Püllna is prepared by merely dissolving a certain amount of sulphate of soda in the water, and impregnating this latter with carbonic acid. Carlsbad water is in a similar manner made by dissolving sulphate of soda, chloride of sodium, and carbonate of soda in water; and in many cases the water is not even pure, but is used just as taken from wells or rivers! It is, therefore, important that, if artificial mineral waters are prescribed, we should insist on Struve's imitations alone being used.

In many Spas, bathing is of even greater importance than drinking the waters. The curative effects of baths are due both to the action of the water and its foreign ingredients upon the skin, and to the action of the gases ascending from the water, upon the mucous membrane of the air passages. In most cases it is advisable that bathing and drinking should not be commenced on the same day. Baths are either taken in single rooms or in common reservoirs, the so-called "piscines," or swimming-baths, in which exercise during the baths is possible. In the majority of cases, the latter are far preferable to the former; but care should be taken that the piscines are spacious and well ventilated, and that the water is constantly renewed. The piscines of Wildbad, in Würtemberg, are patterns of their kind. The fear that contagious diseases may, in these piscines, be transferred by means of the water from one person to another, has by experience been shown to be altogether unfounded.

Baths are generally taken between breakfast and dinner, and no doubt this is, on the whole, a judicious proceeding. In many cases, however, especially if the weather is damp and cold, it is preferable to order the bath to be taken before going to bed, when perspiration is most effectually promoted; and the patient may also indulge the sleepiness generally induced by bathing. It is scarcely necessary to observe that baths should never be taken shortly after hearty meals; and that great caution should be observed regarding their use by persons with a tendency to apoplexy.

"Psydracia thermalis," the "critical bath-eruption," the appearance of which was in former times welcomed alike by Physicians and patients, is now no longer looked upon as a favourable symptom, but rather as an unpleasant occurrence which it is by no means desirable to produce. Critical eruptions as such are by no means connected with an improvement in the condition of the patient, but are the necessary

(a) *Gazette Medicale de Paris*, 1862. No. 6.

physiological consequence of a prolonged contact of water or mineral water with the skin.

The physiological and curative effects of baths are much enhanced by the addition of *graduated brines* and *mother-lye* to the water. Brines are graduated by letting the water slowly run down scaffolds of thorns, which, in many watering-places, are from fifty to ninety feet high, and several thousand feet long. In running over this immense surface, a considerable portion of the water evaporates, especially if the weather is warm and the wind high. The water thus becomes richer in salines, and if this process is repeated several times with the same water, the liquid may at last assume a high degree of concentration. At the same time, minute particles of salines are, by the wind, carried into the surrounding atmosphere, and the inhalation of air thus impregnated with salines has, in many instances, proved useful to patients suffering from diseases of the respiratory organs.

When brines have been concentrated to such a degree that they contain from 140 to 180 grains of salines in sixteen ounces of water, they are, in many watering-places, boiled in order that those salines which are not easily soluble, such as chloride of sodium, silica, carbonate of lime, carbonate of magnesia, alumina, iron and manganese, may be precipitated and removed from the liquid. That which remains after several weeks boiling, is called *mother-lye*. This is half salt and half water, as it contains from 2000 to 4000 grains of salines in the pound. Its chief solid constituents are chloride of calcium, magnesium, and potassium, and bromide and iodide of sodium and magnesium. The Dead Sea is a huge natural *mother-lye*, formed by the long-continued evaporation of water. This lake uninterruptedly receives water, but has no visible outlet; and as it is situated at a very low level, viz., 1300 to 1340 feet below the Mediterranean, the water conveyed into it does not filter below ground, but is removed chiefly by evaporation. Large quantities of salines are, therefore, precipitated, not only at the bottom, but also on its shores.

The chemical composition of the *mother-lyes*, prepared at the several Spas, differs according to the composition of the waters from which they are formed, and the temperature at, and the length of time during, which they have been boiled. The most celebrated *mother-lyes* are those of Kreuznach, Halle, Volterra, and Dürkheim. The quantity of *mother-lye* generally added to baths, varies from two to thirty quarts.

If *mother-lye* is again boiled, the liquid becomes even more concentrated, and after refrigeration crystallisation ensues. The hard substance which at last remains is called *salt of mother-lye*. This contains a considerable quantity of water and is very hygroscopic, so that, if exposed to the air, it soon again assumes a liquid state. Great care is therefore necessary in exporting *mother-lye*. It is scarcely possible to preserve liquid *mother-lye* in barrels, as on account of its high specific gravity it forces its way through the pores and joints of the wood. Salt of *mother-lye* is more easily exported, but if added to baths it does not produce the same effects as if liquid *mother-lye* is used; for as the different salines contained in the liquid have different points of crystallisation, the layers at the top of the barrel are different from those at the bottom. If, therefore, one layer is used after the other, only parts, and not all the ingredients of the *mother-lye* are employed. It would on this account appear advisable either to again dissolve the whole contents of the barrels previous to using, or to export the liquid *mother-lye* in bottles covered with wicker-work, from which there would be no danger of its escaping.

(To be continued.)

## REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

### WESTMINSTER HOSPITAL.

#### CONCUSSION, FOLLOWED IN THREE HOURS BY COMPRESSION—LACERATION OF THE MENIN- GEAL ARTERY—RAPIDLY FATAL RESULT.

(Under the care of Mr. HOLT.)

[Reported by Mr. ARTHUR BEADLES, House Surgeon.]

In a case of injury to the head, related in this Journal on August 30, 1862, at the autopsy the cerebellum was found to

be torn, and the blood effused at the base, and on the surface of the hemispheres. Yet, directly after the accident, the patient walked about one-third of a mile, and could scarcely be persuaded that he was at all seriously ill. He kept apparently well ten hours; then symptoms of compression came on, and he died in five hours. No doubt, the greater part of the effusion occurred shortly before the serious symptoms set in.

In such cases of effusion of blood on the surface of the hemispheres, the paralysis follows the same rule as it does in cases of effusion into the corpus striatum, or thalamus opticus, *i.e.*, the paralysis is on the opposite side of the body. It is in cases like these, *i.e.*, when, after an injury to the head, symptoms of compression come on with paralysis on one side of the body, that trephining in the region of the middle meningeal artery, on the side opposite to the paralysis, has been successfully practised.

Mr. Prescott Hewett ("Holmes' System of Surgery") says—"Of the large extravasations, the most frequent by far is that from the middle meningeal artery. Out of thirty-one cases of fracture of the skull, accompanied by extensive extravasation, the blood had proceeded from the middle meningeal artery or its branches in twenty-seven cases."

A very interesting case, which occurred in the practice of Mr. Adams at the London Hospital, is related in this Journal April 19, 1862. In that case there was paralysis of the right side of the body, which came on after a blow on the right temple. There was, however, also convulsions on the left side. Mr. Adams, in a clinical lecture, a report of which is appended to the case, discusses the question of trephining under such circumstances. The autopsy showed that to have, as Mr. Adams expressed it, "trephined on speculation," would have been of no avail in this instance, as to have trephined over the left middle meningeal artery would have been useless, as the blood did not come from it, was not near it, and was under the dura mater. Besides, the brain was torn.

In the following case the question could never have been raised, as the patient died ten minutes after the symptoms of compression set in:—

John K., aged 25, was brought to the Westminster Hospital at half-past seven p.m. on November 25, 1862, with symptoms of concussion of brain. He had fallen from a scaffold about seven feet from the ground two hours and a-half before admission, and when he was found by his fellow-workmen, about five minutes afterwards, he was standing up against a wall. They spoke to him, and he said, "Never mind, I shall be better in a minute or so," and complained of being cold, and of a pain in his side. When he came into the Hospital he had all the symptoms of concussion of the brain; and, on careful examination by the House-Surgeon, no injury could be discovered except a bruise on the left side of the forehead. He remained in this state for about a quarter of an hour, when suddenly the symptoms of compression came on, the pupils became widely dilated (before being very much contracted), stertor and paralysis of the right side supervened, and he died in ten minutes, three hours having elapsed from the time he fell.

*Post-mortem, Eighteen Hours after Death.*—On opening the skull, a clot of blood, weighing three ounces and a-half, was found external to the dura mater, on the left side and anterior part of the brain, which was much compressed but not lacerated at this point. The hæmorrhage had evidently proceeded from the middle meningeal artery, which was found to be torn by a fracture passing through the squamous portion of the temporal bone on the left side, and also through the great wing of the sphenoid. The fracture had also extended across the petrous bone, the apex of which was broken off.

In this case there was probably at first little or no effusion of blood, the greater part at all events being effused when the paralysis came on.

### MIDDLESEX HOSPITAL.

#### CASE OF CONCUSSION OF THE BRAIN— RECOVERY.

(Under the care of Mr. HULKE.)

At noon, October 22, 1862, a healthy servant-girl, aged 15, was struck on the right temple and shoulder by a falling scaffold-pole, and fell stunned. One hour after the accident, when she was brought to the Hospital, consciousness had

partially returned; she had vomited, passed a loose stool, and voided her urine in her clothes; pulse small, rapid, fluttering; surface of body cold. At 3 p.m., when seen by Mr. Hulke, the eyelids, particularly the upper, were swollen and ecchymosed. The entire right temporal region was occupied by a prominent puffy swelling from extravasated blood. No fracture of the cranium was discoverable. The right shoulder was slightly ecchymosed. She lay on the left side, her legs and thighs flexed, the knees almost touching the belly, screaming and tossing herself restlessly about during the examination of the head and shoulders. When sharply spoken to, she gave a mono- or dis-syllabic answer to any short query; but when a longer question was put, she rambled and muttered incoherently. At 9 p.m. she had again vomited, and passed urine in bed; skin hot. Is very restless, and screams when touched. The left side of the head was shaved, and covered with a constantly wetted rag.

23rd.—3 p.m.—Pulse 104; head hot; answers "No" to every inquiry or request. Refuses food, and has not taken any nourishment since the accident. A caoutchouc bag of ice was laid upon the injured temple, and a small enema of beef-tea was ordered to be administered every four hours. 9.30 p.m. Pulse 72; head cool; she is less restless.

24th.—She talked loudly and incoherently from 3 till 8 o'clock this morning. Pulse 88; head hot; lips dry, but tongue clean and moist. She is more conscious, but still obstinately declines food. The enemata of beef-tea were continued. More hair was cut off, and cold was applied to a larger surface. As the bowels had not yet been moved, a purge of sulphate of magnesia was given.

25th.—Pulse 76. She understands perfectly all that is said, but still obstinately refuses food, and replies "No" to everything. The salts not having acted, a turpentine and castor-oil enema was administered.

26th.—Last evening she drank some milk, the first food she has taken since the accident, and to-day ate a light pudding. Pulse 70; skin cool; she is now quite rational. The swelling of the eyelids has subsided, and the extravasation in the temporal region is fast disappearing. The bowels continue bound, though the purgative enema was repeated.

27th.—Pulse 72; bowels have acted. She now begins to know where she is, but cannot understand that she has had an accident.

From this date her intelligence and general condition steadily improved, and she left the Hospital convalescent November 20. Her recollection of events before the accident was unimpaired, but of the accident itself she knew nothing. She was obstinate after she had acquired sufficient consciousness to understand what was said to her, and refused food, because, she said, she did not know where she was, and thought she had fallen into the hands of designing persons.

#### CASE OF SPINA BIFIDA—PARACENTESIS FIVE TIMES—SUGAR IN THE FLUID WITHDRAWN.

(Under the care of Mr. HULKE.)

THE existence of sugar in the cerebro-spinal fluid after meals has been given by a French Surgeon as an important element in the diagnosis of cysts in the spinal region of doubtful nature. Mr. Hulke first learned its existence in the contents of spina bifida from Esmarch, of Kiel, and in the present case obtained on several occasions clear evidence of its presence.

The condition is so hopeless, and operations for the removal of the tumour, or its obliteration by iodine injections, are so uniformly fatal, that, beyond an attempt to retard the increase of the tumour by methodical compression, surgical interference is only called for where the distension is so great that sloughing and exposure of the interior threaten. The present adds another to the long list of cases which show how rapidly the fluid re-accumulates, and how temporary is the relief which tapping affords.

A well-grown, and otherwise well-made child, one month old, was brought to the out-patient's room, October 16, 1862, with a spina bifida in the lumbar region. The girth of the bag was nine and a-half inches, and the distension so great that rupture seemed imminent. The skin was very thin, red, translucent, and the cuticle desquamating. At the most prominent part of the tumour there was a white radiating scar. There were no convulsions nor paralysis. At birth the tumour was about a quarter of its present size.

To prevent the threatened bursting, the tumour was tapped with a grooved needle, and  $\zeta$ ivss of clear, colourless, cerebro-spinal fluid were drawn off. There was now sufficient flaccidity

to permit the aperture in the spinal column to be felt: it was about three-quarters of an inch long, by half an inch broad, and running from the upper end of this gap across the bag to the radiated scar mentioned on the most prominent part was a soft cylindrical process. The little prick was covered with collodion, and a compress was applied over the spine by an elastic belt.

18th.—The sac is as much distended as at first.

30th.—The distension being very great,  $\zeta$ vij. of fluid were drawn off—clear, colourless water, free from albumen as the first specimen, and giving a marked saccharine reaction with Trommer's test.

November 4.—The fluid collects less rapidly; the child thrives.

20th.—Rupture again threatening,  $\zeta$ v. of fluid were drawn off—clear and colourless as the first specimens, but containing a trace of albumen. The liq. potassæ, sulphate of copper, and fermentation tests, all gave decided proof of the presence of sugar.

At Christmas,  $\zeta$ xij. of fluid, of exactly the same character, were removed, and on January 17,  $\zeta$ x. The day afterwards the child died in convulsions.

#### ST. BARTHOLOMEW'S HOSPITAL.

##### PRIMARY AMPUTATION OF THE THIGH FOR SEVERE COMPOUND FRACTURE OF THE LEG—RECOVERY—SUBSEQUENT FALL ON THE STUMP—NECROSIS OF THE SHAFT OF THE FEMUR—REMOVAL OF THE NECROSED PORTION.

(Under the care of Mr. LAWRENCE and Mr. COOTE.)

MR. HOLMES COOTE said that in this case the points which merit notice are,—first, the imperative necessity of primary amputation in these cases,—a point sometimes overlooked; secondly, the effects of the fall.

Another point is interesting, namely that amputation of the thigh is not the same dangerous, indeed, almost fatal operation in this (as in some other of the London Hospitals) as modern authors, especially of the foreign school, would lead us to suppose.

In the autumn of last year, while the underground railway was in process of construction, a healthy young man, who was driving two horses attached to a truck in one of the tunnels, stumbled over a log of wood, and, clinging to the harness, was thrown down, the wheel passing over the right leg. He was conveyed to St. Bartholomew's Hospital, where Mr. Coote, after satisfying himself of the nature of the injuries received, performed at once the operation of amputation of the thigh by the flap method. There was nothing worthy of remark in the operation, nor in the after-treatment, except that the large intestines were loaded with fecal matter, and the patient experienced great relief from the administration of a purgative shortly after the operation. After the separation of the ligatures, and the closure of the wound by adhesion, he got out of bed, and endeavoured to walk with the aid of crutches. On the first attempt he fell, and violently struck the stump on the floor. Great swelling and a sharp attack of inflammation ensued in the limb; the wound partly re-opened, and fistulous passages formed; finally, dead bone was detected.

On Saturday, February 22, Mr. Lawrence made an incision down to the bone, and drew forth a piece of the entire shaft, three to four inches in length, from a cavity formed of periosteum and new bone, and lined by a highly vascular membrane. The outer surface was beautifully marked by the action of the absorbents, the extremity was as sharp as if just cut by the saw. The discharge of pus was copious and offensive in odour.

Since this time the patient has gone on well, and will have an excellent stump.

#### THE LONDON HOSPITAL.

##### ENCEPHALOID CANCER OF THE ORBIT—CONSTANT HÆMORRHAGE—REMOVAL BY CAUSTICS, WITHOUT LOSS OF BLOOD.

(Under the care of Mr. MAUNDER.)

E. M., aged 6 years, became the subject of a tumour of the orbit, extending the right eyeball, in August, 1862. In September, the globe and tumour were removed in the

Maidstone Hospital. The disease quickly returned, and when Mr. Maunder saw the child there was a tumour the size of the fetal head. There was constant bleeding from its anterior surface. It hung over the nose and the right half of the mouth. The hæmorrhage was so great that it threatened the life of the child, who was already much reduced by it.

To remove the unsightly mass and check hæmorrhage was all that art could be expected to effect, and was accomplished by transfixing the tumour at its base, in several directions (*à la Maisonneuve*), with pencils of chloride of zinc and flour dried hard. These cut off the supply of blood to the mass, and on the tenth day the tumour was drying and shrivelling, and was forcibly torn away from its site, with only a little oozing of blood from the pedicle in the orbit. On the following day the pedicle was cautiously destroyed by the actual cautery.

The child left the hospital on February 6, with a granulating wound occupying the seat of the tumour.

ST. MARY'S HOSPITAL.

CLINICAL REMARKS ON THE RELATIVE VALUE OF ACONITE, OPIUM, AND VERATRIA IN RELIEVING PAIN—ILLUSTRATIVE CASES.

(Under the care of Dr. HANDFIELD JONES.)

In reference to the following cases, Dr. Handfield Jones remarked that the view which he was inclined to take of the action of the three remedies mentioned above, when applied locally, was, that *aconite* is most suitable to acute superficial pain, itching, and hyperæsthesia of the skin; *opium*, to pain of a more wearying, aching kind, more connected with debility, and requiring stimulating or tonic more than sedative treatment; and *veratria* to intermediate states, where a peculiar excitation of the nerve extremities seems to alter the morbid action of the affected nerve. More shortly the same may be put thus,—aconite is a benumber, opium a stimulant, veratria an alterant of nervous power. It is quite permissible, as is often done, to join opium with ammonia, chloroform, or turpentine, as these stimulants, if not in excessive amount, will rather promote the action of the opium. The other drugs should certainly be used alone. Belladonna is highly praised by the admirable Trousseau for its pain-subduing efficacy, especially in the case of external and superficial pains. He (Dr. Jones) had had more experience of its internal than of its external use, but was inclined to look upon it as a sedative akin to aconite.

He would not omit offering a caution as to the use of aconite, which is certainly a most potent drug. It should not be applied to weakly subjects, especially to those who had any tendency to syncope, and care should be taken that the liquid should not come in contact with any excoriated or mucous surface, unless, indeed, it be much diluted. In the case of ordinarily healthy persons it is quite safe, and may be used freely to the unbroken skin. It seems, also, pretty certain that the presence of acute pain, or severe itching, or any like affection, renders its use internally and *à fortiori* externally much more safe, even in weakly persons, than it would be if the nervous system was quite tranquil. He had then a patient under his care who had been taking twelve minims of the Pharmacopœia tincture daily for several weeks, on account of an obstinate spasmodic action of the muscles of one side of the neck. This quantity the patient bore well, and it benefited the spasms, but sixteen minims in the day caused some faintness. In tetanus this tolerance is very remarkable.

Case 1.—A man, 62 years of age. He had prurigo, for which he first used an ointment of veratria—twelve grains to the ounce. This, however, made him feel "as if," he said, "he was in a burning furnace." Dr. Jones then prescribed a lotion of aconite—one ounce of the tincture to two ounces of water. Under this and bichloride of mercury—one-twelfth of a grain three times a day—he was cured.

Case 2.—A man, 48 years of age, had a lichenous eruption ensuing on a state of neurolysis. It was cured by the lotion of aconite.

Case 3.—A female, 31 years of age. In this case the patient had suffered from gall-stone for nine months, and had severe pain in the right side. The pain distinctly relieved by the aconite lotion.

Case 4.—A man, aged 35. A case of cutaneous hyperæsthesia, great itching, cured by the local application of the aconite lotion and the administration of carbonate of iron.

Case 5.—A female, about 30 years of age. Severe rheumatic pleurodynia. She received but little benefit from poultices sprinkled with laudanum, but was very notably relieved by aconite lotion. She took, also, iodide of potassium from the first.

Case 6.—A man, 36 years of age, suffered from neuralgia in the head and in both infra-orbital regions. It was worse in the damp and cold weather. It was greatly benefited by the veratria ointment.

Case 7.—A woman, aged 31, suffered from menorrhagia and neuralgic pains in the temples and left side of the abdomen. The pain in this case was more relieved by opium liniment than by the veratria ointment.

Case 8.—A woman, aged 47. She had been subject to tic douloureux for four years on taking cold. She had the most pain in the left side of her face on eating. Exposure to cold air aggravated the pain very much. She had several decayed teeth, some of which had been drawn, without relief. She took quinine and iron and applied the ointment of veratria with much benefit. She said the ointment caused a pricking sensation and lulled the pain.

Case 9.—A woman, aged 55. For about eight months she had a remittent neuralgic pain of the lower and outer part of the right leg. The veratria ointment alone at first gave her much relief. Afterwards, she took quinine and iron, and used a liniment of opium. She then took iodide of potassium, still using the liniment. She thought the opiate liniment gave her more ease than the veratria ointment.

Case 10.—A man, aged 30. He had had severe pains in his head, probably rheumatic. A node formed. He found that a lotion of equal parts of laudanum and water aggravated the pain, but that the aconite relieved it. Under the use of the iodide of potassium he quite recovered.

Linimentum opii is so commonly beneficial in the various aches and pains of weakly people, that it is not worth while to adduce any instances of its action alone.

In several cases of intense photophobia, evidencing the extreme retinal hyperæsthesia, Dr. Jones has found the application of aconite lotion very beneficial, at least apparently, though it is not always easy to say how much of the improvement is owing to the lotion and how much to the tonics given at the same time.

The strength of the aconite lotion has been one part of the tincture to two parts of water, of the veratria ointment ten grains to an ounce.

Medical Times and Gazette.

SATURDAY, MARCH 7.

THE PRESENT STATE OF THE ARMY MEDICAL DEPARTMENT.

If a distinguished foreigner found himself before that large and imposing pile of buildings known as the "Royal Victoria Hospital," at Netley, and were told that it was for the reception and treatment of sick and wounded soldiers, he could not fail to be struck with the liberality and munificence of the English nation.

This feeling would be increased still further by an inspection of its interior arrangements. Every thing that can minister to the comfort, treatment, and recovery of its inmates is to be found there,—supplied, too, with a profuse and lavish

hand. We here except, of course, the building provided for the Medical staff, which contrasts too strongly with its magnificent neighbour to escape attention. The separate house, provided for the Medical head of the establishment, appears to have been erected under the fear that one of the Medical staff might be married. Within a stone's throw of this, almost, is a much more imposing building, for the *military* governor.

He would, of course, infer that the officers upon whom devolved the trust of guarding the health and curing the diseases of the sick soldier, were participators in the liberality with which the nation had provided for the wants of her sick and wounded protectors. He would conceive the Medical as a highly valued, respected, and well-paid scientific department of her Majesty's army, and that service in it was highly esteemed, eagerly competed for, and not to be won but by men of the highest qualifications. We know how very much this would be at variance with the facts!

But let us suppose that he was informed of all the circumstances which had occurred at the time of the design and during the erection of that Hospital.—How the time is but just past when the little care bestowed upon the unfortunate soldier, or the men whose function it was to guard his health, caused such sore trials as to have amounted to a feeling of national disgrace.—How the nation had determined that, whatever the past might have been, for the future England should be well prepared.—How commissions had been appointed, and men, eminent by birth, position, and ability—in whom the nation had every confidence—had devoted themselves to the task.—How it was determined that thenceforth the Medical department of the army should be placed upon such a footing as to tempt the best men of our universities to enter it.—How—as an earnest of the spirit with which the nation was animated—the whole of this branch of the service had been remodelled; a royal warrant, conceding the long-withheld and just rights of its members, granted; a code of regulations, giving the army Medical element new and important duties, and defining the means by which these should be carried out, published; a Medical school for the special training of Medical candidates established; men of known energy and independence placed in high positions, and this building completed.

Let it be indicated how the wisdom of all this had been ratified by every day's subsequent experience, and that a campaign in an unwholesome soil had tested the new order of things with results which were acknowledged to be almost unparalleled in warfare. Then inform him how all that had been done was quietly but rapidly being undone!

Scarcely has Netley Hospital been completed, and not yet inhabited, before we find the whole Medical department in a ferment of discontent: deficient in the *quantity* of candidates for its appointments—perhaps, still more deficient in the *quality* of these; resignations on the part of the older and more zealous of its members, and a spirit of dislike, distrust, or worse—a stolid kind of apathy—the dominant feelings in every man's mind.

The English nation, liberal to prodigality, testing things by a principle of common-sense, did their best to bring their Government out of the Crimean disasters, and to prevent the recurrence of these: *there* they stopped; *here* the Horse Guards commenced, and have succeeded perfectly. The commander-in-chief has given the word—"as you were," and "as you were" it is accordingly.

At first, the process of destruction was not an easy one, for between the Horse Guards and the Medical department stood a man of markedly independent spirit, in whose talents and unflinching integrity the public and department had confidence. So long as he lived, he formed a breakwater against which the stream of attacks from the Horse Guards broke.

That there is a mournful change for the worse in every thing connected with our Profession in the army cannot be doubted.

There is a staff of professors eminently qualified to afford that instruction, which is at once so novel and practical as to be, perhaps, one of the most useful courses ever given. In what terms does the Government expect these men to address their audiences at Netley next April; or how long are they to press hopelessly onwards against the current which sets in from the Horse Guards so dead against the Medical branch of the service? The work of two Secretaries for War has already been undone, and, unless some urgent need occur, we are not prepared to say at what limits the process will be arrested.

Let us trace in what way the authorities have altered their landmarks and broken the guaranteed rights of the army Surgeon. The circumstances of public irritation under which the warrant of 1858 was wrung from the Government must be fresh in our readers' minds. Among the clauses of that warrant we find the following:—

“‘The relative rank of the Medical officers of our army shall be as follows:—Staff, or regimental Surgeon as major, according to the date of his commission, etc.;’ and again, the seventeenth clause, which defined that ‘such relative rank shall carry with it all precedence and advantages attaching to the rank with which it corresponds (except as regards the presidency of courts-martial, where our will and pleasure is, that the senior combatant officer be always president), and shall regulate the choice of quarters, rates of lodging money, servants, forage, fuel, and light, or allowances in their stead, detention, and prize money. But, when a Medical officer is serving with a regiment or detachment, the officer commanding, though he be junior in rank to such Medical officer, is entitled to a preference in the choice of quarters.’”

We are among those few who conceive that there might have been some other way of fixing the position and remunerating the Medical officer than by the above relative ranks. Still, it is in accordance with the advice of the ablest and most practical men, and the regular principle and custom of the service, and, when once given, it became a written guarantee to every Medical officer of his rights. What remains of it?

In 1861 the Surgeons were ordered to be always of junior rank to majors; and, notwithstanding the irritation this caused, the report of a commission that the terms of the warrant ought to be restored, and the appearance of a paragraph in the *Globe* that it would be, it never has!

Spite of the clearness of the language and meaning of the seventeenth clause, every one of its privileges has been ignored.

The *status* of a Medical officer is at present of such a kind that an ensign may obtain precedence of a Surgeon grown grey in her Majesty's service.

Military orders (as confidential circulars) were given, in direct opposition to the warrant, that no Medical officers should ever be allowed to sit president of a committee, whatever might be its nature, provided a combatant officer were present.

It is perfectly untrue that the Medical officer is desirous of assuming any command, and the warrant justly precludes his ever doing so.

Let it not be forgotten that all allowances (which are all important to the inadequately paid Medical officer) are guaranteed according to the scale of his relative rank—and these have not been given.

To India this warrant has not even been applied; and at this moment not one of its provisions has been allowed in any of the three presidencies. A Surgeon was ordered to be a member of a board there recently; he sent in his claim for lodging allowance, according to the rate of his relative rank as a lieutenant-colonel. His case was exceptional! He was granted the allowance of a captain.

It is proverbial that the Assistant-Surgeon of a regiment serving in India is the worst paid man in it, unless he be so fortunate as to obtain a separate charge.

We appeal to those who know the department for an answer

to this question! In the event of a difference or conflict of opinion between the Medical and combatant authorities abroad, how far have the former had the support of the powers at home—even upon matters of sanitary science, or questions connected with their own Profession?

We now approach another and late instance of injustice, which has been before animadverted on in these columns. We mean the appointment of an Assistant-Surgeon to the army, whose commission was ante-dated so far that he actually passed over the heads of upwards of 400 Assistant-Surgeons!

Let it be remembered that the gentleman in question was in receipt of a handsome salary from Government at and after the period of the ante-dating; that he was not at that time qualified according to the terms of the warrant, and is now over age. Now, we have nothing to say about this officer's merits—and they are said to be great—but this step is manifestly most unfair, and in direct opposition to the warrant, which rules that seniority shall be the means by which Assistant-Surgeons shall be promoted. The fact is, that promotion has been at a stand-still. As vacancies have occurred, they have not been filled up, but the numerical strength of the department has most rapidly decreased. Assistant-Surgeons of eight or nine years' standing will be years before they are promoted. By an easy process of calculation, it may be discovered that a candidate just entering may attain his first step in rank, as Surgeon-Major, after twenty years' service. Under these circumstances, what inducement can there be for any man to enter the service—to say nothing of the better class of men? The difficulty with which these latter are attracted to, and retained in the department, is evidenced from the rapid promotion lately given to the officer to whom we have adverted.

What is the amount of leave granted to the Medical officer compared with his more fortunate combatant brother? Is it not a fact, that men, returning after long years of expatriation, with shattered health, are placed (after a short sick leave) upon half-pay?—or, are not two months' leave conceded and often cancelled almost as soon as the officer has reached his relatives or home?

Of late, we learn, that Surgeons invalided from India must either rejoin their regiments, or go upon the staff; while, hitherto, they have been allowed to effect an exchange.

How many unnecessary moves has a Medical officer to make in a year; and what consideration is shown to his pocket, comfort, or the cultivation of those thoughtful and studious habits which, it is said, ought to characterise him?

The clerk work in the department, instead of being less than it was—when it excited the ridicule of business men—is carried even to a greater extent now. Not only is the Medical officer bound to comply with it, but any failure on his part in doing so is followed by an attack on his pocket—in the shape of his paying for any extra which he may have given, but not daily recorded in his case book.

It is well-known that some defects of vision are, occasionally, most difficult of detection, but woe to the Medical officer who passes a recruit unable to see an object at the longest rifle range, for he will have to pay for that man's kit!—so rules the Horse Guards.

To send a highly-educated and energetic worker in Medical science to the daily drudgery of rifle practice, is but a poor way of training his faculties, though a sure one of disgusting him. Yet, to what an unnecessary extent is this—and his attendance at parades and reviews—carried!

We pass over the ill-advised system of confidential reports, which have excited so much irritation in the members of the Medical department.

Lastly, the teaching of the army Medical school is rendered barren of fruit from the discontent reigning in the department, and the want of respect evinced by the Horse Guards for the opinions of its members.

Such, we believe, is a truthful picture of the present state of the Medical department.

## PROFESSIONAL REMUNERATION.

It has been truly said that the root of the distinction between profession and trade is the all-important fact that the professional man is occupied with the interests of others, relating to mind, body, or estate,—according as his vocation is divinity, medicine, or law,—while the mere tradesman works with his attention directed to his own benefit alone. Independently of this vital distinction, the remuneration of the learned professions must ever stand upon a perfectly different footing from the gain derived from purely commercial pursuits. The payment to be made to a tradesman is a very simple matter. It is to be measured by the value of the goods supplied, or trouble incurred in the particular case under consideration. But the professional man must receive a threefold remuneration. He must be compensated, first, for the enormous amount of time, capital, and exertion which he has expended in qualifying himself for his calling; secondly, for the labour and attention requisite for making himself master of the facts of the case under his care; and thirdly, for conscientiously applying to that case the knowledge derived from his professional education and experience. It is from attempting to extend to the professions the principles applicable only to trade that the present unsatisfactory state of the law as to professional remuneration proceeds.

The Medical and Legal professions are each divided into two classes, one class in each profession being supposed to enjoy some undefined superiority over the other. The remuneration of the superior class in each profession is, or was till lately, of a purely honorary character. The so-called inferior classes, however,—the General Practitioners and Attorneys,—have always been entitled to recover their charges in a court of law. But supposing a General Practitioner and an Attorney to have brought each an action, and to have succeeded in establishing a right to *some* compensation for their services, the amount of such compensation is usually assessed in different ways. In the case of an Attorney, it generally has been already ascertained by one of the Masters of the Court,—gentlemen thoroughly acquainted with the remuneration to which the plaintiff is justly entitled, and whose decision, as a rule, is satisfactory to all parties. In the case of the Medical plaintiff, the damages are assessed by the jury. Here the Medical profession stands at an enormous disadvantage. Were it left to common juries to tax the costs of Attorneys, it would, indeed, go hard with that body. The prejudice which exists against them among ignorant people, combined with the sympathy in the minds of the jury with anyone called upon to pay a lawyer's bill, would reduce the damages to the lowest figure. But, unfortunately, the dislike to pay a doctor's bill, as soon as the necessity for his assistance has, thanks to him, passed away, is no less intense than in the case of a lawyer's costs. The sympathies of the jury are entirely with the defendant, and in the verdict in the recent action of "*Breary v. Green*" we have a fair sample of the usual result.

In this case the learned and witty Baron Bramwell, not without a few facetious observations, told the jury that, if they believed the plaintiff's statement, he was entitled to recover; but kindly added that it was quite competent to them (the jury) to state what sum they thought he ought to receive. After mature deliberation, they came to the conclusion that £201 15s. 1d. was the pecuniary equivalent to the plaintiff's professional services, extending over some three or four years, during which the defendant suffered from a tumour pressing on the urinary canal, and during which the plaintiff supplied (*inter alia*) 2677 draughts and mixtures, had made 778 visits, and performed certain operations.

The fact is, that common juries are unfit tribunals to decide on the remuneration of professional men, whatever be their value (be it great or small it is not our business to determine) in actions on other grounds. The only class

which is, or has till now been exposed to disadvantage from such incompetency, is that of General Practitioners. But our present object in drawing our readers' attention to the case just mentioned is to give them an opportunity of considering its bearing on another question. By the light of such verdicts as this we may estimate the advantage which would accrue to the class of Physicians, should the point, upon the construction of the Medical Act, which was reserved at the trial of "Gibbon v. Budd," be decided in accordance with the plaintiff's contention. In that event, it will have become settled law that the *members* of the Royal College of Physicians may, if they choose, avail themselves of the high privilege now accorded to their more (or less) favoured brethren, of having their fees assessed by the same competent tribunal, and in the same satisfactory manner we have just had the pleasure of contemplating. The Physician will then be in a far worse predicament than the present one of the Practitioner who dispenses his own drugs, for items for goods sold would be viewed with much greater favour than items for advice, though we have in "Breary v. Green" seen "goods sold" fare badly enough. Once let the public get hold of, and become familiar with, the notion that Physicians' fees should be assessed according to the ideas of a common jury, instead of the honour and conscience of the Practitioner and the patient, and the jury standard will become the usual standard, the last state worse than the first.

### THE WEEK.

#### THE LATE DISCUSSION ON OVIOTOMY.

The important discussion at the Royal Medical and Chirurgical Society on ovariectomy, to be found in another part of this number, will be read with much interest. Another discussion, of almost equal interest, on the same subject, took place at the Obstetrical Society last Wednesday, after a very valuable paper by the veteran ovariectomist Dr. Clay, of Manchester, who brought forward the results of 104 cases of this operation in his own practice. Mr. Spencer Wells, in the discussion, alluded to fifty-seven cases in his practice, and Mr. Baker Brown to fifty-three in his. So that the remarkable fact may be cited of three speakers having between them performed this capital operation in 214 cases. The points chiefly discussed were the length of incisions, the mode of dealing with the pedicle, the temperature of the room, and the use of opium. But, for all this, we must refer to our usual report in a future number.

#### SMALL-POX AND VACCINATION.

CONSIDERABLE alarm is felt at the increase of small-pox. The Small-pox Hospital is full to overflowing, and the temporary wards, which have been provided by some parishes, are so equally. Most of the cases occur in adults or young persons who have been vaccinated. Many questions will naturally be raised by this outbreak, especially as to the efficacy of vaccination as usually performed. Doubts will be expressed as to the amount of care taken in selecting *vaccinifers* with good vesicles, and as to the care taken to use only clear lymph, and not serum or blood which may be made to exude by *jobbing* a vaccine vesicle with the point of a lancet. It seems to be universally felt that a large number of cases is requisite in order to enable any vaccinator to keep up a good succession week after week; that it is a mistake to appoint too many vaccinators; and that it is better that students should learn this operation from the public vaccinators than at the Hospital.

#### HALL v. SEMPLE.

THE answer which Sir George Grey gave to Mr. Butt a few nights ago in the House of Commons, when the latter inquired whether it was the Home Secretary's intention to propose

any alteration in the law relating to certificates required in cases of alleged insanity, placed this case in its true light. The real blame rested not so much on Dr. Semple, who signed a certificate believing in its truth, as on Mr. Elliot, who received a patient into his Asylum on an irregular and illegal certificate. The sympathy for Dr. Semple felt by all ranks in the Profession has borne substantial fruit. We are informed that the amount of contributions received by Dr. Forbes Winslow and Dr. Waller Lewis, the joint treasurers of the "Semple Fund," exceeds £500. We have been requested by these gentlemen to state that "the subscription list is now closed, and that they publicly tender their acknowledgments to the members of the Medical Profession and others who have so promptly, kindly, and generously responded to the appeal made to them. It will be satisfactory to the friends of Dr. Semple to know, that the object which the treasurers had in view has been fully attained." This result is equally honourable to Dr. Semple and to the Profession of Medicine.

#### MEDICINAL BISCUITS.

WHAT are the marks of a good remedy? We hold that they are these:—1st. It has been known and used by the vulgar for some indefinite period; 2nd. It is a thing sought for by ignorant instinct, antecedent to scientific research; 3rd. Its use has been confirmed by cautious clinical observation, and in some few cases has been explained on scientific principles. Charcoal is a remedy which has most of these signs. It is greedily devoured by some patients during certain states of stomach disorder, in obedience to a certain instinct; it is an old remedy, and its use is congruous with modern reason. Mr. Bragg, of 2, Wigmore-street, has endeavoured to combine charcoal with the materials of biscuit, so as to produce a not unpalatable result; a little gritty perhaps, but we think this may be overcome. If children were to masticate one of these biscuits at bed-time, it might purify the breath and whiten the teeth, and allay restlessness arising from indigestion and acidity.

Unlike charcoal, bran is a substance which the instincts of civilized man teach him to avoid. Working man exhausts the powers of his digestion, and must give over woody and sclerogenous substances to the lower animals to assimilate for him. Yet experience has shown that a small quantity of bran promotes the action of the bowels; chemistry teaches that it contains a large proportion of fatty and nitrogenous matters, and the experience and sagacity of Dr. Camplin has proved its value as an article of diet in diabetes, in which sugar and starch are inadmissible. The bran biscuits made by Mr. Blatchley, of 362, Oxford-street, are really nice; their flavour is so agreeable, and they please the eye so much, that when the dense branny material comes between the teeth, there is quite a feeling of disappointment. The dryness is of course inevitable, although art has done its best; and any non-diabetic person who wishes a gentle aperient may find that half a bran biscuit *per diem* will answer as well as a family pill. For the diabetic, they are invaluable.

#### KING'S COLLEGE SCHOOL AND HOSPITAL.

WE have to announce the election of Dr. W. O. Priestley to the Chair of Midwifery at King's College, and to the office of Physician for Women and Children to the King's College Hospital. The Council of King's College have secured the services of a Professor who has been educated in the most advanced and philosophical school of modern Midwifery, and whose life has been devoted, almost exclusively, to that branch of Medical science, and who wins universal good opinion. The only shade of regret which we feel is that the appointment of Dr. Priestley has led to the resignation of Dr. Tanner, who, no less than Dr. Priestley, has devoted himself to the Obstetric branch of Medicine; who has acquired vast experience from his position at the Hospital for Women, and as

Assistant-Physician to King's College Hospital; and who, besides, has deserved well of the Profession by his services to the Obstetrical Society; and who has shown himself a laborious and well-informed Physician by the books he has published on more than one branch of Medical science. But it must be so, even as amongst the Knight Templars of old, "When two get on one horse, one must ride behind." In our Articles on the "Medical Schools," which as soon as the gods send us space shall be resumed, allusion was made to the two lines of policy on which a staff of Medical Professors may be chosen by the governing body; the one is to select the best men out of their own school, with the view of creating a strong *esprit de corps*, and encouraging promising men to "hang about" the Hospital; the other is the more Spartan and heroic mode of throwing open the lists to all comers. King's College has followed the latter plan, and although an appointment at King's College is, on this account, one of the greatest prizes in the Profession, still the *alumni* of this scarcely-to-be called *Alma Mater* can hardly be expected to view these arrangements with perfect equanimity, nor can lookers-on help feeling considerable sympathy with those who have devoted their energies to the service of the school, and have then found themselves shut off from its highest rewards. But it is so in the Army, the Navy, the Church, and the Law. A quiet and dignified bearing under disappointment often conciliates esteem and support, which more than compensates the losers in the lottery of life.

---

PARLIAMENTARY.

NOTWITHSTANDING the opposition of Lord Naas, the Secretary for Ireland has carried his point,—the Births and Deaths Registration Bill has been read a third time and passed, and the dispensary Doctors are to be the sole Registrars in each district. Sir Robert Peel has conferred a lasting benefit on Ireland by this measure. His Act only now requires to be supplemented by a Registration of Marriages in Ireland, and we are glad to see that Mr. Monsell has moved for leave to bring in a bill having this for its object. Whatever difficulties depending on the present condition of the laws of marriage in Ireland may lie in its way, there is no question as to its necessity. If the death-rate of a civilised community affords the best test of its vital and hygienic condition, the marriage-rate gives an equally infallible criterion for judging of its prosperity.

Dr. Brady, whose vigilance for the public health and attention to the interests of the Medical Profession in the House of Commons deserve all praise, has obtained leave to bring in a bill to regulate the removal in hired or public carriages of persons suffering from infectious diseases in the metropolis. It is to be hoped that there will be no opposition to a measure which the recent prevalence of typhus, scarlatina, and small pox in London has proved to be absolutely indispensable for the public safety.

The subject of the enclosure of the Essex forest-lands was again brought before the House on Tuesday night. Mr. Torrens moved that a Select Committee be appointed "to inquire into the legality of certain enclosures in Waltham, Epping, and other forests in Essex; also, to ascertain what steps ought to be taken to preserve the rights of the public, of the poor foresters, and of the inhabitants of the Metropolis within the forests, and likewise to investigate the general management." The Attorney-General objected to Mr. Torrens' proposition on the ground that,—

"From the particular terms in which it was couched it sought very plainly to erect a Select Committee of the House into a court of judicature for the purpose of inquiring into and expressing an opinion with reference to the rights of individuals and of the Crown. Instead of the hon. member's proposition he would suggest that a Committee be appointed 'to inquire into the condition and management of the Royal forests in Essex, and into any enclosures which may have

taken place therein since the report of the Commissioners of 1850, and to consider whether it is expedient to take any steps for preserving open spots in some forests.' (Hear, hear.)" Mr. Torrens said he was quite willing to withdraw his motion and accept the proposition of the Attorney-General. The question is of high importance on hygienic grounds, and we are heartily glad that Government have thus consented to entertain it.

---

THE ACCIDENTAL CASE OF POISONING AT SHIELDS.

It will be read with satisfaction by the Profession, that an action for the recovery of damages, brought by the husband of Jane Gilhespie, the woman accidentally poisoned by strychnia dispensed by mistake in Dr. Fenwick's surgery, against that gentleman and his partner has been amicably settled. The barristers, both for the prosecution and defence, spoke in the highest terms of the conduct of the defendants. It will be remembered that the unfortunate blunder was committed by Dr. Fenwick's dispensing assistant. We reprint the report of the speech of Mr. Manisty, the counsel for the defence. Messrs. Fenwick and Peart have done all in their power to make reparation, and they deserve, and will receive, the sympathy of their brethren and the public:—

"Mr. Manisty remarked that he had the honour to appear for Messrs. Fenwick and Peart. His learned friend, Mr. Maule, had done justice to them, and had done it in terms which entitled him to the thanks of the defendants, although he had just done what he expected of him. A more painful case than the present had probably never occurred; and it was because of its painful character, and because of the feelings entertained by both his clients, and because of the sympathy which they had for the man who had lost a wife and the children a mother, it was upon those grounds, and those alone, that they had told him to arrange the matter with no niggardly or illiberal spirit. He might have exceeded the bounds; but he thought it right to deal liberally. He had also been instructed, at the same time, to express, on the part of the defendants, their deepest sorrow at the loss which had resulted from the act of some one whom they were responsible for. His learned friend had done that which he need not do now—he had acquitted the defendants of all personal negligence in the matter. He therefore trusted that their reputation would still be upheld, for there had not been the least shadow of a shade to implicate them. The prescription was right, but the medicine made up was wrong. His clients had considered their servants competent as they had proved them to be, but still they were answerable in the eyes of the law. They had agreed to give £500 as compensation, which would be apportioned, £400 to the plaintiff, and £50 for each of the children, one of which the deceased had by a former husband. He trusted that that would be satisfactory to all parties. The jury having given their assent to the offer, the case was concluded."

---

THE RADCLIFFE INFIRMARY, OXFORD.

In a convocation held on Thursday, the 26th ult., the munificent sum of £1000 was voted from the University chest towards the completion of the new buildings at the Radcliffe Infirmary. These consist of a new accident ward, and an out-patients' waiting hall, attached to which are consulting rooms for the several Medical officers, and a Dispensary. Their shell is finished, having cost about £3000. Besides the University grant, about £1000 more will be needed to complete the internal fittings, and place the whole in thorough working order. Of the many grants made by the University for charitable purposes, not one redounds more to its honour than this recognition of the claims of this deserving and well-managed Institution. We subjoin one or two passages from a paper which was circulated in support of the grant:—

"The out-patients have increased prodigiously in numbers. In 1822 they were but 297; in 1861 they had risen to 2,702, together with 2,184 casualties, amounting in all to 4,886 who received relief out of the house. Twice a week these poor people crowd into the lobby and passages of the Infirmary; and any one who will visit the house on these days will at

once perceive that the polluted air pervading the house must be very injurious to the in-patients. The new hall, with its corridor, dispensary, and consulting rooms, will enable the out-patients to see the medical men, and receive their medicines, without entering the house at all."

We wish some one would have the courage to speak out boldly about this odious out-patient system at Hospitals and Dispensaries. Very likely it is managed better at the Radcliffe than at most others, but what does it amount to? A set of poor wretches, many of whom come long distances in all weathers, are assembled in some waiting-room, where they taint the air and imbibe each other's maladies. After long delay, they are admitted to the medical attendant, who (unless it be the first appearance) asks a preparatory question, and writes the magic word "Pt."—then more waiting, until the turn comes for medicine; then the dirty bottle with its dirty cork is handed in, and the poor wretch receives some compound of drugs put together by guess, for how can there be time for weighing and measuring? If the Dispensary be in debt, the wholesale druggist sends in any rubbish he may have on his shelves—methylated tinctures to wit—but, be the drugs good or bad, two-thirds are wasted, or else are spoiled before they are used. The patient, meanwhile, wastes three or four hours of the best part of the day, for these very equivocal benefits. If people are poor and cannot afford medical attendance, there is the Parish Surgeon, who is generally a man of skill, and whose livelihood depends on his reputation. He might live in luxury, and the patients be well attended, if the sums squandered on Dispensaries were spent in improving his salary.

Now let us look at another extract:—

"It is true that members of the University subscribe largely towards the annual expenses of the Infirmary; but it must be remarked that most subscribers send in the full number of patients allowed by the rules of the house; that the subscriptions given by each person do not nearly cover the expenses of these patients; and that these patients receive the benefit of the interest of the large funded property possessed by the Infirmary. It is true also that all the Colleges subscribe to the Infirmary; but even here far the greater part of the turns are used: and it must be added that, while between 1822 and 1861 the College subscriptions have increased by the gross sum of 6*l.* 6*s.* a year, the patients have increased in the same period from a total of 1,021 to 5,921. It is true also that the delegates and partners of the University Press, and the proprietors of Wolvercote Mill, are subscribers; but in their case also all the turns are usually filled up: and it must be remembered that the casualties occurring at the Press, though few in number for so large an establishment, have all been taken into the House without recommendation, and have in fact cost the Infirmary a very considerable sum."

Thus the Hospital system, instead of being a charity to the sick poor, is, in reality, a bonus to mean rich persons, on whom the responsibility lies of providing for their dependants. Why do Lord Noodle and Lady Screw "support" the neighbouring Dispensary?—For charity? Not a bit of it; but because for every guinea they give they get two guineas' worth of medical attendance and medicine, and of board and lodging, for sick servants and workpeople, whom, otherwise, common decency would compel them to provide for. But then, it is said, these "noble charities" are so useful to the Medical profession! Are they?

#### SUGAR.

In the Annual Report of the Committee of the Mercantile Law Amendment Society objections are urged to the present method of taxing sugar, which are worth the consideration of all persons interested in the science of food supply. Nearly all sugar is made from the same raw material—cane-juice—but it is imported into this country in a great variety of different forms. It may reach us white and nearly pure, or containing a very large percentage of molasses and dirt, and in all intermediate conditions. The different qualities depend

on the different amounts of care and capital bestowed by different producers in converting cane-juice into sugar. All descriptions of teas and coffees, whatever their quality, are taxed equally; the result is that taxation produces no disturbance of the natural value of different kinds of tea and coffee. But it is not so with sugar—

"The Legislature has declared that sugars shall not all be taxed alike, and has devised a clumsy contrivance to assess different rates of duty, not according to the value of the sugar, but according to certain imaginary lines of demarcation in different qualities of sugar, which are to be decided according to the judgment or caprice of a number of Custom-house officers stationed at the different ports. Under this mode of levying the duties, the natural value of sugar is disturbed, and the legitimate profit which ought to reward the skill and enterprise of the producer is intercepted, and goes to the Customs' revenue, while the producer of inferior sugars actually receives a bonus for his careless manufacture, by a remission of the duty charged upon his produce. If a system so unjust was really productive of benefit to the revenue, it might afford some slight excuse for its retention, but it is doubtful whether it is a source of profit to the exchequer, or a positive injury."

The result is, as proved before the Select Committee of Parliament last Session, that the best producers do not send their fine sugars to this country. For instance, evidence was given before the Committee that no fine sugars at all were sent from the Mauritius. The effect is doubtless to increase the business of the English sugar refiners, but to diminish and deteriorate the value of the sugar. On this point, we quote a passage from an able article which appeared in the *Morning Post* of the 19th ult:—

"Another remarkable fact co-existent with the allegation that present fiscal imposts on sugar tend to the production of a low, coarse, impure quality is this—the straw-coloured, moist, aromatic grocery sugars of West India produce, such as were common some dozen years ago, have well-nigh disappeared. The material now commonly sold for moist colonial sugar is, in most cases, an impure refinery product. To an unpractised eye the difference may not be apparent, but the nose must be very torpid that could not detect the home-produced yellow sugar at once; whereas true moist sugar of colonial produce is pleasingly aromatic: the spurious substitute reeks of the dull faint odour of blood. Here, then, is a condition of things strained and unnatural. The refiner finds his interest to consist in manufacturing largely those yellow sugars which lose their best characteristic if they be not made from cane-juice direct; whereas the colonial producer, who has gone to the expense of chemical and mechanical refinements, is not allowed, as he alleges, to work up to the refiner's standard, namely, white sugar."

Sugar, as an article of food, is more important even than tea or coffee. In the case of the latter, the principle of *ad valorem* duties has been discarded with benefit both to the revenue and to the consumer. There can be no doubt that a similar and far greater advantage would result from the abandonment of an obsolete mode of taxation in the case of sugar, a food-product only second to corn in importance.

#### MR. LUBBOCK ON "ANCIENT LAKE HABITATIONS IN SWITZERLAND."

MR. LUBBOCK'S discourse on the "Ancient Lake Habitations in Switzerland," last Friday, was not only a complete *resumé* of that particular subject, but was a capital illustration of the triumph of the modern scientific method—the method not of conflating a huge theory, brilliant as a soap-bubble or a butterfly, and as ephemeral, but of soberly picking up facts, little or great, as they come to hand, and leaving the theory to follow in its own good time. This is the way by which geology has attained its present solid structure, and archæology—the history of man's first doings on this earth—which begins where geology leaves off, must follow the same course. It is well known that the level of the Swiss, as of other mountain lakes, is lowest when the weather is dry and cold. During a dry winter, a few years since, the dwellers on the

banks of the Lake of Zurich seized the opportunity of enclosing a portion of the edge of the lake to enlarge their gardens. For this purpose they built a wall, and filled up the reclaimed land to the desired level by dredging mud from the bottom of the lake. During this operation, piles were discovered, and implements of bone and stone. Further investigations led to the recognition of the remains of very numerous habitations on piles. Then it was remembered that Herodotus described such dwellings as existing on Lake Phasiæ, and said that for the preservation and extension of them, every man who took a wife was compelled to drive in three piles (and most of the men had many wives); further, that the inhabitants of Borneo and New Guinea use such habitations to the present day; one proof, amongst others, that if we want to know the habits of ancient men, we should study those of modern men who are yet un moulded by civilisation. The ancient fortified islands of the Irish were of the same character. It is difficult to conceive how the piles can have been driven in, but it is certain that, in some cases, stones were heaped up around them to keep them in their places. Such dwellings possessed certain tangible advantages: they were secure against enemies, human and feline, and water and fish were accessible. Of such settlements, ninety-three have been discovered. Mr. Lubbock's researches convince him of the accuracy of the expressions "stone age," "bronze age," and "iron age," as representing three consecutive stages of human progress; and he believes that some of the lake habitations belonged to each age exclusively. As a type of the first may be taken the ancient lake village of Wanwyl. Here a large, shallow lake had become a peat marsh, which has since been drained. In the marsh a system of piles was found, which was a puzzle, until it became evident that they originally surrounded an artificial island in the lake. They were of oak, fir, and alder, and varied from fourteen to eighteen feet in length. Under the peat, which of course covered what had once been the bottom of the lake, abundance of objects belonging to the stone age have been found,—*i. e.*, axes of serpentine, but less beautiful than the Danish; arrow-heads; flint flakes, used as knives; hammers; sling-stones; corn-crushers, and whetstones; awls, and chisels of bone, and implements made of split ribs. Fragments of pottery, of the rudest kind, have also been found in abundance. Most probably the inhabitants clothed themselves with skins; but portions of flax, curiously woven, have been found. Their food consisted principally of wild animals, especially the stag and marsh-boar, whose bones are found in abundance; portions of bread and apples have also been found. The fox seems to have been used as food, but not the hare, which, as Cæsar says, was *taboo* amongst the ancient Gauls, and may have been forbidden amongst their more savage predecessors. The same inferences are drawn from the reliques preserved in the Kitchenmiddens of Denmark. It is a comfort to think that there are no traces of cannibalism. No remains have been found of the inhabitants of the Swiss lakes; those of the parallel age in Denmark resemble the Laplanders. There are some traces of barter (or else of periodic excursions) as their best flints came from France. The reliques of villages which flourished during the "bronze age," of which that at Nidau may be taken as a specimen, exhibit axes, neatly ornamented knives, sickles, bracelets, fish-hooks, and rings. Their abundance suggests the idea that they were not merely things which had dropped into the lake and been lost, but that they were offerings cast into the water. And here the observation of the manners of rude peoples of the present day serves to interpret the past—in Scotland even now offerings of money and trinkets are made to Holy Wells. All these bronze implements were cast, and both moulds and bars of tin have been found. The discovery of amber, coral, copper, and tin, points to an extensive system of barter, and probably the art of making bronze had been introduced from Asia. The late Sir Richard Colt Hoare found, in the earliest tumuli

which he explored, the corpse in a sitting posture, with implements of stone or bone. In the bronze age, the bodies were burned, in the iron age burial was resumed. In the "stone age" the preponderance of wild animals over the domestic may be gathered from the following enumeration of the relative frequency of their remains. Wanwyl represents the stone age, Nidau the bronze; and in reading the table the figure 1 is meant to be understood as representing a single individual of a species, 2 as indicating a few, 3 several, 4 a larger quantity, and 5 is used when the remains of the species are very common:—

Wild Animals.	Wanwyl.	Moorseedorf.	Nidau.
Brown Bear . . . . .	..	2	..
Badger . . . . .	2	2	..
Marten . . . . .	3	2	..
Pine Marten . . . . .	3	2	..
Wolf . . . . .	1	..	..
Fox . . . . .	3	2	..
Wild-cat. . . . .	2	2	..
Beaver . . . . .	2	3	..
Elk . . . . .	1	1	1
Urus . . . . .	..	1	..
Bison . . . . .	1	..	..
Stag . . . . .	5	5	5
Wild Boar . . . . .	2	2	..
Marsh Boar . . . . .	5	5	2
Domestic Animals.			
Dog . . . . .	2	2	3
Pig . . . . .	(?)1	..	3
Horse . . . . .	2	(?)1	3
Ox . . . . .	5	5	5
Goat . . . . .	2	2	3
Sheep . . . . .	1	2	4

The idea which this table conveys of the co-existence of ancient man with the wild denizens of the old forests of Europe, and the substitution of a more civilised race, and of domestic animals, is very complete.

DR. BROWN-SÉQUARD'S LECTURES.—LECTURE III.

DR. BROWN-SÉQUARD occupied the greater part of his third lecture, delivered February 19, with a discussion of diseases of the pons Varolii. The substance of his remarks on the symptoms of disease of this part of the brain is as follows:—When one side of the pons Varolii is diseased, there is paralysis of the trunk and limbs of the opposite side. If the lower part of one side of the pons Varolii be affected, the facial nerve on the side of the injury may be also paralysed; but if the injury to the pons Varolii be high up in that organ, the trigeminal nerve of each side will, probably, be paralysed; that of one side before its decussation, that of the other afterwards. The sixth nerve is very often affected, thus allowing the globe of the eye to be drawn inwards. Paralysis of this nerve never exists, except with disease of the pons Varolii. Those fibres of the facial nerve which are distributed to the orbicularis palpebrarum have their roots spread into the pons Varolii, and hence, in disease of the pons Varolii, that muscle is often paralysed. In addition to the above positive evidence of disease of the pons Varolii, there is some negative evidence of great diagnostic value: the third pair of nerves, and hence the superior rectus, levator palpebræ, internal rectus, inferior rectus, and inferior oblique muscles remain unimpaired. There is, however, sometimes a slight constriction of the pupil, which, as has been ascertained, may be caused by injury to the trigeminal nerve. The fourth pair of nerves is not involved, so that the rolling power of the eye remains intact. Unless the disease extends to the medulla oblongata, the sense of hearing is also unimpaired. In ordinary hemiplegia the patient cannot really stand alone on the so-called healthy side; the power of the arm is also somewhat lessened; but in disease of the pons Varolii the strength of the healthy side is not diminished. In cases of disease of the upper part of the brain, the co-existent paralysis is caused by reflex action affecting

the base, and a large proportion of the symptoms, probably amounting to three-fourths, are in such cases purely sympathetic; but in disease of the pons Varolii it is quite otherwise; the accompanying symptoms directly indicate a lesion of that part of the brain. This disease, as ordinarily manifested, does not affect the mind; but, in cases of sudden hæmorrhage into the pons Varolii, there are general convulsions. In illustration of the disease in question, Dr. Brown-Séguard showed three patients afflicted with it. The first patient was attacked, in 1859, with what is called "rheumatism." This is, in fact, a very frequent symptom of inflammation of the base of the brain, as well as of the spinal cord and nerves. The "rheumatic" pains were experienced in the right shoulder, in which there was the same tenderness as is observed in cases of diseases of nerves. These symptoms alternated with sickness, giddiness, and a sense of burning heat at the top of the head, the same burning sensation being also experienced on the inside of the right foot; they were followed by paralysis of the right side of the body, the face excepted. The external rectus being implicated, the patient saw double. In every other respect the senses were unimpaired. The tongue did not deviate to either side (in disease of the pons Varolii is not usually affected in this respect); but there is diminution of the sense of taste, as well as of feeling on the left side. Among the other symptoms, there was spasmodic drawing of the left side. In some cases, Dr. Brown-Séguard observed, this spasm exists on the injured side, and in others, a drawing on the opposite one. This patient moves his face well on the right side, and has now recovered much of his wonted power, but there is still some stiffness and loss of feeling. When he takes a long breath, a certain degree of paralysis of the inspiratory muscles of the chest is observable. The second patient to whom the lecturer called the attention of his audience was a finely-developed man, sixty-two years old; he is a farmer, and, but for the calamity which has befallen him, which shows itself in paralysis of one side of his face, would be regarded as a picture of health and strength. About eleven weeks previously, he was attacked with vomiting and giddiness, followed shortly afterwards by paralysis of the right side, excepting the face, which was affected on the opposite side, there being also incapacity to close the eye. He complains that the right side of the body is very tender and painful, the upper part of the calf of the leg being especially affected, and that he is much troubled by the seemingly great weight of the arm. He gapes frequently, and has jactitation of the limb at the same time—symptoms which the patient previously mentioned also exhibited. There is slight diminution of power in the external rectus; the paralysed arm is wasted; the leg is œdematous; sensation both in the thigh and leg is considerably lessened; and if either salt or sugar be placed on the tongue he pronounces both of them "acid," being unable to distinguish the one from the other. The power of feeling in the face is normal. He has no arcus senilis. The treatment consists of the administration of iodide of potassium. The third patient shown exhibited symptoms of disease of the pons Varolii far more serious: both sides of the body are involved. He feels absolutely nothing in the right arm; there is also great anæsthesia of the leg of the same side; during inspiration the left side of the chest dilates but slightly; and so great is the loss of sensibility on both sides of the face, that he cannot feel two points when four inches apart. The lecturer also showed a patient who has inflammation of the base of the brain above the pons Varolii. There was considerable paralysis of the left side, the arm and leg of which were tender; the right side was also very weak. Dr. Brown-Séguard observed that in a case of this kind tenderness of the calf of the leg often occurs, and, indeed, is generally significant of an affection of the brain. When the so-called rheumatic pain is, as in this instance, all on one side, it affords a strong presumption of cerebral disease, and, on inquiry, giddiness may often be discovered to have been already experienced.

Dr. Brown-Séguard closed his lecture by some remarks on Muscular Ataxy, a phenomenon studied by Romberg and other nervous pathologists, and which latterly has attracted special attention in France. It consists in a diminution of the power of directing muscular movements, the contractile strength of the muscles being scarcely, if at all, impaired. A woman under the care of Sir Charles Bell was incapable of directing the muscles of her arms and hands without looking at them; if, when holding her child, her attention was diverted from it, she would let it fall. One of Dr. Brown-Séguard's patients can neither walk nor stand without reeling when his eyes are shut; and there are cases of patients who can make no movement in the dark, and who, if asked to move a limb, will declare they have done so, although they have, in fact, never stirred. The lecturer showed a case of a man who is obliged to make many attempts before he can complete a movement; his muscular strength is but slightly diminished, but his sight is impaired; he often sees double, and he has a contracted pupil. There is also some chorea intermingled with the locomotive ataxy. Sir Charles Bell demonstrated the existence of a special muscular sense, the seat of which has been alleged by many physiologists,—among whom, in this country, Dr. Carpenter and Mr. Dunn are conspicuous,—to be the cerebellum. Dr. Brown-Séguard asserts, however, that disease of the cerebellum has been often observed to destroy that organ without impairing the power of movement. Several distinguished Frenchmen maintain that this remarkable affection is due to disease of the posterior columns of the spinal cord. In the cases relied on for proof of the correctness of this opinion, there was disease of the posterior columns; but, again, Dr. Brown-Séguard remarks that he has found these columns diseased, and unaccompanied by the phenomenon of muscular ataxy, whereas it has presented itself in cases of pressure on the pons Varolii and other parts of the base of the brain. In his opinion, if we understand him rightly, this impairment of the muscular sense is a symptom, though of rare occurrence, of cerebral lesion analogous to the impairment of the other senses, some of which are so generally affected in diseases of the brain.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY OF LONDON.

WE have been requested to call our readers' attention to the following announcement:—

"The usual meeting of the Society will not be held on Tuesday, the 10th inst., on account of the marriage of H.R.H. the Prince of Wales.

"E. H. SIEVEKING, M.D., } Secretaries."  
"JOHN BIRKETT, }

NEW INVENTIONS.

CARBONIFEROUS PREPARATIONS OF MESSRS. PICHOT AND MALAPERT OF THE PREPARATORY SCHOOL OF MEDICINE AND PHARMACY, OF POITIERS.

THESE preparations consist of a "Carboniferous Charpie," "Spongy Carboniferous Charpie," "Bags, or Sachets of Carboniferous Charpie," "Carboniferous Paper," and "Carboniferous Tissue Paper."

The things themselves are what their name expresses, viz., charpie, or paper thoroughly imbued with some kind of carbon in an impalpable powder, but yet not so as easily to give off a black dust or create dirt. They have two objects. One is to act as disinfectants, and, for this purpose, the little *sachets* seem very handy, and may save trouble to the Practitioner. The other is that of forming applications for the ulcerated surface, so that they shall act as dressings and disinfectants in one. The carboniferous paper is of an absorbent character, so that it is intended to imbibe liquid discharges, and prevent the bed and linen from being soiled. Of course

it is only the old and indolent ulcer which will tolerate the direct application of carboniferous charpie to its surface;—vigorous and vascular granulations must be protected by something intermediate.

As the readers of the *Medical Times and Gazette* are fully aware, our principles are the ancient solid empirical, in contradistinction to the hollow rationalistic. However well-devised a remedy may therefore seem on paper, we feel that it is the practical clinical test which alone can give it the true stamp. But we think that MM. Pichot and Malapert's preparations are well worth trying, and recommend such of our readers as have to do with cancers, sore legs, and the like unsavoury ailments, to send to Messrs. Maw and Son for some of the carboniferous preparations, or, at least, for the little pamphlet which explains their use. We feel strongly inclined to recommend the *carboniferous charpie* to be used instead of plain cotton, as a plug for the outer ear in otorrhœa. If the carbon can really deodorise, here is a scope for it.

## REVIEWS.

*The Renewal of Life: Clinical Lectures, Illustrative of the Restorative System of Medicine, given at St. Mary's Hospital.* By THOS. K. CHAMBERS, M.D., Fellow of the College of Physicians; Physician to St. Mary's Hospital; Lecturer on the Practice of Medicine, and Clinical Lecturer at St. Mary's Medical School. London: John Churchill and Sons. 1862. Post 8vo, pp. 430, price 6s. 6d.

MEDICINE is taught in two ways. By observation and experience at the bed-side the student may be set to gather the facts of disease; then, by a process of sifting and comparison, deduce such generalizations as the facts fairly justify. This is the method always adopted by our most eminent Medical teachers. To it we owe whatever advances have been made from time to time in our science. Or, the student may be sent to the bed-side ready prepared with a theory, and be taught to make the facts of disease accord with it. This latter is the method adopted, as far as we can judge from the book before us, by Dr. Thos. K. Chambers.

In the two introductory lectures, Dr. Chambers enunciates his theory. After endeavouring to prove the radical unsoundness of certain prevailing systems of Medicine—viz., Allopathy, Homœopathy, Evacuation, Counter-irritation, and Stimulation—and coolly stating his belief that these represent all the definite aims now-a-days professed in the treatment of disease,—Eclectic and Expectant Medicine being mere protests or negations,—he observes: "In fine, all confess, either by words or deeds, that a true guiding principle—a single aim—in the treatment of disease is wanting." That is to say, his professional brethren are all victims of delusions: they are still benighted, still groping in the dark, or else misled hither and thither each by his own Will-o'-the-wisp, and yearning for some one true guiding light. Taking compassion on their plight, the restorativist Physician of St. Mary's comes to their assistance, and points out to them the guiding star—the one principle of action which will never lead them astray. Here it is; let us give it in his own words, his own capitals and italics:—

"DISEASE is in all cases not a *positive existence*, but a *negation*; not a new *excess* of action, but a *DEFICIENCY*; not a *manifestation of life*, but *PARTIAL DEATH*; and therefore the *BUSINESS OF THE PHYSICIAN* is, directly or indirectly, not to *take away material*, but to *ADD*; not to *diminish function*, but to *GIVE IT PLAY*; not to *weaken life*, but to *RENEW LIFE*."

These are the principles of what he calls "Restorative" Medicine. A definition of disease so bold and thorough as is here given has been shirked by Medical writers of the present age. Men who have studied disease most profoundly have all acknowledged their inability to do what Dr. Chambers has here done. They have found disease to be deviation from the standard condition of the living body; further they have never gone. The essence of that deviation has been too subtle for them to determine; but to Dr. Chambers the great problems of health and disease no longer present any difficulties: all is clear as daylight. Health he has discovered to be "the most active renewal of the body possible;" disease, the *partial cessation* of such renewal; death, its *complete cessation*. All

the varied phenomena of disease indicate deficient vitality. Excess of vital action is impossible: an organ, whose function is, in common parlance, exaggerated, diminished, or perverted, is an organ defunct or partially dead.

Sunt certi denique fines  
Quos ultra citraque nefas consistere morbum.

Such, briefly, is the theory of disease which Dr. Chambers would have all students carry with them to the bed-side, and apply without compromise in the explanation of all diseases, however widely different. Like most Medical theories, it contains a certain amount of truth, but, when indiscriminately applied, breaks down, and obliges its supporter to have recourse to somewhat ignominious shifts for its defence. Let us test its application in a few instances.

Hypertrophy of the heart is a morbid phenomenon, but if (as is often the case in its earlier stages) it is unaccompanied by degenerative or other change, one does not readily see how it indicates deficient vitality of the heart's walls. Dr. Chambers is bound to admit that, in some cases, "it is, perhaps, not impossible" that the hypertrophy *may* be a positive excess of vitality. Feeling this admission to be slightly damaging to his theory, he tries to make out that the vitality of a part is increased only when the general vitality of the individual is diminished,—i. e., that an hypertrophied heart cannot occur in an otherwise healthy person!—P. 38.

Plethora is a disease in which blood is formed beyond the need of the body. Such, at least, is the view taken by the ablest Medical observers,—men who have no pet theory to support. But how does this square with the dogma, that all disease indicates *deficient* vitality? This difficulty is summarily disposed of by the simple assertion that such a condition as general plethora "has no existence in nature." It is represented, too, as a delusion of "our forefathers."—P. 92.

How about inflammation? Surely the pain, heat, redness, throbbing, etc., of an inflamed part indicate excess of vital action? Quite the contrary, says Dr. Chambers; they are, each and all, evidence of deficient vitality. They *may* be so, but most assuredly Dr. Chambers' extraordinary reasoning does not prove that they *are*. On one occasion, even he himself feels that there is a trifling hitch in his argument. While maintaining (p. 27) that "pain does not indicate an excess of sensibility," he admits (p. 43) that "the occurrence of pain during the inflammation of tissues, destitute of nerves, and insensible under ordinary circumstances, such as the alimentary canal, cartilages, etc., is a very puzzling circumstance," and that he "does not see how this is to be explained as due to a deprivation of life." This is a piece of candour, and we must make much of it. Little difficulties of this kind do not usually disconcert Dr. Chambers. His book abounds in unproved assumption, disregard of proved facts, and in illogical reasoning. We must also observe that the style is oftener that of a popular lecturer to a mechanics' institute than a clinical teacher to a Medical school.

It is some comfort to find that Dr. Chambers, enlightened though he be, appears to treat disease much in the same way as his benighted brethren. Though inflammation is "local death," he still occasionally advocates the local abstraction of blood from the dying part. Though the business of the Physician is "not to take away material but to add," he does not discard "destructives" from his Pharmacopœia. In short, his treatment of disease is that adopted by any intelligent Practitioner, who, without ever having heard of the "Restorative System," aims at restoring his patient to health at the smallest possible cost of bodily strength. And so long as he keeps to practical details of treatment, his remarks are sensible enough; they form the unobjectionable part of each lecture. But his treatment, which is evidently based on experience, he will persist in explaining upon a theory, which looks very like an after-thought. He holds that the Physician who has no theory, has no guiding principle of treatment. True; but still this theory need not, and in the present imperfect state of Medical science cannot, be a supreme law, such as Dr. Chambers fondly imagines himself to have reached. Until we know and rightly apprehend all the varied phenomena of disease (which we are far from doing at present), how is it possible to discover the law which governs them? Improved methods of research, extended observation, and cautious induction may at some future time reveal to us this great secret, and the treatment of diseases will then be the treatment of disease. In the meanwhile we must content ourselves with those imperfect, but still ever-widening genera-

lisations, which are deducible from the accumulating facts of Medical experience. These various rules of treatment applicable to various classes of diseases, in other words, the *Axiomata Media* of Medical science, doubtless savour strongly of empiricism; they do not satisfy our impatient yearnings; they keep us plodding on our feet when we would like to be soaring on wings; but in Medicine, as in every other physical science, they have been, and must long continue to be, the only safe guides to truth.

### GENERAL CORRESPONDENCE.

RUSSELL v. ADAMS.

LETTER FROM MR. F. C. J. PIKE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Certain statements having appeared in some of the Medical journals in reference to the late action of Russell v. Adams, to the effect that I was professionally engaged and my costs paid by Mr. Propert, I beg to state most unequivocally that my services were engaged by Miss Russell and her mother, with the latter of whom I had become professionally acquainted upwards of eighteen years previously. The action of Russell v. Adams was commenced so far back as November 21, 1861; it was not, however, until after incessant solicitations by Miss Russell and her mother, that I, with the consent of Miss Russell's then attorney, assented, on January 22 in the present year, to become the attorney for the plaintiff in that action.

I have not directly nor indirectly received, nor do I expect to receive any portion of my costs in such action from Mr. Propert; and, I may add, that I had no communication whatever with Mr. Propert with reference to my undertaking the prosecution of the action on behalf of Miss Russell.

I am, &c.

F. C. J. PIKE.

6, Serle-street, Lincoln's-Inn, March 4.

### "BRAN BREAD" IN DIABETES.

LETTER FROM DR. CAMPLIN.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the *Medical Times and Gazette* of February 14, page 156, we are presented with two cases of diabetes, under the care of Dr. Laycock and Dr. Smart, in the Edinburgh Infirmary, which I doubt not your readers interested in that subject have perused with attention.

In many particulars these cases confirm my own observations, and I should have deemed any remarks on them unnecessary, had not my attention been drawn to the trial of bran bread, No. 6, in which it is said—"this bread differed in no important particular except in its milder action in the production of sugar, but this difference was trivial." Your readers who happen to be acquainted with my history will not be surprised that I wished to learn what kind of "bran bread" had been used in this instance, and on enquiry Dr. Smart kindly informed me that it was bread made from the ordinary "whole flour," and, consequently, that which would have been termed by us brown (not bran) bread. As brown bread and preparations of bran of various kinds have often been confounded with the bran cake recommended in my work on "Diabetes," and might have been so by some of your readers in the present instance, I am desirous to call attention to this circumstance.

In the work alluded to (a), it is observed that the ordinary brown bread is scarcely, if at all, to be preferred to the white, and that in my own person it was not unfrequently followed by even more sweetness in the mouth. Long experience shows me that there are few cases in which the bran cake *properly* prepared will not be of signal service in the treatment of diabetes; but if brown bread in its various modes of manufacture (in all containing a large quantity of starch), or *ill-prepared* cakes or biscuits, are administered, the result will be disappointment. All this, however, may be easily avoided if my directions are followed.

A provincial Surgeon of eminence connected with an Hospital where the bran is prepared on the spot, writing to me a

few months since respecting a patient who had been under his care, says, "I have often doubted in his case, as in others, whether the bran had not a positive influence in restraining the formation of sugar, as well as the negative action by exclusion of starch; the relief of symptoms has been sometimes so direct and complete as to point to a true remedial action." And I have myself seen so many instances of the rapid change of symptoms mainly owing to the substitution of bran cake for bread, that I do not wonder he should have formed this opinion. I should like to enlarge on several other topics connected with the treatment of diabetes, both Medical and dietetical, but must conclude for the present.

I am, &c.

JOHN M. CAMPLIN, M.D.

33, Compton-terrace, Islington, Feb. 27.

### THE RECENT APPOINTMENT OF A CERTIFYING SURGEON AT OLDHAM.

[To the Editor of the Medical Times and Gazette.]

SIR,—In a recent Number of the *Medical Times and Gazette* you did me the favour to insert a letter in reference to the appointment of a non-resident, recently qualified gentleman as certifying Surgeon at Oldham. As I have reason to believe the subsequent proceedings of the Medical Practitioners here have been watched with considerable interest and anxiety by our brethren in other towns, where similar appointments are in the gift of the inspectors of factories, I ask your indulgence whilst I give your readers—either as a guide or a warning—the concluding chapter of this disgraceful episode.

At a numerous meeting of the Medical Profession resident in this town and neighbourhood, it was unanimously resolved that a deputation should wait upon the Home Secretary, for the purpose of laying before him the whole circumstances of the case, and of urging him, on the grounds of equity, to revoke the appointment. A memorial to the Town Council of Oldham was also signed by every Medical Practitioner in this borough, except by the gentleman who holds the corresponding appointment to the one in question, bringing the matter prominently before them. This appeal, to the honour of the council be it told, was most heartily responded to. Not only was our memorial favourably received, but, by every gentleman who spoke, the appointment was severely animadverted upon, and the council unanimously adopted, on public grounds, the following memorial, and resolved that J. M. Cobbett, Esq., and J. T. Hibbert, Esq., the Members of Parliament for the borough, should be requested to present it:—

"To the Right Honourable Sir George Grey, Bart., Her Majesty's Secretary of State for the Home Department.

"The memorial of the Mayor, Aldermen, and burgesses of the borough of Oldham, in the county palatine of Lancaster, in council assembled, under the common seal,

"Sheweth,—That this council views with much dissatisfaction and regret the recent appointment made by Alexander Redgrave, Esq., of Mr. Robert William Coles, jun., to the office of certifying Surgeon to the factories, lately held by Mr. Earnshaw, inasmuch as there are numerous resident Practitioners in the borough of standing and experience, eminently qualified to serve the office.

"That it is manifestly unjust to the whole Profession, resident and practising in the borough, that their claims and qualifications should be overlooked in favour of a young gentleman entirely unknown to the public, non-resident, and only recently qualified; and your memorialists humbly pray that you will revoke the appointment of Mr. Coles, and give directions that the same be conferred on some resident Medical Practitioner."

This memorial was accordingly presented, and a deputation, consisting of Messrs. Abraham Leach, A. Thom Thomson, and Dr. S. H. Armitage, accompanied by the members for Oldham, afterwards had an interview with Sir G. Grey at the Home Office. They were courteously received, and attentively listened to; but were given to understand that, unless they could advance some legal or moral objection, he (Sir G. Grey) did not think he could interfere with Mr. Redgrave's nomination. The only legal ground the deputation were prepared to urge, and they have authority for thinking it fatal to the appointment, was this:—That the Act of Parliament (7 & 8 Vic. c. 15) provides that the person receiving the appointment shall be *practising* medicine or surgery, and that, as Mr. Coles was only acting as an

(a) Camplin on "Diabetes," &c., second edition, pp. 50 and 51.

assistant to another surgeon in a neighbouring town, he could not be considered to be practising within the meaning of the act. This point Sir G. Grey reserved for consideration, and promised an early decision. That decision has now reached us, and, as we anticipated, is unfavourable. Avoiding altogether the question of justice or equity, he merely, through his secretary, states—that having referred the complaint of the appointment of Mr. Coles, junr., to Mr. Redgrave, the inspector, and having received his reply, he (Sir G. Grey) does not think there are any grounds which would justify him in revoking the appointment, which the inspector was authorised by law to make, and which could only be properly revoked by him on clear evidence of some legal or moral disqualification, of which he considers there does not appear to be any proof in the present case.

So end our efforts, not altogether futile let me hope, in this the first clear case of nepotism in the patronage of these factory appointments. It is to be hoped it may not form a precedent.

Hitherto we have had reason to boast that the rank weeds of nepotism have found no congenial soil in our profession. More favoured in this respect than our clerical sister, patronage in life and limb has been held too sacred a trust to be lightly exercised; and the relative or friend has had to find his natural level in the hard race for public preferment. So much the more is it our duty jealously to watch for and expose any deviation from the strict path of rectitude where a public trust is in question.

In almost all the manufacturing towns, where the position of certifying Surgeon is within the reach of the Profession, the great bulk of the population necessarily consists of the working classes. In such towns, however high a reputation a Medical man may attain, he finds it necessary to build up his practice with such material as exists around him. There are no aristocratic or select practices by which a competency may be realised from a comparatively limited number of patients, but, as a rule, the work is heavy and the remuneration light. Physical and mental toil soon tell their story. (a) "The snow appears early on the mountains," and the appointments connected with the factories—the only appointments of value in these districts, and arising, as it were of necessity, out of the evils from which we suffer—are looked forward to as a haven after the heat and burden of the day.

If patronage is to be exercised, as it has been by Mr. Redgrave in the case at Oldham, a serious question must sooner or later arise between our profession and the civil service. Subordinate officers will educate their sons with a certainty of preferment; the workshop and the foundry will give up their youth; some complaisant member of our profession, holding or expecting to hold, a factory appointment, may be found willing to accept them as pupils without a fee; and a gross professional wrong, maturing for years, may find its consummation so soon as the fortunate neophyte has crossed the portals of the medical profession. It behoves all of us therefore to watch narrowly subsequent nominations emanating from the same quarter. The whole tribe of incompetent mediocrities and subservient hangers-on may, in this instance, sing a pæan over our failure; but if any future Redgrave or Coles, trusting to this as a precedent, should contemplate the perpetration of a similar injustice, there shall at least be found on record the indignant protest of an outraged profession.

I am, &c.

Oldham, March 2.

BETA.

LONDON INSTITUTION.—Mr. Carter Blake's lecture on Wednesday last was devoted to an exposition of the principal classificatory characters afforded by the four great groups of *Mammalia*, known as the *Lyencephala*, *Lissancephala*, *Gyrencephala*, and *Archencephala*. He divided the *Lyencephala* into the orders *Monotremata* and *Marsupialia*, the latter being subordinated under the families *Rhizophaga*, *Poëphaga*, *Carpophaga*, *Entomophaga*, and *Sarcophaga*. The *Lissancephala* were divided into the orders *Rodentia* (*Nonclaviculata* and *Claviculata*), *Insectivora*, (*Talpida*, *Soricida*, and *Erinaceida*), *Cheiroptera* (*Frugivora* and *Insectivora*) and *Bruta* (*Brady-podida*, *Dasypcrida*, and *Edentula*). The next lecture will be devoted to the subclass *Gyrencephala*.

(a) In the town of Oldham, the mortality amongst Medical men has been perfectly appalling. Only three of those practising eleven years ago are now alive. During that period twelve have died; nine of these died before attaining the age of 46, and nine either primarily or secondarily of brain disease.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 24.

Dr. BABINGTON, President, in the Chair.

A PAPER, by Deputy Inspector-General T. LONGMORE, was read, entitled,

REMARKS ON TWO CASES OF KELIS.

The writer referred to the Paper by the late Dr. Addison, in the thirty-seventh volume of the Society's *Transactions*, on the "Keloid of Alibert," and on that form of kelis which he (Dr. Addison) considered to be of a distinct character, and which he designated "true keloid." The two cases now brought to the notice of the Society were very striking illustrations of these two forms of keloid disease; but the writer was led to question whether evidence was not afforded by them that they were only simple varieties of one and the same affection, dependent upon the same keloid constitution of the dermal tissue, and owing their different features solely to the differences in the exciting causes. In the first case, the disease was developed after punishment, by flogging, of a comparatively light nature. There was scarcely any laceration of the skin. About three months after the date of punishment, the soldier noticed a growth upon the spot where the flogging had been chiefly received. This growth gradually increased from a small round tubercle to a large flat mass, nearly as large as a man's hand. It was not accompanied with pain, but there was irritability, itching, and tenderness, when the part was subjected to the pressure of the cross-belt and weight of the knapsack. On the front of the patient's chest were several small tumours, evidently of the same nature, but the date of the first appearance of these growths could not be ascertained. The disease in the second case was more extensive than had been described by any writer hitherto, and presented a most remarkable appearance. It was of the kind which Dr. Addison considered should be separated from the former variety under the name of "true keloid." The patient, a cavalry soldier, of strong, powerful frame, went to India with his regiment in November, 1857. Five months afterwards, at the commencement of the hot season, he began to suffer from lichen tropicus, in common with all the other men of the regiment. About a month afterwards, the keloid disease began to show itself, in the form of a few prominent red tubercles on the right fore-arm. It next appeared over the middle of the sternum, and thence extended gradually toward the two sides of the body. At the same time it appeared on the left shoulder and various parts of the back, and continued to spread until it had covered the entire dorsal surface of the body. The skin of the face was also affected. The physical characters and accompanying symptoms of the disease in both instances were fully described in the historical accounts of the cases presented to the Society. Their characteristic features were represented in the drawings and photographs. The writer urged that no two more striking examples of the two species, "true keloid" and "spurious keloid," according to those who designate them as distinct species, could be met with than the cases brought to the notice of the Society. He argued, however, that, in the case in which the kelis was excited by flogging, the comparative slightness of the punishment, the rarity of such a consequence, but more particularly the presence of the keloid spots in their favourite habitat—the skin covering the anterior part of the chest—established the constitutional nature of the disease, just as fully as it was established in the second case, where it appeared to follow the excitement of the prickly heat. The fact, too, that the general characters of the diseased growths in both instances were alike, and that in each instance the hypertrophy was greatest where the pressure of the cross-belt was chiefly exerted, confirmed still further the identity of their nature. The deduction was hence drawn, that, both the patients being of a keloid diathesis, the difference in the mode of distribution, and in some of the features, of the diseased growths in the two cases could be accounted for by the different natures of the exciting causes. No treatment had appeared to exert permanent beneficial change in either case. The fact that the pressure of the cross-belt acted in

each instance as a stimulus to increased growth was held to be a sufficient argument against treatment by continued pressure, which had been recommended by some Surgeons. The evidence of the constitutional origin in the case where the chief tumour was isolated upon the left shoulder, as well as the nature of the immediately exciting cause, had counter-indicated any attempt at cure by extirpation.

Mr. PARTRIDGE asked Mr. Lee to give the result of a case of kelis on which he had operated some years ago.

Mr. HENRY LEE said that in that case the arms were bound down to the side by contractions of the skin from the disease. There were, however, no interstices. He divided the adhesions, but interfered with the kelis as little as possible. The result was very satisfactory.

Dr. GREENHOW said that a few months ago he saw a young lady who had had a small tumour removed from the shoulder. The cicatrix became hard, and increased in size. It was removed three times, but it recurred again, and when Dr. Greenhow saw her last, there was a pink, hard, and elastic swelling. He advised that it should not be again removed. He found that she had had a number of boils, and that the scars left by all of them had become hard. The small tumour on the shoulder formed in the site of a boil.

Mr. CURLING considered Mr. Lee had been fortunate in his case, as keloid disease generally returned in the cicatrix after excision. Some years ago, he had under his care, in the London Hospital, a case of extensive keloid growth in the cicatrix of a burn on the neck and chest, in which steady pressure and other means were tried without success. The friends wished something more to be done, but, before venturing to excise the whole of the disease, he removed a small isolated growth, but it returned, and he therefore declined performing any further operation. The case afterwards came under Mr. Skey's care at St. Bartholomew's Hospital, and was operated on there, but he did not know with what result. Mr. Curling doubted whether the two cases described by the author were genuine examples of the two forms of keloid disease described by Dr. Addison. Both appeared to him to belong to the form called spurious keloid, though the second did not arise from any injury to the skin. He spoke with some reserve, as the diseases were rare, and he had witnessed only one case of the true keloid. He differed from the author in regarding the diseases as quite distinct, and, therefore regretted that the same term keloid had been applied to both of them by Dr. Addison. In the true keloid, the skin was extensively affected, became like parchment, the part was "hide-bound" and shrunk. Such was the condition in the case he had witnessed, where the side of the face, the neck, and both arms were affected, the motions of the limbs being impeded. In both the cases described by the author, the skin was hypertrophied, and tubercles or swellings existed.

Mr. PARTRIDGE mentioned the case of a young lady who had had boils, in the scars of which were little tumours. One the size of a pea was removed, but the disease returned in the scar of the incision, and also in the scars of the punctures made in closing the wound. The disease was again removed, but it returned.

The Author then briefly replied.

Dr. ROBERT LEE gave

AN ESTIMATE OF THE EXTENT TO WHICH HUMAN LIFE HAS BEEN PROLONGED OR ABRIDGED BY OVIARTOMY.

Dr. Lee, after stating that statistical tables of ovariectomy have been compiled with great labour at different periods by various eminent individuals, proceeds to analyse the tables of Dr. Clay, published in 1860, which comprise in all 567 cases. Of these, 242 were considered successful, and in 235 the patients died from the direct effects of the operation. If 477 cases be deducted from 567, there will remain 90 cases. Whether, however, life was prolonged or abridged in these cases, Dr. Lee cannot state, as he has been furnished with no information on the subject. The author avers that since 1860 the operation of ovariectomy has been performed in numerous cases in Great Britain, and that a number of fatal cases have occurred of which no report has been published. In illustration of this statement, he gives brief accounts of thirteen unsuccessful cases, not hitherto published, of which he has obtained information. Dr. Lee concludes his remarks with the statement that he considers it demonstrated that ovariectomy is an unjustifiable operation where the life of the patient is not in immediate danger, and where there is not a great probability of the life of the patient being saved by the removal of the disease.

Mr. MACILWAIN thought that what was wanted was more accuracy in diagnosis, and had no doubt that there had been even worse mistakes than Dr. Lee had enumerated, and that a great many had died from a want of knowledge of certain circumstances previous to operation. He considered that the facts required to decide a question so important could not possibly be gathered by any single person, however large his experience might be. But by a vigorous action of this Society, enough facts might be accumulated in a few years from which more definite conclusions could be drawn. He considered that this disease ought to be studied from the laws of general pathology, and he felt convinced that the danger of removing the ovary had been exaggerated. He had observed that Mr. Spencer Wells, in his paper on the subject, seemed to regard the after-treatment as the Alpha and the Omega. It was to be repose. Mr. Spencer Wells had given him the addresses of twelve women, residing in the suburbs, who had been operated on, and who are now quite well. He had seen ten of these cases, and he felt convinced that the question of ovariectomy was worthy of most serious consideration, and that it should not be the subject of mere hostile interchange of opinions. The first case he saw (and he would add that they were all pretty much alike), was a young woman from whom Mr. Wells had removed a tumour weighing forty pounds. She and the other nine were quite well. He regretted very much that he had not had the pleasure of Dr. Lee's company. In conclusion, he begged respectfully to suggest to the Council that they should issue a series of questions for the collection of information on cases of this operation. In two years, he thought, a sufficient amount of evidence would be obtained.

Mr. BAKER BROWN stated, that, so far from finding fault with Dr. Lee for bringing this subject so frequently under discussion, he felt extremely obliged to him for so doing, feeling convinced that the greater the investigation the greater must necessarily be the elimination of truth; that he (Mr. Brown) had openly and frankly published every unsuccessful case which had occurred in his own hands, and he believed, as a rule, other ovariectomists had done the same; that he had performed the operation fifty-three times during the past twelve years, the result being twenty-nine recoveries and twenty-four deaths; that, as far as he knew, only two of these had subsequently died—one from fever, after making a perfect recovery; the other from the recurrence of the disease in the other ovary, which at the time of operation was perfectly healthy, and which, as he understood, had lately been removed by another gentleman, and followed by death in three or four days. The mortality of his practice of late years, had been very much less than during the first years, as evinced by the fact that, in the London Surgical Home, of the thirty-one operations performed, there had been only ten deaths; and of the last fifteen operations there, and in private practice, he had only had four deaths. Mr. Brown had been surprised to hear Dr. Lee assert that some speaker on the last occasion on which Dr. Lee had brought this subject before the Society had stated that the operation was simple and not dangerous. Mr. Brown, on the contrary, believed it to be the most dangerous operation that was ever performed; so dangerous, indeed, did Mr. Brown consider the operation, that he never on any occasion advised a patient to have it performed; that he placed the facts of the case frankly and fairly before the patient, and having done so, left her, assisted by her friends, alone to decide; and although easy of performance, it could not be called a simple operation, as the complications were often of the most serious nature. It was not an operation requiring great Surgical skill, but plenty of nerve. Mr. Brown observed, that the most important part of the question was that of diagnosis; that, although he had devoted more than thirty years of his life to the careful study of this subject, and had paid especial regard to the question of diagnosis, he unhesitatingly affirmed that there were no rules which could be laid down so absolute as to enable any Surgeon to diagnose with perfect certainty before operation. He would therefore express a strong hope that Dr. Lee would continue to give his great powers of mind and investigation to the solution of this most difficult problem, believing that he would thereby do more good service, and strengthen the hands of the operating Surgeon, than by any further attempt to discourage ovariectomy. Dr. Lee stated that he had inquired of a Surgeon whether, if he were a woman, he would have submitted to the operation, to which inquiry no answer had been returned. Mr. Brown observed that he could not enter into the question in the way

placed by Dr. Lee; but he could assert that ten years ago he had performed this operation on his own sister; that she had since married, had lately been confined in New Zealand of her fifth girl, and had never had any illness from the date of the operation; that he should, if occasion arose, follow the same plan in any one near or dear to him, if it were a case suitable for operation. Therefore, in conclusion, Mr. Brown observed that he did consider this operation justifiable, and it ought to be recognised as a legitimate one in Surgery.

Dr. TYLER SMITH said that the fatal case in his practice to which Dr. Lee had referred was very inaccurately stated. It was not a case of ovarian disease at all, but of cancerous tumour of the mesentery. The patient was in extreme danger at the time, and had been warned of the probable result of the attempt at operation. He thought it unfair that Dr. Lee should bestow so much time in seeking out the unsuccessful cases, while he paid little or no attention to those which were successful. This plan was as unreasonable as it would be to test any point of Medical or Surgical practice by visiting a cemetery. Dr. Lee maintained, as one of his chief grounds of objection to the operation, that in many cases of ovarian tumour the progress of the disease was so slow that, taking those who were killed by the operation and those who recovered into account, the average duration of life was not, on the whole, prolonged by ovariectomy. On this point his opinion deserved every possible attention. All knew that occasionally cases were met with where tapping was borne a great number of times, or where the tumours remained almost stationary for many years, so that such patients might, and sometimes did, actually reach the ordinary term of life. In the greater number of cases the progress of disease was, however, more rapid, and a time sooner or later came in which life was threatened, and interference, either by tapping or removal, became necessary. Still, the facts respecting the occasionally chronic character of these tumours, as insisted on by Dr. Lee, ought to be well weighed in regard to the operation in every given case. They had undoubtedly an important bearing on ovariectomy. Mr. Spencer Wells had, on the last occasion on which the subject was discussed by the Society said, in reference to this point, that ovariectomy did not differ from other operations, and that the healthier the patient at the time of the operation, the greater were the chances of success; while Mr. Hutchinson maintained that the earlier it was performed the better. He (Dr. Tyler Smith) held a different opinion. There was a great peculiarity about ovarian disease—namely, that beyond the material abstracted from the system, it was only injurious by mechanical pressure. These tumours did not otherwise threaten life. It was not therefore right, in his belief, to operate until the health began decidedly to give way. Of course we ought not to wait till the health was so completely broken as to destroy the chances of the success of the operation. But there should be unmistakable signs of mischief from further delay before we were justified in resorting to ovariectomy. Otherwise there would be many cases of success, but mixed up with them would be cases of women cut off suddenly in the prime of life, merely the subjects of mechanical discomfort, and who but for the operation would have lived many years. Such cases must cause great regret to any operator. He believed that, as regarded the prospect of operating successfully, we did not lose anything by waiting till the disease had begun to threaten life. There was a well-known axiom of John Hunter, that "health bears disease ill." This might be applied to Surgical operations, and persons in good health did not, according to his (Dr. Tyler Smith's) experience, bear ovariectomy so well as those who were in a lower condition. In the latter there was far less risk of peritonitis; and it was acknowledged that women between fifty and sixty years of age, who had passed the meridian of strength, recovered better than the young or middle-aged. Nor was anything lost by waiting. The only evil of such delay as he recommended was the possible formation of adhesions, but even these adhesions did not greatly diminish the chances of success. At all events, we ought not, for fear of their occurrence, to expose women in fair health to the chances of a sudden and violent death. The objections of Dr. Lee were not, then, in his opinion, sufficient to condemn the operation, but only its indiscriminate performance. He had as far as possible gone upon the principles now laid down, and out of fifteen cases twelve had recovered; and he had only made the one error of diagnosis in the case adverted to by Dr. Lee.

Mr. SPENCER WELLS repudiated altogether the practice attributed to him by Dr. Tyler Smith, of performing ovariectomy in all stages of ovarian disease. In both the papers which he had read before that Society, and in one read before the British Medical Association at Canterbury, he had stated his belief, as clearly and strongly as he could, that, while it was wrong to put off any serious operation until the health of the patient was so broken down that there could be no reasonable hope of success, on the other hand, it was wrong to advise any patient to submit to any serious operation unless her life was seriously endangered by the disease. It was by care in the selection of cases that the judgment of the Surgeon must be tested. If he performed ovariectomy before it was rendered necessary by the progress of disease, he would often lose patients who might live for years without operation; but if he did not operate till the disease was very far advanced, his operations would be unsuccessful because they were performed too late. In all his own cases he was guided by these considerations, and there was no foundation for the statement that he performed ovariectomy indiscriminately. Some of Dr. Lee's arguments were also very unfair. He had alluded to one case in which death had followed an incision made into an ovarian tumour at the Westminster Hospital. He (Mr. Wells) knew nothing of the case; but it was obviously wrong to call that case one of attempted ovariectomy because the operator chose to tap with a scalpel instead of with a trocar, in order to empty a cyst more completely of viscid contents. This had to be done occasionally to give temporary relief in cases where ovariectomy could not be thought of. Then Dr. Lee ignored altogether the fact, that fatal cases after tapping were constantly occurring, but no one thought it worth while to record them. It was said to be the natural progress of disease, which tapping could not check. But patients frequently died in a few days, or a few weeks after tapping, whose lives probably might have been saved by ovariectomy. Dr. Lee had shown great industry in collecting unrecorded cases of failure, but nothing would induce him to see patients who had recovered after ovariectomy, and remained in good health. In reply to a request from Dr. Lee, he (Mr. Wells) had given him, some weeks ago, the names of twelve patients, all living within three miles of Savile-row, and told him that he could see them at his own time. Dr. Lee first arranged to see them with Mr. Macilwain; but, at last, Mr. Macilwain was obliged to go alone, and Dr. Lee had not seen one of these patients. It was as unfair to ignore successful cases and make fatal cases only known, as the opposite error, for which Dr. Lee so pertinaciously charged his opponents. Doubtless, some unsuccessful cases had not been reported; but the same might be said of successful cases. That very morning, Dr. Royle, of Manchester, had called upon him (Mr. Wells), and told him of two successful cases which he had not published. In addition to the statistics given by the two previous speakers, Mr. Wells stated that, besides one case in which he had performed ovariectomy for the second time on one patient, he had operated in fifty-five cases, with a result of eighteen deaths and thirty-seven recoveries. In his later cases his success had been much greater than in his earlier cases; for of the last twenty cases eighteen had recovered, and only two had died. These facts were quite enough to prove that the time had passed when an operation performed with such results could be denounced by any man of sound judgment as "unjustifiable." Mr. Wells concluded by expressing the hope that the Council would adopt the suggestion of Mr. Macilwain, would appoint a committee, and would instruct that committee carefully to inquire into the condition, years after operation, of those patients who had recovered.

Mr. CHARLES HAWKINS urged on the Society the adoption of Mr. Macilwain's proposition. He considered that there was a tendency to regard the operation with greater favour than before. He agreed with Mr. Baker Brown, that the question should be fairly stated to the patient. It was a very remarkable thing that the leading Surgeons had not expressed any opinion on the subject. He had attended all the discussions on the subject, in the hope that they would; but, with the exception of those who had made diseases of this class a specialty, not three of the leading Surgeons had said anything either for or against the operation. He was surprised that so little attention was paid to the fact, that women with ovarian disease often live a long time. In one instance a patient lived twenty years, and was tapped three times in that period. There was this in favour of the operation, that, if the patients

got well, they kept well; but then, in the unsuccessful cases, many might have lived with the disease who were cut off by the operation. Mr. Speneer Wells had spoken of patients frequently dying after tapping, but he thought this was really rare. It was quite clear that what was wanted was greater certainty in diagnosis, and also a better account of patients who have been left alone. He did not see any harm in finding out unsuccessful cases, and thought it not wrong to go to churchyards to study diseases. He concluded by seconding Mr. Macilwain's suggestion.

Mr. CURLING did not think the remarks made by Mr. Hawkins respecting the silence of Hospital Surgeons should pass without receiving some reply. The fact was, only a small number of operations for ovariectomy had been performed in the metropolitan Hospitals. With the exception of one large Hospital, it was only in recent years that an obstetric department had been attached to these institutions, so that comparatively few patients labouring under ovarian disease apply there for relief. They resort chiefly to obstetric Physicians, and to Surgeons who cultivate a special department of practice—the diseases of women. It has been questioned whether a large Hospital is the best place for the performance of this important operation, and certainly no Surgeon would be justified in undertaking it whilst pyæmia or erysipelas prevailed in the wards. Then, the application for the admission of other cases are so pressing that it is sometimes difficult to devote a ward solely to a case of ovariectomy. On a recent occasion, at the London Hospital, his colleague, Mr. Maunder, had to wait some weeks before he could obtain a suitable ward for the treatment of an ovarian case. Hospital Surgeons, however, do not shrink from undertaking these operations in suitable cases, sanctioned by their obstetric colleagues. Four operations had been performed at the London Hospital, two of which were done by himself. He believed that the particulars of them had been published. One was successful, and three died. The reason why Hospital Surgeons did not take a prominent part in these discussions on ovariectomy was, because they could speak only from limited experience.

Dr. LEE said his attention had been called to ovariectomy at an early period, in consequence of a fatal case having occurred, in which a fibrous tumour of the uterus was mistaken by another Physician for a tumour of the ovary, and removed. He (Dr. Lee) resolved to investigate the whole subject of the pathology of the ovaries in relation to this operation. With this view he examined carefully every case of ovarian disease that came under observation, preserved accurate written histories, and where death took place the bodies were examined, for the express purpose of determining whether life could have been preserved by ovariectomy. This, he conceived, was the only method by which a knowledge of the diagnosis and prognosis and treatment of ovarian disease could be acquired. Dr. Lee said that he had published 170 cases, and could now communicate double that number. The result of all these inquiries was, that it was impossible in any case to determine before actually laying open the abdomen what the condition of the viscera was, and hence it was not justifiable to perform such a dangerous operation in the dark or at a venture. He thought it most unphilosophical to set aside the experience of the whole world during a long course of years, and now to substitute in its place the experience and the marvellous and boasted success of a few Practitioners during the last two years. The tables referred to in the paper contained abridged histories of 567 cases of ovariectomy—all that had occurred from the period of the first operation in America, about forty-five years ago, up to February, 1860. Of these 567 cases, 242 were stated to have been successful; and 235, or about one half, died speedily after the operation. There then remained 90 cases wherein the operation of ovariectomy was performed, the greater number of which might justly be added to the list of fatal cases, though they had been included in the list of recoveries. The fact being now universally admitted that the diagnosis of ovarian disease was most difficult, the prognosis uncertain, and the operation of ovariectomy fatal in a large proportion of cases, or 50 per cent., he (Dr. Lee) continued to think that it was unjustifiable, except under the circumstances stated at the conclusion of the paper. The personal remarks which had been made he considered it unnecessary again to notice. No one had ventured to impugn the accuracy of the statements made in the paper. In the course of his observations, Dr. Lee said he considered it

not only unscientific, but an inhuman act, to publish all the successful and conceal many fatal cases; and added that he had performed the operation of ovariectomy frequently on the dead body, but never on the living subject. He had, however, recently witnessed the performance of the operation by Mr. Speneer Wells, and a most horrible sight it certainly appeared. The bowels gushed out of the wound, reminding him of the fate of Judas Iscariot. Yet the patient was reported to have recovered; thus showing how very great an injury might be inflicted on the abdominal viscera without causing death, which he considered a striking physiological phenomenon. Some of the occurrences which had taken place during the last twelve months he considered an opprobrium to Surgery and Midwifery. In a case which occurred some years ago in St. George's Hospital, Dr. Lee stated that he had called a consultation of the Surgeons, observing that if the operation was ever to be performed, this was a proper example. The Surgeons refused to operate, unless Dr. Lee gave his sanction, which he could not do conscientiously, believing the patient's life to be in no immediate danger. This young woman had been operated upon by Mr. Speneer Wells, and she was now alive. More recently a case of ovariectomy had occurred at St. George's Hospital, but he (Dr. Lee) never saw the patient, and was not called upon to give any opinion respecting the operation, and therefore was in no way responsible. In conclusion, he referred to a case that had occurred to Mr. Speneer Wells the day before, and, respecting which, it had been reported to him that it was ascites, and not ovarian dropsy.

## MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, February 26, 1863:—

James Hunter Armstrong, Harmer-street, Gravesend; George Branston Valentine Nash, Royal Infirmary, Liverpool; Robert Slade, Pool, Dorset.

The following gentleman also on the same day passed his First Examination:—

Francis W. S. Wicksteed, St. Bartholomew's Hospital.

## APPOINTMENTS.

- ALDRIDGE, RUSSELL, M.D. Edin., has been appointed Certifying Surgeon under the Factory Act.
- BARNES, GEORGE, L.R.C.P. Edin., has been appointed Certifying Surgeon under the Factory Act.
- BIGGS, ROBERT, M.R.C.S., Eng., has been appointed to act as Deputy Coroner for North Somersetshire.
- BONTHRON, ANDREW, M.D. Edin., has been appointed Surgeon Superintendent, on behalf of the Queensland Government, to its immigrant ships. First, the *S. S. Cairngorm*.
- DUKE, STEPHEN, M.D., has been appointed House-Surgeon to the Great Northern Hospital, King's-cross.
- DYCE, ROBERT, M.D. Aberd., has been appointed Consulting-Physician to the Royal Infirmary, Aberdeen.
- HARE, CHARLES J., M.D. Cantab., has been appointed Professor of Clinical Medicine at University College Hospital.
- HEARDER, GEORGE J., M.D. St. And., has been appointed Assistant Medical officer to the County Lunatic Asylum, Worcester.
- HOGG, JABEZ, M.R.C.S. Eng., has been appointed Surgeon Oculist to the Royal Masonic Schools.
- KINGOUR, DR. JOHN S., M.R.C.P. Lond., has been elected Physician to the Cheltenham General Hospital.
- KIRKWOOD, WILLIAM, M.D., has been appointed a Member of the Executive Council of the Bahama Islands.
- PENNY, GEORGE S., M.R.C.S. Eng., has been elected Surgeon-Dentist to the Cheltenham General Hospital.
- RINGER, S., M.R.C.S. Eng., has been appointed Professor of Materia Medica at University College Hospital.
- SAUNDERS, EDWIN, F.R.C.S. Eng., has been appointed Surgeon-Dentist to the Prince of Wales.
- THOMSON, JOHN, L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory Act.
- TIMMON, WILLIAM P., has been appointed Certifying Surgeon under the Factory Act.
- WINTERBOTHAM, LAURISTON, M.R.C.S. Eng., has been appointed Surgeon to the Cheltenham Female Orphan Asylum.

## DEATHS.

- BOGIE, WILLIAM, M.D., of the Bengal Medical Service, at 19, Blacket-place, Edinburgh, on March 1.
- BORLAND, JAMES, M.D., Inspector-General of Army Hospitals, at Bridge-man House, Teddington, on February 22, aged 89.
- CAMPBELL, JOHN, M.D., Surgeon R.N., at Elm-grove, Southsea, on Feb. 24

GRANT, CHARLES, L.R.C.P. Edin., at Heanor, Derbyshire, on February 23, aged 35.  
 GROVES, Dr. W., formerly of York, on January 31, at New York, aged 63.  
 GUGGENBUHL, Dr., the well-known founder of the Abendberg Institution for Cretius, beautifully situated near Interlaken, and as to the efficiency of which so much controversy has prevailed in Switzerland, has just died at Bale. He has left 600,000 francs to the Moravian Brethren on condition that they continue the Abendberg Establishment, under the title of the Guggenbühl Hôspice.  
 LINDSAY, WALLACE, at Corosal, British Honduras, on December 31 last, Staff-Assistant-Surgeon (of Edinburgh), aged 25.  
 McNICOLL, THOMAS, M.R.C.S. Eng., at 102, Crown-street, Liverpool, on March 1, aged 41.  
 SCHMITZ, C. T., M.D., Assistant-Surgeon at Fort Lahore, at Cape Town, on December 24, aged 25.  
 STUART, JOHN GRAHAM, M.D., H.E.I.C.S., at 54, India-street, Edinburgh, on March 2, aged 65.  
 WALKER, JOHN, M.D., at Richmond Lodge, Trinity, Edinburgh, on March 1.  
 WOODS, Dr. W. H., Surgeon R.N., at Sandford, near Dublin, on February 20, aged 36.  
 WOODS, R., Surgeon, at Ilchester, on February 21.

THE Geological Society has awarded the Wollaston Gold Medal to Professor Gustav Bischoff, of Bonn; and the Wollaston Donation Fund to Professor Senft, of Eisenach.

HEREDITARY LONGEVITY.—The papers have lately noticed the death of a Mr. David McVey, aged 101. This gentleman's maternal grandmother lived to 103, his mother to 100, his sister to 92, and a brother, present at his funeral, is now nearly 90 years old.

"PHYSICKED MEAT."—The *Times*' report of a recent case tried at the Central Criminal Court, in which a man named Robert Buxton was found guilty of having sent meat unfit for human food to market, attributes the following evidence to Dr. Letheby:—"Dr. Letheby proved that he examined a portion of the beef, and found it in a most diseased state, and when analysed, he found it to be charged with physic."

INCREASE OF POPULATION IN QUEENSLAND.—On the third anniversary of the separation of Queensland from New South Wales, the *Brisbane Courier* stated that the population with which this new colony started in December, 1859, was about 25,000, and at Michaelmas, 1862, the number was 42,000, and in December was not less than 46,000. The population has thus nearly doubled itself in three years.

HEALTH OF THE NIGER EXPEDITION.—Lieutenant Lefroy's letter which was published in the *London Gazette*, gives an excellent account of the health of the men employed in the ascent of the dreaded river Niger. He writes: "I am happy to state that during the fifty-three days her Majesty's ship *Investigator* was up the river the health of the ship's company was exceedingly good, only a few cases of slight fever occurring, and that among the men received from her Majesty's ship *Brisk*, who had not been accustomed to the river work, my own men remaining perfectly healthy."

THE entire staff connected with the Royal Artillery and Royal Engineer Hospitals at Brompton barracks, Chatham, together with the patients and attendants, vacated the Hospitals on Saturday afternoon, and took possession of Fort Pitt Hospital, which will in future be used as a general Hospital for the entire garrison, on the removal of the Army Medical School and staff to Netley Hospital. A portion of the Hospital hitherto used at Brompton barracks is still to be retained for the purposes of a Hospital, in which the sick troops will be received and inspected previous to their removal to Fort Pitt.—*Times*, March 2.

OVARIOTOMY IN FRANCE.—It will be seen, from our account of the distribution of the prizes in the gift of the Paris Academy of Medicine, that if the cases of ovariotomy have been few in France, their importance is duly appreciated. A reward of 2000 francs has been appropriated from Baron Barbier's bequest (a large sum left to reward the discoverer of a cure of incurable diseases, or the nearest approach to this) to Dr. Kœberlé, Assistant-Professor at the Faculty of Medicine of Strasbourg, for two successful cases of ovariotomy performed by him. These were the first successful operations performed in France.

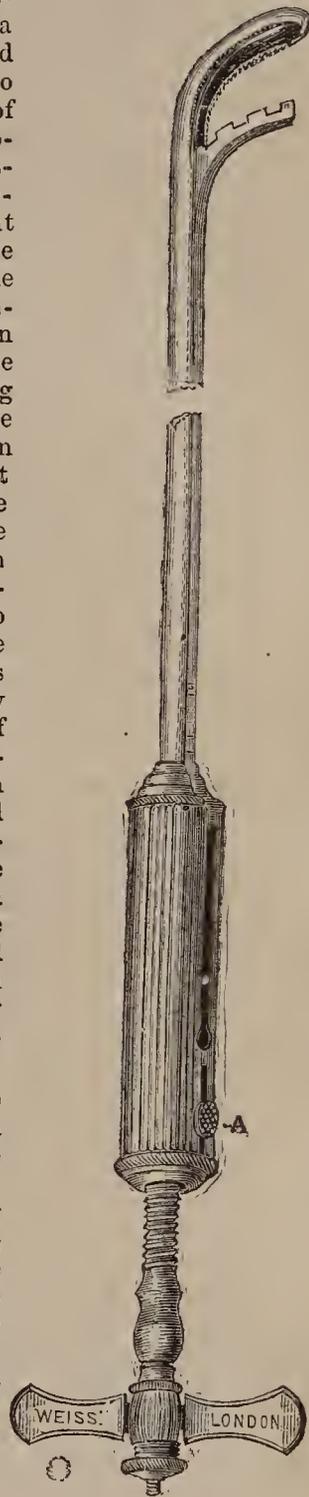

GENERAL TOM THUMB.—The American papers contain the revolting announcement that a miserable little dwarf, under the name of General Tom Thumb, has been married to another dwarf of twenty-one years old and thirty-two inches high. We believe that the original Tom Thumb died, a few

years ago, in poverty and neglected in a European Hospital. Whether this be the case or no, we may safely assert that it is only in America, where a clergyman married the Siamese Twins, that two of the same cloth could be found to perform the ceremony of marriage between a dwarf thirty inches high and another of thirty-two inches.

A NEW LITHOTRITE.—The accompanying is an engraving of a new Lithotrite recently constructed by Messrs. Weiss and Son, and to which we alluded in our report of the proceedings of the Medico-Chirurgical Society, in our impression of January 31. The improvement consists in the movement which attaches and releases the screw power in connexion with the male blade. This renders the instrument more simple in its action than the French Lithotrite, as the change from the screw to the sliding action can be effected by placing the thumb or finger of either hand on the button, A, without in the slightest degree relaxing the grasp, and the movement being effected in a line with the shaft, produces less motion or concussion than the rotary movement hitherto employed. It is also more powerful than the Lithotrite just referred to, and the power is capable of being very gradually applied. The cylindrical form of the handle is also a decided improvement, as it is extremely firm in the grasp of the operator, and admits of the most delicate manipulation when held only between the thumb and finger. The mechanism is of the simplest, and, at the same time, of the strongest and most solid construction; it can be readily taken to pieces for cleaning, is as easily readjusted, and is not liable to derangement of any kind.

CONVICTION FOR CRIMINAL ASSAULT.—A man named Hugh Rankin has been sentenced at the Newcastle Assizes to two years' imprisonment, with hard labour for criminally assaulting a girl of 11½ years of age. The principal evidence against the prisoner appears to have been the stained condition of the girl's linen. It was urged, on the part of the defence, that this might be attributed to natural causes. We should be glad to know what examination of the stains was made in this case.

DISTRIBUTION OF PRIZES AT THE PARIS ACADEMY OF SCIENCES FOR 1862.—1. The Grand Prizes on the Physical Sciences—"The Comparative Anatomy of the Nervous System of Fishes." No memoir is considered to have fulfilled the conditions laid down, and the prize is adjourned until 1864, an encouragement of 1500 francs being in the meantime accorded to MM. Philipeaux and Vulpian for their memoir. The prize on "Vegetable Hybrids" has been accorded, with many eulogiums, to M. Naudin, of the Natural History Museum. 2. Prize on Experimental Physiology—"On the Cardiac Circulation." A prize of 1800 francs has been decreed to M. Balbiani, and one of 1200 francs to MM. Chauveau and Marey. 3. Prize in Medicine and Surgery. Three prizes have been adjudged for works on Pathological Anatomy, one of 2500 francs to M. Cruveilhier for his work on General Pathological Anatomy, one of 2000 francs to M. Lebert for his work on Pathological Anatomy, and one of 2000 francs, to Professor Frerichs, for his work on Diseases of the Liver. An encouragement of 1500 francs has been given to M. Larcher for his researches on the "Normal Hypertrophy of the Heart during Pregnancy," one of 1500

francs to M. Cohn for his work on Embolism, and a third of 1600 francs has been divided between MM. Dolbeau and Luys for researches on Epispadias. 4. The Alhambert Prize—"Experimental Study on the Modifications which the Action of External Agents may Exert on the Development of the Vertebrata," has been divided between Prof. Lereboullet, of Strasbourg, and Prof. Dareste, of Lille. 5. The Breant Prize for a discovery of a cure for cholera has, of course, not been decided; but 2000 francs of the bequest has been adjudged to M. Barralier for his demonstration of the Non-identity of Typhus and Typhoid Fevers.

PRIZES AND PRIZE QUESTIONS AT THE PARIS ACADEMY OF MEDICINE.—The Academic prize for 1862, subject "The Natural Course and Expectant Treatment of Pneumonia," was divided between two competitors, MM. Molland and Duclout. The Portal Prize, "Vascular Obstruction of the Lungs," was not adjudged, 300 francs being decreed as an encouragement to MM. Colin and Goubaux. For the Bernard de Civrieux Prize of 2000 francs, for a memoir on the "Moral Treatment of Nervous Diseases," there were ten candidates. To M. Padioleau was decreed a reward of 1000 francs, and to MM. Pastural and Artance an encouragement of 500 francs each. For Baron Barbier's Prize there were eleven candidates. A reward of 2000 francs was decreed to M. Kœberlé, of Strasbourg, for his account of two successful ovariectomies; and one of 1000 francs to MM. Vulpian and Charcot for their memoir on "Progressive Wasting Palsy." The Capuron Prize, "Pemphigus of New-born Infants," was decreed to MM. Olivier and Ranvier. For the Orfila Prize, "Poisonous Fungi," three memoirs were sent in, none of them obtaining it. Numerous medals were also adjudged to Vaccinating-Physicians, Epidemic-Physicians, and Mineral-Water Medical Inspectors. The following are the *Prize Subjects for 1863*:—1. The Academy Prize, 1000 francs, "Malignant Pustule (*maladies charbonneuses*) in Man and Animals." 2. Portal Prize of 1000 francs, "The Pathological Alterations of the Placenta, and their Influence on the Development of the Fœtus." 3. Madame Bernard de Civrieux Prize of 1000 francs, "Dyspepsia." 4. Capuron Prize of 1000 francs, "Compare the Advantages and Inconveniences of Pelvic Version and the Application of the Forceps in cases of Narrow Pelvis." 5. Lefevre Prize of 2000 francs, "Melancholia." 6. Amussat Prize of 1000 francs. This prize will be decreed to the author of the work or of researches, simultaneously based upon anatomy and experiment, which realises or prepares for the most important advance in Surgical Therapeutics. 7. Barbier Prize of 3000 francs. To be decreed to the discoverer of a complete cure of diseases reputed usually as incurable, as hydrophobia, cancer, epilepsy, scrofula, typhus, cholera, etc. Recompenses will be adjudged to those who, without attaining this end, have approached it most nearly. 8. The Argenteuil Prize of 12,000 francs. This magnificent sexennial prize will be decreed to the author who has made the greatest improvement in the curative Treatment of Stricture during the period 1856-62; or subsidiary to this to the author of the greatest improvement during these six years in the treatment of other Diseases of the Urinary Organs. *Prize Subjects for 1864*:—1. Academy. "Exhibit by the aid of clinical facts the complications which may occur during the course of Acute Rheumatism on the part of the nervous centres and their membranes." 2. Portal. "What is the condition of the nerves in Local Paralyses." 3. Bernard de Civrieux. "The history of Ataxie, Locomotive Progressive." 4. Itard. This triennial prize of 3000 francs is decreed to the author of the best work on Practical Medicine or Applied Therapeutics. The work must have been published at least two years. 5. Orfila (6000 francs). "Poisonous Mushrooms,—Give their general characters, especially such as may be generally appreciated; examine into what effects are exerted upon their poisonous or eatable qualities by climate, exposure, soil, culture, and periods of the year; separate the toxic principles, indicate their physical and chemical characters, and exhibit the means proper to detect their presence in cases of poisoning; examine whether it be possible to separate or neutralise the poisonous principles, and in the latter case determine what has taken place during the decomposition or transformation which has occurred; examine into the action of poisonous mushrooms upon the organism, the means to prevent this, and the remedies which should be opposed to it." 6. Barbier Prize as in 1863.

INDIAN MEDICAL SERVICE.—(From the *Englishman*, December 19).—Sir Charles Wood's victims out here are not

exactly quite so purblind as he thinks them, especially when their own vital interests and rights are concerned; if they cannot always see which way the wind blows when a few odd straws are thrown up, they can pretty well perceive how the atmospheric current is setting when a whole sheaf is scattered in the air. The Medical officers of the late Company's armies have, for a long time, thought and felt that they had suffered serious injustice at Sir Charles's hands, and latterly appear to have settled down into that apathy which marks the demeanour of people who believe that their cup of despair is full. But in this assumption they have been mistaken; as they have just now received the greatest discouragements yet, in our opinion, sustained by them as a service. The blow has been inflicted with a clumsy stealthiness which shows a sense of its injustice even on the part of him who delivers it, but which does not for a moment conceal it from those who are at all acquainted with the actions and manœuvres of the striker. If any person will take up the "Official Quarterly Army List" just published, and will open the pages assigned to the Medical department, he will miss from above the names of a number of officers the heading "Surgeon Majors," and he will find in a side column the date of arrival at that distinguished honour and exalted rank, notified by two small italics somewhat as the Brevet-Captains in the Sepoy Corps used to be indicated in former times. Perhaps it may be thought that this matters little, is of no real significance, and has been arranged by the compiler or printer of the Army List; but we can assure the medical service that such is by no means the case; and that, on the contrary, it is Sir Charles Wood's doing, through the military authorities in this country. Its significance only amounts to this, that the promises and provisions of the Royal Medical Warrant are not to be extended to the Indian medical officers; that their having served up to the rank of Surgeon Majors is to bring no material advantages whatever with it, and that, finally, it is only as it were brevet, or to speak more correctly, titular rank. We are not writing down hasty suppositions or assumed deductions, but are giving to the medical officers and the public the substance of the orders sent out by Sir Charles Wood to this country on the subject in question. There is nothing of doubt, assumption, or supposition about the matter; it is exactly as we have stated. In the Royal Army List the Surgeons Major remain as they have always been, and in the Royal Army their rank, that of Lieutenant-Colonel, carries all the advantages of that rank with it—pay, precedence, quarters, brass spurs, scuttles of coals, and dip candles, colonial allowances when abroad, and, in a word, everything that is desirable, useful, or trivial. But the Indian Medical Service is to "die out," and in the last days of its good and honourable career it is to be injured and insulted, and the faith of sovereign and country—of her Majesty's word and Warrant is to be broken with it by one of the most unjust and unscrupulous men who has held high official employ in England since the days of the Walpoles. In the Army List to which we have referred, it will be seen that the Surgeons who, by the terms of the Royal Warrant, were to rank as majors, have no rank whatever assigned to them, but as, even if they had it, it would bring them no real advantage, they are of course better without it. It is now fully obvious that for the Medical officers of the late Company's armies to expect anything like justice or consideration would be nothing short of stupid infatuation; that they have got all they will ever get from him; and that, in all probability, if he could take from them the little they still have, he would do so. They may now "die out."

## NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Toolespoore.—General Peel.

12 st. 7 lb.—You will pay your money, and you may take your choice.

Dr. J. Ogden Fletcher.—Our present arrangements do not permit us to publish births and marriages.

Methylated Spirits.—We may tell the chemists and druggists that the increasing distrust of the purity of drugs, and the belief that methylated spirit is largely used instead of pure spirit, is producing a most injurious effect.

WILLS, THE AUSTRALIAN EXPLORER.

The series of attempts which have been made by hardy explorers, under the auspices of the Royal Geographical Society, to explore the centre of

Australia, have usually resulted in signal failure. Such, however, was not the case with the expedition which, on August 20, 1860, left Melbourne with the object of following in the steps of Leichardt and Stuart, under the command of the ill-fated Burke. The second in command, William John Wills, was the son of a Medical Practitioner, Dr. Wills, who formerly practised at Totness. We take the following extracts from a review of his life in the *Athenæum* :—

"As a child he was intelligent, and fond of associating with his seniors. A thoughtful, sedate, inquiring urchin, he was never treated as a mere schoolboy; but he was not the less ready to take part in athletic sports and the pursuits of the playground. At eleven years of age he was trusted alone with a gun, and was a notably good shot; and, having no dog to accompany him on his sporting excursions, he trained a favourite cat to follow him about the fields, and hunt the hedge-rows. At the Ashburton Grammar School, which he entered in his twelfth year, he gained no distinction at examinations. A hard-working, nervous boy, he was far from brilliant; and through the defect of a slightly-impaired utterance, he failed to take so good a position in the class as he would otherwise have attained. In the May of 1850, he left Ashburton School, and was apprenticed to his father, who at that time thought of educating him for the Medical profession.

"Two years later he came up to London, where he pursued his Medical studies in an irregular manner,—picking up a knowledge of anatomy in the Guy's Museum, witnessing surgical operations at the theatres of different hospitals, and attending Dr. Stenhouse's practical chemistry class at Bartholomew's Hospital. With the summer of 1852, however, his student-life in London ended; and on October 1 of the same year, he and a younger brother went on board the *Janet Mitchell*, emigrant ship, off Dartmouth, and on the first day of the following year sighted the Australian coast." He there first got employment as a shepherd, afterwards practised medicine in the bush, and ultimately obtained an appointment in the Meteorological Observatory at Melbourne.

When selected to join the expedition which had been long contemplated "he was twenty-seven years of age; but, though he wore a beard, and had decision stamped on his face, it was remarked that he did not look more than twenty. Some photographic artists, present amongst the crowd who witnessed the exodus of the explorers, wished to take his likeness; but he refused, saying with a sad smile, 'Should it ever be worth while, my father has an excellent one which you can copy from.' On June 27 of the following year, the poor fellow, with unsteady hand, was penning these last words of his last letter to his father: 'You have great claims on the committee for their neglect. I leave you in sole charge of what is coming to me. The whole of my money I desire to leave to my sisters; other matters I pass over for the present. Adieu, my dear father. Love to Tom. I think to live about four or five days. My spirits are excellent.'

#### A FEW WORDS OF WARNING TO THE MEDICAL STUDENTS OF GREAT BRITAIN.

Among the large body of Medical students now qualifying themselves in the various schools of the United Kingdom for the practice of their Profession, there are numbers who look forward with confidence to a future career of honour and emolument in the Army Medical Service. The British Government, on the other hand, expects, with equal confidence, that the needs of the public service will continue to be supplied, as they have hitherto been, by a never-failing tide of skill, energy, and devotion. But each party may find itself mistaken, when the rising generation of Medical students learn, as they may, that Military Medical officers, so far from being honoured and cherished by the Government, are treated as of light estimation; that their rights and privileges, acknowledged and granted by the Crown and guaranteed by Act of Parliament, may be set aside and held in abeyance; while false hopes of benefits to come, ever seeming near at hand, and ever fading away in the distance, are held out to them to cover broken faith and cold indifference.

Medical Students of Great Britain! listen to the voice of one who now speaks to you from India, in the hope that you will, as you can, unite to obtain justice and fair treatment for your Professional brethren now, for yourselves hereafter; justice and fair treatment which are denied to the officers of the Indian Medical service to-day, and which may be refused to yourselves at a future time. The Indian service, it is true, is closed, and you may think that better treatment awaits you in that of the Royal Army; but pause and reflect ere you put faith in a Government, which, wishing to be rid of a service that has ever nobly done its duty, can cast it away with ingratitude and contempt; which can raise hopes only to disappoint them; scatter to the winds privileges secured by Act of Parliament; nullify and make void a Royal Warrant. That such has been the action of the Government towards its Medical officers in India, let the following statement prove :—

In the year 1858, when the government of India passed from the hands of the Honourable East India Company into those of the Crown, there existed in India two distinct Medical Services—the Queen's and the Company's. Each had its own privileges and advantages, and was in all things independent of the other. The latter service, with the military and naval forces of the Company, was then transferred to the Crown, the pay, pensions, and privileges, as regards promotion and otherwise, which they had enjoyed in the service of the Company being guaranteed to them by Act of Parliament (21 and 22 Vict., cap. 106)

It was determined to amalgamate the two Medical services, and to make them equal in pay, promotion, and pension; but various difficulties were found to stand in the way, and, as a temporary measure, a Royal Warrant was issued, bearing date February 1, 1859, which was supposed to confer upon the Indian Medical officers certain advantages, which had, in the preceding year, been conceded in like manner to the Royal service. This warrant, by some of its provisions, altered existing rules with regard to promotion in the Indian Medical Service, and might therefore be regarded as an infringement of the covenant under which the Indian officers enlisted, and a breach of their privileges guaranteed by Act of Parliament. Professing to place both services on the same footing, it in reality gave an inferior position to the Indian, and it was, in consequence, regarded as not entirely satisfactory. Nevertheless, it was accepted as an omen of promise, an evidence of goodwill, an earnest of better things to come. Time only was wanting to show that the Royal Warrant was but "a mockery, a delusion, and a snare." Four years have passed away since it was penned, and it remains an empty, unfulfilled promise. Nominally, indeed, the Warrant is in force; its titles are conferred, but the rank, precedence, and pay which they should carry are all withheld.

Surgeons, after twenty years' service, are appointed Surgeons-major, and should, according to the original Warrant, hold the rank of lieutenant-colonel, but junior of that rank. Regimental Surgeons should rank with majors according to the dates of their commissions. Such relative rank should, in the words of the Warrant, "carry with it all precedence and advantages attaching to the rank with which it corresponds," and should "regulate the choice of quarters, forage, and prize money." Actually, however, it carries none of these advantages. The Surgeons-major are not even recognised as a separate class in the official Army List. A re-issue of the Warrant by the Horse Guards decrees that the Surgeons shall rank as majors, but junior of that rank; precedence is refused them; it has been ruled that they hold only brevet rank, and they are allowed to draw only captain's pay.

Thus is the shadow only given where solid advantage has been promised; but the substance is freely conferred when the provisions of the Warrant are injurious to those for whose benefit it was designed. Henceforth, in the words of the Warrant, "No Assistant-Surgeon shall be eligible for promotion to the rank of Surgeon, until he shall have passed such examination as our Principal Secretary of State for India in council may require, and shall have served in India, with the commission of Assistant for five years, of which two shall have been passed in or with a regiment." And "a Surgeon, whether on the staff or attached to regiments, must have served ten years in India, of which two must have been passed, with the rank of Surgeon, in or with a regiment, before he will be eligible for promotion to the rank of Deputy-Inspector-General of Hospitals. These rules, applied, as they are to be to officers who entered the service prior to the date of the Warrant, are breaches of faith, alterations of existing rules for promotion, the continuation of which had been guaranteed by Act of Parliament, as above stated.

Every Assistant-Surgeon who enlisted prior to the date of the Warrant entered a seniority service, and understood that promotion would be his when he arrived at the head of the list, without reference to the nature of his past employment; and he has as just a right to promotion by seniority as he will have to pension on the completion of his service. Under the new rule, Assistant-Surgeons who have been transferred to the Civil Department before completing two years of military service, who have held charges of the most responsible nature, and have enjoyed the advantages of a far wider field of practice than is generally offered by a regimental Hospital, must resign these appointments and seek military service, or indefinitely forfeit their promotion. Pecuniary loss and great personal inconvenience will thus be the reward of years of useful service; and every officer who comes under this regulation will have reason to complain that faith has not been kept with him, and that he has been subjected to what, in former years, would have been considered as the punishment of a fault. Recently, as if in mockery of the wrongs under which these officers smart, the option of resigning their appointments has been offered them. They have been invited, "should they desire it," to arrange for fulfilling the period of army service required; to reduce themselves probably from positions just fairly remunerative and no more, to the smallest military allowances while doing duty with a regiment, to the ruin of themselves and their families. Hereafter, when the promotion, which should be theirs by good service and by right, is denied, they will be told "It is your own fault, you were duly warned."

The rule which requires two years' military service as full Surgeons, as a necessary qualification for the rank of Deputy-Inspector-General of Hospitals is equally objectionable. Among the Surgeons of the Indian Medical Service are many who have spent their whole time in civil employ. After having given their best energies to the service of Government for years, after having held appointments entailing the most onerous Professional duties, these officers are to be considered unfit for the rank of Deputy-Inspector-General of Hospitals, unless they forfeit their appointments and perform the required amount of regimental duty.

A similar rule to this, indeed, formerly existed in the Indian Medical Service; but, owing to its injurious action, it was wisely repealed. Such regulations, while they effect no public good, serve only to irritate and annoy individuals, to raise a general feeling of discontent, and to make every officer feel that he belongs to a service which the Government delights to dishonour.

The examination of Assistant-Surgeons, to ascertain their fitness for promotion, has not yet been brought into practice. It cannot be enforced in the case of officers who entered the service prior to the date of the Warrant, without interfering with their privileges, guaranteed by Act of Parliament. In any case, it would be as absurd, as it is insulting to the Profession at large. The proposal to examine men whose fitness has been proved at the commencement of their career by proper authority, and, subsequently, by years of successful practice and unchallenged good repute, is preposterous. The Universities and Examining Boards are in duty bound to protest against such treatment of their graduates. Assistant-Surgeons should unanimously refuse promotion offered to them on terms so derogatory to the honour of their Profession; and properly-qualified Medical men should decline to enter a service which threatens them with so degrading a condition.

While some portions of the Warrant have been dealt with in the manner before described, others have been kept entirely in abeyance; but it is not necessary to take notice of these; enough has been said to show that the original Warrant, designed in a spirit of liberality, has been so tampered with, that it tells against, rather than in favour of, those who expected to receive in it a boon. The officers of the Indian Medical Service asking for bread have received a stone; they have trusted to a broken reed, and it has pierced them. There are at least four years' arrears of the pay of their rank, promised in the Warrant, due to them; and they may justly complain that they have been treated with injustice and contempt, and that they have purchased their commissions at the cost of their birth-rights as Englishmen.

Lastly, during the four years which have elapsed since the Warrant was signed, what has been the conduct of the Government towards the service? Well knowing the anxiety felt by the Indian Medical officers, has it vouchsafed them one word of explanation and encouragement? In all its futile deliberations concerning the amalgamation of the services, has it called to its councils any of those most interested? The answer must be No. Military officers have been employed to draw up schemes for the amalgamation, and to officiate as amateur actuaries in winding up the affairs of the Medical Retiring Fund. That fund, a private association for the grant of annuities to retiring officers, to which subscription was made compulsory by Government, is now dying of inanition. The closure of the Indian Medical service has sapped its roots; no new subscribers are added to its list, while its expenditure in annuities increases yearly. It is said, indeed, that the Government guarantees the advantages

of the fund to the present subscribers; but of what value is a Government guarantee to men with whom the Government has already broken faith?

It is, unfortunately, a fact, too well established to be doubted, that Medical officers of all branches of the service have ever been hardly treated by the Government, and that what consideration they now enjoy, has been granted to them only by degrees, and under pressure. But, a few years ago, the position of the Medical officers of the navy was so degraded, that no candidates could be found for employment in that service. The students unanimously refused to enter the navy, and at length the Secretary of the Admiralty reported that no Surgeons were forthcoming to fill the vacancies. Then, and not till then, were naval Medical officers treated as gentlemen and members of a learned Profession (a).

Such a crisis is now at hand; a paucity of Medical officers is becoming felt in India; many of the seniors, disgusted with the treatment they have received, are anxious to retire; let their want and their worth be felt. Now is the time for the students of Medicine to assist their elder brethren, and to secure their own future prospects. Let there be a cry for military Surgeons, and no response; then, and then only, will military Surgeons receive the treatment which is their due. Let vacancies in the army Medical service remain unfilled, until an order of Government is published and communicated to the schools, promising that the original Warrant prepared in a true spirit of liberality by the late lamented Sydney Herbert, shall be strictly and faithfully observed; that the rights and privileges of the Medical officers in India shall be respected; and that they shall receive, in accordance with the terms of the Warrant, their proper pay and staff allowances, and *bond fide*, not brevet rank.

Let it ever be remembered that the rank and position of the army Medical officer must be established on the firm and permanent basis of the royal command; not on a sand so shifting and treacherous as the favour and good will of any subordinate authority. So long as a Royal Warrant may be altered at the pleasure of a Secretary of State, so long will it be unworthy of the name, so long will the position of the Medical officer be uncertain and unsatisfactory, and dependent only on the urgency with which his services are required. So long, in fact, will it be undesirable to become

AN ARMY MEDICAL OFFICER.

RUSSELL v. ADAMS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—There is a mistake in the report of the meeting. I asked, "I there any friend of Mr. Propert present who will answer the question, whether Mr. Pike is or is not Mr. Propert's private solicitor?" No one did answer, and therefore I believe now, as I had been informed before, that Mr. Pike, who conducted the plaintiff's case, is Mr. Propert's solicitor.

I am, &c.

H. H. CANNAN.

A HOLIDAY FOR MEDICAL ASSISTANTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Probably no other class of individuals are so over-worked, ill paid, and less thought of by their governors and the public than the Medical assistants, and to them a holiday would prove a great boon. The retail ones are pent up in shops or surgeries from Monday morning till late Saturday nights without a change of air, and the out-door visiting ones, have duties to perform night and day through the whole year, with even scarcely an hour's liberty to call their own. As every one is likely to be taking advantage of the occasion of the forthcoming rejoicings, can you in any way intercede in behalf of such a large class, and call on the Medical Profession generally to lighten the day's duties, particularly for those in the suburbs of town, who are for ever toiling in the same monotonous way? I feel certain you will confer a blessing on many by using your influence in your widely circulated Journal in asking for a share in the rejoicings of the nuptial day for all such.

L. S. A.

THE TERM "PYTHOGENIC."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I entirely agree with the observations of your learned correspondent "Querens," in the last number of your Journal, in regard to the attempted introduction into the Medical nomenclature of fevers of the term "pythogenic," and for this simple reason, that to give a name to a form of fever from its supposed (but erroneous) cause is absurd.

It may be in accordance with the views of those visionary theorists, who ascribe the origin of enteric fever, its proper and pathological name, to putrid emanations; but the so-called facts, or arguments, on which this assumption rests are so futile and easily overthrown, that I trust the effort to perpetuate this fallacy will be resisted by the more practical and sober-thinking members of our Profession, and that the two leading forms of continued fevers may be henceforth distinguished by the simple and intelligible terms "typhus" and "enteric."

In my lectures on "Fever," I have invariably adopted these terms—the former being distinguished by the absence of the invariable intestinal and abdominal lesions which characterise the latter.

17, Pall-mall, March 3.

A TWEEDIE.

THE WIRE COMPRESS A SUBSTITUTE FOR THE LIGATURE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Referring to Mr. Dix's letter on the above subject, I have briefly to state that "my share of the matter" is simply this: I saw Mr. Dix's paper on "Acupressure," which "suggested as a crude hint the use of fine suture wire instead of the needles." I immediately and voluntarily supplied Mr. Dix with a description and illustrations of a method of employing the fine wire, which was devised by me six months previous to his suggestion; the plan he at once ridiculed, but, after a lapse of time, he made trial of it, and found it to answer. Mr. Dix, I believe, was the first Surgeon to test the method on a bleeding vessel, and the success may fairly be attributable to his care and dexterity; in addition, he has favoured the plan with a name, and with his sanction and approval; if, therefore, the "wire compress" becomes "a substitute for the ligature," I shall regret if it is not always known as the method of arresting hæmorrhage adopted by Mr. Dix.

(a). The Naval Medical Warrant, however, has been indirectly tampered with, and is susceptible of improvement. The rank of the executive officers relatively with the army has been raised so as to keep the Medical officer below. A lieutenant of eight years' standing in the navy now ranks with a major in the army, and so obtains precedence of a Medical officer of the same standing.

Had the published reports contained the passage which Dr. Dix's letter supplies, I certainly should not have initiated this correspondence, and I will not now prolong it, or increase the receiving effect of certain sentences in his letter by any comments.

I am, &c.

## APPOINTMENTS FOR THE WEEK.

March 7. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.

MEDICAL SOCIETY OF LONDON, 5 p.m. Anniversary Meeting. Oration by Dr. Habershon. 6½ p.m.—Dinner.

ROYAL INSTITUTION, 3 p.m. Professor Max Müller, "On the Science of Language" (Second Series).

9. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.

MEDICAL SOCIETY OF LONDON, 8½ p.m. Clinical Discussion—Dr. Thudichum, "On Cancer of the Pancreas; and on Purulent Disease of the Kidney, Complicated with Disease of the Bladder;" and on other Communications.

10. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Meeting.

ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Mechanics."

11. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.

HUNTERIAN SOCIETY, 8 p.m. Dr. Fowler, "On the Autopsy of a Case of Artificial Anus, in the Groin Successfully Treated."

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 p.m. Croonian Lectures—Dr. Risdon Bennett, "On Some Points Connected with Bronchitis, and its Results."

12. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.

ROYAL INSTITUTION, 3 p.m. Prof. E. Frankland, "On Chemical Affinity."

13. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 p.m. Lumleian Lectures—Dr. Chambers, "On Formation of Mucus and Pus."

ROYAL INSTITUTION, 8 p.m. Dr. J. Hall Gladstone, F.R.S., "On Fogs and Fog Signals."

ORIGINAL LECTURES.

PROFESSOR HUXLEY'S LECTURES  
AT THE  
ROYAL COLLEGE OF SURGEONS.

LECTURE II.

(Being the First of Six Lectures on Classification.)

MR. PRESIDENT AND GENTLEMEN,—The classification of any series of objects means the arrangement together of those which are like and the separation of those which are unlike; the purpose of this arrangement being to enable the mind to appreciate and to recollect the resemblances and differences of the objects in question. So that there may be as many kinds of classification of natural, or of other bodies, as there are distinct common properties in the whole of that series of bodies; and it would be more proper, perhaps, to speak of a classification, than of the classification of the animal kingdom. The galleries of this museum are sufficient evidence that, for the physiologist, the classification of the animal kingdom has a different end altogether from that which it has for the student of pure anatomy. John Hunter arranged his original collection upon the principle of illustrating the modifications of physiological organs in the animal series, and that arrangement was a perfectly good and valid one,—an arrangement which a physiologist might with great propriety adopt. But the student of geographical distribution might with equal fairness adopt a different arrangement, corresponding with the provinces which exhibit particular assemblages of organic beings. The student of palaeontology might adopt yet another, and arrange the animal world according to the order and succession of its groups in time. The kind of classification, however, of which I propose to speak here, and to which I intend to devote these preliminary lectures, is none of these, but is a morphological classification—a classification according to structure. It is the great object of this classification to arrange together those animals which resemble each other in structure, and to separate those animals from each other which differ in structure, and so to subordinate the different groups, and classes, and subdivisions, that the arrangement shall serve on the one hand as a *memoria technica*, while, on the other hand, it shall be a useful and important instrument of investigation by suggesting new inquiries, and enlarging the present bounds of knowledge.

But the possibility of the existence of a morphological classification at all depends upon a circumstance which is by no means obvious *a priori*, or for any reason that we can see in the mere nature of the case. It is possible and conceivable that every separate animal should have been constructed, so to speak, upon a different architectural plan. The possible diversity of the combination of natural forces into a physiological machine is practically infinite, and there does not appear to be any necessity, in the nature of the case that between a horse and a fish, for example, or between a bird and an ape, it should be possible to discover any unity of organisation at all. But, although we do not know why it should be,—although, in the nature of things, as I have said, there does not appear to be any good and valid reason why it should be,—yet, as a matter of fact, the relations which do exist between the different members of the animal kingdom are totally different from these. There is no such independence of arrangement among animal forms; on the contrary, there is a clear and distinct community of organisation running through the whole, so that the highest and the lowest, the most similar and the most diverse, are connected by certain common features of construction. The connexion may be closer or wider, the resemblance may be great or little, but however this may be, there is a certain definite amount of resemblance; so that, turning the matter another way, any classification of animals which arranges them according to their structural resemblances (that which I speak of as a morphological classification), is a statement of the empirical laws of animal form; that is to say, of those laws of co-existence or correlation of animal structure which are brought out by study and by experience. We can rarely see our way to a rational understanding of the causes on which these laws of correlation depend, but they are not the less

useful or valuable on that account. On the last occasion on which I addressed you, I pointed out that in the great *Glyptodon* the lower jaw consisted of a single piece of bone on each side, and articulated with the squamosal element of the skull; and I stated that, from that amount of information, it was quite possible to predict that the animal suckled its young. In fact, it has been established by an enormous multitude of examples, that when you meet with one of those characters in any animal you meet with the other. No one can tell why one of these circumstances should accompany the other, and this, therefore, is a purely empirical morphological law. All our definitions of orders and classes, if we have done our work properly, are statements of those co-existences and correlations of animal structure observed and determined in this empirical way. The fact that this is the case is what lends to the study of classification its immense and predominant importance; for, if classification is a statement of the observed laws of correlation of animal forms, it follows upon the validity of that classification, and upon the perfect accuracy of all its definitions that it puts into our hands the power of using our knowledge of animal structure as a means of reasoning from the known to the unknown; so that, apart from its immense usefulness in remembering a chaos—or what would otherwise, perhaps, be a chaos—of facts—a classification, which in this way throws our knowledge into the fewest possible general propositions, is of profound importance, and becomes one of our most powerful instruments of investigation. Therefore, that which is required of a classification, and the absence of which largely destroys its value, is, that, before all things, it shall be accurate and precise.

In the infancy of zoological science, when the knowledge of the great majority of animal forms was necessarily imperfect, the persons who devoted themselves to this study acquired a sort of learned tact—a kind of classificatory instinct—and even where the naturalist could not be sure of the structure of an animal there was often, to a practised eye, a look about it—a sort of similarity—which would lead him, and that, too, in many cases with great justice, to class it. It was by means of this sort of tact, as well as of his vast knowledge, that Linnæus was able to frame his great generic divisions so well; it was not so much that he had the means of ascertaining the structure of the species he grouped together with rigorous precision, but he felt that they were alike. That is a state of things which is very necessary and even desirable in the earlier conditions of science; in fact, it is only by breaking ground in this way that we can hope ultimately to arrive at exactness of knowledge. But nevertheless the object of further study is to end this transitory condition, and to substitute for such rough tact and feeling of resemblance an accurate definition of the nature of that resemblance. I propose, therefore, to take a course somewhat different from that which is usually adopted in dealing with classification. The great point is to get firm standing-ground, and from thence to see what we can do in the way of further advances in one direction or another. I propose to see whether we cannot get this kind of firm standing-ground by comparing all those groups which are called classes in the animal kingdom.

*The Classes of the Animal Kingdom, the Limits of the Four Cuvierian Sub-Kingdoms being Indicated by the Brackets and Dotted Line.*

RADIATA.

Lamellibranchiata.		Reptilia.
Pteropoda.		Aves.
Pulmogasteropoda.		Mammalia.
Branchiogasteropoda.		
Cephalopoda.		

Not that I mean to say that it is necessary for my purpose that the groups of which you see named on this table should

be absolutely and precisely equivalent one to another, but at any rate the sum of them is the whole of the animal kingdom, and each of them embraces one of the principal types or plans of modification of the animal kingdom, so that if we have a precise knowledge of that which constitutes the typical structure of each of these groups, and of the characters which are possessed by every member of the groups, we shall have, so far, an exhaustive knowledge of the animal kingdom.

Having endeavoured to define in this way these various groups, I shall afterwards ask you to take up with me some of those points which are more open to discussion; to see how far we can group these classes into larger assemblages, with definite and constant characters; and, on the other hand, to inquire how far the existing subdivisions of the classes are well based or otherwise. But the essential matter, I repeat, is to be quite clear about the different classes, and to have a distinct knowledge of the clearly-definable modifications of animal structure in the animal kingdom.

FIG. 1.

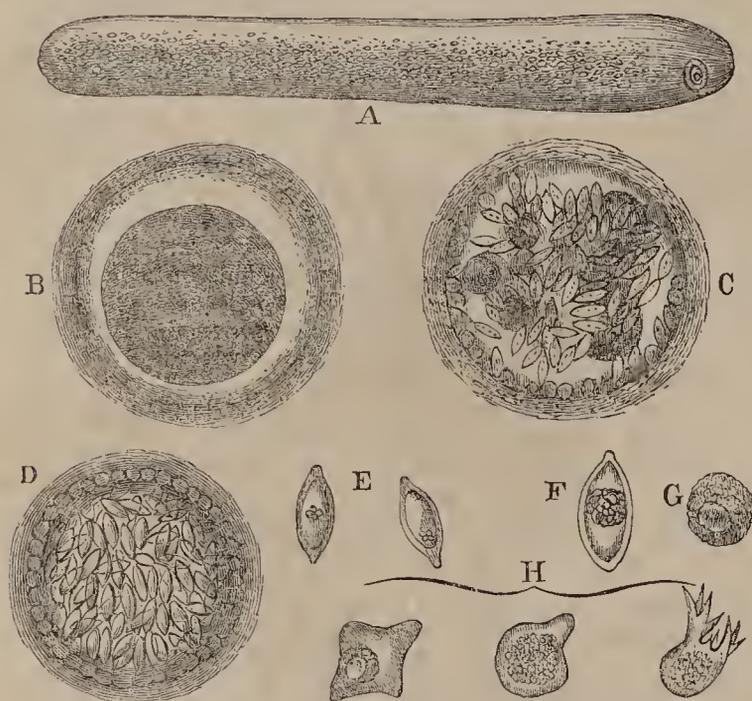

FIG. 1.—A, *Gregarina* of the earthworm (after Lieberkühn); B, encysted; C, D, contents divided into pseudo-navicellæ; E, F, free pseudo-navicellæ; G, H, free amebiform contents of the latter.

The first class of which I shall speak is the group of the *Gregarinida*. These are among the simplest animal forms of which we have any knowledge. They are the inhabitants of the bodies for the most part of invertebrate, but also of vertebrate, animals; you may find them commonly in abundance in the alimentary canal of the common cockroach, and in earthworms. They are all microscopic, and any one of them, leaving minor modifications aside, may be said to consist of a sac, composed of a more or less structureless, not very well-defined membrane, containing a soft semi-fluid substance, in the midst of which lies a delicate vesicle; in the centre of that, again, is a more solid particle. (Fig. 1, A.) No doubt many persons here will be struck with the close resemblance of the structure of this body to that which is possessed by an *ovum*. You may take the more solid particle to be the representative of the germinal spot, and the vesicle to be that of the germinal vesicle; while the semi-fluid sarcodic contents might be regarded as the yolk, and the outer membrane as the vitelline membrane. I do not wish to strain the analogy, but it is, at any rate, interesting to observe this close morphological resemblance between one of the lowest of animals and that form in which all the higher animals commence their existence. These animals—sometimes more lengthly, sometimes constricted—always have this peculiar and fundamental character. They are devoid of mouths and of digestive apparatus, living entirely by imbibition of the juices of the animal in whose intestine or body cavity they are contained. The most conspicuous of those phenomena, which we ordinarily regard as signs of life, which they exhibit, is a certain contraction and expansion along different diameters, the body slowly narrowing and then lengthening in various directions. Then, at a particular time, though the conditions of the change are not thoroughly understood, it is observed

that one of these *Gregarinida*, whatever its form may be, will convert itself into a well-rounded sac, the outer membrane ceasing to exhibit any longer those movements of which I spoke, and becoming coated by a structureless investment or "cyst" (B).

The substance of the body contained within the cyst next undergoes a singular change. The central nucleus and the vesicle disappear, and, after a time, the mass breaks up into a series of rounded portions, and then each of those rounded portions elongates, and, becoming slightly pointed at each end, constitutes a little body which has been called a "pseudo-navicella" from its resemblance to the Diatomaceous *Navicula* or *Navicella* (C, D). Next, the capsule bursts; the pseudo-navicellæ (E, F) are scattered and passed out of the body which they inhabit, and though, of course, a great number of them are destroyed, some, at any rate, are devoured by other animals; and when that is the case, the little particle of protein substance which is inclosed within the pseudo-navicella is set free from its shell, and exhibits much more lively movements than before, thrusting out processes in various directions, and drawing them in again, and, in fact, closely resembling one of those animalcules which have been called *Amœbæ* (H). The young Amœbiform *Gregarina* grows, increases in size, and at length assumes the structure which it had at first. That, in substance, is all that we know of this lowest division of animal life. But, you will observe, there is a hiatus here; I mean to say that our knowledge is not complete. We cannot say that we know the whole nature and mode of existence of this or any other animal until we have traced it to its sexual state; but, at present, we know nothing whatever of this condition among the *Gregarinæ*, so that in reasoning upon them we must always exercise a certain reticence, not knowing how far we may have to modify our opinions by the discovery of the sexual state hereafter.

The process of becoming encysted (after that conjunction of two *Gregarina* which often occurs) was formerly imagined to correspond with what is termed among plants "conjugation,"—a process which in some cases, at any rate, appears to be of a sexual nature. But the discovery that a single *Gregarina* may become encysted and break up into pseudo-navicellæ seems to negative this analogy. You will observe, as a very remarkable characteristic of this group, that there is no separation of the body of the animal into distinct layers or into cellular elements.

But now, leaving this, I pass on to the next class—that which is indicated in this table as the *Rhizopoda*. And I have put a query against it, as I shall have to return to it as another of those respecting which our knowledge is incomplete. And at this moment I beg merely to direct your attention to the salient and characteristic features of the whole group (Fig. 2).

FIG. 2.

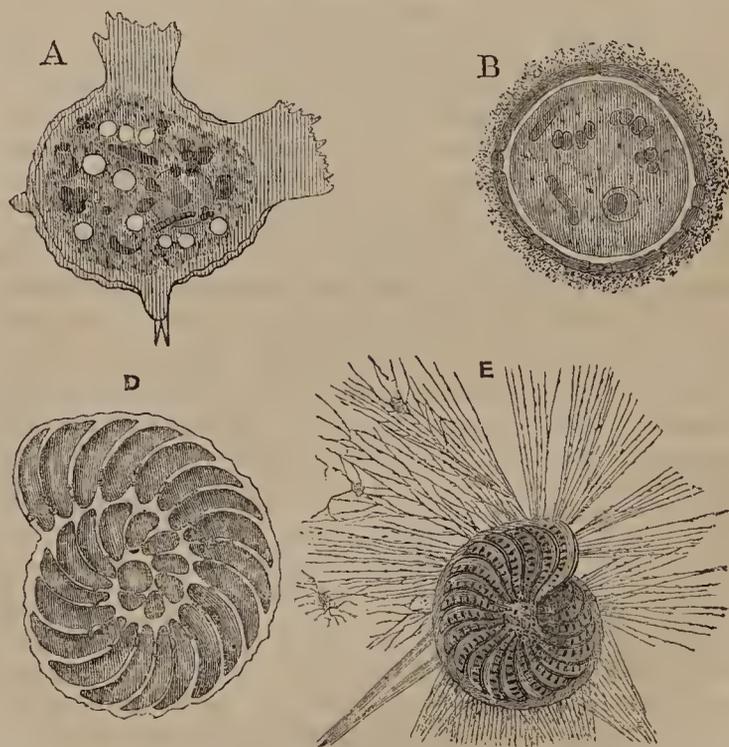

FIG. 2.—A, B, Free and encysted conditions of an *Amœba* (after Auerbach); C, E, a Foraminifer (*Rotalia*) with extended pseudonodia; D, its shell in section (after Schulze).

It seems difficult to imagine a stage of organisation lower than that of *Gregarinida*, and yet many of the *Rhizopoda* are still lower. Nor is there any group of the animal kingdom which more admirably illustrates a very well-founded doctrine, and one which was often advocated by Hunter himself, that life is the cause and not the consequence of organisation; for, in these lowest forms of animal life there is absolutely nothing worthy of the name of organisation to be discovered by the microscopist, though assisted by the beautiful instruments that are now constructed. In the substance of these creatures, however, nothing is to be discovered but a mass of jelly, which might be represented by a little particle of thin glue. I do not mean to say it corresponds with the latter in composition, but it has that texture and sort of aspect; it is structureless and organless, and without definitely formed parts. Nevertheless, it possesses all the essential properties and characters of vitality; it is produced from an organism like itself; it is capable of assimilating nourishment, and of exerting movements. Nay, more, it can produce a shell—a structure of the greatest possible complexity and most singular beauty,—as we may see by these few examples on the table.

That this particle of jelly is capable of combining physical forces in such a manner as to give rise to those exquisite and almost mathematically-arranged structures—being itself structureless—and without permanent distinction or separation of parts, is to my mind a fact of the profoundest significance.

Though a *Rhizopod* is not permanently organised, however, it can hardly be said to be devoid of organs; for the name of the group is derived from the power which these animals possess of throwing out processes of their substance, sometimes of great length. These processes may flow into one another so as to form a network, and they may be thrust out from any part of the body and retracted into it again.

If you watch one of these animals alive, you see it thrusting out these pseudopodia,—first one and then another,—exhibiting motions which are comparable to those singular movements which anybody may see for himself, by simply taking a drop of his own blood and by means of a microscope watching the movements of the white corpuscles in it. The movements of these *Rhizopods* are quite of the same character, only they are much more extensive. The *Rhizopod* feeds itself by means of these pseudopodia, which attach themselves to nutritive particles, and then draw them into the substance of the body.

There is neither ingestive nor egestive aperture, neither special motor nor prehensile organs, but the pseudopodia perform each function as it may be required. But here, again, we labour under an imperfection of knowledge. For, although it is quite certain that the *Rhizopoda* may multiply by division of their substance—in a way somewhat analogous to that which I detailed when speaking of the *Gregarinida*—yet, as in that case, we have no knowledge of any true sexual process. It is a most remarkable circumstance that though these animals are excessively abundant, and are constantly under observation, we are still in ignorance upon that essential point,—still uncertain whether there may not be some phase in the cycle of vital phenomena of the *Rhizopoda* with which we are unacquainted; and, under these circumstances, a perfect definition of the group cannot even be attempted.

The next division is the group of the *Spongida*, which exist under such multitudinous forms in both salt and fresh water. Up to the last few years we were in the same case with respect to this class as with the *Gregarinida* and the *Rhizopoda*. Some zoologists even have been anxious to relegate the sponges to the vegetable kingdom; but the botanists, who understood their business, refused to have anything whatever to do with them. And the botanists were quite right; for the discoveries of late years have not left the slightest doubt that these sponges are animal organisms, and animal organisms, too, of a very considerable amount of complexity, if we may regard as complex, a structure which results from the building up and massing together of a number of similar parts.

The great majority of the sponges form a skeleton, which is composed of fibres of a horny texture, strengthened by needles, or spicula of silicious or calcareous matter; and this framework is so connected together as to form a kind of fibrous skeleton. This, however, is not the essential part of the animal, which is to be sought in the gelatinous substance which during life invests the fibres of the skeleton, and is traversed by canals which open upon the surface of the sponge, directly or indirectly, by many minute and fewer large apertures.

If I may reduce a sponge to its simplest expression—taking the common *Spongilla*, for example, of our fresh waters,—the structure, removing all complexities, and not troubling ourselves with the skeleton, because that has nothing to do with what we are now considering, may be represented by this diagram (A, Fig. 3). There is a thin superficial layer formed

FIG. 3.

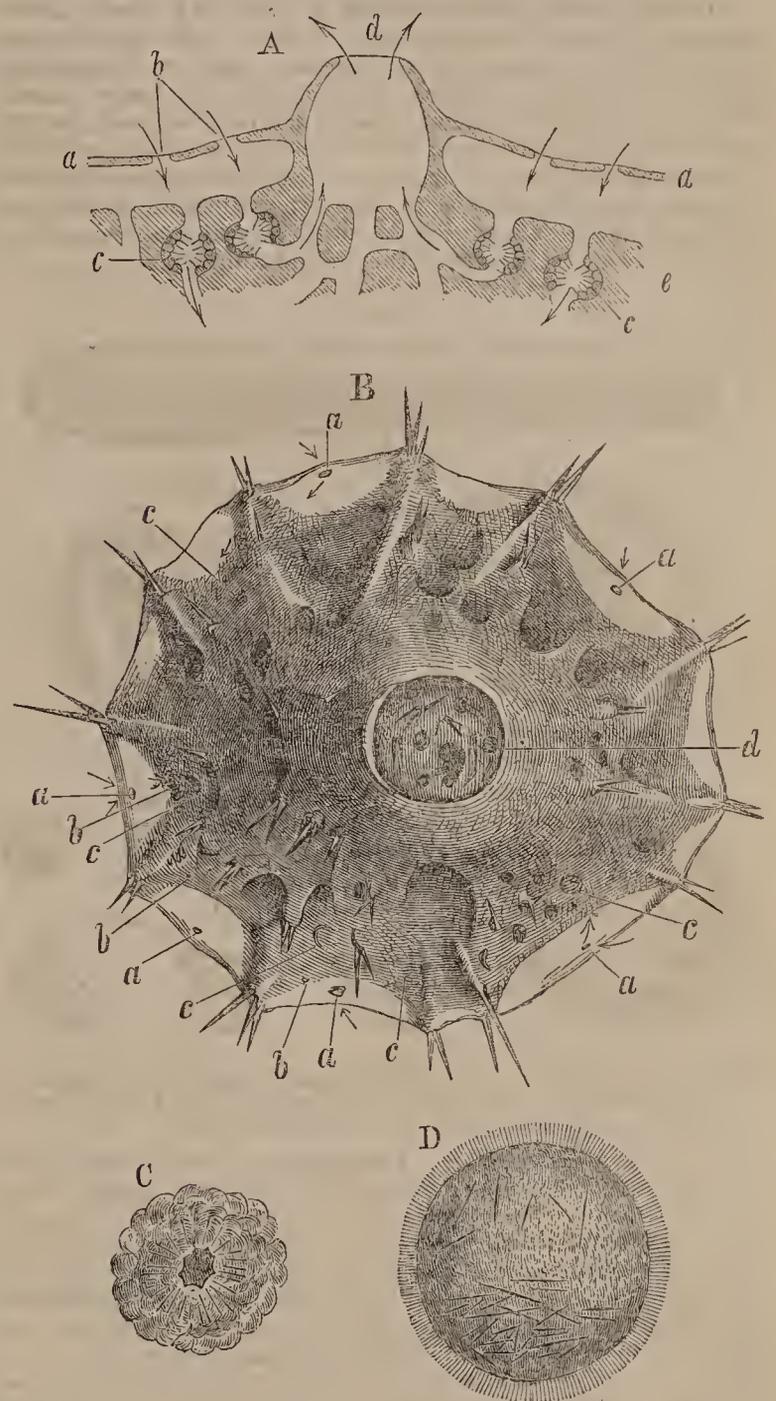

FIG. 3.—A, Hypothetical section of a *Spongilla*; a, superficial layer; b, inhalant apertures; c, ciliated chambers; d, an exhalant aperture; e, deeper substance of the sponge. The arrows indicate the direction of the currents. B, A small sponge with a single exhalant aperture, seen from above (after Lieberkühn); a, inhalant apertures; c, ciliated chambers; d, exhalant aperture; C, a ciliated chamber; D, a free-swimming ciliated embryo.

entirely of a number of these so-called sponge particles, or ultimate components of the living substance of the sponges, each of which is similar to an amœba, and contains a nucleus. These are all conjoined in a single layer, so as to form a continuous plate, which constitutes the outer and superficial layer of the body. Beneath this is a wide cavity, communicating with the exterior by means of minute holes in the superficial layer, and of course filled with water. This cavity separates the superficial layer of the sponge from its deeper substance, which is of the same character, being made up of a number of aggregated sponge particles, each of which has a nucleus and is competent to throw out numerous pseudopodial prolongations if detached. If, while the living sponge is contained in water, you watch it, you will find a great number of currents of water are setting in to the superficial chamber through the minute apertures. Then, at the bottom of the chamber, there are a number of other apertures which lead into canals ramifying

in the deep layer, and eventually ending in the floors of certain comparatively lofty funnels or craters, the top of each of which presents one of those larger and less numerous apertures, which have been referred to as existing on the surface of the sponge.

As Dr. Grant discovered, many years ago, strong though minute currents of water are constantly setting out of these large apertures, being fed by currents which as constantly set in by the small apertures and through the superficial cavity and the canals. The cause of this very singular system of currents remained for a long time unknown. It was rendered intelligible by Dr. Bowerbank's discovery of the existence of vibratile cilia in the genus *Grantia*, but it is only quite recently that the precise nature of the arrangement of the apparatus, which gives rise to these currents in ordinary sponges, has been made out by Lieberkühn and by Carter. The canals which enter the deep substance of the sponge become dilated into spheroidal chambers, lined with sponge particles, each of which is provided with a vibratile cilium, and as all these cilia work in one direction—towards the crater—they sweep the water out in that direction, and its place is taken by fresh water which flows in through the small apertures and through the superficial chamber. The currents of water carry with them such matters as are suspended in it, and these are appropriated by the sponge particles lining the passages, in just the same way as any one of the *Rhizopods* appropriates the particles of food it finds in the sea-water about itself. So that we must not compare this system of apertures and canals to so many mouths and intestines, but the sponge represents a kind of subaqueous city, where the people are arranged about the streets and roads in such a manner that each individual can easily appropriate his food from the water as it passes along.

In the sponges two reproductive processes are known to occur: the one of them, a sexual, corresponding with the encysting process of the *Gregarinide*; and the other, truly sexual, and answering to the congress of the male and female elements in the higher animals. In the common fresh-water *Spongilla*, towards the autumn, the deeper part of the body becomes full of exceedingly small bodies, sometimes called "seeds" or "gemmules," which are spheroidal, and have, at one point, an opening. Each of these bags—in the walls of which are arranged a great number of very singular spicula—is, in point of fact, a mass of sponge particles which has set itself apart—gone into winter quarters, so to speak—and becoming quite quiescent, wraps itself round and remains still. The whole *Spongilla* dies down, and the seeds inclosed in this case remain uninjured through the winter. When the spring comes, the encysted masses within the "seed," stimulated by the altered temperature of the water, creep out of their nests, and straightway grow up into *Spongilla* like that from which they proceeded.

But there is, besides, a true sexual process, which goes on during the summer months. Individual sponge particles become quiescent, and take on the character of ova, while in other parts particular sponge particles fill with granules, the latter eventually becoming converted into spermatozoa.

These sacs burst, some of the spermatozoa come into contact with the ova, and impregnate them. The ova develop and grow into ciliated germs, which make their way out, and, after swimming about for a while, settle themselves down and grow up into *Spongilla*.

Now that we know the whole cycle of the life of the sponges, and the characters which may be demonstrated to be common to the whole of this important division of the animal kingdom, I do not think any one who is at all acquainted with the organisation or the functions of plants, will be inclined to admit that the sponges have the slightest real affinity with any division of the vegetable kingdom.

### HYDROCYANIC ACID IN THE TREATMENT OF INSANITY.

By KENNETH MCLEOD, M.D.

AMONG many trials of the efficacy of particular medicinal agents and modes of remedial treatment in particular forms of mental derangement, which I have instituted since coming into asylum practice, I have made a careful series of experi-

ments into the effect of hydrocyanic acid in allaying cerebral irritation and excitement. The results which I have obtained are, upon the whole, so satisfactory that, although I should desiderate a more extended and minute induction for the sake of indicating exactly the cases and circumstances in which it is most suitable, still I consider it better to give them publicity, in order that the use of the drug, if it is as valuable and effectual as I believe it to be, may be extended, and that its merits and defects may become a subject of inquiry at the hands of others. As far as I have been able to learn by reading and personally inquiring into the practice of other asylums, though prussic acid is, in over-dose, the cause of such immediate and striking effects upon the brain, its moderate use has not been applied to any form of disease of that organ whose activities it is capable of extinguishing in less than a minute.

Aware of the fallacies which are so liable to complicate investigations into the modes of action of therapeutical agents, and to cripple, nullify, or falsify results, I have with care attempted to guard against them. The most common sources of fallacy are—

1. The natural course and resolution of the disease after removal of a cause or causes, or the completion of the changes which constitute its term.

2. The effects of regimen, diet, moral treatment, and other circumstances operating simultaneously with the administration of the remedy as causes in a course of events.

3. The effect of other remedial agents given at the same time or previously.

4. The tendency to anticipate results and to "explicate appearances—not as they are, but as the observer pleases."

I have endeavoured to obviate these, which attach largely to a practice in insanity, by—1st. Estimating the probable issue from a consideration of existing circumstances and symptoms, and comparison with other similar cases. 2nd. Making due allowance for the effect of other means in existence as causes of cure. 3rd. Administering the drug void of combination. And, 4th. Cultivating a salutary scepticism as to results, and taking rather the unsolicited testimony of other observers than depending solely on my own observation.

The evidence which I possess of its action has been gained from—1. Personal observation, as constant and close as possible. 2. The observations of attendants upon the insane. 3. The statements of other patients. And, 4. The admission, in several cases, of the patients themselves.

The trials have extended over six months, and the number of patients who have for a longer or shorter period been under treatment with it exceeds forty. I shall, in what follows, consider in order—1. The circumstances and cases in which the drug has been administered. 2. The effects of the administration. 3. The preparation, dose, and mode of administration employed; and 4. The indications derived from my experience of it, of its further use or trial; and give, shortly, a few of the most remarkable illustrative cases.

I. The feature or symptom which has in every case indicated the administration of the drug as a reputed calmative, is excitement—the manifested excess of cerebral activity which almost invariably accompanies, or assists in constituting, most forms of acute insanity, however caused or conditioned.

This increase of manifested energy may consist in an excessive activity of any or all of the representative faculties, gesture, feature, voice, or an intensified action of the brain itself, resulting in a morbid rapidity of ideation.

A simple increase of the evolution of nerve force, causing a more rapid rate of brain action and greater intensity of representation in the form of muscular acts, when excited by sufficient motive, and devoted to any end or a rational end, is a phenomenon of sound psychological action, and is manifested as emotion, passion, etc.; but when it exists in excess, without an adequate motive or any motive at all, and is not, consequently, devoted to any rational end or any end at all, it constitutes a pathological fact of the same sort, as every other pathological action or phenomenon characterised by excessive activity in a particular direction. Beyond recognising this excessive and sakeless cerebral vigour, or hypernoia (*ὑπερνόσος*), as it may be appropriately termed, as a simple, ascertained pathological fact, we cannot go; and, admitting it as such, we instinctively look for its conditions and causes, and, in the way of treatment, strive either to remove the cause, or introduce new causes—the knowledge of the causes and conditions of the pathological manifestation, as well as the

causes and conditions which will remove it, being matter for investigation.

The *hypernoia* may co-exist with more or less mental derangement. It may be an utter delirium, in which reason and design are totally wanting, or may exist along with incoherence and delusions of all sorts and degrees, and with one or several active propensities, erotic, destructive, dirty, malevolent, homicidal, suicidal, etc. It forms the element of acuteness in many different forms of insanity, is the main object of the exhibition of medicines and plans of remedial treatment, morphia, antimony, warm bath, douche, emetic, purge, etc. Its degree measures alike the gravity of the disease, and the success of treatment; its abatement is a token of amelioration, and removal a triumph; the treatment of the faculty disorganisation or *paranoia* (*παράνοια*) being subsequently accomplished mainly by tonic, dietetic, and moral means.

The particular forms of insanity in which I have employed this remedy are—

	Cases.
1. Mania, acute . . . . .	13
2. „ chronic . . . . .	2
3. „ chronic, acute paroxysms . . . . .	2
4. „ menstrual . . . . .	2
5. „ puerperal . . . . .	2
6. „ recurrent . . . . .	1
7. „ epileptic . . . . .	2
8. „ epileptic, with menstrual excitement . . . . .	2
9. „ with hemiplegia . . . . .	2
10. „ with general paralysis . . . . .	5
11. „ with chronic hydrocephalus . . . . .	1
12. Melancholia, acute . . . . .	3
13. „ chronic, with acute paroxysms . . . . .	3
	40

II. The effect in every case has been very manifest. It has been almost purely psychal, consisting in a very remarkable, sudden, or gradual cessation of hypernoetic manifestations, with or without the induction of sleep. While its repeated exhibition has never failed to have some calmative effect, this has varied, according to the circumstances of the case, and has occurred in all degrees from the gradual, slight, and temporary, to the immediate, absolute, and permanent.

1. In cases of mania and melancholia of great severity and long duration, with organic disease of the brain and body, its calmative action has been more slowly produced, with more difficulty maintained, more evanescent and futile.

2. In recent cases of mania and melancholia, where no grave structural change exists, and the morbid condition has not become so stereotyped by constant repetition of similar changes, its exhibition has been followed by an immediate and sustained change for the better.

3. In the violent, paroxysmal mania of epilepsy and general paresis, in menstrual mania, and acute melancholic paroxysms, a single administration, or a few full doses at short intervals, have effectually dispelled the paroxysm.

The effect is thus of two sorts. 1. Immediate. In a few minutes, one to five generally, a patient who has just been shouting, chattering, dancing, swearing, thumping, &c. &c., becomes settled and quiet, sits upon a seat, and perhaps falls into a sound sleep. And 2, gradual; the patient becoming, as the hypernoia is thus, from time to time, warded off, more rational, companionable, and useful. While changes in psychal manifestation are thus very obvious and striking, observed and appreciated by attendants, and confessed to by patients themselves, who, on being questioned, admit the calmative action, and conferred power of self-control, concomitant physical phenomena are very obscure or wanting. Only in two cases have I observed a very decided change in the character of the pulse, which became slower, weaker, and, in one, slightly irregular; but this is probably owing to the difficulty of accurately observing it in such circumstances. In two other cases in which a slight over-dose was given, a semi-comatose condition was induced, with complete adynamia, partial ptosis, the accumulation of frothy saliva, pallor, slight affection of breathing and pulse, phenomena almost exactly resembling those immediately preceding an epileptic paroxysm. In a few cases the subjective sensations were described as—1. Slight transient vertigo; 2. Slight nausea and a peculiar constrictive feeling at the back of the throat; 3. An unwillingness and almost inability to energise in any way, and sometimes

a desire to recline. These feelings were experienced in a few minutes after the dose was taken.

The result of administration in the forty cases in which I have noted the effect, may be represented as follows:—

1. Slight, or well-marked temporary amelioration, without any decided effect on the cause of the disease. This result I have observed in 10 cases: 1 of puerperal mania, in which the dose was probably insufficient; 1 of melancholia, in which the treatment was altered; 1 of menstrual mania; 3 of acute mania of long standing and great severity, ending in exhaustion and death, and resisting every mode and plan of treatment; 2 in recent mania, the effect being sustained and cure completed by other means; 1 in acute mania, when its administration was not sustained; and 1 in an acute paroxysm of chronic mania.

Even in these cases the effect has been most beneficial, the patient becoming very much more manageable, giving over violence, noise, excitement, stripping, restlessness, etc., and becoming more amenable to moral and dietetic management.

2. A more decided and permanent effect, the disease being still stationary or progressive. Of this class I have noted 19: 5 general paralytics, in whom, while the morbid excitement has been vastly abated or expelled, the disease has progressed to its fatal termination; 5 chronic maniacs, in whom an intercurrent acute paroxysm was effectually dispelled; 3 melancholics, in whom acute manifestations were permanently removed; 1 case of acute dementia, in which excessive hypernoia was immediately arrested; 2 epileptics, in whom a paroxysm of excitement was summarily dismissed; 2 cases of epilepsy with menstrual excitement, in which the contrast of duration with former attack was most striking; 1 case of hysterical mania, in which the disease oscillated from an extreme of hypernoia to an extreme of hyponoia; 1 case of puerperal mania, in which rest and sleep were induced after other measures had signally failed; 1 case of mania with hemiplegia, in which an intercurrent excitement was disposed of; and 1 case of mania with chronic hydrocephalus, where a change in conduct and demeanour was very evident.

In all the cases the benefit conferred has been simply obtained, satisfactorily established, and duly appreciated by the attendants and patient.

3. Cases in which the drug has been a factor, and a very main one, in rapid restoration to reason. The cases of this class have been 8 in number: 6 of acute mania, and 2 of acute melancholia. I shall append some of the most interesting cases of each class.

III. The preparation which I have employed in every case has been Scheele's dilute acid, which I have found remarkably uniform and convenient.

The dose has varied from *mij.* to *mvj.* Beyond that, disagreeable effects are apt to occur; *mv.* is the most convenient dose, and if the effect is not promptly established, a repetition every quarter of an hour effectually secures it. The effect is rather evanescent, and has been observed in some cases to disappear within an hour; but if a slight degree of hypernoia recurs, a subsequent administration is apt to have a more potent effect, in consequence of a prior. The interval may vary according to the nature and exigencies of the case, and the effect produced. Short at first, until an effect is produced (5' to 15'), it may be prolonged after the excitement has disappeared (to one or two hours). It may, in many cases, be left, within limits, to the discretion of an intelligent attendant.

The only modes of administration I have employed have been mixture and subcutaneous injection. The simplest and best menstruum is water, and *mv.* may be easily and safely introduced beneath the skin, combined with *mxxx.* of water, by means of Wood's syringe, when the patient resists all other means. Of its application to the extensive pulmonary mucous membrane, by means of pulverisation and inhalation, I have no experience; but I should anticipate interesting and important results from such a method of administering it, and other medicines, in insanity.

IV. The advantages of the drug, in comparison with other calmatives and hypnotics, are:—1. The rapidity, certainty, and simplicity of its effects. 2. Its manageability and freedom from any cumulative property. 3. The absence of any disagreeable, concomitant, or consequent physical disturbance, which most other analogous modes of remedial treatment possess. 4. Its small bulk, want of colour, and miscibility. 5. Its want of repulsive smell and taste—a very great virtue with the insane, who are very apt to rebel against medicines.

6. Its not impairing appetite and digestion, but rather improving both.

On the whole, I should recommend and urge the adoption of the drug in every case of insanity with hypernœia, as an empirical antagonist to that pathological phenomenon, combining or exhibiting it simultaneously with any other remedy or plan of treatment which an ascertained pathological condition may demand. Simply as a "quietener" it has its merits, proving an invaluable auxiliary to the moral management of a ward generally, or the patient in particular. Very often, I have heard the attendants express their sense of the great value of "the medicine" as completely altering the character of their gallery and the conduct of their patients,—benefiting the latter, and assisting themselves in the performance of their duties. But, in acute cases of mania and melancholia, and in maniacal and melancholic paroxysms, I attach a much higher value to it, and should more strongly advise its trial, as, from the experience I have had, I feel convinced of its potency and efficacy. I have no doubt that it has the power promptly of staying cases running on to chronic insanity on the one hand, or exhaustion and death on the other, and of obtaining, simply and satisfactorily, results which are at present aimed and arrived at by boiling a patient in hot baths, half drowning him in douches, narcotising with opium or morphia, nauseating with tartar emetic, exhausting with purging, roasting with blister, or debilitating with lancet, leech, or cup.

*Case 1.—Congenital Imbecility—Intercurrent Mania—Violent Hypernœia—Subcutaneous Injection of Hydrocyanic Acid—Calmative Effect sustained by Morphia—Gradual Amendment under Stimulants, with Sedatives, Nutrients, and Tonics—Cure.*

W. S., aged 18, single; admitted on March 24, 1862; father eccentric, admitted, subsequently, labouring under acute mania; mother drunken; has been much neglected by parents; half-starved, ill-fed, uneducated, trained to no employment, ill-treated, and cast adrift. Was at the age of 15 affected with insanity; has been always delicate, and frequently under Medical treatment.

*On Admission.*—Is a slender, emaciated youth, of very feeble physical organisation, and low diathetic status. Is pale and cachectic; no organic disease discoverable. Appears to be an imbecile. Until April 10 no acute manifestation declared itself; he was restless and silly, but quiet and amenable to control. Complained of pain after food, vomited, and suffered generally from gastro-hepatic derangement. Treated successfully with bismuth, rhubarb, and opium; feeds well, but does not appear to assimilate food.

10th.—Presents a change for the worse; gesticulates, crouches, strips, means, shouts, etc.; very disorderly and unmanageable. Broke several panes of glass in his dormitory last night.

11th.—Excitement progressive; is most violently maniacal this morning; darts out of bed, flies at the windows, struggles most tenaciously with the attendants; is utterly delirious, repeating incessantly the same expression; strength surprising. 10 a.m.—Slightly calmed by a cold shower-bath. Effect did not last beyond a quarter of an hour. Bowels much constipated. ℞ Ol. crot. tig., gt. ij., statim. 8 p.m.—Has become still more excited; is making intense efforts to strangulate himself; is being held in bed with difficulty by three attendants; resists all medicine. ℞ iij. acid. hydrocyanic dil. was injected over the scapula. Became almost instantly quite quiet; gave over violent struggling, stood beside his bed, and looked about him. Took vin. rub. ℥ij., morph. mur. gr. j. Latter to be renewed at hour intervals, until sleep induced, diminishing morphia to gr. ss.

12th.—Rested well up to 4 a.m., when he became excited, but not so violently as before. 8 a.m.—Is still restless, repeating, gesticulating, etc. 10 p.m.—Had bread-and-milk and Oj. beef-tea. To have Oj. porter and gr. j. morph. mur.

14th.—Has been much quieter during the last two days, and slept during the last two nights. Still raves; is very restless; pulse 80.

17th.—Has continued to improve slightly since last report. Eats and sleeps better; more manageable. ℞ Ol. tec. asselli, ʒss., ʒcc. daily; quinae disulp., gr. ij., ter. in dies. Continue porter, with morphia and generous diet.

23rd.—Continues very disorderly, but by no means so violent; is dirty, destructive, restless, and incoherent. Improves slightly in general health.

October 1.—Has continued uniformly to improve, both in general health and mental condition. Amendment caused mainly by dietetic and moral treatment. Is now as well as ever he has been, both physically and mentally.

(To be continued.)

## RESEARCHES IN ETHNOLOGY.

By the late R. KNOX, M.D., F.R.S.E.

### ON THE APPLICATION OF THE ANATOMICAL METHOD TO THE DISCRIMINATION OF SPECIES.

THE discovery of true descriptive anatomy, and its application to all classes of the zoological kingdom, led the illustrious Cuvier to the discovery of the fossil world. Many distinguished observers had previously, no doubt, made some happy conjectures respecting the antiquity of the fossil world, and the advantages to be derived from the application of the anatomical method in the discrimination of species. Daubenton, Vicq d'Azyr, and Pinel, in France; Pallas, Blumenbach, and others, in Germany; Hunter, in England, had long prior to the era of Cuvier discovered and appreciated the utility of anatomical inquiry in zoology; but the credit of having placed this method on a new basis, and of having demonstrated by its means the true nature of the fossil world, belongs, unquestionably, to Cuvier. As many observations and hypotheses have been ascribed erroneously to this illustrious man, and more especially in England, it seems best to ascertain in the first place his own opinions of the value of the method he had discovered.

In the fossil world, those external characters by which an animal species is at once discriminated from all others, had been, with but few exceptions, wholly destroyed. I allude more especially to the animals we call mammals; and thus, if the species of these fossil animals were to be discovered at all, it could only be done through their osteological remains, including the teeth. The plan succeeded admirably, and led to the most astounding discoveries by Cuvier. As was to be expected, it threw the Linnean method into the shade, and all but extinguished the reputation of the greatest naturalist of any age, the Count de Buffon. It led Cuvier imperceptibly, and seemingly without his being aware of it, to the adoption of some theories or hypotheses still maintained in England, but abandoned everywhere else. One of these was the attempt to prove distinct epochs of zoological formations, called in this country "creations," a word never used by Cuvier. As a strictly scientific man he strenuously opposed the philosophical ideas of Goethe and his school, declaring them to be pantheistic and not scientific; he denied an animal series, and refused to intercalate the extinct with the living world. Species he held to be unchangeable under every circumstance, and, drawing his proofs from monumental and written records, he showed that the living animal kingdom had remained unaltered since the earliest historic period. To man and to the now living world he ascribed a late origin, as compared with the fossil and extinct. Shortly before his death his theory of the fixity of species was called in question by Goethe and Geoffroy St. Hilaire; the animal serial was demonstrated by De Blainville, and the fossil intercalated with the living world; the metamorphosis of forms was proved, beyond all dispute, by embryogeny, and the philosophic and transcendental theories of Goethe came to be accepted for scientific truths, and embryonic forms were supposed to portray the extinct or fossil world. But even Cuvier himself was aware that anatomical characters could not in every instance characterise species, and he instanced the genus *Equus*, or natural family of the horse, whose species cannot be distinguished from each other by the anatomical method; he might have mentioned many others. How is it with the natural family of man—with mankind?

As most natural zoological families show affiliations with other families, and do not stand alone, it seems proper to inquire, in the first instance, into the relation of mankind with other kinds, that is, other families of animals. Notwithstanding a tolerably strong resemblance between man and the animals usually, but erroneously, as I think, called *Quadrumana*, or four-handed, there is a sharply-defined and deep gulf between these two great natural families. They differ remarkably in their external characters, and equally so in their osteological; and, although it be true that the brain in these two classes is almost identical in its forms, and that the retina in the apes of the old continent has the foramen of Soemmer-

ing, a structure, perhaps, peculiar to man, there is yet enough to show that it requires many natural families to bridge over the gulf which exists between them, or, in other words, to fill up the serial. Now, the researches of De Blainville lead us to conjecture, with every show of probability, that the wanting links will be supplied hereafter—(1.) By palæontological discoveries of animals lower than man, yet above the apes; or (2.) By the formation of other species in the course of time, when the existing order of things shall have passed away, following the fate of all its predecessors.

The determination of distinct species in mankind can be made only on the same principles we employ in determining species in other natural families. The characters are either external or anatomical. We have seen that the anatomical method failed in Cuvier's hands when applied to the natural family *Equus*, and De Blainville showed that it also failed in many other instances. Should it fail when applied to man, I shall not be in the least surprised; for, although it be certain, as I think, that the internal structures differ essentially in every species from all others, yet it is obvious that such differences are not sufficiently strong to be readily recognised, and, therefore, are of little value to the zoologist, and of no importance to mankind generally, who ever have, and ever must look to the exterior alone. Thus, Blumenbach was wrong, as I think, when he attached so much importance to the configuration of the human cranium, thus inducing many persons to suppose that a distinctness of species was only to be determined by constant specific differences in the form of that section of the skeleton. That such differences exist I believe; but even if they did not, this were no argument against the specific differences in the races of men, for it is to the external characters mainly that we must look for specific distinctions. Supposing the Jewish race to have become extinct, and no monumental or other artistic productions have recorded their physiognomy; who, from their osteological remains, could have described the race, or guessed at those physical and moral characteristics which distinguish them in so marked a manner from all other races?

The skeleton of the head, usually spoken of as the skull or cranium, encloses and protects the encephalon. It has relations externally with powerful muscles, and its inner table is in harmony with the external surface of the encephalon. The capacity of the cranium, properly so called, may generally be assumed to be the measure of the encephalon, to which, however, even in mammals, there is one exception—certain cetacea. Besides providing cavities for the protection of certain organs of sense, it articulates with the vertebral column, of which it seems but the continuation. Goethe first used the expression "cranial vertebræ," and its correctness is now all but universally admitted. Between its tables we find osseous cavities, with prolongations into them of the mucous membranes of the nose and pharynx; the uses of these sinuses are absolutely unknown. They are also wanting in the cetacea.

Now, when we look at the form of the skeleton of the head in the various races of men, it is easy to observe that they differ remarkably from each other, not so much in the capacity of the cranium as in the shape or configuration of the skull and face, and in the relations of the face to the cranium, differences still more remarkable during life. This difference in form was first observed by Hippocrates, and ascribed by him to artificial pressure of the head of the child, which practice being continued for some generations, the malformations, at last, became hereditary. But the artificially deformed feet of Chinese women have never become hereditary. So that the theory of Hippocrates seems, at least, extremely doubtful. Blumenbach himself doubted if these differences in the configuration of the human skull were constant; the candid Pritchard denied that they were, and he has been followed lately by others,—Williamson, Owen, etc. In respect of the capacity of the cranium, Dr. Tiedemann fancied that he had found in my own museum several crania of African negroes quite as large and as finely proportioned as the highest of the white races. Out of the exceptions he established a law, and in this he has been followed by others. But if such variations in form were frequent and permanent, the race would in a century or two become entirely altered: now this, we know, never has happened. Such varieties extend only to a generation or two, and then cease, the primordial forms returning—those forms, namely, which are in unison with nature's great scheme and with the existing order of things. Not that there is or can be any selection, as Mr. Darwin expresses it. Nature is not an intelligent being, and,

therefore, there can be no selection, properly speaking. Again, if varieties in any one race were numerous and frequently occurring, this circumstance surely ought to have told upon races favourably situated in other respects; yet, in so far as I can perceive, in examining the monumental records of Egypt, the Copt and negro have remained unaltered for at least 6000 years. The same law seems to hold good with other races so long as they do not abandon their aboriginal land. When this happens, they perish.

The exceptions so much dwelt on by Pritchard, Williamson, Owen, and others, have been greatly exaggerated. They have no influence over the exterior, and probably none over the intellectual qualities of the race; whilst against the hereditary extension of these varieties stands the physiological law of non-vitality and extinction. Many years ago I remarked that varieties in the distribution of the arteries, implying other varieties in structure, were much more common in the very young than in the adult, implying, as I thought, a want of vitality or of viability in these individuals. Thus, nature checks the extension of all important varieties in structure, the individuals being either non-viable or non-productive. This accidental approximation of the individuals of any race to another seems wholly to be without any real results, otherwise hybrids, amongst such, might be fertile. Now, as I asserted long ago, they never are; and, lately, M. Boudin placed before the scientific bodies of France incontrovertible proofs of the correctness of my views on this point.

A conformation of the osteological head distinct from all other races characterises the Australian and Tasmanian, the Esquimaux, the Bosjesman, the Kaffir, the negro, the pure Mongol, the Carib, the Peruvian: all these races have race characters more or less marked, and not to be observed in other races. That these races may be converted by education into white men is, I fear, an entire delusion.

The situation of the foramen magnum of the occipital bone is still a matter of dispute. Dr. Pritchard thought it to be "the same in the negro as in the European"; and so it may be, if no allowance be made for the face. The situation of the foramen magnum of the occipital bone is not the same in the negro as in the European. Dr. Pritchard says it is exactly behind the transverse lines, bisecting the antero-posterior diameter of the base of the cranium. Supposing this measurement to be correct, which it is not, it has nothing to do with the *pose* or position of the head upon the vertebral column, which, all must know, depends on the position of the condyles of the occipital bone. A line bisecting the antero-posterior diameter of the skull, and dividing it into two equal parts, passes in the European head through the centre of the condyles of the occipital bone; and the same measurement applies nearly to the antero-posterior diameter of the entire head. Not so in the coloured races. In speaking of the base of the cranium, I am not quite sure to which Pritchard and his followers allude; for very generally in anatomical works the base of the skull, including the upper jaw, is confounded with the true base of the skull.

Now, as regards other measurements. The diameter of the cranium, measured with callipers, between the fronto-parietal sutures and midway between the vertex and the base of the skull, will be found, on an average, to be less by nearly an inch in the dark races than it is in the European. This seems to me an extraordinary difference in the capacity of that portion of the brain which all fancy to be the region of the higher intellectual qualities—of calculation, of comparison, and of reflection.

It is admitted by Mr. Williamson, that in the German the frontal diameter was 5 inches; in the French, Spanish, and English, 4.5; in the dark races as low as 3.6 and 3.7. This is all I contend for. The measurements of the occipito-frontal arch, inter-mastoid, etc., are of no value. The length of the head and face (skeleton of the head) is a true natural motory character, and strongly characterises the fair from the dark races; but the mingling up the two segments of the head leads to confusion and to erroneous inferences. The cranium being divided into two parts by a line (which I presume was perpendicular) drawn from the anterior edge of the foramen magnum occipitale to the centre of ossification of the parietal bones, so as to divide the interior into two chambers, an anterior and a posterior, the respective capacities of these chambers were next ascertained. The results gave,—

*Anterior Chamber.*

German . . . . .	51
English . . . . .	43

Esquimaux . . . . .	40
American Indian . . . . .	32
Tasmanian . . . . .	32

The numbers speak for themselves.

The remark, that in some crania the ring of the sphenoid does not reach the parietal on one side, was first made by me. I do not attach much importance to it, excepting as tending to illustrate the history of retrogressive development.

Mr. Williamson remarks "that the position of the foramen magnum occipitale was found to be exactly behind the transverse lines bisecting the antero-posterior diameter of the base of the cranium, which is the position in European skulls. The situation of the foramen magnum is, therefore, the same in negro as in European skulls."—Page 24.

But these measurements, admitting them to be correct, which they are not, does not touch the real question at issue, which is the position of the negro head on the vertebral column, as compared with that of the European. Had the measurements been made through the centres of the condyles of the occipital bone, the results would have been very different.

In a report on a collection of skulls of various tribes of men inhabiting Nepâl, collected and presented to the British Museum by Mr. Hodgson, late resident in Nepal, Mr. Owen expresses an opinion "that it is only with regard to the Australian and Tasmanian aborigines that he could feel any confidence in detecting the distinctive characters of a race; that, in fact, negro-shaped skulls occur amongst all races; that the white races have no advantage in this respect over the dark-coloured races."

Now, German and Russian travellers have made similar remarks in respect of the inhabitants of the Caucasus; and I was informed by my esteemed friend, Dr. John Sutherland (of the War Office), that whilst travelling in the Tyrol he found numerous specimens of those models of beauty whose portraits have been placed on canvas by the early Italian painters—women with beautiful oval Greek face and head, combined with fair hair and blue eyes—figures, in short, not to be seen in any Italian race. In troublesome times, nations and races, out of which nations are formed, flee to the mountains, where their descendants long find protection. The country of Nepal describes in some respects the regions to which I have alluded.

Nepâl is in a long and narrow tract of land, bounded to the north by the great mountain-wall of the Himalayas, separating it from Thibet; to the south, extending into the plains, bounded there by Delhi, Oude, Bengal, etc., and extending to the Chinese frontier. Situated between 27° and 31° north lat., it is extremely varied in climate, and presents numerous narrow valleys of great altitude. It has been long known that the numerous valleys are inhabited by a variety of mixed races, which cannot be traced to their origin. The aborigines were probably Tartars or Chinese; they were invaded by the Hindoos about, probably, the fourteenth century; then came the Mohammedan sovereigns of Delhi; the inhabitants fled to the mountains.

All this has been carefully described by Dr. Latham in his admirable work on "Descriptive Ethnology." A small population thus tossed between two, or rather three, overpowering foreign empires, cannot be expected to show the characteristic forms of a purely primitive aboriginal race. In addition to these circumstances connected with Hindoo, Mongol, Chinese, and Arab conquests, must also be taken into account the peculiar social habits of the Nairs—habits the reverse of those of the western world, and of all other races known to me.

#### ON THE DEFORMATIONS OF THE HUMAN CRANIUM, SUPPOSED TO BE PRODUCED BY MECHANICAL MEANS.

History informs us that in very ancient times a belief prevailed that, by mechanical means applied to the head of the infant, another form might be given to it than that intended by nature. Hippocrates was the first, I believe, who mentions the circumstance, ascribing the practice to certain people who resided near the shores of the Euxine. Like a true professor of the conjectural art, he added theory to the fact (if it really was one), that at first the deformity produced by art required to be practised on each individual child; but that afterwards, the deformity having become hereditary, the mechanical means were no longer required. It is needless for me to remark that artificial deformations never become hereditary, and, therefore, the theory

of Hippocrates falls to the ground. But the facts still remain, that is, admitting them to be facts, for there are two, not one. The first is, did there live by the shores of the Euxine a race of men with deformed heads (the Macrocephali)? Secondly, were these deformations produced by mechanical means, or were they mere exaggerations of a peculiarly-shaped skull, to which mechanical pressure might give a more distinctly marked character? I lean to the opinion that such a race existed, more especially since crania have been found near Kertch, in the Crimea, presenting well-marked deformations. So far as I can learn from the reports, they were a flat-headed race, with depressed foreheads and skulls, which bulged out tolerably, and in this resembled the Chenooks and Caribs of modern times. What gives a peculiar interest to the remarks of Hippocrates, and to the discovery of deformed crania at Kertch, is the finding similar crania in Germany associated with palæontological remains of great antiquity. Thus, a flat-headed race seems to have extended in ancient times from the shores of the Euxine, probably not a sea at that time, to the centre of Europe, coeval with races of animals which are now extinct, like the flat-headed race of men themselves. With the area or centre of their creation, the Fauna and Flora of the region have disappeared, and new forms of life, including new races of men, have taken their place; not new creations, but new forms of men and animals adapted to, viable and reproductive in, the media surrounding them. Perhaps the most remarkable of these deformed, flat-headed crania was found in a cave at Engis, near Luthik, in Germany, and geologists do not hesitate to ascribe to it an antiquity equal, at least, to the extinct fossils of the formation. Another cranium was found at Neanderthal, between Düsseldorf and Elberfeld, perhaps quite as old as that from the cave of Engis. I do not think them much more deformed than some crania I have seen picked up on the shores of desert islands in the Pacific ocean, one of which was in my own museum. They have a certain resemblance to the chimpanzee, but not to the gorilla. It is stated also that the limb bones are thicker and broader than those of the present races of men, implying that they retained to their adult condition certain foetal peculiarities. These facts rest on the authority of Professor Schaaffhausen, of Bonn, and may, no doubt, be entirely depended on. A race of men coeval with that period, having round crania resembling those of the present Lapps, but with a prominent ridge over the eyes, has been described by Lartet; and Danish naturalists speak of a race of Molluscophagi; but I have not seen their observations nor Mr. Lubbock's memoir. They do not, however, belong to the class of deformed skulls, whether by mechanical means or otherwise.

In other regions we find deformed crania, showing that such were by no means confined to the regions I speak of. The Chenook skull has been often described; also the Carib. These are skulls which seem as if they were flattened from before backwards; such also was the case with the Aztec. In his remarks upon the deformed crania of Central America, Mexico, and Peru, M. d'Orbigny has the following observations:—"No head is to be found amongst the present Aynaras. They have the same form of head as the Quichuas, comparable to the flattened skulls of their ancestors seen in tombs in the lake of Titicaca, in those of the province of Muñecos, in the wildest part of Carangas, and in the valleys of Jucua. What proves, if any proof were wanting, that this deformity is owing to a mechanical process, and is not a part of the natural structure of the race, is the fact, that in the same tombs, together with the depressed skulls, others are found of a very different shape."—P. 470, "Pritchard." In this conclusion I do not agree; the fact merely shows that two distinct races occupied the same country. On the other hand, the Peruvian skulls I have examined in this country seem to me to present a quite different deformity than that now spoken of. It consists in a highly irregular-shaped cranium combined with a remarkable want of symmetry, and this extends to and includes the bones of the face. I have observed this to be all but constantly present in Peruvian skulls, whether ancient or modern. Could we accept in *totalité* the views of the excellent Prescott on the civilisation of the ancient Peruvians and Mexicans, we should feel inclined to arrive at the conclusion, that the shape of the cranium, and, by inference, of the brain, has no influence over human civilisation; but against this view there exists a mass of evidence which cannot be readily set aside, even admitting the view I adopt to be the correct one, namely, that all or most races are quite equal to the invention of all the

social arts, which, originating in necessity, clearly follow the exigencies of each race. But such inventions are no proofs of the capability of the race for that high civilisation which embraces not only the social but the emulative or fine arts, including an ennobled literature, profound science, and abstract philosophy, as was first distinctly placed before mankind by the antique Greeks.

The questions discussed in this memoir naturally lead to others, such as the origin of species, the antiquity of man on the earth, and the development of all living forms from a primitive, original, living molecule—in a word, to the philosophy of zoology, or the system of nature. Prior to Cuvier's great discovery no true philosophy of zoology could ever be imagined; the system most in vogue at present was invented by Goethe; it belongs wholly to him, and probably could not have originated with any other race than that to which he belonged—the race which produced Leibnitz and Kant, Gall and Wolff, Niebuhr and Schelling. Translated into English it has assumed a very plain and practical character, and has even been mistaken for science. But philosophical speculation is not science, nor did Goethe ever mistake the one for the other.

## REPORTS OF HOSPITAL PRACTICE

### IN MEDICINE AND SURGERY.

#### SAMARITAN HOSPITAL.

#### FIVE CASES OF OVARIOTOMY—ALL SUCCESSFUL —CLINICAL REMARKS.

(Under the care of Mr. SPENCER WELLS.)

[From notes by Mr. E. PARSON, House-Surgeon.]

IN our Number for December 20, 1862, we related four cases of ovarian disease treated in the Samaritan Hospital, and we stated that Mr. Wells had since operated in two other cases, which would appear in a future report. We now publish this report, and add a short account of three other cases, from the notes of Mr. Parson, with some remarks made at the bedside by Mr. Spencer Wells.

#### Case 1.—Multilocular Ovarian Tumour—Two Tappings— Ovariectomy—Recovery.

A. D., married, aged 50, was sent to Mr. Wells by Dr. Woodhouse, of Hertford, and first admitted on March 13, 1862. A multilocular ovarian cyst occupied the abdomen, the girth of which at the umbilicus was forty-one inches. The uterus was pushed over to the left side by a portion of tumour in the pelvis, and was not movable. She was tapped on March 18, and twenty pints of fluid containing much cholesterine were removed. Groups of secondary cysts were felt to be movable beneath the abdominal walls after the tapping, but the uterus was still drawn up and pushed over to the left side. She was discharged on March 26. The cyst refilled. She was re-admitted on June 23, tapped again, and discharged on the 28th. She filled more slowly, improved in health, and was admitted for the third time October 13, 1862. Great doubt was felt as to the closeness of the connexion with the uterus, and it was decided to make an exploratory incision, and to be guided by the result. The operation was performed on November 17, 1862. Dr. Greenhalgh administered chloroform. Dr. Robert Lee and many other visitors were present. Mr. Wells commenced by an incision, between four and five inches long, midway between the umbilicus and symphysis pubis. The abdominal wall was very thin, and the cyst being covered by a little ascitic fluid was easily exposed. Some slight parietal adhesions were broken down. A large cyst was tapped, and about twenty pints of fluid withdrawn from it. Finding that the pelvic connexions were not intimate, Mr. Wells separated a very strong adhesion between the upper part of the cyst and the thickened suspensory ligament of the liver. He then opened the large cyst, passed his hand into it, and broke down several inner cysts; the outer one being withdrawn, and the abdominal walls being kept so pressed against it that no ovarian fluid could pass into the peritoneal cavity. After separating a small piece of omentum, the tumour was entirely withdrawn, and the pedicle, which was moderately large, was secured by a clamp. A little serum was sponged from the pelvic cavity. The right ovary

was healthy. The wound was closed by four deep and several superficial silk sutures.

She soon rallied, never vomited, had two opiate enemata during the evening on account of pain, and for two or three days was troubled by cough, but she made an excellent recovery, and was discharged in good health on December 10. Dr. Woodhouse wrote, on February 21, "She continues quite well."

#### Case 2.—Ovariectomy—Pulmonary Congestion—Venesection— Recovery.

E. W., single, aged 17 years and 2 months, admitted November 13, 1862, with a very large ovarian tumour, dating only from the previous May. She had never been tapped, and was much emaciated. The ensiform cartilage was pushed forward by the tumour, which filled the whole abdomen, the girth being thirty-nine inches. The uterus was far back, but movable; and a portion of the tumour could be felt between the uterus and bladder, but above the brim of the pelvis, and apparently movable.

Ovariectomy was performed on November 26. Mr. Clover gave chloroform. Dr. Kumar, of Vienna, Dr. Burckhardt, of Berlin, and other visitors, were present. An incision was made from two inches below the umbilicus for four inches directly downwards. The cyst adhered closely all over the abdominal wall anteriorly. Mr. Wells separated it as far as his finger would reach, tapped, and emptied the cyst. He then introduced his hand, and separated some very firm adhesions around the suspensory ligament of the liver and in the right iliac fossa. As the cyst was withdrawn, a large piece of omentum was separated from the upper part and kept outside. The pedicle was secured by a clamp, and the cyst cut away. As the omentum did not appear to be healthy, and was much torn, Mr. Wells cut away a large piece and tied four vessels, which bled freely, with very fine silk, cutting off the ends close, and then returning the omentum. The wound was closed as usual.

She soon rallied and began to perspire; she complained of no pain, but the pulse was 130 at 6 p.m., and 145 at 10 p.m. There was a very troublesome suffocative cough, but no pain. Some four to six ounces of blood had oozed from the surface of the pedicle, which did not seem to be perfectly compressed by the clamp, the cough having disturbed it. Mr. Wells cut away some of the stump to find the bleeding vessel, which he tied, and applied perchloride of iron to the rest of the surface. The loss of blood appeared to relieve the chest, and the pulse, though so rapid, was not feeble. She passed a pretty good night, though the cough was very troublesome at times. The next morning the pulse was 150, not weak. Scarcely any respiratory murmur could be heard in either lung, and the action of the heart was very tumultuous. Perspiration was free, and secretion of clear urine abundant. Some abdominal pain began in the forenoon, and twenty drops of laudanum were thrown into the rectum, after which she slept. During the afternoon the pulse kept up to 150, and at 6 p.m. had reached 160. The lips were parched, and the skin was hot and dry, with occasional suffocative cough. Mr. Wells accordingly opened a vein in the arm, and drew off ten ounces of blood rapidly, stopping as soon as she felt faint. She fell asleep at once, a very profuse perspiration broke out, and within ten minutes the pulse was down to 140. The blood was very much cupped, but the coat of fibrin was not thick.

The pulse gradually fell during the next day from 140 to 130. A little champagne was given occasionally, five grains of carbonate of ammonia every two hours, and the air about the bed was ozonized by iodine; a few grains being placed in chip boxes, the lids of which were replaced by a piece of muslin.

After this, recovery was progressive. There was no abdominal pain whatever. She was discharged December 20, 1860, and has called at the Hospital since in very good health.

#### Case 3.—Ovariectomy—Albuminuria—Recovery.

E. B., married, aged 42, was admitted December 12, 1862, with a large multilocular cyst of the left ovary, which had probably existed for several years, but had only increased rapidly since the preceding January. The girth at the umbilicus was forty-three inches, and the distance from symphysis pubis to ensiform cartilage twenty inches. The uterus was large and soft, but quite movable. The left broad ligament was depressed. She had never been tapped.

Albumen was found in the urine, and this proved not to be due to admixture with vaginal discharge, because, after filtration, it was found in the clear urine, and in urine drawn off by the catheter. But as the deposit consisted almost entirely of urates, and no casts, blood, pus, or any other sign of kidney disease, could be detected, it was considered that the albumen must be due to pressure only, and was no objection to operation. It appeared, also, that the urine passed in the morning was copious, clear, and free from albumen; while towards night it became scanty, concentrated, and albuminous.

Ovariectomy was performed on December 15. Mr. Clover gave chloroform; Dr. Acland, Mr. Partridge, Mr. S. Haden, etc., were present. An incision, four inches long, was made downwards from two inches below the umbilicus. The adhesions were so close that it was not easy to make out the exact limits of the cystic and parietal layers of peritoneum. But Mr. Wells did so after a little careful examination, and separated some firm adhesions as far as one finger would reach. He then tapped, and removed a pailful of dark fluid, which contained many lumps of fatty fibrinous matter, which became solid on cooling. The lower part of the cyst was then easily withdrawn, but the upper part was held by a piece of adhering omentum, about six inches square, which was separated, and then by a very firm band of adhesion, which extended above and to the right of the umbilicus. This was separated, a long, very narrow pedicle secured by a clamp, and the cyst cut away. One bleeding vessel in the omentum was stopped by torsion. There was rather free oozing of blood from torn adhesions, but no vessel seemed to require a ligature. On examining the right ovary, Mr. Wells found one small cyst on its surface, which burst on pressure, and one distended Graafian vesicle, out of which he squeezed a clot, but, as the ovary seemed to be atrophied, he did not remove it. The wound was closed by deep and superficial silk sutures.

She rallied well, and had a good night; no opium was given, as there was no pain. On the first and second days after operation there was occasional vomiting of watery fluid with greenish mucus, and on the third day there was some sanguineous discharge from the uterus, which was followed by relief. She gradually regained strength, was discharged in good health January 7, and Dr. Acland wrote, on February 20, to say that she was perfectly well.

*Case 4.—Multilocular Ovarian Cyst—Seventy-two Pints of Fluid removed by Tapping—Ovariectomy—Recovery.*

J. W., married, aged 32, admitted December 20, 1862, with a very large ovarian cyst, dating from the birth of her third child, six years before. Increase in size was slow for the first four years, but more rapid during the last two years. She had been subject to prolapsus uteri before the confinement, and it became more complete afterwards, being at the time of admission irreducible, and complicated by vaginal cystocele and rectocele. She had been greatly distressed by the abdominal distension, and had kept her bed for six months before admission. The catamenia had been regular as to time and quantity ever since the birth of the last child. The annexed cut, from a photograph by Dr. Wright, gives a good idea of the size of the abdomen. The girth at the umbilicus was fifty-four inches, and the distance from ensiform cartilage to symphysis pubis thirty-six inches; while from one anterior-superior spinous process of the ilium to the other it was forty inches. Mr. Wells tapped her on December 30, and removed seventy-two pints of clear, highly albuminous fluid. A movable, multilocular cyst remained. The uterus was then easily returned. She was feeble for a few days after the tapping, and the fluid began to reform rapidly, but she soon regained strength. On the 18th of January the measurements were—girth, thirty-five inches, instead of fifty-four; perpendicular, seventeen inches, in place of thirty-six; and anterior, seventeen inches, in place of forty.

Ovariectomy was performed on January 19. Mr. Clover gave chloroform. Dr. Marion Sims, of New York, Mr. Macilwain, etc., were present. Owing to the extreme looseness of the folds of skin, Mr. Wells made the first incision by transfixing a fold of skin, thus making an opening, six inches long, down from one inch below the umbilicus. The peritoneum was opened, as usual, on a director. Some loose, but extensive, adhesions were separated by the hand. The chief sac was tapped, emptied, and withdrawn; but a mass of

secondary cysts, as large as a child's head, made it necessary to enlarge the incision. The whole was then easily withdrawn, a short pedicle secured by a clamp, and the wound closed as usual.

She only required one opiate, and went on well from the first. The only peculiarity in the progress after operation was a sort of projection or hernia of the pedicle below the clamp, which went on increasing after the clamp was removed, the prolapsed portion becoming œdematous. Mr. Wells removed this on the seventh day, after transfixing it, and tying it in two halves at the level of the skin. The ligature and slough came away five days afterwards, and she was discharged, in excellent health, on February 17. The union of the pedicle with the abdominal wound acted as a very effectual safeguard against prolapsus of the uterus.

*Case 5.—Ovarian Cyst—Sixty-nine Pints of Fluid Removed by Tapping—Ovariectomy—Recovery.*

M. W., married, aged 56, admitted January 17, 1863, having been sent to Mr. Wells by Dr. Williams, of Rugeley, as a fit case for ovariectomy. She had only been married four years, and had noticed an abdominal swelling on the right side about a year before marriage. The swelling increased, and she was tapped in July, 1861, sixty-four pints of fluid being removed. She was not tapped again for eleven months, namely, June, 1862, when seventy-two pints were removed. She was very low for a time after each tapping, and soon began to fill again. On admission, the girth at umbilicus was fifty-seven and a-half inches; ensiform cartilage to umbilicus, fourteen and a-half inches; umbilicus to symphysis pubis, twenty-nine and a-half inches; right anterior-superior spine of ileum to umbilicus, nineteen and a-half inches; left, an inch less. She was tapped, and sixty-nine pints of fluid were removed; the girth being lessened from fifty-seven inches to thirty-four, and the distance between sternum and pubis from forty-four to fourteen. The skin fell into loose folds, and the oblique muscles, hypertrophied by carrying so much weight, were felt as thick bands on either side. No secondary cysts could be felt.

It was not till a considerable quantity of fluid had re-collected that it was possible to say whether there was an ovarian cyst or not; but at length there was very marked dullness in the right loin, and equally well-marked resonance in the left, which led Mr. Wells to the diagnosis of a tumour of the right ovary.

Ovariectomy was performed on February 9, 1863. Mr. Parson administered chloroform. Drs. Williams, of Rugeley; Duke, of Chichester; Hoffmann, of Margate, &c., were present. An incision, four inches long, was made midway between the umbilicus and symphysis pubis. Extensive and rather firm parietal adhesions were broken down, the cyst

tapped, emptied, and withdrawn, the pedicle secured by a clamp, the cyst cut away, the left ovary found to be healthy, and the wound closed by deep and superficial silk sutures, after tying three superficial vessels divided in the first incision.

She rallied well, had two opiate enemata during the evening on account of pain, and for three days was troubled by cough and viscid expectoration. The bowels acted on the fifth day after an enema. From this time she went on perfectly well, only complaining of occasional flatulence, and returned home on the 7th of March.

Mr. Wells made some remarks at the bedside upon these cases, enlarging especially upon the diagnosis between ascites, ovarian dropsy, and ascitic fluid surrounding an ovarian or uterine tumour; but these we must postpone until we are able to publish the particulars of a very interesting case upon which he operated on February 23, removing a large quantity of ascitic fluid which surrounded a small adenoid tumour of the right ovary, deferring the removal of the tumour. The patient has gone on remarkably well hitherto, and is watched with much interest. Mr. Wells said that, in the fourth and fifth cases reported above, he had adopted the practice of tapping two or three weeks before doing ovariectomy. He had some doubts as to the wisdom of the practice, but it had answered well in these cases. In both, the distension was very great; and he feared that the sudden removal of so much fluid at the same time as the cyst would be too much for the patient. The tapping was also useful in clearing up doubtful points of diagnosis. The obvious objection was the danger of the tapping itself being followed by changes which would preclude ovariectomy. He also entered at some length into the question of venesection after Surgical operations, explaining that, in the second case recorded above, he bled in order to afford mechanical relief to the oppressed heart. With a super-fibrinated condition of the blood, there was great danger, especially after bleeding, of fibrinous clots forming in the cavities of a weakened heart. Champagne was accordingly given after the bleeding, and ammonia—the normal solvent of fibrine—to assist in maintaining the force of the heart and the fluidity of the blood. Dr. Richardson's suggestion of iodising, or ozonising the air—by the simple means we have described—has been adopted by Mr. Wells in many cases very successfully. The relief to cough is often remarkable, and the deodorising effect of the iodine vapour is immediate.

### MIDDLESEX HOSPITAL.

#### MULTILOCULAR OVARIAN TUMOUR OF TWO YEARS' DURATION—OVIOTOMY—RECOVERY.

(Under the care of Dr. PRIESTLEY and Mr. DE MORGAN.)

THE following two cases are reported by Mr. Langford, Obstetric Assistant:—

C. C., aged 46, admitted September 23, 1862. She is tall and well developed; complexion sallow. Has been a washer-woman for the last eighteen years. Was married at 18, and had one child, which died three weeks after birth. She thinks she was injured during the birth of this child, as she did not get about for six months afterwards. Since then the catamenia have always been regular. About two years ago she felt a pain in the left iliac region, and discovered there a small movable tumour, which gradually enlarged. She avers that the suffering and discomfort constantly increase, and that now she is seldom if ever entirely free from pain. Her nights are frequently restless, and her capacity for exertion gradually diminishes.

On admission, a large ovarian tumour, believed to be of the multilocular form, was found occupying the abdomen, and reaching almost to the epigastrium. Its outline was somewhat irregular; and although mobility was rendered difficult by its size and the distension of the abdomen, it gravitated readily towards either side when the patient was placed in one or other lateral position. There was no evidence of pelvic adhesions.

The circumference on October 18 was forty inches and a-half, and it steadily but slowly increased.

The operation was performed on October 28 by Mr. De Morgan, in a small ward in which she was to remain, and from which the other patients had been removed. The ward was warmed up to 70°, and the atmosphere kept moist with steam. Chloroform was used. She inhaled it quietly; but

as soon as the first incision was made, violent straining, like efforts to vomit, came on, and recurred frequently during the operation so as to retard it in some degree. The straining usually ceased when she was brought more completely under the influence of the chloroform. An incision of four inches in length, and commencing about an inch below the umbilicus, was made through the skin, tendon, and fascia, when the peritoneum was protruded under the straining efforts by fluid contained in its sac. There was no bleeding. The peritoneum was then opened, and a large quantity of dark coloured ascitic fluid allowed to escape. On introducing the hand no adhesions could be found. The tumour was now tapped with Mr. Spencer Wells' double canula trocar; but only about an ounce of thick curdy stuff escaped. The trocar was then pushed through a deeper cyst-wall; but with no result. As the tumour was not diminished in size by these punctures, and was too large to pass, the incision was enlarged to about an inch above the umbilicus, and the tumour was partly drawn, partly forced by the straining, through the opening, a portion of the bowels being at the same time protruded. This was at once covered with hot flannels. There was no adhesion. The pedicle was short, but not very thick. As the bulk of the tumour and the shortness of the pedicle did not allow their point of connexion to be seen, and some loops of intestine were protruded in the neighbourhood, an attempt was made to lessen the size of the cyst by making a free incision through it; but it was found to be made up of clusters of small cysts, from which very little fluid escaped, and no diminution of size ensued. The clamp was therefore very carefully applied to ensure the absence of any part of the gut, and the tumour was cut away. There was not any hæmorrhage into the peritoneal cavity, nor any escape of the contents of the cysts into it. Some of the peritoneal fluid was removed by means of sponges; but some remained behind. The opposite ovary (the left) was found to be quite healthy, as was also the uterus. The edges of the wound were brought together by silver sutures placed about half an inch from one another, and included half an inch of peritoneum on each side, the pedicle held by the clamp being left outside the wound. When the patient was cleaned and dried, a large casing of doeskin, spread with soap plaster, which extended from the middle of the chest to the hips, was placed beneath her. This case came up on either side so far as to leave about six inches of the front of the abdomen exposed. Bands of broad elastic were fastened to one edge, and buckles to the opposite edge, so that an elastic support could be maintained and regulated over any part of the abdomen. A large linseed-meal poultice, covered with cotton-wool, was applied over the whole abdomen, and the straps buckled over it. She was then placed in bed, and wrapped in blankets. The temperature of the room was maintained to about 65°. The pulse, after the operation, was 100 to 104, irregular, small, and weak; but it soon gained more power, and became fuller. Three hours afterwards she complained of great pain throughout the abdomen; the pulse 96, small and irregular. She was ordered ten grains of compound soap pill.

She passed a good night, and was free from pain next day. She took arrowroot and milk-and-water during the night, and was free from sickness, though complaining sometimes of nausea. In the evening she again had pain, which was relieved by opium. On the whole, she had a quiet night, though not without occasional pain from flatulence.

The clamp was removed on the next day, forty-eight hours after the operation, and the stump was washed with a solution of carbolic acid. The wound was quite quiet, and appeared to have united throughout the deeper part. She was now taking a little wine-and-water.

November 1.—The bowels not having been relieved since the operation, and great griping pain being complained of, she had an enema of castor oil and turpentine, and turpentine fomentations were applied over the abdomen. No evacuation followed the enema. At night the pain was severe, and there was fulness and marked tenderness over the left iliac region. She was ordered a grain of calomel and a quarter of a grain of opium every four hours.

On the 2nd, she was much easier; but the pulse was 112, and sharp. Half an ounce of castor oil was given, which towards evening caused a free action from the bowels twice with great relief.

The calomel was discontinued on the following day, as all the symptoms were so much more favourable. She went on in this way, occasionally suffering much from wind, which

was generally relieved by opium, chloric ether, and sal volatile, with turpentine fomentations. There was always, however, some tenderness in the old situation, which on the 18th was so much more severe that she was again put on calomel and opium.

Dr. Priestley now made a vaginal examination, and found a decided fulness in the left broad ligament and iliac fossa, and the posterior surface of the uterus was fixed by inflammatory adhesions, so as to interfere with its mobility.

The calomel and opium were continued till the 24th, the tenderness and fulness diminishing day by day. At this time the gums were very slightly affected. From this period she went on improving, and soon began to sit up and to move about. At first she was very weak; but she gained strength steadily, and left the Hospital on December 16. The wound was perfectly cicatrized, and measured only four inches and a-half. The tumour weighed ten pounds, and was made up of one large and pretty solid cyst, and a number of small ones.

#### CASE OF OVARIOTOMY—DEATH—AUTOPSY.

(Under the care of Dr. PRIESTLEY and Mr. HULKE.)

A country woman, aged 56, was admitted into Prudhoe Ward October 21, 1862, with a large abdominal tumour. The distended belly had a globular shape. Its greatest girth at the navel was forty-two inches. The hypogastric, the iliac, the umbilical region, as high as a horizontal line three fingers' breadth above the navel, and the neighbouring portion of the lumbar regions were dull, whilst the epigastrium, the hypochondria, and lumbar regions behind were resonant on percussion. For a limited space around the navel there was fluctuation, so distinct that the wave was apparent to the eye, and throughout this area, on making sudden and firm pressure with the finger, a solid or very firm resistance was encountered at a certain depth, after the displacement of an overlying stratum of fluid. Below this, about the middle line, in the lower part of the umbilical and upper part of the hypogastric region the tumour felt solid and bossy. On applying the flat hand firmly to the flanks, fluctuation was obscurely felt across through the tumour, across the belly. The liver, not enlarged, was thrust upwards by the tumour, from which it was separated by a resonant space. The abdominal walls could be slid freely upon the surface of the tumour without creaking, and the tumour itself could be readily swayed about. The uterus was movable, independently of the tumour.

The patient stated, that, with the exception of two attacks of jaundice, the second thirteen years ago, she had enjoyed good health, so that till her present illness she had earned her living by hop-picking and field labour. She had had two children, and continued to menstruate regularly until her fifty-third year. Soon after the cessation of the menstruation she became aware of the tumour in the lower part of the belly, about the size of a teacup, but she could not say whether it lay at first more on one side than the other. It increased in spite of treatment, and had latterly caused her much distress by its weight and bulk, and constant pain. Her health was evidently fast failing; she had a worn, anxious expression, and rather sallow complexion; the pulse was irregular, and the lower extremities, and also the pubic and inguinal regions, were œdematous. The heart sounds were normal; the urine free from albumen, its specific gravity 1010.

*Diagnosis.*—An ovarian tumour, probably multilocular, and in great part very firm or solid, and the solid portion chiefly in front in the lower part of the umbilical and upper part of the hypogastric region; probably no adhesion, or but slight ones; the fluid around the navel probably contained in a thin superficial cyst, overlying the more solid mass of the tumour, its restriction to the highest part of the belly, and its absence from the flanks behind, shown by their resonance, being against the supposition of ascites.

As the usefulness of tapping was excluded by the apparent solidity of a great part of the mass, and it was evident that the tumour would before long destroy life, the applicability of ovariotomy was considered by the staff and confirmed.

The œdema of the extremities appearing to be mechanically produced by the tumour, was not considered a contra-indication. The patient was very desirous for the operation, and clearly understood her risk.

December 2, at 2 o'clock p.m., the operation was performed in the ward in a moist atmosphere, at a temperature from 65 to 70. A cut in the middle line, began just below the navel, was carried downwards for nearly four inches, towards the

pubes. On dividing the peritoneum, several translucent, yellowish vesicles bulged through the wound. These so closely resembled the small pendulous secondary cysts sometimes seen within the larger cysts, that for the moment it seemed as if the ovarian tumour had been inadvertently opened; they were, however, only the thinned omentum pushed outwards by ascitic serum, and on throwing them aside the white, glistening ovarian tumour came into view. At the lower angle of the incision a thick vertical fold of peritoneum passing between the ovarian tumour, and the abdominal wall, slightly to the left of the mesial line, came into view. By prolonging the incision downwards this fold was found to reach the back of the pubes, and end near the summit of the bladder; it was so strong that it could not be torn through. The tumour was soon tapped, and ten pints of a chocolate-coloured fluid drawn off; particular care was taken to prevent any of this getting into the peritoneum, and as it flowed off, the tumour, a unilocular cyst, was pulled out through the wound; the pedicle, long, and not very thick, was clamped and divided; and, lastly, the thick peritoneal fold was detached from the cyst with some trouble, on account of its great strength; it bled so freely from so many points that it appeared more safe to put a second clamp on this than to tie each vessel separately. The wound was closed with interrupted wire stitches, the peritoneum being included.

At 8 o'clock p.m., pulse 76, firm; patient restless; pain in right flank eased by pressure. Orderd tinct. opii. mxxx., followed by sleep till 2 p.m., when sick.

December 3, 8 a.m.—Pulse 76; sickness continues. Tongue moist and clean; less pain in flank; none about the wound; no tenderness on pressure. 2 p.m., pulse 68; more pain in flank, relieved by a turpentine stupe; less sickness. 10 o'clock p.m., belly rather swollen with flatus, but not tender, except over transverse colon.

4th, 9 a.m.—Less restless night; pulse 100; thirst; belly less swollen; wound looks well; tenderness still in situation of transverse colon; less sick. Her strength is failing. Champagne ʒjss. every two hours. A rigor this morning; passed a small hard stool; the clamps were removed. 12 o'clock.—Pulse 100; panting, pain, and tenderness in epigastrium; sickness worse. 10 o'clock p.m.—Pulse 116; restless; features pinched; free from all pain; hiccough.

5th, 2 a.m.—Vomited two lumbrici. 7 a.m.—Great restlessness; death.

*Post-mortem Examination.*—The abdominal cavity contained about two pints of turbid serum; the intestines and omentum were glued together with recently effused lymph. The capsules of the liver and spleen presented smooth white patches of tough fibroid tissue, sequela of former inflammation; and in the interior of the latter organ, near the hilum there was a pultaceous deposit enclosed by condensed tissue. There was an entire absence of extravasated blood. The greater part of the wound had united; the pedicle was glued to its lower angle; the fallopian tube had not been included in the clamp; the sub-peritoneal cellular tissue at the fundus of the uterus was hyperæmic and œdematous. Death was evidently due to peritonitis; and this seemed to have its focus about the lower end of the incision, where the two clamps had been lying, and to have thence extended to the viscera.

#### KING'S COLLEGE HOSPITAL.

#### SUCCESSFUL CASE OF OVARIOTOMY.

(Under the care of Mr. FERGUSSON.)

[Reported by Mr. SMITH, House-Surgeon.]

EMMA R., aged 26, single, a pale, delicate, but not unhealthy-looking woman, was admitted into King's College Hospital, under Mr. Fergusson, February 2, for ovarian dropsy.

*History.*—About four years ago she noticed a slight swelling in the abdomen, which rapidly increased, but without much pain. For this she applied to a medical man at Scarborough, who tapped her, but she does not know how much fluid was drawn off. The swelling quickly returned, and the operation was repeated five times. When last tapped, January 20, 1863, seven gallons of fluid were drawn off. She began to menstruate when between 15 and 16 years of age, and has continued to be regular until lately, when she has menstruated at varying intervals; during the last month she has menstruated twice.

There is, upon examination, a large swelling in the abdo-

men, extending from the pubes to the sternum, and bulging a little at the flanks; the tumour, she says, has rapidly increased since she was last tapped. No solid matter can be felt, and the cyst was thought by Mr. Fergusson to be unilocular. The circumference of the body was forty-eight inches. On February 13, Dr. Tanner saw the patient, and considered, with Mr. Fergusson, that it was a fit case for ovariectomy. The dangers of the operation were fully explained to the patient before she left the country, but she was most anxious to have the tumour removed.

*Operation.*—February 21.—The patient was brought into the theatre and put under chloroform. Mr. Fergusson began his incision about an inch and a-half below the umbilicus, and extended it downwards for about three inches and a quarter. A rapid but cautious dissection was then made through the abdominal walls, and the fibrous coat of the tumour exposed. An examination was then made to discover whether any adhesions existed. A few were found about the neighbourhood of the incision; but these were slight and very easily torn. The tumour was then tapped with a large trocar, to which was attached a long flexible tube by which the fluid contents of the tumour were emptied into a receptacle placed under the table. Three and a-half gallons of a pale, thick viscid fluid were drawn off. After the cyst had been emptied of this, Mr. Fergusson again introduced his hand, passed it round the whole surface of the bag of the tumour, and found that it was quite free, and bound down by no adhesions. The sac was then drawn out without any difficulty, and the pedicle, which was long and narrow, was secured by the ordinary clamp. After the tumour had been removed, the margins of the incision were brought together by ordinary silk sutures, and a large compress and bandage applied. The patient was immediately removed to the ward, and a pill of two grains of opium was given.

The operation lasted about a quarter of an hour. The tumour, when examined, was found to consist of a thick fibrous cyst, springing from the inside of which, on the right side, were three smaller cysts about the size of a hen's egg, each containing thick fluid.

6 p.m.—She has vomited a little since the operation, but this has now ceased. She feels comfortable, and complains of very little pain. Skin moist; pulse 93. She has taken some brandy. Ordered to suck ice, and to take five grains of the compound soap pill every three hours.

10 p.m.—She feels comfortable; pulse 126.

22nd.—11 a.m.—Has slept pretty well during the night, and this morning looks cheerful. Has had no vomiting since yesterday. There is no tenderness in abdomen. The tongue is a little dry; pulse 126. To continue the soap pills.

10 p.m.—Feels pretty well; pulse 120; tongue moist. Since operation has taken eleven grains of opium. Pills to be discontinued.

23rd.—10 a.m.—Has passed a quiet night; pulse 128. Complains this morning of a little pain in abdomen. Ordered five grains of compound soap pill to be taken immediately.

10 p.m.—Going on well, but during the evening the pain in the abdomen has returned. Pulse 124. Tongue a little dry. Pil. sapon. co. gr. v. h. s. s. Still free from vomiting.

24th.—10 a.m.—Has not had a good night, and complains this morning of a great deal of pain on the right side of the abdomen. Pulse 128. The pill to be repeated.

10 p.m.—Since the morning has been very comfortable. The incision has now quite united, except by the side of the pedicle, and the sutures were removed to-day. The clamp was not interfered with. She has been a little purged to-day, but this has given her no pain. Ordered, pil. sapon. co. gr. v.

25th.—Going on well. Pulse 120. Her bowels have been during the day very much relaxed, but she has no pain. Ordered five grains of soap pill at bed-time. Tongue moist.

26th.—Still going on well. Pulse 120. Five grains of soap pill at bed time.

27th.—She says that she feels quite well, and would like to get up. Pulse 102. Evening.—She does not feel quite so well, has a cough, which harasses her very much. Ordered fifteen minims of the liquor morphia.

March 3.—Since the last date she has been doing very well. The cough has now ceased. The pulse has been varying, ranging from 90 to 126. She has been occasionally relaxed in her bowels, with sharp, gripping pain, but this has always been relieved by some opium. To-day the clamp was removed. The pedicle had contracted adhesions, and did not retract.

4th.—To-day the slough formed by the portion of pedicle

included in the clamp came away, and a small granulating surface is left, which is rapidly healing over. The patient feels very well. Has a moist, clean tongue, and pulse 98.

8th.—Has gone on well since last date, and without any complaint. To-day she was allowed to get up, and sit for two hours by the fire. This evening feels quite well. Tongue clean. Pulse 93.

12th.—The patient still keeps well.

SATURDAY, MARCH 14.

ROYAL MARRIAGES.

THE universal national rejoicing called forth by the marriage of the Prince of Wales, on Tuesday last, naturally draws our attention to the subject of royal marriages in general. The conditions under which such marriages are contracted differ so greatly from those which prevail in less exalted walks of life, that we often find that the tone adopted by English people, when royal marriages are in question, is one in which a feeling akin to pity has no small share. The limitation of choice by political and religious considerations, the want of previous opportunity for free social intercourse, the fact of the high contracting parties being in most cases natives of different countries—all these, and many other circumstances, concur to make many people look upon a royal marriage which produces domestic happiness as the exception rather than the rule.

This feeling can exist probably in no other country but England, since in no other country are marriages of affection so often made as here, though it has even been gravely argued by more than one writer that, on the whole, the amount of matrimonial felicity is not greater in England than in those countries where, as in France, marriages are determined upon rather as a matter of business by parents than as one of sentiment by the parties more immediately concerned. This question, however, is one which we can afford to leave to our non-professional contemporaries, but we think it will not be uninteresting to our readers if we take the present opportunity of reviewing slightly the history of some few royal marriages, with a view of seeing how some of their circumstances have affected the condition and character of their offspring—matters which have a somewhat nearer affinity to those hygienic questions which it is our ordinary province to discuss. In so doing we shall confine ourselves chiefly, though not entirely, to instances comparatively modern; for though it might be interesting to investigate some of the conditions of such unions as that by which Edward II., the first Prince of Wales, was ruined, or that by which the crown of Henry VI. was almost saved against his will; or those, again, which led to the extinction of the male descendants of Charles V., and fixed the Bourbons on the throne of Spain, yet the manners—and, we hope, the morals, too—of those times are so remote from our own that such investigation could be little more than curious, even if our space permitted it, or the materials at hand were such as could be trusted.

Let us consider, then, what are the causes to which infelicitous marriages are commonly supposed to be due, bearing in mind that we are concerned with the hygienic, not the social, aspect of the question, and see how far they can be supposed to affect the unions of kings and queens in a greater or less degree than those of their subjects. They may be enumerated as follows:—

(1.) Want or deprivation of the necessaries of life. (2.) Unhealthy employments. (3.) Unwholesome dwellings. (4.) Vicious and intemperate indulgence. (5.) Blood relationship between the husband and wife. Of these it is plain that the first two are practically excluded from all influence in the cases under discussion by the ordinary conditions of modern civilised life. No royal personage in Europe, we suppose, since the time of Charles XII. of Sweden, has ever been placed in a situation involving personal privation. The third cause, too, we might have been equally disposed to eliminate, had we not all but too sad reason to remember that even palaces are subject to the evils of imperfect drainage; and that, if we are to believe the most recent doctrines on the subject, the greatest national loss which England has deplored for many a year was due to this very fact. The two last items on our list are, however, beyond a doubt those which are popularly supposed to exercise most frequently a baneful influence upon royal and princely marriages, or upon their issue. Let us see how far recent history tends to support or invalidate this time-honoured popular belief.

From the time of the Restoration to the accession of George III., our readers will remember that royal mistresses were almost as much an institution in England as they were during a somewhat longer period in France, and though such a fact bears in itself a somewhat closer resemblance to the polygamy of eastern nations than to what is ordinarily understood by vice, it may be taken as an indication of a prevailing standard of social ethics by no means high. Accordingly, we find that both the father and grandfather of George III., though much more really attached to their wives than to their mistresses, are represented as having led very irregular lives in their youth; yet their legitimate children were respectively eight and nine in number, and most of them survived their parents, and were therefore presumably of fair average health. A little earlier than this, however, James II. may perhaps be considered as affording an instance of an opposite kind, since of thirteen children, the issue of his two marriages, three only survived him, and the third generation saw the extinction of his race. It is curious that of the five cases, during the last 300 years, in which the Sovereign of England has left no legitimate descendant, four are scarcely to the point. Elizabeth never married; Charles II. avoided the society of his wife; Mary II. and Anne, though themselves most virtuous and dutiful wives, were daughters of James II. It would appear, therefore, that it is impossible to show any constant relation between the immoral lives of some of our kings and the fate of their offspring, unless the case of James II. and his family, which we have just noted, be considered an exception.

We pass on to consider in the last place the other supposed cause of degeneracy in royal stocks, by marriages of consanguinity. And here the first remark which suggests itself is that, frequently as it may be repeated as a commonplace that by this time all the royal personages in Europe are cousins of each other, any one who takes the trouble to investigate the subject will be surprised to find out both how difficult it is to discover what the relationships actually subsisting are, and how very much more remote they are than is commonly supposed. The whole question of the effects of marriages of consanguinity upon their issue is still *sub judice*; this, indeed, is literally true, inasmuch as a commission of the French Academy of Sciences is sitting upon it; and within the last twelve months a large number of papers have been contributed both to French and

English scientific periodicals supporting severally the most opposite views. We do not therefore commit ourselves in the present state of the discussion to a decided opinion upon it, but we may say without hesitation that the history of the marriages of the English royal family within the last few generations will not help the argument much either way. It is idle to speak of a marriage beyond the degree of first-cousinship as a marriage of consanguinity at all. Two kings of England only have, in recent times, married their first-cousins, viz., George I. and George IV. In each case the marriage was unhappy, and the number of children small; but in each case neglect and misconduct on the part of the parties themselves was the cause of the unhappiness; and in neither does the mental or bodily health of the offspring appear to have suffered in the smallest degree. It is to ancient times that we must look for the most remarkable historical instances of marriages of consanguinity in a royal race. We mean, of course, those afforded by the long line of Greek kings of Egypt—the Ptolemies. Niebuhr, it is true, speaking, in his Lectures on Ancient History, of their habit of marrying their own sisters with that horror and repulsion which such a custom of necessity excites in the mind of a civilized man, says that they degenerated both in body and mind; but it is a remarkable fact, and one hard to reconcile with his view, that the dynasty of the Ptolemies continued in an unbroken line for nearly 300 years, and was brought to an end in the person of the celebrated Cleopatra, a princess almost as famous for the extent of her learning (she is said to have conversed in seven languages) as for the perfection of her personal beauty.

The only conclusion which can be drawn from any historical survey of Royal marriages is, that if they differ in any respect from those of subjects, it is in their social, and not in their physiological or hygienic circumstances, and if only the former are as they should be, there is little fear of any ill effects resulting from the latter. In the case of the particular royal marriage which has suggested these reflections, we can but re-echo the voice of all our contemporaries and of the nation at large. From no point of view can we discover a cloud upon the horizon, and can heartily join in the universal strain of hope, and congratulate the Prince and Princess of Wales on commencing their married life with perhaps the very brightest prospects which ever opened even upon a royal pair.

#### ENGLISH AND DANISH.

“ For Saxon, or Dane, or Norman we,  
Teuton, or Celt, or whatever we be,  
We are each all Dane in our welcome of thee,  
Alexandra ! ”

So has written the poet laureate; but we doubt whether a ten-thousandth part of the countless multitudes who on Saturday last assembled to welcome the fair daughter of Denmark to the heart and home of the English nation had anything like a just conception of the intimate ties of relationship which bind the race of her fatherland to the inhabitants of these islands. Even highly-educated men—ethnologists and historians—are commonly in error in giving undue, and almost exclusive prominence to the Anglo-Saxon element in our nationality, whilst the infusion of Scandinavian blood, which, from the close of the eighth century to the Norman conquest, constantly reinvigorated and regenerated the nation, giving it strength and acuteness, nerve and muscle, self-reliance and daring, has had scant justice paid to it in the common accounts of the formation of the English race and character. It is not generally acknowledged or believed that the Anglo-Saxon strain, pure and unmixed, had notably degenerated during the early centuries which succeeded the introduction of Christianity; that they were no longer the manly, hardy, energetic race who had won the kingdoms to which they gave their names; and that they could no more have been progenitors of the English nation, with its qualities

of brain, heart, and hand, than could the Britons whom they had expelled.

But we cannot here glance at historical evidence. It would be foreign to the complexion we wish to give this article. Let us look at the facts ethnologically, the deductions to be fairly drawn from language, *physique*, and the genius of the people. First, with regard to *physique*. It is a trite observation that the modern English are a mixed race. Cropping up on all hands we find veins of population in whom can be detected the marked features of various stocks. But it is equally true that in different parts of the British Isles different types are found to prevail, and we believe that in England itself the population of the Midland and Northern districts, the agricultural tracts and country towns north of the Watlinga-*street*, revert more closely to the Scandinavian type than they do to any other. The somewhat broad face, with slightly projecting cheek bones; the nose inclined to be broad and to turn a little upwards; the light eyes, and hair with a warm, reddish tinge; the strong, compact frame, not over tall, mark the Yorkshire or Northumbrian farmer, as they equally characterised the followers of the Danish and Norwegian Viking. Danish travellers tell us that in the Midland and Northern parts of England faces every moment present themselves closely resembling those they have left at home,—faces which, if they saw in Denmark, they would not for a moment suppose to be foreign.

Such evidence is valuable as far as it goes, nevertheless it must be acknowledged that the general resemblance of the Northern races of Europe is considerable, and in the case of a nation with the historical antecedents of the English, it may be said that we are trenching on slippery ground when we base an argument upon mere likeness. The main conclusion must rest on the part which the Danish element has borne in the development of the English tongue and character. The names given to places are probably the most enduring part of any language. The Saxon has left his stamp on all towns the names of which end in "ton," "ham," "bury" or "borough," "forth" or "ford," and "worth." Such terminations are most common in the south of the island. But the numerous towns, villages, and localities ending in "by," "thorpe," "thwaite," "ness," "ey," "with," "toft," "beck," "tarn," "dale," "fell," "force," "haugh," or "how," "garth," and many others, are all Danish. Sheerness, Dungeness and Holderness (*næss*, a promontory) have retained the names given them by Jarls and Vikings; and the islands along our coast—Sheppey, Anglesey, Orkney, still in their terminations keep the Scandinavian *ey* or *öc*, (an isle), by which they have been known since the barks of the northern invaders anchored in their bays. The second city of England, York, was a Danish capital, and its name is the modern rendering of the Danish "Jorvik." Altogether, 1373 places in England alone, exclusive of Scotland and Ireland, are Danish-Norwegian; of these 292 are in Lincolnshire, and 409 are in the three Ridings of Yorkshire. The evident conclusion to be drawn from such facts is, that the Danish colonisation and settlement of England was but little inferior in importance to that of the Anglo-Saxon.

Take, again, the names of families. Surnames ending in son or sen are Danish. The termination is never found in Saxon patronymics. Johnson is as comparatively common in Iceland, colonised by the same stock, as it is with us; and our greatest naval hero, Nelson (Nielson), bore a name which there can be little doubt he inherited, together with the high qualities of his race, from some Scandinavian sea-king. The valour of Havelock was celebrated by the Northmen in song nearly a thousand years before a scion of the stock saved the Indian Empire of Great Britain. Coningsby, Normanby, Danby, Ashby, Crosby, Thorpe, Sibthorpe, Willoughby, Scoresby, Derby, Selby, Wilberforce, and a hundred others, familiar as household words, all revert to that original stirps whence we all hope is to bourgeon a long succession of English princes.

How near is the affinity between the spoken languages of the two countries is proved by the fact that Chaucer's "pure well of English undefiled" is made his own by an educated Dane, who has no knowledge of modern English, with comparative ease. Numbers of our most common words are Danish, and most of the northern provincialisms have the same origin. The words dough (*Dan. deig*), thatch (*thack*), loft (*loft*), reek, smoke (*Dan. Rög*), mirk or murk (*Dan. mörk*), bower, a lady's apartment (*Dan. buur*), neat cattle (*Dan. Nöd*), crib, manger (*Dan. krybbe*), muck (*Dan. Mög*), are a few examples. Of all the dialects of the Danish, that spoken in Jutland approaches nearest to the English. Just as the Englishman uses the article "the" before words, the West Jutlander prefixes "ø." The Jutland dialect contains many words which are not only essentially the same as in English, but they are pronounced similarly. Such are—fowl (*Jut. foul*), cow (*Jut. kow*), food (*Jut. fued*), stood (*Jut. stued*), drown (*Jut. drown*), forenoon and afternoon (*Jut. forenoon* and *aternoun*), cock (*Jut. kok*), want (*Jut. want*).

But we will not load our readers with details. It must be remembered that the Norman invasion was only a fresh infusion of the same Scandinavian blood. It was the crowning act of the great drama of Northern victory. The effect of Northern admixture on the English character is not easily over-estimated. We have derived from it much of our love of personal freedom, our intrepidity, our perseverance, and our poetry. The pure, unmixed Anglo-Saxon race, we believe, would never have colonised America, Australia, and New Zealand, have conquered India, or have attained the maritime supremacy of the globe. The old Danes were merchants as well as fighters. The Danish merchants settled in London—for whom a large part of the borough of Southwark (*Sudrvirki*) and the parish of St. Clement Danes were set apart—were numerous and powerful enough to influence the election of English kings. The fleets of the Scandinavians traded to Iceland and Greenland, and discovered the far-off shores of America centuries before it had been visited by any other nation of Europe. The passion for individual liberty which is inherent in all the Northern races had well-nigh died out in Saxon England, when it was revived and nurtured by the men whose characters had been formed amid the storms and dangers of the Northern Atlantic. It is believed by many that we English owe one of our best safeguards of freedom—trial by jury—to Danish settlers, for it is found that the earliest traces of it are to be discovered in the "Danelag." The Danish word "husting" survives, whilst its Saxon synonyme "gemot," is merely remembered by antiquaries, and every time a municipal or corporate body enacts a "bye-law," it is indebted for the name of the enactment to the same source.

But here we must stop. Ethnology is fairly a collateral science with medicine, and we therefore offer no apology for our present observations. They have been suggested by an event which our profession, in common with all our countrymen, regard with feelings of the warmest satisfaction. We hope that from the advent of the last Royal Dane who has conquered the hearts of the English people, will result a closer intercourse between the two countries. We owe to Denmark a fresh debt of gratitude. As ethnologists, we may try to repay it by acknowledging, in a fuller measure than we have hitherto done, the obligations of bygone centuries.

The son of our beloved queen, himself descended lineally from the conquering Northman, has transplanted into our midst the fairest flower of Scandinavia. Science and history equally join in bright auguries. May she live amongst us to be instrumental in dispelling the cloud of sorrow that has shrouded the most revered of royal houses, to influence to high purposes and noble aims the proud nation that has adopted her, and to be the mother of a dynasty that shall eclipse all kingly races in kingly virtues,—all historic lines in universal blessing!

## THE WEEK.

THE MEDICAL OFFICERS OF THE ARMY.

(Copy.)

"Horse Guards, August 28, 1862.

"H.R.H. the General Commanding-in-Chief, in concurrence with the Secretary of State for War, is pleased to direct that soldiers sentenced to be discharged with ignominy, and marked with the letters B.C., shall be so marked by the Hospital Sergeant of the Regiment or Dépôt to which the offender belongs, *under the direction of a Medical Officer*: the marking to be effected prior to the man's committal to a Civil prison, and to be carried out after the present mode of marking with the letter D. "By command,

"JAMES YORKE SEARLETT, Adjutant-General."

The above is one among the very many objectionable duties required of an Army Medical Officer. Nothing can be more reprehensible nor ill-advised than that those employed about the sick soldier should be called upon to perform duties of this kind. A Medical officer is armed with neither military nor other legal authority to execute the sentence of court-martial, and when such is required to be carried out, it ought to be done on parade, under the command of a combatant officer, and in the presence of a Medical officer, or a *South Sea Islander*, who would probably be better able to tattoo his subject indelibly without any chance of outrage to his self-respect!

## DEATH FROM THE VAPOUR OF NITRIC ACID.

MR. STEWART, a master in the Edinburgh Educational Institution, in Queen-street, and a porter in the same establishment, died last week from inhaling the fumes of nitric acid. Mr. Stewart was in the laboratory of the school preparing for some chemical experiments, and while carrying a jar of nitric acid across the room, it fell on the floor and was broken. He called the janitor to his assistance to wipe the floor and to endeavour to save a portion of the fluid. In this effort both unwittingly inhaled the fumes. Mr. Stewart went home to dinner unconscious of having received any injury. After an hour or two he began to experience difficulty of breathing, and sent for Medical advice, but he very rapidly became worse, and died at two o'clock on Wednesday morning, about ten hours after the accident. The janitor was also taken ill, and, though he rallied for a time on Wednesday, he afterwards sank, and died at five o'clock on Thursday morning. In the year 1854 a similar occurrence took place at Sheffield, and it is worth remarking that the victim in that case, Mr. Haywood, a chemist, experienced no great uneasiness until three hours after the accident, when difficulty of breathing came on. In this respect the effect of the vapour of the acid is in marked contrast to that of ammonia.

## DR. JOSEPH BROWN'S "MEMORIES OF THE PAST AND THOUGHTS ON THE PRESENT AGE."

THE venerable Dr. Joseph Brown, of Sunderland, has just issued a volume of "Memories of the Past, and Thoughts on the Present Age." (a) He begins with his recollections of the flight of Louis XVI., and the horrors of the French Revolution, and entertains his readers with a series of reflections on the moral bearing of political events since that time, with more especial reference to the present civil war in America. He treats also of prison discipline, and of the difficult subject of that line of demarcation which separates "the extreme of depravity from insanity." With regard to murder committed under an "irresistible impulse," by an insane man, he says, another question must be asked, "How has this insanity originated? Is it a disease which may be termed 'a visitation of Providence,' or has the accused, by hugging evil passions to his breast, or by a long course of sensual indulgence, produced his own malady? Has he by his own misdeeds passed the narrow line which separates the

extreme of depravity from insanity? Has he been, in fact, the author of his own insanity?" Dr. Brown thinks that the quiet, tax-paying part of the community deserve protection, and that even weak men should be made to feel the necessity of curbing their evil propensities by the knowledge that if they should gloat over their evil thoughts until insanity overtake them, they will not therefore go unscathed. On questions of religious controversy, which are needlessly introduced, Dr. Brown is feeble in logic; but the greater part of his work deserves respectful attention.

## THE MURDERS AT PORTLAND AND WALDITCH.

THESE murders are exactly alike in circumstance. In each a young man, of some little eccentricity, and with some ill-defined history of previous bad health, deliberately, publicly, and in open day commits a murder. Ffooks, a farmer of Walditch, shoots his first-cousin in the open street. He had long been on bad terms with him, had evidently been brooding over some causes of animosity, and had often said that he would shoot him. Preedy, a convict at Portland, stabbed Evans, a warder, with the knife which had been given him to eat his dinner with. In court during his trial he behaved like a wild beast or a demoniac, and was obliged to be manacled heavily before the trial could go on with safety to those about him. Sullenness and violence had been his characteristics in early life, but there was no evidence of insanity. It was remarked that his conduct in Dorchester Gaol after the murder was influenced by reasonable motives; he became less violent when promised that he should not be placed in solitary confinement if quieter. He was fond of tame sparrows, *tended a lame bird affectionately, and wept at its death.*

## DR. BROWN-SÉQUARD'S LECTURES.—LECTURE IV.

DR. BROWN-SÉQUARD'S fourth lecture, delivered February 26, was opened by some remarks on the treatment of what he designated "that peculiar symptom," namely, muscular ataxy, or want of co-ordinating power. The lecturer observed that if the affection were a disease it would need uniform treatment, but being regarded by him as only a peculiar symptom, he recommends that the treatment should be varied according to the nature of the disease with which it may happen to be associated. When connected with lesion of the posterior columns, and with many other affections of the spinal cord, including epilepsy, where no inflammation exists, nitrate of silver in doses of one-tenth of a grain each will prove of the greatest use. If this medicine be given in these doses, and omitted occasionally for a week during the course of the treatment, it will induce no discoloration of the skin. This result may be equally avoided by giving the oxide of silver in doses of from three-quarters of a grain to five grains, three or four times a day. Being enabled to exhibit two additional cases of wasting palsy on this occasion, Dr. Brown-Séquard recurred to that disease. One of the patients was an elderly labouring man, who, when striking some hard substance with a pickaxe, experienced a rebound from the instrument which seriously injured his hand. He lost the use of it, and a year afterwards was attacked with erysipelas, which was followed by wasting both of the hand and arm. There is great pain in the palm, which was the seat of the injury; the pain also extends up the arm and along the shoulder. The first phalanges are drawn backwards, the palmar interossei seeming to have wholly lost their power. The pectoral muscles exhibit that peculiar quivering described by Dr. Brown-Séquard, when lecturing on this disease, as characteristic of wasting palsy. He observed, however, that such quivering may exist without wasting, and adduced in support of his statement two instances, occurring in his private practice, one of a man who had quivering twelve years, and another fifteen years, without any wasting in either case being observable. The second patient whom he exhibited

(a) Longmans.

as illustrative of wasting palsy, was an intelligent, cheerful-looking woman, about 35 years of age, who, in consequence of her affliction, supports herself by keeping a school, that being, as she thinks, the only occupation possible to her, as she cannot use her hands. There is extensive wasting of both fore-arms, and almost total loss of power. The muscles of the chest and legs quiver, and the disease seems to be extending over the whole body. She describes her health as being perfectly good in every other respect, and certainly her mental liveliness and activity indicate that the brain is in excellent condition. The utmost that Dr. Brown-Séguard hoped to be able to do in this case was to prevent, or at least to retard the further progress of the malady. The next case to which the attention of the audience was directed was that of a woman who had suffered from meningitis, from which she had completely recovered. The inflammation in this case was mainly restricted to the part of the cord, and to the roots of the spinal nerves at their exit, between the shoulders. The affection was accompanied by pimples, bullæ, tingling, burning, jerkings, and pain in the back. It is very important to know that meningitis, even when it has continued for a considerable time, as in this case, may be perfectly cured; but, if in the beginning, the disease be allowed to go on, it extends, the membrane secretes an abundance of serum, and even in some cases of pus; the whole cord becomes compressed, and general paralysis supervenes. The pains extending all over the body in such cases are generally regarded as rheumatic. The treatment should consist in repeated applications of "temporary or flying blisters" between the shoulders and on the nape of the neck, and in giving three-grain doses of iodide of potassium, or when the patients are feeble or cachectic, six-grain doses of iodide of ammonium three times a-day, together with some alkaline salt or bitter tonic. The amount of blood circulating in the cord should also be lessened by means of ergot of rye, belladonna, Indian hemp, stramonium, aconite, or conium. Some patients who cannot bear a double dose of belladonna, which may not unfrequently be desirable, will bear a full dose of each of the other narcotics taken together. In treating neuralgia, the intense pain of which often necessitates recourse to large doses of narcotics, the knowledge that a given quantity of each of them taken together may be thus borne, while the same quantity of one only could alone be tolerated, is of the highest practical importance. The lecturer next adverted to a "somewhat puzzling" case of paralysis, that of a woman, to whom he directed the attention of his audience. She is in good general health, but her upper extremities have been paralysed for several years. Their strength began to diminish five years ago. There is no paralysis of the legs, there is no marked wasting of the arms, and there are no hysterical symptoms; but as no organic cause of the malady can be detected, the lecturer held himself justified in calling the paralysis hysterical. The absence of paralysis of the legs certainly excludes the idea of disease in the brain or spinal cord. The patient is subject to headache, is not unfrequently depressed, and often sheds tears. Although the malady from which she suffers may be held as a sufficient cause for the latter symptoms, they are nevertheless a slight indication in the direction of hysteria, and this opinion receives confirmation from the fact observed at the close of the lecture, that she moved her left arm somewhat more than it had been seen to move before. She herself admitted that she thought there was a very slight increase of power in it. *Apropos* of this case, the lecturer remarked that though her limbs are in no degree wasted, this fact must not be regarded as indubitable evidence of hysterical paralysis. It is true that the limbs of patients suffering from this affection are usually not wasted, or, at least, not so beyond what would be the result of simple inaction; but, in other cases, wasting occurs, and that in a very marked degree. The next case shown by the lecturer illustrative of this disease was an in-patient of the Hospital, a girl, who, eight years ago, had

hysterical clavus on the right side of the head and tenderness of the part. About a year ago she lost the power of her right leg, and soon afterwards that of the left. Then extreme stiffness of both supervened, the adductors of the thighs being powerfully contracted. Referring to the strength of these contractions, the lecturer mentioned a case in which fracture was the result of an attempt to force the limbs apart. In the case shown it was impossible for a long time to separate the knees so far as to be able to insert the hand between them. In the course of the malady, the sphincters became paralysed, and in succession the right and left arms. There was difficulty of swallowing, tremulousness of the muscles of the neck and arms; the sight was a little affected; the other senses, as well as the muscles of the face and of the chest, continued normal. The circulation was sluggish, and the skin, which was habitually cold, exhibited partial anæsthesia. There was no tenderness of the spine. This symptom, though very common in hysteria, is by no means invariably present. The patient is already much improved; though the arms still tremble, they have regained considerable strength; the knees are now separable; and the sphincters have wholly recovered their power. Concerning the essential nature of hysteria, as well as of trembling palsy, Dr. Brown-Séguard here confessed that he knows nothing. Some symptoms, however, may be explained,—the absence of the sense of touch, for instance: if a cupping glass be applied to a part of the insensible skin, so as to redden it by drawing blood into it, the anæsthesia immediately ceases; in like manner, if an attempt to draw blood by cupping or by leeches be successful, there will be no longer anæsthesia of the parts acted upon. These facts prove that the anæsthesia is not due to a centric cause, but wholly to the want of circulation at the periphery. Referring to the morbid volition, Dr. Brown-Séguard mentioned a case of a young lady (one of his private patients) whose right arm had been completely paralysed for six years. She had evinced other symptoms of hysteria, and her mother was also liable to this malady. He requested his patient to hold her arms to her sides, and, while doing so, to bend the body forwards. The body having been thus inclined, the right arm remained close to it. Of course, had the paralysis been due to a structural cause, the arm, instead of being retained in its position, would have fallen forwards. Another similar case was that of a girl having a violently shaking hand. Dr. Brown-Séguard stood before her, and said, "I am sure I shall soon be struck by her"; and very soon a movement beyond the ordinary shake occurred, by which he was struck, thus proving the power of the will over the limb. He also described a very singular case of persistent shaking, affecting each part of the body in succession: if, for instance, the arm actually shaking were forcibly held still, the other arm would immediately begin to shake; if the two arms were held, a leg would carry on the movement; if that also were secured, the other would begin; that being also held, the head was violently agitated. If the four limbs and head were all restrained, then the body itself was powerfully shaken. Another curious manifestation of hysteria was spoken of, consisting of swinging the arm round four or five times, then striking the chest with it, the two motions being continued alternately. The affection began immediately after the subject of it had received bad news, and ended as suddenly. The lecturer insisted strongly that hysteria is a very real, and often a very serious, disease. He expressed the opinion that, out of ten hysterical cases, eight would never completely recover, and that even the remaining two would, on some rare occasions, exhibit remnants of the malady. Sometimes muscular atrophy, together with complete and permanent stiffness of joints, follows, and results from hysterical attacks. Calling the attention of his audience to a case of hysterical hypochondriasis, with slight aphonia, the lecturer observed that the malady in this instance was due to poverty of the blood, which, as Dr. Todd has already insisted, is a very frequent

cause of hysteria. The appetite of hysterical patients, occupying a good social position, often fails, and thus induces the malady where the tendency to it exists. The more we know of nervous complaints, the more convinced we become of their intimate relation to each other. When transmitted from one generation to another, it frequently happens that they are not transmitted directly, but, as Morell and Pritchard have asserted, a parent having one nervous disease will transmit another [to his child, while the several children of one parent will often severally exhibit a distinct form of nervous disease. Not unfrequently one person will present a blending of several forms, as evidenced by a girl whom the lecturer introduced to his audience. When eleven years of age she had scarlet fever, resulting in albuminuria and dropsy. There was extensive ulceration of the neck, and this was followed by a deviation of the spine. There is now a forward and a slight lateral curvature. She was subsequently attacked with what was called rheumatic gout, and at present has great pain in the right arm, but no swelling. In July, 1861, she had hysterical fits, which reappeared some months afterwards, and finally merged into genuine epilepsy. She has also a slight choreic movement of the arm and hand. The movement is not tremulous, and the will seems to have some share in it. The eyes protrude a little; both pupils are large; and, owing to an irritation of the sympathetic nerve, one is larger than the other. Another case, exhibiting a like blending of nervous diseases, was also shown: a man, aged 33, who had convulsions when three or four months old, preceded by hæmorrhage from the bowels, afterwards became paralysed on the left side, where the convulsive movements had been most powerful. Epilepsy supervened, and was followed by jerkings and twitchings of the limbs, and a peculiar contorting spasmodic movement, which still continues, of the arm and hand. The arm has been more affected from the first than the leg, and is considerably shorter than that of the other side. The hand and fingers may be extended if the force be applied gently; but on its withdrawal the original position is immediately resumed. The treatment in this case simply consists in the application of circular blisters to the arm, in the hope of producing a modification of nutrition in the nervous centre. This lecture was closed by some remarks upon infantile paralysis; but as they were resumed in the following one, we reserve them until our next report.

### AMERICA.

---

(From our Special Correspondent.)

CAMP NEAR FALMOUTH, VA., February 16, 1863.

EVERYTHING has remained quiet along the line of the Rappahannock since I last wrote you (about six weeks ago), at least so far as fighting is concerned. About the middle of January we had a move, and expected a bloody battle to take place, but the elements interfered and surrounded us with mud, through which we found it impossible to move onwards and difficult to return; this latter, however, by the end of three days was accomplished, but not without severe suffering being entailed on the troops by this exposure to the storm.

We have now been occupying the same ground, I may say, for three months, yet owing to effective drainage, and well policed camps, acute dysentery and low fevers, though to be seen amongst us, are by no means prevalent. Deaths, indeed, seem to be no more common among the members of this army than among the adult citizens of any populous town. Scarcely a trace of scurvy can be discovered; indeed, the army is in as robust a state of health as it has ever enjoyed.

For the sick that we do have we have every accommodation, tents and stores, with food fit for sick men; for since we became stationary here we have enjoyed opportunities of obtaining many little delicacies that to an army in motion are ungetatable.

The U.S. Sanitary Commission, for instance, have established a depôt at the railway terminus near Falmouth, and from them the Medical officers can obtain for their sick preserved soups, chicken, fruits, condensed milk, arrowroot, &c.

A general Hospital within the last few weeks has been established near Aquia Creek—a handsome village it is of white tents, cosily furnished with stoves and iron bedsteads, and since it is within half-a-dozen hours' sail of Washington, everything that a government, careless of expense, can procure for its sick is readily obtained.

Dr. Swinburne's (Medical Director of the New York State troops) report on the Medical service at the battle of Fredericksburg, has been made public lately. He says that on proceeding to the Army Field Hospitals he found that the wounded had been rendered as comfortable as possible within the shortest periods, and that afterwards they were removed rapidly from these temporary accommodations to more pleasant ones at Washington, Alexandria, etc.; so promptly, indeed, had this end been effected, that one week after the fight only 800 remained, and these were severe cases, which, at the time, it would have been injudicious to attempt to remove. He then goes on to disabuse the public mind of false impressions concerning "bad Surgery," "horrible butchery," propagated by the newspaper reporters, who, their unprofessional eyes being unable to see the necessity in many cases for operation, characterise the acts of the Surgeon as "butchery," etc.

Next, he makes a somewhat lengthy apology for the suggestions he deems it necessary to make, and which may be briefly summed up as follows:—

He allows that this army is furnished with a vast amount of professional talent, but he would suggest that that talent is not laid out to the best advantage. The time and talents of an eminently good Surgeon are thrown away in providing for the "inner man" of the wounded. The labour is not apportioned so that the task of each officer is that for which his qualifications peculiarly fit him. Seniority, he complains, is everything, merit nothing. Next, he suggests that conservative Surgery should be more extensively practised than heretofore. He does not believe that there were more than a dozen cases of resection performed after Fredericksburg. He only saw two—whereas it is now an established fact that the upper extremity should rarely be amputated for any bullet wound. This he attributes to what he complains of above—the misapplication of talent. The operator feels himself incompetent to resect, and so amputates, while the conservative Surgeon is superintending the manufacture of the soup. In addition to the ordinary arguments in favour of conservative Surgery, he looks at the case financially. Government pays fifty dollars for an artificial limb, and gives a yearly bounty of 200 dollars to the mutilated soldier. Conservatism can keep this money in the public treasury.

In order to remedy the effects springing from the above cause, he would propose—1st. That an agent should follow the army, carrying with him tents for a thousand wounded, four thousand stretchers for beds instead of hay, than which they are better and cheaper, together with some readily-made form of food. Now, this is a suggestion, the propriety of which is self-evident. In my last, you may remember, I told you how much the wounded suffered from the want of food and shelter. 2nd. He proposes that a staff of pre-eminently accomplished Surgeons should accompany this agent, some of whom should be called into consultation before the performance of every capital operation. This, methinks, is but a clumsy remedy for evils arising from the misapplication of talents already in the service.

### AUSTRIA.

---

CARLSBAD, December 11.

THE CONGRESS OF GERMAN NATURALISTS AND PHYSICIANS.

I TO-DAY conclude my reports of the proceedings of the above Congress, by mentioning some of the more important communications made to the sections for gynecology and clinical Medicine.

Professor Braun, of Vienna, whose name is probably known to your obstetric readers as the inventor of a key-hook for the decapitation of the fœtus in utero, read a very interesting paper on the "Statistics of Puerperal Diseases as observed in the Vienna Lying-in-Institution," which is con-

nected with the University. Only a small wing of this Hospital is set apart for private cases, the most considerable part of it being devoted to clinical instruction. Within the last ten years the average annual number of births in the private department amounted to from 300 to 400, and in the public portion to from 7000 to 8000. There are two separate schools in the institution, one of which is destined for Medical students, and the other for midwives. The former consists of eighteen wards, which are spacious and well aired. The rooms for sick, lying-in, and pregnant women are somewhat deficient as regards comfort; there are 479 beds for lying-in patients, each ward containing about 26 beds. The clinical instruction is continued all the year round; there are about 250 to 300 students annually in the first, and about 200 midwives in the second school. Within the last twelve years, the highest mortality occurred in 1854 and 1855, when it amounted to 8.5 and 5.3 per cent.; the lowest in 1858 and 1859, when it was only 1.6 and 1.5 per cent. Washing the hands with chlorine-water produced no perceptible change, as in 1856, when only soap was used, the rate of mortality was just as favourable as in previous good years. The year 1861 seemed at first a very promising one. In summer, there were only a few cases of erysipelas migrans; but from the latter part of October numerous cases of puerperal diseases occurred. In the last week of that month there fell ill on the first clinique 50 women out of 65, of whom 22 were dead by November 1. There was no overcrowding; the greatest cleanliness was preserved, ventilation was good, and the drains satisfactory. Every woman who fell ill was at once separated from the rest; the midwives did not come in contact with them; every room was, ten days after a confinement, emptied and thoroughly aired; before every examination the hands were well washed with soap. From November 1, Professor Braun enjoined the following rules:—Only nurses and no students were allowed to examine the women; the clinical instruction and the courses of operations on dead bodies were discontinued; almost all patients were transferred into other rooms, and fumigations with nitrous acid, chloride of lime, essential oils, and vinegar were used. In spite of these measures, however, which were persisted in for six months, the mortality rose to 6 per cent. per annum; and if those were included who had been transferred from the lying-in institution to the general Hospital, the number was even 9 per cent. In the second clinique there died, of 365 women who came in during November, altogether 19 per cent., and yet not a single post-mortem examination had been made there, nor did the Physician-Accoucheurs once enter the dissecting-room.

One of the last and best papers read was that by Professor Jacksch, of Prague, on "Disturbances of the Function of the Peripheral Nerves," and in which he adverted principally to anodynia and cutaneous anæsthesia. In the former affection the nerves had lost the power of transferring the perception of pain to the encephalon, so that the prick of a pin, blisters, and Faradisation, by means of wire-brushes, remained unperceived; while in the latter the sense of temperature, pressure, and locality were wanting. There were different degrees of both affections; the anæsthesia was either complete or incomplete. With regard to its extent, there was the greatest variety. Anodynia frequently occupied only one half of the body, but it sometimes extended beyond the median line; in other cases it was confined to a very small circumference. Anodynia of the tongue was often associated with that of the skin. The sensibility of the muscles was only seldom increased, but generally diminished or entirely gone. This affection might be likewise either partial or general, and did not follow certain courses of nerves; as, for instance, the trapezius might be affected, while the sterno-cleido-mastoid remained in its normal condition. The electro-muscular contractility and the voluntary movements were, generally, not impaired; sometimes, however, he had seen them deficient, especially in the lower extremities. The mucous membranes might be affected in a similar manner; there might be loss of smell and taste, anodynia of the Schneiderian membrane, of the mucous membrane of the aërial passages, the vagina, and the rectum, anæsthesia of the retina, etc. The duration of the affection varied from several days to several years. It generally ensued after emotion, and sometimes disappeared after cold aspersions. Amongst the diseases most frequently associated with anodynia, Professor Jacksch had observed chorea, epilepsy, catalepsy, somnambulism, melancholia, paralysis, and contrac-

tions, fits of laughing, vomiting, neuralgia, dysphagia, Brodie's tumour of the subcutaneous cellular tissue, and paroxysms of apparent ague. The affection was more frequent in females than in males, more in Jews than in Christians, and was chiefly observed in persons between twelve and thirty years of age. The prognosis was not very favourable, as relapses were frequent. The medicines chiefly to be employed were zinc, quinine, secale cornutum, morphium. Cold aspersions, the douche, etc., were also serviceable; but by far the best remedy was Faradisation, especially if paralysis, contractions, and neuralgia were at the same time present.

Dr. Stamm, of Berlin, then spoke on the annihilation of epidemic diseases generally, and of plague especially. He said the highest aim of the Physician was not to cure diseases, but to search as closely as possible for the causes of their origin, and to endeavour to annihilate these latter. The chief questions to be settled were, what single or concurrent circumstances had afforded special aid to the propagation of disease; how and whereby a disease was propagated; what circumstances were originally, or at the present time, in existence favouring the development of disease; what measures should be taken in order to prevent the spreading of diseases; and how it was possible to annihilate the causes of their origin? He then entered into a description of the chief symptoms of plague, and showed the failure of all remedial methods which had been tried for it; as in almost all epidemics, whatever might have been the treatment followed, about two-thirds of those affected had succumbed. The country in which plague originated was Egypt, and he had, during his stay in that country, in 1844, satisfied himself that in most epidemics Cairo and the neighbouring villages of the Delta of the Nile had been first invaded, and had most intensely suffered. In 1844, no case of real plague came under Dr. Stamm's notice beyond the boundaries of Egypt, although he searched for them in Constantinople, Broussa, Damascus, Acca, Nazareth, Jassa, and Jerusalem. He, therefore, concluded that plague had disappeared from the other parts of the Turkish Empire, because it was no longer propagated to them from Egypt, where only a few cases of a mild character occurred. Further investigations showed, that in the same degree as plague had become rarer in Cairo it had more and more disappeared from the whole of Egypt. The question, therefore, arose, how it was that Cairo and its neighbourhood, which had been the focus of infection for the whole of the Turkish Empire, no longer caused plague in the present time? The town had several hundred thousand inhabitants. Before the introduction of irrigating and cleansing the streets, it was full of dirt and mire; the interments of dead bodies were made in the most negligent manner, the corpses being often left in the houses themselves, and only slightly covered with earth. The town was intersected by a canal, which received the sewerage, and the neighbourhood of which had always been considered most unwholesome and most invaded by plague. Epidemics of plague had generally commenced when the water receded, in the beginning of the year, and disappeared in June with the heat of summer. Dead fish, vegetable matter, etc., were decomposed by the sun after the river had fallen, and thus miasms were produced. There were, moreover, the gases arising from the decomposition of the badly-interred dead bodies. It seemed obvious that the more careful interment which had been insisted upon by the Government of Mehemet Ali, had gone far towards diminishing plague; but neither the origin nor the gradual disappearance of the epidemic could be well accounted for by this circumstance; for even after the sanitary police had already done good work in Cairo, plague would, nevertheless, appear; and Dr. Stamm found that, in 1844 and 1845, superficial and negligent interments were still adhered to in the smaller towns and villages of Egypt; but, nevertheless, no plague was developed. He, therefore, was struck by the idea that some change must have occurred in the locality of Cairo itself, and found, by comparing maps of the place and questioning the inhabitants, that the town had formerly been surrounded by a much more extensive chain of hills, by which it had been almost entirely enclosed. These hills had an elevation of from 450 to 600 feet, and prevented the access of the winds and of the dry air of the desert. Dr. Stamm is of opinion that the levelling of these hills, which was done by the command of the Viceroy, Mehemet Ali, for the purpose of filling up the low marsh land and embellishing the neighbourhood with gardens and plantations, has caused the gradual disappearance of plague. He found, indeed, that, as the work men-

tioned progressed, and the winds and the air of the desert were allowed free access to the town, plague gradually disappeared, not only from Cairo, but from Egypt and the whole of the East, and that from the time when these works were finished not a single case of true plague has ever occurred.

## GENERAL CORRESPONDENCE.

### THE ARMY MEDICAL DEPARTMENT.

[To the Editor of the Medical Times and Gazette.]

SIR,—I was glad to perceive, in your last number, that you have adverted to the subject of the discontent existing among the members of the above department.

It is deplorable that the opening of the Medical School at Netley should be under circumstances like the present—a cloud of gloom and discontent in the department, and great unpopularity of the service in our Medical journals and universities. In every way that can be done, the authorities have apparently endeavoured to disgust the present members of the Medical branch, and to prevent the entrance of others. The present position of a Medical officer is so ill-defined, his duties so onerous, and sometimes so menial, that it would be better for those who value their self-respect to discard at once any idea of becoming candidates for so unthankful and unprofessional an office.

What with returns, correspondence, case books, figures, circulars about jelly, confidential reports, *the superintendence of the marking of soldiers with "D." and "B. C."*, useless attendances at reviews and rifle practice, there is left no room for the cultivation of one's profession.

A Medical man is respected in the army by the possession of the self-same qualities that gain him this out of it, viz., his gentlemanly bearing, general education, and social qualities; of which all can judge, and his professional attainments, which officers and men are not slow to discern.

It was to entice men possessing these qualities into the service that Lord Herbert and others laboured. They knew that of material such as this anything could be made; but to obtain it matters had to be put upon a very different basis to what they once were and now are. I, for one, wish that there could be some other plan devised than that of relative ranks for fixing the position and allowances of the Medical officers, since no step can be taken by them apparently without treading upon the sensitive corns of the combatant officer and invoking the jealous dislike of the Horse Guards.

There is no good to be obtained from concealment or exaggeration, and it is possible that here and there a member of the department may not have been perfectly blameless in the way he availed himself of these privileges of relative rank. I am certain, however, that the great body of the Profession in the army is desirous of acting with proper delicacy and right feeling in these respects, and it is unjustifiable that the whole department should be visited with the presumed sin or defect of an individual member. We are treated as if we were naughty schoolboys instead of intelligent members of a profession, and P. M. O.'s are converted into monitors, furnishing confidential reports to the head schoolmaster. Under such a system the reward is to the "time-server," and the punishment to the independent and zealous man.

No doubt the Warrant of 1858 has been all but cancelled, and the Horse Guards neglect no opportunity for curtailing the remnant that remains of it. But, Sir, the department has sunk so rapidly of late that one naturally tries to discern some defective elements in its own organisation. We have not to go far, I am sorry to say, to indicate where this has been. The position and prospects of the Army Medical officer have taken so steady a retrograde movement since the death of Mr. Alexander that one is compelled to follow the inference suggested by the facts. I am, &c.

March 9. A WELL-WISHER TO THE DEPARTMENT.

### POISONING BY MORPHIA.

LETTER FROM DR. MORELL MACKENZIE.

[To the Editor of the Medical Times and Gazette.]

SIR,—The case of poisoning by morphia related by Dr. Anstie, in your Number for February 7, though interesting in many respects, is scarcely sufficient in itself to "confute

signally the notion which unaccountably (?) prevails, that opiates do not act so powerfully when given per anum, as when given by the mouth."

In considering the relative effects of the two different methods of administering opiates, the case has undoubtedly a certain value, and tends towards a certain conclusion—a conclusion, however, which is opposed by the inexorable logic of a considerable number of facts.

Common observation notices that wine, brandy, and nutritive enemata generally, do not produce nearly the same effect when administered per anum as when taken in the ordinary way. Structural examination of the two absorbent surfaces yields a scientific explanation of that, which is a matter of familiar experience. If opium is exceptional as regards absorption, as perhaps it may be, on account of dialytic laws, the *onus probandi* certainly rests with those who take up that position.

Dr. Anstie's case can only be looked at as a unit in the arithmetic of the question, and one which will certainly be cancelled by the following case, which occurred last year in one of the Metropolitan Hospitals:—A young woman, who was suffering severely from phlegmasia dolens, was ordered a liniment for external use, which contained two ounces of tincture of opium, and two ounces of soap liniment; at the same time a common enema was prescribed. By mistake, the liniment (which contained the two ounces of tincture of opium) was injected per anum, and the whole was retained. The patient became very drowsy towards evening, the enema having been administered in the afternoon, and remained in a semi-comatose state the whole of the next day. The pupils were contracted to a pin's point. The feeble condition of the patient rendered it impossible to adopt the ordinary treatment. She, however, recovered without any artificial means having been employed to "keep the brain in a state of activity."

Many of the cases on record, in which everything has been done to stimulate the nervous powers, have proved fatal; whilst others, which have been left to themselves, have recovered. The question arises whether the nervous system, already overpowered by the poison, is not still further exhausted by the ordinary treatment.

I am, &c.  
London. MORELL MACKENZIE, M.D. Lond.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

ANNIVERSARY MEETING, MARCH 2, 1863.

Dr. BABINGTON, President, in the Chair.

THE annual general meeting of this Society took place on the 2nd inst., and was attended by a large number of the Fellows. After the ballot for the election of the officers and Council for the ensuing year had been declared open, the Treasurer's Report for the year 1862, and the Report of the President and Council were read, from which it appeared that the Society continued in a state of great and increasing prosperity. The total number of Fellows, resident and non-resident, in the last Report was 630, and they now amounted to 642. The total ordinary income was £1343 13s. 11d. against an expenditure, ordinary and extraordinary, of £1090 9s. 4d., leaving a balance of £253 4s. 7d., which, added to a previous balance of £47 0s. 2d., and the amount of composition fees in lieu of further subscriptions, £57 15s., gave an entire balance of £357 19s. 9d. in the hands of the Society's bankers. There had been a loss of six Fellows by death and of four by resignation, and the Society had received an accession of twenty new Fellows, thirteen of whom were resident, and seven non-resident. The Report referred to the excellent results which had followed the appointment of Scientific Committees by the Society, as shown in the valuable Report of the first Committee on Suspended Animation, and mentioned that the Council had recently appointed a second Committee on the Uses, Effects, and Modes of Administration of Chloroform. The Council considered that the state of the income of the Society appeared to offer a further encouragement to extend as widely as possible the usefulness of the Society, and more particularly the labours

of the scientific committees already so auspiciously commenced; by such means increasing the dignity of the Society, and realising the highest aspirations of the distinguished members of the Profession who founded it, and of those who had since watched over and fostered its growth. It was stated in the Librarian's Report that 266 new works (independent of journals and continuations) had been added to the library, and, an increase of room for journals and serials being required, that shelving had been added, capable of containing 1800 additional volumes; also that a new feature had been added to the library, at the suggestion of one of the Fellows, Dr. H. G. Wright, in the shape of portfolios containing photographs of subjects of professional interest. A hope was expressed that Fellows possessing copies of such photographs would present them to the Society.

The adoption of the Report was moved by Dr. Burrows and seconded by Mr. Curling. On being put from the chair, a discussion ensued, in which Dr. Greenhow, Mr. Charles Hawkins, Dr. Barker, Dr. Webster, Mr. Hilton, and Mr. Arnott took part.

Dr. GREENHOW drew attention to what he considered the still imperfect state of the ventilation of the meeting-room, notwithstanding the alterations introduced the year before last, and hoped that further steps would be taken to bring it to that state of perfection which a Society embracing so many Officers of Health amongst its members was entitled to expect.

Mr. CHARLES HAWKINS thought that the only remedy would be the enlargement of the room, which had been proposed at several previous anniversaries of the Society, and for which plans and estimates had already been made.

After some discussion, in which differences of opinion were expressed as to the real financial *status* of the Society, as shown by the balance-sheet, an amendment was moved by Mr. CHARLES HAWKINS, and seconded by Dr. STEWART, "That a meeting of the Society should be called on the subject, and that the plans and estimates obtained should be laid before the Society."

The PRESIDENT took the sense of the meeting on the amendment, and declared it to be lost.

After some further remarks, in which the speakers congratulated the Society on its flourishing condition, financial and otherwise, and more particularly on the successful introduction of the appointment of scientific committees, which were considered a most valuable addition to the Society's means of usefulness, the original motion for the adoption of the Report was put and carried.

The PRESIDENT then addressed the meeting, and after a few introductory remarks expressive of his regret at taking leave of his colleagues and of the Society, from whom he had received such courtesy during his term of office, proceeded to a biographical notice of those Fellows who had been removed by death since the last annual meeting. These were six in number: Mr. Eusebius Arthur Lloyd; Dr. George Darling; Mr. Edward Stanley, F.R.S.; Sir Benjamin C. Brodie, Bart.; Mr. Peter Bossey; and Mr. John Gunning. He then alluded to the abortive attempt which had been made at the commencement of his Presidentship to effect an amalgamation of the Pathological, the Obstetrical, the Epidemiological, and the Royal Medical and Chirurgical Societies; and stated that, as a substitute for this proposed change, a new function had been bestowed on the Society, in the formation, by its council, of scientific committees for the investigation of subjects of special interest and importance. He eulogized the report drawn up by the first of these scientific committees, to which was allotted the subject of "Suspended Animation;" and augured favourably of the working of a second committee on "Chloroform," whose labours had just commenced. He characterised the creation of these new functions as a move in the right direction; and indicated two other modes in which, in his opinion, the flourishing state of the funds would permit the Society to promote the object for which it was founded—namely, the advancement of Medical and chirurgical knowledge. These were—first, to present medals, under due regulations as to time and value, to professional men who should prove themselves most deserving of such distinctions; and, secondly, to aid by grants persons who needed funds for the publication of valuable works, or the prosecution of useful researches. He also made favourable mention of the suggestion of one of the Fellows of the Society, that a new order—namely, that of Corresponding Foreign Fellows—should be created, and gave reasons why such an order had become necessary. The President stated that

the question of either changing altogether the locality of the Society or enlarging the present premises had been under consideration, but that neither the one proposal nor the other had been approved; that arrangements, however, had been made for the accommodation of more books by putting up new shelves; and that an improved system of ventilating the meeting room had been adopted. He finally craved permission, ere he took his leave as the oldest President who had ever occupied the chair, to avail himself of his character of a veteran, and advert to the impassioned tone of address which on some rare occasions he had observed speakers to adopt at the meetings, and to recommend that in future discussions those personalities, those ebullitions of emotion, those impugnments of motives, which were so unnecessary and so out of place in the consideration and discussion of scientific questions, should be avoided. After enlarging somewhat on this topic, he concluded by expressing his great satisfaction at being succeeded in office by a gentleman whose high talents and prominent station rendered him so eminently qualified for those important duties which he would be called on to perform.

At the conclusion of the President's address, the proposed new bye-laws relative to the scientific committees were (with a few technical alterations moved in an amendment by Dr. Balfour) adopted. Thanks were then voted to the members of the Scientific Committee on Suspended Animation—namely Dr. C. J. B. Williams, Dr. Kirkes, Dr. Harley, Dr. B. Sanderson, Dr. Brown-Séguard, Dr. Hyde Salter, Mr. Savory, and Dr. Sieveking—for the able and zealous manner in which they had carried out their investigations; and also to the authorities of University College, the Royal Humane Society, and the Royal National Life-Boat Institution, for their courtesy and assistance in advancing the inquiry. The thanks of the Society were also voted unanimously to the retiring President for his able conduct in the chair, and for his admirable address; and to Mr. C. H. Moore, Secretary, and the other retiring officers of the Society, for their valuable services during the time they had been in office.

At the conclusion of the meeting, the result of the ballot for officers and council for 1863 was announced by the President as follows:—President: Mr. Partridge. Vice-Presidents: Dr. Hodgkin, Dr. West, Mr. Hilton, and Mr. Ferguson. Treasurers: Dr. Pitman and Mr. Dixon. Secretaries: Dr. Sieveking and Mr. J. Birkett. Librarians: Dr. Stewart and Mr. Henry Lee. Other members of Council: Dr. Cotton, Dr. Gream, Dr. G. Johnson, Dr. Markham, Dr. Sibson, Mr. G. V. Ellis, Mr. Barnard Holt, Mr. Holthouse, Mr. E. Newton, and Mr. Toynbee.

## THE PATHOLOGICAL SOCIETY.

TUESDAY, FEBRUARY 17.

Mr. PRESCOTT HEWETT, President, in the Chair.

DR. PEACOCK exhibited specimens showing the

STATE OF THE HEART IN PHTHISIS; AND DISEASE OF THE KIDNEY, URETER, BLADDER AND PROSTATE, AND OF ONE SUPRA-RENAL CAPSULE.

The first specimen was removed from a man 46 years of age, a patient at the Victoria-park Hospital, under the care of Dr. Birkett, who had been seriously ill for four months, and ailing for some years. In this case the heart weighed 9 oz. and 14 drachms, indicating some degree of hypertrophy, and the cavities also were considerably increased in size. The other specimen was from a man, 26 years of age, who died of acute phthisis, and in this instance the heart weighed only 7½ oz., and all the cavities were small, especially the left ventricle, the walls of which were increased in thickness. Dr. Clendinning, in a paper published in the *Medico-Chirurgical Transactions*, stated that the heart was increased in size in phthisis. This opinion was not, however, strictly correct. In cases of phthisis of long duration, and especially in those which supervene on bronchitis, or are complicated with bronchitis, the heart is often found hypertrophied and dilated, as in the specimen first exhibited. When, however, the disease runs its course more rapidly—is more purely a disease of nutrition—the heart is very generally diminished in weight, and not unfrequently the cavities are small, and the walls, especially of the left ventricle, increased in thick-

ness. This condition constitutes one form of what has been termed concentric hypertrophy very incorrectly, for it is simply that the cavities are small from the diminution in the amount of blood which they receive, and the walls contract in proportion. Of this condition, the second heart shown to the Society formed a characteristic example. It appears, however, that the heart does not, in these cases, emaciate to an equal degree with other parts of the body,—the tendency to diminished nutrition being modified by the increased exertion which the organ has to undergo to maintain the circulation. In the first case, there was also strumous pyelitis of the right kidney, with entire obliteration of the corresponding ureter as far as the bladder, and complete destruction of the corresponding renal capsule. The base of the bladder was thickened and ulcerated, and there was an abscess in the left lobe of the prostate, which had opened into the neck of the bladder. The left kidney, uréter, and supra-renal capsule were healthy. The patient had been of a dingy colour during life.

Dr. LEARED showed a specimen from a case of obstruction of the bowels :

#### LOOP OF INTESTINE STRANGULATED IN A SLIT IN THE MESENTERY.

A boy, 14 years of age, in apparent good health, suddenly complained of pain in his abdomen, lay down and writhed in agony. He died in twenty-four hours. At the autopsy it was found that a loop of intestine had passed through a slit in the mesentery. There were no signs of peritonitis. In reply to Mr. Gay, Dr. Leared said that the edges of the slit were rounded. It had been one of the boy's duties to exercise a large dog. The dog had once thrown him down, and then dragged him on the ground.

Dr. BRISTOWE showed a specimen of

#### RUPTURE OF THE ASCENDING ARCH OF THE AORTA.

A young man, who had been considered healthy, one Saturday afternoon, after carrying a ladder, had what appeared to be a slight degree of faintness. He went home, and then had pain in his back, which was treated for lumbago. On Wednesday he now and then had pain in the chest, and the pain in the back was worse. He also had dyspnoea, and died two or three hours after this aggravation of the symptoms. The ascending arch of the aorta was found dilated and thin, but not diseased. There was a rent in it an inch and a-quarter long, and a smaller one, half an inch. There was blood in the cellular tissues around the aorta. The pericardium was full of blood. No doubt the first symptoms corresponded with the effusion of blood into the coats of the vessel, and those just before death with effusion in the pericardium.

Mr. HOLMES exhibited a specimen of

#### PARTS AFTER EXCISION OF THE HIP-JOINT.

The patient, when 4½ years old, was admitted into the Children's Hospital for disease of the hip-joint of two and a-half years' duration. Mr. Holmes excised the joint, and child recovered completely. In six months the parts were soundly healed. The child afterwards returned to the Hospital, and died of double pneumonia, probably from cold. The bones were connected by fibrous bands, and Mr. Holmes thought, if the child had lived, a false joint would have been formed.

Mr. NUNN remarked on the change in the shape of the acetabulum.

Mr. HOLMES said that this was probably due to gouging at the time of the operation.

Mr. MAUNDER thought that the specimen ought to encourage Surgeons to operate more frequently in such cases.

Mr. HOLMES said that he could not agree with Mr. Maunder, as, of six cases in which he had operated or had watched carefully, this was the only one in which the slightest benefit had been derived.

Mr. GASKOIN showed a specimen of

#### RUPTURE OF THE AORTA, WITH EFFUSION OF BLOOD INTO THE PERICARDIUM.

A woman, 65 years of age, was found dead in bed. At the autopsy, the pericardium was found to be full of blood. The aorta was found to be atheromatous, and there was a small vertical rent in its coats, just above the aortic valves. From this opening the blood had escaped into the pericardium. The loose cellular tissue about the roots of the great vessels was infiltrated with blood. There was disease of the aortic valve.

Dr. Peacock was appointed to furnish a report on this specimen, and on Dr. Bristowe's.

Mr. MAUNDER exhibited a portion of the anterior abdominal wall containing the

#### INCISION WHICH HAD BEEN MADE FOR THE REMOVAL OF AN OVARIAN TUMOUR.

It was shown—First, in order to record the fact, that the patient, 25 years of age, had died of acute peritonitis on the fifth day; and secondly, that in order to secure perfect coaptation of the edges of the incised peritoneum it was not absolutely necessary to include that membrane in the suture; in this specimen the sutures were still *in situ*, were quite superficial to the serous membrane, and yet the original peritoneal wound presented a linear cicatrix, excepting at the point at which the pedicle intervened. This case appeared to be in all respects favourable for operation, but having terminated fatally, Mr. Maunder deemed it more desirable to record that circumstance rather than the success of the operation, supposing the facts to have been reversed.

Mr. SPENCER WELLS said that when ovarian tumours were not closely connected with the uterus—in other words, when the peduncle was long—they often moved from one side of the abdomen to the other, as the patient moved from side to side. Of course there would be corresponding movements of intestines, and necessarily variations in the situation of dulness and resonance on percussion. When a loop of intestine adhered between an ovarian cyst and the abdominal wall, the extent of resonance would vary with the contents of the gut. In some large ovarian tumours the movements are so free that the pedicle has been found twisted round upon itself, and in more than one turn. He (Mr. Wells) had seen one case in which death resulted from gangrene of a cyst, its supply of blood having been cut off by such a twisting of its pedicle, and of the vessels contained in the pedicle.

Mr. MAUNDER said that in the case he had mentioned the tumour was very large, and adherent to the anterior abdominal wall.

Mr. SPENCER WELLS exhibited

#### FOUR OVARIAN TUMOURS REMOVED BY OVARIOTOMY.

The first was removed last January, from a patient upon whom ovariectomy had been performed, in the previous May, by another surgeon. Mr. Wells did not enter into the details of the case, as he was about to bring it before the Medico-Chirurgical Society. The second tumour was removed, on the 19th of January, from a married woman, 32 years of age. The largest cyst had contained seventy-two pints of fluid, and the pressure had caused complete prolapse of the uterus with bladder and rectum. Extensive adhesions had to be separated, but the patient recovered well, and left the hospital on the day of the meeting. The third tumour was removed from a single lady, 25 years of age, on the 3rd of February. It had consisted of a large cyst holding twenty-five pints of fluid, and of masses of adenoma. Sections of the latter were shown, and portions of the wall of the large cyst, to show how small cysts are developed between the layers of larger ones. The patient died, two days after the operation, of exhaustion. The fourth tumour was removed from a married woman, in her 57th year, on the 9th of February. The largest cyst contained sixty-nine pints of fluid. There were large groups of secondary cysts, and extensive adhesions, but the patient was convalescent. This case made fifty-five in which Mr. Wells had performed ovariectomy, with a result of thirty-seven recoveries to eighteen deaths—and one case, in which he had done it for the second time, the result being fatal. If this case were classed by itself, there were only two deaths in his last twenty cases to eighteen recoveries.

Mr. SPENCER WELLS presented a

#### FIBROUS TUMOUR OF THE UTERUS REMOVED BY GASTRO-HYSTEROTOMY

on January 12 from a single lady, 35 years of age. It weighed seventeen pounds after one or two pints of serous fluid had drained off from imperfect cysts or cavities observed in the interstices of the fibrous layers of which the tumour was composed. The uterus from which it had been removed was also shown. The connexion between the tumour and the uterine parietes was not very intimate, so that after dividing the parietes it was detached without much difficulty. In some places a very thin stratum of uterine tissue and the peritoneum were the sole coverings of the tumour. It had formed in the right half of the body and fundus of the uterus,

and had been accompanied by hypertrophy of the uterine tissue on the left side of the body, with atrophy of the cervix. Mr. Wells said that he brought this case forward, not as an example, but as a warning. He thought it would only be under most unusual circumstances that he would again remove an interstitial fibrous tumour of the uterus. A peritoneal outgrowth, or an ingrowth towards the uterine cavity and vagina, offered far more probability of successful removal than an interstitial tumour. In undertaking the operation he knew perfectly well that the risk must be great. He and Dr. Stewart had explained to the patient that the risk was an "unknown risk;" but she had begged to run any risk in hope of a cure. The tumour had been noticed for several years, and its growth had been accompanied by profuse menorrhagia; but it had only attained a very large size during the last four years. Since then her life had been repeatedly in danger from profuse hæmorrhage, and she had become quite unable to earn her living as a governess. A very accurate diagnosis had been made, and the patient was advised to try and obtain admission to the Hospital for Incurables; but she was most anxious to avoid such an end, and careful consultations were held as to the possibility of removing the tumour, and the best means of doing so. The impracticability, or very great danger, of removal by the vagina being evident, it was thought that removal by a sort of Cæsarian section offered the best hope of a good result. Accordingly, Mr. Wells laid open the abdomen, as in ovariectomy, and pressed the uterus and tumour outwards. He then cut through the uterine wall, and detached the tumour by his hand from its connexion. The uterus at once contracted. There was very free bleeding at first, but it soon stopped. Two ligatures only were used, and the opening in the uterine wall was closed by the uninterrupted suture. The abdominal wound was closed in the usual manner. The patient never rallied, and died four hours after operation, death being attributable partly to loss of blood, partly to shock, and partly to the effects of chloroform. There was no bleeding after the close of the operation, and no blood was found in the uterine sac, or peritoneal cavity, after death.

In reply to Dr. GIBB and other speakers, Mr. WELLS repeated that peritoneal outgrowths, more or less pedunculated, had been successfully removed by the abdominal incision—as by Dr. Grimsdale and Mr. Fletcher, of Liverpool—and that ingrowths towards the uterine cavity and vagina were sometimes detached spontaneously, and had been often removed successfully after division of the mucous membrane, but that *interstitial* fibrous tumours of the uterus, like that now before the Society, were under much less favourable conditions for the Surgeon.

Mr. GAY exhibited a specimen of  
 CONGENITAL TUMOUR, REMOVED FROM THE SOLE OF THE FOOT OF A CHILD.

Mr. Gay first saw the child when he was seven months old. The tumour was elastic, and appeared to be unconnected with the deep tissues. He removed the tumour, with part of the tarsus and the metatarsus. The meshes of the tissue of the tumour were filled up with large fat cells, containing also crystals of margaric acid. The patient recovered.

Dr. Harley was requested to examine the tumour, and to report thereon to the Society.

Mr. HOLMES showed a specimen of  
 CONGENITAL TUMOUR, REMOVED FROM THE OCCIPITAL REGION. It was removed by the écraseur. The child recovered, and there was no contraction of the neck, although the wound was a large one.

The PRESIDENT said that he once removed a small fibrous tumour from an infant two hours old. It projected from the upper jaw into the mouth, so that the child could not suck.

Mr. SHILLITOE exhibited a  
 CONCRETION PASSED FROM THE BLADDER OF A WOMAN. She had consulted him for symptoms like those of stone in the bladder; but on examining her, dilating the urethra, and passing the finger into the bladder, he could not find any stone. The substance passed consisted of phosphates coated over a thin metallic substance.

The PRESIDENT doubted whether it had been passed from the bladder.

Dr. LEARED believed it was a deposit from a kettle.

Mr. SHILLITOE thought that Dr. Leared's explanation was the correct one. This patient also consulted him for swelling of the end of one of the fingers, for which she could give no

cause. It was removed at the first joint, but soon the stump inflamed, and another piece was cut off. He had recently heard that a third operation had been performed in the country.

M. SPENCER WELLS asked Mr. Shillitoe if the lady had brought an action against him for breach of promise of marriage.

The PRESIDENT then related a case of simulation of symptoms of uterine disease.

Dr. HARLEY then exhibited a

CONCRETION FOUND IN THE ABDOMEN.

Concretions might occur in any part of the body, but when consisting entirely of inorganic matter they were rare in serous cavities.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following members of the College, having been elected Fellows at previous meetings of the Council, were admitted as such on the 11th inst. :—

John Thomas Gilson, of Chelmsford, diploma of membership dated September 2, 1825; William Cathrow, Weymouth-street, Portland-place, November 5, 1830; Benjamin Barrow, Ryde, Isle of Wight, June 27, 1836.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, March 5, 1863 :—

John Lacey, Wylo Cop, Shrewsbury; Robinson Boustead, Buckingham-street, London; William Irving Page, Ulster-place, Regent's-park, N.W.

APPOINTMENTS.

- ANDERSON, WILLIAM, M.D., has been appointed Resident Physician and Medical Tutor to the Birmingham General Hospital.
- FALCONER, HUGH, M.D., has been elected Foreign Secretary of the Geological Society.
- JONES, J., M.R.C.S. Eng., has been appointed House-Surgeon and Secretary to the Isle of Wight Royal Infirmary.
- KNAGGS, SAMUEL, M.R.C.S. Eng., has been elected Surgeon to the Huddersfield Infirmary.
- NEWETT, ROBERT H., L.R.C.S. Ed., has been elected Resident Surgeon to the Belfast Union Workhouse.
- NEWTON, H. W. PRIESTMAN, has been appointed House-Surgeon and Dispenser to the Chesterfield and North Derbyshire Hospital.
- OLLARD, JOHN F., M.R.C.S. Eng., has been appointed one of the Honorary Medical Officers to the Isle of Wight Royal Infirmary.
- PEACOCK, ALBERT L., L.S.A. Lond., has been elected Assistant House-Surgeon to the Sheffield Public Hospital and Dispensary.
- PINNIGER, BROOME, M.R.C.S. Eng., has been appointed one of the Honorary Medical Officers to the Isle of Wight Royal Infirmary.
- POPE, J. ROBINSON, M.R.C.S. Eng., has been elected Surgeon to the East Sussex, Hastings, and St. Leonard's Infirmary.
- PRIESTLEY, WILLIAM O., M.D., has been elected Professor of Midwifery at King's College.
- RHODES, GEORGE W., M.R.C.S. Eng., has been elected Surgeon to the Huddersfield Infirmary.
- SANDERSON, JOHN B., M.D., has been appointed Assistant-Physician to Middlesex Hospital.
- SHEPHEARD, PHILIP CANDLER, M.R.C.S. Eng., has been appointed Assistant Medical Officer to the Three Counties Asylum, Stotfold, Baldock.
- WITHAM, J., has been appointed House-Surgeon to the Male Lock Hospital, Dean-street, Soho.

DEATHS.

- BOYCE, WILLIAM, at Edinburgh, on March 1.
- DALLAS, J. I., M.D., at Hamilton, Upper Canada, on January 24, aged 46.
- HAYWOOD, R., M.R.C.S. Eng., of Locust-cottage, Landport, Portsea, late Surgeon R.N., lately.
- HOPKINS, WILLIAM, M.D., at Boulogne-sur-Mer, on March 6, aged 86.
- HOUGHTON, FREDERICK W., M.R.C.S. Eng., at North End, Portsmouth, on February 25, aged 27.
- McMATH, ALEXANDER, M.D., Q.U.I., at Benin, West Coast of Africa, on December 2, aged 33.
- MEDCALF, GEORGE, M.R.C.S. Eng., at Richmond-road, Dalston, on February 26, aged 33.
- MITCHELL, JOHN, L.F.P.S. Glasg., at Kilmarnock, Ayrshire, on February 14, aged 46.
- NEWTON, THOMAS, M.R.C.S. Eng., at Knayton, Thirsk, Yorkshire, on February 22, aged 60.
- O'BRIEN, CHARLES G., L.F.P.S. Glasg., at Lymm, Cheshire, on February 24, aged 70.
- SIMPSON, THOMAS, M.D. Edin., at Minster-yard, York, on February 28, aged 75.
- WILLIAMS, THOMAS, M.R.C.S. Eng., at Temple-row, Birmingham, on February 26, aged 53.

**ACADEMIE DE MEDECINE.**—The recent election into the section of Hygiene and Legal Medicine has terminated in favour of M. Lélut, who obtained 43 votes, 66 electors being present

**NON-INFLAMMABLE FABRICS.**—MM. Westermann and Oppenheim, at the last meeting of the *Académie des Sciences*, laid on the table several specimens of articles of clothing rendered unflammable. They state that they communicated their researches to a society as far back as 1859; but that they do not attach any importance to this priority, as they were only following in the footsteps of Gay-Lussac. As the result of their experiments, they find that three salts unite the requisite conditions,—cheapness, facility in their employment, and harmlessness to the tissue itself or the colours which cover it. These are the sulphate and phosphate of ammonia, and the neutral tungstate of soda. The last is preferable to the others when the articles have to be frequently washed. It is mixed in water in the proportion of 20 per cent., and the solution is used as in starching.

**BIRDS AS DESTROYERS OF INSECTS.**—A distinguished naturalist, M. Florent Prévost, conceived the idea that it would be a matter of great interest to collect, at different periods of the year, the stomach of every description of bird he was enabled to procure, and to examine and preserve its contents. This collection, commenced thirty-five years since, has now reached a considerable size. The stomachs, opened and dried, together with their contents, are fixed on cardboard, upon which are inscribed, besides the name of the species of the bird, the indication of the locality and the date of its death, together with the names of the animals or plants which have been recognised as forming part of the contents of its stomach. It results from these researches that birds are in general far more useful than hurtful to the agriculturist, and that the mischief done at certain periods by the granivorous species is largely compensated by the consumption of insects they effect at other periods.

**THE POPULATION OF GREECE.—RACE v. FAITH.**—“Nationality cannot exist on the sole basis of a common creed. Even the scattered Jews, in many leading features the first-cousins of the so-called Greeks, combine race with religion, and we fix nationalities by the test of race, not of faith. But in Greece we find the bullet-headed Albanian without an occiput; the flat-face and heavy-limbed Sclavonian; the sharp-eyed and hooked-nose Sciot, betraying the orientalism of his origin; the comparatively fair and handsome Islander, whose features remind us of Genoa and Venice; the dark and sombre Cephalonian from Acarnania; the piratical Mariot; the Italianised Zantiot,—all utterly different in physical conformation, speaking brokenly a broken language, or idioms of it so varied as to be scarcely intelligible to each other, and the early habits and education of whom have been widely different. This heterogeneous mass, collected under one common banner, and held together by no stronger tie than that to them very loose one of superstition to which the Oriental Church has become practically degraded by the channels through which its stream has flowed—this spontaneous concourse of atoms presumes to dub itself a nation. In such a nation there can be no feeling of patriotism, even according to its lowest definition, no community of feeling or interest, no unity of action. It is a continuous struggle of man against man, for every man is of a different race and of different associations. Centuries must pass before such elements will be, if ever they can be, amalgamated. However unwillingly, we must abandon all hopes of a nation without nationality, and which has no claim to our regard but that of being the recent occupiers of a once classic soil.”—*Standard*.

## NOTES, QUERIES, AND REPLIES.

*He that questioneth much shall learn much.*—*Bacon*.

- A. B. C.—1. It is not usual for Medical men to take fees of each other.  
2. We doubt whether such a claim could be legally resisted.

We are informed that Mr. Propert has made no further communication to Mr. Adams or his friends in explanation of his alleged encouragement of the Russells. The heaviest charge against Mr. Adams was that of *indiscretion*—of allowing himself to be imposed upon in a manner derogatory to a man of sense, accustomed to the world, and having the dignity of a Profession to support. We regret that Mr. Propert should lay himself open to a similar charge.

We have received the two first numbers of “*L’International*,” a cheap family French newspaper, published in London, and devoted to free trade and liberal ideas of the Imperial cast. We wish it all success.

The following lines will be recognised as proceeding from the pen of one of the most popular and accomplished Physicians of the day:—

“THE MARRIAGE OF THE PRINCE OF WALES WITH THE PRINCESS ALEXANDRA OF DENMARK.

“After the darkest night comes glorious morning,  
When sunbreak bursts from out the golden sky,  
With every beauty the fresh Earth adorning,  
The glittering sea, and glowing clouds on high.  
A night of sorrow on our land has rested,  
But now the coming day is seen to dawn;  
The heart is not of its regrets divested,  
Although a veil o’er its regrets be drawn.

“The morning opens cloudless and all glorious;  
The shadows of the night fast fade away;  
Love, Hope, and Joy o’er every ill victorious,  
The nation holds high jubilee this day.  
With love and loyalty each heart o’erflowing,  
All hail the Nuptials of the Royal Pair;  
Deepest devotion to our Sovereign showing,  
While Denmark’s Daughter weds with England’s Heir.

“Hail, Alexandra, first of Denmark’s daughters,  
Hail, lovely Princess, now Great Britain’s pride;  
Welcome a Danish fleet in British waters,  
That brings to England’s shore our Prince’s Bride.  
Joy to thee, youthful Prince! May truest glory  
Around thy Royal brow be ever seen,  
Until thy name shine forth in future story  
Worthy of thy Great Sir and our Good Queen.

“A Jubilee of Nations! Each rejoices  
As with exultant shouts we rend the air,  
Or join in reverential tone our voices,  
To ask for blessings on that youthful Pair.  
Each joy of Earth be granted without ceasing,  
Each gift that Heaven on mortals can bestow,  
Until, their happiness each day increasing,  
No more is left to wish for here below.

“May England’s Star, still glorious and ascendant,  
In Freedom’s frontlet ever foremost shine,  
Showing to all who would be independent  
How Law with Liberty man must combine.  
A nation, as one brotherhood, united,  
Who guard a Regal Right even as their own;  
A Land where Wrong is still by Justice righted,—  
A People bound by Freedom to the Throne.

“Torquay, March 10, 1863.”

THE MEETING IN THE CASE OF RUSSELL v. ADAMS.  
TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I shall feel obliged by your allowing me to correct an error in your report of the meeting respecting the case of Russell v. Adams in your impression of Saturday last.

At the close of the offensive observations of Dr. Rogers, you state that “the speaker was called to order by the chairman.” Such was not the case. It was because he did not do so, and that the offensive observations were tacitly acquiesced in by this meeting, that I felt called on to make the remarks I did. That the chairman did not call Dr. Rogers to order is proved by the fact, that in interrupting me he said, that if the allusions “had been made with a personal application he would have called the speaker to order.”

I feel bound to state that after the close of the meeting I received the hearty congratulations of nearly three-fourths of those present. In justice to me I hope you will give insertion to this note. I am, &c.

30, Upper Montagu-street, W., March 4.

WILLIAM O’CONNOR.

THE CASE OF HUGH RANKIN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Seeing a brief notice in your valuable paper of the 7th inst. respecting the case of Hugh Rankin, of this place, who was convicted at the last assizes at Newcastle for a criminal assault on Mary Brister, a child, 11½ years of age, in which you desire to know to what examination the stains on the filthy garment produced in court had been subjected, I am induced to forward this communication to you.

I was employed to examine the prisoner, and of course had no opportunity of examining the child’s linen, but the Medical witness for the prosecution distinctly stated that he was unable to say whether the stains were produced by gonorrhoea or from a disease to which female children were liable from natural causes. When I examined the accused, about ten days after the alleged assault was said to have been committed, instead of finding him suffering from gonorrhoea (under which he was said to be labouring), I merely observed a slight moisture at the mouth of the urethra, and a little redness around its lips. This led me to suspect that he was afflicted with stricture, and on requesting him to urinate, saw at once, from the forked character of the stream of water, that he had an obstruction in the passage.

As the prisoner had been some years in India with his regiment, I was led to believe that the stricture might have been of several years’ standing, and that it was exceedingly doubtful whether he could have communicated disease to the child, whose evidence was given in such a bold, immodest manner, that I cannot but regret that the accused was condemned on testimony apparently so little deserving of credit.

As it is a matter of the greatest importance, will you kindly give your opinion, whether you consider a man in the situation of Hugh Rankin capable of communicating gonorrhoea; for if the testimony of a precocious child is taken as evidence of guilt, no man will be safe. I am, &c.

Alnwick, March 10.

THOS. BRADLEY.

THE PURTON SPA WATER IN PSORIASIS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have just had my attention directed to a letter in the *Medical Times and Gazette* of the 24th of January last, from the pen of Dr. Moriarty, giving the history and treatment of a case of psoriasis inveterata, in which the following passage occurs:—“From long observation I have come to the conclusion that the only medicines deserving of a trial in this disease, as well as lepra, are Fowler’s solution and quinine.”

Having lately had a case of psoriasis in veterata, or lepra vulgaris (which I prefer to call it), under my care here, which I have successfully treated by the Purton sulphated and bromo-iodated saline water, it may be interesting to Dr. Moriarty and many of your readers if I briefly relate the history of the case, which I prefer to do in the words of the patient himself, who is a gentleman of high position and scientific attainments:— I am fifty-eight years of age, and have always enjoyed pretty good health. I have never suffered from dyspepsia. It is twenty years ago that I first observed some red, scaly spots on my arms, and some months after this they appeared on my legs and thighs, and subsequently on my back, particularly my shoulder-blades and buttocks. The scalp of my head then became involved. It has gone on spreading, but more particularly during the last twelve months, and now the greater part of my person is affected with this scaly eruption. From the commencement of the disease till I came to Purton I have had the best of Medical advice, in France as well as England, without deriving benefit. I have taken sarsaparilla, then on to dulcamara, arsenic, with vegetable tonics, arseniate of potash and soda, iodide of potassium, chloride of mercury, oxysulphuret of antimony, etc. He was advised by H. W. Rumsey, Esq., of Cheltenham, F.R.C.S., to go to Purton and try the mineral water, which he commenced to do in June last, and by the middle of the month of December the disease had entirely disappeared; and I am pleased to say that he remains well at the present time. He has just written a pamphlet, entitled, "Six Months at Purton Spa, etc.," published by Hamilton, Adams and Co., London.

Purton, Swindon, Wilts. I am, &c. SAMUEL C. SADLER, F.R.C.S.

THE TREATMENT OF SKIN DISEASES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Knowing the extensive circulation of your valuable journal, I take this opportunity of placing before the members of the Profession, through its columns, certain facts, in order that those whose province it may be to treat cutaneous diseases may have an opportunity of testing the correctness of the statements, and reporting accordingly.

Case 1.—Psoriasis Palmaris, of Five Years' Duration, Cured by Vaccination, November, 1861.—A. B., aged 25 years, robust conformation of body; temperate habits; not the subject of scrofula; has had psoriasis palmaris for a period of five years, subject to occasional improvement of the disease under various methods of treatment, but never entirely free from the disease, which presented the annulated character,—red, dry, cracked, and exfoliating, and extending from the wrists to the fingers. During a sojourn in the Southern states, the action of various alteratives, such as iodide of potassium, bichloride of mercury, iodide of iron, as well as the triple solution of mercury, iron, and arsenic had been well tested. As a *dernier ressort*, I resolved upon vaccination, in order to observe the alterative effect of the vaccine virus upon his system, not without previous consideration, but with a firm conviction that, under certain circumstances, vaccine introduced into the system is one of the most powerful blood-purifiers we possess. The operation was successfully performed, the pustule passing through the various stages from incubation to its separation. Having carefully observed its progress, I found that, as it advanced from the third to the seventeenth day, the disease on the hands and fingers gradually receded, and, on the twentieth day from the date of vaccination, the parts recovered their natural appearance and continued so. Was successfully vaccinated when a child.

Case 2.—Tinea Nummularis seated on the right fore-arm; boy, aged 13 years, of florid complexion, vigorous habits of body, and healthy parentage. This disease existed over two months, and covered a space about two square inches near the front aspect of wrist-joint. Vaccinated on the opposite arm; operation successful. About the seventeenth day the disease disappeared, no other treatment having been adopted. Was previously vaccinated when one year old.

Case 3.—J. S., aged 25 years, a somewhat stout man, with fair skin, temperate habits, and non-scrofulous aspect. States that three months ago he had an indurated chancre, and eight weeks afterwards observed an eruption on the face, and more or less over the entire body. December 15, 1862, came under my charge, when the case was well marked "tubercula syphilitica," round, small, and of a copper colour, and possessing more or less density and elevation. Vaccinated on the arm successfully, and on the fourteenth day afterwards the tubercles over the whole body flattened down, and at the end of four weeks only a slight discoloration of the skin, at several points where the eruptions were worst, could be observed. From this date he went on gradually improving in general health under the influence of tonics.

Case 4.—Psoriasis Lepraformis.—S. G., aged 24 years, married, and the mother of four healthy children. July, 1862, first observed what was termed a "rash" on the elbow-joints, subsequently on the knee-joints, from which points, within a period of three months, it extended more or less over the entire body, even to the roots of the hair. November 10, 1862, I was first consulted, and placed her under the action of the usual alteratives for three weeks without any marked improvement. January 2, 1863, vaccinated successfully over a clear part of the skin on left arm. As the pustule passed through the successive stages, the eruption gradually disappeared, and the skin recovered its previously healthy aspect, about four weeks having elapsed from the date of vaccination to the disappearance of the disease *in toto*.

Various other cases illustrative of the effect which vaccine produces upon the system, as an alterative, might be cited. However, on the present occasion I consider the above cases sufficient evidence that the simple process of vaccination should not be confined alone to its protective influence against small-pox, but also extended to the treatment of many cutaneous diseases, not of parasitic origin, but arising from irritant poison, generated in the organism or in that vital fluid, the blood. Over such existing impurities, vaccination, beyond a doubt, possesses a powerful influence. Such facts prove nothing unfavourable to the claims of vaccination as a protective agent against small-pox; they prove only that which each day's experience tends to corroborate, namely, "that man has still much to learn."

Trusting that this point may merit the attention of the leading dermatologists, to whom we Canadians look forward for an expression of opinion such as can alone be formed from an enlarged experience,

I am, &c.

APPOINTMENTS FOR THE WEEK.

March 14. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m. ROYAL INSTITUTION, 3 p.m. Professor Max Müller, "On the Science of Language."

16. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m. MEDICAL SOCIETY OF LONDON, 8½ p.m. Clinical Discussion—The President, "A Case of Successful Excision of the Elbow-joint;" Dr. Greenhalgh, Dr. W. Abbotts Smith, Dr. Gibb, and Mr. Henry Lee; and other Communications.

17. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m. ETHNOLOGICAL SOCIETY, 8 p.m. Robert Swinhoe, Esq., "Ethnological Notes on Formosa." John Crawford, Esq., "On the Commixture of Races—Western Asia." PATHOLOGICAL SOCIETY, 8 p.m. Meeting. ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Mechanics."

18. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m. ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 p.m. Lumleian Lectures—Dr. Chambers, "On Formation of Mucus and Pus."

19. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopaedic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m. HARVEIAN SOCIETY, 8 p.m. Dr. Sanderson, "On Asthma." ROYAL INSTITUTION, 3 p.m. Dr. E. Frankland, "On Chemical Affinity."

20. Friday.

Operations, Westminster Ophthalmic, 1½ p.m. ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 p.m. Lumleian Lectures—Dr. Chambers, "On Formation of Mucus and Pus." WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON, 8 p.m. Mr. Rouse, "On Rheumatic Iritis." ROYAL INSTITUTION, 8 p.m. Balfour Stewart, Esq., "On Magnetic Forces."

### No. 12, Ward's Patent Albert

Lounging Chair, the most simple and luxurious extant, is fitted for the Drawing Room, Boudoir, Cabin, or Camp; is made in Wood, Iron, or Brass, and folds into a small compass for shipment. From 4½ Guineas.

No. 17, a Four-wheel Victoria Pleasure-ground Chair, mounted in a very light Iron-framed Carriage, upon C and patent India-rubber Springs, is either drawn by Hand or Animal, and is the most elegant and easiest Chair made. No. 16, a ditto, upon three wheels, mounted same as four wheels, on C and India-rubber Springs.

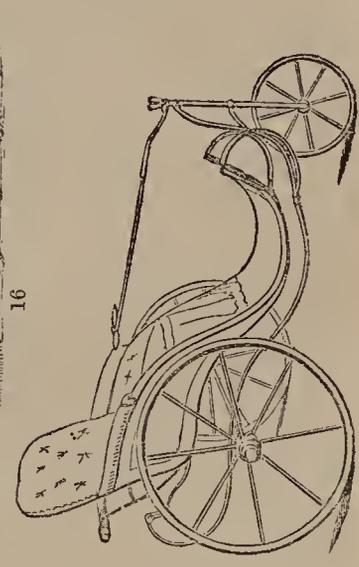

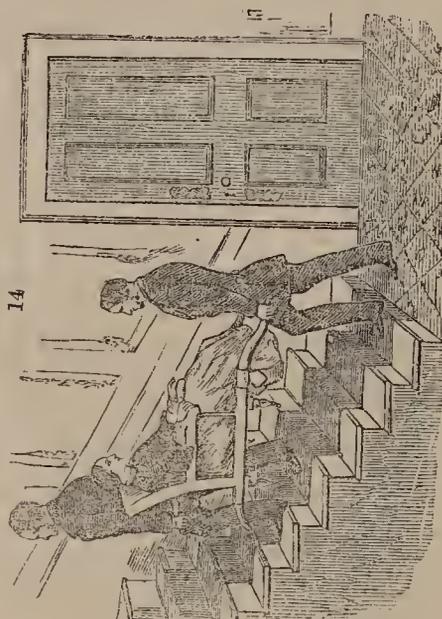

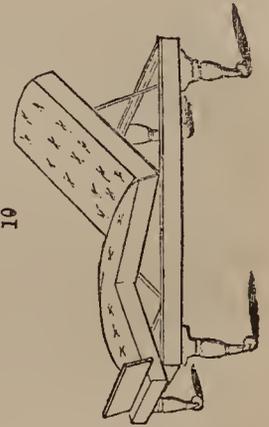

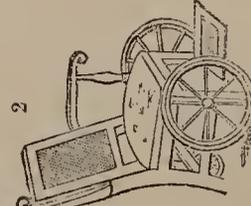

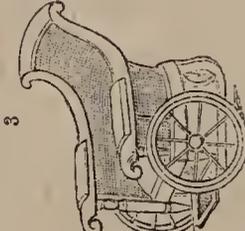

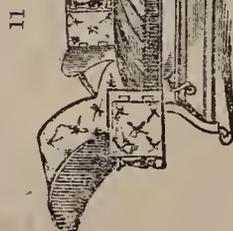

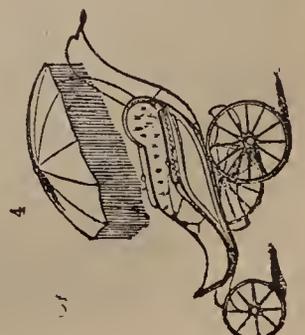

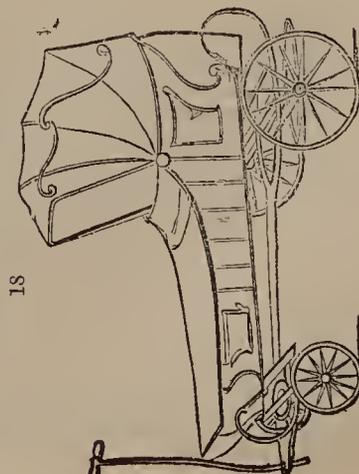

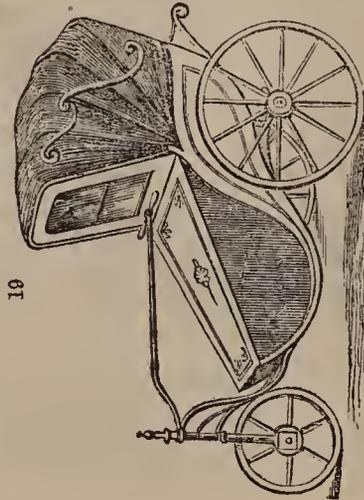

No. 19, a Bath Chair, with Leather Head, and Folding German Shutter.

No. 18, a Sofa Britska Spinal Carriage, with the inside Tray made to take out and in, on which an Invalid may be taken from her room to the carriage.

No. 8, Ward's Improved Operating Dentist Chair, suitable for a Child or Adult.

No. 14 is the simplest and best-constructed Chair for carrying Invalids up and down stairs, the lower handles for level ground, the upper ones for ascending or descending a staircase: the sketch conveys the exact idea: it is also made portable for travelling. Several other kinds are always in stock, upon various principles.

N.B.—The largest Assortment in the World of INVALID CHAIRS, CARRIAGES, CRUTCHES, and BEDS always on hand, for Sale or Hire. Established more than a Century.

### Nos. 10, 10, 10, sketch of Earl's

General Invalid Couch or Bed, made with or without a Convenience; it adjusts the back seat and legs to any given position by means of machinery, and is recommended by the Faculty as being the most complete Bed ever made for confirmed Invalids, or for Fractured Limbs. No. 11 is Ward's Patent Reclining Chair, with Shifting Elbows for more easily getting on and off the Chair when the leg-rest is drawn out, as shown in the drawing. No. 7 is an elegant Patent Recumbent Chair.

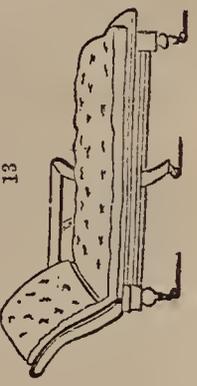

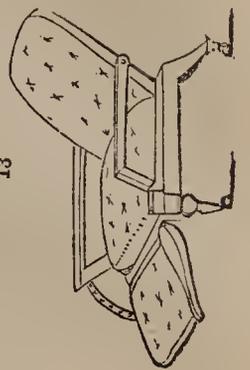

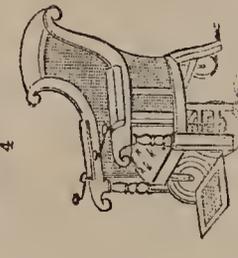

Nos. 13, 12, is a Couch-Chair or Bed invented by Dr. Hester, and may be placed in any position by the Invalid without the assistance of a second person.

Nos. 2, 3, and 4, are all Self-Propelling Chairs, upon the best and most scientific principles; either may be used by a child eight years of age with perfect ease.

No. 24, Ward's Improved Child's Perambulator, with Patent Parasol. A variety always on hand.

No. 7 is an elegant Patent Recumbent Chair.

ORIGINAL LECTURES.

PROFESSOR HUXLEY'S LECTURES  
AT THE  
ROYAL COLLEGE OF SURGEONS.

LECTURE II.

(Being the First of Six Lectures on Classification.)

(Continued from page 262.)

THE next group upon our list is the division of the Infusoria; and here, again, within the last few years, most prodigious strides have been made in our knowledge of the subject. Although the Infusoria have been favourite studies for many years, still it is only within the last few that our knowledge of the complete cycle of life of these animals has been made known, and that we have become acquainted with the true sexual process as it occurs in them.

FIG. 4.

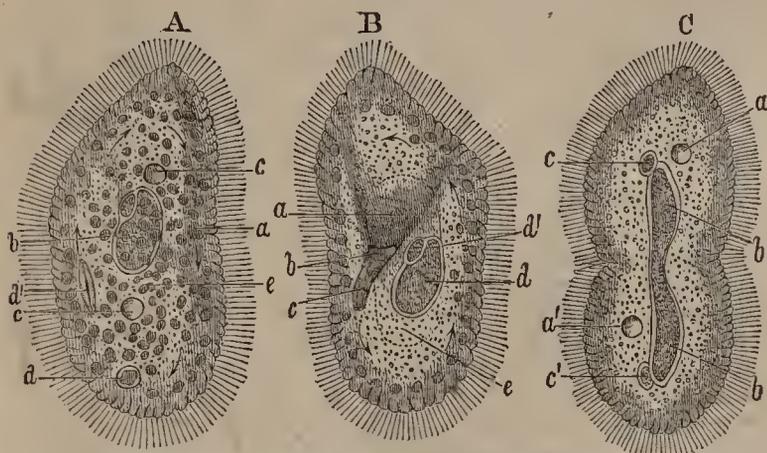

FIG. 4.—*Paramœcium bursaria* (after Stein): A, The animal viewed from the dorsal side; a, cortical layer of the body; b, "nucleus;" c, contractile space; d d', matters taken in as food; e, chlorophyll granules. B, The animal viewed from the ventral side; a, depression leading to b, mouth; c, gullet; d, "nucleus;" d', "nucleolus;" e, central sarcode. In both these figures the arrows indicate the direction of the circulation of the sarcode. C, *Paramœcium* dividing transversely; a a', contractile spaces; b b, "nucleus" dividing; c c', "nucleoli."

The different species of the genus *Paramœcium* are very common among the microscopic inhabitants of our fresh waters, swimming about by means of the vibratile cilia with which the whole surface of their bodies is covered; and the structure which essentially characterises these animals is that which is common to the whole of the Infusoria, so that a definition of the leading structural features of *Paramœcium* is, in effect, a definition of those of the group. Imagine a delicate, slipper-shaped body enclosed within a structureless membrane or *cuticula*, which is formed as an excretion upon its outer surface. At one point (Fig. 4, B a) the body exhibits a slight depression, which leads into a sort of little funnel (b c) lined by a continuation of the same cuticular investment, which stops short at the bottom of the funnel. The whole of the bag formed by the cuticula is lined by a soft layer of gelatinous matter or "sarcode," which is called the "cortical" layer (Fig. 4, A a); and then inside that, and passing into it quite gradually, there being no sharp line of demarcation between the two, is a semifluid substance, which occupies the whole of the central region of the body. Neither in the cuticle, the cortical layer, nor the central substance has any anatomist yet discovered the slightest differentiation into cellular layers, nor any trace of that histological composition which we meet with in the tissues of the higher animals; so that here is another case of complex vital phenomena proceeding from a substance which, in a histological sense, is structureless. At two points of the body (Fig. 4, A c c) the substance of the cortical layer exhibits a remarkable power of contraction and dilatation. If you watch one of those points, the sarcode suddenly seems to open like a window, and for a while a clear space is visible, which then quite suddenly shuts again. After a little time the same diastole and systole are repeated. As the systole takes place, it is possible occasionally to discern certain radiating canals, which extend from the cavities into the surrounding sarcode,

and then disappear again before diastole occurs. There is no doubt that the clear space is a chamber filled with fluid in the cortical layer, and as good observers maintain that there is an aperture of communication through the cuticula between this space and the exterior, this fluid can be little more than water. Perhaps the whole should be regarded as a respiratory or secretory apparatus. It is an organ which in one shape or another is eminently characteristic of the Infusoria. Besides this singular apparatus, there is embedded in another part of the cortical layer a solid mass, of an elongated oval shape (Fig. 4, A B d), which has been called the nucleus (though it must be carefully distinguished from the "nucleus" of a cell). Then upon one side of this there is, as it were, stuck on to it, a little rounded body (Fig. 4, B d'), which has received the name of the "nucleolus." The animal swims about, driven by the vibration of its cilia and whatever nutriment may be floating in the water is appropriated by means of the current which is caused to set continually into the short gullet by its cilia.

But it is a most singular circumstance that you have here an alimentary canal consisting of a mere gullet, open at the bottom, and leading into no stomach or intestine, but directly into the soft central mass of sarcode. The nutritious matters pass down the gullet, and then into the central more fluid substance, become surrounded by a spheroid of clear liquid (Fig. 4, A d), consisting apparently of the water swallowed with them, so that a well fed *Paramœcium* exhibits a number of cavities, each containing a little mass of nutritious particles. Hence originally arose the notion that these animals possessed a number of stomachs. It was not unnaturally imagined that each of the cavities in question was a distinct stomach, but it has since been discovered that the outer layer of the sarcode is, by means of some unknown mechanism, kept in a state of constant rotation, so that the supposed stomachs may be seen to undergo a regular circulation up one side of the body and down the other. And this circumstance, if there were no other arguments on the same side, is sufficient to negative the supposition that the food-containing spaces are stomachs; for it is impossible to imagine any kind of anatomical arrangement which shall permit true dilatations of an alimentary canal to rotate in any such manner. Fæcal matters are extruded from an anus which is situated not far from the mouth, but is invisible when not in use. It is an interesting and important character of the *Infusoria* in general that under some circumstances they become quiescent and throw out a structureless cyst around their bodies. The infusorium then not unfrequently divides and subdivides, and, the cyst bursting, gives rise to a number of separate infusoria.

The remarkable powers of multiplication by fission and gemmation which many of the group possess are well known; but within the last two years the investigations of Müller, Balbiani, Stein, and others, have shown that these minute creatures possess a true process of sexual multiplication, and that the sexual organs are those which have been denominated nucleus and nucleolus. The nucleus is the true ovary—the nucleolus the testis, in *Paramœcium*. At particular times the latter increases very much in size, and its substance becomes broken up into rod-like bodies, which represent spermatozoa. Two infusoria in this condition become conjoined, and the nucleolus (now become a spermatic capsule) of each passes into the body of the other. The spermatic filaments are said to enter the nucleus, which then enlarges, and either divides into, or gives off, a number of rounded germs, which become oval ciliated bodies provided with long processes. These make their way out of the body, and, it is believed, are metamorphosed directly into young *Paramœcia*. But, perhaps, further information is required before we can be quite certain on this point.

In giving an account of these lowest forms of animal life, I have substituted for a definition of each class a description of the structure of some particular member of that class, or of the organic features which are most obviously characteristic of the class; because, in hardly any group has the structure of many and widely-different members been thoroughly and exhaustively worked out.

I entertain little doubt, however, that the main features of the description of *Spongilla* might substantially be taken as a definition of the *Spongilla*, and those of the description of *Paramœcium* as a definition of the *Infusoria*. On the other hand, we possess no such complete knowledge of the vital cycle of any *Gregarina* or *Rhizopod*, and neither description nor defini-

tion of the corresponding classes, of a thoroughly satisfactory kind, is attainable.

No such difficulties beset us in studying the next class, the *Hydrozoa*, which may be defined with as much precision as any group in the animal kingdom.

All the *Hydrozoa* exhibit a definite histological structure, their tissues primarily presenting that kind of organisation which has been termed cellular. Again, the body always exhibits a separation into at least two distinct layers of tissue—an outer and an inner—which have been termed respectively *ectoderm* and *endoderm*. The endoderm is that layer which lines the inner cavities of the body from the mouth inwards; the ectoderm is that which forms its external covering.

These two layers are shown in the accompanying diagrammatic sections of the leading forms of *Hydrozoa*, the ectoderm being represented by the thin line with the adjacent clear space, the endoderm by the thick dark line.

FIG. 5.

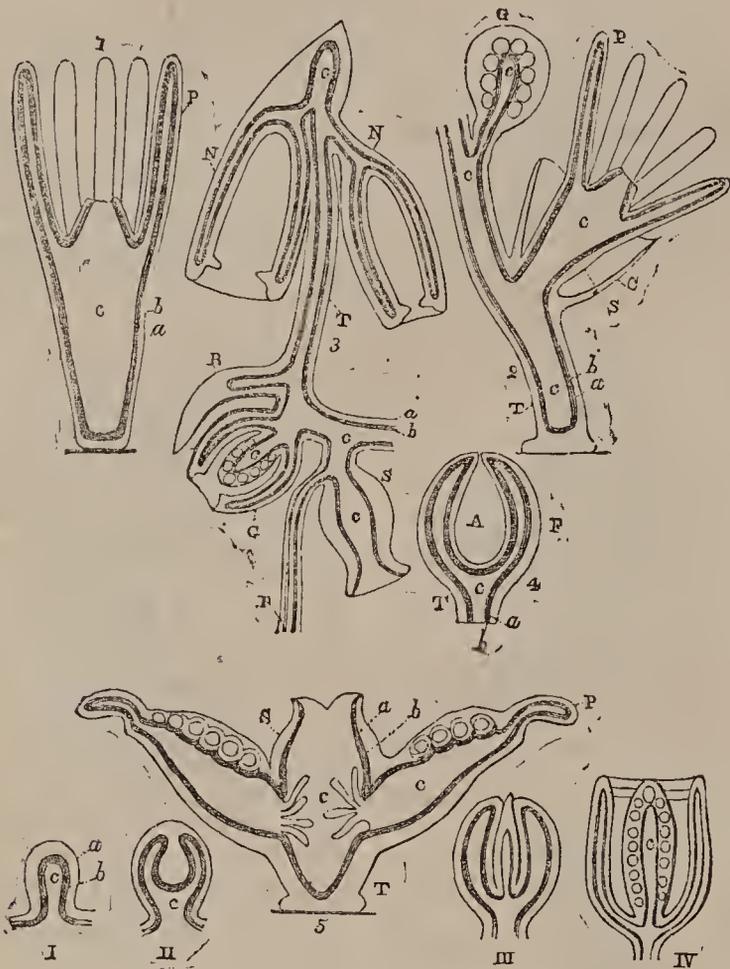

FIG. 5.—Diagrams illustrative of the mutual relations of the *Hydrozoa*.—1. Hydra. 2. Sertularian. 3. Diphyes. 4. Physophorid. 5. Lucernaria. a. Ectocyst. b. Endocyst. c. Their enclosed cavity.

P. Tentacles. N. Natatorial organ. T. Coenosarc. B. Bract. C. Cell. S. Polype. G. Reproductive organ. A. Air Vesicle. F. Float.

I., II., III., IV. represent the successive stages of development of a Medusiform zooid or reproductive organ.

A third distinctive character of the *Hydrozoa* is, that the digestive cavity communicates directly by a wide aperture with the general cavity of the body, the one, in fact, passing by direct continuity into the other. Furthermore, the digestive sac is not in any way included in the substance of the rest of the body, but stands out independently, so that the outer wall of the digestive cavity is in direct contact with the water in which the animal lives, and there is no perivisceral chamber; and the like is true of the reproductive organs, which may vary very much in form, but have the common peculiarity of being developed as outward processes of the body wall, so that their outer surfaces are directly in contact with the surrounding medium.

No nervous system has yet been discovered in any of these animals. The majority of them seize their prey by means of tentacula developed either around the mouth or from the walls of the digestive cavity, or from the body wall, and these tentacles, as well as other parts of the body, are provided with those peculiar weapons of offence which have been termed "thread-cells."

## A CLINICAL LECTURE

ON THE

## DIAGNOSIS OF HERNIAL AND OTHER TUMOURS OF THE GROIN AND SCROTUM.

DELIVERED AT THE

Westminster Hospital.

By CARSTEN HOLTHOUSE,

Surgeon to the Hospital, and Lecturer on Surgery in the Medical School.

(Continued from page 131.)

GENTLEMEN,—The tumours in the scrotum which bear some resemblance to hernia are hydrocele, hæmatocele, varicocele, sarcocele, and other solid tumours of the testis; and in the labium cysts and chronic abscesses. Although at first sight it would seem almost impossible to confound any of these diseases with hernia, experience proves the contrary; and what has happened before may happen again, so I will briefly call your attention to the chief points which should engage your attention in forming a diagnosis.

Recollect, in the first place, that most herniæ are reducible; it is only irreducible herniæ, therefore, which are liable to be mistaken for the diseases just mentioned. And first as to hydrocele. This is so common and so simple a disease that it is usually one of the first which a student learns to diagnose, and the fluctuation and translucency of the swelling, its pyriform shape, and its commencing at the bottom and not at the top of the scrotum, are at once pathognomic of the affection. But this *ensemble* of symptoms is not always present, nor are they always unequivocal; the patient's evidence, for example, as to whether the swelling began at the bottom or the top of the scrotum, can rarely be implicitly relied on. The fluctuation, likewise, as I told you in my last lecture, may be simulated by certain solid tumours, or may be so obscure as to afford us little aid in diagnosis; even the translucency is not invariably present, nor, when present, is it always indicative of fluid. A thickened condition of the tunica vaginalis, or the dark colour of the contained fluid, may interfere with the transmission of light; while a knuckle of intestine may be so distended with flatus, and the skin of the scrotum so thin, as readily to transmit it. Arnaud and Teale both relate cases of scrotal enterocele which, from these causes, were as translucent as an ordinary hydrocele. But there is another source of fallacy: if the hydrocele be so large as to extend into the inguinal canal, not only will it resemble a hernia in shape, but it will also have an impulse communicated to it on coughing, because the part within the canal will be compressed between the abdominal muscles. A hydrocele, then, may be so large as to resemble a hernia in its shape, and in having an impulse communicated to it on coughing; its coats may be so thick and so tense as neither to transmit light nor to fluctuate; while its history may be so doubtful as not to be depended on. None of the symptoms of hydrocele, then, which are usually enumerated, are in every case so unequivocal as to be absolutely pathognomic of the disease; but there is one other sign which, taken in conjunction with those already mentioned, renders its diagnosis certain, and that is, dulness on percussion. It seems extraordinary that this simple test of percussion should not have been pointed out by any English author; yet, with the exception of Teale, no English Surgeon even alludes to it as a means of distinguishing hydrocele from scrotal enterocele, or the reverse.

I will now give you an example of a scrotal hernia which was mistaken for hydrocele and punctured, which came under my notice a few years ago:—J. C., aged 43, was admitted into this Hospital, in 1856, with a large scrotal tumour. He complained of having some pain in it, said his bowels had not been opened for three or four days, and that he had had vomiting. His face was pale; his pulse 120, and feeble. Two strips of plaster, placed X in front of the scrotum, concealed a puncture which had been made by a Surgeon prior to his admission. Some fluid, he says, came away, and some dark-coloured liquid was afterwards injected. He died thirteen hours after his admission, gradually exhausted by repeated vomiting. The post-mortem examination revealed a perfectly healthy condition of all the viscera, except those within the hernial sac. This contained the cæcum, and from two to three feet of the lower end of the ileum, glued together and

to the walls of the sac by recent lymph; this likewise covered the whole of the inner surface of the sac, but did not extend to the abdominal peritoneum. No portion of the bowel which formed the hernia was in any way constricted, nor had it any marks of strangulation, nor had it given way at any part. In fact it was obvious to all present, that the poor fellow had died from the effects of injecting tincture of iodine into his hernial pouch under the supposition that it was a hydrocele. Had the simple test of percussion been had recourse to in this case, the patient's life would not have been sacrificed. Hæmatocele, as you know, differs from hydrocele in blood being the fluid which is effused into the tunica vaginalis, and its symptoms will differ from a hernia according as the latter is composed of bowel or omentum. In the former case the tumour would be lighter than a hæmatocele, resonant on percussion, and have an impulse on coughing; in the latter case, the tumour, although heavy, non-translucent, and dull on percussion, and therefore so far resembling an hæmatocele, would differ from the latter in its history, in its not fluctuating, and in its occupying the inguinal canal as well as the scrotum. This last symptom, however, requires investigation, because a hæmatocele, when large, will also extend into the canal, as we saw was the case with hydrocele under the same circumstances. As a further aid to the diagnosis of hydrocele, hæmatocele, and scrotal epiplocele, you should also bear in mind the following facts:—Hydrocele and scrotal epiplocele are essentially chronic affections; hæmatocele is acute, and generally due to traumatic causes. An epiplocele would take some time to reach the bottom of the scrotum, and a hydrocele some time to reach the top so as to distend the inguinal canal; a hæmatocele, on the contrary, commences at the bottom, and rapidly ascends till it reaches the inguinal canal.

A patient was admitted under the care of Dr. Radcliffe, on November 23, 1858, suffering from chronic bronchitis and ascites; he had also hydrocele of the left tunica vaginalis, and a varicose condition of the hæmorrhoidal veins, and of the superficial veins of the leg. On December 7, at the request of Dr. Radcliffe, I tapped the hydrocele, and drew off about twelve ounces of fluid. A week afterwards some blood was observed to come from the puncture, and the scrotum, which, after the operation, had much diminished in size, had become larger than it was before the tapping. Fœtid gas also escaped from the aperture on pressure. Under these circumstances, I made an incision an inch and a-half long through the anterior wall of the scrotum, and turned out a large quantity of clotted and decomposed blood. This, and the application of ice to the scrotum, did not prevent the re-accumulation of the blood, which also became effused into the right vaginal sac, filling it to distension. The whole scrotum was now very large, and both inguinal canals very prominent, so that any one unacquainted with the case would, in all probability, have pronounced it a double scrotal rupture, which, indeed, it very much resembled. The sequel of this case is not less curious:—On December 26 the patient died; but, three or four days previous to this event, the scrotum had resumed its normal size and aspect, and the walls of the abdomen had become perfectly flaccid, all traces of fluid having disappeared both from the vaginal and peritoneal cavities. No post-mortem examination was permitted.

A varicocele is one of those diseases said to resemble hernia, though I cannot say I ever saw them confounded with each other, nor do I think they could be by any but a mere tyro in the Profession. The particular form of hernia supposed to bear a resemblance to varicocele is scrotal epiplocele. Now you know that this would be situated *in front* of the cord and testis, and would not have that "bag of worms" feel which is so characteristic of varicocele; nor could it descend again into the scrotum, after reduction, so long as pressure was kept up over the external abdominal ring. If the hernia were irreducible, which I am all along assuming, the position of the patient would exercise no influence over it, while a varicocele would disappear when the patient was recumbent, but reappear when he stood up, notwithstanding pressure were made over the external abdominal ring.

Enlargements or tumours of the testicle may be distinguished from herniæ by their solidity and weight, by their history, by the absence of all other structures from the scrotum, and by the undistended condition of the inguinal canal.

Hitherto I have assumed that you had to deal with one of the diseases I have named uncomplicated with any other, and

I have pointed out to you how you are to distinguish such cases from hernia; but you would be wrong in supposing these diseases are always met with in this simple form. It is by no means unfrequent to find two or more of them combined in the same patient,—hernia and hydrocele, for instance, sarcocele and hydrocele, or hydro-sarcocele, as it is termed; and these combinations sometimes make it difficult to form a certain diagnosis at first sight, so that you are obliged to rest satisfied for a time in determining what the tumour is not, rather than what it actually is; this negative evidence is, however, often of great value, especially where an operation is in question. If, for instance, some of the symptoms of strangulated hernia were present in connexion with a tumour in the scrotum, could it be determined that, whatever might be the nature of the tumour, it was certainly not a hernia, a great positive advantage would be gained,—the advantage, namely, of not subjecting the patient to a needless and dangerous operation. And here I must go a little out of my way to caution you against being in too great a hurry to operate. I do not mean in the cases just alluded to, where the nature of the tumour was doubtful, but in many cases even of undoubted hernia. I was called up by a Surgeon a few nights ago to see a case of strangulated hernia, and was requested to bring my instruments with me, as he thought there was no time to be lost. I found a tolerably large scrotal rupture; it was tense and somewhat sensitive to handling, and attended with a sensation of dragging in the abdomen. The patient had been the subject of hernia for many years, but had always been able to reduce it till about fourteen hours before I saw him; from this time all the efforts both of himself and his Surgeon had proved unavailing. I put him under chloroform, and tried the taxis for about fifteen minutes, but was not successful in returning the rupture. I declined, however, to operate, because there were really no symptoms of strangulation present; the hernia was for the time irreducible, but it was not strangulated; a pill of two grains of opium was therefore prescribed, and ice was directed to be applied to the tumour. Before eight o'clock the next morning the hernia had gone back of its own accord.

Another case bearing on this practice, and also illustrating some of the difficulties which occasionally beset the diagnosis of scrotal tumours, is the following:—J. S., aged 54, was admitted into Henry Hoare Ward, on the morning of the 8th of October, 1859, for a supposed strangulated hernia. A large, tense, and slightly red swelling, which was somewhat tender on pressure, occupied the scrotum and inguinal canal on the right side; the bowels had not acted for two days, and there had been slight sickness the day preceding, and also on the morning of his admission. The patient stated that he had been ruptured since the age of 14, but had worn no truss till after the age of 30, when, on raising a heavy weight, the rupture suddenly increased in size, and was returned with difficulty; since then he had constantly worn one. A few days before admission, the swelling became much larger than usual, which the patient attributed to having over-exerted himself in raising timber. There could be no doubt of the existence of a rupture in this case, and it was now irreducible and apparently inflamed; but, as there was no constitutional disturbance, and the symptoms were not urgent, I determined to wait awhile before operating, apply ice to the tumour, and watch the case. The patient had no sickness after his admission, and on the same evening his bowels acted spontaneously. The subsequent history of this case is not less instructive, and is as follows:—After the subsidence of the more active inflammatory symptoms, the scrotum was found to contain a considerable quantity of fluid, in addition to the solid mass which before and now occupied its cavity; and on the 5th of November I punctured it, and drew off six ounces of a clear, straw-coloured fluid. On the 16th of the same month, the operation was repeated, the fluid this time amounting to ten ounces four drachms, similar in appearance to the last, and containing some fibrin and much albumen, with a small quantity of bile. I was now enabled, for the first time, to make a satisfactory examination of the solid portion of the swelling. It was oblong in shape, reaching to the bottom of the scrotum below, and into the inguinal canal above; it was uniformly hard throughout, and the lower part could be distinctly recognised as the testicle, though neither the epididymis nor spermatic cord could be felt. The upper part of the tumour was obviously omentum, but it could not be

separated from the testicle, not did it yield to attempts at reduction. A week after the last tapping, the scrotum was as distended as ever; I therefore decided, instead of again letting out the fluid, to rub in the dilute mercurial ointment for ten minutes night and morning, with the view of acting on the solid contents of the scrotum, and on the 29th the whole tumour had sensibly diminished, both as regards the quantity of fluid and the size of the solid portion. On December the 10th the note is—"The whole of the fluid has been absorbed, but the body of the testis continues very large and hard. The epididymis cannot be distinctly made out, and appears to be blended with the hard substance (omentum) which occupies the upper part of the scrotum and inguinal canal." The friction with the mercurial ointment was continued daily till the patient's discharge on the 24th, when the following note was made:—"The testis is now smaller and softer than the patient ever remembers it to have been. The epididymis can be felt distinctly and also the cord, an omental hernia, quite soft, occupies the upper part of the scrotum, and is apparently adherent to the globus major and the testis."

The interpretation of the symptoms which characterised this case is probably the following. The man had been for many years the subject of an irreducible scrotal epiplocele, and had worn a truss for it; the pressure of the pad of this instrument upon the upper part of the hernia must have impeded the return of venous blood from that portion which occupied the scrotum, and also from the testicle, producing therefore chronic congestion and some enlargement of these parts. This being the ordinary condition of things, inflammation is suddenly set up in the tumour, followed by a great increase of its size and a commensurate increase of constriction of its upper part; the effect of this would be to impede still further the return of venous blood from the scrotal portion of the tumour, and hence give rise to passive effusion into the vaginal sac, or, in other words, to hydrocele; and so we had a hernia, orchitis, and hydrocele combined.

Hernia in the female is less common than in the male, and the only variety with which cysts and chronic abscesses of the labium are likely to be confounded is the pudendal; for the inguinal, though it may descend into the labium, can only do so through the inguinal canal and external abdominal ring, whereas the course of a pudendal is by the side of the vagina into the middle or lower part of the labium, leaving its upper half and the above-named passages free. Chronic abscesses usually originate in some part of the pelvis, and may descend by the same route as is taken by a vaginal or pudendal hernia; but the history of these collections of pus, the grave symptoms which generally accompany them, and the fluctuation, sufficiently distinguish them from hernia. Cysts are more likely to be mistaken for herniæ than abscesses, inasmuch as they not only occupy the same position as a pudendal hernia, but they have the same feel; they are also unattended with pain or other constitutional symptoms; they differ, however, from herniæ in having no impulse communicated to them on coughing, and in not being reducible by pressure or position. When the hernial tumour consists of a portion of the urinary bladder instead of intestine, cystocele as it is termed, its resemblance to an ordinary cyst is very close; but the latter cannot be emptied by pressure, whereas the former can, the act of pressure producing at the same time a desire to micturate, which the handling of a cyst does not give rise to. All doubts, however, on this point may be cleared up by desiring the patient to empty her bladder, and then refilling it with warm water; a mere cyst will remain unaffected by these proceedings; a cystocele will partially disappear and reappear, or alter its dimensions under this treatment.

## ORIGINAL COMMUNICATIONS.

### CLINICAL MIDWIFERY.

By FRANCIS H. RAMSBOTHAM, M.D.

Physician-Accoucheur to the London Hospital, etc.

(Continued from page 236.)

The following seven cases of puerperal convulsions occurred in my practice during the last nine months of the years 1843 and 1844:—

On April 16, 1843, I was sent for to a patient whom I was engaged to attend in her first labour, and who had been the

subject of epileptic seizures for some few years. She possessed a contracted pelvis, and I was compelled to deliver by the crotchet. About two hours after her delivery she was attacked by a convulsive fit. She recovered, and I have twice brought on premature labour for her since, in each case the child being born living. I have already detailed this among the craniotomy cases of this series of reports. Case 133.

#### *Convulsions before and after Delivery.*

Case 183.—On April 24, 1843, at 4:30 p.m., a Medical friend requested me to visit Mrs. R., a stout, young woman, living at Pentonville, after the birth of her first child. She was taken in labour at 7 a.m., and soon after the pains had commenced a copious hæmorrhage took place from the uterus, sufficient to occasion syncope and pallid countenance. As a draining continued after the first eruption had ceased, my friend ruptured the membranes at 12 noon, and gave some ergot. This put a stop to the discharge, and increased the strength and frequency of the pains. At four o'clock, when the head was on the perineum, she was attacked with a very strong convulsion fit, which lasted five minutes. A dead foetus was soon after expelled; but she continued comatose with stertorous breathing. Twelve or fourteen ounces of blood were drawn, and I was sent for. I found her sensible, but very drowsy. She did not complain of any pain. I ordered the head to be shaved, and a cold lotion to be used, twelve leeches to be applied to the forehead and temples directly, ten grains of calomel to be given at once, and a tablespoonful of a strong purgative mixture frequently. I recommended also, should another fit occur, that ten or twelve more ounces of blood should be abstracted. She continued much in the same state until 7 p.m., when another strong fit took place. Ten ounces more blood were taken, and an enema injected, which acted copiously. After this she had no more fits, and at my visit at 2:30 next day, I found her quite sensible, and she had slept comfortably. The bowels had acted six or seven times, and she had passed water; but the uterus was exceedingly tender on pressure. I recommended fomentations to the lower abdomen, and that some leeches should be applied if the tenderness did not abate. It, however, gradually disappeared, and she was speedily convalescent.

#### *Convulsions coming on Six Days after Labour.*

Case 184.—Mrs. N., High-street, Shadwell, was delivered by a friend of mine of her ninth child, after a very good labour on June 2, 1843, at 9 p.m. She nursed her infant, and went on exceedingly well without a check till the 8th at 9 p.m., when, without any assignable cause or the least warning, she was attacked with a violent convulsion. The fits recurred frequently through the night, and in the intervals she lay in a state of coma. I saw her at 9:30 the next morning, the 9th. She was then quite insensible, with the pupils widely dilated. She had been bled to fourteen ounces, and ten leeches had been applied to the temples. I ordered ten more leeches, the hair to be removed, and a cold lotion applied, and although the bowels had acted freely since her labour, I directed her to have ten grains of calomel and a turpentine enema. At 5:30 p.m. she was still quite unconscious, and had been constantly throwing herself about the bed; but she had not had any convulsions since the morning. The pupils were widely dilated and immovable. On the 10th, when I saw her at 1:30 p.m., she was quite maniacal; she had had no sleep, her head was hot, and she was talking incessantly. I directed one-third of a grain of morphia to be given every hour till she slept. She went to sleep after four doses, and slept six hours. When she awoke at 5 a.m. she was quite rational, and complained of great pain in the head. She could not bear the light, and the pupils acted well. She continued to improve during the 12th and 13th. On the 14th, after a very good night, she was seized with convulsions again about 9 a.m. without any warning, and they continued more or less frequent all day. More leeches were applied, and mustard poultices to the feet and pit of the stomach. The fits ceased before night, and she again slept; but on the 15th we remarked that she was paralysed on the right side, while the left arm and leg and left side of the face were the subjects of frequent twitchings. She again became gradually insensible, and died on the 16th. An inspection of the body was not permitted. I learned that mania supervened after her first child was born, sixteen years before.

#### *Convulsions after Delivery.*

Case 185.—On October 28, 1843, at 8 a.m., I was requested by a Medical friend to see Mrs. D., Old-street-road, a strong,

plethoric woman, aged 28, who had just been delivered of her first child naturally after a labour of two days and nights. Immediately after the placenta had passed she was attacked by a violent convulsion fit. I found her comatose, with stertorous breathing; when shaken or spoken loudly to she could just be roused to look up, and she muttered something unintelligible. She was bled to twenty ounces, and had ten grains of calomel and a purgative administered. She had only that one fit; at 1.30 she was rational, knew the people about her, and answered questions sensibly. Finding the bladder distended, I drew off nearly a quart of urine. It was loaded with albumen, but contained less urea than usual. From this time she recovered without a bad symptom, complaining only of a slight pain in the head. In a week she was sitting up. The urine then did not contain a trace of albumen. Eventually she recovered well.

N.B.—Shortly before this time my attention was directed to the fact of the urine in women who became the subjects of convulsions in labour containing more or less albumen, sometimes in considerable quantity; and I have found in my own practice this to be the case in about every five cases out of six where I have been able to make the observation. But, as the patient is recovering, it gradually becomes less and less, and it has almost entirely disappeared at the end of twelve or fourteen days, sometimes earlier, though occasionally it persists for a longer time. Some pathologists imagine that the presence of albumen under such circumstances indicates granular disease of the kidneys, and therefore attribute the convulsive seizures to those bodies having become the seat of that particular organic change. On the contrary, we are told by M. Blôt and others that the excretion of albumen by the kidneys in small quantity is not an unusual occurrence in pregnant women. If organic disease of the kidneys was present in all cases of puerperal convulsions, how could we account for the disappearance of the albumen so soon after delivery,—we should expect it to remain permanently. The following is the explanation which has occurred to my own mind:—We know that the fibrine is in excess in the blood of pregnant women, we have reason to believe that the albumen is in excess also; and from the observations of M. Blôt, that a part of that excess is got rid of by the kidneys, we may easily imagine that if there is a much greater quantity formed than healthy blood ought to contain, the superfluous albumen may excite the apoplectic seizure which is the occasion of the fits; and that thus the connexion between albuminous urine and puerperal convulsions as cause and effect is manifest.

#### *Convulsions before Delivery.*

Case 186.—On Monday, April 1, 1844, at 9.30 a.m., I was sent for by a Professional friend to a poor woman in Rosemary-lane, in the last month of her sixth pregnancy. She was a "teetotaller." At 2 p.m. on the day before she was seized with a strong convulsion. She had complained of violent pain in the head for five or six days, which was not attended to. She had had fifteen fits in all, and had never spoken since the first seizure. She had been bled to sixteen ounces shortly before I saw her. I found her perfectly comatose; and her hands, feet, and legs were as cold as marble; indeed, she was dying. As the os uteri was dilated to the size of a crown-piece, and it is one of my maxims never to let a woman die undelivered, if the child can be removed without injury, I introduced my hand and turned the child, extracting it by the feet. I found the membranes had given way, but the delivery was not difficult, and she was quite unconscious during the operation. The placenta was readily extracted also. The child was putrid. She died in the course of the day.

N.B.—This woman might probably have been saved if blood had been taken when she complained of the pain in her head, or even when she was first attacked by the fits; but the lancet was used much too late, and indeed doubtless hastened her death.

#### *Convulsions before and after Delivery.*

Case 187.—On the same day, April 1, 1844, at 2 p.m., a Medical friend requested my opinion in the case of Mrs. R., Mile-end New Town, in labour of her seventh child. She seemed going on very favourably, when at 8 a.m. she was seized with a convulsion, and had had five, one each hour, since; the last was at 1 o'clock. At first she continued sensible between the fits, but at my visit she was comatose. She mumbled something when she was spoken to; but when I tried to rouse her, she began rolling about the bed, and very soon went into another fit. Another followed almost immediately

after. I took twenty ounces of blood from the arm at once. The os uteri was then almost entirely dilated, and the head was in the pelvis, but the people about her did not know that labour had commenced. The pains continued, and the child was born in an hour dead. She had four more fits between her delivery and 8 p.m., for which her hair was removed, and cold was applied to the head. She took also ten grains of calomel, and a tablespoonful of a purging mixture frequently. The fits gradually became less severe as the bowels acted; she became conscious during the night, and from this time gradually recovered.

N.B.—It will be observed that I was sent for to these two last patients on the same day, and that two other of the cases just detailed happened within a few days of each other. Smellie and Denman both remark that it is not uncommon for three or four cases of this kind to occur quickly after each other in a particular district; and that women seem more predisposed to such attacks in some seasons than in others, attributing this predisposition to the "constitution of the atmosphere." My father says puerperal convulsions are more frequent "when there is thunder in the air;" Andral has more recently given expression to the same sentiment, and I entertain a similar opinion myself.

On December 26, 1844, I delivered by craniotomy, under puerperal convulsions, Mrs. C., Bucklersbury, which case I have already detailed among the craniotomy cases in this series of reports. It is marked case 139.

It will be thus seen that during the five years between January 1, 1840, and the last day of December, 1844, I treated nineteen cases of serious cerebral disturbance in labour, and that four of these proved fatal,—a larger proportion than my practice generally would show. But it must be recollected that one of these cases was pure apoplexy, without any convulsive movements, which I believe in labour invariably proves fatal; and that in another case the woman was dying when I first saw her for want of having been bled early enough. In fifteen of these cases the fits came on either before or during labour, and in four after the child's birth. Three were twin cases, in one of which both children presented with the feet, which were brought down artificially; in another both were delivered by forceps. One child was delivered by turning, five by craniotomy, and twelve passed naturally.

(To be continued.)

## HYDROCYANIC ACID IN THE TREATMENT OF INSANITY.

By KENNETH MCLEOD, M.D.

(Continued from page 264.)

Case 2.—*Mania, of an Extremely Restless and Incoherent Character—Amaurosis—Cachexia—Emaciation—Improvement under Hydrocyanic Acid—Renewed on Three Separate Occasions—Gradual Weakening and Wasting—Death—Structural Lesion of Brain, Lungs, Heart, Liver, Kidneys, Cap-sules, and Spleen found.*

A. J., aged 53, a widow, admitted June 4, 1862; belongs to a very low order of a town population; has always lived in poverty and dissipation; had syphilis several years ago; no hereditary tendency ascertained; husband died eighteen years ago; has been more or less affected mentally since that event; has lived in great poverty; obliged to send her children out to beg; sight has gradually failed; has become latterly quite amaurotic; has been extremely excited and unruly during last three weeks. "Violent shouting, singing, spitting, and biting" have been the most prominent symptoms.

*Symptoms on Admission.*—Is a woman of strong, arthritic diathesis, but in a feeble physical condition; wasted, weak, and anæmic; has melasma around eyes, and dilated capillaries on cheeks; a few small naevi on different parts of body; is in very delicate health; vital processes feebly performed; completely amaurotic; has a soft systolic murmur at the apex of the heart, left side; pulse weak, beats generally at 80; liver enlarged; labours under mania; characterised by incessant muscular motion of every possible kind,—of tongue, feature, and limb,—but usually of a rhythmical and repeated kind; shouts, screams, rubs, knocks, sings, etc.; sensation normal; attention and memory wanting; is utterly delirious;

cannot converse at all coherently; has not, during the day, a moment's repose; is exceedingly restless and noisy during the night; to have a nutritious diet, and Oj. porter, with gr. j. morph. mur., at bedtime. ℞ Vin. rub. ℥iv., in dies.

July 9.—No improvement whatever; is rather worse; more noisy, and restless; is incessantly in motion; constantly shouting, screeching, etc.; tosses off the clothes; gets out of bed whenever she is left alone; no sleep at all last night. To have—℞ Acid. hydrocyani dil. miv., every hour in ℥ss. aq. camph.

10th.—Almost immediately after the first dose became quiet and still; effect sustained during the whole of the afternoon; slept well last night, a very marked contrast to several nights preceding; is much more settled this morning; does not shout or scream, although conversation is unconnected and rhapsodical; takes her food better.

12th.—Improvement still sustained; is much more manageable; eats her food better; is cleaner in habits; keeps her bed; ward generally quiet.

14th.—Is not so well; rather more restless and noisy; is still affected for the better by the hydrocyanic acid, but not so much as formerly.

The acid was about this time discontinued from failure of the supply of it, and she relapsed to nearly her former condition, being unaffected by large doses of hyoscyamus and morphia. It was resumed again towards the end of June, and again she improved amazingly; was able to get up every day; was generally quiet, but occasionally became excited; her physical condition, notwithstanding the administration of wine, porter, and a generous diet, gradually declined; she emaciated more and more; feet became œdematous, and bones every day got more prominent. She again became disorderly and acutely maniacal on remission of the drug, and was a third time habitually quelled by it.

She lingered on till August 16, an attack of pneumonia accelerating her death, and died almost a perfect skeleton.

On post-mortem examination, the optic nerves were found completely atrophied, the optic tracks partially so, and only the posterior transverse bands of the commissure remaining. Brain showed signs of meningeal irritation, and was the subject of chronic congestion throughout. There was no softening or any other structural change. The liver and kidneys were very gravely degenerated; capsules and spleen softened, and heart dilated; right lung solidified.

*Case 3.—Maniacal Melancholia Coincident with Anæmia and Cachexia—an Acute Paroxysm Treated Successfully by Hydrocyanic Acid—Gradual Improvement under Tonics and Dietetics—Recovery.*

H. S., aged 29, married, admitted December 12, 1861. No history, except the facts contained in the reception order. They are—Labours under a second attack of four months' duration. The first occurred at the twenty-eighth year of her age. Cause not known. Is suicidal and dangerous to others. In the latter part of October attempted suicide by cutting her face and neck with a razor. Imagines her domestic affairs are disordered. Has not slept for more than an hour at a time during the last six months. Is restless, incoherent, and occasionally very desponding.

*Symptoms on Admission.*—Patient inclines in diathesis to a strumous type. Is in very delicate general health, anæmic, and melasmic. Has not menstruated for months. Labours under maniacal melancholia, deploring with tears and lamentations the loss of everything; contrasting former comfort and happiness with the blighting ruin which involves not only her own affairs but every object in the world. Trees are withering, houses falling, property destroyed, cattle dying, etc., she the cause of all.

April 5, 1862.—Treatment since admission has been tonic, sedative, and dietetic. Has not improved much. Is very much pre-occupied with delusion; will not work at all; repeats the same expressions, conduct, and acts every day, without the slightest variation. 2 p.m.—Is in a state of frantic and unrestrainable excitement—shouting, struggling, and throwing herself about with great violence; crying aloud in her usual strain, but with greater intensity. Is exceedingly emotional. Pulse 144. miv. dilute hydrocyanic acid was administered instantly, but no effect appearing, the dose was repeated in five minutes. This was followed by a very well-marked gradual amendment. Screaming, struggling, emotion, etc., disappeared by degrees. In ten minutes she was left alone, and in fifteen minutes became perfectly quiet. Pulse 120. In thirty

minutes she continued silent and still, looking quietly out of the window. Medicine was continued every hour. She remained perfectly quiet during the afternoon; pulse falling to 96.

October.—No such paroxysm as that related above has occurred again. Patient is now very much better; cheerful, industrious, stout, and ruddy. Change for the better induced principally by means of tonics, iron and quassia, and generous diet.

*Case 4.—General Paresis—Extreme Excitement Rapidly Quelled by the Use of the Hydrocyanic Acid—Habitual Quietness secured by Prolonged Treatment.*

W. D., a tall, stalwart man, of arthritic diathesis, middle-aged, by trade a gas-fitter, was admitted June 3, 1861, labouring under the general paresis of the insane. On admission the physical signs of paresis were slight and mental, consisted in an incapacity for work, a bouncing manner, self-complacency, and self-confident, boasting familiarity, with occasional emotional paroxysms. The disease became soon more intense; vocalisation became more impaired; appetite voracious. He became liable to excitement, stole, accumulated, repeated, and began to entertain extravagant optimistic delusions.

June 9, 1862.—Disease has become very much more acute. He is liable to the most fearful paroxysms of excitement, when, with raised look and frantic gesture, he rushes about screaming, and shouting incoherently of his wealth, power, position, importance, means, etc. Property he has without limit—40,000 guineas, ship-loads of parrots, an inconceivable quantity of anything that can possibly be imagined. Deeds he performs of the most miraculous description,—“goes to Italy and knocks down the rocky mountains;” does wonders “at the Crimean war;” talks of marrying Mary Magdalene, the mother of God, etc. His nights are most boisterous and disturbed. He gets out of bed, tosses his bed and bedding about, knocks at the door, and shouts incessantly.

10th.—Had a most dreadful night; shouted and screamed during the whole of it; got out of bed and battered at the door with might and main; besmeared himself with fæces; could not be pacified by the night attendant. ℞ Acid. hydrocyanic dil. miv. every hour.

11th.—Became perfectly quiet towards the afternoon; was obviously affected by the first dose of his medicine, and decidedly quelled by the second. Slept soundly all night. Is quite another man this morning; sits quietly on his seat, and does not talk except when addressed.

13th.—Continues to improve. The change of conduct during the night is most wonderful. He lies in bed and sleeps. No less remarkable is his altered demeanour during the day.

September 24.—The acid was on one occasion discontinued, when the patient reverted to his former violence of manifestation. Under prolonged treatment by it, he has become habitually quiet and tractable. Nothing similar to the former excitement has at all appeared.

October 22.—Continues much the same, disease making slow progress. The excitement appeared again, but was promptly dismissed by another administration of prussic acid.

November 1.—No recurrence of excitement. Is somewhat stouter; looks better. Occasions no disturbance, and gives very little trouble.

*Case 5.—Congenital Imbecility with Epilepsy—Severe Paroxysm of Excitement—Subcutaneous Injection of Hydrocyanic Acid—Immediate Effect—Another Paroxysm Treated Successfully by its Oral Administration.*

J. S., aged 15, admitted June 2, 1862. A congenital imbecile and epileptic; harmless and ineducable till within a few weeks ago, when he began to manifest excitement, which has recurred paroxysmally with considerable violence.

*Symptoms on Admission.*—Is a stout, strong, well-developed youth, of fair complexion and hair, blue eyes, rounded face and features, microcephalous, ears small, thick, and deficient in lobule. Appears to enjoy excellent health. Is very deficient mentally; slow of impression, ideation, and expression. Stock of thoughts and words exceedingly limited.

June 4.—Has manifested no excitement until to-day; was out during the afternoon in the airing-yard; attempted to escape; got over the wall; overtaken by an attendant; resisted being brought back most desperately; had to be carried into the house by four men; roared loudly and incessantly, kicked, struggled, bit, scratched, etc. Excitement continued

without abatement, the efforts of four men hardly sufficing to keep him on his bed, until 8.30 p.m., when five minims of dilute hydrocyanic acid were introduced beneath the skin by Wood's syringe. A very slight change only being manifest, the dose was repeated in five minutes, when he became perfectly quiet, gave over his violent actions, and was asleep in about fifteen minutes. He slept well during the whole of the night.

10th.—No further excitement until to-day, when he had a severe fit, followed by very great excitement, roaring, kicking, tossing about floor, etc., which lasted till 6.30 p.m. He was then ordered *mix. hydrocyan. acid. dil.* every hour. After the first dose he calmed down almost instantaneously, rose up off the floor, and had a drink of water; went to bed quietly; seen lying awake, but perfectly still, in bed at 10; slept shortly after.

November, 1862.—Has had several fits of sulkiness since last report, but no paroxysm of excitement. Does a good deal of work, both indoors and outside. Mental condition unaltered. Is, for the most part, cheerful and happy.

(To be continued.)

### CASE OF OVARIOTOMY — PERITONITIS — DEATH ON THE NINTH DAY.

By EDWARD CHARLES HULME, F.R.C.S.

Surgeon to the Great Northern Hospital, and to the Central London  
Ophthalmic Hospital.

Mrs. S., aged 38, married, a spare, but healthy woman, had one child fifteen years ago. Within the last two years her attention was drawn to a tumour, commencing on the left side of her abdomen, which rapidly increased, and for the symptoms attendant upon this increase and inconvenience she consulted Mr. Harding, who diagnosed ovarian disease. The symptoms had assumed such extreme urgency by March, 1862, that Mr. Harding proposed tapping, which I performed on March 5. Twenty-eight pints of thick, coffee-ground-looking albuminous fluid were evacuated, which was followed by immediate relief, and a complete cessation of all the urgent symptoms. The abdomen became quite flaccid, and on careful examination no solid substance was detected. She began gradually to fill again, and on October 31, before the symptoms became so painfully distressing as in March, I relieved her again by tapping, and evacuated the same quantity and quality of fluid.

Being an intelligent person, and having obtained some knowledge of the nature and treatment of her complaint, she resolved to try pressure after her own fashion, and accurately moulded to the flaccid abdomen thin leaden sheets, altogether amounting to near 4 lbs in weight. This she wore constantly by day and night. For the first month no perceptible increase took place, but during December her abdomen began to enlarge. She could no longer bear the pressure of the weight, and by January, 1863, having passed the intervening time in the country for the benefit of her health, she was as large as ever, with a commencement of the same distress as before. Having had the operation suggested to her, as the case seemed in every way favourable for it, with a full conviction of its risks, she quite determined to abide the chance of success, and freely assented to its performance. After several careful examinations (at one of which I have to thank my friend Dr. Greenhalgh for his opinion), we came to the conclusion that it was a single cyst, no solid substance present; that the uterus was perfectly free and movable on the introduction of the sound; that ascitic fluid was present, and that in all probability there were no extensive adhesions. I therefore determined upon operating early in the month; but her menstrual period having come on a week before its proper time, it was deemed prudent to wait. During this delay a sharp attack of pain, attended with still further increase of size, supervened, and the well-defined circumference of the tumour was lost at its upper part; this increase was evidently due to the sudden effusion of ascitic fluid; the secretion of urine being at the same time much diminished. Treatment by hot applications, morphine, and mild aperients allayed these symptoms; and on January 27 I operated, assisted by my friends Drs. Greenhalgh, Murray, Meadows, Messrs. T. Carr Jackson, and Harding.

The abdomen measured forty inches round the umbilicus. The usual precautions having been taken as to heat of room,

etc., etc., and chloroform having been administered by Dr. Meadows, an incision, about three inches long, was made, commencing about one inch below the umbilicus; on the peritoneum being opened, a profuse quantity of ascitic fluid gushed out; numerous adhesions existed on the abdominal surface of the tumour, and the incision was enlarged to about four inches, to enable my hand to be passed in to break down adhesions which were numerous, but slight, and generally readily yielded. The cyst was tapped, brought forward, being free from any pelvic adhesion, and the clamp placed upon the pedicle, which was short, but well-defined from the tumour; gentle pressure evacuated the remains of the ascitic fluid, and the intestines were not exposed during the operation. Five waxed twine sutures were inserted through the whole thickness of the abdominal parietes, with two or three sutures through the skin, the pedicle remaining at the bottom of the wound, with the clamp outside. The patient was thirty-five minutes under chloroform; she was sick for a few hours after, but the vomiting was allayed by sucking ice; and the pulse, which was 120 after the operation, fell to 90 that evening. She passed a quiet night without opiates. Slight dragging pain at the back, with nausea and some retching was experienced on the following day. She, however, retained her iced milk and beef-tea. Pulse 105. Tongue clean. The sickness, with vomiting of green, bilious, acrid fluid, had increased on the third day; and the abdomen became tympanitic, with slight tenderness on the left side. Pulse 115. Hot turpentine fomentations were constantly applied, and opium suppositories every six hours, with iced drinks. On the 30th I removed the clamp; a quantity of serous fluid, slightly tinged with blood, escaped from the lower end of the incision, which had not healed, and to which the pedicle had but slightly adhered. The edge of the wound, however, looked healthy. Not to enter into unnecessary detail, the patient remained much in the same condition till February 3. The pulse kept up regularly to 120; abdomen tympanitic, but without much tenderness; the sickness continuous, and yielding to no treatment; the lower edge of the wound looked unhealthy, and discharged offensively. She passed tolerably quiet nights by means of opiate injections, and was fed by nutritive enemata, which were generally retained, and she was hopeful and clear about her case. The bowels had been relieved by injection on the fifth day. After February 3, the pulse rose, the vomiting of an acrid, brownish fluid became continuous, and she sunk exhausted at nine o'clock in the morning of the 5th, the ninth day after operation.

*Post-mortem Examination Thirty Hours after Death, assisted by Mr. Harding.*—The abdominal wound had healed throughout its whole thickness, to within the lower inch of the incision. On laying open the abdomen, the whole of the viscera appeared matted together on their surface with lymph, which was thickly poured out at the lower part. The omentum was closely and strongly adherent to the intestines, requiring to be torn off with some force. The peritoneum on the abdominal wall was roughened with old lymph deposits; the edge of the wound had well united on its peritoneal surface, the stitches showing no especial marks of inflammatory action. Towards the left and lower part of the incision a small abscess, of the size of a nut, had formed into the parietes. The pedicle had retracted, showing a dark, sloughy, linear edge. The reflexion of the peritoneum over the fundus of the uterus was especially red and inflamed. The right ovary on section showed a small cyst of the size of a marble, white, and shining in its interior, with a distinct lining membrane. The peritoneum over the liver was reddened, and was adherent firmly to the under surface of the diaphragm in its whole extent, showing marks of old inflammatory action. The kidneys healthy; the head and chest not examined.

Probably more is to be learnt in order to facilitate diagnosis by the report and post-mortem of an unsuccessful case than the mere detail of a successful one, and the desire to add to our stock of statistics has been my object in publishing the above. I do not believe there is that reticence in the operators of the present day in withholding from the Profession the results of their cases, whether favourable or otherwise. That previous attacks of peritonitis had existed in this case was more manifested at the post-mortem examination than I could obtain from the history of the patient. The firm adhesions around the liver, about the omentum, and the slight attack which preceded the operation, I think

prove this predisposition. The questions which arose, under the circumstances were whether I should tap again, with a view to future operation, or wait till the menstrual period should pass over, in the meantime subduing the existing symptoms by treatment. It must be remembered immediate action one way or the other was absolutely necessary. To tap again, after so rapid an accumulation of fluid and the abstraction of so large an amount of albuminous fluid from the system, would only have been to have left her a worse chance for future operation, and with her general health in all probability more impaired. I preferred operating, therefore, although somewhat impressed with the idea that my chance of success would have been one shade better had I not been prevented operating at the time I wished by the circumstances above narrated.

Gower-street.

## REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

### THE LONDON HOSPITAL.

#### CASE OF EMBOLISM—GANGRENE OF THE FOOT— DEATH—AUTOPSY—CLINICAL REMARKS.

(Under the care of Dr. FRASER.)

[Reported by Mr. CARTER and Mr. GWYNNE.]

ANN D., married, aged 29, admitted August 21, 1860. Has had two children at ten years' interval; has ailed ever since her last confinement, six months ago; flooded a great deal at the time, and for five weeks after; she then had pain in her stomach, shoulders, and chest; nausea, slight headache in the morning, and shortness of breath. On one occasion her bowels were not relieved for twelve days (probably from having had opium largely). Her appetite not good. The pains and nausea continued for some time, then left her, and returned once more; they left again, but the nausea returned with increased violence, vomiting all her meals; her breathing became more troublesome, and she suffered from severe paroxysms of dyspnoea, causing her to turn almost black in the face. She went into the country for some weeks, but was not benefited by the change. When admitted, she was suffering from intense dyspnoea, pain in her stomach, and frequent vomiting, pains across her loins and between her shoulders, the lumbar pain accompanied by a bearing down. The whole of the left side of the abdomen is painful when touched; right side not affected; a small amount of peritoneal effusion detected; lower extremities œdematous; there is a larger extent of præcordial dulness than natural; and the heart-sounds are very feeble and indistinct, but no bruit, and no pneumonia or bronchitis. Pulse feeble, tongue white, bowels open, urine rather scanty. To have the ethereal tincture of lobelia and other anti-spasmodics.

August 23.—Pain very acute in loins and side; breathing very much distressed; lobelia found too depressing. To have brandy  $\zeta$ ij. Pain was very severe. Ordered twenty drops of laudanum, and to be repeated every hour for three times, and fomentations to the abdomen in the evening.

24th.—Is easier this morning; vomiting ceased, and very slight dyspnoea.

25th.—She is much better, but still great lumbar pain. Heart-sounds very indistinct. To have gin, diuretic mixture, and blister to region of heart.

September 1.—During the preceding seven days the foregoing symptoms continued, and varied more or less. She had opiates, antispasmodics, neurotonics, embrocations, etc. On September 1, the nausea stopped, and she complained of intense pain in knee, instep, and big toe of left leg, which is cold as high as knee, and the toes purple and shrunken. Limb was enveloped in cotton wool and oil cloth; had opium internally, and a hot embrocation of laudanum.

2nd.—Much relieved by embrocation; no pulsation in tibials, pain in the course of the femoral artery.

3rd.—No sickness, and feels better. Seen by Mr. Luke, who recommends to wait for "line of demarcation."

4th.—Much relieved; foot and leg warmer.

5th.—Ordered the sesquicarbonate of ammonia.

6th.—Pain in ankle very severe; no feeling in foot when

simply touched, but intense pain on its being moved; describes the pain as if running knives into the knee and ankle.

12th.—Vesications appeared on dorsum of foot and tibia.

19th.—The symptoms have continued as before. The ammonia has been continued, and to-day the iodide of potassium was added.

22nd.—Describes the pain as if the foot was being "broiled on a gridiron."

28th.—Cuticle beginning to be detached from instep; temperature of foot and leg still maintained. To have bark, chlorate of potash, iodide of potassium, and chloric æther, and intermit the ammonia.

October 6.—Line of demarcation well marked; pain and tenderness in left iliac region, and bearing down pain of rectum, and peritoneal effusion. Seen by Mr. Luke and Mr. Adams, who decided that amputation was inadvisable.

12th.—Symptoms have been much the same since last date. She is very weak and worn out by pain, which is little alleviated by large doses of opium.

15th.—An irregular sугgillated spot, the size of half-a-crown, on inner side of left thigh, two inches below Poupart's ligament, and very painful to the touch.

17th.—Mortification extending, and she expired on the morning of October 18.

*Post-mortem Eight Hours after Death.*—Face livid; rigor mortis persistent. On opening pericardium about four ounces of limpid yellow serum was observed; the heart was large, its walls thicker and softer than usual. The cavities partially distended by semi-coagulated blood; no old fibrine found in them; valves quite healthy. Lungs were slightly emphysematous at apices, and the right pleura was partially adherent by old lymph; though congested, they were healthy in structure. Liver large; softer than usual; of nutmeg appearance. Kidneys paler than usual; no suppurations of calices, or calculus found; the bladder contained a minute calculus, the size of a millet-seed; it was white and friable. In spleen, which was small and firm, there were found three deposits of fibrine the size of half a walnut beneath the capsule. A small quantity of peritoneal effusion present. The uterus was small and firm; its internal surface was injected, and a very small quantity of blood was found in its cavity. Ovaries healthy, and one Graafian vesicle mature. On tracing the aorta, on its internal surface were found several scattered white patches beneath its serous coat (atheroma?). At the bifurcation of the iliac arteries a rope of recent fibrine was found reaching from left into right common iliac. At commencement of left common iliac artery was found a firm plug of yellowish brown fibrine; this could be felt externally, and traced by the finger down to the femoral, but it was much firmer for about the first inch and a-half, and not adherent to the arterial walls. All the branches given off by the artery, as far as to the middle of the thigh, were found obstructed by coagula, but in the lower parts they were looser and darker than that in the common iliac artery. The great veins were quite healthy, and contained only fluid blood. From the gangrenous condition of the limb the arteries were not traced lower, but they were in all probability plugged for their whole length. On slitting up the common iliac for a short distance, the inner coat was found to be of a deep red colour.

*Clinical Remarks by Dr. Fraser.*—The points to be noticed are—1st. Was the clot formed during life? Of this, from its situation, consistency, and non-adhesion to the walls of the vessel, apart from the symptoms during life, there cannot be a doubt. 2ndly. What were the special causes operating in this individual favouring a fibrinous deposit? namely, the loss of blood at the period of parturition, and the weakening effects of the subsequent protracted hæmorrhage, from the effects of which she never rallied. It is not easy, however, to determine where the coagulum was first, or where it was laid down? Most probably in the left heart, which will explain all the symptoms under which the patient laboured on her first admission. 3rdly. Can a coagulum be originally formed in any other part of the circulation, except in the cavities of the heart, in an aneurismal sac, or at the seat of a ligature? I think not. In this case it may be said that there was no valvular lesion to give a basis for the deposit. This, however, is not necessary, for in a languid circulation, with fibrine either in absolute or relative excess, it is easy to suppose a deposit to begin among or around the columnæ carneæ, for it is not necessary that actual stasis shall be present, as fibrine may be seen to attach itself to the stick or spoon while

actively stirring fresh ox blood. All the symptoms are readily explained by the supposition of the deposit being in the left auricle, or ventricle, for by the aid of auscultation the absence of all pulmonic obstruction or inflammation was ascertained, thereby limiting the cause of the symptoms within the circulation. I conclude that the disentanglement took place on or about August 25, and on September 1, it was finally arrested at the bifurcation of the iliacs, on which day appeared the prominent sign of obstruction. In a therapeutic point, the volatile alkali did not manifest a dissolving power. In a practical point, the removal of the limb was contra-indicated from absence of a well-marked line of demarcation, as well as by the debilitated state of the patient, and the uncertainty as to the seat and extent of obstruction.

The wisdom of this decision was manifested at the post-mortem examination. Since the foregoing case occurred, a large experience has been obtained in this Hospital in the successful treatment of a great number of cases of rheumatism by the administration of very large doses of the fixed alkalis; the details of these cases will be given at another time. At present I would suggest that in embolism, as in rheumatism, there is a sub-alkaline state of the blood, and a consequent tendency to coagulation; and therefore this condition may be obviated by the employment of alkalis.

### KING'S COLLEGE HOSPITAL.

#### CYSTIC TUMOUR OF THE BREAST—REMOVAL—RECOVERY—CLINICAL REMARKS.

(Under the care of Mr. FERGUSSON.)

For the notes of the following cases we are indebted to Mr. Smith, House Surgeon.

Susannah H., aged 44, single, was admitted December 18, for a large tumour in the left breast. She was a cook, a care-worn and cachectic-looking woman, and said that her grandmother and one of her aunts died of cancer.

*History.*—About two years ago, she observed a tumour in her left breast about the size of a walnut; at first she felt no inconvenience, but later suffered a great deal from sharp shooting pains in the swelling. For the first fifteen months that she noticed it, it grew very slowly, but during the last seven months it had increased very much in size, although it had caused her less pain. She could not give any cause for the tumour; did not remember to have had any blow upon the breast.

Upon admission, there was a large tumour in the left breast, about the size of a child's head. The skin was highly stretched over it, blue and congested, but not inclined to ulcerate. At the upper part there was distinct fluctuation, but below this there was a large hard, nodulated mass. The glands in the axilla were not enlarged; her health was not very good, and she had menstruated very irregularly.

December 20.—The patient having been put under the influence of chloroform, Mr. Fergusson made two elliptical incisions in the skin over the tumour, including between them the nipple. The skin was then carefully dissected back over the tumour on each side, then separating away the growth from its deep connections, the walls gave way, and a quantity of thick, grumous-looking fluid was poured out. Ten small arteries were tied, and the flaps of skin were brought together by sutures.

Mr. Fergusson, in his remarks to the class after the operation, stated that this kind of disease, though occasionally seen in other organs, was very rare indeed in the breast,—in fact, he himself had never seen one before. It was a cyst with very thin walls, loosely connected with the surrounding tissues, and containing in its interior a quantity of dark, thick fluid, somewhat like venous blood in colour. From the inner surface of this cyst there were attached several pedunculated cauliflower growths, the largest of which was about the size of a man's fist,—in fact, the tumour was one large cyst, although before removal it felt like a tumour made up together of hard tissues and several small cysts.

The woman went on uninterruptedly well after the operation. The edges of the wound gaped a great deal, and tore away from the sutures, but it healed up well by granulation, and the patient was discharged cured January 10.

#### FATTY TUMOUR UNDER THE DEEP MUSCLES OF THE BACK—REMOVAL.

Caroline L., aged 27, was admitted under the care of Mr. Fergusson, January 29, for a swelling in the back. She was

a healthy-looking woman, married, and had had one child. About seven years ago she had a severe blow upon the back, but noticed nothing until nine months ago, when she found that there was a large swelling on the left side of the spine, and about midway between the lower ribs and the crest of the ilium. This had increased very slowly since, and without any pain.

Upon admission there was a soft, doughy tumour to be felt, the precise nature of which could not well be made out. She was taken into the theatre February 14, put under chloroform, and an exploratory incision made; it was then found to be a fatty tumour, deeply embedded under the trapezius and longissimus dorsi muscles, and about the size of an orange; it was easily squeezed out, and the flaps of the incision brought together by sutures.

The patient did very well, the wound healing partly by first intention, partly by granulation, and she was discharged cured February 27.

### MIDDLESEX HOSPITAL.

#### CASE OF OBLIQUE INGUINAL HERNIA IN A LITTLE GIRL FIVE AND A HALF YEARS OLD.

(Under the care of Mr. HULKE.)

A LITTLE girl, 5½ years old, was brought to the out-patient's room, July 31, 1862, with a swelling in her right groin, about as large as a pullet's egg, which was evidently an oblique inguinal hernia, and was easily reduced. The mother had discovered it four days before, when the child complained of great pain in the part immediately after a fit of cough. Recognising the resemblance of this swelling to the congenital scrotal hernia of another of her children, which she had been taught to reduce, she tried pressure, and in a few minutes the swelling disappeared, with immediate relief of the pain.

From the silence of text-books on this subject, a common impression prevails that inguinal hernia occurs much more rarely in female children than is actually the case. The valuable tables drawn up by Mr. Kingdon, for the reports of the City of London Truss Society, show that in 1860, 29, and in 1861, 41 cases of this form of hernia in girls under five years of age were seen in that institution; the proportion of these to those in male children of the same age being in 1860 as 1:14 nearly, and in 1861 as 1:15.

### HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

#### CANCEROUS TUMOUR OF THE MEDIASTINUM—CANCER OF THE LUNG—EXTERNAL TUMOUR OVER THE STERNUM—CONTRACTION OF THE LEFT PUPIL—CLINICAL REMARKS.

(Under the care of Dr. POLLOCK.)

IN this case (Dr. Pollock remarked) the existence of pressure on the root of the left lung was manifest enough from the various physical conditions existing during life, viz., enlargement of the external chest veins, inequality of the pupils and of the radial pulses, and alteration in the pitch of the voice; while a dulness more complete and extensive than could be attributed to tubercle or circumscribed empyema, with evidence of obstruction to the entrance of air into the left bronchus, pointed clearly to the existence of aneurism or other tumour in the mediastinum. The ordinary signs of aneurism, as murmur or pulsation over the dull part, murmur above the clavicles, or propagated to the vessels of the neck, were absent. There was no external tumour when the diagnosis of malignant disease was made; but the later appearance of a swelling over the sternum of a hard, inelastic character, rendered the evidence of malignant disease more decisive. Clubbing of the fingers, present in this instance to a remarkable extent, has always been associated with tubercle. Were the cicatrices and cretified masses observed in the right lung due to former tubercular deposits? The coincidence of cancer and tubercle in the same individual has been pointed out by many observers, and a case is recorded by Dr. Pollock in the *Pathological Transactions*, vol. iii., 1851-52, p. 254.

Another interesting feature in this case is the contraction of one of the pupils, due, no doubt, to pressure on the trunk of the sympathetic. Dr. Gairdner was the first to point out that alteration of the pupils is often a symptom of intrathoracic tumours, and that it is due to interference with the

sympathetic. In a case of thoracic aneurism, under the care of Dr. Fuller, related in this Journal for January 3, 1863, there was extreme contraction of one pupil; and in another case, under the care of Dr. Davies, in the London Hospital, this symptom was present and was clearly due to pressure of the aneurism in the trunk of the sympathetic. We shall speak more of this symptom in connexion with a series of cases of disease of the spinal cord, in which contraction of the pupil is sometimes present, and also in relating several cases of aneurism.

Chas. L., aged 54, teacher of German, was admitted on August 8, 1862, as an in-patient. He had no known predisposition to tubercular or cancerous disease. He had gout four years ago, and had been more or less out of health ever since. Hæmoptysis occurred sixteen weeks ago, and also repeatedly in small quantities since. He complained of much dyspnœa on exertion, and of severe lancinating pains through the left chest and shoulder. He had slightly lost flesh, and his fingers were clubbed to a remarkable degree. The right pupil was larger than the left; the right radial pulse was fuller than the left; pulse intermittent, occasionally as high as 132. On inspection, the movements of the left side seemed nearly lost. The external chest veins were enlarged, and more so lower down on the left side. The left side was absolutely dull over the front from the clavicle to the base, the dulness extending across the sternum. There was complete absence of respiration over the dull part. Posteriorly in the supra-spinous fossa there was bronchial respiration and bronchial voice, and very tubular respiration along the spine, where the vocal fremitus was much increased. The posterior part of the base presented slight, moist crepitation. On the right side the respiration was puerile, excepting along the spine, where it was slightly tubular. There was much tenderness over the left front, so that repeated examinations became impossible. There had been no hectic; dysphagia never existed; decubitus, generally slightly turned over on the left, with the head low. His natural voice was a deep bass; he now spoke in a high treble.

The diagnosis recorded on the first examination was, that a tumour occupied the mediastinum, pressing on the root of the lung—that its nature might be either malignant or aneurismal, but that the presumption was in favour of the former.

In about a week a slight prominence of the chest walls was manifest at the second rib and intercostal spaces above and below. This was hard, exquisitely tender, and the centre of the lancinating pains from which he suffered. This swelling daily increased till he died, the integument over it remaining of a natural colour. He sank on October 15, 1862. Death appeared to occur from exhaustion; there was never any excessive dyspnœa. The physical signs at the last only differed from those already mentioned in the fact, that the crepitation at the left base had ceased, and no respiratory sounds of any kind were heard over this side. The left radial pulse became imperceptible some hours before the right.

*Autopsy, Thirty Hours after Death.*—Body well nourished; a hard, inelastic swelling over the second and third ribs of the left side and part of the sternum, about two inches long by three wide. The left pleura contains a large quantity of clear fluid; it is universally and firmly adherent, except at the base. A cancerous growth is seen in the posterior mediastinum, which is adherent to the vertebræ as low down as the sixth dorsal, and extends upwards a little way along the neck. It presses on the left lung, and surrounds the various structures at the root of the lung, and is continuous anteriorly with the tumour, which is seen externally. The left lung, rather larger than a man's fist, is infiltrated in its upper third with cancerous matter. It is firmly united, along with the pleura, to the inner surface of the sternum and ribs. There does not appear to be direct continuity of structure so much as infiltration of all the tissues with cancerous matter. The parts composing the root of the left lung are all involved in the morbid growth; the left bronchus is nearly obliterated in calibre; the left pulmonary artery much narrowed; the arch of the aorta is not pressed on. The right lung is of an average size: in the lower lobe were found two cancerous deposits, white, cerebiform, and possessing the usual microscopical characters of cancer. A puckering of the lung is seen on its surface in the lower lobe, and, on cutting into it, there is a small cretified mass. There are two cicatrices at the apex of this lung; no recent tubercle exists. One of the bronchial glands at the root of this lung is converted into a cretaceous mass.

## HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.

### MEDULLARY CARCINOMA OF THE LUNG AND BRONCHIAL GLANDS, AND OF THE STOMACH.

(Under the care of Dr. PEACOCK.)

[Reported by Mr. LANCHESTER, Resident Medical Officer.]

CHARLES T., aged 42, was admitted June 6, 1862. He had been ill about six months with a cough and some frothy expectoration; for the previous fortnight, mixed with blood. He was a large-made man, with a sallow complexion. He had been losing flesh; the pulse was 108, soft; tongue rather thickly furred; appetite bad; bowels confined; the urine, sp. gr. 1030; acid reaction; contained abundant lithates; no albumen. Sleeps well; decubitus almost entirely dorsal. The physical signs were not very marked. The chest, at the upper part, somewhat hyper-resonant; respiration harsh at both apices, more particularly the right.

*His Previous History.*—He had been a carpenter in the country. He had been a very strong man, though, for the last year or so, subject to rheumatic gout, and had probably lived a fast life. He was the youngest of a large family, all of whom were alive and healthy. He had one daughter, who was said to be phthisical. No other evidence of hereditary disease in the family was obtained.

The diagnosis at this time was incipient phthisis; but in a very few days it became evident there was more depression and general debility than would be occasioned by tubercular consolidation alone.

June 12.—He lies in bed nearly all day, feeling great disinclination to move, and complains of much pain at the epigastrium, and there is some tenderness to pressure. Tongue much furred; bowels confined. This pain continued for some days, and he was troubled with continual vomiting. Urine scanty, but contained no albumen.

24th.—The pain had become more general over the abdomen. No enlargement or irregularity could be felt of the liver or in the epigastric region. The vomiting continued troublesome.

29th.—To-day the expectoration has a very peculiar appearance, consisting of frothy mucus in large bubbles, intimately mixed with blood of deep red colour.

The physical signs have also become more marked, as the following note shows:—Impaired expansion and resonance on percussion; great deficiency of respiratory sounds, and absence of vocal fremitus on the right side. On the left still signs of general emphysema. The chest was not examined posteriorly, on account of the weak state of the patient. From the physical signs and peculiar "currant jelly" character of sputum, the surmise was hazarded that the case would prove to be one of carcinoma of the lung, involving also some of the abdominal organs.

There was some hæmoptysis the next day; probably, altogether, there was some four to six ounces of blood.

On July 7 he was attacked with erysipelas (no cause could be traced for this), and, though very weak, he lingered on some days, and died on the 13th. The vomiting had continued to two or three days previously.

*Autopsy, Forty Hours after Death.*—Rigidity marked; body smewhat emaciated; some discoloration of dependant parts. *Thorax.*—The superficial cardiac region was almost covered by the left lung, which also extended rather beyond the middle line above. On the right side, the pleural cavity contained a large quantity of serous flaky fluid; and the lung was compressed against the vertebral column, except where it was held by some adhesions at the apex; the layers of the pleura were much thickened.

*Lungs.*—*Right.*—Compressed to about half its natural size, but its weight much increased (39½ ozs.). The lower lobe, the limits of which could be traced by the line of thickened pleura, contained encephaloid cancer diffused through its substance. The upper lobes were much condensed, and contained a few scattered masses of the same character. *Left.*—Large, generally emphysematous, with some congestion posteriorly (probably hypostatic). It was perfectly free from any deposit. (Weight, 22¾ ozs.) In the posterior mediastinum was a large mass of encephaloid, apparently formed round, or in the substance of, the bronchial glands.

The pericardium contained about two ounces of fluid, chiefly serous, with some flakes of lymph. Heart (weight 10¼ ozs.) somewhat large; cavities dilated; substance flabby; valves

normal, except some slight thickening of the mitral; aorta and pulmonary artery much blood-stained; some patches of commencing atheroma at origin of innominata, carotid, and subclavian. *Abdomen.*—Liver (weight, 4 lbs. 6¼ ozs.) large, soft, and fatty. On section, the hepatic veins appeared dilated; no carcinomatous deposit; gall-bladder and bile-ducts normal. *Stomach.*—In the lesser curvature, situated four inches from the cardiac orifice, at the posterior part, was a mass of encephaloid, about the size of a large walnut. It was contained in the walls of the organ, between the muscular and mucous coats; on section, was of moderate firmness; the mucous coat over it was entire, but a good deal congested; there were two smaller masses situated near it; the duodenum and intestines were healthy; the mesenteric glands were enlarged; no secondary deposit was found. In the head of the pancreas was a soft white mass of encephaloid, about the size of a marble. Spleen (weight 17¾ ozs.) very soft, quite diffuent; apparently no deposit. *Kidneys* (weight, 6¼ ozs.)—Renal capsules stripping easily; both somewhat congested; in the cortical portion of the left kidney, a small secondary deposit; none in the right.

SATURDAY, MARCH 21.

CHILD MURDER.

SOME energetic philanthropist, who assumes the name of "Eagle Eye," has circulated an analysis of coroners' inquests in England and Wales on children under two years of age, during the year 1861, and the first six months of 1862. From this it appears that 5113 such inquests were held, and that in 1860 of the number there was presumption of violent death. In 222 cases a verdict was returned of "Wilful Murder;" in 680 the verdict was "found dead;" and in 958 deaths was ascribed to suffocation, overlaying in bed, etc. It is assumed, therefore, that about 1200 infants are annually murdered in England and Wales, including about one-third of that number as the *quotum* for London and its suburbs.

A practical acquaintance with the subject induces us to demur to one of the chief items of this heavy bill, so far, at least, as London is concerned. It is assumed that the verdicts of "found dead," which are chiefly upon newly-born infants, whose remains are found "in ditches, fields, drains, cesspools, wells, canals, rivers," etc., point to that number of infants murdered. But there is another hypothesis, disgusting enough, it is true, but still capable of accounting for the finding of these children on more charitable grounds. A large majority of the infants "found dead," are really found with no marks of murder about them. They are still-born infants, which the parents have thrown away to avoid the expense of burial, or which the low undertakers' men have got rid of in this way for the like purpose. The *fee* at cemeteries for the interment of a still-born child is usually 5s., besides which there are the undertaker's charges. If the child have been baptised, and

have ever been registered amongst the number of Christian human beings, the charges are nearly doubled. Hence a discouragement to baptism and to Christian burial. Further, the parents of a still-born child usually leave it to a nurse or undertaker to make all the arrangements for its sepulture. But if the undertaker's man gets rid of the body without burial, of course he can pocket the fees for his own perquisite. A case is reported lately, in which an undertaker tried to smuggle away a still-born child by putting it under the lining of a coffin for an adult. Moreover, bodies of these children are always forthcoming at dissecting-rooms for 5s. a-piece. Clearly, then, there is evidence to show that a great majority of the children found dead in London were not murdered.

But far too heavy a list remains undisputed. There stands the fact; and it is one against which all the Acts of Parliament or other positive enactments conceivable would fall harmless. We would lay down the aphorism that the number of deaths of young children in any community is proportionate to the want of education, of moral training, of social and material position, and that it can only be lessened by indirect measures.

What are the facts? A boy or girl finds him or herself suddenly—at a very tender age, long before body or mind has attained that power of resistance which maturity confers and experience strengthens—brought face to face with the most subtle, alluring, and overwhelming emotions. Let it be granted that the youth has been prepared for this internal conflict, that he or she has been instructed in those means of resistance which religion and morals confer,—like, as it were, to a shield in which fiery darts are quenched,—and that there are all worldly motives on the side of restraint, yet the temptation is always there, and it needs but "opportunity," that mother of vice, to give occasion for the victim to fall into the snare. Then what happens? Possibly, such a heart-rending spectacle as was exhibited at a police court last week, where a mere child of seventeen was committed for the wilful murder of an infant to which she had secretly given birth.

God forbid that we should palliate crime; but in any such case as this we should like to see the parents and guardians indicted conjointly as accomplices, to give them the opportunity of proving that the fall and subsequent crime were not to be attributed to their neglect. Was the girl properly trained in morals generally? Had she ever received from her mother cautions against this breach of morals specifically? How came the opportunity? Had the parents adequate grounds for trusting the girl? Would they have entrusted her whole fortune in money, be it much or little, to a girl of seventeen? If not, did they consider themselves justified in trusting her with her own honour?

When we consider the imperfect training of many girls, the low tone of their associates, the powerful nature of their internal emotions, and then the reckless mode in which they are cast loose, with nothing but their own slender discretion to trust to, we can only wonder that infanticide is not more common; and we see no chance of any diminution, until the whole facts of sexuality, as a part of natural science, are known to those who have the care of young women, and until the same amount of precaution is taken as there is against physical pestilence.

Vice is born of inclination and opportunity. Subtract both if you can. If not both, at least the latter. "Clap your padlock on the mind," if you can; but if you cannot, though it is said "love laughs at locksmiths," yet the locksmith is no mean ally to virtue.

THE PLEA OF INSANITY.

Is it possible that a clear line of demarcation can be established between criminal madness and madness the result of crime,—between the condition in which criminal impulses,

voluntarily nursed and cherished, become the irresistible rulers of a man's being and destiny, and the condition in which, without any wilful yielding to the dictates of vicious instincts, a course of crime is the first, and it may be for a time the only symptom of disease? We fear not. We at least know of no rules that can be applied in the diagnosis. In both conditions the individuals are equally of unsound mind, and are equally proper subjects for curative or palliative treatment; the sole difference from a Medical point of view being, that in the one the person has become diseased from causes over which he had no control, in the other that he has of his own accord pursued a course of thought and action which has given rise to a similar pathological state. In the same way certain diseases may arise from hereditary or constitutional causes, or they may be produced by drunkenness and vice. In either instance they are equally morbid states claiming the skill of the Physician. But in the case of insanity, the moment we quit the Medical point of view and regard the conditions we have specified in relation to society at large, their aspect entirely changes. The necessity of exactly estimating the nature of the chain of causes in the case of mental disease becomes forced on us by the question of responsibility. If the condition of drunkenness be no valid excuse for crime committed during intoxication, it cannot be allowed that a condition of insanity, induced by a voluntary course of vice, renders the agent irresponsible. Such at least will be the judgment of practical men who weigh equally the claims of society and the claims of the diseased.

But the etiological is not the only question of difficulty which encumbers the subject of criminal insanity. Leaving it out of consideration, an equally important inquiry is whether, in certain states of insanity, responsibility is lost? Can responsibility attach to an insane person, or, in other words, is any degree of insanity compatible with any degree of responsibility? For the settlement of this question it becomes at once necessary that a clear line of demarcation should be drawn between sanity and madness. If a man feels within him an impulse to commit a crime, knowing at the same time his moral obligation not to commit it, and resists the impulse, who will say that such a man is insane? But should he yield, is the fact of his yielding to be taken as a proof that the impulse was irresistible, and therefore that the man was mad? Such a conclusion could only be justly drawn in the case of a person who had previously displayed unequivocal signs of mental alienation.

There is no doubt that in all cases the previous condition and circumstances of the criminal are the only sure *indicia* for forming a valid opinion. But to draw from these a sound conclusion requires a thorough acquaintance with the causes, pathology, and symptoms of mental disease. To throw the *onus* of a decision on an uneducated, or even on an educated, jury is a wrong to them and a wrong to the criminal. It may be said that in such a case the judge directs the jury. But it is not so. Even were the judge competent to throw scientific light on the question, it is not part of his duty so to do. He usually states what is the law, gives a digest of the evidence, and leaves the matter of responsibility or non-responsibility where he found it—as *the* question to be decided by the jury.

The cases of Charles Fooks and Edwin Alfred Preedy, to which we referred last week, are striking instances of the unfair demands which the law thus makes on men who, however honest their intention, must be unfitted by previous pursuits, education, and habits of mind to act as judges. In both cases the plea of insanity was advanced, and in each it was supported by a certain amount of evidence. In the case of Charles Fooks, the farmer who shot a man named Stone, against whom he was known to have entertained a grudge, strong evidence of unsound mind was advanced by the prisoner's niece, Dr. Tuke, and Dr. Smith, of Weymouth—evidence which, we think, would have entirely justified

another verdict. But, on the other hand, it was also proved that the prisoner was capable of managing his ordinary affairs; that during six months' residence in gaol he had exhibited no symptom of insanity, and that at the time of the murder the murderer was cherishing the strongest feelings of hatred against Stone—declaring that "if Stone came on his premises he would shoot him as he would a rook." Since the trial the incumbent of the parish in which Fooks lived has written to the *Times* a letter urging a commutation of the sentence. In this the writer states that—

"Whatever the scientific definition of the mental disability from which he (Fooks) suffers, I can bear my testimony that, after an acquaintance of fifteen years, I have never known a man more insane as a sane man, nor more sane as an insane man than Fooks."

Again, in the case of Edwin Alfred Preedy, a convict, who stabbed his warder at Portland, it was proved by the prisoner's aunt and mother that he had received injuries to his head in his childhood, that he had been eccentric in his behaviour, and that he had been always considered by his relatives not in "his right mind." On the other hand, the Surgeon and attendants in the gaol had never observed any real symptom of madness, and it was perfectly clear that the prisoner not only knew what would be the consequences of the crime to his victim, but also was aware of the punishment which awaited him. Shortly after the act he said "he hoped the man was dead, for he intended to murder him."

Another recent case is that of the man Burton, who was tried on the 18th, at Maidstone, for the murder of a poor little boy on Chatham lines. The prisoner not only confessed his crime, but said he did it in order to be hanged, as he was tired of life. The motive so stated was urged by the defence as a proof of the man's insanity—by the judge as evidence that he was fully aware of the nature of his act and its consequences. We confess that in this case, allowing the man to be insane, we should be inclined to refer his insanity to the sway and mastery which he had voluntarily permitted his lower instincts to acquire. He had been a brutal as well as an eccentric lad, and confessed that previously to his crime he had made up his mind to murder somebody, and that had one of the witnesses been at the time in Chatham he should have murdered him. However, in this case, the judge, Mr. Justice Wightman, cut the Gordian knot by virtually ignoring the existence of moral insanity except where the intellect is also diseased. In so doing it is needless to say that he placed himself in opposition to every competent authority on Medical psychology.

But in none of these cases is it our main intention to criticise the verdicts of the juries. We have already said that in the instance of Fooks we think that the evidence would have warranted a different decision. But we feel bound to assert that the machinery employed for arriving at a true settlement of such questions is not adequate. In these cases we hold it absolutely necessary that both judge and jury should have the benefit of the highest Medical opinion,—not proffered as evidence by prisoner or prosecution, but supplied by the Government for their assistance and guidance. The questions which surround moral insanity are the most difficult in the whole round of forensic practice, whilst on them depend the most momentous issues. Is it fair to themselves, to the public, or to the prisoner, that a jury of twelve ordinary men should have the whole responsibility of deciding—unassisted by competent and, at the same time unbiassed, scientific opinion?

---

## THE WEEK.

### THE WATER OF THE THAMES.

We fear it is too late to urge further the suicidal nature of the policy pursued in the main drainage scheme. That it will prove a gigantic failure is a conclusion which has already

forced itself upon most unprejudiced persons. If the main end to be secured be the purification of the Thames, the means adopted will assuredly have the exactly opposite effect. The following report by Dr. Letheby on the water of the Thames during 1861 and 1862 re-asserts what has been stated over and over again, that the river during the summer and autumn will be polluted to such an extent as to be unbearable. Dr. Letheby proposes, as the only remedy, that the sewers be defœcated. How is a scheme to be characterised which necessitates a considerable annual expenditure in order that incalculable wealth may be thrown away with safety?

“First,—The water in the middle of the river is invariably charged with a larger proportion of dissolved matter than that near to the shore, but the quantity of suspended matter is greatest in the shore water.

“Secondly,—That the proportion of saline matter in the water is greatly influenced by the rainfall and by the temperature of the river; for when the former is less than two inches in the month, and the latter is over 60° of Fahrenheit, the quantity of saline matter quickly rises from the normal proportion of about 32 grains in the gallon to upwards of 100 grains.

“Thirdly,—That when from evaporation and a diminished rainfall the supply of water to the river is from the ocean, instead of from the land, the mixture of the sea water with the sewage causes an offensive decomposition, which gives an unpleasant odour to the river.

“Fourthly,—That during strong winds, and at the time of the equinoxes, the quantity of suspended matter in the water is greatly increased.

“Lastly, it may be said that the normal composition of the river water is indicated by the proportions of the several constituents of the water during the first six months of the year—namely, from January to June. At that time the amount of saline matter ranges from 22 grains to 34 grains in the gallon, and of this quantity about 3.5 grains are organic. In the summer and autumn months, when evaporation from the river is considerable, the quantity of dissolved saline matter in the water sometimes exceeds 150 grains in the gallon. This shows that at those times of the year there is a strong upward current from the ocean, and it indicates the necessity at those periods for a very perfect defœcation of the sewage of the metropolis which is to be discharged into the river at Barking Creek. If this circumstance is disregarded, the condition of the river in after time, when the main drainage scheme is completed, will be unbearable and absolutely dangerous to health.

“Finally, I may say that the result of the constant examinations of the river water during the last five years shows that the quality of the water has been gradually improving, and that the special manufacturing impurities which were once so constantly present in the water are now no longer there. I attribute this to the careful supervision which is exercised by the officers of the Conservancy in preventing the discharge of such matter into the stream.

“HENRY LETHEBY, M.B., M.A.”

EXCISION OF THE ANKLE-JOINT, AND SYME'S AND PIROGOFF'S AMPUTATION OF THE FOOT—DISCUSSION AT THE PATHOLOGICAL SOCIETY.

At the last meeting of the Pathological Society there was a discussion as to the relative merits of excision of the ankle-joint and amputation of the foot. Excision of the ankle-joint has been performed several times lately by Mr. Paget and Mr. Hancock, and last night Mr. Canton exhibited parts removed in a recent operation. Mr. Holmes raised the question as to whether excision of the ankle was preferable to amputation, and asked especially for information as to how long it was before the patient could use his foot, and, if after recovery, the limb was really more useful than after amputation by Syme's or Pirogoff's method. The discussion, in which Mr. Partridge, Mr. Canton, Mr. Prescott Hewett, Mr. Henry Thompson, and Mr. Holmes took part, then diverged to the consideration of the relative merits of Syme's and Pirogoff's operation. Considerable interest seemed to be excited, and it was resolved that the matter should be practically investigated. Members are therefore requested to

bring before the Society, at the meeting to be held on April 21, patients who have recovered from these operations (Syme's, Pirogoff's, and excision of the ankle), in order that the Society may judge as to the comparative usefulness of the limb after each.

DR. BROWN-SÉQUARD'S LECTURES.—LECTURE V.

DR. BROWN-SÉQUARD'S fifth lecture, delivered on the 5th inst., commenced by resuming the subject with which he closed his previous lecture, namely, Infantile Paralysis. According to the lecturer, this affection is not generally, as is usually supposed, of the “essential” kind—the word “essential,” as now used, being understood to denote a form of paralysis unaccompanied with structural lesion. In the beginning of his practice, he shared the general opinion of the Profession concerning the pathology of this disease, and looked carefully for cases illustrative of it; but an extensive experience has now convinced him that the alleged essential paralysis of children is, at all events, exceedingly rare, and that a great majority of the so-called cases are really instances of paralysis having lesions of some part or parts of the cerebro-spinal axis as its cause. This malady is generally accompanied by some symptoms of structural change: squinting; a difference in the size of the two pupils; different degrees of sensibility; screaming, indicative of acute headache; pain in the calves of the legs; spasms; twitchings; jerking of the limbs; and muscular atrophy, not the simple effect of rest, are indications of organic disease, one or more of which may usually be noted by an observant Physician in cases of the kind in question. The reason why this disease, when it appears in children, is regarded as essential or reflex, and not organic, is, that in them inflammation or congestion of the brain or spinal cord quickly passes away, although it leaves its results, viz., partial or complete hemiplegia or paraplegia. Post-mortem examinations of children who have suffered from this malady, but who have died from some other cause, have frequently afforded evidence of effusions of serum within the dura mater and ventricles of the brain, and, though more rarely, of inflammation of the substance either of the brain or cord. The difficulty of diagnosis of diseases of the nervous system affecting children is of course greatly increased by their incapacity to explain their symptoms; otherwise there is no doubt it would be possible to discover all the phenomena, including the various degrees of anæsthesia and hyperæsthesia demonstrated by the compasses, which adults suffering from like diseases exhibit. The lecturer showed a patient who was affected with paralysis when three years old; she is now probably twelve or fourteen, and is subject to a peculiar spasmodic movement of the arm and hand. She has been treated with iodide of potassium, and a blister has been applied round the arm, with the view of inducing a modification of nutrition in those parts of the brain related to the limb. The result has been great and rapid improvement. The next case shown was illustrative of the extreme violet hue caused by the use of nitrate of silver, and was the more interesting (though not in a medical point of view) because the subject of it, a Monr. Racine, is a descendant of the poet. The lecturer next adverted to a case of facial paralysis, showing the extensive reflex effects of cold water. The patient, 44 years old, was out in the rain, and got very wet in October, 1862. The following night he was affected with facial paralysis. He was unable to shut the right eye; and, the tongue and lips being affected, he could not pronounce certain letters; for the same reason drinking was difficult; there was slight motor paralysis of the right side of the tongue; the sense of taste on the same side was lost; the eye, was very sensitive to light; the sense of hearing on the right side was lessened; there was hyperæsthesia on both sides of the face; but the sense of feeling in the tongue was normal; and there was no tinnitus aurium and no headache. The power of the

nerves on the left side, corresponding to those affected on the right, was also slightly impaired. As will be seen from these symptoms, this case is not one of simple paralysis of the portio dura; the patient frowns on the left but not on the right side, and, as already stated, the right eye remains open; but in addition to these evidences that the facial nerve is involved, the slight loss of motor power in the tongue, the loss of taste, and the diminution in the sense of hearing, show that three other nerves are affected, and yet it is clear that the affection is not centric but entirely peripheral; if any central cause existed, the sense of feeling in the tongue would be lessened; and if the portio dura were affected within the cranium, the function of the auditory nerve would be intensified. There is a further reason for concluding that the brain is in no degree affected; there is no loss of power of, and there are no abnormal sensations in, any of the limbs. It is undoubtedly an instance, though a rare one, of purely peripheral paralysis caused by cold. The next case referred to by the lecturer was one of a man who had hæmorrhage of the brain five years ago, and who, a year and a half ago, became affected with apoplexy of the retina, which was observed by Dr. Jackson, Assistant-Physician to the Hospital. This patient is now suffering from albuminuria, but was not so when first attacked with cerebral apoplexy. This case serves as a good illustration, that when the arteries have given way in one part, the degeneration affecting them will be found to be general, and will sooner or later show itself by serious lesions elsewhere. The remainder of the lecture was occupied in treating of syphilitic diseases of the nervous system. One great feature of these diseases is, that the syphilitic matter, which may easily be detected by the microscope, has a tendency to become deposited in many parts of the cerebro-spinal axis and nerves at the same time: the levatores palpebrarum are peculiarly liable to attack—ptosis of course ensuing; the branch of the third nerve distributed to the iris is also often affected, thus causing constriction of the pupil; frequently deposits in the dura mater, shown by rapid jerks of one side, often the same side as that of the deposit, occur, and are followed by epilepsy. Indeed, any nerve of the body may be affected, of course causing paralysis of the muscles or anæsthesia of that part of the skin to which it may happen to be distributed. Squinting is a frequent result of these deposits. If the patient has had primary syphilis, there is no need to assure ourselves that he has had secondary symptoms before becoming convinced that this poison is the cause of the nervous disease in question, if we find that the nervous system is affected in several distinct parts at the same time. Virchow has satisfied himself by his investigations, that a man who has had a primary sore thirty years before, and no secondary symptoms, may yet have syphilitic deposits in the nervous system, which themselves may be regarded in his case as the secondary symptoms of the disease. If ten, fifteen, or twenty grains of iodide of potassium, and a small addition of the bichloride or proto-iodide of mercury (half a grain of the latter) be given, the effects of the medicine will soon prove the nature of the case. A remarkable instance of syphilitic disease of the nervous system was shown: the man thirteen years ago had a primary sore, two years ago he had itching of the limbs, followed by a node on one hip-bone, and afterwards by a slight eruption of the skin. The swelling of the cervical glands, which Ricord alleges to be characteristic in these cases, but which Dr. Brown-Séquard says he has rarely observed, did not occur in this instance. Succeeding the eruption of the skin the patient experienced dimness of sight in the right eye; both pupils are small, but especially the left one, thus proving an irritation of the branch of the third nerve to the iris. It is clear that this constriction is not due to paralysis of the dilator branch of the sympathetic nerve, for the constriction in such cases is never so great as in the one in question. The sixth nerve on the right side is

also paralysed, causing the patient, of course, to see double. Eight or nine months ago he began to have pains in the head and legs, especially at night; he has great weakness of the right side, less on the left; he has also considerable difficulty in directing his movements (locomotive ataxy), tingling of the limbs, and marked anæsthesia of both legs, pointing to an affection of the roots of the spinal nerves; the sense of hearing and that of taste are both lessened; and there is great difficulty of swallowing, which implies some lesion of the pons Varolii or of the pneumogastric nerve. The protean form of this disease is especially characterised by its tendency to affect particular branches of one nerve: some of the nerves distributed to the eye are almost invariably affected. This patient is much wasted and generally cachectic. The treatment consists in giving large doses of iodide of potassium. Fifteen or twenty grains three times a-day is an amount commonly given by French and German Physicians, and in such large doses there is little fear of injurious consequences. If given with neutral or alkaline salts when the stomach is empty—*i.e.*, there being no acid in it—it is then rapidly absorbed instead of being decomposed. It is best to accompany it with some bitter tonic. But if it should do harm, iodide of ammonium in doses double those of the iodide of potassium, and united with sesquicarbonate of ammonia, may be used instead with success. The secretion from the nose caused by taking iodide of potassium, may be checked by the use of finely powdered sugar taken as snuff. When syphilitic patients, having their minds impaired, are unwilling to take iodide of potassium, it may nevertheless be given to them mixed with fresh butter instead of the usual salt, or it may be employed as an ointment.

---

#### PARLIAMENTARY.

THERE appears to be a remote possibility that the condition of suspense and discontent in which the Medical Departments of the Royal and Indian Armies have so long found themselves will at some future time be terminated. On Thursday, the 12th, Mr. R. Mills asked the Secretary for India when the details for the Amalgamation of the Medical Service of the late East India Company with that of the Royal Army were likely to be promulgated. Sir Charles Wood's answer was in the true official tone, "that the amalgamation in question was a very complicated and difficult matter, and must be attended with considerable expense." He went on to say, "that a plan had been sent out to India some time ago, but a totally different one was suggested by the Indian government in return. The latter plan had been submitted to the judgment of military and Medical men connected with India, who happened to be in this country, and upon the whole they approved it. It had been since sent to the highest military authorities here, and was now under consideration, but he was not in a position to say when the details would be promulgated. He hoped they would be soon."

We are glad to see that General Peel, one of the framers of the original warrant for the Medical Department of the Royal Army, came forward as its champion on Monday, the 16th, on the occasion of the vote of 255,993*l.* for Medical establishments, services, and supplies.

"General Peel expressed regret at the diminution of the staff. The warrant founded on the report of the Sanitary Commission of 1858, was calculated greatly to improve the Medical establishment, by inducing talented men to join. Its provisions had not, however, been carried out, and he thought the Medical officers had just ground for complaint. The result was that the number of candidates was falling off, so that on a recent occasion when there were forty-five vacancies, only fifteen candidates appeared, and some of these broke down under the qualifying examination.

"Sir G. C. Lewis said there had been some difficulty in the navy in regard to the warrant. Negotiations had been opened with the admiralty, and he hoped that before long the

warrant would be issued in a form likely to be satisfactory to all the Medical officers. (Hear, hear.) The numbers of the staff Medical officers were given in accordance with the return of the Medical Director-General. The reductions had been chiefly effected in foreign stations."

We cannot at all admit the validity of Sir G. C. Lewis's explanation. The Army warrant was promulgated long before that of the Navy, and was completely independent of it. However, the facts stated by General Peel, as to the number and quality of the candidates presenting themselves for commissions, will not be lost on Parliament. The Medical students of the United Kingdom are masters of the position, and, if they be true to their Profession and to themselves, they will compel the Government to redeem the promises they have given.

On Wednesday, Mr. Brady moved the second reading of his Bill for the prevention of the spread of disease, by the conveyance of patients suffering from infectious and contagious disease in cabs. The provisions of the Bill were few and simple. The principal clauses enacted:—1. That suitable carriages for conveying infected persons should be provided by every local authority executing the Diseases Prevention Act within the City of London, or the Metropolitan Police district. 2. That the rate of charge for such carriages should not exceed ordinary cab-hire. 3. That persons conveying patients whom they believed to be suffering from contagious or infectious disease in ordinary hackney carriages should be subject to a fine, not exceeding ten pounds. 4. That it should not be necessary that the nature of the disease be proved; it would be sufficient if the disease were believed to be infectious. Lastly, that for the purposes of the Act the word "infectious" should include "contagious," and every contagious disease should be deemed infectious.

"Mr. Brady hoped the Government would see the necessity of passing the measure, because the public mind was greatly alarmed on the subject. The report of the Fever Hospital abundantly demonstrated the necessity of some such measure as the present. There were in one year 663 patients taken to the Fever Hospital, and out of that number 110 died, showing that the diseases under which they laboured were most serious; and it was evident that patients of that class labouring under typhus or typhoid fever must necessarily infect any public conveyance, and lead to the spread of disease. In families where servants were taken ill, the first thing that was done was to have the person removed either to a public institution or sent home, not through unkindness, but for the sake of protection of the family; and such persons were invariably conveyed in public conveyances. In the case of scarlet fever, there was no knowing how long the contagion lurked in clothes or in drawers; and there could be no doubt that any person sent home or to the Hospital with scarlet fever would infect the public conveyance in which they were carried. Out of the large number of cases he had alluded to, it was a remarkable fact that 530 were sent to the Hospital by the parish authorities. That satisfied him that the parish authorities, being the natural guardians of the poor and the representatives of the ratepayers, were the proper persons to carry into operation the provisions of the bill he now moved. There were undoubtedly cases in which ladies and others had taken fevers in consequence of travelling in cabs which had previously been employed in conveying patients to the Fever Hospital. If his bill were not perfect, it might be amended in the committee, but there could be no doubt that some measure of the kind was absolutely necessary.

"Mr. Ayrton opposed the bill, as an example of minute and trifling legislation, which would do more harm than good. Cabmen might refuse to take any one, under the plea of suspecting the person hiring the cab of being infected with a contagious disease, and thus open the door to the extortion of cabmen. What real evidence was there that disease had been extensively propagated in public vehicles? In his opinion the bill itself was not equal to carrying out what it professed to accomplish.

"Mr. D. Griffiths was of opinion that the hon. gentleman who introduced this measure deserved the thanks of the community at large. He mentioned a case within his own knowledge, in which a servant with the small-pox had been sent to the Hospital in a public cab, to the great danger of the

public. It was plain that that cab might be, and probably was, engaged within five minutes after the departure from the Hospital, and it would be a most extraordinary thing if some measure could not be passed to mitigate the evil. He should be sorry to believe that this matter was beyond the power of legislation.

"Mr. Henley regretted that there was no Minister whose special duty it was to be informed upon all matters relating to the conservation of the public health. The House was quite in the dark with reference to the working of the Act passed two years ago, or whether it had been evaded, and by whom. With reference to the more difficult part of the Bill, the enacting parts, and the penalties attached, it was impossible to see how it should be carried out. There ought to be an interpretation clause at the beginning. The Bill said that every infectious disease was to be considered contagious, and every contagious disease infectious, but that did not inform them what diseases were contagious or infectious. They all knew that the itch was considered somewhat catching, and there were other diseases in reference to which it was hard to say whether they were infectious or not; people therefore ought to be made aware, when a £10 penalty was to be imposed, in what cases they would be subject to the penalty. If the Secretary of State for the Home Department could see that a Bill of this nature could be put into a proper form, and be supported by the Government, he would support it; but if the Government did not see their way to make it a useful measure, he should not support it.

"Sir G. Grey referred to the withdrawal of the clause affecting this question in the Diseases Prevention Act, and observed that although he quite admitted the importance of the subject, yet he did not think that the present measure could be altered in committee so as to make it an effective measure. The hon. gentleman wished to make the permissive clause in the bill of 1860 compulsory, but there was no machinery whatever in the bill to accomplish the object sought, nor could it be amended in committee in his opinion. The subject was fraught with difficulty, and the real effect might be, that it would deter people from using public conveyances at all. Besides this, there really ought to be some evidence as to the necessity of the proposed special conveyances, and he could vouch for the fact that in one extensive district in which such a conveyance had been provided, there had not been one application for it. If the object was to be accomplished at all, it could only be accomplished by means which the honourable gentleman objected to, namely, by the police, who had conveyances and stretchers; and he thought that stretchers in particular might be very usefully employed, while it was evident that it would be far easier to apply to the nearest policeman, who would get a stretcher in a few minutes and remove the diseased person. He suggested that the motion should be withdrawn until further inquiries into the subject were made.

"Mr. Brady consented to that course, and the motion for the second reading was postponed until May 27.

"The House then adjourned at twenty minutes past one o'clock."

We are sorry that the bill which, whatever its deficiencies in detail, was excellent in principle, was thus withdrawn, and we hope that Mr. Brady will not hesitate to take the earliest opportunity of again bringing the subject into notice. Sir George Grey's instance of disuse of the carriage provided by the district authorities, merely shows how necessary it is to make the employment of such a carriage compulsory. The proposal to take patients suffering from typhus, small-pox, and scarlatina through the open streets on stretchers, is worthy of the genius which presided at the Home Office on March 7 and 10, 1863.

**MEDICAL PROFESSION IN VIENNA.**—According to the most recent statements, there are at present in Vienna 560 physicians, 179 surgeons, and 912 midwives. Of this number 93 physicians, 13 surgeons, and 9 midwives are paid from government funds; 92 physicians, 32 surgeons, and 14 midwives are employed in institutions; and 375 physicians, 134 surgeons, and 890 midwives are engaged in private practice. There is 1 physician to 947 inhabitants, 1 surgeon to 2,961 inhabitants, and 1 midwife to 291 women.

## REVIEWS.

*The Tropical World; a Popular Scientific Account of the Natural History of the Animal and Vegetable Kingdoms in the Equatorial Regions.* By Dr. G. HARTWIG, Author of the "Sea and its Living Wonders." With eight Chromoxylographic Plates and numerous Woodcuts. London: Longmans. 1863. 8vo, pp. 566.

*The Weather Book: a Manual of Practical Meteorology.* By Rear-Admiral FITZROY. London: Longmans. 1863. 8vo, pp. 464.

*The Earth and its Mechanism; being an Account of the Various Proofs of the Rotation of the Earth, with a description of the Instruments used in Experimental Demonstrations, to which is added the Theory of Foucault's Pendulum and Gyroscope.* By HENRY WORMS, F.R.A.S., etc. With numerous Woodcuts and Diagrams. London: Longmans. 1862. 8vo, pp. 296.

WE include these books under one notice, because they form parts of the extensive series of works on Physical Geography which are published by the Messrs. Longman, and because we are thus able to give, with more economy of our limited space, an account of the characters of each.

Dr. Hartwig's "Tropical World" is, as its title-page declares, a "popular" book. If we may be pardoned the play on the word, it well deserves popularity, and is just the book to interest young persons who have the sense to perceive that the truths of nature are not only stranger, but far more profitable than some fictions. All that intelligent women and children desire to know about the tropics will be found here;—the aspects of nature, the rivers and coasts, the great sandy deserts, the gigantic vegetation, and the animal denizens from insects to apes; but excluding the tropical varieties of man. Livingstone, Emerson Tennant, and other great travellers, are resorted to for the facts which Dr. Hartwig has woven into the handsome and instructive book before us.

Rear-Admiral Fitzroy's "Weather Book" is not intended solely for scientific persons, nor yet for sailors, but for all persons of education who may wish to understand the phenomena of the weather, and to make practical use of the various instruments which are commonly employed to test and indicate its varying conditions. The writer begins with a familiar account of the atmospheric ocean with which our terraqueous globe is environed; and of the great influence—heat—by which its equilibrium is disturbed. He then describes the properties, construction, uses, and cost of the various instruments used in meteorological research, with a notice of various popular and unscientific marks from which the weatherwise peasantry are in the habit of gathering indications. Then he speaks of the registration and comparison of observations, and of the history of their appreciation and use. On this last head he shows how great an interest the public at large have in the matter, because a knowledge of wind and weather tends greatly to shorten sea voyages; and considering that the expenses, the wear, and tear, and wages of a large ship vary from £50 to £200 *per diem*, the price of freight and passage, and the cost of all commodities brought from distant countries is lowered in proportion as voyages are shortened. Then we have a practical account of climates all over the world; an account of the system of simultaneous meteorological observation and telegraphy carried on at the Board of Trade, and the principles on which weather may be *forecast*. An abundance of tables and diagrams conclude the book, with an appendix, in which we notice a great variety of interesting matters:—Amongst them, an account of that "Weather Glass"—a closed tube, containing camphor and sal ammoniac, which is seen at most philosophical instrument makers, and which is a puzzle to most people.

Mr. Worms's book on the "Mechanism of the Earth and its Rotation," although the introductory chapters are written in a popular style, is a work of more exclusively scientific character than those which precede it in our list, and is, in its greater part, intended for the mathematician exclusively. It contains accounts of the application of Wheatstone's revolving mirror to the determination of the velocity of electricity and light; of experiments with falling bodies, made by Professor Reich in the mines at Freiburg; and of the experiments of Foucault with the pendulum and the gyroscope.

Our readers will recollect the pendulum experiments made four or five years ago at King's College and the College of Surgeons; they are described in Mr. Worms's book.

*A Manual of Elementary Chemistry, Theoretical and Practical.* By GEORGE FOWNES, F.R.S., late Professor of Practical Chemistry in University College, London. Ninth Edition, Revised and Corrected. London: Churchill and Sons, 1863. 12mo, pp. 820.

THIS work has attained so large a popularity at all Medical schools, and other institutions in which chemistry forms a part of the curriculum, that it is unnecessary for us to do more than briefly announce this, the ninth edition. Its main characteristics are brevity, yet fulness and clearness. It begins with an account, in rather more than 100 pages, of such portions of physics as the Medical student is generally expected to be master of; including specific gravity, the constitution of gases, heat, light, electricity, and magnetism. In this part is introduced a very clear and good account of the principles of spectrum analysis and of photography. In 300 pages it then treats of inorganic chemistry. And under the head of hydrogen compounds gives the details of Mr. Graham's process for separating *colloid* from crystallisable substances by *dialysis*. In 400 pages more it recounts the principles of organic chemistry, and throughout is illustrated by woodcuts, not enough to make it a "picture-book," nor yet, with some exceptions, to exhibit common apparatus, but to explain special devices, such as Graham's Dialyser. About forty pages are devoted to an exposition of Gerhardt's system of notation, which we gave an account of in the *Medical Times and Gazette* for Sept. 27, 1862. Although the editors conceive that it would be inexpedient to adopt this system in the body of the work, they yet judge, quite rightly, that some knowledge of it is essential to the student. When we add that this ninth edition has been revised by Dr. Hofmann and Dr. Bence Jones, we need not say that it will commend itself to the notice of the student of chemistry pure and simple, as well as to him who desires to study chemistry because of its relation to Physiology and Medicine.

## FOREIGN AND PROVINCIAL CORRESPONDENCE.

## FRANCE.

PARIS, March 3.

PERIODICAL literature has had a striking influence upon the progress of Medical science in France. It is carried on with unceasing energy, and employs the time and powers of some of the most intellectual men in Europe. No less than forty journals appear at stated intervals; there are some that are published as often as three times in each week, and they are all fully supported by the reading Medical world. "The appetite seems to increase by what it feeds upon." Scarcely is there a person interested in the cultivation of the healing art that does not see at least two periodicals weekly. They are found equally necessary for the student and for the experienced Practitioner; and no one can feel that he keeps pace with the march of science if he does not know what is contained in their prolific pages. The journals in Paris are, for the most part, either three times a week or weekly; and whilst some of them have their *spécialité*, and are devoted to a single branch of the Profession, others embrace all its parts, give outlines of lectures, hospital cases, clinical observations, transactions of the Medical societies, and reviews of the works that are likely to excite much interest.

*La Gazette des Hôpitaux* makes its appearance three times in each week, under the careful superintendence of Doctor Brochen; it is deservedly a favourite with the Medical world, and furnishes a faithful picture of all that is passing. *L'Union Médicale* likewise gives three times in each week a mass of scientific and practical observations; its chief editor, M. Amadée Latour, pursues his task with great care and zeal.

The *Gazette Médicale* is superintended by Dr. Jules Guerin, who offers the result of his experience and his acquaintance with the different branches of knowledge. This is brought out only once a week, as well as the *Gazette Hebdomadaire*, which is much esteemed, and its editor, Dr. Dechambre, is considered as admirably adapted for the task he has under-

taken. Dr. Brown-Séguard superintends the *Journal de Physiologie*, which appears twice in each month. The *Journal des Connaissances Médicales* is circulated every ten days.

Each branch has its journal. Psychology and mental alienation have their exponents; Dr. Baillauger and Dr. Delaseauve superintend their respective periodicals. Dental Surgery, Ophthalmology, and even Homœopathy find the means of giving publicity, either weekly or monthly, to the subjects to which they are devoted.

The Medical Societies are occupied in debating upon a question rather relating to the moral duties of the Physician than to science. It has undergone not only warm discussion within the walls of the Schools, but is filling long columns in the journals. This question is,—Ought a Physician to disclose to any individual the malady which calls for his attendance upon a patient. The law in France, as laid down in the *Code Napoleon*, formally forbids a Medical man to communicate to any one the professional secrets confided to him. But, may not there be sufficient reason for him, according to his judgment, to commit a breach of this law? A case has been put which has brought into the field some warm advocates for a frank disclosure under certain circumstances on the part of the Physician.

A young gentleman had paid his addresses to a lady of delicate health, and had been accepted by the family; it, however, came to the ears of the young lady's father that her betrothed had been for some time under the care of a Practitioner of considerable eminence, and he had heard such hints thrown out that he judged it proper to call upon the Physician with the hope of learning from him whether his intended son-in-law had any complaint that might prove injurious to his daughter, who was herself somewhat of an invalid. He was courteously received by the Doctor, who, however, positively refused to give the slightest information as to the state of the youth, his patient. He declared that it would be a breach of confidence which no circumstance could warrant. The father dwelt upon the necessity of arriving at truth, and stated that the approaching marriage of his daughter filled him with anxiety from what he had accidentally heard. He pleaded in vain; not a syllable was to be obtained from which he could glean any shadow of information. The marriage took place, and fearful were the results. The young wife was affected with secondary syphilitic symptoms, which, from her ignorance and her delicacy, assumed a most formidable character, she not disclosing her state to anybody. An infected infant is brought into the world; the mother, always delicate, dies, and a tragedy of a most afflicting character supervened, in consequence, as it has been alleged, of the improper silence of the Medical man. Arguments on both sides have been heard. At two of the Medical societies, the opinion has been given by large majorities that one of the first duties imposed upon the Doctor is silence. The oath of Hippocrates to that effect is quoted, and there seems to be a disposition generally to consider that the Physician is never warranted to give information as to the state of those consigned to his care. The words of the law which appear in the penal code are,—“Physicians and other persons who by profession are depositaries of secrets confided to them, and who, unless called on by law, shall reveal such secrets shall be punished by imprisonment from one to six months, and by fine from 100 to 500 francs.”

Dr. Civiale has delivered his annual retrospect of his practice in calculous disease within the last year. He has had 69 cases of stone in the bladder for treatment,—66 men, 2 women, and 1 child; 45 of these were private patients, 24 were at the Hospital; 61 had stone for the first time, 8 had already been subject to the disease; 58 of these cases were operated upon, 45 by lithotrity; 1 fatal occurred only. There were 8 cases relieved only, 10 were submitted to the ordinary operation, of which 3 were cured, 2 relieved, and 5 died; 3 have been operated on by joining together the two methods of lithotrity and cutting; of these 2 were cured, the third has irritable bladder; 11 did not undergo any operation. An analysis of this *compte rendu* would occupy more space in the *Medical Times and Gazette* than could be given to it, but it would prove highly interesting; it is to be found in the *Gazette des Hôpitaux*, in the number published 27th of the last month.

Syphilographie has had an addition in a memoir by Docteur Amedée, Paris, in which he points out the advantage of filiform setons in suppurating buboes.

## SCOTLAND.

MARCH, 1863.

As your faithful correspondent, I sit down to write my usual letter.

Mr. Syme has had another important aneurism case in the Royal Infirmary. The tumour situated in the left groin above and below Poupart's ligament. The operator laid the sac open, and applied ligatures to the external iliac and superficial femoral arteries. Professor Lister came from Glasgow to compress the aorta, and all seemed to go on well; but unfortunately the patient died. No doubt a full report of this case will be published. Mr. Lister's abdominal tourniquet, described in “Holmes' System of Surgery,” seems to the bystanders here very efficient. I have heard, however, that it has elsewhere induced faintness and vomiting. When M. Nélaton, some years ago, injected gluteal aneurisms with perchloride of iron, he had the abdominal aorta compressed by the hand of an assistant.

The President and Council of the Royal Society gave a *conversazione* the other evening. Professors Bennett and Balfour exhibited a large number of microscopic preparations. The Astronomer Royal for Scotland had a huge magic lantern, and exhibited views illustrative of his ascent of Teneriffe. A photograph of the moon was also shown on a large scale, which, from its weather-beaten and decayed appearance, seemed, as the Yankee said of the Coliseum, to be “a fine thing in its way, but requiring a deal of repair.”

A gentleman, whose name I forget, showed an ingenious electric lamp for mines. The light is contained in a gas-tight, glass-sided box, set on wheels. As it would not do to completely exhaust the box and expose it to a dangerous degree of atmospheric pressure, there is an elastic bag suspended underneath, which receives the surplus air after the glass sides of the box have cooled, and *vice versa*. The electricity is generated by a steam-engine, which does the other work of the mine.

Messrs. T. and H. Smith, the well-known chemists, exhibited pharmaceutical preparations, among others, a vase of “Muriate of Thebaia,” the beauty of which was a general theme. To produce this Circean goblet required the manipulation of “five tons of opium, costing about £11,000, and requiring for their production about 1100 acres of poppies.”

The College of Surgeons held a somewhat similar meeting lately. Dr. Newbigging (the President) had about 300 guests, including many from Glasgow. Professor Syme narrated a case of removal of the scapula, and one in which he excised the head of the humerus for a tumour. The latter case had been in a neighbouring metropolis, and temporising was recommended. Our Clinical Professor thinking, with Lady Macbeth,—“If 'tis to be done, 'twere better 'twere done quickly,” operated at once and successfully. The scapula case was then shown, and the singular fact demonstrated, that one with a hand and arm can move the same, nay, swing about a chair, in spite of being minus a shoulder-blade, the bone generally used in these movements. He could also tuck his elbow under his chin; and in short, so far as his right upper extremity goes, deserves admission to “the Society of India-rubber Brothers.”

Mr. Turner then gave a lecture on “Cellular Pathology,” characterised by clearness, condensation, and facility of demonstration. Dr. Wilson, his colleague in the dissecting-rooms, had furnished him with many diagrams which admirably illustrated the lecture, while they did great credit to the clever artist and accomplished anatomist who could tear himself from the charms of a putrid dog-fish to draw them for his friend.

Virchow's theories seem to be in favour here; many of our most active students and young Practitioners have been his pupils, and industriously propagate his doctrines in opposition to those of Professor Bennett. The most practical remark in Dr. Turner's paper was that cancer cells may be found in the muscular fibres near a malignant tumour, but sufficiently far off to escape the knife. I believe Professor Bennett made this fact public some years ago, but I fear Surgeons would scarcely wait while their microscopic brethren adjusted their slides and lenses. It is one thing having to examine a piece of morbid tissue on your study table, and another having to cut it from the quivering flesh of an enfeebled patient.

After Mr. Turner's lecture, Dr. Craigie, President of the

College of Physicians, thanked both gentlemen in the name of the audience, especially congratulating Professor Syme on having so successfully followed out a practice (removal of the scapula) suggested many years ago by Mr. Liston, and subsequently accomplished successfully by several Surgeons in London and elsewhere. Dr. Craigie did not mention the name of Mr. Jones, of Jersey—no doubt an unintentional omission.

At the Medico-Chirurgical Society, Mr. Spence read a paper on Amputation. He gave a sketch of the various methods,—how Messrs. Syme and Liston advocated flaps, how the former had subsequently modified his views, and now performs a mixture of the flap and circular. The author prefers a long anterior flap, the skin being first dissected up, then the muscles divided, and the flap doubled over the end of the bone,—apparently Teale's operation, but with little or no posterior flap.

From the subsequent discussion it would seem that we have no means of ascertaining accurately what is the average mortality after amputations performed in this Infirmary. Mr. Spence had a table of his own experiences there, but had not drawn any important results from it. When we consider the number of amputations performed here we cannot but regret, not only that the poor patients are not crustacean, but that the results of operations are not made public in a tabular form.

Dr. Handyside made some allusions to acupuncture, which is now frequently used here. Many cases were cited, but it still possesses what Balzac called "l'amertume de la nouveauté," and is therefore not to the taste of the Infirmary Doctors.

Professor Lister, in his article already referred to, says clipping off one end of the ligature is not worth the *time* or *trouble*. Mr. Spence alluded to cases where eighteen or even twenty-four vessels have been tied on the same stump. Now, if even the smaller of these had been compressed between the wire and needle they could have been removed in a few hours, and surely would have been well away.

Mr. Annandale read an interesting paper "On Grangrene, following Obstruction of the Femoral Artery."

Among the other demonstrations on the 10th there was to have been a procession by torch-light of nearly a thousand students. They were to march through the town and up the zig-zag paths of the Princes-street-gardens. No doubt this would have added greatly to the picturesque. The worthy authorities did not exactly stop the procession, but excluded it from the main streets and the gardens. Now, as walking about carrying a torch, with nowhere to go to, and nobody to look at you, is not an exhilarating way of spending a winter night, the students preferred studying human nature without the adventitious aid of oakum.

The Edinburgh College Hall Company (Limited) seems likely to obtain a complete and rapid success. There are at present in Edinburgh 1050 students who have come here, and chiefly lead a solitary life in lodgings. The site proposed for the building is somewhere near the schools, and the accommodation contemplated in the first instance comprises a dining-hall for students generally, bedrooms for fifty residents, reading-rooms common to several residents, and separate parlours for those who may require them. The charges are estimated at £48 on an average for the winter session of six months, and £24 for the summer session of three months, leaving a return of 5 per cent. yearly to the shareholders for their advances. The cost of building and furnishing a suitable hall for fifty students is estimated at £15,000.

Every one who knows the natural history of students will see at once how desirable it is that such a building should exist. Its success cannot in any way affect the interests of private families taking in boarders, or of the regular lodging-house keepers. The only appreciable effect it can have on the latter will be to create a healthy opposition. Indeed, I do not despair of seeing the windows of lodging-house parlours occasionally open (I allude to the old town); to see bed-closets put to their original purpose of coal depôts; nay, when maids-of-all-work will be no longer afraid of spoiling their complexions by soap-and-water, and a weary student may regale on well-cooked chops and steaks. The new College Hall is much wanted, and I have no doubt will do a great deal for the moral and physical benefit of the students, and, through them, advance the reputation of our already-celebrated University.

## GENERAL CORRESPONDENCE.

RUSSELL v. ADAMS.  
LETTER FROM MR. ADAMS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to forward to you a letter from Mr. Maitland, the secretary of "the Royal Benevolent Society," which you may perhaps deem of sufficient importance to publish in the *Medical Times and Gazette*, since from an official source it exposes the system of trading upon one of the charitable institutions of London—and others have equally suffered by a similar practice—adopted by a Mrs. and Miss Russell, who have also for many years systematically traded upon the benevolence of members of the different professions, more especially the clergy and Medical men.

As one of their last victims, I have lately been dragged before the public, in the Court of Exchequer, as the defendant in the most absurdly ridiculous action for breach of promise of marriage which ever disgraced an English court of justice.

I am, &c.,

WM. ADAMS.

5, Henrietta-street, Cavendish-square, March 18.

"Royal Benevolent Society, Sussex Chambers, S.W.

"10, Duke-street, St. James's-square,

"March 12, 1863.

"*Re Russell.*

"MY DEAR SIR,—In reply to your letter of yesterday's date, I beg to subjoin an account of the above case:—Mrs. Russell was first referred to the Society by Lady Mary Ross for investigation in 1859. On inquiry it was found she was of respectable extraction, and in great want. A situation had been obtained for her daughter at Little Hampton, and a sum of money was requisite for the purpose of conveying them both to that place. Under these circumstances the case was brought before the Committee, and a loan of £12 (without interest) was granted. Of such loan £6 10s. only was repaid, the securities, Lord Raynham and Dr. Major, having liquidated the balance.

"In January, 1860, they left Little Hampton, in consequence of some disagreement, and went to reside with a Mr. Crump, at Andover-road, Hornsey. In the summer following they procured a list of subscribers to this Institution, and commenced a system of *begging-letter writing*. I cautioned them if they did not desist I should be obliged to warn all the members, which, in consequence of their persevering, I did.

"In March or April, 1861, she left Mr. Crumps in consequence of a quarrel. She refused to go at first, and it was only on Mr. Crump bringing in the brokers that they vacated their quarters. They have since led a roving life, going from lodging to lodging, in Osnaburgh, Coleshill, Warwick, Portland, streets, etc., and invariably leaving in debt and disgrace.

"In November, 1861, they wrote several letters of a similar description, and Miss Russell came to me requesting me to recommend donations, as she required them for an action of breach of promise against Dr. Adams. Of such fact I at once apprised the various subscribers.

"With respect to your friend, Dr. Adams, I am not aware I can be of much service. However, it is a fact not to be denied, that they were from first to last well aware he was a married man, for long before the alleged proposal in September or October, 1860, I had been asked by Miss Russell to advance money for the purpose of procuring certain materials to make up goods for a stall Mrs. Adams was to hold at some bazaar.

"Miss Russell asked me to commence the action for her, but I informed her the Royal Benevolent Society was not instituted for such purposes. I recalled the above facts to her mind, asked her how she could reconcile them, and recommended her, if true, at once to accept Dr. Adams, to marry him, and, on leaving the church, give him into custody for bigamy. I told her that course would be the shortest and most efficacious, but she stated she preferred an action, as the money would be so acceptable, and that he never would dare go into court.

"On her again pressing me to commence the action, I told her an attorney was the proper person, upon which she went to the solicitor belonging to this Society, and who afterwards threw up the case. Subsequently Miss Russell informed me Mr. Propert had taken up her cause, and was to carry it on at

his own risk; in fact, she showed me a letter stated to be from Mr. Propert, in which he informed Mrs. Russell of the above. The letter was dated from New Cavendish-street, it being stamped on the head with blue ink.

"If you require any further information on the subject, of course I shall be happy to give it to you as a subscriber to this Society.

Faithfully yours,

"WM. H. MAITLAND.

"The case was carried on by Mr. Pike, Mr. Propert's solicitor.

"To —, a Subscriber to the Royal Benevolent Society."

## REPORTS OF SOCIETIES.

### EPIDEMIOLOGICAL SOCIETY.

MONDAY, FEBRUARY 2, 1863.

DR. BABINGTON, F.R.S., in the Chair.

A PAPER, by THOMAS HUNT, F.R.C.S., was read, on DISEASES OF THE SKIN DEVELOPED IN SCHOOLS, WORKHOUSES, AND FACTORIES, FROM DEFECTIVE HYGIENE.

The author wished prominently to bring forward the effect of congregating and incarcerating many children or young persons under one roof, of feeding them on one and the same diet, and thus promoting locally the more or less permanent inroads of certain cutaneous diseases, which diseases often subside spontaneously upon the removal of the sufferer from the locality. These diseases are chiefly the common ringworm (*porrigo sentulata*) and scabies, the former being usually aggravated by the presence of a vegetable, the latter by an animal parasite. He had never visited a workhouse, or a detachment of pauper children, or a large boarding-school occupied by the poor, without observing many cases of ringworm and scabies; one of these two diseases prevailing at one time, the other at another period, and both showing a tendency to pustulation. These cutaneous plagues will often persist month after month, in spite of the most careful treatment and the most scrupulous attention to cleanliness and ventilation. He had already published an account of an endemic scabies which infected, for many months together, a large girls' school in the neighbourhood of London, where cleanliness, ventilation, good drainage, good nursing, and good Medical care were conspicuously apparent. But nothing was of any permanent service until an entire change of diet was introduced, together with the daily exercise of the inmates away from the premises. Accounts of similar endemic difficulties reached the author from Medical Practitioners who had the charge of institutions of the same character in different parts of the country, and the same kind of treatment proved equally effectual in all of them. In those factories where children are employed, and boarded and lodged on the premises, like occurrences are observed, involving the clean and the dirty, the well-fed and the ill-fed. The doctrine of contagion fails to explain the cause; nor, indeed, is any one imaginable cause to be named that is capable, *per se*, of accounting for all the peculiarities of the case. But it appeared to him, that by duly reflecting upon all the sanitary circumstances in which these children are placed, we may be able to discover an aggregate of influences, so to speak, which not separately but concurrently may combine to produce these morbid conditions. Atmospheric impurity, unnatural diet, deficient exercise, and contagion, are the four conditions which appear to unite their several forces to perpetuate these loathsome affections of the skin. And yet not one of these causes alone ever presents a formidable difficulty in the treatment; neither do any of them exist in any prominent degree in these establishments. There is no sensible vitiation of the atmosphere, no bad smell, no defective drainage, no neglect of ventilation. The diet is excellent in quality, plentiful in quantity, wholesome in character, and correct in its chemical elements. Exercise is allowed and encouraged within the walls of the institution, and contagion is for the most part antagonised by care and cleanliness, and often by individual segregation. So that, considered apart, these causes of disease exist, if at all, in scarcely an appreciable degree. And yet, together, they are capable of establishing a most formidable cachexia. They poison the blood, producing not only their immediate effects in the form of parasitic skin disease, but laying the foundation probably of more serious disorders,

manifested in after life by the presence of lumbrici, ascarides, tapeworm, pediculi, fungi, hydatids, tubercles, and perhaps cancerous germs, in the various organisms which, under morbid changes, become capable respectively of nourishing these distinctive parasites. The author then considered the causes referred to singly, and of sameness of diet he said:— There is a daily dole of potatoes with boiled mutton, or potatoes without boiled mutton; there is the eternal pea-soup or oatmeal gruel, with so many ounces of bread, and so many grains of salt. Oh, what a luxury would a red herring be to those poor creatures, or a lettuce, or an apple, or a dish of greens, or carrots, or turnips. Man was made capable of living upon a *variety* of food, animal and vegetable, fish, flesh, fowl, root, leaf, stem, fruit, and seed. But no man can live on bread alone; no, nor on mutton chops alone, nor on any two or three articles alone. The life supported by half-a-dozen changes only is in a feeble, imperfect, half-poisoned condition. It appeared, then, to the author, that these four causes, atmospheric impurity, sameness of diet, insufficient exercise, and contagion, all of them trifling in degree, are yet capable of working together for evil, and may thus become powerful agents in the promotion and perpetuation of disease. The blood becomes vitiated from the unvarying character of the diet, from impure and stagnant air, from deficient perspiration, and restricted activity of limb, and the agents of contagion triumph over the low degree of vitality which results. If this be sound pathology, these combined evils will probably be found to play a busy part in the production or aggravation of other diseases, endemic or epidemic in their character. Fortified by an ample, generous, and varied diet, free ventilation, active exercise, and cleanly habits, our junior population might set at defiance cholera, diphtheria, dysentery, and typhus, and probably half the physical "ills which flesh is heir to."

Mr. FRENCH said that his experience of the itch in a London Workhouse, viz., that of St. James's, Westminster, did not accord with that of the author of the paper, "that the disease was produced by a uniform diet," or the other circumstance to which he alluded. In that establishment there were about 200, who were fed unvaryingly upon boiled mutton every day, and had been so dieted for many years—who took little or no exercise, and were in every respect so circumstanced as to favour the occurrence and maintenance of the disease, according to the view expressed by the author; yet these were the very people among whom the disease did not occur. It was a disease frequently admitted into the workhouse for the purpose of being cured, and only spread when sufficient care was not bestowed on the separation of the infected, and this very rarely happened. On the other hand, at the Parochial School, at Wandsworth Common, where the diet was varied, where fresh vegetables of every description were freely used, and exercise in the open air was abundantly taken, where no fresh comers were admitted with the slightest papulæ upon them—here the disease would continually break forth unless the most rigid inspection were constantly observed, the patients with papulæ immediately separated, and active treatment adopted. It is true that neither vesicles nor pustules ever appeared except in cases where the treatment was purposely deferred in order to afford conviction of its necessity; indeed, nothing but ample experience can convince the mind of a medical observer of the necessity of dealing peremptorily with symptoms of so slight a character as those which furnish the first evidence of itch. He thought that the author attached too much importance to some of the circumstances which accidentally surrounded the patients as the cause of the disease; and the same remark applied to the conjectures which he hazarded as to cholera being influenced by the same causes.

Mr. HARRIS agreed fully with the author of the paper as to the primary importance of improved diet in all cases of scabies when occurring in a large number of children, wherever collected. He also cordially subscribed to the opinion that next to an improved diet (especially avoiding all boiled meats) fresh air, and exercise in it, were of primary importance. Cleanliness was essential, but to prevent overcrowding was not less so. Mr. Harris resorted, as the correct treatment of what he believed to be true scabies (but only acknowledging a vesicular and a pustular form), to the wash recommended by the Poor-law Board and their Medical officers, but which he had used long prior to his reception of their printed formula in preference to sulphur ointment, either simple or compound. The form of wash was this—2 lb. of sublimed sulphur, 1 lb.

of quicklime recently burned, and 3 lb. of water (to which Mr. Harris added a small quantity of sulphuric acid and common salt when boiled); but the above three ingredients, in these specified proportions, were boiled together for one hour, or until a green colour was produced; then poured off without straining, and kept in stone jars well stopped; and this wash applied after a warm bath in which soap had been used, would cure scabies in the vesicular form in two days, with only one dressing per diem, and the pustular form in four days; and no sheets, or blankets, or clothes would be messed or spoiled; for if rubbed in with a bit of sponge or tow before the fire it would dry in ten minutes, causing some shrinking of the skin and a smarting warmth, but the cure was most satisfactory. Yet scabies becoming endemic in wards and schools compelled the non-return of the cured patient to their old ground, or it would quickly recur. Mr. Harris alleged that numbers alone would not render scabies endemic; but the persistence of a succession of cases in the same ward; and he instanced the Workhouse of St. Luke's, to which he was Medical officer. He was also Medical officer to the Orphan School, Haverstock-hill, wherein, with nearly always 400 children, he had never seen a case of scabies, and very little ringworm. The other disease specially mentioned by the author of the paper, ringworm, like itch, was another term so loosely applied, that, to Mr. Harris, it appeared all children's eruptions were called either ringworm or itch. Fifty per cent. of ringworm, so called, was eczema of scalp; thirty per cent. was impetigo; and twenty per cent. only was tubercular, strumous, or true favus, frequently commencing as the disease called porrigo decalvans, and passing on into true tubercular ulcers, minute, clustering, confluent. Of the treatment here he would not speak, under such uncertainty that each meant the same thing; but to corroborate Mr. Hunt's views, he would say that an improved diet of roasted and broiled meats was imperative, much free exercise out of doors, and but few children in any one department, however large. These, conjoined with free ablutions with hot water and soap, would go a long way to effect cures; and the specific treatment might be safely left to each individual Medical attendant, never forgetting that in strong solutions of nitrate of silver and iodine we possessed the main elements of local success, and that in steel we had a most energetic and valuable constitutional auxiliary.

Dr. Murchison, Dr. Buchanan, Dr. Hillier, and Dr. Seaton, also took part in the discussion.

A paper, by Dr. BUCHANAN, was read on

#### RECENT TYPHUS IN LANCASHIRE.

Since the great typhus-epidemic in Lancashire at the time of the Irish famine in 1847-48, there has scarcely any of this disease in the cotton towns. In 1862, however, positive maculated typhus has made its appearance. The disease has been most prevalent at Preston, and next at Manchester. Several cases have been met with in Chorley, a town not far from Preston, and more recently at Accrington; and scattered attacks, still of true typhus, appear to have been observed at Salford and Blackburn. As the chief interest centres on Manchester and Preston, Dr. Buchanan confined his remarks to the outbreaks in these towns. He had visited Preston late in October under the directions of the Privy Council. The earliest case of distinct typhus he could trace had occurred on July 7, in a four-roomed cottage, 17, Castle-street, at some distance from the centre of the town. It was not known that the first patient had been exposed to contagion. In this cottage eight persons had crowded by night into a room whose utmost cubic capacity was 800 feet. They were dirty, underfed, and the boy who first felt ill had also been much exposed to the weather. The boy was removed to Hospital, and returned home on his convalescence. In the last week of August six other persons were attacked in this house. They were removed and the house closed. Meanwhile new cases of typhus had occurred in another part of the town, apparently without communication with the former. These were in a district that was afterwards subjected to the chief violence of the epidemic. The locality consisted of very confined and dirty courts, lying low, near the canal, and densely inhabited. At the end of August a third neighbourhood, distant from either of the other two, became affected with typhus. A fourth outbreak, apparently unconnected with the rest, was seen in another central part of the town in the middle of September. By the end of this month cases had occurred in five out of the six wards into which the town is divided. The general progress of the outbreak in the town may be estimated from

the following return of reported cases of typhus:—Cases occurring in July, 2; August, 8; September, 23; October, (5 weeks), 109; November 89; December, 38; week ending January 3, 13,—a third more than in the previous week, and double the number occurring in the week ending December 20. Week ending January 10, 15; and since then a still further increase, though not to any great extent. At the time of Dr. Buchanan's visit at the end of October, the House of Recovery (Fever Hospital), which was constructed for 40 patients, contained 52 cases of typhus. Afterwards there were upwards of 60 inmates at one time. In some wards the space for each bed fell short of 600 cubic feet, and the air was here very foul. At the beginning of November a wooden building was erected in contiguity to the House, capable of containing 60 patients, with a space of 1500 cubic feet to each. This building was put up in ten days; but there was a lamentable delay before the patients were removed into it at the end of December. In the meanwhile upwards of twenty persons in attendance on the sick had caught the fever, the Medical officer and the Master of the House of Recovery being among the number. It deserves mention, for the sake of those who refuse to acknowledge an epidemic influence that does not show itself on the general death-rate, that in the September quarter of 1862 the mortality from all causes in Preston was very markedly below the average, 464 deaths only being registered, against 607 in the corresponding quarter of 1861. This subsidence was entirely among children under six years of age, and resulted, there is reason to believe, from the greater care bestowed by mothers on their infants during the time of industrial depression. The following returns from the Parish Fever Hospital will indicate the progress of the outbreak of typhus in Manchester. In July, 7 cases of the disease were admitted; in August, 8; September, 12; October, 20; November, 25; December, 17. From December 29 to January 13, not one case, but on the last named day, two cases, and since then a few who had contracted the fever in adjoining wards of the Workhouse. Scattered cases of typhus have probably occurred in Manchester from time to time, but very rarely, since 1847-48. The earliest instance of true typhus in the Infirmary occurred at the end of May, and two cases were admitted in June. At present there is very little typhus in Manchester, but it would be premature to reckon on the complete subsidence of the disease. Dr. Buchanan referred to his recent report to the Privy Council, "On the Health of the Operatives in the Cotton Towns of Lancashire, affected by the Prevailing Distress," for a detailed account of the circumstances contributing to the outbreaks of typhus in Preston, and Manchester, and other towns. He was at a loss to explain why the typhus influence should have fallen chiefly on Preston. Manchester was exposed to the danger of imported typhus. The limitation of the fever to these towns chiefly was to be ascribed to the strict removal of cases to Hospital; the maintenance of a high standard of relief, increasing almost every month; the liberal distribution of bedding and clothing as the winter has advanced, and the almost unprecedented mildness of the weather since November, which was the coldest month since the distress began, witnessed the maximum of typhus cases both in Preston and Manchester.

Dr. MURCHISON observed that the Society was under great obligations to Dr. Buchanan for the important facts which he had brought before it. The points of especial interest in the communication were two, viz. :—1. The circumstances under which the epidemic of typhus commenced. 2. The circumstances under which it began to subside. As to the first, he could corroborate Dr. Buchanan's statement, that true typhus had not been met with at Preston, and most of the other large towns of Lancashire, for many years before the autumn of 1862. The fever which had prevailed in these towns was typhoid, or enteric fever, which was very frequently confounded with, and, when fatal, returned to the Registrar of deaths as, typhus. In proof of this, Dr. Murchison read an extract from a letter, which he had received in May, 1862, from a very intelligent Surgeon at Preston, who was well versed in the distinctions between typhus and fever. During four years that the writer had been in extensive practice among the poor of Preston, he had only seen a single case of typhus; but, though typhoid fever was far from uncommon, the deaths from typhus, as returned to the Registrar, far exceeded the deaths from typhoid fever. Characteristic cases of typhoid fever, which had come under the writer's own notice, had been reported to the Registrar as examples of typhus.

Dr. Murchison observed that the epidemic of typhus did not commence until after the population had been for many months in a state of great destitution, and that it was unquestionably the indirect result of this destitution. He did not pretend to say that any amount of starvation would in itself produce true typhus, but destitution led to overcrowding, and it was this which generated typhus. In the *Times* of October 13 it had been stated that numbers of cottages at Preston were untenanted, from the inability of the inhabitants to pay the rents, and that it was the practice for several families to congregate into one house. As many as six different families had been said to be collected in one house scarcely above the ordinary size, and now the Society had been informed by Dr. Buchanan that the first cases of true typhus observed at Preston had been in a family of four persons, who had been living in a small room with only 600 cubic feet of space, and who were in a state of extreme want. It was important to observe that there was no evidence that any of these persons had been exposed to the poison of typhus, nor that typhus had been imported into Preston. In the next place, Dr. Murchison observed that the epidemic at Preston began to subside at the beginning of December, at the very time that the condition of the people began to improve, as shown by the diminished numbers in receipt of relief. Whether the disease, once generated, might not spread by contagion, remained to be seen; but every effort had been taken on the part of Government and of the local authorities to prevent it spreading. The immense amount of pecuniary relief which had been sent to the distressed operatives in Lancashire, the ability with which this relief had been distributed, and the energetic measures adopted by Dr. Buchanan and others for arresting the spread of the fever after it had commenced, had alone prevented an epidemic of typhus like that which resulted from the Irish famine in 1847. The epidemic of typhus which had been raging for the last fourteen months in London, would no doubt also have been prevented, if the condition of the poor in the Metropolis had attracted the same amount of public attention as that of the suffering operatives in Lancashire.

Mr. Harris also took part in the discussion.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, March 12, 1863 :—

John Davies, Coleshill, Warwickshire; William Arthur Bracey, General Hospital, Birmingham.

### APPOINTMENTS.

\* \* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ATWELL, GEORGE H., L.R.C.P. Lond., has been appointed Senior House Surgeon and Secretary to the York Dispensary.

BEVERIDGE, ROBERT, M.B. Aberd., has been appointed Lecturer on Pathology and Morbid Anatomy at the Royal Infirmary, Aberdeen, and Curator of the Museum.

BRUMWELL, JOSEPH C., M.D., St. And., has been elected Medical Officer and Public Vaccinator for the Burnley District and Workhouse, also Medical Officer and Public Vaccinator for the Colne District of the Burnley Union.

CARR, GEORGE, M.B. Aberd., has been appointed Physician to the Royal Infirmary, Aberdeen.

CRAIG, J. WRIGHT, M.D. Glasg., has been elected Assistant Medical Officer of St. Giles's and St. George's Infirmary, Bloomsbury.

FISHER, LUKE, M.D., has been appointed Senior House Surgeon to the Dispensary, Preston, Lancashire.

HASTINGS, JOHN CHARLES, M.R.C.S. Eng., has been appointed one of the Assistant-Surgeons to the East Sussex, Hastings, and St. Leonards Infirmary.

JONES, J. LLOYD, M.R.C.S. Eng., has been appointed Junior House Surgeon to the Dispensary, Preston, Lancashire.

PENHALL, JOHN T., M.R.C.S. Eng., has been appointed one of the Assistant-Surgeons to the East Sussex, Hastings, and St. Leonards Infirmary.

TURNER, G. BROWN, M.D. St. And., has been elected Surgeon to the East Sussex, Hastings, and St. Leonards Infirmary.

WOLFE, JOHN R., M.D. Glasg., has been appointed Ophthalmic Surgeon to the Royal Infirmary, Aberdeen.

### DEATHS.

COOPER, J., M.R.C.S. Eng., at Great George-square, Liverpool, on March 3, aged 73.

JONES, JOHN, Surgeon, at Gnosall, Staffordshire, aged 84.

LITTLE, D., M.D., at Clarence River, New South Wales, on November 23.

MARSHALL, BUCHANAN, M.D. Glasg., at Islington, Liverpool, on March 3.

MARSHALL, RICHARD, M.R.C.S. Eng., at Marlborough-place, Walworth-road, S., on March 11, aged 48.

PROWSE, JOHN, M.R.C.S. Eng., at Nuneaton, Warwickshire, on February 26, aged 43.

RUTTER, JOHN SIMPSON, M.R.C.S. Eng., at Hunter's-lane, Handsworth, Birmingham, on March 4, aged 52.

WILSON, ROBERT, M.R.C.S. Eng., 28, Cannon-street-road east, E., on March 12, aged 47.

**THE ILLUMINATIONS.**—Eight deaths have occurred by accidents at the illuminations. The last victim was Mr. John Walker, who died from fractured ribs and other injuries at Guy's Hospital.

**ROYAL MEDICAL COLLEGE, EPSOM.**—The collegians and aged pensioners of this institution celebrated the marriage of H.R.H. the Heir-Apparent and the Princess Alexandra, on Wednesday, the 11th inst., by a dinner given by the Council of the College.

**THE ARSENICAL POISONINGS AT MAREHAM-LE-FEN.**—John and Elizabeth Garner were tried at Lincoln, on March 17, for the murder of Jemima Garner, the mother of the male prisoner. It will be recollected that arsenic was unequivocally detected in the body by Prof. Taylor. No new evidence was adduced. The jury took the view that the poison was administered negligently, and not wilfully, and therefore returned a verdict of "Manslaughter." The Judge, in sentencing the prisoners, said that the jury had taken a very merciful view of their case, but that he felt bound to pass upon them the severest sentence of the law. He then sentenced them to penal servitude for life.

**THE SANATORIUM ASSOCIATION.**—A company has been started under this name for the establishment of a Lunatic Asylum, on what their prospectus calls "a commanding scale," for patients of the better classes. It appears that they have already purchased a property at Hendon, Middlesex, on which they propose to erect a building furnished with all the means and appliances that science can suggest for the treatment of insanity. A resident physician is to be appointed, at a salary of 1000*l.* per annum, and under him is to be another Medical officer, at a salary of 300*l.* Dr. R. Quain and Dr. H. Stevens are chosen visiting physicians, and Messrs. Partridge and Pollock consulting surgeons. If the management and resources of the Institution fulfil the promise of the prospectus, the Sanatorium Association need not fear receiving the support of the Medical profession. As a pecuniary speculation the undertaking is based on the fact that nearly one-fourth of the 24,800 lunatics in England and Wales belong to the wealthier classes, whose friends are willing to pay liberally for their Medical and social treatment.

**TRIAL FOR POISONING.**—At the Spring Assizes, Northern Circuit, a man named Fox and a woman named Walker were tried for the murder of George Walker, the husband of the female prisoner, a miner, at Balley, near Dewsbury, by the administration of arsenic. The fact of death having been caused by arsenic appears to have been clearly proved. Arsenic was found in all the internal organs except the brain. The analysis was made by Drs. Scattergood and Baildon. Five grains of arsenic were found by Dr. Scattergood in the stomach of the deceased, half a grain of this being in a solid state, leading to the inference not only that poison had been administered from the beginning of the deceased's illness, but up to within a few hours of his death. It was, however, proved that the deceased had himself bought the arsenic for the purpose of killing rats, and had kept it in an open drawer. There was no evidence to connect the male prisoner with the administration; and the jury, seeming to adopt the theory of the defence that the poison had been given by accident, acquitted the woman.

**SPIRITS.**—A return under this head, issued on Wednesday, the 18th, states that the number of gallons of proof spirits on which duty was paid during the year ending December last was—For England, 8,857,121, and the duty £4,428,561 10*s.*; for Scotland, 6,189,356, and the duty £3,094,678 19*s.* 10½*d.*; and for Ireland, 4,653,773, and the duty £2,326,885 18*s.* 6½*d.*; making for the United Kingdom 19,700,250 gallons, and the

gross duty £9,850,126 8s. 5d. The total number of gallons of methylic alcohol sold by the Excise for the period mentioned was 51,897, and the methylated spirits sent out by persons licensed to sell the same under 18 and 19 Vict., c. 38, amounted to 538,088 gallons.

**STATISTICAL SOCIETY.**—On Saturday, March 14, 1863, at the twenty-ninth annual meeting, Sir John Pakington, Bart., M.P., in the chair, the following gentlemen were elected council and officers for 1863-64:—*President.*—Colonel W. H. Sykes, M.P., F.R.S. *Council.*—Charles Babbage, M.A., F.R.S., James Bird, M.D., Sir John Boileau, Bart., F.R.S., Swinton Boulton, Samuel Brown, William Camps, M.D., William Farr, M.D., D.C.L., F.R.S., \*Right Hon. Earl Fortescue, Humphrey William Freeland, M.P., Sir Francis Henry Goldsmid, Bart., M.P., Q.C., William Augustus Guy, M.B., James Thomas Hammick, Frederick Hendriks, James Heywood, F.R.S., Sir Rowland Hill, K.C.B., William Barwick Hodge, Charles Jellicoe, Leone Levi, F.S.A., William Golden Lumley, LL.M., Right Hon. Holt Mackenzie, F.R.G.S., Matthew Henry Marsh, M.P., \*Right Hon. Lord Monteagle, F.R.S., William Newmarch, F.R.S., Right Hon. Sir John S. Pakington, Bart., M.P., G.C.B., Frederick Purdy, Right Hon. Lord Stanley, M.P., Col. W. H. Sykes, M.P., F.R.S., \*Major-General Sir A. M. Tulloch, K.C.B., \*Richard Valpy, \*Cornelius Walford, \*Rev. William Whewell, D.D., F.R.S. (Those marked \* are new members.) *Treasurer.*—William Farr, M.D., D.C.L., F.R.S. *Honorary Secretaries.*—William Augustus Guy, M.B., William Golden Lumley, LL.M., Frederick Purdy.

**TESTIMONIAL TO E. A. PARKES, M.D., F.R.S.**—On Tuesday, March 17, Dr. Parkes, late Professor of Clinical Medicine at University College, was invited by a large number of his old pupils to a meeting for the purpose of being presented with a bust of himself, subscribed for on the occasion of his resigning his office in that College. The bust, a striking likeness, is the work of Edward Davis, Esq., of Charlotte-street, Fitzroy-square. The presentation took place in the botanical theatre of University College, before a large assemblage of old and present students, and many of the professors, former colleagues of Dr. Parkes. Dr. Jenner, the Professor of Medicine, presided. The following address was read:—“To Dr. Parkes,—Sir,—We have invited you here to-day that we might have an opportunity of presenting you with this testimonial of the affectionate esteem entertained for you by your old pupils. When, three years ago, you resigned your post of Professor in this College, there was a general feeling amongst us, not originated by one man, but one that seemed to take possession of all at the same time, that you should not be allowed to depart without taking with you some token of the affection you had inspired during your connexion with us. We could not but feel that, not contented with being merely a teacher, you had striven to be a friend as well; that you had not only fulfilled most perfectly the duties which the office required, but had added thereto kindnesses such as no office could require and no student expect. There are amongst us some who, of course, feel this more strongly than others, there are amongst us those who have experienced at your hands kindnesses so great that no memento can fitly express their gratitude, but we beg you to believe that there is no one who has taken part in the preparation of this testimonial who does not feel that in his remembrance of you there is something warmer than mere admiration of your skill as a teacher, something better than mere respect for your eminence as a man of science. That said, there is little more to add. You will at once perceive that we who are present here are but a few out of the number of those who have united to present you with this bust; we should have preferred, if it had been possible, having all the subscribers present, but their very absence furnishes the, we think, not unpleasant reflection that all over the kingdom are scattered men who were once your pupils, and who still think, and will ever think, of you with affection and respect.”

**GREEN OYSTERS.**—We described a few days ago two methods employed by M. Cuzent for discovering copper in the oysters which come from Marennes, and which are remarkable for their green hue. The *Moniteur* now publishes a letter from the mayor of that town, which is intended to counteract the unfavourable impression caused by M. Cuzent's revelations regarding the unwholesomeness of these oysters. He states in his letter that the trade in green Marennes oysters has increased to such a degree during the last fifteen years,

that the white oyster beds of the neighbourhood had become insufficient to stock those peculiar beds where the creature acquires a green colour, together with that delicious taste which causes the Marennes oyster to be so eagerly sought after. In order, therefore, to meet the demand, white oysters have had to be imported from Spain, Bretagne, Ireland, and England. The Marennes oyster is in fact, in its ordinary state, as white as any other, and only receives its green colour and peculiar taste when transported to certain beds covered with a small submarine kind of moss, and formed of the slime deposited by the sea from the small gulf called the Rivière de Seudre. Now, a considerable quantity of oysters are imported from Falmouth by the inhabitants of Marennes, and these oysters really contain a certain quantity of copper, which gives them an acrid taste. On their arrival they are deposited in certain beds apart from the others, and kept there for six months, after which period experience has shown that they lose their copper salt, and consequently their bad taste. Now, as to M. Cuzent's experiments, and the results obtained by him, the mayor explains that a Marennes fisherman, whose trade is not very extensive, got over from Falmouth a few thousand oysters, which, out of thirst for gain, he sent off to Rochefort before they had sojourned more than three weeks in the beds set aside for their purification. These oysters having caused alarming symptoms, copper was found in them by M. Cuzent, but they were not real Marennes, but Falmouth oysters, the former still retaining the excellent qualities for which they are known.—*Galignani's Messenger.*

**MEETING OF THE MEDICAL PROFESSION AT GLASGOW.**—On Thursday, March 12, a numerously attended meeting of the members of the Medical Profession who have formed themselves into an association to procure a repeal of that section of the Scotch Registration Act, under which forced unrequited Professional labour is exacted from the Medical men of Scotland, was held in the Lower Room of the Trades' Hall, Glassford-street—Dr. H. Thomson, the President of the Association, was in the chair. The Chairman stated that this meeting had been called specially to consider an overture which the Lord Advocate had made to Mr. Dalglish, and which had been communicated to the Association by Mr. Dalglish, in a letter to the secretary. Before calling on the secretary to read Mr. Dalglish's letter, he begged to remind the Association of the progress made. After their body had been fairly constituted, the secretary, as instructed, addressed a letter to the member for Glasgow, to ascertain exactly how he stood and felt affected towards our movement; whether, in fact, he was prepared to introduce a repealing bill, should the Profession throughout Scotland back him up with a large number of petitions. As some of the gentlemen present had not heard Mr. Dalglish's letter in reply read, he would go over it again.

“House of Commons, February 18, 1863.

“DEAR SIR,—I was anxious to have had a conversation with the Lord Advocate before writing to you on the subject of the clause in the Registration of Deaths Act which enforces a penalty on medical men if they do not return a certificate of the cause of death.

“I would advise that the medical profession send a deputation to the Lord Advocate (who is still in Edinburgh), and endeavour to persuade his lordship to introduce a short bill to amend the present Act so far as the objectionable clause is concerned, so as to place the Medical profession in Scotland in the same position as their friends in England and Ireland. If the Lord Advocate refuse to bring in such a bill, perhaps the deputation may get a pledge from his lordship that the Government will not oppose a bill for that purpose, if brought in by a private member.

“In either case I shall place my services at the command of the profession. I am, dear sir, yours very truly,

“Dr. Walker.”

“ROBERT DALGLISH.”

On receipt of this letter, the secretary convened a meeting, when the proposition of our hon. member was discussed, and unanimously agreed to. Drs. Walker, M'Carron, and myself (the chairman), being the parties appointed to wait on the Lord Advocate. As time was exceedingly pressing, the secretary at once addressed a letter to his lordship, requesting an interview, at which it was proposed to submit to his lordship a scheme for the transmission of the certificates from the Practitioners to the registrars, which would greatly facilitate the collection of the desired information, and prevent the documents passing through the hands of relations of the deceased, as well as prevent any use

being made of them, but for the purposes of the Act. Unfortunately, rapid as our movements had been made, we were too late; the Lord Advocate left for London immediately thereafter, so that any interview he may favour us with must be after his return.

The Secretary then read the following letter which he had received from Mr. Dalglisch:—

“House of Commons, March 4.

“Dear Sir,—I have had a conversation with the Lord Advocate on the subject of the penal clause in the Scotch Registration of Deaths Act. His lordship says that if an alteration of the Act to the extent of only enforcing the penalty after three consecutive cases of neglect or refusal to make the return on the part of the Medical man would satisfy you, he would be inclined to make such an alteration as would accomplish that object. It appears to me that this is a compromise which is worthy of your consideration. It relieves the Profession from the penalty, so far as any breach of the Act from mere inadvertence is concerned; and I do not suppose that any Professional man would willingly obstruct the compilation of statistics so valuable to the Profession.

“I shall be glad to have your opinion upon the proposal.

“I am, dear sir, yours truly,

“Dr. Walker.”

“ROBERT DALGLISH.

Now he (the Secretary) had taken the earliest opportunity of calling the Association together to consider this proposal. To every member of the Association the eminently absurd nature of the thing was at once apparent—it was begging the whole question. He was astonished that such an idea could have entered the Lord Advocate's head, or that the city member could in the least degree have countenanced so ridiculous a notion. Although the proposal were carried out tomorrow, the unjust and unconstitutional system of exacting compulsory labour would still remain in its full force, and the odious admission that the Medical Practitioners of Scotland are of a lower type or caste, and not entitled to occupy “the same position as their friends in England and Ireland,” would still remain unwiped out. However, a proposal by a Lord Advocate is not a matter to be slightly passed over. He would suggest that a meeting of the whole Profession in Glasgow and neighbourhood be called, to consider not only this proposal, but the whole question. A requisition to call such a meeting might be presented to the President of the Faculty of Physicians and Surgeons, or this Association might take the initiatory steps, and request Dr. W. I. Gairdner to preside. After the meeting had been addressed by Drs. M'Carron, Reid, Glass, Cowan, Coats, and Lapraik, Dr. Thomson, the President, in a few remarks, brought the proceedings to a close. He thought it impossible that the Royal Colleges of Edinburgh could longer refrain from expressing some opinions on this question. Sir R. Peel, in his place in the House of Commons, deliberately said that the Scotch penal system was altogether unfitted for the Medical men in Ireland. The free English system was the only one that would be tolerated there. He had come to this conclusion from conversations with the President of the Royal College of Surgeons of Ireland, and from information supplied from other sources. Now he (Dr. Thomson) could not see how our Scotch Presidents of Colleges could keep silent any longer. As to the Faculty of Physicians and Surgeons of Glasgow, he was afraid to mention their name. Probably it was too much to expect them to put in an appearance. Situated far from the centre of power, their small voice was seldom or never heard when the honour and dignity of the profession was at stake.

**CHILD STEALING.**—A remarkable case of child stealing engaged the attention of the Salisbury magistrates for three or four hours on Saturday. A woman, named Annie Shipsey, was charged with stealing an infant from the wife of John Yarlett, and her husband, John Shipsey, stood charged as an accessory after the fact. A summons had likewise been issued against Mr. Samuel Pyle, a Surgeon of more than twenty years' standing at Amesbury, to show cause why he also should not be similarly charged as an accessory. The facts, as they were deposed to in evidence, were these:—On Tuesday, the 3rd inst., Mrs. Yarlett, the prosecutrix, who had been confined only about five weeks, was on her way to see her mother, having her baby in her arms, when she was accosted by the female prisoner, who inveigled her into a public-house. She had not been more than a few minutes in the house when she was asked by the female prisoner to go to a shop in the town for a parcel which had been left there for a Mrs. Brown, and which she herself was too ill to

be able to fetch. Mrs. Yarlett went, leaving her baby in the hands of the prisoner, but when she returned to say that there was no parcel for any Mrs. Brown, the prisoner and the infant were nowhere to be seen. The woman Shipsey was traced by Superintendent Caldow, of the Salisbury police, who went to her house, on a farm at Milston, where her husband was shepherd, and there found an infant being nursed by her sister. The female prisoner, who was in bed upstairs, stated that she was confined immediately after her return from Salisbury on Tuesday evening, and that two women, neighbours, were present. These women, however, did not appear to have been called in until after the “little stranger” was in the house, and having his suspicions that the said “little stranger” was considerably more than two or three days old, Mr. Caldow called in Mr. Pyle, and paid him the usual fee to examine the woman. He went upstairs, and in a few minutes gave it as his opinion that she had been recently confined, that she had milk, and that the child might be about four or five days old. Further suspicion was, however, excited, and on the following day Mrs. Shipsey was examined by Mr. Winzar, a Surgeon of Salisbury, who gave it as his opinion that she had not been recently confined, even if she had ever been confined at all, and that the child was at least four or five weeks old. A warrant was obtained for the apprehension of Mrs. Shipsey and her husband, but on Saturday Mr. Pyle refused to allow the police to enter the house, on the ground that the woman was suffering from inflammation of the bowels. Later in the day, Mr. Martin Coates, another Surgeon of Salisbury, was taken over to examine her, and, while his opinion fully corroborated that of Mr. Winzar, he could discover no traces of inflammation, although the woman complained of pain on pressure. The child, and a calico bandage in which it was wrapped, were ultimately identified by the mother. On Sunday evening Mr. Pyle consented to the prisoner's removal, and expressed his regret at not having originally made a more minute examination. Mr. Lewis, who defended Mr. Pyle, contended that the latter had committed no offence. Mere negligence did not render him liable to an indictment as an accessory. The Bench, taking this view of the case, dismissed the summons. The woman Shipsey was committed for trial at the Salisbury Borough Sessions.

## NOTES, QUERIES, AND REPLIES.

Be that questioneth much shall learn much.—Bacon.

*A Surgeon.*—1. No. 2. We think not.

*M.D.*—We do not know the individual's name, and we think it very unlikely that he has any fixed address.

*Dr. R. Lyle.*—We shall be happy to receive our correspondent's communications.

*Derby.*—We know nothing of the circumstances of the case which has led to the misunderstanding between Messrs. Gisborne and Fearn; but we regret to see professional differences of opinion discussed in a personal tone in the columns of a provincial newspaper.

*Hood's "Song of the Shirt."*—The “Song of the Shirt” was sent down by Hood to Mr. Lemon for insertion in *Punch*; and with it this apologetic note, “I sent it to a first-class magazine, and they wrote back, ‘it is hardly the thing for genteel people.’ What say you?”

*Ethnological.*—The royal family of Denmark is descended from Hedwig, own sister to Adolphus, Duke of Sleswick, who was the lineal descendant of Sophia, wife of Gerhard, Count of Holstein, whose mother, Richissa, was the second daughter of Eric the Fifth, who was the lineal descendant of Gormo, the first Christian King of Denmark, A.D. 765, who was the son of Harold the Fourth, who was descended from Roric Slingiband, and through him from Humble, of Zealand, B.C. 1038.

### HYDROCHLORIC ACID IN TYPHOID FEVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you allow me to recommend a full trial of hydrochloric acid in cases of typhoid fever to be made in some of the London Hospitals, as I have found it an excellent remedy for this disease during a slight epidemic which occurred here last autumn. Thirty-seven cases came under my treatment in the Chinese Hospital, and with the usual treatment about 28 per cent. died; but after adopting the hydrochloric acid treatment, mortality fell to about 7 per cent. I gave half a drachm of the dilute acid in half an ounce of infusion of quassia every three hours. When stimulants were required, I added half an ounce of brandy to the mixture.

I am, &c.

J. HENDERSON, M.D.

Shanghai, January 23.

### THE MEETING AT THE FREEMASONS' TAVERN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I should have allowed the report of the meeting at the Freemasons' Tavern, contained in your Journal, to have remained undisturbed by any

communication from me, if Dr. O'Connor had not thought fit to refer to the subject in a letter contained in your this week's number.

I have now to inform you that as Dr. O'Connor himself admits, I was not called to order by the chairman, who gave as his reason for not doing so, that I had made only a general observation, and no personal attack whatever.

I will leave your readers to determine who indulged in offensive personality, when I state that when in the course of the attack made upon me by Dr. O'Connor, he attempted to depreciate my standing in the Profession by stigmatising me as a pettifogging parochial Apothecary, not only three-fourths, but apparently the whole meeting rose up, amid loud cries of "Order," and sat down.

The sense of the meeting as regards Dr. O'Connor's attack upon me was sufficiently expressed in my favour for me to state that I shall consider it beneath my dignity further to notice anything he may write or say on the subject. Apologising for the necessity of thus addressing you,

I am, &c.

33, Dean-street, Soho-square, March 13.

JOSH. ROGERS.

#### HEALTH ASSURANCE SOCIETY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Being desirous, with many others, of calling the attention of the Medical Profession to the necessity of forming a Medical Health Assurance Society somewhat on the principles of the Clergy Mutual Association, whereby an incapacitated invalid member may receive a certain sum weekly, I should feel obliged if you would, with other periodicals, kindly co-operate in the promotion of the same for the benefit of your readers and of the Profession generally, and to the end that some idea may be formed, if a feasible plan would be sufficiently supported, I shall be glad to receive communications from gentlemen, stating their views, and if they would join a society when proper rules are satisfactorily arranged and submitted for inspection. I am disposed to think that an annual subscription, varying from £5 to £15 annually (provided that 200 or more subscribed as members), would be sufficient to allow of from £2 weekly during sickness, an annuity after a certain age, and a sum varying from £100 upwards at death—the society being formed on mutual principles. If gentlemen write to me personally, wishing an answer, perhaps they will favour me with an envelope, stamped and addressed. Having been in active business for nearly thirty years, and within these four years had a fearful illness, incapacitating me for nearly twelvemonths (from which I am now thoroughly recovered), no one can better than myself judge of the absolute necessity for an association of the kind proposed.

I am, &c.

JOHN M. BRYAN, M.D., F.R.C.S.,

Hon. Sec. and Treasurer to the South Midland Branch of the British Medical Association

#### POISONING BY MORPHIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your impression of last week a case of poisoning by opium is related by Dr. Morell Mackenzie, of London, where recovery took place without having recourse to the ordinary method of treatment, and which induces that gentleman to raise the question, "whether the nervous system, already overpowered by the poison, is not still further exhausted by the ordinary treatment." That considerable latitude should be exercised in the treatment of cases already debilitated by disease is unquestionable, but that the "do nothing" system is the proper course to adopt in cases of opium poisoning generally, I am inclined to doubt, and my conviction is further supported by the following case, which to every impartial observer will appear as a typical example of the good effects of the ordinary method of treatment, or at all events, that "keeping the brain in a state of activity" in such cases is erring upon the side of safety.

On January 4, 1862, at 4 p.m., John D., aged 60, a gouty old butcher, swallowed six pennyworth of laudatum with intent to commit suicide. Symptoms of poisoning soon came on, which rapidly merged into complete insensibility. On my visiting him three hours after, his condition was as follows:—He lay upon his back with his neck arched forward; the breathing was loud and stertorous; countenance bloated and livid; pupils contracted; eyes fixed, and insensible to all external impressions; even free manipulation could be tolerated without creating the slightest resistance. In short, he resembled a person straining laboriously, and at the same time holding the breath. The rousing system was immediately adopted, but without evincing a shadow of sensibility. The stomach-pump was used with great difficulty, owing to the fixation of the muscles of the neck and chest, and that viscus thoroughly washed out, and afterwards had hot milk and tea injected into it.

At 12 p.m. of the same evening, the breathing became less comatose, though even now several seconds elapsed between each inspiration, but, in other respects, the same insensibility continued. As a *dernier ressort*, hot jars and bricks were ordered to be kept to the feet and legs during the night, and half-a-dozen mustard-poultices to be applied along the spine to vesication. By some mistake the hot applications were so assiduously applied as to blister the feet and legs severely, but with the happy effect of "keeping life in the old sinner," as the nurse quaintly remarked in reply to my inquiries the following morning, and to which, no doubt, in this case, the recovery must be mainly attributable.

I am, &c.

Cleveland-place, Bath, March.

K. N. MACDONALD, L.R.C.S. Edin.

#### THE PERCENTAGE SYSTEM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I received this morning the circular which I enclose. Any inclination which I might feel to assist a brother in distress is stifled in the present instance by that most unfortunate and degrading offer of a "percentage," which, if accepted, would place me on as low a level as that of the meanest tradesman or swindling contractor. Let us suppose that a "handsome percentage" means 10 per cent.; then "Medicus" proposes that I should inveigle an unfortunate wretch into living with him, and receive myself £15 per annum. But in order to do so, I must be a thief somehow; either I pick the pocket of the person whom I recommended, by the surreptitious abstraction of £15, so that he pays £150 for what costs only £15, or I am mean enough to accept this gratuity for helping a man who pleads poverty and appeals to the commiseration of his brethren on account of his "urgent position." Was there ever a more ludicrous attempt to combine lovingkindness and larceny? If you travel in the East you may hear *La Allah ill Allah—Baksheesh!* "The rage of the vulture and love of the turtle, mixed like the bump of benevolence and Thurtell," is nothing to it.

I wish this were a solitary case, but I fear it is not. There are grievous suspicions afloat about the connexion of Medical men with Orthopædic and other Surgical instrument makers, chemists, mineral water vendors, corncutters, elastic stocking and truss makers, keepers of hotels and sea-side boarding-houses, and even with undertakers. This kind of thing might have done a century ago, but ought to be tabooed now that the trading element is being eliminated. We look to the *Medical Times and Gazette* to keep us straight.

I am, &c.

London, March 16.

AN OLD SUBSCRIBER.

(Circular.)

"A doubly-qualified married Medical man, residing in Clifton, whom a chain of unfortunate circumstances have brought into great embarrassments, will feel very grateful to any of his more fortunate brethren who could and would recommend him a resident patient, invalid, requiring change, or other inmate. His house is well suited for the purpose. His terms are at the rate of £150 per annum and upwards, according to requirements. The writer would be glad to pay a handsome percentage to anybody who could forward his views, the urgency of his position being great. Name, address, and references to some of the most eminent London Practitioners, forwarded on application to 'Medicus,' care of Henry Roupe, Esq., Kensington Dispensary, London."

#### ETYMOLOGY OF "PYTHOGENIC."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—One of your correspondents, signing himself "Quærens," but whom another correspondent has unwittingly, though appropriately, styled "Querens," has expressed his ignorance as to the derivation of the word "pythogenic." If I mistake not, Dr. Murchison first used the word some four or five years ago, and it has been since in frequent and unquestioned use. He derived it from the root of the Greek verb *πύθωμαι*, *putresco*, and *γείνομαι*, *nascor*, from which would come the compound word *πύθογενής* (pythogenic), literally signifying "born of putridity."

Your correspondent, on the other hand, thinks that "genetic" must be derived from *γεννητικός*, possessing generative power, or "genic" from *γενικός*, equivalent to the Latin word *gentilis*, and seems to be ignorant of the fact that the best Greek writers, as Æschylus, Euripides, Hesiod, and Sophocles use the terminal "γενής" to imply "born of" or "produced by." For instance, amongst many others we find such words as *γηγενής*, born of the earth; *νεφελογενής*, born of the clouds; *πυριγενής*, born of the fire, etc. It may be worth mentioning that a similar word to pythogenic has long been in use. "Pyogenic" is not only applied to a membrane supposed to produce pus, but "pyogenic fever" is used as a synonym of pyæmia, or a fever which is supposed to be produced by pus.

"Quærens" further states that if the word pythogenic be derived from *πύθος* (*sic.*), and *γενικός*, it would signify "belonging to the race of Pytho," and this latter word, in combination, might either imply a native of Pytho, or one of the great serpents named after the Pythian one slain by Apollo. It is a pity that your correspondent did not refer to any good dictionary, and then he would have found that the serpent in question was called *πύθων*, *Python*, because it was believed to have been born of putridity. "*Πύθων, draco vel serpens, quem Apollo intermit, sic dictus quod ex putridine terre ortus esset.*"—*Scapulae Lexicon*. I do not know in what dictionary he would find "*πύθος*." It appears, then, that the word Python was derived from the same root as *πύθωμαι*, *putresco*, which is also the root of "pythogenic," their parent being the Sanskrit word "*puj.*" *corruption*.

Whether Dr. Murchison's view, now so generally accepted by the Profession, that the fever in question is generated from putrifying matter, be correct or not, I cannot offer an opinion, not being a Physician, but it seems unaccountable that in these days of barbarous nomenclature a word having so respectable a parentage as pythogenic should be singled out for cavil. The word "enteric," which Dr. Tweedie and Quærens so strangely agree in upholding, was first proposed many years ago by Dr. Wood, of America. It is sufficiently explicit, but it also pledges one to an opinion that the fever is the result, and not the cause, of the intestinal lesion.

I am, &c.

F.R.S.

#### MAN'S PLACE IN NATURE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I find two or three things in Professor Huxley's "Man's Place in Nature" which puzzle me, a poor third year's student, not a little. May I hope that some one of your readers will clear up my difficulties, which occur for the most part in a long note at pp. 102-103 of the above work. The gist of this long note, if I understand it aright, is that there is really very little difference between an ape's brains and a man's; and that if a great gulf does separate the two animals, it is not so much that man originally surpassed the ape in the quantity and quality of his brain, as that he was superior to him in the quality of certain of his motor apparatuses, "especially those which are concerned in prehension and in the production of articulate speech," and so was enabled to develop himself into what he now is. In other words: construct an animal which shall have the brain of the highest ape, and the hands and vocal apparatus of a man, and this animal will in the course of time develop itself into a being but little inferior to man.

Now, I of course allow, as every one must, that the human brain has probably increased both in quantity and quality in consequence of man's possessing hands and a vocal apparatus, still I had always thought that it was not so much because he possessed these that he was superior to the ape, as because he had originally bestowed upon him a brain far superior both in quantity and quality to the ape's, and was enabled by it to make use of his hands and vocal apparatus. Else why does not an idiot speak? He has commonly a far larger quantity of brains than the highest ape, and there is no reason for believing that what there is is defective in quality, and there need be no defect in his vocal apparatus; but it seems that he has not *brains enough* to speak. A parrot has a vocal apparatus sufficiently good to enable him to speak very distinctly, yet *from want of brains* parrots cannot frame a language, and so remain what they originally were. Again, in the latter part of the same note, Professor Huxley seems to compare the human and the ape's brain to a watch that will and a watch that will not go. Is he justified in doing this? Does he mean to say that the ape's brain does not perform all that it *can perform* as well as the human brain does; in other words, that its capabilities are not all called into play? Or are we to believe that an ape's brain, if it had only hands and a vocal apparatus to work upon, would be able to direct them?

And, again, at the end of this note he tells us that he finds it very easy

to comprehend that some structural difference, as inconspicuous as that between the vocal apparatus of man and the ape, "may have been the primary cause of the immeasurable and practically infinite divergence of the human from the simian stirps." Should a man who sneers at Owen for basing "man's dignity upon his great toe," or hippocampus minor, *i.e.*, for basing the distinction between man and the ape upon two facts (though, it may be, *false facts*)—should such a man, I say, base his distinction upon a *gratuitous assumption*.

Lastly, after telling us in plain terms that man has been evolved, both body and mind (p. 109) from something far below an ape, Professor Huxley bids us (p. 111) discern in man's long progress through the past a reasonable ground of faith in his attainment of a nobler future. That is, we are to rejoice because our *posterity* may at some distant day be evolved into something like an angel! What consolation is this to us? And what consolation, indeed, is there to be derived from the whole book, unless it be a consolation to convince oneself that one cannot believe in the progressive development of man and at the same time believe in the doctrines of the New Testament, according to which *individual human beings*, if they ever reach heaven, will never reach it by progressive development! No, according to the theory of progressive development, progression for the *individual* must end with the grave; progression for the *race* will never end. But this is no comfort to the *individual*. I am, &c.

STUDENS PERPLEXUS.

A CASE OF DIVISION OF THE ULNAR AND MEDIAN NERVES BY ACCIDENT, AND THE REMOTE EFFECTS ARISING THEREFROM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your impression of February 14, 1863, Mr. Hutchinson reports an interesting case showing the remote effects of division of the ulnar nerve. The following case has many points in resemblance:—

Isabella J., aged 19, servant, states that in the course of her avocations she had occasion to get on to a bench, but being in danger of falling, she thrust out her right hand, which passed through a pane of glass, thereby inflicting a deep wound on the anterior aspect of the fore-arm. She states that the bleeding was very copious, but was completely controlled by compression, which was applied by a Surgeon, under whose care she remained until the wound healed up, which it did quickly. Ultimately she came under my observation.

*State of the parts, December 2, 1862, six weeks after the Accident.*—On examination there was a well-marked cicatrix, about two inches long, extending transversely across the wrist, and half an inch distant from the joint. There was slight pain and a feeling of tenderness over the cicatrix, which at one part seemed to be adherent to the superficial tendons beneath. The hand presented a peculiar leaden or bluish appearance, as if it had been exposed to cold. The temperature was much below that of the left hand, varying from 4½ to 6 degrees at different parts. The circulation was exceedingly languid, as evinced by the capillaries filling very slowly on exerting pressure. There was no appreciable difference in the size of the two hands. She had lost all motion and sensation in those parts supplied by the ulnar and median nerves in the hand. She could move the thumb, however, to a very limited extent, and experienced slight sensation in it, also in both sides of the index and radial side of the middle finger. This sensation was only experienced on the dorsal aspect of the hand, showing that it was to the branches of the radial nerve this was due. I should here state that in consequence of the loss of power in the hand she was obliged to leave her situation. I recommended her to employ gentle friction to the parts, which should be performed at regular intervals, and also to keep the hand enveloped in cotton.

At the end of two weeks she came back, when I found that other symptoms were manifesting themselves, namely chilblains had formed on the tips of the middle, ring, and little fingers. These were treated by the method usually recommended, namely, stimulating liniments, and keeping up the temperature of the parts by means of cotton; also friction was still persevered with. Having pursued this plan of treatment during one week, it was found of no effect in checking the spread of the chilblains, nor yet did they manifest any tendency to heal up. I now passed a galvanic current through the fingers and hand for the space of fifteen minutes each day. On the fourth application it was seen that the spread of the chilblains was checked, and that a reparative action had commenced, which continued until all the parts were quickly healed up. Under the continued use of the galvanic current for ten days she regained power in the thumb and index finger, but there was no appreciable increase of motion or sensation in any of the other fingers.

At this date, January 3, 1863, she went to stay with some friends for a short time. On January 14 she returned, in consequence of the fingers becoming flexed upon the palm of the hand. On resorting to extension of the fingers she said that it caused pain; but when the extending force was removed, the fingers immediately became flexed again. A small splint padded with cotton was then applied, and the hand carefully bandaged. The splint was taken off at the end of three days, and she was told to return should flexion recur again. She returned in two days afterwards stating that "the fingers were closing again." The splint was reapplied, and kept on for ten days, without causing any inconvenience. Since that time she has not returned again.

I visited her on February 28, when I found the temperature of the injured hand had increased since I last saw her, so much so, that there was scarcely any difference in the temperature of the two hands. The muscles of the hand were considerably atrophied, so that the difference in size of the two hands was very distinct. There was slight flexion, but no return of motion or sensation in the middle, ring, or little fingers.

I am, &c. ROBERT SYLE, M.D., L.R.C.S. Edin.

APPOINTMENTS FOR THE WEEK.

March 21. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.  
METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH, 7½ p.m.  
William Acton, Esq., "On the Increasing Mortality from Infantile Syphilis in London, with Suggestions for its Prevention."  
ROYAL INSTITUTION, 3 p.m. Professor Max Müller, "On the Science of Language" (Second Series).

23. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.  
MEDICAL SOCIETY OF LONDON, 8½ p.m. Mr. W. J. Coulson, "On a Case of Obturator Hernia—Operation."

24. Tuesday.

Operations at Gny's, 1 p.m.; Westminster, 2 p.m.  
ANTHROPOLOGICAL SOCIETY OF LONDON, 7½ p.m. Captain Burton, V.P., "On a Day amongst the Fans." Prof. Raimondi, "On Indian Tribes of Loreto, North Peru."  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Dr. Greenhow, "On Diphtherial Nerve Affections." Mr. Henry Thompson, "On Treatment of Severe Stricture of the Urethra by Gradual Distension at a Single Sitting."  
ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Mechanics."

25. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.  
HUNTERIAN SOCIETY, 8 p.m. Dr. McDonnell, "On a Case of Disease of the Knee-joint, with Abscess, and Necrosis of the Tibia." Mr. Hutchinson, "On a Case of Injury to the Brachial Plexus, supposed to be torn through near the Spine."

26. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopaedic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.  
ROYAL INSTITUTION, 3 p.m. Prof. Frankland, "On Chemical Affinity."

27. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.  
ROYAL INSTITUTION, 8 p.m. W. Crookes, Esq., "On Thallium."

EXPECTED OPERATIONS.

King's College Hospital.—The following Operations will be performed on Saturday (to-day) at 2 p.m.:—  
By Mr. Fergusson—Staphylorrhaphy; For Necrosis of Femur; Ligature of Nævus.  
By Mr. Henry Smith—For Varicocele; For Necrosis of Tibia.

# CHLORODYNE.

"INVENTED AND DISCOVERED, IN 1844, BY RICHARD FREEMAN."  
(Extract from Affidavit made before S. C. WARD, Esq., Chancery Record Office, Chancery-lane, London, June 16th, 1862.)

The Inventor begs to thank the Medical Profession for the liberal support he receives from them, and to assure those who have not yet tried his Chlorodyne that it is superior to any other maker's, being more certain and more lasting in its effects; and the low price which he charges for it allows the poorest sufferer to enjoy its extraordinary beneficial influence. The immense demand for it by the Profession is a convincing proof that they find it a most valuable therapeutical agent. The following are a few out of many voluntary Medical Testimonials:—

From W. VESALIUS PETTIGREW, M.D., Hon. F.R.C.S. Eng, formerly Lecturer upon Anatomy and Physiology at the St. George's School of Medicine.

"I have had the opportunity of trying the effects of Mr. Freeman's Chlorodyne, and find it an excellent Anodyne and Antispasmodic medicine."

From H. J. O'DONNELL, M.R.C.S.E. and L.M., &c., &c.,  
Albert-terrace, London-road, S.

"I can with much confidence bear testimony to the efficacy of Mr. Freeman's Chlorodyne as a Sedative and Antispasmodic, having used it for some years in Colic, Neuralgia, Phthisis, and Asthma. I daily administer it in after-pains, and in all cases find it infallible. It is the most valuable medicine we have in Labour cases. I find, since I have used it, the pains

seldom or ever exceed the third day, while with the former remedies my patients suffered eight or nine days. In fact, I cannot speak too highly of it."

From F. W. HOOPER, M.D., M.R.C.S. Eng., &c., &c., Medical Officer,  
Christ Church District, Camberwell.

"I have much pleasure in stating that, after a sufficient trial of Mr. Freeman's Chlorodyne, I am fully persuaded that it is superior to any preparation of the kind, and, from its moderate price, is a great boon to the suffering poor, who daily acknowledge its salutary benefit."

From W. G. KING, M.D., M.R.C.S. Eng., Hackney.

"I have used your Chlorodyne for some time, and can bear testimony to its efficacy and value in all cases in which a Sedative has been indicated."

Manufactured by RICHARD FREEMAN, Pharmacist, Kennington-road, London, S.;  
And Sold by all Wholesale Houses, in bottles, 1 oz., 1s. 6d.; 4 oz., 5s.; and 8 oz., 10s. each.

## *Pulvis Jacobi ver, Newbery*

Is the ORIGINAL & GENUINE, was ESTABLISHED A.D. 1746,  
And is Prescribed, with the greatest success, "by the highest authorities," for  
Fevers, Ague, Cerebral Congestion, Rheumatism, Chills, Influenza, &c. &c.  
**FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.**  
Prices for Dispensing—1 oz., 9s.;  $\frac{1}{4}$  oz., 3s. 4d.

### TOWLE'S CHLORODYNE.

**CAUTION.**—For the convenience and safety of prescribing Chlorodyne, in combination with other ingredients, so as to avoid decomposition (a result known to have taken place) through the use of SECRET COMPOUNDS, Mr. TOWLE begs to call the attention of the Profession to the following component parts in his Preparation:—

CHLOROFORMYL.  
ÆTHER.  
OL. MENTH. PIP.

ACID. PERCHLOR.  
TINCT. CANNABIS INDICÆ.  
ACID. HYDROCYAN.

TINCT. CAPSICI.  
MORPHIA.  
THERIACA.

The proportion of Morphia— $\frac{3}{4}$  gr. inf. ʒi. Dose—Five to Twenty Drops.  
The Profession is respectfully referred to the various letters that have appeared in the Medical Journals against the use of "SECRET" REMEDIES. The above Preparation, having had extensive sale in London and the Provinces, may now be obtained from almost any Chemist. The Proprietor would suggest the following designation in the writing of Prescriptions, should a preference be given to the above Preparation—

"CHLORODYNE" (TOWLE'S).

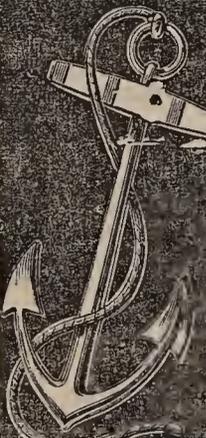

Sold in bottles, 1 oz., 1s. 6d.; 2 oz., 2s. 6d.; and 4 oz. to 20 oz., 1s. per fluid oz.

Sole Manufacturer—A. P. TOWLE, CHEMIST, &c., 99, STOCKPORT-ROAD, MANCHESTER.

Medicinal Properties:—

Anodyne, Diaphoretic, Sedative, Astringent, and Anti-Spasmodic.

TRADE MARK

# CHLORODYNE

WAS DISCOVERED AND INVENTED IN THE YEAR 1848 BY  
DR. J. COLLIS BROWNE, M.R.C.S.L. EX. ARMY-MED. STAFF  
AND IN 1856 HE CONFIDED  
THE ORIGINAL AND ONLY FORMULA  
FOR ITS MANUFACTURE  
SOLELY TO J. T. DAVENPORT, PHARMACEUTIST,  
33, GREAT RUSSELL ST. BLOOMSBURY SQUARE LONDON  
REGISTERED, 1856.

### NOTIFICATION.

The attention of Medical Men is directed to the Piratical application, by some parties in the Trade, of the term "Chlorodyne" to various mixtures compounded of Chloric Æther Opium, Indian Hemp, and Peppermint, in Imitation of the ONLY Genuine preparation of this name.

The dangerous expedient of encouraging or advocating the assumption of a name specifically indicating a particular property or remedy—such as *Chlorodyne* is to spurious imitations and substitutions—ON THE GROUND OF CHEAPNESS, is a subject of surprise and grave reproach, supremely so, when the adulteration, sophistication, and tampering with Drugs, becomes so serious and important a consideration in the successful practice of Medicine.

The fact of these Piracies must fully convince the Profession of the extraordinary efficacy of the Genuine Chlorodyne; whereas the sad results and disappointment arising from the use of spurious compounds cannot be expressed.

Each Genuine Bottle bears a Red Stamp, with the words, "Dr. J. COLLIS BROWNE'S CHLORODYNE," in White Letters.

To be obtained from all Wholesale Druggists in 1oz., 2oz., 4oz., and 8oz. Bottles.

**NOTICE. — REDUCTION OF PRICE TO THE PROFESSION.**

In Bottles, 1oz., 3s.; 2oz., 5s.; 4oz., 8s.; 10oz., 15s. To Hospitals and Charities in large quantity, a Liberal Discount.

PROFESSOR HUXLEY'S LECTURES  
AT THE  
ROYAL COLLEGE OF SURGEONS.

LECTURE III.

(Being the Second of Six Lectures on Classification.)

MR. PRESIDENT AND GENTLEMEN,—At our last meeting we carried our study of the structure of the principal groups of the animal kingdom so far as the *Hydrozoa*; and I propose to-day, commencing with a similar examination of the *Actinozoa*, to carry that study, if possible, through the *Mollusca*. The class of the *Actinozoa* contains those animals which are familiar to us as sea anemones and coral polypes, the creatures which fabricate the remarkable skeletons on the table, and by the activity of which, in many tropical parts of the world, those huge reefs which are so well known to navigators are constructed. It embraces the Sea pens and the Red coral, and those creatures which are known to us under the names of *Berœe*, *Cydippe*, *Pleurobrachia*, etc., transparent, beautifully symmetrical, free-swimming animals, provided with eight rows of longitudinally-disposed large cilia. In all these animals we find a great uniformity of structure, and their plan of construction is quite as readily definable as that of the preceding class, with which they exhibit a close affinity. Like the majority of the *Hydrozoa*, most *Actinozoa* have their mouths surrounded by tentacles; there is the same primary distinction of the body into two cellular layers—the ectoderm and the endoderm—though in the adult forms of the more highly organised *Actinozoa* these primitive layers become further differentiated into bundles of definitely disposed muscular fibres, and even into nerves and ganglia.

As in the *Hydrozoa*, again, the alimentary canal communicates freely and by a wide aperture with the general cavity of the body, but the whole of the *Actinozoa*, polype-like as they are in external appearance, differ from the *Hydrozoa* by a very important further progress towards complexity. We found that in the *Hydrozoa* the digestive cavity was completely outside the general cavity of the body, the digestive portion of the organism being continued into, and not in any way contained within the part which contains the general cavity. But if you make a vertical section of a sea anemone (Fig. 1), you will find that the digestive cavity—as freely open at the bottom as in the *Hydrozoa*—is enclosed within a part of the body which contains a prolongation of the general cavity. If you could suppose the stomach of a *Hydrozoon* thrust into that part of the body with which it is continuous, so that the walls of the body should rise round it and form a sort of outside case containing a prolongation of the general cavity, the *Hydrozoon* would be converted into an *Actinozoon*.

FIG. 1.

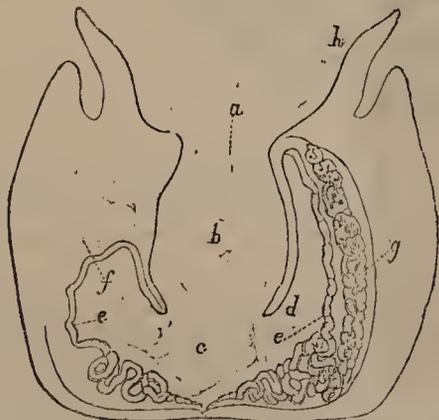

FIG. 1.—Perpendicular section of *Actinia holsatica* (after Frey and Leuckart); a, mouth; b, stomach; c, common cavity; d, intermesenteric chambers; e, cord containing thread cells at the edge; f, the mesentery; g, reproductive organ; h, tentacle.

The prolongation of the general cavity thus produced, which, as it surrounds the chief viscus, may be termed the "perivisceral cavity" (d), receives the products of digestion mixed with much sea-water; and the nutritive fluid which

thus fills the perivisceral cavity and its ramifications plays the same part as the blood of the more highly organised animals. The gastric chamber of the *Actinozoa* does not lie free in the interior of the body, but is connected to the sides of it by means of membranous partitions, the so-called "mesenteries" (f), which pass radially from the stomach to the side walls of the body, and so divide the "perivisceral cavity" into a number of chambers which communicate with the bases of the tentacles. In the whole of the *Hydrozoa* the reproductive organs were attached to the exterior of the body, and projected from it. In the whole of the *Actinozoa*, on the other hand, the reproductive organs, which are, very frequently, both combined in the same individual, are internal, inasmuch as they are situated in the substance of the mesenteries (g).

These are the universal and distinctive characters of the *Actinozoa*. That some are simple and some are compound organisms; that some are fixed and some free swimmers; that many are soft, while a great number are provided with very dense skeletons; that some possess a rudimentary nervous system, while the majority have as yet afforded no trace of any such structure, are secondary circumstances in no way affecting the problem before us, which is, to find a diagnostic definition of the group.

FIG. 2.

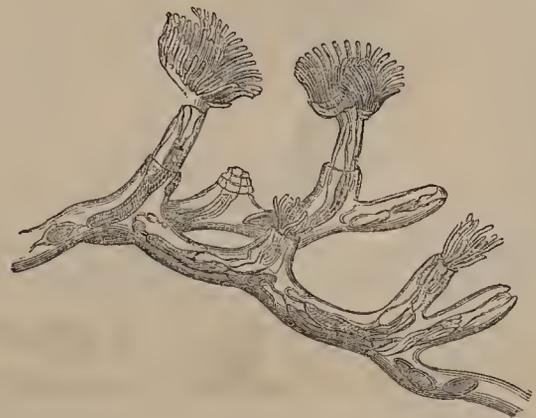

FIG. 2.—*Plumatella repens*, a freshwater Polyzoon, magnified (after Allman).

In the next class on the list—the *Polyzoa*—we meet (notwithstanding the invariably minute size of these organisms) with a very great advance in complexity of structure. In such a compound *Polyzoon* as this specimen of sea-mat, or *Flustra*, the entire surface of the foliaceous expansion, on being examined by the microscope, will be found to be beset with an infinitude of minute apertures leading into little chambers, out of which, when the animal was living and active, you would have seen multitudes of little creatures, one from each chamber, protruding the oral extremities of their bodies. The ends of the branches of the freshwater form *Plumatella*, represented in this diagram, present a similar spectacle. Each mouth is surrounded by a circle of tentacles, and, as every tentacle is fringed with long and active vibratile cilia, lashing the water towards the mouth, hundreds and thousands of little Maelströms are created, each tending to suck down such nutritious bodies, living or dead, as come within its range. Each mouth (Fig. 3) leads into a long and wide pharyngeal and œsophageal tube, which opens below into a definite stomach. From this is continued a distinct intestine, which bends upon itself towards the oral end of the body so as to form a sharp angle, and then terminates upon the outer surface near the mouth; so that we have here, for the first time in our ascending survey of the animal kingdom, an animal possessing a complete intestine, not only structurally separated from the general substance of the body, and provided with permanent apertures, as in the *Hydrozoa* and *Actinozoa*, but completely shut off from the perivisceral cavity, and in direct communication only with the external medium. All the *Polyzoa* possess a nervous system, the characters and the position of which are very well defined. It always consists of a single ganglion (Fig. 3, w), placed between the oral and the anal apertures, and sending off nerves in various directions. It has been affirmed that in some *Polyzoa* there is a more extended system of nerves by which the various zooids of the compound organism are placed in communication; but of that we want further evidence. In these animals no heart has been discovered as yet, the matters which result

from digestion percolating through the walls of the intestine, and becoming mixed with the perivisceral fluid. One of the structural characters which I have mentioned is exceedingly

FIG. 3.

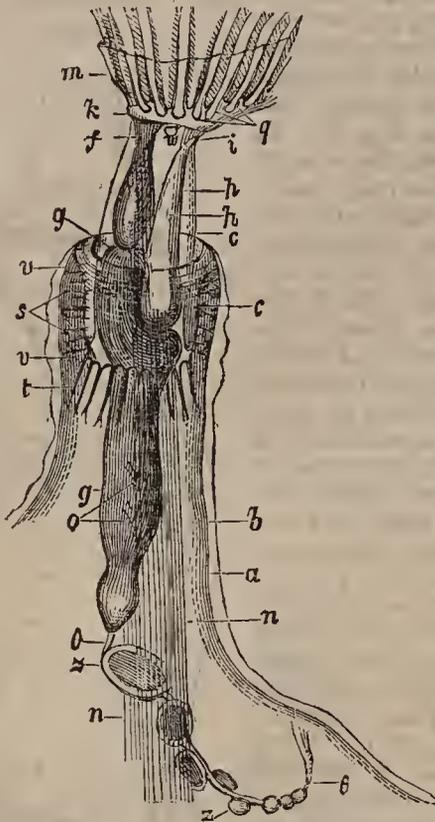

FIG. 3.—*Plumatella repens*, a single cell more magnified; *m*, calyx at the base of the ciliated tentacula borne by the disk or lophophore; *k*, gullet; *g*, stomach; *h*, intestine; *i*, anus; *v*, nervous ganglion.

important. As I have said, the intestine is not straight, but is bent upon itself (Fig. 3), and the direction of flexure is such that the nervous ganglion, which corresponds with those called "pedal" in *Lamellibranchiata*, is placed in the re-entering angle between the gullet and the rectum. In order to express this relation of the nervous system to the alimentary canal, the flexure of the latter has been called "neural"—the side of the body on which the principal ganglion is placed, and towards which the intestine is bent being the "neural" side. Whatever our terminology, however, the great point is to remember that the structural relation which it expresses is constant throughout the *Polyzoa*. In the next division, the *Brachiopoda*, which are animals differing very much in external appearance from the *Polyzoa* we shall find, nevertheless, a singular fundamental resemblance of internal structure to the latter. All known *Polyzoa* are compound animals, that is to say, the product of every ovum gives rise by gemination to great assemblages of partially independent organisms or zooids. The *Brachiopoda*, on the contrary, are all simple, the product of each ovum not giving rise to others by gemination. All the *Brachiopoda* possess a bivalve shell—a shell composed of two horny or calcified pieces, which are capable of a certain range of motion on one another, and are very commonly articulated together by teeth and sockets. The proper body, which is small when compared with the size of the shell, has its dorsal integument produced into broad membranous expansions, which line the interior of the valves, of the shell, and are called the lobes of the mantle or "pallium." The aperture of the mouth is situated in the middle line between the pallial lobes, and on each side of it is a longer or shorter prolongation of the body, provided with ciliated tentacula. It is from the presence of these "arms" that the class has received its name. Suppose the tentaculate oval disk of a *Polyzoon* to be pulled out on each side to a much greater extent than is the case in the "Hippocrepian," division of that group, and you would give rise to "arms" closely resembling those of the *Brachiopoda*.

FIG. 4.

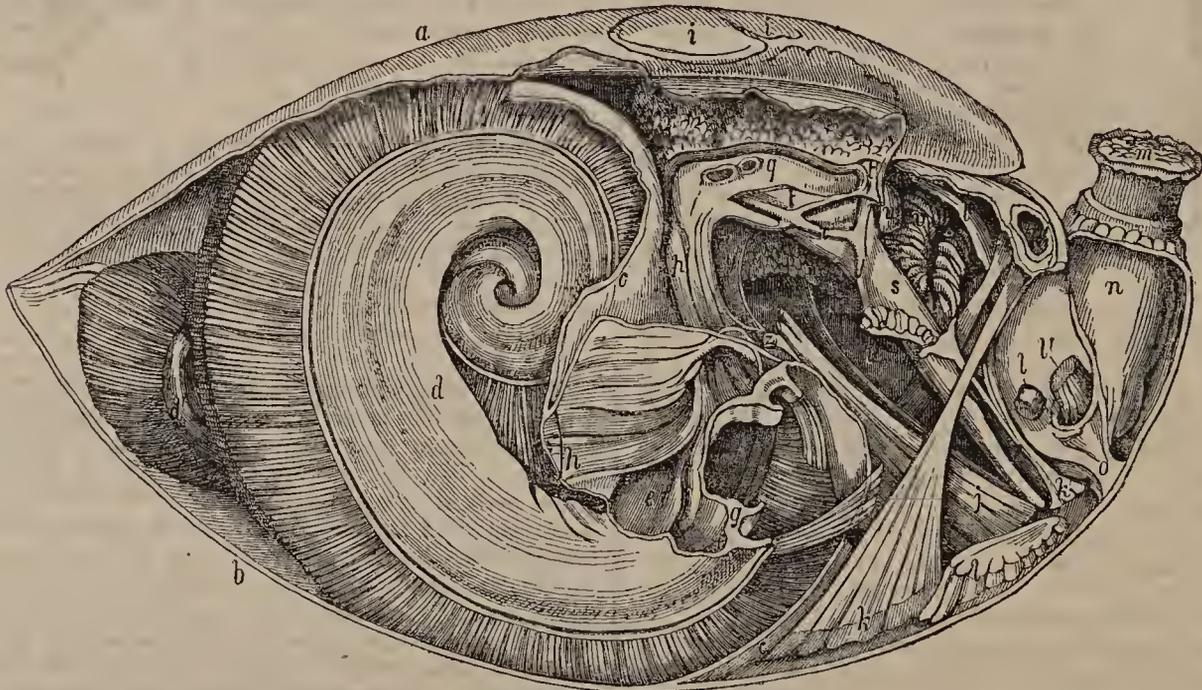

FIG. 4.—Lateral view of the viscera of *Waldheimia Australis* (after Hancock). *a*, anterior layer of mantle; *b*, posterior layer; *c*, anterior walls of the body between the mantle lobes; *d*, arms; *p*, gullet; *q*, stomach, with cut biliary ducts of the left side; *r*, right hepatic mass; *s*, intestine ending caecally below; *v*, so-called "auricles" of the right "pseudo-heart," the left being almost wholly removed; *w*, pyriform vesicle fixed at the back of the stomach, and probably performing the function of a true heart; *z*, oesophageal ganglia.

The mouth leads into a gullet which is directed towards or lies along that side of the body, from which one lobe of the mantle, the anterior, is continued; the gullet opens into a stomach provided with a well-developed liver; and from the stomach an intestine proceeds, which is directed towards, or along, that side of the body from which the other lobe of the mantle proceeds, and then either, as I pointed out some years ago (a), ends blindly in the middle line (Fig. 4), or else terminates in a distinct anus between the pallial lobes.

(a) Professor Owen, in the second edition of his lectures on the "Comparative Anatomy and Physiology of the Invertebrate Animals," published in 1855, thought it not unbecoming to sneer at this discovery. "There may be blindness somewhere, but I think not at the termination of the

The principal ganglionic mass is situated behind and below the mouth, in the re-entering angle between the gullet and the rectum; in other words, the intestine has, as in the *Polyzoa*, a neural flexure (Fig. 4). In all *Brachiopoda* which have been carefully dissected a singular system of cavities and canals situated in the interior of the body, but in free communication with the surrounding medium, has been discovered. This, which I shall term the "atrial" system, from its close correspondence with the system of cavities, which has re-

intestine of *Terebratula*."—L. c., p. 403. As my statements have subsequently been fully borne out by Mr. Albany Hancock and by M. Lacaze Duthiers—two of the best minute anatomists of the day—I trust Mr. Owen is now fully satisfied as to where the "blindness" really was in 1855.

ceived the same name in the Ascidiæ, has been wrongfully regarded as a part of the true vascular system, and the organs by which it is placed in communication with the exterior have been described as "hearts." There are sometimes two and sometimes four of these "pseudo-hearts" situated in that part of the body wall which helps to bound the pallial chamber. Each pseudo-heart is divided into a narrow, elongated, external portion (the so-called "ventricle"), which communicates, as Mr. Hancock has proved, by a small apical aperture with the pallial cavity, and a broad, funnel-shaped inner division (the so-called "auricle"), communicating on the one hand by a constricted neck with the so-called "ventricle," and on the other by a wide, patent mouth, with a chamber which occupies most of the cavity of the body proper, and sends more or less branched diverticula into the pallial lobes. These have been described as parts of the blood vascular system; and arterial trunks, which have no existence, have been imagined to connect the apices of the ventricles with vascular networks opening into the branched diverticula, which are of a similarly mythical character.

In fact, as Mr. Hancock has so well shown in his splendid and exhaustive memoir, published in the *Philosophical Transactions* for 1857, the true vascular system is completely distinct from this remarkable series of atrial chambers and canals, the function of which would appear to be to convey away excretory matters, and the products of the reproductive organs which are developed in various parts of the walls of the atrial system.

The precise characters of the true vascular system of the *Brachiopods* probably require still further elaboration than they have yet received, and the same may be said, notwithstanding

FIG. 5.

FIG. 5.—*Phallusia mentula*; a, oral; b, atrial aperture; c, base of attachment.

the valuable contributions of F. Müller and of Lacaze Duthiers, of their development; but the shell, the pallial lobes, the intestines, and the nervous and the atrial systems, afford characters amply sufficient to define the class.

The next great division is that of the *Ascidoida*, which, like the *Brachiopoda* are marine animals, and are very common all over the world; the more ordinary forms of them being always easily recognisable by the circumstance that their external integument is provided with two prominent, adjacent apertures, so that they look very much like double-necked jars (Fig. 4). At first sight you might hardly suspect the animal nature of one of these singular organisms when freshly taken from the sea; but if you touch it, the stream of water which it squirts out of each aperture reveals the existence of a great contractile power within; and dissection proves that this power is exerted by an organism of a very considerable degree of complexity. Of the two apertures, the one which serves as a mouth is often—but not always—surrounded by a circlet of tentacles (Fig. 5). It invariably leads into an exceedingly dilated pharynx, the sides of which are, more or less extensively, perforated. The gullet comes off from the end of the pharynx; and then dilates into the stomach, from which an intestine, usually of considerable length, is continued to the anal aperture. The latter is almost always situated within a chamber, the external aperture of which is that second aperture seen upon the exterior of the tube to which I referred just now. Furthermore, in all Ascidiæ which I have examined the first bend of the intestine takes place in such a manner that, if the intestine continued to preserve the same direction, it would end on the opposite side of the mouth to the nervous ganglion (Fig. 5); in other words, the nervous ganglion would not be situated in the re-entering angle between the gullet and the rectum. Therefore the flexure of the intestine is not neural, as in the *Polyzoa*; but as, on the contrary, the intestine is primarily bent towards the heart side of the body, its flexure may be termed "hæmal." And this hæmal flexure of the intestine in the Ascidiæ thus constitutes an important element in the definition of the class.

In these animals there is an atrial system, the development of which is even more extraordinary than in the *Polyzoa*. The second aperture to which I have referred (b, Figs. 5 and 6) is continued into a large cavity lined by a membrane,

which is reflected, like a serous sac, on the viscera, and constitutes what has been termed the "third tunic," or "peritoneum." From the chamber which lies immediately within the second aperture (k, Fig. 6) it is reflected over both

FIG. 6.

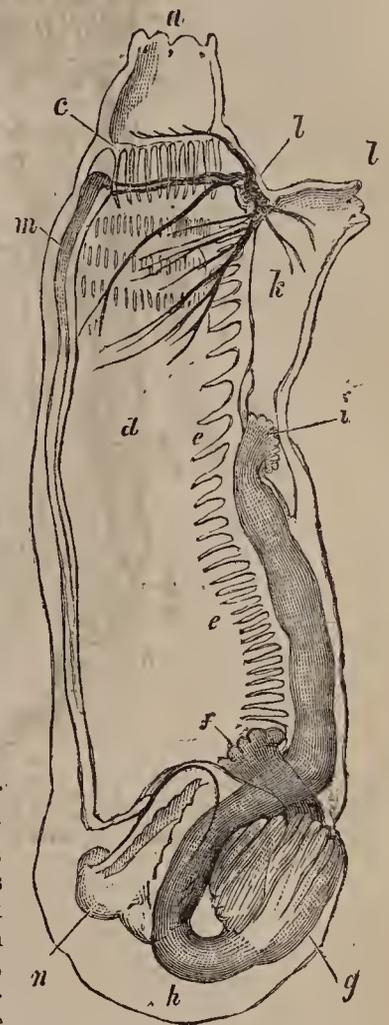

FIG. 6.—*Phallusia mentula*; the test removed, and only so much of the animal drawn as would be seen in a longitudinal section. a, oral aperture; b, atrial aperture; c, circlet of tentacles; d, pharyngeal or branchial sac; e, the languets; f, cesophageal opening; g, stomach; h, intestine performing its hæmal flexure; i, anus; k, atrium; l, ganglion; m, endostyle; n, heart.

which is reflected, like a serous sac, on the viscera, and constitutes what has been termed the "third tunic," or "peritoneum." From the chamber which lies immediately within the second aperture (k, Fig. 6) it is reflected over both sides of the pharynx, extending towards its dorsal part very nearly as far as that structure which has been termed the "endostyle" (m, Fig. 6). It then passes from the sides of the pharynx to the body-walls, on which the right and left lamellæ become continuous, so as to form the lining of the chamber (k), into which the second aperture opens—the "atrial chamber." Posteriorly, or at the opposite end of the atrial chamber to its aperture, its lining membrane (the "atrial tunic") is reflected to a greater or less extent over the alimentary canal and circulating organs, sometimes inclosing each of their parts in distinct plications (as in the genus *Phallusia*), sometimes merely passing over them, and limiting the blood sinus in which they are contained (as in *Clavelina*, etc.). Where the atrial tunic is reflected over the sides of the pharynx, the two enter into more or less close union, and the surfaces of contact become perforated by larger or smaller, more or less numerous, apertures. Thus the cavity of the pharynx acquires a free communication with that of the atrium, and, as the margins of the pharyngo-atrial apertures are fringed with cilia, working towards the interior of the body, a current is produced, which sets in at the oral aperture, and thence out by the atrial opening. Hence the current, which, in a living Ascidian, is constantly setting in this direction.

The Ascidiæ possess a distinct heart, but of a very simple construction, seeing that it is merely an incomplete muscular tube, open at each end, and devoid of valves. Functionally, it is not less remarkable than structurally, for, in the great majority of Ascidiæ, if not in all, it exhibits an alternation in the order of the peristaltic contractions of its muscular substance, which has no parallel in the animal kingdom. The result of this reversal in the direction of the contractions of the heart is a corresponding periodical reversal of the course of the circulation of the blood, so that the two ends of the heart are alternately arterial and venous.

The perforated pharynx serves as a branchial apparatus, the blood contained in its perforated walls being subjected to the action of constant currents of aerated water. All Ascidiæ possess a single nervous ganglion placed upon one side of the oral aperture (l, Fig. 6), and, in all known genera but *Appendicularia*, it is situated between the oral and atrial apertures, and, indeed, between the oral and anal apertures; for the intestine, after it has made its hæmal bend, in all genera but that mentioned, curves down towards the neural side of the body, and opens into the atrium on that side of the body, and behind the nervous ganglion.

The outer integument of the Ascidiæ secretes upon its surface, not a calcareous shell, but a case or "test," which may vary in consistence from jelly to hard leather. And it is not one of the least remarkable characteristics of the group that this test is rendered solid, by impregnation with a sub-

stance identical in all respects with that "cellulose" which is the proximate principle of woody fibre, and forms the chief part of the skeleton of plants. Before the discoveries of late years had made us familiar with the production of vegetable proximate principles by the metamorphosis of animal tissues, this circumstance was justly regarded as one of the most remarkable facts of comparative physiology.

The last common and distinctive peculiarity of the Ascidians which I have to mention is one which acquires importance only from its constancy. The middle of the hæmal wall of the pharynx from near the oral to the œsophageal end, in all these animals, is pushed out into a sort of fold, the bottom of which projects into a blood sinus, and has a much thickened epithelial lining. Viewed from one side, the bottom of the fold consequently appears like a hollow rod, and has been termed the "endostyle" (*m*, Fig. 6). The functions of this structure are unknown, but it has been noticed in all genera of Ascidians hitherto examined.

## ORIGINAL COMMUNICATIONS.

CASE OF

### INTRA-CAPSULAR FRACTURE OF CERVIX FEMORIS WHERE OSSIFIC UNION IS SUPPOSED TO HAVE TAKEN PLACE.

By FRED. J. MASON, M.R.C.S. Eng.

ON Thursday, February 13, 1862, I was sent for to see Mrs. L., aged 69, a healthy-looking woman, residing in an adjoining village, who had sustained an injury by falling on her left hip. The cause of the fall was attributed to her having received a blow on the chest. On my arrival, I found her reclining in a chair, and suffering much from pain in the hip. I ordered her to be carried to bed, when I made a careful examination of the injured part. The limb was perfectly powerless, the trochanter less prominent than one on opposite side, the foot was everted, and the limb shortened nearly an inch. By making extension and rotating the limb, crepitus could be distinctly felt. She suffered much pain at the upper and inner part of thigh. The small amount of shortening in the limb was owing, I imagine, to the capsular ligament having been but slightly lacerated. There was no swelling or bruise about the part.

The plan of treatment adopted in this case was the application of a Liston's long splint and a band round the hips for five weeks. The splint was then discontinued, and the limb supported merely by pillows up to the end of the tenth week, when, her health beginning to suffer, she was allowed to leave her bed. At this time she had not the slightest power to use the limb. Her diet all the time had been on a liberal scale, and she was allowed a certain amount of stimulants. At the end of the fourth month she could begin to use the limb a little, and, with the aid of crutches, got about tolerably well. She left her home for change of air, and I did not see her again until eight months after the accident, when she could walk with the assistance of a stick only, which she continued to use until the beginning of the eleventh month. I have seen her lately; she can walk (limping slightly) without the aid of either crutch or stick. There is very little shortening of the limb. She states that it gains strength, and she improves in her walking daily.

Foston.

### SEVEN CASES OF OVARIOTOMY IN PRIVATE PRACTICE.

By T. SPENCER WELLS, F.R.C.S.

Surgeon to the Samaritan Hospital, etc.

IN a Clinical Lecture published in the *Medical Times and Gazette*, July 26, 1862, a short account is given of a case in which I divided with an *écraseur* the connections between the uterus and an ovarian tumour. The patient has continued in excellent health. Since that case I have performed ovariectomy seven times in private practice, and I now propose to lay a short account of these cases before the Profession. Reports

of cases occurring in the Samaritan Hospital during the same period may be found in the *Medical Times and Gazette* for December 20, 1862, and March 14, 1863.

*Case 1.*—On June 30, 1862, I saw a single lady, 49 years of age, in consultation with Dr. Cahill, of Brompton. She was in a state of great distress, and we tapped her that afternoon to obtain relief. Fourteen pints of fluid were removed from an ovarian cyst, and great relief was afforded. The history of the disease showed that growth had commenced about four years before, but that the tumour had only risen from the pelvis into the abdomen about eighteen months before, since which time she had suffered a great deal, and latterly the increase had been rapid. On August 16, the cyst having refilled rapidly, I again removed fourteen pints of fluid by tapping, and agreed with Dr. Cahill to perform ovariectomy without much further delay. On September 3, Mr. Parson gave chloroform, and assisted by Dr. Savage, Dr. Cahill, and Dr. Buchanan, of Glasgow, Professor Schuh, of Vienna, being present, I removed the tumour through an incision six inches long, after separating some parietal adhesions. The pedicle was very short, but was kept outside by a clamp. The left ovary was atrophied. A description of the tumour may be found in the *Medical Times and Gazette*, October 25, 1862, in the report of the Pathological Society. I described it as an example of *Adenoma*, being identical in structure with the chronic mammary tumour. The patient recovered rapidly, went to Worthing five weeks after operation, and has since enjoyed excellent health.

*Case 2.*—On August 22, 1862, I saw a single lady, 32 years of age, in consultation with Dr. Walshe, and Mr. Denne, of Winslow. Her health had been failing for two or three years before, but she had not noticed any abdominal enlargement until the beginning of 1862. The whole abdomen was occupied by an ovarian cyst, and it was agreed that she should be tapped. On September 4, I removed ten pints of thick fluid, and found a large group of secondary cysts on the left side. It was therefore arranged that another tapping would be useless, and that ovariectomy should be performed as soon as the emptied cyst refilled, which it did very soon. I operated on November 6. Mr. Clover gave chloroform, and I was assisted by Dr. Savage and Messrs. Lawson and Peirce. There were no parietal adhesions, and I removed a very large cysto-sarcoma through an incision four inches long. The peduncle was on the left side, and very short, so that there was considerable traction on the clamp, depressing the lower angle of the wound close to the sacrum; but this was not followed by any unpleasant symptom; recovery was uninterrupted, and she has since remained in excellent health.

*Case 3.*—Several times in September, 1862, I saw a single lady, 23 years of age, in consultation with Dr. Hawksley, who had made the diagnosis of a multilocular ovarian cyst on the left side. There being no large cyst, tapping was evidently useless, and it was agreed that I should perform ovariectomy as soon as the operation was warranted by the state of the general health, or the urgency of any symptom. Dr. Savage met us on November 8, and it was decided that I should operate a clear week after the cessation of the catamenial period. On November 15, Mr. Clover gave chloroform, and, assisted by Drs. Hawksley and Savage and Mr. Parson, I removed a non-adherent cyst through an incision four inches long. The peduncle was very short, and the traction on the clamp considerable, but the stump was kept outside. There was a good deal of pain on recovery, but it was relieved by an opiate. During the next four days the pulse only varied from 76 to 84, and there was no bad symptom; but she was very hysterical, and complained of a severe sciatic pain at times. This ceased when the clamp was removed on the 20th, and the bowels acted. After this she gradually improved, went to St. Leonard's on December 18, afterwards to Brighton, and has since been gradually recovering perfect health.

*Case 4.*—On October 23, 1862, I was consulted by a single lady, 25 years of age, with a very large multilocular cyst of the left ovary, of two years' standing, for which she had consulted Dr. Grimsdale, of Liverpool, who had said that tapping could be of no service, and that ovariectomy was her only resource. I entirely agreed with him, and performed the operation on November 25. Mr. Clover gave chloroform, and I was assisted by Professor Pirrie, of Aberdeen, Dr. Druitt, and Dr. Kumar, of Vienna, removing a cyst (after emptying it of thirty-two pints of viscid fluid), and groups of secondary cysts, through an incision four inches long.

There were some unimportant adhesions, easily separated, above and to the right of the umbilicus. Professor Pirrie kept the abdominal wall so closely pressed against the cyst as I withdrew it through the opening that we did not even see the intestines. The right ovary was felt to be healthy. The peduncle was unusually long. She recovered well, but for several days after operation complained of severe pain in the course of the left sciatic nerve, but never of any pain in the abdomen. The pain seemed to be due to a hernia or prolapse of the pedicle behind the clamp, forming a swelling which increased daily after the clamp was removed from the size of a walnut until it was about three inches in height and four in circumference. On the summit were the remains of the slough, and the peritoneal surface around was covered by flakes of lymph and bedewed by serum which exuded in considerable quantity. The rapid increase in the stump was evidently the result of œdema caused by pressure of the contracting wound. The sciatic pain it caused was becoming so severe and continuous that, on December 1, I placed a loop of wire around the neck of the prolapsed pedicle, and proceeded to tighten the wire with an *écraseur*, but the pain thus caused in the thigh was so great that I took away the wire, and, with the kind assistance of Mr. Hulke, who gave her a little chloroform, I transfixed the stump, tied it in two portions, and cut it away. There was some bleeding, which was stopped by a ligature tied below the spot of transfixion. Dr. Kumar carefully examined the portion of stump, and found in it some very large vessels, and a nerve as large as the ulnar at the wrist, but it was chiefly made up of cellular tissue. After this she steadily improved, the sciatica disappeared, she went to Liverpool on December 26, and has since been in excellent health.

*Case 5.*—In July, 1862, I was requested by Dr. Martin, of Rochester, to see a single lady, 53 years of age, and found the abdomen, from an inch above the umbilicus downwards, occupied by a multilocular ovarian tumour. She had been well until about a year before, and the tumour had only been detected about three months before I saw her. As there was no urgent symptom, we advised her to wait. She went on pretty well until October, when she began to increase in size, and early in December the legs became œdematous. I saw her on the 15th of December, and found that a considerable quantity of ascitic fluid had formed around the ovarian tumour. A nodulated tumour could be felt in the pelvis behind the uterus. This tumour moved freely in every direction with the abdominal tumour. The cervix uteri was normal, and movable independently of the tumour. There was no albumen in the urine, and I advised ovariectomy without delay as the only hope of saving life. Dr. Gream saw her on December 16, and Dr. West on December 17. Both these gentlemen agreed that she could not live a year if left alone, or if the ascitic fluid were removed by tapping; and it was agreed that ovariectomy should be performed. I operated on December 23. Mr. Clover gave chloroform, and I was assisted by Dr. Savage, Dr. Martin, of Rochester, and Dr. Kumar, of Vienna. After making an incision five inches long from an inch below the umbilicus, and allowing about twelve pints of ascitic fluid to escape, a non-adherent, semi-solid tumour, of very irregular shape, was exposed. I tapped this in two places with a very large trocar, but the contents were too viscid to escape. Rather than enlarge the incision, I passed my hand into the tumour and broke it up, gradually squeezing it outwards. A short pedicle was secured by a clamp, and the peritoneal cavity very carefully cleansed by sponges from all serum and ovarian fluid. The wound was closed as usual. Healthy reaction soon came on. She had a comfortable night after one opiate, and went on remarkably well afterwards. The pulse remained rapid—100 to 110—for three weeks, but there was no re-formation of ascitic fluid. She returned to the country a month after operation, and I had a letter on March 14, stating that "she complains of nothing, and takes her drives and walks, and enters into society as she always used to do."

*Case 6.*—On January 31, I saw a single lady, 25 years of age, who was suffering greatly from an ovarian tumour which occupied the whole abdomen, and extended beneath the false ribs, pushing them outwards, and the ensiform cartilage forwards. The girth was forty-two inches, the measurement from sternum to pubes nineteen inches. I wrote to Dr. Watson (by whom the parents of the young lady had been advised to consult me) stating that I found a large cyst of the right ovary and groups of smaller cysts on the

same side; that there was no proof of disease of the left ovary, and that the tension of the abdomen was so great that it was impossible to determine the extent of adhesion. There was no albumen in the urine, nor any proof of any other than the ovarian disease. As tapping could only be of temporary service, I proposed to make a small incision, and be guided by the extent of adhesion, as to whether I should do more than empty the large cyst; and it was arranged that I should do so. On February 3, Mr. Clover having given chloroform, and assisted by Dr. Savage, Mr. Burton, of Doverstreet, Mr. Cowell, of Piccadilly, and Dr. Kumar, of Vienna, I made a small incision midway between the umbilicus and pubes. The large cyst being firmly adherent here, I opened it and allowed its contents to escape before proceeding. A large group of secondary cysts was then felt to be freely movable above and to the right of the umbilicus, and as the adhesions seemed to be chiefly near the incision, I enlarged it to between four and five inches, separated some adhesions, and passed my hand into the cyst, breaking up the smaller cysts as I gradually withdrew the whole of the tumour, separating a small piece of adherent omentum, and lastly a very firm patch of adhesion in the right iliac fossa. The pedicle was very broad and short, and there was considerable traction on the clamp, which was fixed outside. The left ovary was healthy. The abdominal cavity was carefully cleansed by sponging. She was restless, and complained of much pain for about two hours after operation, but it subsided after a second opiate, and I was told that she had been in a very similar state some months before after taking chloroform for tooth-drawing. The skin and kidneys acted freely during the evening; she became easy; the pulse rose to 110, and she passed a good night. The next morning she appeared to be doing very well, had not required more opium, and was cheerful; but the pulse had risen to 130. Still as it was soft and not feeble I was very hopeful. In the afternoon the urine, which had been clear and abundant, became scanty and concentrated, and there was a return of pain. An opiate was given, and the pain was relieved, but a tendency to vomit came on. At night she became weaker. The pulse rose to 140, and was more feeble. Champagne was given, and a mixture of eggs and brandy thrown into the rectum. Early in the morning she became faint, and a profuse discharge of serum—upwards of a pint—escaped beside the peduncle. Brandy was given freely, both by the mouth and rectum, and she rallied for a time, but afterwards continued to sink, and died forty-four hours after operation. Dr. Kumar, Mr. Cowell, and Mr. Burton were present at the post-mortem examination. There was not a drop of blood, nor any clot in the peritoneal cavity, but there were evidences of a low form of diffuse peritonitis, shown rather by the effusion of serum than of lymph. Two or three coils of small intestine were united together by recent lymph. The process of repair had commenced by a coating of lymph on the surfaces where the adhesions had been separated, and the peritoneal edges of the wound were well united. There was a little bloody serum in the subperitoneal tissue of the uterus and left ovary. On the right side the broad ligament and Fallopian tube which had formed the peduncle were firmly secured.

On reflecting upon this case, I can see no reason to regret that the operation was performed; while, if the patient had been allowed to die a few weeks or months later of the natural progress of the disease, there would have been great reason to regret that the effort to save her life had not been made. The true lesson it appears to teach is,—not to delay the operation too long, nor waste time in useless or merely palliative treatment.

*Case 7.*—On the 23rd and 27th of last February I saw an unmarried mulatto lady from Jamaica, in consultation with Dr. Hare, who had made the diagnosis of a multilocular cyst of the left ovary. The early symptoms of the disease had commenced when she was about eighteen years of age, but it was not until the autumn of 1861 that any increase in the size of the abdomen was observed. In February, 1862, she was tapped, and seven pints of fluid removed. She was relieved for a time, but was tapped again in September, 1862, when fourteen quarts of fluid were removed, and a hard, movable tumour left. She filled again rapidly, and when I saw her with Dr. Hare, she was larger than she had ever been before. The girth was forty-six inches; from sternum to pubis, twenty-six inches; and thirty-one inches from one anterior superior spine of the ileum to the other. She was very unwilling to be tapped again; and as I considered the

case to be a fairly favourable one for ovariectomy, it was decided that the operation should be performed. It was done on March 9. Mr. Parson gave chloroform, and I was assisted by Dr. Savage, Dr. Druitt, and Mr. T. H. Smith. The incision extended five inches midway between the umbilicus and symphysis pubis. The cyst was firmly adherent there, and I opened it and allowed the contents to escape before exposing the peritoneal cavity by separating any adhesions. When the cyst was empty, careful examination was necessary to make out the exact line of demarcation between the cyst and parietes, and it was necessary to separate some very firm and extensive adhesions. When this was done, I passed my hand inside the large cyst, and broke up a number of smaller cysts, pressing out quantities of hair and fat, and then withdrew the whole of the tumour, Dr. Savage assisting by steady pressure on the varietes, which he kept closely applied against the cyst as it escaped. The pedicle was secured by a clamp, the left ovary found to be healthy, the pelvic cavity thoroughly cleansed by sponging, and the wound united as usual. A loose shred of vascular tissue, which hung loosely from the abdominal wall on the left of the incision, was brought out beside the pedicle, tied, and cut away. It consisted of a portion of the cyst wall, and of some organised fibrine, which had been the medium of connexion between the cyst and the parietes. There were forty-six pints of fluid collected, and the cysts weighed four pounds. Some of the smaller ones contained hair, and several teeth grew from the lining membrane of two of them. She soon rallied after the operation, did not vomit once, and had a good night after one opiate. A return of pain on the fourth day led to a second opiate, and this was the only medicine given, except a teaspoonful of castor-oil on the sixth day, which was followed by easy action of the bowels. Dr. Hare called upon her on March 23, and found her sitting up in an arm-chair, convalescent.

3, Upper Grosvenor-street.

## HYDROCYANIC ACID IN THE TREATMENT OF INSANITY.

By KENNETH McLEOD, M.D.

(Continued from page 291.)

### Case 6.—*Melancholia—Paroxysms of Acute Excitement Successfully Treated by the Administration of Hydrocyanic Acid.*

M. E., married, admitted January 29, 1861. Labours under a second attack of insanity; the first occurred at the age of 20; is now upwards of 50; present attack of two months' duration; cause, "hereditary predisposition"; mother died in an asylum; despondency has been the principal feature; has attempted self-destruction by strangling.

*Symptoms on Admission.*—Is a tall, strong, stout woman, of arthritic diathesis; large face and features; has a very florid complexion from dilated facial capillaries; general health fair; complains of severe frontal cephalalgæ, giddiness, rheumatic pains, etc.; mentally, is very melancholic, recriminating, entertaining dark views of present circumstances and forebodings of future.

September 23.—Until recently has exhibited no acute symptom; has been habitually gloomy, silent, and sad; expression distracted and desponding; declares that she is miserable, beyond hope in this world, and that she will be lost in the world to come; has not attempted suicide in any way; has employed herself with needlework, knitting, etc.; has complained constantly of headache, want of sleep; occasional vomiting; been treated, without much benefit, by tonics, sedatives, and liberal diet. Lately, she has given way to emotion, violent and suicidal manifestations; has rushed along the corridor of her ward, wringing her hands in despair, crying, attempting to rush through the window, and refusing any consolation or comfort. These paroxysms have been treated with perfect success by the administration of  $\text{m.v.}$  of Scheele's dilute hydrocyanic acid. She describes the effect as overpowering; says that it effectually prevents her fretting or shouting. Generally asks to lie down a few minutes after taking a dose; gets up in an hour or two quite calm and void of excitement. When the excitement recurs, the same treatment is pursued, with the same result.

November, 1862.—Has not had any paroxysm of excitement for upwards of a month; is low and desponding, but settled, calm, and industrious.

### Case 7.—*Melancholia—Improvement under Tonics, Sedatives, and Stimulants—Acute Paroxysms—Successfully Treated by Hydrocyanic Acid.*

E. M., aged 49, a widow, was admitted on April 12, 1862. Labours under a second attack of insanity of seven days' duration. The first occurred at 34 years of age. The causation of this attack appears to be partly physical, nervous diathesis, and low state of health, predisposing; and moral, her husband's death exciting. She has manifested the symptoms of suicidal melancholia, declares that her soul and body are lost, and has attempted suicide by cutting her throat.

*Symptoms on Admission.*—1. *Physical.*—Is of neuro-arthritis diathesis; is emaciated, cachectic, anæmic, and melanic. No structural change or acute disease of any part of the body discoverable. 2. *Mental.*—Labours under deep melancholia, which is general, as to past, present, and future, and envelops all her feelings and memories of their circumstances and relations with gloom. Refuses her food. Repeats that she is lost, and wishes she were dead.

The treatment resolved on, and pursued, consisted of—1. The ingestion of as much nutritive food as possible, at first artificially, and, when she began to feed spontaneously, by concentrating as much as possible; 2. Stimulants—wine, porter, etc.; 3. Tonics—the citrate of iron and quinine, in doses of gr. v. thrice daily; 4. Sedatives—a combination of hyoscyamus, morphia, and ether, at bed-time; 5. Open-air exercise and light employment.

July 29.—Has gradually improved in physical health and mental condition; has become more stout and ruddy; expression more cheerful; is industrious; has lost most of her delusions.

September 7.—Was visited yesterday by her son. The occasion has caused a recurrence of melancholia. Is more excited than she has been since admission; in constant motion; gesturing despairingly; wringing her hands; clenching her teeth. Is completely pre-occupied, crying, and incessantly repeating distracted exclamations and expressions. To have acid. hydrocyanic dil.  $\text{m.v.}$  every hour.

8th.—Settled down almost immediately after the first dose of the medicine ordered; became calm, quiet, cheerful, and gave over her gesticulations and expressions. Slept well last night. Excitement appeared in slight degree this morning; was promptly stayed by the administration of the acid. Describes its effect thus:—"Goes all over me"—"makes me 'most drunk"—"makes my head light"—"can speak, but feel as if I could not stand"—"feel calmer; more able to control myself"—"takes effect in a minute or two after taking it."

November.—No excitement has occurred since the report of September 8. Former treatment resumed. Has continued to improve satisfactorily, and will probably, at no distant date, be discharged.

### Case 8.—*Mania—Third Attack—Extreme Excitement—Immediate and Sustained Improvement from the Use of Hydrocyanic Acid—Gradual Convalescence and Ultimate Recovery.*

E. R., aged 39, single, poor, a dressmaker, of respectable family, well educated, amiable, industrious, chaste, religious. At some former period, suffered from disease of the right knee-joint, which occasioned for a long time great suffering, to which she attributes her mental affection; caused considerable lameness from ankylosis. Was admitted into the asylum on two former occasions, in August, 1858, labouring under an attack of mania similar in phenomena to the present, and in June, 1861, labouring under melancholia. From both attacks she made most excellent recoveries, becoming very useful, industrious, sensible, and cheerful. She was discharged in December last, and continued very well during the month or two following. She has recently, however, exhibited in conduct and conversation generally a great amount of eccentricity, and during the last six days has been in a state of very great unruliness and excitement. Admitted on June 11, 1862.

*Symptoms on Admission.*—Has defective palatal development; lateral incisors of upper jaw wanting; the front incisors very large and bucked; development otherwise excellent; is stout, well-nourished, and in good physical health; is menstruating.

*Mentally.*—Is in a state of extreme mania; incessantly moving and talking; grimaces; winks; gesticulates; shouts; swears; scolds; repeats the same expression over and over again; gets out of bed; exposes herself; is excited when any of the Medical officers enter the ward.

June 12.—Continued very excited during the afternoon, evening, and night. Was specially watched. 9.30 a.m.—Is in a state of intense excitement, struggling, gesticulating, grimacing, screeching, yelling, kicking, screaming, nudifying, swearing, etc. Ordered acid. hydrocyanic dil.  $\text{miv.}$  every hour. Became quiet after the first dose in a few minutes. The calmative effect was uninterruptedly maintained during the afternoon. Seen at 10 p.m.—She was sitting quietly on her bed talking rationally. She stated that the medicine soothed her. Explained the occurrence of delirium by a "rush of blood to her head." Has been conversing quietly and rationally with patients and attendants during the whole afternoon.

13th.—Slept during most of the night; when awake talked somewhat whimsically, but not obscenely or loudly. The contrast with the night before is alleged, by an intelligent patient who slept next her, to have been as "marked as between night and day"—"she has been quite a different person." In the morning seemed inclined to be restless and talkative, but after having got one or two doses of prussic acid she became quiet and capable of self-control; was up all day; sat quietly, and conversed with a considerable degree of rationality.

14th.—Slept well; up all day; did a little work; is rapidly regaining the rational use of her faculties.

30th.—Since last report there has been no re-accession of excitement. During the day she sits quietly, talks to the patients or attendants, and employs herself in sewing. Sleeps well at night; is still incoherent, and occasionally winks and laughs, but there has not been the slightest approach to the same degree of aberration and intensity of manifestation which she exhibited formerly.

July 16.—Has been rational, quiet, and industrious since last report; complains of pain in both ears; there is occasional otorrhœa, and sometimes discharge of small quantities of blood, with relief of pain and head symptoms.

November.—Has continued uniformly to improve; may now be considered perfectly restored to reason; will be discharged soon.

## REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

### METROPOLITAN FREE HOSPITAL.

#### OVARIOTOMY IN A WOMAN AGED SIXTY-FIVE —RECOVERY.

(Under the care of Mr. HUTCHINSON.)

[From Notes by Dr. WARNER, House-Surgeon.]

THE patient in the following case is probably the oldest on whom the operation of ovariectomy has yet been performed, we may also add that she makes the fourth recovery after ovariectomy, in succession, at this Hospital. Mr. Hutchinson pointed out to those present at the time of the operation that although the woman's age, counting her years, was 65, yet in constitution she was at least ten years younger. There seemed every probability that, if relieved of her disease, she might enjoy active life for many years to come. Her own strong wish for the operation must also, he remarked, be allowed its weight. She was a monthly nurse, and until the tumour had formed, had been in constant employment. For the last six months the size and weight of the tumour had wholly incapacitated her for any engagements. She was losing flesh and strength, and if not relieved of her disease, there was nothing before her but an illness, more or less slowly tending towards death, and involving throughout its course deprivation of almost all her accustomed sources of enjoyment. He had therefore felt that the mere fact of the patient's age was not one which ought to induce him to decline the operation. He directed attention to an œdematous state of the integuments of the abdomen, and in some degree of the lower extremities, stating that the urine had been examined and found to be free from albumen. The œdema had much diminished during the fortnight that the woman had been in the Hospital. He expressed his opinion that the tumour was polycystic, and had unusually thick walls. He did not expect to encounter any firm adhesions, as there was no history of peritonitic tender-

ness until quite recently. The following are the facts of the case:—

S. B., aged 65, looking much younger than she really was. She had been sent to Mr. Hutchinson in order to the performance of ovariectomy, by Dr. Sutton, under whose observation she had been at times for three years. Dr. Sutton first discovered the tumour three years before. It was then very small, and at first it increased slowly, and caused no inconvenience; latterly, it had grown much more rapidly; the woman's health had also much failed. She was a widow, and had borne five children. The abdomen measured forty-five inches in circumference, and was everywhere dull excepting in the right loin. The integuments, especially of the hypogastrium, were œdematous, and the prominence of the tumour was greatest in the hypogastric region. Fluctuation could be elicited, but it was indistinct, and as if transmitted through very thick structures. The uterus was ascertained by vaginal examination to be high up, and quite normal.

On December 9, ovariectomy was performed. An incision, just large enough to admit the hand, was made through the integuments down to the cyst. The hand being introduced, some slender adhesions over the whole front of the tumour were broken down very easily. The chief cyst was then punctured by a large trocar. When the cyst was nearly empty, it was drawn out at the wound, its withdrawal being very greatly facilitated by turning the woman over on her right side. It was necessary during the withdrawal to puncture two or three of the smaller cysts. The pedicle was long and thick. It was secured in a clamp, and the tumour was then cut away about three inches above it. The intestines had not been seen, Mr. Chance, who was assisting, having carefully kept the edges of the wound closed during the concluding steps of the operation. The wound was closed by hare-lip pins, a flannel bandage applied, two grains of opium introduced as a suppository, and the patient returned to bed. The operation had occupied but a very short time, and the woman had borne it remarkably well.

With the exception of a few teaspoonfuls of brandy with ice during the afternoon and evening, nothing was done or required in the way of treatment. During the following night she slept well, and on the next morning her countenance was cheerful, tongue clean, pulse 80, soft and full. A little tea and dry toast was now allowed.

On the 12th the clamp was removed, and on the 13th the pins were taken out. The wound had now entirely healed, but the stump of the pedicle was of considerable size, and occupied its lower end. Excepting a little trouble from vesical irritation, at the end of ten days, and for which quinine and opium were prescribed, the woman had not the slightest ailment during her convalescence. She left the Hospital in excellent health on January 8, thirty days after the operation.

NOTE ON THE IMPORTANCE OF A SIDE POSITION IN PERFORMING OVARIOTOMY.—In commenting on the above case, Mr. Hutchinson adverted to the great assistance derived in ovariectomy from turning the patient on to one side. It was convenient to perform the first steps of the operation with the woman on her back, but as soon as the tumour was partially emptied, the side posture had great advantages. The patient should be turned to the side opposite to that from which the tumour grew, as the intestines would thus be less likely to protrude. The advantages obtained are two—first, in the greatly increased facility of dragging out the cyst, and, secondly, the much diminished risk of any cyst-fluid finding its way into the peritoneal sac. With the patient on her back, and the cyst nearly empty, there is often still considerable difficulty in getting the tumour out, owing to the circumstance that the remaining fluid by its gravitation drags the cyst back again at one part as fast as the operator extracts it at another. All this is remedied by the side position, and the operation may be completed much more quickly and with a smaller incision. The importance of preventing cyst-fluid or blood from gaining access to the peritoneal sac is obvious, and can scarcely be overrated. It is clear that there would be much less likelihood of any doing so with the patient on her side. Mr. Hutchinson added that he had several times tried the side position, and found it more than realise the advantages expected. It had also been tried, at his suggestion, in a case in which he was not the operator, and with a result which was all that could be wished for. In cases of polycystic tumours, in which it was needful to cut into many cysts in succession, the side position was especially desirable, and in

some such it might even save time to turn the patient well over, and then cut freely into the tumour, without any attempt at emptying it by means of the trocar. It was of course important to arrange for a good light from below in adopting this position.

### GUY'S HOSPITAL.

#### ACUTE RHEUMATISM—ENDOCARDITIS— PERICARDITIS AND PLEURITIS—CLINICAL REMARKS.

(Under the care of Dr. HABERSHON.)

[Reported by Mr. EDWIN MOORE.]

THE following remarks on the case were made by Dr. Habershon when the patient left the Hospital:—

In this case of acute rheumatism, the symptoms were well marked; and although no cardiac bruit existed at the time of admission, it soon became apparent that both the pericardium and endocardium were acutely and severely involved. The pericardial friction-sound was very distinct, but in a few days dulness in the cardiac region increased, and the friction-sound ceased in consequence of effusion into the serous sac. The pleura also, on the left side, became affected; and pain in the chest, which had previously been absent, now distressed the patient, showing the truth of a remark often made by Dr. Addison, that pain is not a sign of pericarditis; previously, the cardiac complication was accompanied with a sense of distress, but with the pleural affection the dyspnoea was more manifest. The pain in the joints soon subsided, but the effusion into the serous cavities, both of the pleura and pericardium, increased; an endocardial bruit became more distinct, and assumed a harsh, almost musical character. The patient was very ill, and the pulse soft and rapid. Wine and ammonia were given, and afterwards quinine. The distress then quickly subsided, and the effusion into the pleura rapidly lessened, whilst the pulse became more steady; at the same time, the endocardial bruit became less harsh, and has continued to lessen till the present period. The pericardial dulness has also steadily lessened, and the patient is now convalescent.

As to the treatment, potash salines and opiates were given, and mercurial purgatives were administered when necessary. Mercury, however, was not given so as to affect the system, and we regard his present condition as more favourable than if mercury had been so used; for we have seen acute pericarditis come on, and advance during salivation, and have witnessed effusion increase till the mercury was discontinued. Neither have we any proof that effusion upon the valves becomes lessened under its influence, but too frequently the patient is left for many weeks in a blanched, anæmic condition, and the cardiac disease advances more rapidly, and relapses after exposure seem to be more frequent.

W. C., a butcher, living in London (his previous health had been good), was admitted on May 29.

On Sunday, the 26th, he began to feel ill, with pains in the limbs and back, and a general feeling of chilliness, loss of appetite, headache, and languor.

On Monday, the 27th, he noticed that his ankles and knees were beginning to swell. His symptoms increased until his admission, on May 29.

He is a stout, muscular, florid-looking man. His countenance is now anxious, and expressive of great pain. He has slight headache, and his tongue is covered with a white fur; pulse, hard and full, 100; no cough; perspiration profuse; urine scanty and high coloured; ankles and knees swollen and painful; heart-sounds normal. ℞ Pil. cal. c. col., gr. xv., statim. ℞ Potassæ bicarb., gr. xv.; ex. julep. potassæ nitratis, ℥j., 4 hōris. ℞ Pulv. opii, gr. i., o.n.

30th.—Bowels have been freely acted on by the aperient. Shoulders, knees, and ankles swollen and painful; heart-sounds somewhat muffled, but no bruit; pulse 110, full, hard, and jerking.

31st.—A systolic bruit to be heard under the left nipple. It can be traced into the axilla. He complains of a sense of oppression in the cardiac region. Shoulders, elbows, and wrists most affected by the rheumatism; tongue very much furred. To continue the mixture and the opiate at night.

June 1.—Bruit much louder and musical, and he complained of pain in the left side. A blister was applied over the region of the heart.

2nd.—The blister has relieved his chest symptoms, but his tongue is very much furred, and his countenance anxious.

3rd.—To-day a "to-and-fro" murmur and a pleuritic friction-sound are heard under the left breast. He complains of pain over the region of the heart, increased no pressure and prolonged inspiration, and of dyspnoea. His pulse is 110, and smaller; his tongue is much furred; the joints a little less painful.

4th.—The friction-sounds are well marked, but he has less pain and dyspnoea, and his countenance is less anxious; tongue furred. An aperient of calomel and colocynth. To continue the mixture and the opiate.

5th.—Pulse 110; countenance more cheerful; pain in chest less, but friction-sound still distinct, and with it the systolic bruit also heard.

8th.—The friction-sounds are nearly inaudible; the endocardial murmur continues well marked; pulse 110; no pain in the chest. The hands, wrists, and elbows are much swollen, but are less painful.

10th.—No friction-sounds are now audible. There is dulness on percussion over the region of the heart to the extent of three inches and a-half. Joints better; tongue cleaner; pulse 110.

13th.—Joints less swollen and painful; pulse still rapid, but smaller and soft; tongue cleaner. ℞ Julep ammonia, ℥j., ter. die.

15th.—A blister to the region of the heart. Four ounces of wine.

19th.—The joints are much better; the countenance is still pale, but he is more cheerful. His tongue is clean, and his appetite much improved. The dulness over the region of the heart is a little less in extent, but there is evidently some effusion into the left pleural cavity; dulness on percussion, imperfect respiratory murmur and tactile vibration, and well-marked œgophony. To take now the mistura quina.

24th.—Joints nearly well; pulse very irregular in power, jerking, 100 in the minute; endocardial bruit very loud, most distinct about two inches to the left of the nipple; other chest symptoms continue much the same.

July 3.—Pulse still continues quick, but it is much more regular; pericardial dulness more than normal; in other respects the patient is better. Five grains of the ammonia citrate of iron three times a-day.

6th.—Loud pleuritic friction-sound heard over the whole of the lower half of the posterior aspect of the left side of the chest. No pain. Pulse more regular, 100.

10th.—The friction-sound has disappeared, and no fluid can be detected in the pleural cavity. Pericardial dulness less, but still exceeds normal limit. Pulse regular, 100.

He is free from pain and dyspnoea, and for some days has been walking about the ward. The endocardial bruit is still distinct; has now less harsh character.

### HOSPITAL FOR SICK CHILDREN.

#### EXCISION OF THE HIP-JOINT—RECOVERY— SUBSEQUENT DEATH FROM PNEUMONIA— AUTOPSY.

(Under the care of Mr. HOLMES.)

MARGARET K., aged 4½ years, was admitted under Mr. Holmes's care on May 21, 1862, on account of an abscess communicating with the left hip-joint, attributed to an accident two and a-half years before, since which time she had always limped with that leg. The opening, which was near the trochanter, led down to diseased bone, and on moving the joint under chloroform grating could be felt. The child's health was good, and little pain was experienced when she was at rest.

The affection had been the subject of careful Surgical treatment during the last two years, but she continued to grow gradually worse. The viscera having been reported sound, it was decided to operate.

The operation was performed on June 28, under the influence of sulphuric ether. It was tedious from the depth of the parts, but not bloody. The head of the femur was found much eroded, flattened, and quite altered in form. In the neck, towards the base of the trochanter, was a large cavity, containing a fragment of dead bone. The finger passed into this cavity so readily that its edge was taken at first for the lip of the acetabulum. The section was made just above the

trochanter minor; the bone exposed by the section looked healthy. There was a good deal of superficial ulceration of the acetabular cavity. Its surface was freely gouged. The limb was then put on an interrupted splint, but so much pain and swelling followed the operation, that it was necessary to remove it. Suppuration having been established in the wound, the slight fever which followed the operation soon subsided, the splint was re-applied under chloroform, and matters went on quite well till the end of July, by which time the wound had begun to heal. The child was now attacked with measles, which retarded her convalescence. The disease, however, was not in a very severe form.

On September 1, it was noted that the wound had nearly healed.

By the 15th the splint was dispensed with.

In the early part of October the child was able to stand, and towards the end of the month she began to walk a little.

The wound healed in the month of November, and on December 6 she was sent to Brighton for change of air. She could then walk quite nimbly. There was a difference between the limbs of one inch and a-quarter in length. The spine did not appear at all twisted.

When she went to Brighton she seemed perfectly well, but after a short stay there she was sent back, with the report that she had taken cold and fallen off in health. Soon after her return, well marked double pneumonia showed itself, against which she struggled for a considerable time, but gradually became weaker. General œdema set in, and she died on February 10, 1863. The wound was ulcerating for some time before her death.

On post-mortem examination, a good deal of both lungs was found to be consolidated. No tubercles were discovered in the lungs, or any other part of the body. The kidneys were smooth, and rather increased in density. All the other viscera were healthy. The remains of the end of the femur were drawn up into the acetabulum by the tendon of the psoas muscle. The end of the bone was rounded off and enlarged by the deposition of a quantity of substance resembling cartilage. This was united to the surface of the acetabulum, in all parts of its circumference, by a large quantity of cellular adhesions, which, however, allowed of a good deal of motion between the bones. The cavity of the acetabulum was enlarged and its walls thickened by inflammation condensing the bone. The whole was enclosed by a capsule of thick, fibrous tissue, much resembling the original capsular ligament. The wound was separated from the bones (which were perfectly sound) by a thick mass of cicatrix. The preparation on the whole bore a very close resemblance to the one preserved in the museum of the College of Surgeons from the original operation of this kind, performed by Mr. White.

#### CLINICAL REMARKS ON THE ABOVE CASE, AND ON FOUR OTHER CASES OF EXCISION OF THE HIP-JOINT.

The above is given as a successful case of excision, inasmuch as the wound healed in a moderate time, and the patient was restored to a condition in which the limb was perfectly useful, and seemed likely to remain so. Unfortunately this has not been the case as a rule with the few operations of this nature which have been hitherto performed at this Hospital, where, notwithstanding the very large number of cases of diseased hip that are admitted, the excision of the joint has been but rarely practised. The number of cases of which some kind of record has been preserved is only five, and this is believed to be, if not the total, at any rate very nearly the total number of excisions of the hip performed since the establishment of the Hospital. Besides these five cases of complete excision of the joint, an exploratory operation was performed some years ago, on account of deformity, the result of disease, in which the neck of the femur was sawn through, and the limb restored to a natural position. (Holmes' "System of Surgery," iii., 814.) Of the five cases of complete excision, none of the others can be said to have succeeded, although in one case the operation has certainly been the means of saving the child's life. The case alluded to was under the care of Mr. Athol Johnson about three years ago, and the child was at that time rapidly sinking under the effects of the suppuration and irritation. He was seen at the Hospital the other day in good general health; but the wound and sinuses had never closed (although no bone could be found exposed in them) and the limb was still useless. In this case the disease was in an active condition at the time of the operation, and the part

left behind was in a doubtful state. In another case, under Mr. Holmes' care, the section of the femur looked healthy, and the parts concerned in the operation went on tolerably well at first; but soon abscess showed itself in or near the opposite hip-joint; the child sank into a hopeless condition, in which he was discharged from the Hospital after a residence there of eight months, and died a few months afterwards.

The two other cases were operated on by Mr. T. Smith. One of them died about two months after the operation. On *post-mortem* examination quiescent tubercle was found in the apex of each lung. A good deal of the surface of the pelvis exposed at the operation was found to be carious, and there was an abscess between the innominate bone and the pelvic cellular tissue. The condition to which the name of diffuse phlebitis has been applied was discovered in the thigh operated on. In the fifth case the operation appeared to be followed by temporary improvement; but then the boy's health failed, and, after many months' residence in the Hospital, he was sent home with the wound unhealed, and with tubercular deposit commencing in the lungs. After the tolerably full account which we have given of the successful operation, it will not be necessary to reproduce the details of these cases. They appear to bear out the conclusion (which seems to be the one usually adopted by those who have looked on this matter without prejudice) that successful cases of excision of the hip are of rare occurrence, and would be still rarer if only those cases were operated on which are not susceptible of a natural cure. The successful case, and still more forcibly the second partially successful operation, also show the great length of time which this operation requires before a cure is fully obtained. In the latter instance, although three years have passed away, during the whole of which the wound has remained open, and fresh abscesses have formed around it, it cannot be said at present that the operation has failed in its secondary object,—that of giving the patient a useful limb; while it has certainly succeeded in its primary one,—of preserving his life. On the whole, although this series of cases is not a very favourable one for the operation, they do not tend at all to condemn it; since in the first the operation succeeded in every particular; in the second it certainly saved the patient's life; and in the others, although it failed to prevent the bad issue of the disease, it had nothing to do with causing death, while it appeared rather to mitigate suffering.

#### CASES OF FISTULÆ IN VARIOUS PARTS OF THE BODY — CONTRACTION OF ANAL ORIFICE — IMPERFORATE NOSTRIL.

(Cases under the care of Mr. THOMAS SMITH.)

##### FISTULA IN THE PERICARDIUM (?)

M. C. D., aged 2 years and 4 months, living at Woolwich, was admitted on November 7, under the care of Mr. Thomas Smith, for a fistulous opening on the left side of the middle line of the abdomen, between the cartilages of the eighth and ninth ribs. A probe passed into the opening glided between the ribs and passed upwards towards the middle line of the chest for about four inches. When in this position the probe follows the movements of the diaphragm closely, that part of the instrument which is external ascending during inspiration, and descending as the diaphragm goes up in expiration. The end of the probe quivers with each pulsation of the heart.

The *history* of the case was as follows:—Five months ago the child was ill and had a swelling at the seat of the present fistula. This swelling was opened, and a pin was searched for, which the child was thought to have swallowed. No pin was found. The child was very ill and feverish after the operation, and the wound had ever since remained open, nor did it seem inclined to close. There was a scanty but persistent discharge from it.

##### CONGENITAL LACHRYMAL FISTULA.

J. K., aged 6½, was brought to the Hospital in October for an opening over the right lachrymal sac, as large as a pin's head; it had existed since birth. There was no obstruction to the lachrymal passage either in the eyelid or nose. A probe could easily be passed downwards through the fistula into the lower nasal meatus. Caustic applied to the edges and the actual cautery failed to close the opening, and the boy left off attendance after an unsuccessful attempt to cure the fistula by paring the edges and uniting them with metallic suture.

##### UMBILICAL FISTULÆ.

Among other fistulæ, two of an unusual kind have pre-

sented themselves at the umbilicus, from which bile has been, and still continues to be discharged.

The following is an instance of a more common form of umbilical fistula from patency of the urachus:—

*Open Urachus.*—A little boy, aged 2 years, was brought in July with a papillary projection at the umbilicus. In the centre of it was an opening, from which transuded at all times a fluid which was decidedly urinous in smell and appearance. A ligature was firmly applied to the button-like protrusion. After a few days it dried up and then fell off, and the fistula seemed permanently closed.

These papillary moist-looking projections at the umbilicus are not very uncommon; they are often quite unconnected with fistula—they are safely treated by ligature.

#### CONGENITAL CONTRACTION OF ANAL ORIFICE.

A girl, a few months old, came under care for a malformation, which, Mr. Smith said, was not unusual, though almost unrecognised.

On March 7, it was brought, with suspicion of having calculus, though its symptoms were great pain and straining, and difficulty in defecation. On examination, the anal orifice was found to be so minute as to account for the symptoms complained of. The orifice was about the calibre of a No. 6 catheter.

Mr. Smith said that on the next visit he should treat this child as he had done others with the same malformation, and he hoped with the same success. The plan hitherto adopted is to make an incision at the anal margin, in the middle line towards the coccyx, and, if necessary, on either side as well, and to tell the mother to insert from time to time a piece of oiled sponge pretty tightly screwed up so as to expand.

#### IMPERFORATE NOSTRIL.

A little girl, about 5 years old. The right nostril was closed, and had been so from birth. The corresponding ala of the nose was flat and unsightly, the nose being unsymmetrical in appearance. The child suffered inconvenience from the insufficient nasal aperture, snoring at night and snuffling by day. A narrow bistoury was passed into the nose through the united margins of the nostril, and these were then separated from one another to the required extent by main force; a piece of gum catheter was tied in. This was changed and replaced from time to time, and in three weeks' time was finally removed, the nostril being patent, and the corresponding ala nasi having assumed its natural position.

SATURDAY, MARCH 28.

#### INSANITY AND CRIME.

THE present assizes have been already unusually fruitful in cases which will cause great "exercisings of the mind" in, and much shedding of ink by two classes of reasoners: those who demand that capital punishment shall be abolished, as being a stain upon the enlightenment and civilisation of the age; and those who would virtually abolish it by declaring every great criminal insane.

To the first class of amiable enthusiasts—amiable that is to the criminal; their vials of wrath are ready enough for their opponents—we have nothing to say now.

We confess, indeed, that we are by no means blind subscribers to the doctrine that "the worst use you can put a man to is to hang him." If the choice is to lie between that and the present Joshua Jebb system of secondary punishments, we are not at all sure that in some cases hanging is not the best thing for a man *quâ* individual; and we are quite sure that it is the best use you can make of him *quâ* member of society; as the fear of the lash has proved eminently effectual in deterring from some kinds of crime, so, we doubt not, the dread of the gallows may be made a powerful help to weak brutal men in restraining their impulses and passions—a successful schoolmaster for the wholesome education of the will.

But into this question we do not mean to enter. Hanging is the punishment awarded by the English law for the crime of wilful murder; so the only practical question is, in any given case, has a prisoner, having killed some one, been guilty of wilful murder? And here steps in the second class of enthusiasts, and say, "Every man who commits such a crime as this is mad; the prisoner undoubtedly has committed this crime, therefore the prisoner is mad; but no madman can be guilty of wilful murder, therefore the prisoner is not guilty of wilful murder." And when it is not possible to prove the existence of what is ordinarily understood by the term mad, they set up the plea of "uncontrollable impulse," or "homicidal mania," a plea which has failed to convince the jury in the cases of Fooks, Preedy, and Burton; and this result has been hailed with exultation by a portion of the press as a triumph of common sense over the fancies and refinings of the Medical Profession. "A few more such assizes as the present (says a writer in a powerful and well-known weekly journal), and we shall have heard the last of the doctrine of homicidal mania."

Now, our readers are aware that we do not entirely reject the doctrine of "homicidal mania." We are not prepared to deny that there have been a few cases in which insanity has declared itself suddenly, and solely through an irresistible impulse to commit murder; and if such cases have been, such cases may be again; but we entirely repudiate Mr. Justice Wightman's assertion, that "the Medical view is, that it is not enough that the criminal knew the act to be wrong; it must appear that he had the full control over the functions of the will." Some few Medical men—one or two especially among those who are rather maliciously called 'Mad Doctors'—may hold such a doctrine, but we deny that it is held by the Medical Profession generally. The *Saturday Review* is contemptuously wroth with Dr. Tuke for his evidence in the case of Fooks, but, it appears to us, very unjustly so. Dr. Tuke held that Fooks was a madman, in the ordinary sense of the term, and, that being a madman, he had an insane impulse to murder. He did not call it a case of "homicidal mania," or of "moral insanity;" he expressly stated that he "did not believe in kleptomania, pure and simple." We must therefore suppose that he does not believe in "homicidal mania," pure and simple; and no one will deny that a madman may be the subject of "homicidal and suicidal tendencies." But we are not disposed to criticise very harshly the evidence of Medical men in these cases; they are never brought into court as purely scientific witnesses, but as *advocates*, on the one side or the other; if they attempt to enunciate large and scientific views, they are liable to be snubbed as being unintelligible and vague; if they attempt to apply principles to particular cases, they are equally liable to be snubbed for "usurping the functions of the jury." We admit that this is a most undesirable state of things; but who can deny that it exists? Moreover, both Medical witnesses and jurors are apt to allow themselves to be influenced by the thought of the punishment which awaits the prisoner if found guilty,—a consideration with which they have nothing whatever to do; their sole business being to determine whether the charge be true, or the defence.

The legal test of insanity, as settled by the judges in conference, is the consciousness of right and wrong. If you would prove a man insane, you must prove that he did not know that his acts were criminal. Undoubtedly this test is far from being a perfect one. Insane men have committed crimes knowing them to be crimes, but then it has been possible to adduce proofs of insanity entirely separate from the acts so committed; and so every case must be judged separately, by its history and circumstances. It is not possible to devise definitions and tests which can be rigorously applied to every case. We hold that, in the vast majority of cases, if a man *be* mad, it will be possible to bring forward proof of his insanity other than the commission of the deed which has brought him to the bar of justice; and we fully concur in the opinion that every attempt to erect crime alone into proof of insanity should be regarded with great suspicion and distrust. Even in the most striking cases of sudden, irresistible, evanescent impulse to murder,—the strongest cases of “homicidal mania,” cases, namely, where women, in certain conditions, murder those dearest to them,—we believe that, in the large majority of such cases, proofs of insanity, prior to the commission of crime, can be found if carefully sought for. We confess to having very little sympathy with those who talk of “latent insanity;” nor do we profess to comprehend what is meant by “diseased will,” as distinct from “insanity,” or as a “partial insanity.” The will, or volition, is not a separate faculty; it is the mind in action, under the excitement of our appetites, passions, and affections. According to Reid, it is “the determination of the mind to do, or not to do, something which we conceive to be in our power.” Morell says: “An act of the will embodies the effort of the whole man, implying, at the same time, intelligence, feeling, and force; physiologically speaking, this state of mind will stand in correlation with the total affection of the nervous system. We regard it as an expression of the totality of our organic power, the whole governing the parts, and directing the fulfilment of one purpose.” But there may be a perverted application of the will, as under the incitement of the delusions and impulses of insanity, or as in an hysterical girl who wills to lie in bed or on the sofa, under the delusion that she cannot use her limbs. Supply a motive, an incitement, religious or other, more powerful than the delusion, and she wills to get up and walk. In the same way a man may choose to will that which is wrong rather than that which is right. “Our bodies are our gardens, to the which our wills are gardeners, so that if we will plant nettles or sow lettuce, set hyssop and weed up thyme, supply it with one gender of weeds, or distract it with many; either to have it sterile with idleness, or manured with industry; why the power and corrigible authority of this lies in our wills.” And a man may cultivate the weeds till they choke out all the flowers; he may voluntarily cherish and indulge thoughts of lust, revenge, and avarice, till his will feels only vicious incitement; and virtuous incitements and motives pale, fade, and die out. He “willfully makes himself a wretched thrall,” and is a criminal in thought long before he is a criminal in act. But is such a one a whit less responsible for his acts than he who “puts an enemy into his mouth to steal away his brains?” Responsible in a degree varying with the extent to which his mind has been injured by his vicious indulgences, but always in a greater degree than the man who is insane “by the visitation of God;” and we would punish him, not by shutting him up in a lunatic asylum, but by subjecting him to hard labour, and such discipline of mind and body as might in time restore health to both. The recognition of such a distinction as this between the criminally insane and the insane by the visitation of God, would, we think, remove the difficulties now felt in judging many cases of crime. At present life-long imprisonment in a madhouse is the only alternative to the gallows; and dreadful as such an alternative is—cruel as the tender

mercies of the wicked—it is life, and to secure it every effort is made to gain the verdict “Not guilty, by reason of insanity.” Theories of disease are stretched and strained, and the refinements of the mental philosopher are still further refined, till there is danger lest man’s prerogative of free-will should be subtilised away, and lest,—

“divine Philosophy  
Should push beyond her marks, and be  
Procuress to the Lords of Hell.”

THE PROPOSED CHANGE AT OXFORD.

ON Tuesday, April the 21st inst., at two o’clock, a statute, having very important bearing upon the system of education at Oxford, will be put to the vote in Convocation. Many Oxonian members of our Profession living away from their University, but none the less entitled to vote, are possibly unaware of the exact nature of the question on which they are on that day invited to exercise their prerogative. In their behalf, as well as for our other readers, we will explain briefly what the proposed change is, and how it is likely to work, more particularly in the case of intending Medical Students. We would first, however, observe that it has already passed through Congregation by a large majority, and that it is strongly advocated by the larger and most distinguished section of the resident Professors and Tutors, the men of all others most competent to pronounce upon its merits.

Under the present system every candidate for the B.A. degree (or the corresponding status of S.M. Studiosus in Medicinâ), has to pass the following examinations, viz.: 1. Responsions; 2. The First Public Examination, commonly called Moderations; 3. The Second Public Examination.

This last has to be passed in two schools (a) that of Literæ Humaniores, (b) one other to be chosen by the candidate himself from the three Schools of Mathematics, Natural Science, Law and Modern History. These three, or practically four, examinations are at present imperative upon all students—upon classmen who acquit themselves with high credit, as well as upon passmen who “shave through” with little or none at all.

Now the gist of the proposed alteration is this: that (under certain reasonable conditions,\* *classmen* should be *allowed the option* of passing their second public examination in a *single school* instead of being *obliged* to pass it in *two schools*. Passmen, be it observed, are in no way affected by the proposed change. The same amount of work will continue to be required of them as is required at present. It is the classmen alone (the “working classes” of the University, as they have been not inaptly termed) for whose benefit the measure has been framed; and when we consider that it amounts to nothing more than a *permissive exemption in favour of industry and ability*, we cannot foresee anything but good as likely to result from its adoption.

Its first and most obvious effect will be to induce many men to take a class who would otherwise take merely a pass. This alone would be a sufficient recommendation of it. Every one knows that pass-reading and class-reading differ as widely in their respective mental discipline as they do in

\* What these conditions are will be apparent from the following clauses, which we quote from the Statute:—“3. Liceat tamen cuiquam pro primo gradu supplicare si modo in Schola Literarum Humaniorum in classem primam vel secundam vel saltem tertiam, aut in Scholis Scientiarum Mathematicarum et Physicarum sive Scientiæ Naturalis sive Jurisprudentiæ et Historiæ Modernæ in classem primam vel secundam relatus fuerit. Proviso semper ut in hisce tribus Scholis nulli Candidato examinatio sua cedat pro forma, nisi prius Moderatoribus in tribus saltem libris, et Examinatoribus in Literis Humanioribus quoad rudimenta religionis et fidei, aut, si sit extra Ecclesiam Anglicanam et in rudimentis religionis examinari nolit, quoad libros hac in parte Examinationis substituendos satisfecerit. 4. Si quis autem quoad rudimenta religionis et fidei aut, si sit extra Ecclesiam Anglicanam et in rudimentis religionis examinari nolit, quoad libros hac in parte Examinationis substituendos jam examinatus se ambire classem primam vel secundam in Schola Mathematica et Physica aut in Schola Scientiæ Naturalis aut in Schola Jurisprudentiæ et Historiæ Modernæ professus fuerit, nec in classem primam vel secundam relatus fuerit, satisfecerit tamen Examinatoribus, liceat ei examen in Schola Literarum Humaniorum postea subire, et, si in ea Schola Examinatoribus satisfecerit, pro gradu primo supplicare.”

moral effect. The former is too often mere schoolboy cram; the latter is nearly always a course of more or less severe, solid mental training. Further, while in the one case the incentive to study is the degrading fear of a "pluck," in the other it is the ennobling ambition to stand high in the class-list.

But the proposed scheme will work well in another way. It will enable students at a period of their career earlier than is now possible, but still not too early for the purposes of a good classical education, to throw their whole energies into those studies for which they may happen to have a natural bent, or which will be practically useful to them in after life. It is in this latter respect that the scheme would prove such a boon to the intending *Medical* student. After passing Responsions and Moderations, *i.e.*, about the 7th or 8th term from his Matriculation, he would be permitted to lay aside classical studies, and to commence reading for his final school, which in his case would of course be that of Natural Science. He would then have a clear eighteen months or more to read for this Natural Science class, and this without the vexatious interruption of a third classical examination. In the meantime he would be mastering Human and Comparative Anatomy and Physiology, Chemistry, Botany, etc., *i.e.*, those very subjects which form the groundwork of his future Professional knowledge, and for whose study Oxford affords every conceivable facility. So that when the time comes for him to attend the Hospitals of London or other great cities, he will have all these subjects at his fingers' ends, and be able to devote his undivided attention to Pathology and the clinical study of disease.

Under the existing system, a man cannot commence the serious study of Natural Science, or of any non-classical subject, till after passing his third classical examination, *i.e.*, about the 12th or 13th term from Matriculation; and consequently, unless he defer his final school to the latest allowable period (the 18th term), which the Medical student with so much before him can rarely afford to do, he has barely sufficient time, without a pernicious system of cramming, to work for Honours in the same.

The fact of the proposed change finding favour with so large a majority of the resident Professors and Tutors is very strong evidence that the present system of examinations does not work satisfactorily. The present curriculum is too exclusively and too imperatively classical. Sufficient provision is not made for those whose mental idiosyncrasies unfit them for attaining classical Honours at all, but who could still attain even high Honours in other subjects,—say Mathematics, Law and History, or Natural Science. Many a poor fellow at present barely scrapes through the University, cowed by an ignominious succession of "shaves" or "plucks" in his different schools, who would have come off with flying colours, and braced up for the race of after-life, had he been allowed to give the bulk of his time and the freshness of his energies to studies more congenial to his taste. We should grieve to see classics superseded in Oxford, but let them not have undue preponderance. Make a course of classical study compulsory upon all *up to a certain point* (as is suggested in this new measure), but *after that* let the diligent and meritorious student take up whichever subjects may be most to his taste, or most practically useful to him in after life, be the subjects classical or non-classical. The thorough mastering of these, for his future and final "class," will do him far more good, mentally and morally, than a grudgingly-acquired smattering of authors and subjects he cares nothing about.

#### ARMY MEDICAL DEPARTMENT.

WE took occasion, in a recent Number, (a) to advert to the lamentable state of the Army Medical Department. We confess that we were then unable to catch a glimpse of that

silver streak which imaginative persons will tell you is present in every cloud. The statements of the Secretary for War, in answer to General Peel, upon Monday, the 16th, however, do yield some rays of hope. Sir G. C. Lewis announced that a Warrant was to appear, based upon the recommendations of a late Commission upon the pay and duties of Army Medical officers, which *he* trusted would satisfy all parties. Let us trust, on our parts, that there will be no longer any vexatious delay, for the department has been well trained in the lessons inculcated by deferred hopes. During the interval, we think it better to maintain silence upon this head. We desire to receive the revised Warrant in no carping spirit, but as a just concession to the rights of the Army Medical officers of both services. Let us hope that its terms will be more fairly interpreted and more honourably fulfilled than those of its now ill-famed predecessor.

We wish that we could say this promised Warrant was the result of some other cause than pressure from without—the appearance of fifteen candidates to fill forty-five vacancies in the Army Medical Department, for instance. We wish we could feel that it had resulted from the independent and sustained avowals of the Medical head of that department that its duties could no longer be carried on.

We now propose—in a candid and frank spirit, but we hope an impartial one—to say a few words upon the management and organisation of the department within the control of its own head and members.

The duties of conducting such a department as the Army Medical, confessedly must be onerous and difficult. The reticence imposed upon a Government official is such that he will often be blamed for labours not his own, and oftentimes fail to obtain the praise which might be found rightly to belong to him, if all the facts were open for criticism and judgment. The feeling is evidently prevalent among Medical officers that they do not gain that support in the performance of their duties which obtained during the lifetime of the late Mr. Alexander.

It is essential that a Director-General should *identify* his wishes and interests with those general among the members of a department whose affairs he directs; and not only so, but, if he desires to attain popularity and respect, it must be felt that such is the case.

Now—with what amount of justice we do not pretend to decide—the fact is obvious that, however much Dr. Gibson may have fulfilled the first requirement, he has failed to make this generally felt. There is an undercurrent of feeling running through all the correspondence and articles which have been appearing of late in the public journals, whether military, Medical, or political, which is as unmistakable as it is lamentable.

By some means there has been a return to that working of the department of bygone days, which savoured so much of over-inspection, circulars, returns, and clerkwork, that it does not form a pleasant subject of contemplation.

Duties have been imposed upon Medical officers which they generally disliked, and which—to say the least of them—are not such as tended to elevate the tone of the Profession in the service, or to improve the capacities of those whose duties are, above all, the practice of their Profession.

We can only regard the present stringent regulations connected with the giving of any extra diet, however trivial, as framed to restrain the hand of the prescribing officer.

With regard to the mode in which soldiers are directed to be marked with the letters D. and B.C., we conceive that it might be strongly represented that the infliction of any part of a sentence of court-martial should be either on parade or in prison, and *not at the Regimental Hospital*; and that it is as false a position for a Medical officer to supply the instrument, and superintend and instruct his Hospital sergeant in branding, as it would be for him to supply the cat, and superintend and instruct a drummer in plying it at his Hospital.

The duty of a Medical officer is very plain indeed in all these cases, and whatever tends to obscure it is injurious to the discipline of the soldier, and productive of a feeling in the Medical officer of his being put in a false position. He has to see that in the infliction of any punishment no unnecessary injury or risk to life or limb be caused.

Again, we can hardly conceive that the Horse Guards would have directed a Medical officer to pay for the kit of any recruit he might have passed with defective vision, if the occasional difficulties attending this had been fairly but firmly pointed out. If in any given case there had been obvious negligence upon the part of an individual Surgeon, it might surely be met by arming the Director-General with some discretionary power in the matter. As the rejection of a recruit must be by Medical Board, the Medical officer would hardly fail to perceive that justice had been rendered him.

Here we touch upon another matter, which has been the subject of very frequent remark. Some member of the department has taken some course which is open to grave reprehension. Now, however, although the case is an isolated one, it forms the subject of an Order, or Circular Letter, directed to the department generally! This can only prove vexatious and annoying to the zealous and honest workers in the department, who feel irritated at being "schooled" for an occurrence they would not dream of doing or taking part in.

If the case be worthy of notice it ought not to go unpunished; if it be one which is open to general misconception, then a Circular indeed is required.

These afford a sample of that for which we consider the Medical Department has only itself, in some way or other, to blame. With whom the fault rests we do not say; but this we may assert, that if it be desired to fill vacancies in the Department with the abler and better class of Professional students, these are not by any means subjects of secondary importance.

The practice of Medicine is becoming every day more and more a matter of science, and not one of administration of drugs: it is, we really believe, daily taking a higher and different position among Professions, and it will do least of all for Medical men occupying high positions to retard these beneficial changes or clog the steps of its progress.

We are sorry to see it stated by the Secretary for War—but we trust that this is capable of bearing a very different aspect when properly explained—that the recent reductions in the Medical Department were in accordance with the recommendations of the Director-General!

Not to mention any other result,—surely, considering the small amount of leave now enjoyed by the Army Medical Officer, any further reduction will prevent his having any at all.

---

#### MR. PROPERT AND MR. ADAMS.

THE whole Profession have expected some explanation from Mr. Propert of his conduct towards Mr. Adams, and have expected it in vain. As we said in a recent article, the very least that Mr. Propert could do, judging from the facts then before us, was to send a handsome letter of apology to Mr. Adams, and a cheque for his costs. Mr. Propert continues obstinately silent; he neither justifies his position nor withdraws from it; we are therefore compelled, in the interests of the Profession, to make a brief note of the case as it stands.

Mr. Propert had been on friendly terms with Mr. Adams, when all at once, without the slightest notice to that gentleman, he assumes him to be guilty of conduct which, in the eyes of any man of the world, would be seen to be absurd or impossible at first sight. When explanations are formally and repeatedly offered him, he refuses even to examine them. As a kind of *official* personage—"the protector of Medical widows by common consent"—he comes to a conclusion, without inquiry, in a manner which smacks of personal bias,

certainly not of official coolness. Although warned by persons of benevolence and experience, such as Mr. Toynbee and Mr. Kesteven, that Mrs. Russell and her daughter were not fit objects of charity, he backs their application to the Benevolent Fund. He distinctly, by his own confession, places the case of the Russells in the hands of his solicitor, sneers at Adams's protestations of innocence, and refers him to a jury. When one attempt at an action was made and given up, he visited the Russells at a sponging-house, and tendered his cheque for their costs. He is to this day, as we are informed, in friendly communication with the Russells, and supplies them with medicine from his own surgery in New Cavendish-street. He affirms, and does it with an oath, contrary to the practice of English gentlemen who rely on their word, that he had nothing to do with the late action. But setting this point aside, the inexplicable fact remains, that this protector of widows and orphans pursued a course which might have ruined a man less successful than Adams, and have crazed or killed one with less nerve. He has brought the honour of his whole Profession into jeopardy, by countenancing this most odious charge. He has diverted many a charitable act which men have done for stray and solitary women, but which they will now abstain from for fear. After this, we tell Mr. Propert that it is not a few easy-flowing tears, or appeals on behalf of an honest, hard-working Welshman, that will restore him to the confidence of his Professional brethren.

---

#### THE WEEK.

##### THE ORMSKIRK PROSECUTION.

THE Branch Medical Council for England, at its last meeting, remitted to Mr. C. P. Symonds, of Ormskirk, the sum of £20 (the amount of a penalty which the treasurer of the Council had received), towards defraying the expenses of a prosecution under the 40th Section of the Medical Act. Mr. Symonds undertook that prosecution in August last, by the desire and with the support of the Medical gentlemen of that neighbourhood, against a person named Josiah Archer Bowen, "for falsely pretending to be and using the name and title of a Surgeon, and then and there giving a certificate of death . . . and writing under his name the letters 'Sub. M.R.C.S. Eng.' implying thereby that he was recognised by law as a Surgeon." The magistrates of Ormskirk inflicted on the defendant the full penalty of £20, and costs, which costs were taxed against the defendant at £25. Notice was given of appeal to the Court of Queen's Bench, but the intention to appeal was presently abandoned. It ought to be more generally known that convictions may be obtained under the 40th Section of the Medical Act, and that the Medical Council are ready to remit any fines that may be recovered, in order that they may be applied towards defraying the expenses of successful prosecutions.

---

#### PARLIAMENTARY.

ON the 23rd inst. Sir Robert Peel moved the second reading of the Irish Vaccination Bill. The chief objection to it as a measure appears to us to be, that it enforces more unpaid labour on the Medical Profession. The Registrars of Births and Deaths are to be registrars of vaccination, but they are not to be remunerated for the trouble when they themselves have been the vaccinators. When the Registrar is not the vaccinator, he is to be allowed the magnificent fee of three-pence for making the registry. With this exception, the Bill appears likely to be a useful one. Sir R. Peel stated that,

"From the census returns, he found that no fewer than 50,000 persons had died of smallpox in Ireland since 1841; and in 1860 there was a diminution of 33,000 in the number of vaccination cases as compared with those of the previous year. The cost of the proposed measure would be very trifling. The Registrars of Births and Deaths would also act as registrars of vaccination. The Treasury would bear the

expense of the books, but in cases in which the Registrar himself was not the vaccinator he was to be allowed a fee of threepence for making the registry. Under an existing Act, dispensing Doctors were allowed about a shilling a head for each child they vaccinated. There were about 200,000 children born in Ireland each year, and it was calculated that of these, three-fourths, or 140,000, would receive gratuitous vaccination. The total expense imposed on each of the Poor-law Unions by the Bill which he now proposed would be about £3 16s. 8d.—a mere trifle compared with the benefits which it would confer on the country."

Several members objected to the measure on various grounds. An adjournment of the debate was moved, and ultimately agreed on.

In the House of Lords, on Tuesday night, their lordships went into Committee on the Irish Births and Deaths Registration Bill. The Marquis of Clanricarde had previously presented petitions from the King's and Queen's Colleges of Physicians, and from two Boards of Poor-law Guardians, the former urging objections to the appointment of superintendent registrars to be placed over the Medical men who were to act as registrars, the latter praying that the whole expense of carrying on the act might be defrayed out of the Consolidated Fund.

"Clauses up to 21 inclusive were agreed to, with amendments.

"In clause 22, the Marquis of Clanricarde moved an amendment altering the title to be given to clerks of Unions from 'superintendent registrars' to 'superintendents of registers.'

"The Earl of St. Germans opposed the amendment.

"After a short conversation their lordships divided, when the numbers were:—

"Contents . . . . . 32

"Non-contents . . . . . 5

"Majority against the amendment . . . . . —27

"The clause was then agreed to, as were also the remaining clauses of the Bill."

In the House of Commons, Mr. Hubbard moved his resolution affirming the principle—

"That the incidence of an income-tax touching the products of invested property should fall upon net income, and that the net amounts of industrial earnings should, previous to assessment, be subject to such an abatement as may equitably adjust the burden thrown upon intelligence and skill as compared with property."

Mr. Hubbard's motion was, of course, opposed by the Chancellor of the Exchequer, and finally negatived by 118 to 70. Mr. H. Lewis's motion for a return of the number of persons killed in the city on the night of the illuminations was replied to, on the part of the Corporation, by an amendment, moved by Mr. Norris, that the number of persons killed on the occasion of the funeral and lying-in-state of the Duke of Wellington should be appended, together with a copy of any order issued by the metropolitan police authorities, with a view to prevent a recurrence of such accidents. The motion as amended received the assent of the House.

#### THE REGISTRATION OF BIRTHS AND DEATHS IN IRELAND.

A COMMITTEE has been appointed by the King's and Queen's College of Physicians to examine Sir R. Peel's Registration Bill. They have sent in their report, and, as might be expected, it presents several exceptions to particular provisions, although the committee approve of the general character of the measure. They argue that as the Registrar-General, officers, and clerks are to be paid out of the Consolidated Fund, so also the registrars' salaries should come from the same undeniable source. The bill, it will be remembered, proposes that the Medical registrars should be paid by the guardians of each union. We can quite understand the repugnance of the committee to such a distinction. They argue the question, however, fairly, on political grounds.

"The statistical and sanitary objects of a Registration Bill do not come within the same category as the support of the

poor, the maintenance of public institutions for prisoners, or asylums for the insane, or improvements of roads, etc., which are all objects more or less directly local necessities, or advantages for the district, and therefore, in the same degree, may be considered justly chargeable on the locality. The objects of the Registration Bill now under consideration are imperial. The results are for the benefit of the whole United Kingdom; the statistical and sanitary data furnished by the poorest union in the country may prove of more advantage to the wealthiest district in the United Kingdom than they ever can be to the district which furnishes them."

The committee express a regret that there is no provision in the bill for obtaining returns of endemic and epidemic sickness, and they urge that the central authority, whose business it is to exercise a supervision over vital statistics and mortality tables, should be a highly-educated Physician. They cite the instances of the Army and Navy in which such duty is delegated to a Medical officer:—

"The civil statistics of a country as regards health, sickness, and death, are much more complicated and more difficult to comprehend and supervise than those of the Army and Navy; and if there be a country in Europe that stands in need more than another of high scientific professional attainments in the central authority to superintend its statistics of disease and mortality, it is Ireland, from the frequent visitations it has suffered from epidemic and endemic diseases. A Registrar-General of births and deaths, who does not possess the qualifications referred to, no matter what his other attainments may be, will be ever reading a language in the returns which he does not comprehend, and supervising tables the true value of which he cannot estimate, and must therefore be incapable of directing inquiries to lead to useful results."

Another point to which they take exception is the proposed salary of the Registrar, which is less than in England or Scotland. That the duties of the Registrar are in Ireland to be performed by Medical men and gentlemen, is, we suppose, the reason that the framers of the bill propose to lower the price of the labour.

"The remuneration for the duties of registrar must, under any circumstances, be very small. By the Bill now before us, it is proposed to fix it at one shilling per entry. Under the English Act, section xxix., 6 & 7 Wm. IV., cap. 86, it is, 'for the first twenty entries of births and deaths in every year, two shillings and sixpence each, and one shilling for every subsequent entry.' In Scotland, the registration of marriages is included, being an additional source of fees, and the remuneration is higher:—It is 'for the first twenty entries of births, deaths, and marriages, in each half year, two shillings each, and one shilling each for every subsequent entry.'—17 & 18 Vic., cap. lxxx. The income-tax is the same in England, Ireland, and Scotland. Railways have equalised the expenses of living throughout the United Kingdom, and it is only justice that the State should pay the same sum for the same services whether in England, Ireland, or Scotland." We need scarcely add that the committee, by this temperate and well-reasoned report, have well represented the interests and feelings of the Profession.

#### DR. BROWN-SÉQUARD'S LECTURES.—LECTURE VI.

THE sixth and last lecture of this course was upon epilepsy, and was delivered on the 12th inst. Much light has been thrown upon the nature of this disease by Dr. Brown-Séquard's remarkable discovery that an affection resembling, if not identical with it, may be produced in animals by injuring the spinal column in any part above the third lumbar vertebra, but more especially in the part intervening between the third lumbar and the fifth or sixth dorsal vertebra. Animals so injured begin to have fits, which come on spontaneously—and which may be induced if the animals are irritated in a particular manner—about three weeks after the date of the injury. Various forms of lesion will produce the fits: for instance, a complete transverse section of a lateral half of the spinal column; a transverse section of its two posterior columns, together with the posterior cornua of grey matter and a part of the lateral columns; a transverse

section of either the posterior, the lateral, or the anterior columns, only; a complete transverse section of the whole column; or, finally, a simple puncture, may each severally result in producing the fits. But some of these sections have much more power than the others in producing them, and that of a lateral half of the cord appears to be invariably attended with this result. Two guinea-pigs, which have been operated on in the manner last mentioned, were exhibited: by irritating the side of the face, a fit was immediately induced in one of them; the other one, having, as the lecturer suggested, probably been in a fit recently, did not respond to the like stimulus. The fit of the guinea-pig first introduced was certainly wonderfully like that of ordinary epilepsy. In these animals there is one particular part of the skin, irritation of which is almost invariably followed by a fit,—indeed invariably, if the animal irritated has not had a fit a short time previously. The part in question is limited by the following four lines:—One drawn from the ear to the eye; a second from the eye to the middle of the length of the inferior maxillary bone; a third from the lower end of the line last mentioned to the angle of the lower jaw; and a fourth, forming half a circle, from this angle to the ear, the convexity of the half circle being towards the shoulder. Such is the irritability of this area, that merely blowing upon it will often induce a fit; and at times, when the animal shows a tendency to have a fit, a mere movement of the head will bring it about. This irritability resides in the extremities of the nerves which ramify in the skin itself. Irritation of the trunks of the nerves—as, indeed, is often observable in man—fails to induce a fit. In both these animals there is opacity of the cornea, a phenomenon which sometimes presents itself in man when the spinal cord is injured, and which may rapidly disappear. Such an opacity, presenting itself in a case of spinal injury under the care of Velpeau, speedily disappeared, to the great astonishment of that distinguished Surgeon. It is thought that the power of action of muscles and nerves, and their excitability, are equal or co-ordinate; but this is not the case. Of two muscles, one atrophied and one healthy, the former may respond to a certain stimulus, while the latter will not; a weak person will jump or start on hearing a noise which will produce no effect on a strong one. Animals whose spinal cords have been divided during six months will, by their sudden movements, show themselves peculiarly impressionable by external influences, which by healthy animals are either unfelt or disregarded. This is strikingly exhibited if both the injured and uninjured animals be submitted to the galvanic current. These facts illustrate the nature of epilepsy. Epileptics are usually very weak, often partially paralysed: their reflex excitability is increased, while their voluntary muscular power is lessened. This departure from the proportion normally subsisting between reflex excitability and voluntary muscular power constitutes the condition of, and tendency to epilepsy, and should be carefully distinguished from the immediate or occasionally exciting cause of the fits. The tendency to epilepsy having become established, the fits are often induced by some exciting cause existing in the periphery of the body. This is proved by the fact that the frequent and well known prelude to the fits—the aura epileptica—may often be traced to its origin in some external or excentric influence or abnormal condition of the skin. It is probable that certain nerves which are incapable of transmitting the ordinary sensations of pain are the media of an aura epileptica, or the proximate cause of fits, even when the patient is wholly unconscious of its existence. There are nerves which are not sensitive, but which are capable of producing reflex actions. It is well known that worms in the intestines often bring on fits, although in such cases the irritation which they undoubtedly cause, and which is propagated to the spinal cord, is not consciously felt. A great variety of sensations and excentric influences will induce fits in persons in

whom the epileptic tendency exists; but pain will not necessarily do so. The parts of the cerebro-spinal axis usually affected in epilepsy are the medulla oblongata and the upper portion of the spinal cord; but the seat of the disease in each particular case is that part of the nervous centre directly related to the special area of the periphery from which the aura, felt or unfelt, proceeds. Now that pathologists have entered on that new and inestimably important field of Medicine comprehending the action of nerves on blood-vessels, they are enabled to appreciate the significance of many phenomena of epilepsy, the nature of which was until recently wholly unknown. Of the two well ascertained influences which nerves exert on blood-vessels, viz., contraction—arresting or decreasing the circulation, and dilatation—increasing it, the former is explicable, the latter not yet completely so. Contraction of the blood-vessels of the face causes the paleness often observable in the first stage of an epileptic fit; contraction of those of the brain induces syncope of that organ only, and of course loss of consciousness at the same time. This contraction of the cerebral vessels is analogous to the first contraction in organic muscles. The variety of effects from irritations is surprisingly great: the sensation of light will produce an increase of blood in the tubercula quadrigemina; singing in the ear may in like manner cause contraction of the veins; sudden and general paralysis may occur, as in the case of the son of a Medical man, mentioned by Dr. Brown-Séguard, whose consciousness and breathing power alone continued; there may be loss of memory of words only; or, suddenly, a paleness of the face; a peculiar affection of the eyes; a flow of tears, or of saliva; the bladder alone may contract; or there may be simply an ejection of semen; or the irritation may show itself in some one superficial muscle, as in the case of a boy who had frequent and sudden pain in the belly—only one muscle of the abdominal wall being much enlarged, and for years subject to cramps, which were ultimately followed by complete epileptic fits. Dr. Brown-Séguard does not believe that the epileptic aura ever originates in the healthy womb itself, but he is of opinion that when the irritation is propagated from that organ, it results from an abnormal change in the quality of the blood within its vessels, or of its secretions. In the *petit mal*, or minor fits only of epilepsy, the patient loses consciousness more or less completely; the pulse is not weak, but often strong—sometimes especially so—and is thus emphatically distinguishable from that of syncope; the blood-vessels of the face, animated by a branch from the cervical portion of the sympathetic, may contract and cause sudden paleness; and there is always more or less contraction of the muscles of the neck and face. In a case of *typical* epilepsy, the fit is ushered in by an aura, felt or unfelt, or, in other words, by an excentric irritation propagated to some part of the cerebro-spinal axis, the first results of which are contractions of the blood-vessels of the cerebrum and of the face, and tonic spasms of some muscles of the eye and face; then follow loss of consciousness and paleness of the face; blood accumulates in the base of the encephalon, and in the spinal cord, resulting in *tonic* contractions of the laryngeal, cervical, and respiratory muscles. These contractions produce asphyxia, in the course of which the sudden cry and fall occur; the asphyxia is succeeded by general *clonic* convulsions; then may supervene contractions of the bowels, of the bladder, of the uterus; erection; seminal emission; increase of various secretions; efforts at inspiration; and, finally, muscular relaxation, with cessation of the fit, followed, possibly by coma, but most usually, by fatigue, headache, and sleep. Among the forms of curable epilepsy are those due to syphilis, to slight inflammatory states of the base of the brain, to diseases of the nerves or spinal cord, to worms in the intestines, and to disturbances of the uterine system. In fact, whenever a connexion between the fit and some disease from which the patient is suffering can be traced, there is much reason for hoping to effect a cure. Persons having had a blow on the

head, and subject to fits many years afterwards, may often be cured by blistering the spot where the blow was received. Application of the actual cautery (a), or a blister to any part from which an aura may proceed, will often prove effective. If the aura or irritation proceed from the hand, arm, foot, or leg, a blister, an inch wide, may be applied round the limb. A ligature round the limb will also often stop the fits. Both it and the blister produce their effects by causing a modification of the parts of the brain to which the nerves acted upon are related. Blisters are most effective when the base of the brain is affected. Narcotic injections sometimes effect a perfect cure: half a grain of sulphate of morphia, a sixtieth of a grain of atropia, and a minim of dilute sulphuric acid, in fifteen minims of water, should be injected into the part where the *aura* originates. The morphia and atropia, each of which used separately would be dangerous, when used together counteract each other: the one contracts the pupil, the other dilates it, and the general action of each on the system is correspondingly different. The best remedies for epilepsy induced by syphilis are the iodide and the bromide of potassium, taken together or separately. The dose of the bromide must be fifteen or twenty grains two or three times a-day. When taken in large doses for a considerable time, it causes congestion of the brain and loss of feeling in the urethra, and probably in the seminal vessels. If the pulse of the epileptic patient be weak, he should take ammonia and quinine. Contrary to the advice of Dr. Watson, iron, which he recommends, should be avoided, unless the fits be due to anæmia or chlorosis. Iron causes alterations of circulation in the brain of a kind not conducive to the cure of epilepsy. If it must be given, the ammonio-citrate of iron, along with aconite in suitable doses, is the best form in which to administer it. The same salt of iron, together with strychnine, may also be given sometimes with advantage. Epileptic coma is best treated by Junod's boot, applied with great care during half an hour. Or ligatures may be placed round the four limbs, in order to impede the venous circulation, and thus the return of blood to the brain. In some cases of paralysis, even when there is no hysteria, a cure will follow a series of epileptic fits. In such cases the cure is probably due to absorption of effused fluid, promoted by the increase of circulation occurring during each fit. This very interesting, but necessarily very hurried, lecture was concluded by the exhibition of several illustrative cases; among them was a girl who has suffered from hemiplegia and paraplegia, from both of which she recovered after having had several fits; and a man who had stopped his own fits "hundreds of times" by clasping his legs, by using ligatures and blisters, and by burning himself.

## REPORT ON THE PHYSIOLOGICAL ACTION OF PODOPHYLLIN.

By FRANCIS ED. ANSTIE, M.D., M.R.C.P.,

Assistant-Physician to the Westminster Hospital, and Lecturer on Toxicology to the School.

In commencing an inquiry into the action of podophyllin upon the organism, the following appear to be the chief questions, to the solution of which research ought to be directed:—*a.* The doses respectively in which podophyllin is a safe, and those in which it is a poisonous agent. *b.* The nature of the catharsis set up by different doses respectively. *c.* The symptoms and anatomical appearances resulting from medicinal, and those resulting from poisonous, doses administered to mammalian animals.

Such are the objects of the present inquiry, but I shall not follow the order above indicated. It appears to me that inasmuch as there is far more certainty about the results obtainable from animals which it is in our power to examine anatomically, than in those observed in human beings with

(a) When the instrument is heated to a white heat it gives little pain and leaves no scar.

regard to whom we have no such privilege, the record of experiments upon animals should come first. Accordingly I proceed to this at once.

I must premise that in the first series of the following experiments I have used always a uniform alcoholic solution of the resinous extract of podophyllin, kindly prepared for me by Mr. Morson, and containing four grains in each drachm. I was not without misgivings, at first, that the effects of the alcohol would seriously interfere with the success and value of the experiments, but multiplied trials proved conclusively that this was not the case; and that, provided the error of giving a fatal dose of alcohol were avoided, the symptoms proper to the action of podophyllin were regularly produced.

The mode of introducing the agent into the body which was adopted was that of injection of the above-described solution into the peritoneal cavity. Large experience of the effect of various agents upon the peritoneum gave me the belief (which it will be seen was just) that neither the quantity of alcohol, nor the podophyllin contained in it which would be required for any experimental purpose of mine, would excite peritonitis.

The animals experimented on were dogs, cats, and rats.

*Experiment I.*—5ss. of the alcoholic solution was injected into the peritoneal cavity of a full-grown dog (about eighteen inches in height). The animal was not at all discomposed by the operation, and a few minutes after was eating food.

Up till ten hours afterwards the dog was perfectly lively, and showed no signs of uneasiness. He now commenced retching violently, and brought up only a little mucus. This symptom continued, and was soon accompanied by purging; the stools consisted of glairy mucus; and, after a time, were mixed with blood; the animal whined constantly, and seemed in pain, it also drank water eagerly. Four hours from the commencement of the symptoms, the breathing was shallow and hurried, and the pulse rapid and feeble. During the next four hours the animal could not be watched; at the end of that time it was found lying on its side, totally insensible, with glazy eyes, heart's action slow and very weak; respiration consisted of from four to six convulsive gasps per minute. In this state it lay, with little change, for the next eight hours. At the end of this time a slight general convulsion occurred, and the breathing ceased about two minutes and a-half later. The thorax was quickly opened, and the heart was found still beating; it continued to pulsate for five minutes, and its irritability persisted for some time after this. On post-mortem inspection, there was no fluid of any kind in the peritoneal cavity, and the membrane was quite smooth and polished and transparent. The kidneys were rather congested; the liver was moderately congested; the gall-bladder contained a very little bile.

The alimentary canal was slit open from end to end. The pharynx, œsophagus, and stomach were healthy, except that the stomach contained some bloody fluid, evidently brought into it from the intestine by repeated retching. The mucous membrane of the whole small intestine was intensely inflamed, especially that of the duodenum; in the latter situation were nine ulcers, rather less in size than a threepenny piece, and there was one smaller ulcer near the lower end of the ileum. The mucous membrane of the whole small intestine was covered with tenacious bloody mucus. The inflammation ceased abruptly at the ileo-cæcal valve; the large intestine was healthy; nowhere was any bile observed in the bowels. Mucous membrane of bladder slightly congested.

This dog had never showed any signs of alcoholic intoxication, except a slight drooping of the hind quarters, which went off in five or six hours.

*Experiment II.*—Fifteen minims of the solution (equal to one grain podophyllin) were injected into the peritoneal cavity of a small dog (fully grown). The animal was rather frightened; but evidently suffered no pain, and ran about immediately afterwards as if nothing had happened. No symptoms whatever of uneasiness were observed during the next twenty hours. At the end of that time the dog was taken with vomiting, and soon afterwards purging commenced. The vomiting soon ceased, but the purging continued with violence, and the stools soon came to consist entirely of thick mucus mixed with a very little blood. The purging continued for eight hours, and then ceased, and the animal lay in an extremely exhausted condition; the breathing was very slow and gasping, though not so much so as in Experiment I. Temperature of the body very low.

Two hours later, the animal, though still very much depressed, was evidently recovering from the effects of the drug, as it was able to get on its legs and stagger feebly along. The carotid artery was now opened; this quickly caused a general convulsion, in which the heart ceased beating, before any very large hæmorrhage had occurred.

Post-mortem examination showed that the peritoneum was not in the least inflamed. The mucous membrane of the whole small intestine was pretty deeply congested, especially that of the duodenum, and there was much thick bloody mucus on its surface. There were no morbid appearances in the large intestine. Liver slightly congested; gall bladder empty. Kidneys slightly congested.

*Experiment III.*—Fifteen minims of the solution (one grain of podophyllin) were injected into the peritoneal cavity of a dog, about the same size of the subject of the last experiment, but not fully grown. No symptoms were developed for the next fifteen hours; at the end of this time the animal was seized with vomiting and purging, and moaned a good deal, as if in pain.

The purging continued during the next five hours, and then ceased; but the animal had now become entirely insensible; the respirations were ten per minute, sighing; circulation 75, irregular and intermittent. One hour and a quarter later respiration ceased; the heart continued to beat a few minutes longer.

Post-mortem examination showed an entire absence of peritonitis. The appearances in the alimentary canal were similar to those observed in Experiment II., but more pronounced; in the lower part of the duodenum were three small ulcers of the mucous membrane. No bile-coloured matters in the intestines, so far as could be observed by the eye; liver of a natural appearance, perhaps somewhat congested; gall-bladder empty.

*Experiment IV.* was a test experiment with alcohol, a mere repetition of what I had often done before, to satisfy my mind that the influence of alcohol had not produced the effects described in the experiments already narrated. ʒss. of rectified spirit (P. L.) was injected into the peritoneal cavity of a dog of about the same size as the subject of Experiment I. The only effect of any kind which was produced was, that two hours after the operation the dog began to mope a little, and vomited two or three times; there was, however, no severe retching or straining, and no purging; in an hour or two the animal was perfectly well again, although a little weak in the hind quarters, and rather staggering in its gait. No further ill effects followed.

*Experiment V.*—A young but strong cat had ʒss. of the alcoholic solution (containing two grains of podophyllin) injected into its peritoneal cavity at 4.50 p.m.

5.3 p.m.—The cat vomited.

5.8 p.m.—The cat vomited and passed solid fæces.

5.15 p.m.—Being roused up, and made to walk, the cat exhibited some of the phenomena of alcoholic intoxication—*e.g.*, it staggered and dragged its hind-quarters somewhat.

6 p.m.—The cat has just vomited again, but otherwise it seems quite lively. There is still some remaining weakness of the hind-quarters.

11.30 a.m. (about nineteen hours from the injection of the podophyllin).—The characteristic effects of the alcohol have now completely disappeared, and no symptoms of irritant poisoning have appeared. The animal is quite lively, and eats food eagerly.

12 o'clock.—Forty minims more of the alcoholic solution (equivalent to three grains of podophyllin) were injected into the peritoneal cavity.

12.30 p.m.—The ordinary signs of alcoholic intoxication, in its early stages, are exhibited. The animal vomits now for the first time since the second injection.

4.15 p.m.—The animal is lying down, as it has been doing for some time past. On rousing it, paralysis of the hind-quarters is seen to exist to a considerable extent, and the animal staggers.

4.22 p.m.—The cat falls on its side. Examined, it is found to be totally insensible. Circulation 90, weak and irregular. Respiration 45. During the last hour or two the animal has been almost incessantly purged, and recently the dejections have contained blood.

4.25 p.m.—The cat is violently convulsed in all its limbs. Respiration rapid and panting. Profound insensibility. Circulation 120, forcible.

4.28 p.m.—The convulsions are incessant; they affect

chiefly the fore-legs, the eyelids, and the anterior muscles of the neck.

5.10 p.m.—Convulsions incessant. Respiration 75. Circulation 124, very weak. Profound insensibility.

This state of things continued, with little alteration, except the gradual failure of the strength of circulation and respiration, up to 8 p.m., when the animal expired, the final struggle leaving all the limbs extended.

On post-mortem inspection, the body (a few hours after death) was perfectly rigid, the limbs extended. On opening the belly, a few drops of fluid were found effused in the peritoneal cavity; this was clear, straw-coloured serum. On the surface of the intestines, at one point, was found scattered a small quantity of a dark-coloured resinous powder, which was evidently the residual podophyllin, which had not been absorbed. There was no effusion of lymph, nor adhesion of the coils of intestine, but there were spots of inflammation around the grains of podophyllin.

The alimentary canal was slit open from end to end; pharynx and œsophagus healthy; stomach very much congested in patches, possibly owing to the severe vomiting which had taken place.

In the duodenum, and throughout the small intestine, there existed traces of the most violent irritation of the mucous membrane. The whole surface of the membrane was thickly sown with bloody points, and a layer of tenacious bloody mucus covered the membrane; there was, however, no actual ulceration. The cæcum and the first part of the colon were similarly affected, but in a less degree.

The liver was somewhat congested, but otherwise presented a perfectly normal appearance; the gall-bladder contained a small quantity of healthy bile.

The bowels were encumbered with dead specimens of *tania crassicollis*; kidneys slightly congested; bladder healthy.

*Experiment VI.*—Forty minims of an alcoholic solution (equivalent to three grains of podophyllin) were injected into the peritoneal cavity of a remarkably strong young cat at 1.8 p.m.

1.45 p.m.—Decided symptoms of alcoholic intoxication, but not very profound.

2.30 p.m.—The signs of alcoholic intoxication have persisted, and now, for the first time, the cat vomits.

3 p.m.—The symptoms of alcoholism are subsiding, but the cat seems very uneasy. Circulation, 100; respiration, 30.

3.20 p.m.—The animal utters cries, and passes solid fæces.

3.32 p.m.—The animal cries loudly, and passes a liquid, dark-coloured stool.

4 p.m.—Another liquid stool, attended with much straining, the animal uttering loud cries.

4.30 p.m.—The animal cries almost constantly, and is evidently in much pain; purging very frequent, with a great deal of straining, and occasionally the passage of a little blood.

5.50 p.m.—The purging has continued at intervals till lately; at present this has ceased, and the animal lies exhausted, and apparently insensible, on its side; breathing slow and gasping.

At 8.30 p.m. the animal died, respiration and the heart's action gradually ceasing.

Post-mortem examination showed a complete absence of peritonitis. The cavity of the peritoneum did not contain, apparently, five drops of liquid, nor was there any effusion of lymph, or any external reddening of the intestines. Pharynx and œsophagus healthy. Mucous membrane of stomach a good deal congested, in patches. Duodenum, jejunum, and ileum, from end to end, exhibiting most intense and bright-coloured injection of the mucous membrane: this was particularly well-marked at the lower part of the duodenum. No positive ulceration; mucous membrane a good deal softened, however, in places, and covered with bloody mucus. Only a very slight degree of inflammation in the cæcum and colon; none in the rectum. Liver quite natural in appearance. Gall-bladder contained a small quantity of bile. Kidneys healthy.

*Experiment VII.*—One grain of podophyllin (in fifteen minims of alcohol) was injected into the peritoneum of a young and healthy cat at 12.30 p.m. The animal evidently suffered no pain from the operation, and a few moments after was purring.

6.30 p.m.—Up to the present time no symptoms whatever have presented themselves.

9.30 p.m.—The cat has not shown the least sign of uneasiness.

7 a.m.—The animal is quite well and lively this morning, it has evidently passed its urine during the night, but no fæces, neither has it vomited.

9.45 a.m.—The cat has just passed one solid, pretty copious dejection; of perfectly natural appearance.

10.30 a.m.—The cat has passed one more dejection, rather softer in consistence than the first, but there is nothing like purging, and the animal is lively and apparently quite free from pain. At this moment I administered ʒss. of Scheele's hydrocyanic acid, which was immediately fatal. Even while the heart was still beating I opened the abdomen freely, and was able to observe the appearance of the liver: this was entirely natural, there was nothing that could be called "congestion." The gall-bladder was nearly empty.

The intestines were observed to be writhing actively in a vermicular movement. On opening the alimentary canal, the stomach proved to be quite healthy; the duodenum exhibited a slight rosy tinge of its mucous membrane, which was found, on close inspection, to depend upon the existence of numerous fine points of injection. Slighter appearances of the same kind were noted at several points of the small intestines. A good deal of whitish mucus was present in the bowels. The cavity of the peritoneum was quite free from fluid, and the surface of the membrane everywhere smooth and polished.

(To be continued.)

## REVIEWS.

*Researches on the Nature, Pathology, and Treatment of Emphysema of the Lungs, and its Relations with other Diseases of the Chest.* By A. T. H. WATERS, M.D., etc. London: Churchill. Liverpool: Holden. 1862.

WE are glad to meet Dr. Waters in the field of practical medicine. Having won no inconsiderable position amongst contemporary investigators of healthy structure by his prize essay on the anatomy of the lungs, he has now given us what we hope is only an instalment of results to be achieved by the application of his powers of observation and research to the phenomena of disease. We conceive that the most valuable portions of his book are those which treat of the morbid anatomy, pathology, and mechanical production of emphysema. On the first topic, Dr. Waters' observations enable him to speak authoritatively. With regard to the pathology, determining causes, and mechanism of emphysema, his views, although theoretical, are to a considerable extent supported by observed facts, and may probably prove to have anticipated future discovery.

Three forms of vesicular emphysema are described by Dr. Waters. The anatomical differences between them are simply those of extent, although he believes that the two first differ from the third both in pathology and mode of mechanical production. The first, which he calls "partial lobular emphysema," is that in which small patches only of dilated air-sacs occur, principally along the margins of the lobes. The second, "lobular emphysema," is the most common form of the disease, and involves one or more lobules in different parts of the lung. It is more especially found along the margin of the base at the anterior border and apex. It is the form of the disease so frequently met with in persons who have died phthisical. The third form, "lobar emphysema," is the most important. It consists of emphysema of the whole pulmonary tissue of a lobe or lung. The author has found it more commonly attacking both lungs than one, and the lower as well as the upper lobes. It frequently destroys life at an early period.

The anatomical changes which have taken place in the diseased lung have been examined by Dr. Waters by the same methods which he employed in his researches on the healthy lung tissue, viz., by inflation through a bronchial tube and desiccation. In some instances he previously injected the blood-vessels with a coloured solution of gelatine. We prefer to give his account of the anatomy of vesicular emphysema in his own words:—

"In the early stages of the disease we recognise a simple dilatation of the air-sacs, an increase in the size of the alveoli, and a diminution in the height of the alveolar walls, which, yielding with the distending cavities, become partially obliterated. As the disease progresses, the air sacs become still more distended, and the alveolar walls in some instances completely obliterated, so as to give a regular and smooth

appearance to the inner surface of the air-sacs, instead of the honeycombed appearance characteristic of their normal state. This distension of the air-sacs is necessarily attended with a divergence of the elastic fibres which enter into their composition, and with a general thinning of their walls—a condition which prepares the way for the next stage in the progress of the disease, viz., a perforation of the walls themselves. This at first is but slight; here and there a circular or oval opening may be seen in the membrane; as the disease progresses these openings become more numerous and larger; in some instances the whole of the walls of the air-sacs, and the septa of the alveoli being perfectly riddled with small openings, so that a horizontal section of the lung-substance has a general cribriform appearance. These openings are for the most part either circular or slightly oval. They exist in all parts of the walls, and are often seen in the septa between the alveoli, before the air-sacs are sufficiently distended to obliterate the septa."

"The subsequent steps in the progress of the disease consist in a further distension of the air-sacs, an enlargement of their perforations, and a rupture of the fibres of which their walls are composed. As these results take place, the walls become more and more imperfect, and the openings in them coalesce. A further breaking down of the walls then occurs, so as to leave but very partial partitions between the cavities; and in the most advanced stages of the disease these partitions undergo other changes, and are reduced to mere membranous shreds, or thin, fibrous cords, passing in various directions, traversing, in fact, the distended sacs, two or more of which, by the destruction of their walls, have united to form a single cavity. These cavities occasionally assume a large size, and project from the margin of the lung; they sometimes also form appendages, being connected with the body of the lung merely by stalk-like processes." Pp. 15, 16.

The author observes that distension of the air-sacs may exist to a considerable extent, with, at the same time, but little or no perforation; and, on the contrary, that extensive perforation may be found with even a less amount of dilatation than in the former instances. Those cases in which the dilatation is considerable as compared with the perforation, are usually cases of lobular emphysema, whilst those in which perforation is in excess, are generally of the lobar form of the disease. The conclusion drawn is that rupture under an amount of distending force which in other cases is insufficient to produce such rupture must be referred to some previous degeneration of the lung-tissue.

Emphysematous lung tissue is anæmic. In the early stages, when there is simple distension, the capillary meshes are wider, and the vessels farther apart. On perforation and further distension taking place, the capillaries become ruptured, and give rise to the hæmorrhage which is occasionally observed in the progress of the disease. In the further stages, where the air sacs are converted into large cavities traversed by membranous septa and shreds, small blood-vessels are seen to course along the latter; but their vascularity is but slight, and their respiratory function can be but inconsiderable. Occasionally, dilatation of the bronchial tubes, the marks of acute or chronic bronchitis, and an increased development of the circular muscular fibres surrounding the bronchial tubes, are collateral anatomical changes. The increased development of the muscular fibres is especially found in old cases of lobar emphysema.

Interlobular emphysema, an infiltration of the areolar tissue with air, has never been seen by the author except in conjunction with extensive vesicular emphysema, when it is present, to a greater or less extent, in almost every case. Dr. Waters differs from Lebert as to the period of the vesicular form of the disease at which the interlobular becomes super-added. Lebert speaks of it as an early result. The author has rarely seen it except where vesicular emphysema has been largely developed.

The pathology of the disease, or the nature of the morbid action which results in the anatomical changes above described, is confessedly a difficult subject. Dr. Waters is of opinion that all cases of emphysema cannot be referred to the same determining cause. He believes that the cases of partial emphysema, where the disease has supervened on chronic bronchitis, or other disease of which cough has been a prominent symptom, must not be classed, as regards their pathology, with those cases in which the disease has commenced and crept on insidiously, the patient probably being a young

person, and having never suffered from severe or long-continued cough. The changes in the former cases may be attributed to mechanical violence. In the latter they owe their existence to some morbid degeneration of the lung tissue, and involve large portions of one or both lungs. What the exact form of degeneration is which gives rise to "lobar emphysema," it is not easy to determine. By Mr. Rainey and Dr. C. J. B. Williams it has been considered to be fatty change. Dr. Jenner, on the other hand, holds it to be "fibrous degeneration—the consequence of the exudation of that variety of lymph which escapes from the capillaries, when they are the seat of slight but long-continued congestion." Dr. Waters' observations have not led him to adopt either of these views in its totality. With regard to the former, he writes:—"In the large majority of cases I have found no indications whatever of fatty matter; in some few instances, however, I have seen deposits of fat in the walls of the air-cells." He therefore believes that the production of fat is an occasional accompaniment of the disease and not its essential cause. The theory of degeneration arising from congestion, although it may apply to those cases where emphysema is secondary to chronic bronchitis, does not appear to account for the primary form of the disease, which comes on without any pre-existent congestive affection of the bronchial membrane. Although Dr. Waters' actual observations have not led him to positive results, their value must not be underestimated. He has investigated the condition of the blood-vessels from their commencement to their termination in the pulmonary plexus, surmising that they would probably be found to be the seat of atheromatous or fatty change. In some cases he has found atheroma existing in the pulmonary arteries and their capillaries, but in others no indication of it: and he has made the further observation, that atheroma does not occur in the pulmonary arteries without its being found in the aorta as well, proving that the affection of the former vessels is the result of a general tendency to arterial degeneration, rather than that it is connected specifically with the production of emphysema.

The result of his examination of the elastic fibres of the emphysematous lung is that there is no marked distinction between the diseased and healthy fibres, except that the outline of the former is sometimes less regular, and that they have less disposition to curl at their ends. But he has never observed any structural change in the fibre.

Although, however, unable to define the exact form of tissue degeneration which he believes to be the first step in the production of lobar emphysema, he insists on the existence of such a change, not only on the grounds which we have already noticed, viz., the supervention of the disease, unpreceded by cough, and the large portion of the organ involved, but also because of the known hereditary character of emphysema, and the good effect produced by those remedial measures of a tonic and supporting character which act beneficially on other diseases attended with degeneration of tissue.

Our limits will not allow us to give an analysis of Dr. Waters' argument on the determining cause and mechanism of emphysema. He agrees with Dr. Jenner in adopting an expiratory theory where emphysema has followed bronchitis, pertussis, and other affections in which long-continued and violent coughing is the most marked symptom. But in cases which fall under the other category, where there has been no cough or bronchitis, and where the disease involves the greater part of the lung, the expiratory theory will not apply, and he is then disposed to think that the distension is brought about by inspiration. He believes "that in these cases the lung tissue, being in an unhealthy condition, and abnormally weak, gives way before the pressure which it would, in a state of health, resist, and that, having once yielded, it is unable to recover itself, from having lost its elasticity. Consequently, it undergoes further distension, as increased efforts are made to dilate the chest in order to meet the requirements of respiration; until at length, the thorax having reached its extreme point of dilatation, no further enlargement of the lungs can ensue.

The remainder of Dr. Waters' work contains chapters on the symptoms and physical signs, sequelæ, and treatment of emphysema. As a whole, we can most conscientiously recommend it to our readers. We think it one of the most valuable contributions to pathology made during the past year.

MASON, FRANCIS, F.R.C.S., Assistant-Surgeon to King's College Hospital, has resigned the post of Surgeon to the St. Pancras and Northern Dispensary.

PROVINCIAL CORRESPONDENCE.

LIVERPOOL.

March 16.

SINCE the date of my last letter there has been some increase of fever in this town, and I think that a few facts and figures in reference to it may not be without value to those who are interested in the effort to ascertain the true relation between Lancashire famine and Lancashire fever.

The following tables show, first, the total number of deaths from "fever," *i. e.*, all cases registered as typhus, typhoid, or gastric fever this year, and the average of the corresponding week for the last ten years; and, secondly, the number of cases under treatment in the Parish Fever Hospital, with the mortality resulting therefrom during the present year and the corresponding part of last year:—

1. Deaths from Fever in the Borough of Liverpool.

Date.	No. of Deaths.	Average.
January 3, 1863 . . . . .	24	11
" 10 " . . . . .	35	8
" 17 " . . . . .	28	10
" 24 " . . . . .	22	9
" 31 " . . . . .	20	9
February 7 " . . . . .	18	9
" 14 " . . . . .	14	10
" 21 " . . . . .	25	10
" 28 " . . . . .	19	10
March 7 " . . . . .	14	10

2. Cases Admitted into the Parish Fever Hospital.

	1863.		1862.	
	Cases.	Deaths.	Cases.	Deaths.
January 7 . . . . .	90	6	21	1

March 4 . . . . .	134	11	71	6
" 11 . . . . .	130	7	70	3

There have been scarcely any cases of typhoid fever at the workhouse. Most have been true typhus, with well-marked mulberry rash. I find on inquiry that these cases have come mainly from the fever foci, which, in spite of the Health Committee, still exist in the courts and alleys, where whole families are huddled into single rooms, where there is much dirt, and little light and air, where the food is bad, and the drink worse still.

I have no doubt matters might have been much worse had it not been for the supervision which is exercised in neighbourhoods in which the disease is known to exist, by the inspectors on the staff of the Medical Officer of Health, and for the removal of the cases which the Medical officers of the parish send into the Workhouse Hospital. One good result is likely to be brought about in consequence of the pressure which the multitude of fever cases has thrown upon the parochial Fever Hospital: namely, that it has been resolved by the Select Vestry to pull down the present Hospital and build another on its site.

The present building was erected in 1800, at the instance of the celebrated Dr. Currie, and contains ninety beds. The Medical officers reported to the vestry that the space it afforded might suffice for the treatment of sixty patients—a number much beyond the average of the past few years—but that it was not adapted to meet any extra demands that might arise. It is now proposed to erect an Hospital that shall accommodate 150 patients. I may add here what I thought of saying in my last letter, that I hope the experience of the past winter at Preston may convince those who have influence in that wealthy town, that the want of some Hospital accommodation superior to that which can possibly be afforded by the "House of Recovery" is one which ought to be met, and I trust that when some future local historian comes to reckon up the effects of the cotton famine he may have among the positive advantages which have, under the merciful hand of Providence, resulted from the lessons learnt in these hard times, to include the establishment of an

Hospital worthy of the town of Preston, which the "House of Recovery" assuredly is not.

An important addition is about to be made to the Liverpool Royal Infirmary by the erection and endowment of wards devoted to the treatment of the special diseases of women, the sum of 10,000*l.* having been some time since placed at the disposal of the committee for this purpose by Mrs. Thornton, of West Derby. The plans are now under the consideration of the committee, and will, I hope, soon be carried into effect. It is, I think, most satisfactory that in this instance the arrangements for the treatment of these special cases are made in connection with a general Hospital, and that we have not another to increase the already numerous Medical Institutions of this town, to which two additions have just been made, to wit, a Dispensary for Diseases of the Skin, in Brownlow-street, and an Hospital for Cancer and Diseases of the Skin, in Roscoe-street. What public necessity called these establishments into being is an inscrutable mystery. Skin diseases and cancer are not excluded from the Hospitals and Dispensaries, nor are their physicians and surgeons incompetent to the treatment of these diseases. It would be a great benefit to the profession, and, I believe, to the public also, were it possible for us to arrive at some definite opinion as to the use and abuse of special Hospitals and Dispensaries. Whether still further division of labour is desirable—whether, for example, as we have institutions for diseases of the skin, it might not be well to inaugurate some for the diseases and injuries of bones, and thus cut-out the "bone-setters;" and having got thus far, whether we ought not to provide special help for diseased mucous and serous membranes. Is it not worthy of consideration whether, as the eyes, ears, and teeth are already specially cared for, the nasal organs might not claim a share of attention, and so on *ad libitum*. On the other hand, may it not be suggested that we have as many special Institutions as are needed. I do not doubt that separate Hospitals for obstetric cases, for fever, etc., for diseases of the eye, may do good service by accommodating patients who cannot be attended to elsewhere; but it does appear to me, that Institutions for cases which are received at any Hospital cause a waste of public money if supported by voluntary contributions, help to aggravate the evils of gratuitous advice, impair the clinical opportunities of other Hospitals, and hinder rather than help true science.

An interesting discussion took place at the Medical Society on February 5, in reference to a case in which Mr. Higginson tied the internal iliac artery, in order to arrest hæmorrhage from the gluteal region. Five weeks before admission, the patient had fallen, and received a severe blow a little behind the great trochanter of the femur. Under the treatment of Dr. Thomson, of Argburgh, he appeared to have nearly recovered, when, after walking about a mile, suppuration occurred in the gluteal region. The collection of matter was opened—no hæmorrhage took place then; but four days after there was bleeding to a considerable extent. Pressure stopped the bleeding for the time, but the pus which was discharged was tinged with blood; and about eight days after the first hæmorrhage a second attack occurred; a compress was then put on, and the patient sent to the Southern Hospital. Mr. Higginson found that the finger passed through a large cavity filled with pus and sloughing tissues to the bony edge of the sciatic notch, and that bleeding was still going on. The internal iliac artery was tied without difficulty, and without any loss of blood; but the man gradually sank, and died fourteen hours after the operation. At the post-mortem, there was found fracture of the sacrum, the soft parts around ecchymosed and sloughy, but it was impossible to ascertain the precise source of the hæmorrhage.

There was considerable diversity of opinion as to whether or not it would have been more advisable to have laid open the abscess and tied the wounded vessels. Mr. Higginson believed that the danger to the patient would have been greater had he been subjected to the further loss of blood, which must have occurred during the search for the bleeding point, than that which was incurred by the shock of the operation. He regretted that the man had not had the chance of recovery which transfusion would have afforded him, and mentioned a case, hitherto unpublished, which occurred at the Southern Hospital in 1860, in which a man reduced to an almost hopeless condition by profuse suppuration and repeated hæmorrhage was saved by the injection of about twelve ounces of blood into his veins. This being another case to

add to the seven previously published by Mr. Higginson, which will be found in the first number of the *Liverpool Medico-Chirurgical Journal*.

It is, I think, to be regretted that this operation is not more frequently adopted, now that experience has demonstrated its safety and its efficiency.

## REPORTS OF SOCIETIES.

### WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, FEBRUARY 20.

Dr. BAINES, Vice-President, in the Chair.

A PAPER, by Dr. ANSTIE, was read on

#### THE THERAPEUTICAL VALUE OF COD-LIVER OIL IN CHRONIC CONVULSIVE DISEASES.

The author's attention had first been directed to cod-liver oil as a remedy for affections of this class in consequence of his obtaining some years ago an unexpected success with it in a case of chorea, which had resisted all the ordinary modes of treatment. The convulsive diseases in which the author has employed cod-liver oil are paralysis agitans, simple epilepsy, chorea, and mercurial tremor, and in all these affections it has appeared to be more constantly useful than any other medicine. Of paralysis agitans, four cases were detailed, of which three were very decidedly improved, and one of them may have been said to be cured, although the affection had been very severe. Of chorea, one case was detailed, and others were alluded to in which the benefit produced was very marked. Of mercurial tremor, one most remarkable case was related, in which the cause of the mischief was a very unnecessary salivation inflicted by Medical authority some thirty years previously; the patient was attacked immediately afterwards with dreadful tearing pain in the muscles of the fore-arms and calves, and with violent muscular tremors, and ever since that time she has been liable to a recurrence of the symptoms when much fatigued or depressed from any cause. On application to Dr. Anstie, at the Chelsea Dispensary, cod-liver oil was prescribed and persisted with for five weeks, at the end of which time all the symptoms had perfectly disappeared, the patient declared that she had never been cured before in less than six or eight months, and she doubted whether any other medicine than the oil had ever really done her any good. Twice since she has had slight recurrence of the symptoms, but a short course of cod-liver oil has on each occasion given complete relief. Of simple epilepsy, twenty cases were given, in which the treatment had been confined to the use of cod-liver oil. Of these there were five upon whom no good effect whatever was produced; seven had completely recovered; two had disappeared from supervision at a time when they were rapidly improving, although they could not be said to be cured; in two others the mental symptoms had greatly improved, but the fits remained as before. Four patients remain still under supervision; in two fits have ceased, although there are still frequent prodromata; and in the remaining two but little good has yet been effected. Besides this general summary of results, Dr. Anstie detailed the particulars of three cases which from their severity might be said fairly to test the remedial power of the oil. The patients were respectively a girl, aged 17, a boy, aged 13, and an infant, aged 7 months; in all of them the fits were very frequent and severe, and the nervous system exhibited signs of great depression. The case of the infant was specially noticeable, because it was proved by microscopic inspection that the milk of the mother was very deficient in oily matter, and it appeared that in a former infant of the same mother precisely the same train of symptoms had appeared, and had terminated fatally. In all these three cases the treatment had proved perfectly successful, and the author commented strongly on the fact that in all these cases the general nutrition of the body had been excellent, and only that of the nervous system had appeared deficient, and said that conclusion appeared inevitable that the oil had expended itself in enriching the nervous centres. This, indeed, was the principal point of the paper. The author directed attention to Dr. Radcliffe's remarks on the necessity of fat to the nutrition of the nervous centres, and mentioned the fact that that gentleman had found cod-liver

oil of the highest value in the treatment of convulsive diseases. He observed, also, that the beneficial action of cod-liver oil was quite consistent with what we know of the action of the few other remedies which careful therapeutical investigation has credited with a really beneficial action in chronic convulsive diseases. Steel, arsenic, quinine, all these may fairly be spoken of as foods. With regard to sedatives, the author remarked that in the first place the good effects which could be expected from them were chiefly temporary, and such as result from breaking through for a time the evil habit, so to speak, of convulsive action. Secondly, and this was most important, there was strong reason to believe that it is not the really narcotic effect of these remedies which are of service in preventing or arresting convulsive action, but merely the stimulant effects which can be obtained from small doses; for there is no class of remedies which is more useful in preventing or arresting convulsions than the pure stimulants. The author concluded his paper by deprecating strongly any return to the absurd system of hunting about blindly for "specifics" for chronic convulsive diseases. The progress of clinical observation was blasting the reputation of one after another of the strange, out-of-the-way remedies which had once been accepted with the blindest faith, and was pointing unmistakably to a rational treatment of convulsive diseases by means of medicines whose action it is possible to understand.

MEDICAL NEWS.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, March 19, 1863:—

Charles Edward Caudle, Henfield, Sussex; Walter Rumbell, Ramsbury, Wiltshire; Charles Henry Allfrey, Stamford-hill; Alfred Averill, Broadway, Worcestershire; George Herbert Holden, Presteign, Radnorshire.

APPOINTMENTS.

\* \* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

- COTTRELL, T. S., has been appointed Certifying Surgeon under the Factory Act.
- DAVIS, JOHN HALL, M.D. Lond., has been appointed Lecturer on Midwifery at the Middlesex Hospital.
- GRAHAM, F. L., has been appointed Certifying Surgeon under the Factory Act.
- HARRIES, GWYNNE, M.R.C.S. Eng., has been appointed Physician-Accoucheur's Assistant at King's College Hospital.
- HART, ERNEST A., M.R.C.S. Eng., has been appointed Lecturer on Ophthalmic Surgery at St. Mary's Hospital.
- HEAD, EDWARD, M.B. Lond., has been appointed Professor of Botany at the Charing-cross Medical School.
- HUNTER, GEORGE YEATES, M.D., of Margate, has been appointed a Cinque Port Justice of the Peace.
- KEAL, WILLIAM, M.R.C.S. Eng., has been elected Coroner for the County of Rutland.
- MEADOWS, ROBERT, M.D., has received a Commission as an Assistant-Surgeon in the Anglo-Chinese Squadron.
- OFFICER, Dr., has been elected Speaker of the House of Assembly, Tasmania.
- RANDALL, JOHN, M.D. Lond., has been appointed Lecturer on Medical Jurisprudence at St. Mary's Hospital Medical School.
- SMITH, H. SPENCER, F.R.C.S. Eng., has been appointed Surgeon to St. Mary's Hospital.
- TAYLOR, GEORGE, M.D. Glasg., has been appointed Principal Medical Officer of Chatham Garrison.

DEATHS.

- GEOGHEGAN, GEORGE E., L.Q.C.P.I., late of Rathmines-road, Dublin, at New York, on February 13.
- HOLLIER, EDWARD, M.R.C.S. Eng., at Hammersmith, on March 18, aged 72.
- HUTCHESON, WILLIAM, M.D. Edin., at 4, Bath-place, Wellington-square, Ayr, N.B., on March 24.
- OSLER, EDWARD, M.R.C.S. Eng., at Truro, Cornwall, on March 7, aged 65, Editor of the *Cornwall Gazette*.
- PHILLIPS, GEORGE, F.R.C.S. Eng., at Haverfordwest, on March 19.
- SMITH, Dr. RICHARD, at Elmbank, Lasswade, Edinburgh, on March 16, aged 69, Surgeon R.N.
- SODEN, JOHN SMITH, F.R.C.S. Eng., at Sydney-place, Bath, on March 19, aged 83.

THE students of St. Bartholomew's Hospital have forwarded to the Mansion-house Fund, for the relief of the Lancashire distress, a further subscription of £12 13s. 6d., in addition to the sum of £38 forwarded by them in December last, thus making a total of £50 13s. 6d. subscribed by the students of the above-named Hospital for this object.

**SCARLET FEVER IN THE TRAINING SHIPS, DEVONPORT.**—Scarlet fever has appeared among the boys on board the training ships *Impregnable*, 78, Commander F. S. Tremlett, and the *Implacable*, 24, Commander Samuel B. Dolling, in Hamoaze, Devonport. There are about 22 cases on board the *Implacable*. Her complement of boys is 400, but she has at present 450; of these 225 have been sent to a sanitary hulk.

DR. S. FENWICK being on the eve of leaving the parish of Tynemouth, where he has practised for many years, the local clergy were desirous of marking their high esteem for his character as a man, and his skill as a Physician. They have therefore united in presenting him with a very handsomely bound Bible, in which was inserted an inscription on vellum, designed and written by Edward Offor, of Leadenhall-street, London. Dr. Fenwick will be greatly missed, not only by his personal friends, but by the large labouring population of North Shields, to whom his Professional services were freely given.

**THE HUNTERIAN MUSEUM.**—This collection has been enriched with a magnificent series of preparations illustrating the pathology of the human eye, nearly 200 in number, and about 500 microscopic slides prepared from the same specimens. The whole have been made with consummate ability by Dr. C. Bader, of the Royal London Ophthalmic Hospital, and a former assistant in the museum of the College of Surgeons. The preparations are accompanied with a description of the appearances at present exhibited by the specimens, with a history of the case, and a general and microscopic description of the morbid appearances presented by the eye when recent. Such a collection does not exist at home or abroad, and great credit is due to the Council of the College for securing it for their unrivalled museum.

**PROPOSED NEW HAT FOR THE CITY POLICE.**—It will be recollected that some time since Mr. G. Borlase Childs, Surgeon to the City police force, recommended, among other improvements in the dress of the police (some of which have been adopted), a new description of hat, which he proposed to call the "Britannia Hat," and which was designed after the Greek *galea*. It has been manufactured by Messrs. Hall, and is thus described by a writer in the *City Press*:—"The hat, which is a modified form of helmet, certainly appears to be a very desirable substitute for the present cumbrous shape. In form it is admirably calculated to resist a blow, so also is it in substance, though it is not heavier than the hat now worn. It is next to impossible to knock it off the head—a great desideratum—and, indeed, with the strap under the chin, which may or may not be worn, it appears quite impossible. It is well ventilated, has a neat and not conspicuous appearance, and possesses also a covering, which may be worn at pleasure, for the ears. A similar hat has been adopted for the police force of two towns in the north of England.

**THE APOTHECARIES' COMPANY OF IRELAND.**—The King's and Queen's College of Physicians of Ireland have addressed a letter to the Irish Poor-law Commissioners on the subject of the licence of the Irish Apothecaries' Company. They assert that the certificate or licence which the Apothecaries' Company of Ireland are empowered to issue is only such as specified in sect. 18, 31st of Geo. III., cap. xxxiv. Irish, viz.—"That we think him properly educated or qualified to become an apprentice or journeyman (as the case may be) to learn or transact the business of an Apothecary." And in sect. 22—"That no person shall open shop, or act in the art and mystery of an Apothecary within the kingdom of Ireland, until such person shall have been examined as to his qualification and knowledge of the business," etc. They go on to state that there is neither in these clauses, nor in any part of the Act, any authority given to grant any licence or certificate in Medicine; and on this point it seems requisite to observe that, in the case submitted to Sir R. Bethell, there is a mis-statement calculated to mislead counsel, where it is stated that, "Such, then, was the legal and recognised position of the Irish Apothecary, analogous in every respect to that of the Apothecary in England, when the Medical Registration Act (21 and 22 Vic., ch. 90) was

passed," etc., etc. They, moreover, go on to show that the constitution of the Board of Governors of Apothecaries' Hall of Ireland, from whom the examiners must be selected, under the Apothecaries' Act, is not such as to insure a satisfactory guarantee that the examiners are competent examiners in the science and practice of Medicine.

AN Examination for three Foundation Scholarships, and also for three Minor Scholarships, will be held in Downing College on Monday, the 18th of May next, and the two following days, and will begin at 9 a.m. on Monday. The examination will be chiefly in classics and elementary mathematics, but some weight will be given to proficiency in French and German. To the candidates for Foundation Scholarships two additional papers will be set, one on moral philosophy in connexion with the principles of jurisprudence, the other on the elements of the natural sciences (human and comparative anatomy, physiology, chemistry, mineralogy, and botany) in connexion with Medicine; and in awarding two of these Scholarships considerable importance will be attached to any special proficiency in the legal or in the Medical subject. Persons who have not been entered at any college in the University, or who have not resided one entire term in any such college, are eligible to the Minor Scholarships, which will be of the value of £40 per annum, and tenable for two years, if the holder be not elected before the end of that time to a Foundation Scholarship. Students of the college, or of any other college in the University, who have not kept more than six terms, will be eligible to the Foundation Scholarships, which will be tenable for three years, and of the value of £50 per annum, with rooms, and with commons during residence in term time. Those Foundation Scholars who shall obtain a first-class in any tripos will be entitled to hold their Scholarships till they are of standing for the degree of Master of Arts, or, if they should be elected fellows of the college before that time, until such election. No one elected Scholar will receive any emoluments until he has commenced residence as a student of the college. Satisfactory testimonials as to their moral character must be sent to the Master by all candidates for these Scholarships, on or before Wednesday, May 13. Further information will, if required, be given by the Rev. W. B. Pike, tutor, Downing College.

DEATH FROM RUPTURE OF THE STOMACH.—On Tuesday last Mr. Humphreys resumed, at Stepney, an inquiry respecting the death of Jane Utting, aged 18 years. The evidence went to show that deceased was a single woman, residing with her mother in White Horse-lane, Stepney. She had been in her usual health, and on the night of Tuesday, the 10th inst., she proceeded to King William-street and London-bridge to witness the decorations. Soon after returning home she complained of extraordinary violent pains in the chest. A doctor was sent for, but all treatment was unavailing, and she died shortly afterwards. It was supposed that she received some fatal injuries in the crush. Dr. Sykes said that he was quite surprised at the suddenness of deceased's death. He could not see any cause other than the alleged crushing to account for death without a *post-mortem* examination, which he had made, and death he found had resulted from rupture of the stomach from old disease. There was a dark patch externally, but he could not say that it had been produced by violence. The coroner said that in his opinion nearly all those who had perished in the fearful crushes in the city during the late rejoicings had been previously in a state of disease of the heart or other internal organ. It was a matter of some interest as well as importance to ascertain the fact beyond doubt, both to reassure the general public and also to warn persons so afflicted of the great danger into which they inevitably ran in subjecting themselves to the pressure and excitement of such scenes, and the *post-mortem* examinations made placed the fact beyond a doubt. A verdict of "Death from rupture of the stomach" was returned.

ODONTOLOGICAL SOCIETY.—At the meeting of the society on the 2nd inst., a paper was read by J. Walker, M.D., M.R.C.S., "On Dental Exostosis: its Pathology and Diagnosis." The author commenced by defining what was to be understood by the term exostosis, and described the various forms of the disease, which were illustrated by diagrams and specimens. He then considered the causes of exostosis regarding inflammation of the peridental membrane as the first step in the morbid process leading to an exudation of organizable lymph which is converted first into fibrous and then into osseous tissue. The causes of inflammation of the

peridental membrane were caries, concussion, looseness of the tooth, and its apparent elongation from rising in the socket, rheumatism, syphilis, gout, and mercurialism. Hence exostosis may affect the fangs of sound as well as of carious teeth, though in a less degree. Speaking of rheumatism, the author expressed his opinion that this was a much more common cause of periostitis around the fangs and in the sockets of the teeth than is generally supposed, and one chief reason for this opinion was the very great relief from pain which he had repeatedly seen follow the use of iodide of potassium when all other remedies had failed. The last division of the subject was the diagnosis of exostosis from other diseases about the face and mouth, particularly neuralgia and incipient disease of the temporal bone from otitis: he placed its chief distinction in the character. In exostosis the pain comes on gradually, is continuous, and often severe. In neuralgia it is intermittent, often severe from the commencement, but the patient has intervals of ease. In otitis the pain is always increased by pressure about the ear, and at length is relieved by the occurrence of a discharge of puriform matter. Hearing will also be impaired or confused. The author more completely illustrated this division of the subject by cases occurring in his own and in the practice of others; he showed also an interesting specimen of a monkey's head with the cancellous structure of the bones of the face highly hypertrophied, without extending to the bones of the skull, from irritation and inflammation arising from a diseased canine tooth, the fang of the tooth being exostosed.

THE NEGRO RACE IN AMERICA.—In the South, where they are well cared for, the negroes increase and multiply. In the North, where nobody cares for them—for Abolitionists never talk of the free black man, but only of the slave—the race is perishing. The last official census of the United States gives the figures. "In the interval from 1850 to 1860," says Mr. Kennedy, the official Superintendent, in his preliminary report to Congress, "the total free coloured population of the United States increased from 434,449 to 488,005, showing an annual increase of one per cent. This result includes the number of slaves liberated and those who have escaped from their owners. . . . In Boston, during the five years ending in 1859, the number of coloured births was one less than the number of marriages, and the deaths exceeded the births in the proportion of two to one. . . . In Philadelphia, during the last six months of the census year, the new city registration gives 148 births against 306 deaths among the free coloured people. . . . In the State registries of Rhode Island and Connecticut, where the distinction of colour has been specified, the yearly deaths of the blacks and mulattoes have generally, though not uniformly, exceeded the births. . . . Owing, among other causes, to the extremes of climate in the more Northern States, and in the Western States to expulsive enactments of the Legislatures, the free coloured race shows a decrease of numbers in Indiana, Maine, New Hampshire, New York, and Vermont." The Superintendent says nothing of the social misery and degradation of the negroes in the North—misery and degradation that break what little spirit is possessed by the race; but, doubtless, these operate injuriously on their health and fecundity, and aggravate the rigours of a climate for which their constitution and temperament are not suited. But while thus dying out of the North and West by slow, though sure decay, the condition of the Southern negroes shows a totally different result. "The slave population of the South," says Mr. Kennedy, "amounts to 3,950,000 persons. During the decennial period from 1850 to 1860 their numbers advanced no less than 749,931, or at the rate of nearly 23½ per cent." These figures show that if the condition of the Southern negro be slavery, it is slavery with health and life; and that if the condition of the Northern negro be liberty, it is liberty with disease and death, as well as with social degradation. The English Abolitionists should look these facts in the face, and make the best of them; not forgetting, at the same time, that Mr. Lincoln, who proposes to set free the great bulk of these poor people, also proposes to deport and expatriate every one of them to Central America, or back again to Africa.—*Times Correspondent.*

PROPORTION OF BIRTHS AND DEATHS IN AUSTRIA.—This varies exceedingly in the different provinces of the empire. Of births there take place in the Military Frontiers and in Galicia 1 in 20 inhabitants; in Hungary, 1 in 21; in Silesia, Croatia, and Bukowina, 1 in 23; in Dalmatia and Venetia, 1 in 24; in Lower Austria, Bohemia, and Moravia,

1 in 25; in Siebenburgen, 1 in 27; in Craniola and Styria, 1 in 30; in Upper Austria, Carinthia, and the Tyrol, 1 in 32; and in Salzburg, 1 in 33 inhabitants. Deaths occur in the Military Frontiers in the proportion of 1 in 25 inhabitants; in Hungary, 1 in 30; in Lower Austria, Galicia, and Venetia, 1 in 31; in Salzburg, 1 in 32; in Upper Austria and Croatia, 1 in 33; in Craniola, 1 in 34; in Styria and the Tyrol 1 in 35; in Bukowina, 1 in 36; in Carinthia and Moravia, 1 in 37; in Bohemia and Silesia 1 in 38; in Siebenburgen, 1 in 41; and in Dalmatia, 1 in 45. A consequence of these differences is an unequal increase of the population. This is greatest in Dalmatia (2.06 per cent.) exceeds  $1\frac{1}{2}$  per cent. in Silesia, Galicia, and in the other Slavonic and Hungarian provinces is more than 1 per cent. The German crown provinces exhibit an increase of less than 1 per cent., while in Salzburg for a series of years the number of deaths has exceeded that of the births.—*Wien. Allg. Med. Zeit.*, 1862, No. 45.

**DEATHS IN BERLIN DURING 1861.**—The entire number of deaths amounted during 1861 to 15,177, viz., 1 death for 36.0 inhabitants, and 100 deaths taking place for 134 births. As is usually the case, the greatest mortality took place in July and August, almost exclusively caused by infantile diarrhoea and marasmus. The smallest number occurred in February. As in every year, phthisis was the cause of the greatest number of deaths. Next in frequency came infantile convulsions—this disease, together with the diarrhoea and marasmus of children, constituting 28 per cent. of the mortality. Still-born children amounted to 6.4 per cent., being 4.6 per cent. of the new-born infants. Deaths from acute diseases of the chest were 4.1 per cent., from inflammation of the brain 4.0 per cent., from fever 3.2 per cent., from croup 1.4 per cent., and from puerperal fever 0.9 per cent. Apoplexy is returned at 4.9 per cent., and pulmonary paralysis (?) at 3 per cent. The fatality of scarlatina, measles, and pertussis was almost confined to the first ten years of life, increasing in scarlatina until the fourth year, the maximum in measles and pertussis being attained by the second year. Erysipelas chiefly proved fatal in children in early life. The greatest mortality from typhus took place between the twentieth and thirtieth years. Inflammation of the brain prevailed most in infancy, but it also occurred very frequently between the ages of thirty and forty. Phthisis killed chiefly between twenty and thirty, the deaths continuing frequent even until the fiftieth year. Thus, of 100 deaths from all causes between the ages of twenty and thirty, 44 per cent. (49 males and 38 females) died from phthisis, as did 39 per cent. between thirty and forty, and 32 per cent. between forty and fifty. Illegitimate children formed 20 per cent. of the entire number of dead children, while they only constituted about 16 per cent. of the entire births. The suicides were returned at 7.4 per 1000 of deaths, 85 per cent. being males, and 15 females. It is probable, however, that several of the persons found dead in the water were suicides. Most suicides took place in July, fewest in January. After drowning, hanging was the favourite mode of death, then came shooting (only in males), and next running over on railroads. Accidental deaths were returned at 13.8 per 1000, the great majority occurring through the agency of water.—*Preuss Medicin. Zeitung*, 1862, Nos. 37-42.

## NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon.*

We have received a statement from Mrs. Russell which is denied, and would have nothing to do with her charge against Mr. Adams if it were admitted.

M.D.—1st. 12,500. 2nd. About 5 per cent. The exact number may be obtained by counting up the names, with the prefix of non-registration attached, in Churchill's Medical Directories.

### CHLOROFORM ACCIDENT—RECOVERY.

The following has been sent us by Dr. Kidd for publication:—

The following is an important instance of recovery from chloroform death, so to term it,—the first, we are assured, in which a peculiar form of electricity has been tried in the human subject. A lady, of the middle period of life, was placed under chloroform one day this month, in a public institution in London, previous to a plastic operation in the perineal region. It was observed, at first, that she did not "take" the anæsthetic well; she gasped and held her breath in a hysterical manner. The Surgeon about to operate thought the "inhaler" at fault. Then a handkerchief was tried; then sulphuric ether substituted for the chloroform; till, finally, the patient became, at the expiration of about ten minutes, fully narcotised in the ordinary degree for such operations, the anæsthesia being kept up by small doses of chloroform and ether, mixed in a drachm measure glass.

The operation was commenced, and about half performed, when, at the expiration of about ten minutes more, the pulse was noticed to waver, then suddenly to stop; there had been some unavoidable hæmorrhage, and the sudden change was ascribed to this circumstance. Cold dashing of water, and fanning the patient with a lady's fan, restored the pulse again, but its beat was uncertain and slow. The sutures were now being quickly inserted, and the chloroform was put away. There was no steady rally, however, of the patient; respiration had stopped. The pulse, which had been carefully watched all along by Dr. Kidd (who assisted another gentleman in the administration), was noticed again to flicker and stop, the face quickly assuming the fixed, cold aspect of death; the face and neck were so cold that it was thought better to cease the cold dashing. The utmost alarm seized some thirty Surgeons—bystanders; one cried to draw out the tongue; another to turn the patient on her side; ammonia was placed to the nostrils in vain. A sense of agonising suspense ensued; there was no pulse; no breathing; death had set in, or was setting in fast. The great desideratum in such cases is to re-establish the action of the diaphragm and respiratory muscles. It is idle to attempt to act on the heart or pulse except through the respiration; the right side of the heart is gorged with blood which the fixed lungs and thoracic parietes do not receive. It is very difficult even to notice if the respiration is going on; the patient may remain as in catalepsy—fixed and staring, the heart still receiving blood into its right cavities from the rough manipulations and pressure and rubbings of bystanders on the surface to restore life. All this took place in the present case. The arm was raised, and the "Sylvester method" tried, but all in vain; there was still no rally, no pulse, no breathing; the eyes had assumed the opaque, ghastly stillness of death; the face was like white paper. Nearly all the usual resuscitation methods had obviously failed; three, five, ten minutes elapsed; tracheotomy was next thought of, but, rushing away for a moment, Dr. Kidd brought his portable electric battery, and, pulling a pin out of his necktie, stuck it into the region of the phrenic nerve as it lies in the sterno-mastoid, another pin into the diaphragm, and quickly applying the wetted sponges of the "Faradisation" current, the effect astonished himself and every one present; where, a quarter of a minute before there was to all intents a body all but stone dead—cold, ghastly, and still as death—now the chest heaved and fell with each interruption of the galvanic circuit, the sterno-mastoid was thrown into strong contractions; there was a moan, a sigh, followed by natural breathing, and a gradual flicker of the restored pulse.

We are assured, as the result of a long series of experiments with chloroform on the lower animals, that electricity in any other shape is not effectual, or even this form of electricity on the old theory of "cardiac syncope" of Snow, direct to the heart itself; and Dr. Kidd, who explained these facts to the Surgeons assembled, mentioned a remarkable case of apparent death from drowning, the man supposed to have been an hour under water, at any rate pronounced by every one irretrievably dead, where a triumphant recovery followed the same method of resuscitation.

### HEMICRANIA A SEQUELA OF INFLUENZA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Perhaps some of the contributors to your columns of "Notes and Queries," etc., would kindly say if, during the late epidemic of influenza, they have noticed the disease to be followed in many instances by hemicrania, or more rarely facial neuralgia? I have observed it in too many cases for me to think it a mere coincidence. So far as I have noticed, the pain subsides on the accession of returning strength without any special treatment. I am, &c. HUGH NORRIS.

South Petherton, Ilminster, March 19.

[We find four grains of quinine, every two or three hours, the treatment.]

### EXTRAORDINARY DEATH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have thought you might be willing to reprint, among the varieties or memoranda, the enclosed (from this evening's paper), as the case is by no means unique.

In the Anatomical Museum of the Edinburgh University there is a solefish preserved (eight inches long and two and a-half broad) which, many years ago, caused the death of a fisherman precisely in the same manner as the mullet did in the case here mentioned. The man was in a boat drawing a net, and, having his hands engaged, seized the fish by his teeth to prevent its escape through the meshes. A sudden convulsive effort carried the animal down his throat, and, after death, the head was found within an inch of the cardiac orifice of the stomach. The man died from suffocation before the boat gained the shore.

I am, &c.

Zoological Society of London, March 24. T. SPENCER COBBOLD, M.D.

"Extraordinary Death.—The Toulon journals relate the following:—'A warden of the baigne here, named Durand, has just met with his death in an extraordinary manner. He was amusing himself, while off duty, with fishing in the dock from a narrow floating raft, when having caught a mullet, and not knowing where to place it to prevent it escaping into the water, he conceived the idea of holding it between his teeth while he baited his hook. The fish, struggling in the convulsions of death, ended by slipping its head first into the mouth of the man and then down his throat, completely filling up the cavity. The man rushed out of the dock for Medical aid, but soon dropped dead from suffocation. The autopsy, which took place on the following day, showed that there had been no possibility of saving the man's life. The position of the fish, and the action of the viscous matter with which the scales were covered, while facilitating the mullet's entry into the gullet, had rendered its extraction impracticable without such injuries to the throat as would also have caused death. The author of this involuntary homicide measured about seven inches long and two broad.'"

### HUNTERIAN SOCIETY.—RECENT CHANGES OF LAW.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have just received the report of this society's last annual meeting, and finding that each year brings with it some constitutional change tending to vest the entire control of the society in the hands of a clique who are practically self-nominated, I ask permission to bring this matter before those distinguished men, who, while remaining with us in name, yet manifest no personal interest in our welfare, and as it is well known that our meetings are free from that redundant eloquence and ability which so often embarrasses the less oriental societies, to ask that those members will throw their occasional presence into the gap, and dispel a suspicion that they are ashamed of an old connection. Reference to last year's report will show that the presidency has been made biennial instead of annual, and that the mode of electing the council has been changed, "so

that the services of the more active members may be retained from year to year." Again, the present year's report states that the council have deemed it desirable to introduce a new bye-law, and the wording of this is such, that though its precise effect evades the perceptions of any ordinary intellect, yet it shows that the alteration is another step in the same direction, and it appears to give the council power to propose the resignation of any member for whom they may have a personal distaste. At the same time it contains no sort of provision for making such member acquainted with his offence, or for providing him with an opportunity for defending himself.

As no preliminary notice of this last innovation accompanied the circular which announced the annual meeting, it was not known that anything more than mere formal business would be transacted, and the meeting was, I am informed, an exceedingly select one, consisting, indeed, principally of the aforesaid council, although other members would certainly have availed themselves of the opportunity to express their sentiments upon the proposition had they been acquainted therewith. Moreover, this new bye-law is the more questionable in its present unguarded terms because the council just now rest under a charge of sheltering a tale-bearer among their number, and of having given currency to his statements in every way but that which would enable the injured party to meet them, and it may be suggested that this new bye-law is a mere matter of self-defence on the part of the council in the shape of an *ex-post facto* law, devised for the purpose of unconstitutionally menacing a member who has brought against them a charge which they are unable to answer.

Should, however, those now in office feel that they are gifted with a prestige and a sagacity which justify them in ignoring the laws of jurisprudence and in violating the forms of justice when dealing with the personal character of an individual member, I nevertheless hope that we may be favoured with a preliminary notification of any further improvements which the council may deem it desirable to introduce.

I am, &c. A MEMBER AND WELL-WISHER.

#### INSANITY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your able article of last week on this question has suggested a few thoughts which I beg permission to express. Can it be wondered at when learned doctors disagree on cases of this kind before a legal tribunal that the lawyers should claim the right of deciding upon careful investigation and evidence before them? and also when persons believe that ordinary intelligence and practical association with mankind will qualify them for deciding a question of insanity the same as any other. I wish to advert only to one description of case—an individual who has abandoned himself to his impulses, or passions, or drink, commits murder; he is responsible; the same individual, we will suppose, has allowed himself to advance to delirium tremens and hallucinations, doing a number of extravagant things, and ending with murder. Is he, or should he be then responsible? Suppose a repentant consciousness of crime wakes up reason in this instance, as it frequently does in that of passion and intoxication, are not the deeds to be viewed under divine and human intelligence much the same? If the state of mind under the second condition persisted, then I can believe a difference must be allowed. Another instance occurs to me which I think the law has dealt too leniently with: an imbecile who has strong passions and is at large and employed, commits murder by a scheme or mental process to get the victim within his power; he is let off on the plea of insanity. I think unjustly so to the victim and society. Monomania and homicidal mania, where the persons are like others except in the one particular, ought such persons to escape penal law in the commission of their particular propensities? if they employ concerted means to an end, as they mostly do, why should they be considered irresponsible?

I am, &c.

AN OLD SURGEON.

March 24.

#### "THE PLEA OF INSANITY."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I, in common, I am very certain, with most Physicians who devote themselves to practice in mental disease, was cordially glad to read the enlightened leading article of last Saturday's *Medical Times and Gazette*, entitled, "The Plea of Insanity." It constitutes a weighty and well-merited protest against both the artificial and conventional dogmas of written law on the subject of mental alienation, and the absurd exposition of lawyers who adopt that, and not actual occurrence and reason, as the basis of their disquisitions and judgments, and, unfortunately, of their application to particular cases.

If it can be demonstrated, by an induction of numerous unmistakable cases—if it is true, on the strongest and most indubitable evidence that human reason can desire—that moral insanity does exist unassociated with any intellectual aberration; that, in the case of a particular individual, given some special moral impression,—say association, suggestion, temptation, inducement, inclination, or opportunity—a corresponding and correlated mode of action or conduct, which is manifested in all men, and in certain circumstances rightly and suitably, in this case is, instantly, constantly, inevitably, thoughtlessly, and inconsiderately, exhibited, without care of consequence or power of restraint; or that many or any such impressions arise, each its proper and co-ordinated expression, as conduct, act, etc., while the individual knows what he is about, can descant intelligently enough on the moral quality and consequences of actions, and even his own actions, can perceive, attend, observe, remember, compare, abstract, and judge as well as most men, and has no delusions, crotchets, whims, or eccentricities,—is it rational, far less just and humane, to ignore the reality as a general fact, resting on hosts of particular instances, and rely in reasoning and judgment upon a delusion or fiction? Numerous cases might be related of individuals who could as soon help existing as help committing some fault, crime, or sin, or several or any faults, crimes, or sins (for the inevitable tendency exists in every degree of generality), when a stimulus thereto acts upon them, as a moral impression, and yet could discourse most excellently on the evil of moral delinquency, or their own delinquency, and satisfy every test which the most ingenious alienist or lawyer could devise as to their intellectual soundness.

In such cases it is not the knowing of moral principles and relations of actions that is at fault, it is the caring; not the perception but the sense. In fact, according to my way of thinking, the knowing without the caring—the perception without the sense of wrongness—renders the commission a greater act of madness than in the case of an utter lunatic, destructive, dirty, noisy, incoherent, who steals, lies, strikes, fornicates, or kills when temptation allures and opportunity offers, without thought or compunction. Indeed, in as many cases, or more, of intellectual derangement or

defect, the moral perception and sense is preserved and powerful as an informant of wrongness in act and conduct, and causal motive, as it is lost and powerless in the intellectually sane.

Such being undoubtedly the state of matters in existence and reality, and the nature of the written law of the subject being what it is, what are we to do? How are we, in accordance with the principles of science and dictates of common sense, to proceed in the way of amendment? 1. The first step should clearly be the thorough renovation of the law—the total expunging of that which absurdly and erroneously ignores and denies the existence of a positive fact, and the substitution of statute based upon multitudinous observation and ascertained reality. 2. The next step should meditate such a general description and definition of cases of pure moral insanity as will embrace in general terms every known instance of the malady and its essential features, and exclude cases of delinquency with moral sense and responsibility—actual crime. 3. After this has been done, and not till then, the question of treatment should be fairly discussed, and, as far as possible, settled, taking into account the causation, nature, and pathology of the malady, as well as social bearings, differentiating special divisions and groups of cases for special modes of treatment—penitentiary, reformatory, segregative, medicinal, etc. 4. In considering any case judicially, the next step of the process, the questions arise—(1.) Does it fulfil the description, definitions, or conditions of moral insanity—fall, in fact, under the category? This involves investigation and diagnosis. (2.) What form of moral insanity is it? This will be determined by the causation, nature, and pathology of the particular instance. Lastly, What kind of treatment is most suitable?

Such is an indication of the only mode of dealing with the perplexity of moral insanity which can ever in reason and reality satisfy justice and tend to good. Founded on the basis of human intuition as well as strict scientific method, its only possible failure must consist in and result from imperfection and ignorance of those who frame and apply.

As these yield to science and enlightenment, possibility of failure will become more distant, justice will be more surely satisfied, humanity will triumph, and goodwill accrue. The foregoing statements may appear to the blindly conservative Utopian, but, assuredly, the sooner that the present delusive and fictitious law is abolished, and a more rational, equitable, and scientific procedure instituted in such cases adopted, the better for the credit of law makers and dispensers, and the sake of the unfortunate morally insane.

I am, &c.

Durham Co. Asylum, March 23.

KENNETH McLEOD, A.M., M.D.

#### ETYMOLOGY OF "PYTHOGENIC."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—“F.R.S.” undertakes to resolve my difficulty as to the derivation of “Pythogenic,” and informs me that the word is derived from *πυθομαι* and *γεινομαι*. He says, indeed, from the root of the Greek verb *πυθομαι*; but where is this root to be found as a separate word? Surely this is a very unusual mode of origin for a Greek compound. Will “F.R.S.” oblige me by citing, from good authors, a few examples of Greek adjectives compounded of two verbs? The words he quotes as being similar to pythogenic in their mode of formation,—*γηγενης*, *κεφαλογενης*, *πυριγενης*,—are, unfortunately, specimens of a directly opposite kind, being all compounded of a verb and a noun.

“F.R.S.” triumphantly refers to *pyogenic* as “a similar word to *pythogenic*.” On the contrary, it is quite dissimilar, being formed from a noun and a verb, like the three Greek adjectives above quoted. It is surely very unreasonable to make the term “pyogenic” perform the double duty, assigned to it by “F.R.S.,” of signifying, when applied to a membrane, a producer of pus; and, when applied to a fever, a product of pus! If pyogenic membrane be a membrane producing pus, then pythogenic fever, according to “F.R.S.’s” rule, should mean a fever producing putridity.

I did “refer to a good dictionary,” probably the same from which “F.R.S.” obtained his learned-looking bit of Sanskrit, and, as far as I have looked into Liddell and Scott, I do not find that two verbs are ever yoked together in composition to form such adjectives as “pythogenic.”

“F.R.S.” winds up by saying that “the word enteric, which Dr. Tweedie and Quærens so strangely agree in upholding, . . . pledges one to an opinion that the fever is the result, and not the cause, of the intestinal lesion.” The word pledges one to nothing of the kind; it simply announces the fact that intestinal phenomena and a certain form of fever are always associated together.

I signed my first letter of inquiry “Quærens;” but, after “F.R.S.’s” explanation, I am quite content,—quoad bad Greek,—to accept his preferred cognomen of

QUÆRENS.

March 21.

#### POISONING WITH MORPHIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—My attention has just been drawn to a letter from Dr. Morell Mackenzie, in your Journal of March 14, in which that gentleman disputes the accuracy of my statement that opiates are absorbed with equal rapidity from the rectum as from the stomach. As Dr. Mackenzie seems to think that this doctrine is peculiar to myself, and based on a solitary case, I must now state the very substantial reasons which enforce it.

First, as to the *a priori* argument from anatomy, I am quite unable to understand Dr. Mackenzie's allusion to “structural” differences which make the rectum inferior to the stomach as an absorbent. The structural conditions which are necessary to the effective performance of absorption of soluble matters are, I take it, a delicate mucous membrane, and a copious supply of sub-mucous veins; and it is difficult to imagine that the stomach can be superior, as regards this combination, to the rectum.

Secondly, as to the argument from clinical and experimental facts.

1. So far is it from being true that alcoholic liquors act comparatively slowly when introduced per rectum, that I have often known undoubted symptoms of the constitutional action of alcohol to commence within two or three minutes after the injection of an ounce of brandy, or a corresponding dose of wine. Moreover, it is possible (as is probably known to every practical toxicologist) to intoxicate animals with the greatest rapidity by injections into the bowel, which is only inferior, as a conduit for this agent, to the peritoneum.

2. Liebig mentions (*Animal Chemistry*) that a solution of common salt, in the proportion of one part to eighty of water, disappeared so completely in the rectum, that an evacuation one hour afterwards was found to contain no more than the usual proportion of salt.

3. I have repeatedly observed typhoid fever patients in whom cinchonism has been produced very quickly by injections of quinine. One patient of my own was decidedly cinchonised within forty minutes of using a single injection containing one scruple of quinine.

4. With regard to opium and its preparations, it happens that the evidence is particularly copious. A very common measure for the arrest of colliquated diarrhoea in patients who are greatly exhausted, is the injection of a small dose of laudanum (ten minims is amply sufficient); and it is a frequent occurrence for the miserable sense of nervous depression to be greatly relieved in from ten to fifteen minutes after this has been done, and for a general stimulant effect to be produced, which is obviously due to the drug. Again, I have in several cases observed the pain of severe cystitis to be soothed, and sleep produced within half an hour, by the use of a suppository containing no more than one-fourth of a grain of morphia; and I have been informed by Surgeons that the same remedy is very effectual in relieving chordec.

Lastly, I have made direct experiments as to the comparative rapidity of action, upon myself, of morphia introduced by different routes into the body, and I am completely satisfied that, with me, the rectum (proper precautions being taken) is a more rapid channel of introduction than the stomach, though not so convenient; in fact, it is about on a par with the cellular tissue as to the celerity with which morphia enters the system through it; and I have found that in cats, next to injection into the veins or the serous cavities, there is no more rapid mode of poisoning by opium than the use of rectal injections of morphia.

In short, the more we extend our observations, the more probable does it become that for all soluble substances the rectum forms quite as effective a channel as the stomach. I need not say, however, that the bowel must be empty at the time of the injection, or its absorption will be delayed; possibly it is the neglect of this precaution which has led to the idea which I have combated.

I am, &c. FRANCIS ED. ANSTIE, M.D.  
15, Onslow-square.

THE PROGRESS OF SCIENCE.—RESPIRATION ABOLISHED, "OWING TO THE EXCELLENCE OF ARTIFICIAL LIGHT!"

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.  
SIR,—I saw it stated the other day in a scientific journal that Dr. Gibb, who was demonstrating his larynx at St. George's Hospital, "was enabled to open and shut his glottis at pleasure, without breathing." Perhaps one of the spectators will kindly inform me, as I am a great collector of curiosities, whether the experimenter turned blue in the face from want of breath, and how the air was prevented from passing into and out of the air-tubes during this extraordinary feat. I am, &c.

Lowther Arcade, Monday. GOBEMOUCHE.

Vide *Lancet*, March 21, 1863, *Medical News*, "Auto-Laryngoscopic Demonstrations."

INSURANCE SOCIETIES AND MEDICAL FEES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.  
SIR,—The enclosed correspondence may be interesting to the Profession. (Letter No. 1.)

"High-street, Stourbridge, March 21, 1863.  
"SIR,—Henry Grove, who is insured in your office, applied to me this morning to sign a certificate respecting the nature of his injuries, with many other questions respecting the date when the injury was received, and its probable duration, etc.

"I shall be happy to supply you with information on these subjects on the receipt of a fee. I am, sir, yours obediently.

"THOS. MASSEY HARDING.  
"To the Secretary of the Norwich and London Accident and Casualty Insurance Company, St. Giles'-street, Norwich."  
(Reply.)

"Norwich and London Accident and Casualty Insurance Association, St. Giles'-street, Norwich, March 23, 1863.

"SIR,—You seem to be labouring under some mistake in supposing that an office which takes a few shillings a year can afford to pay medical fees the same as if the premium were pounds. We do not desire to obtain any information from Medical men without its being paid for, only we say that we are not in a position to pay it. The directors will not recognise Henry Grove's claim without a Medical certificate; see the fifth condition on his policy. We have settled nearly 4000 claims, and this is only the second time of being asked to pay a fee.

"Yours obediently,  
"T. M. Harding, Esq., Stourbridge." "CHAS. R. GILMAN.  
(No. 2.)

"High-street, Stourbridge, March 24, 1863.  
"SIR,—I have received your letter, in which you say that I seem to be 'labouring under some mistake,' etc. It is not a question of amount, nor do I wish that my fee should be in any way out of proportion to the amount insured. You require information respecting an injury for your own guidance and protection, and in my opinion you ought to pay for it. If you intend to throw that expense upon the person insuring, you should take care that the insurer fully understands his position. I simply decline to give any information to your office without a fee, and, if you will not pay it, Mr. Grove must.

"If you have occasion to favour me with any further correspondence, be pleased to remember that I do not 'labour under any mistake.'  
"I am, sir, yours obediently,

"THOS. MASSEY HARDING.  
"To the Secretary of the Norwich and London Accident and Casualty Insurance Association."

"High-street, Stourbridge, March 21, 1863.  
"SIR,—Mr. Bristow, of this town, who is insured in your office has asked me to sign a certificate respecting the nature of his injuries, the date when received, probable duration, etc., for your information.

"I shall be happy to give the information on receipt of a fee.  
"I am, sir, yours obediently,

"THOS. MASSEY HARDING.  
"To the Secretary of the Railway Passengers' Assurance Office, 64, Cornhill, London, E.C."  
(Reply.)

"Railway Passengers' Assurance Office, 64, Cornhill, London, E.C.  
"DEAR SIR,—I am in receipt of yours of 21st inst., but am at a loss to understand why you apply to me for a fee in Mr. Bristow's case, as I have never applied to you for a certificate. I require of Mr. Bristow, as of any other claimant, certain evidence in support his claim, and it is for him to obtain that evidence, and if necessary pay for doing so.

"I supposed that giving a certificate if required was as much incidental to the attendance of a Surgeon as the supply of pills and plasters; but, so far as forming an opinion on any case, I find it more useful to retain a Surgeon as our referee in most districts, and Mr. Freer acts for us in yours.

"I am, Sir, yours truly,  
"W. J. VIAN."

"High-street, Stourbridge, March 24, 1863.  
"SIR,—I have received your letter this morning. I am of opinion that the information required in the certificate offered to me for signature is for your guidance and protection, and ought therefore to be paid for by you, but of course you can leave it to the person insuring to pay for it if you think proper. I am also of opinion that your system of employing a Medical gentleman to call upon and examine the patients of other practitioners for your satisfaction is a very offensive mode of obtaining information, which would be more naturally obtained from the gentleman who has the actual charge of the patient.

I beg to say that it is my intention to send the correspondence to the *Medical Times*, that the question may receive the attention of the Profession.

"I am, Sir, yours obediently,  
"THOS. M. HARDING.  
"To the Secretary of the Railway Passengers', &c."

APPOINTMENTS FOR THE WEEK.

March 28. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.  
ROYAL INSTITUTION, 3 p.m. Professor Max Müller, "On the Science of Language" (Second Series).

30. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.  
MEDICAL SOCIETY OF LONDON, 8½ p.m. Dr. Palfrey, "On Obstructive Dysmenorrhoea Treated by Incision of the Cervix Uteri;" and other Communications.

31. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

April 1. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.  
OBSTETRICAL SOCIETY OF LONDON, 8 p.m. Dr. Swayne (Bristol), "On a Case of Cæsarian Section." Other Papers by Dr. Skinner (Liverpool), Dr. Tyler Smith, Dr. Eastlake, Dr. Gervis, etc.

2. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.  
HARVEIAN SOCIETY, 8 p.m. Dr. Pollock, "On Pneumothorax."

3. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

**PICHOT & MALAPERT'S CARBONIFEROUS PREPARATIONS.**

*Extensively used in all the French Military and Civil Hospitals.—(See Notice in MED. TIMES AND GAZ., March 7, 1863, p. 248.)*

CARBONIFEROUS CHARPIE, in 1 lb. and  $\frac{1}{2}$  lb. boxes, 7s. 6d. per lb.; Bags of ditto, ditto, each box containing 10, 4s. per box.

CARBONIFEROUS PAPER FOR COMPRESSES (containing 100 Dressings), 2s. 3d. per packet;

Ditto, ditto, large size (containing 25 Dressings), 1s. 4d. per packet; Ditto, ditto, Tissue, 9d. per sheet.

*May be had of all Respectable Chemists.*

WHOLESALE AGENTS—S. MAW & SON, 11, ALDERSGATE-STREET, LONDON, E.C.,  
Of whom Pamphlets on its uses and mode of application may be had, post free, on application, gratis.

*Pulvis Jacobi ver, Newbery*

is the ORIGINAL & GENUINE, was ESTABLISHED A.D. 1746,

And is Prescribed, with the greatest success, "by the highest authorities," for Fevers, Ague, Cerebral Congestion, Rheumatism, Chills, Influenza, &c. &c.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.;  $\frac{1}{4}$  oz., 3s. 4d.

**NEPENTHE, OR ANODYNE TINCTURE.**

OBTAINED EXCLUSIVELY FROM OPIUM.

Prepared only by FERRIS, TOWNSEND, LAMOTTE, & BOORNE, Manufacturing Chemists and Wholesale Druggists, Bristol.

Messrs. FERRIS AND COMPANY take leave to direct the attention of the Medical Profession to a selection from various reports upon the use of this most valuable form of Opium. NEPENTHE may be used with perfect safety in every case where an opiate is indicated; and, from the peculiar process by which it is prepared, it is deprived of all constituents which render the Tinctura Opii, and most other forms of opium, in numerous instances, wholly inadmissible. NEPENTHE is always of uniform strength, and, in this respect, possesses high advantages. It may be procured direct from the Manufacturers, Messrs. FERRIS and COMPANY, Bristol, or through the leading Wholesale Druggists in London, and from most respectable Dispensing Chemists in Great Britain and Ireland. Every bottle has a fac-simile of Messrs. FERRIS and COMPANY'S Signature pasted over the Cork, to imitate which is forgery.

The price of NEPENTHE to the Profession is 8s. per lb., and the dose the same as the Tinctura Opii.

*Report from F. PORTER SMITH, Esq.*

I have pleasure in bearing testimony to the decided advantages possessed by Messrs. Ferris and Company's preparation of Opium called "Nepenthe" over other preparations of that important drug. I have used it for several years in Cancer of the Uterus, continuing it, with scarcely abated advantage, as a sedative, in one such case, for the long period of eighteen months, in doses of, at the utmost, half a drachm, which served the purpose to the end. I have used it in "Subcutaneous Injection" for Neuralgia, without producing any local irritation, such as abscess, &c. In the cases of unusually

severe "after-pains" in connexion with labour, I can strongly recommend and endorse its successful and satisfactory employment. I have never met with any unpleasant symptoms, such as sometimes occur in some constitutions after the administration of morphia, &c., during an extensive use of this valuable addition to that "Practical Pharmacopœia" which waits for no "imprimatur" from College or Council.

F. PORTER SMITH, M.B. Lond.,  
Everecrech, March, 1862. Associate of King's College, London, &c.

\* \* \* Fresh Reports will be published in the Medical Journals from time to time.—Bristol, 1862.

TRADE MARK

**CHLORODYNE**

WAS DISCOVERED AND INVENTED IN THE YEAR 1848 BY  
DR. J. COLLIS BROWNE. M.R.C.S.L. EX. ARMY-MED. STAFF.

AND IN 1856 HE CONFIDED  
THE ORIGINAL AND ONLY FORMULA  
FOR ITS MANUFACTURE  
SOLELY TO J. T. DAVENPORT, PHARMACEUTIST,  
33, GREAT RUSSELL ST. BLOOMSBURY SQUARE, LONDON.  
REGISTERED, 1856.

**NOTIFICATION.**

THE attention of Medical Men is directed to the Piratical application, by some parties in the Trade, of the term "Chlorodyne" to various mixtures compounded of Chloric Æther Opium, Indian Hemp, and Peppermint, in Imitation of the ONLY Genuine preparation of this name.

The dangerous expedient of encouraging or advocating the assumption of a name specifically indicating a particular property or remedy—such as *Chlorodyne* is to spurious imitations and substitutions—ON THE GROUND OF CHEAPNESS, is a subject of surprise and grave reproach, supremely so, when the adulteration, sophistication, and tampering with Drugs, becomes so serious and important a consideration in the successful practice of Medicine.

The fact of these Piracies must fully convince the Profession of the extraordinary efficacy of the Genuine Chlorodyne; whereas the sad results and disappointment arising from the use of spurious compounds cannot be expressed.

Each Genuine Bottle bears a Red Stamp, with the words, "Dr. J. COLLIS BROWNE'S CHLORODYNE," in White Letters.

To be obtained from all Wholesale Druggists in 1oz., 2oz., 4oz., and 8oz. Bottles.

**NOTICE. — REDUCTION OF PRICE TO THE PROFESSION.**

In Bottles, 1oz., 3s.; 2oz., 5s.; 4oz., 8s.; 10oz., 15s. To Hospitals and Charities in large quantity, a Liberal Discount.

ORIGINAL LECTURES.

PROFESSOR HUXLEY'S LECTURES

AT THE

ROYAL COLLEGE OF SURGEONS.

LECTURE III.

(Being the Second of Six Lectures on Classification.)

(Continued from page 314.)

In the next group, that of the *Lamellibranchiata*, which comprises those creatures which we know as mussels, cockles, and scallops, all the fabricators of the so-called bivalve shells, we meet with an important advance in organization. The body in all these animals, as is exemplified by this diagram (Fig. A) of a freshwater mussel (*Anodon*), is included within a mantle or "pallium," which is formed by a prolongation of the dorsal integument,—a structure in principle quite similar to that which we met with in the *Brachiopoda*.

FIG. A.

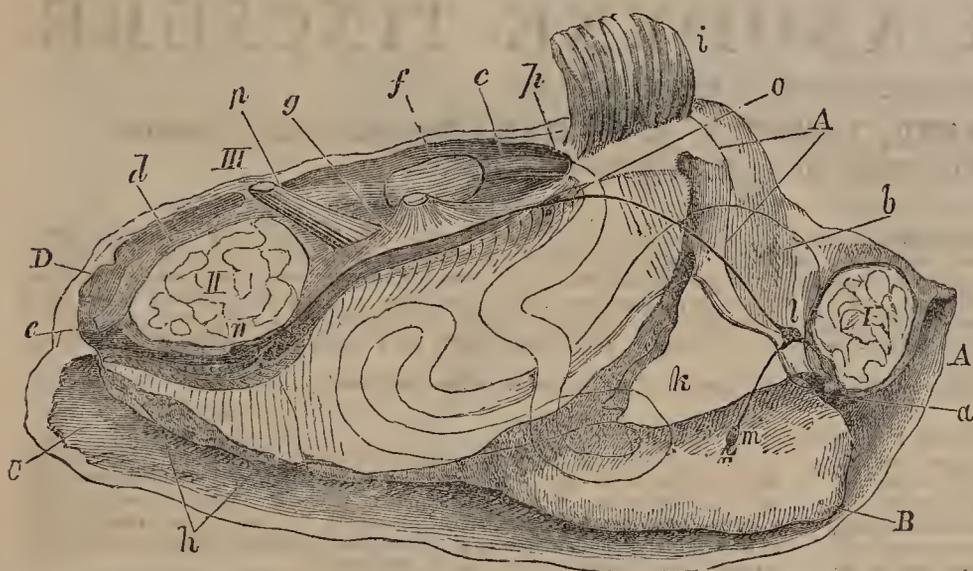

FIG. A.—Sectional diagram of a freshwater mussel (*Anodon*). A A, mantle, the right lobe of which is cut away; B, foot; C, branchial chamber of the mantle cavity; D, anal chamber; I, anterior adductor muscle; II, posterior adductor muscle; a, mouth; b, stomach; c, intestine, the turns of which are supposed to be seen through the side walls of the foot; d, rectum; e, anus; f, ventricle; g, auricle; h, gills, except i, right external gill, largely cut away and turned back; k, labial palpi; l, cerebral, m, pedal, n, parieto-splanchnic ganglia; o, aperture of the organ of Bojanus; p, pericardium.

The nervous system presents a no less distinct advance than the other organs. All Lamellibranchs possess at least three pairs of principal ganglia—a cerebral pair at the sides of the mouth, a pedal pair in the foot, and a third pair on the under surface of the posterior adductor muscle, which are commonly called "branchial," but which, as they supply not only branchial, but visceral and pallial filaments, may more properly be termed "parieto-splanchnic." Three sets of commissural filaments connect the cerebral ganglia with one another, with the pedal, and with the parieto-splanchnic ganglia. The inter-cerebral commissures surround the mouth, and the other two pairs of cords extend respectively from the cerebral to the pedal, and from the cerebral to the parieto-splanchnic ganglia.

Finally, there is always in these animals an external shell, which is formed as an excretion from the surface of the lobes of the mantle, and is composed of layers of animal matter hardened by deposits of carbonate of lime, which may or may not take a definite form, and so give rise to "prismatic" and "nacreous" substance. As the lobes are right and left, so the valves of the shell are right and left, and differ altogether from the valves of the shell of the *Brachiopoda*, which are anterior and posterior. The valves of the shell can be brought together by adductor muscles. Of these one (II) always exists posteriorly on the neural side of the intestine. A second (I) is commonly found anteriorly to the mouth on the hæmal side of the intestine.

The hiatus between the next class, which is termed *Branchio-*  
VOL. I. 1863. No. 666.

But there is this essential difference between the two,—that whereas in the *Brachiopoda* the mantle lobes corresponded with the anterior and posterior regions of the body, in the *Lamellibranchiata* they correspond with the right and left halves of the body. The intestine, which always terminates by a definite anus between the mantle lobes at the posterior end of the body, has its first flexure neural. There is always a well-developed heart, which is much more complex than that of the *Ascidians* or *Brachiopods*, being divided into distinct auricular and ventricular chambers. Commonly, there are two auricles and one ventricle, as is the case in *Anodon*; but in other *Lamellibranchiata*, such as the oyster, there is a single auricle and a single ventricle, and in some exceptional cases there are two auricles and two ventricles, forming two distinct hearts. Distinct respiratory organs, which usually have the form of lamellæ, as the name of the class implies, are found in all *Lamellibranchiata*, and are situated upon each side of the body, in a chamber which extends between the foot and the mantle lobes in front, and between the mantle lobes posteriorly (Fig. B). The branchial organs may consist of distinct filaments, or of plates composed of tubular rods supporting a network of blood-vessels, and covered with cilia; by the action of which they are constantly bathed by currents of water.

FIG. B.

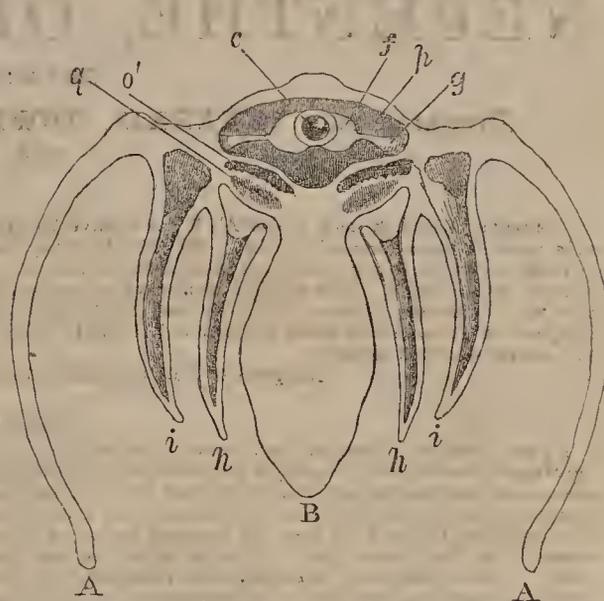

FIG. B.—*Anodon*, vertical and transverse section of the body through the heart; f, ventricle; g, auricles; c, rectum; p, pericardium; h, inner; i, outer gill; o', organ of Bojanus; B, foot; A A, mantle lobes.

*gasteropoda*(a) in this table, and that just defined" is considerable, though perhaps not quite so well marked as that between the *Ascidians* and the *Lamellibranchiata*. This group, which contains the whelks, periwinkles, sea-slugs, and the *Heteropods* of Cuvier, consists of animals which, like the *Lamellibranchs*, possess (in their young state, at any rate) a mantle; a foot, which is the chief organ of locomotion; and three principal pairs of ganglia—cerebral, pedal, and parieto-splanchnic. When they are provided with a heart, which is usually the case, it is divided into auricular and ventricular chambers; but the mantle, instead of being divided into two lateral lobes, is continuous round the body, and when it secretes a shell from its surface, that shell is either in a single piece, or the pieces are repeated from before backwards, and not on each side of the median line. The shell of a *Branchiogasteropod* may, therefore, be univalve, or composed of a single conical piece, straight or coiled; or it may be multivalve—formed of a number of segments succeeding one another antero-posteriorly; but it is never bivalve.

Sometimes a shelly, horny, or fibrous secretion takes place from the foot, giving rise to a substance resembling the byssus of some *Lamellibranchs*, or to the so-called "operculum," which serves to protect the animal when retracted into its shell; but as these structures are developed from the foot and not from the mantle, they have obviously no homology with

(a) I have here changed the order in which the classes were treated of in my Lectures, though the substance of what I said is unaltered.

the valves of either a Brachiopod or a Lamellibranch. The *Branchiogasteropoda* commonly possess a distinct head, provided with a pair of tentacles and a single pair of eyes, both of which are supplied with nerves from the cerebral ganglia. Cephalic eyes of this kind are not known in the *Lamelli-branchiata*. But the characters which most definitely distinguish the *Branchiogasteropoda* are to be found in the alimentary canal. The cavity of the mouth is invariably provided with an organ which is usually, though not very properly called the tongue, and which might more appropriately be denominated the "odontophore." It consists essentially of a cartilaginous cushion, supporting, as on a pulley, an elastic strap, which bears a long series of transversely disposed teeth. The ends of the strap are connected with muscles attached to the upper and lower surface of the hinder extremities of the cartilaginous cushions, and these muscles, by their alternate contractions, cause the toothed strap to work backwards and forwards over the end of the pulley formed by its anterior end. The strap consequently acts, after the fashion of a chain-saw, upon any substance to which it is applied, and the resulting wear and tear of its anterior teeth are made good by the incessant development of new teeth in the secreting sac in which the hinder end of the strap is lodged. Besides the chain-saw-like motion of the strap, the odontophore may be capable of a licking or scraping action as a whole.

The other peculiarity of the alimentary canal of the *Branchiogasteropoda* is that the alimentary canal is always bent upon itself, at first, not to the neural, but to the hæmal, or heart side of the body—the rectum very commonly opening into the mantle cavity above the cephalic portion of the body.

In most *Branchiogasteropoda* the foot is a broad, flat, muscular body, without any distinct division of parts; but in some forms, such as the *Heteropoda* of Cuvier, it is divided into three very well-marked portions—an anterior, a middle, and a posterior, which are termed respectively the *propodium*, *mesopodium*, and *metapodium*, while the *Aplysiæ*, in which the foot proper has the ordinary form exhibit developments from its lateral and upper surfaces in the form

of great muscular lobes, which serve as a sort of aquatic wings to some species, and are termed *epipodia*.

The *Branchiogasteropoda* are such of the *Gasteropoda* of Cuvier as breathe water either by means of the thin wall of the mantle cavity (*Atlanta*, e.g.), or by special pallial branchiæ (*Pectinibranchiata*, *Tectibranchiata*, etc.), or by certain parts of the integument of the body (*Nudibranchiata*) more or less specially modified. The next class, the *Pulmo-gasteropoda*, (b) on the other hand, are the Pulmonate *Gasteropoda* of Cuvier, the snails and slugs, which agree with the *Branchiogasteropoda* in the general characters of their body, mantle, nervous and respiratory systems, and in possessing an odontophore, but differ from them, not only by breathing air by means of the thin lining of the pallial chamber, but, as I believe, by the direction of the flexure of their intestine. A careful dissection of a common snail, for example (Fig. D), will prove that, though the anus is situated in the same way as in the *Branchio-*

*gasteropoda* on the dorsal or hæmal side of the body, the primary bend of the intestine is not to the hæmal but to the neural side, the eventual termination of the intestine on the hæmal side being the result of a second change in its direction.

How far this neural flexure of the intestine really prevails among the Pulmo-gasteropods is a question which must be decided by more extensive investigations than I have as yet been enabled to carry out.

The members of the class *Pteropoda* are small or even minute molluscs; all marine in habit, and for the most part pelagic, or swimmers at the surface of deep seas. Like the two preceding groups, they possess three principal pairs of ganglia, an odontophore, a mantle, which is not divided into two lobes, and which secretes a univalve shell, if any. But the propodium, mesopodium, and metapodium are usually rudimentary, and locomotion is almost wholly effected by the epipodia, which are enormously developed, and in most of the genera perform the office of aquatic wings still more efficiently than those of the *Aplysiæ*. Furthermore, the intestine is flexed towards the neural side of the body, and the head with the organs of sight are usually quite rudimentary. I include in this group not only *Criseis Cleodora*, *Hyalosa*, *Pneumodermon*, etc., but

FIG. C.

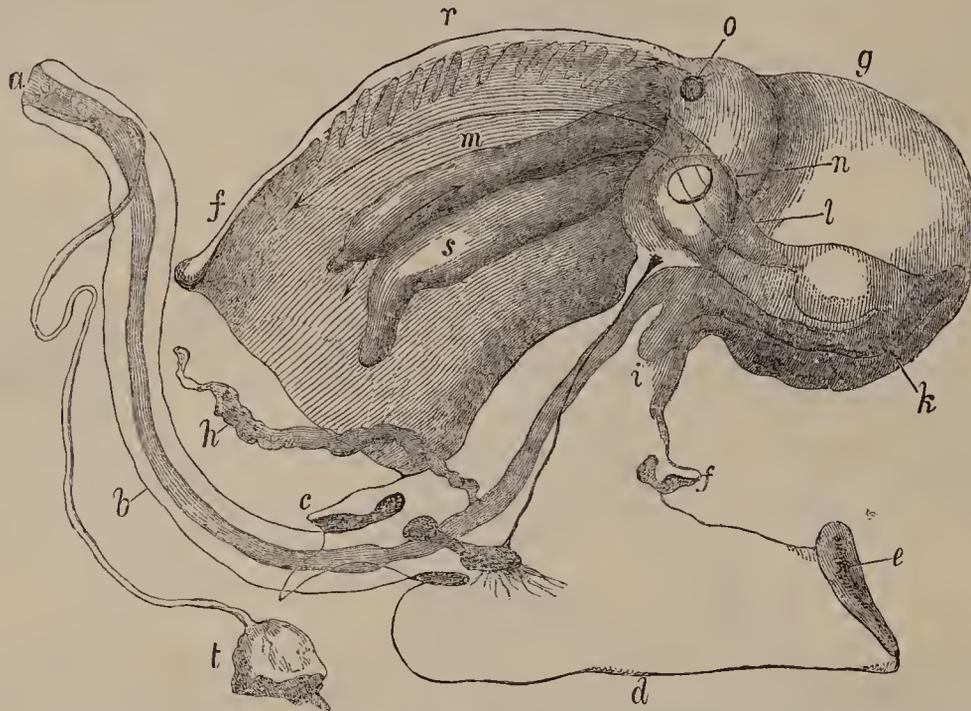

FIG. C.—Section of a female whelk (*Buccinum*). The organs marked *t* and *h* removed from their proper places; the others seen *in situ*. *a*, mouth; *b*, gullet; *c*, head; *d*, foot; *e*, operculum; *f*, free part of the mantle; *g*, that part which invests the visceral mass lodged within the shell; *h*, a gland of unknown function connected with the gullet; *i*, crop; *k*, stomach; *l*, intestine; *m*, rectum; *n*, heart; *o*, aperture of renal organ; *r*, mucous gland developed from the wall of the mantle cavity; *s*, oviduct; *t*, salivary gland. The arrows indicate the position of the branchiæ. The cerebral, pedal, and parieto-splanchnic ganglia closely surround the gullet, and the latter send off a long ganglionated cord towards the head and branchiæ.

FIG. D.

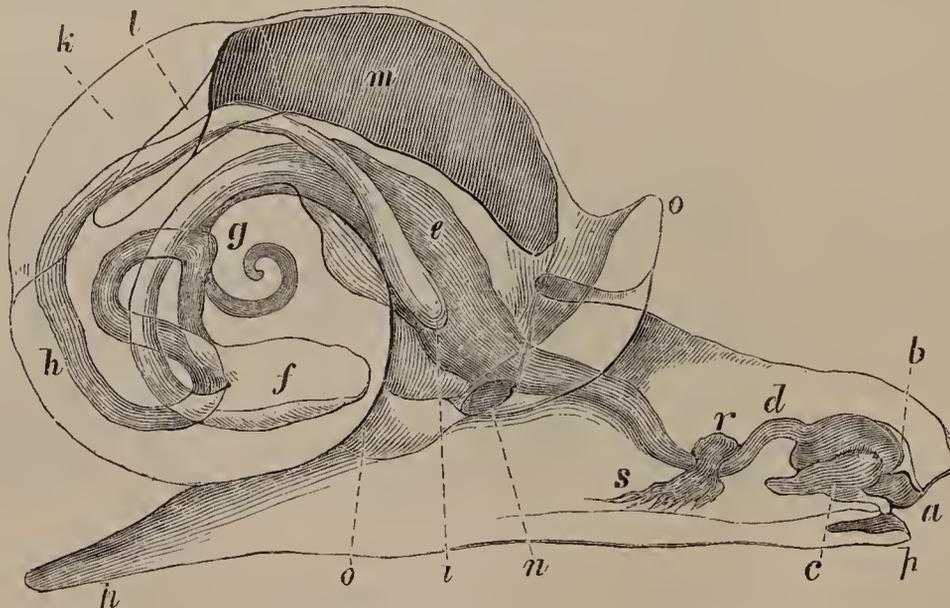

FIG. D.—Diagram exhibits the disposition of the intestine, nervous system, etc., in a common snail (*Helix*). *a*, mouth; *b*, tooth; *c*, odontophore; *d*, gullet; *e*, its dilatation into a sort of crop; *f*, stomach; *g*, coiled termination of the visceral mass; the latter is also close to the commencement of the intestine, which will be seen to lie *under* the œsophagus, and not over it as in the whelk; *h*, rectum; *i*, anus; *k*, renal sac; *l*, heart; *m*, lung, or modified pallial chamber; *n*, its external aperture; *o*, thick edge of the mantle united with the sides of the body; *p*, foot; *r*, cerebral, pedal, and parieto-splanchnic ganglia aggregated round the gullet.

(b) I adopt these convenient names at the suggestion of my friend Professor Greene.

also the aberrant genus *Dentalium*. The last class of which I propose to speak to-day, is that of the *Cephalopoda*—the Cuttle-fishes, the Squids, and the pearly Nautilus; a group definable by most marked and distinct characters from all the preceding, though it resembles them in fundamental characters. Thus, the mantle is related to the body as in *Pteropods* and *Gasteropods*; when an external shell exists it is composed of a single piece, and the *Cephalopods* have an odontophore constructed upon just the same principle as that of the other classes. The nervous system, the foot, and the epipodia exhibit the same primary relations as in these groups, and there is a marked head with ordinarily well-developed optic and olfactory organs. That which essentially characterises the *Cephalopoda*, in fact, is simply the manner in which, in the course of development (as Kölliker long since proved), the margins of the foot proper and the epipodia become modified and change their relations. The margins of the foot are produced into more or less numerous tentacular appendages, often provided with singularly constructed suckers or acetabula; and the anterior lateral parts of each side of the foot, extend forwards beyond the head, uniting with it and with one another, so that at length, the mouth from having been situated, as usual, above the anterior margin of the foot, comes to be placed in the midst of it. The two epipodia, on the other hand, unite posteriorly above the posterior margin of the foot, and where they coalesce, give rise either to a folded muscular expansion, the edges of which are simply in apposition, as in *Nautilus*; or to an elongated flexible tube, the apex of which projects beyond the margin of the mantle, called the "funnel" or "infundibulum."

The *Cephalopoda* present a vast number of the most interesting features, to which it would be necessary to devote much attention if we were studying all the organic peculiarities manifested by the class; but it is in the characters of foot and of the epipodium that the definition of the class must be chiefly sought. In addition, the flexure of the intestine is, in all cephalopods, neural; and the mouth is always provided with a horny or more or less calcified beak, like that of a parrot, composed of two curved pieces, which move in the median antero-posterior plane of the body, and one of which, that on the neural side, is always longer than the other.

[The publication of the figure illustrative of the structure of the *Cephalopoda* is unavoidably postponed.]

ORIGINAL COMMUNICATIONS.

NOTES ON CAUSES OF EARLY MORTALITY.

By J. WHITEHEAD, M.D.

No. V.

GENERAL DEATH-RATE.

It was previously shown that the highest rate of mortality of the viable human product occurs at the moment of birth; for, according to the French records, the percentage of still-births amounts to 4.27, representing the events of a day, while the general diurnal rate after birth is only .24 for France, and .18 for England. But to compare the deaths at birth with those of the most fatal epoch of life, namely, of the first seven days, it is found that the percentage for this period is 2.77, or .4 per day; so that the rate of mortality on the first day is at least ten times greater than on any one day afterwards.

The first year's death-rate for England in 1859 was 15.29 to 100 births; that for France in 1856, 16.02. As from the first to the fourth week during the first month, and for each succeeding month during the first year, as was exhibited in the preceding article, so also in similar order, though with lessening pace at each move, does the death-rate decrease, from 15.29 per cent. of the births in the first, down to .29 per cent. in the fifteenth year,—the lowest annual estimate until after the age of seventy years.

In France the same order of decrease is observable, and takes place with like regularity; the number of deaths being,—

During the first year	. . . . .	451 daily.
From 1 to 5 years	. . . . .	259 "
" 5 to 10 "	. . . . .	86 "
" 10 to 15 "	. . . . .	54 "

After which the estimate, as in England, gradually increases, and is not again so low until after the age of seventy years.

Hence it would appear that at or about the age of fifteen years the system is much less susceptible of diseased action, or more powerfully resistant of its assaults, than at any other time of life; and that at this season it possesses in highest perfection the qualities of energy of reparation and resiliency,—the integrity of the physical functions being no longer liable to be imperilled by infantile maladies, and the soul as yet unharassed by care.

It has been roundly stated, and seems to be popularly believed, that half of the children born die before they have attained the age of five years. This erroneous notion, for erroneous it is, has probably had its origin in a solitary instance, or possibly in a few instances of a high death-rate in some unhealthy locality, or during the prevalence of an unusually fatal epidemic, and has acquired a general meaning by repetition. Such examples, indeed, it would be possible to adduce. At the present rate of mortality in this country, however, the proportion of deaths in relation to births does not amount to fifty per cent. until after the age of sixty years; the number of deaths which had occurred at this age in England in 1859 being 49.7 to 100 births.

Even during the two most fatal years that have been known in France in the present century, when the number of deaths considerably exceeded that of births, the death-rate did not reach fifty per cent. of the births until after the age of thirty years. In the year 1854, for instance, with a notable failure of the crops—not only of cereals, but of all alimentary substances—the ravages of the most fatal cholera epidemic which that country has yet known, and the exhausting demands of the Crimean war, the number of deaths exceeded that of births to the amount of 67,318; and in the following year, although the force of this compound panic exhibited signs of considerable amelioration, the deaths were still in excess of the births to the amount of 37,274. Yet in the former of these two years the death-rate reached fifty per cent. of the births only at 31½ years, and in the latter at about 33½. Again, in 1857, the deaths, although considerably below the births in number, still exceeded the normal average by about 25,000, the rate of mortality did not reach fifty per cent. until the age of 41½.

The general death-rate in England for the twenty-three years ending with 1860 stands, in its relation to births, at 67.27 per cent. Dividing this term of twenty-three years into two periods of thirteen and ten years respectively, the following average percentages will be furnished:—

	To 100 births.
From 1838 to 1850 . . . . .	69.73 deaths.
" 1851 to 1860 . . . . .	65.06 "

Showing a diminution in the rate of mortality for the last as compared with the first of these periods to the amount of 4.67.

This result, however, is not to be looked upon as a fair representation of the actual decrease, seeing that with the first group are included the years of the Irish famine, whereby the death-rate was augmented to a pitch considerably above the usual average. Setting aside therefore the five years—from 1846 to 1850—during which this panic and its immediate consequences continued to operate, we have in contrast the results of two remote periods, in each of which the public health was uninfluenced by any disturbing agency sufficiently powerful to change the relations beyond the ordinary scale of fluctuation.

	To 100 births.
From 1838 to 1845 . . . . .	67.50 deaths.
" 1851 to 1860 . . . . .	65.06 "

So that the average amount of decrease in the general death-rate between the first and second of these periods is represented by 2.44.

But the actual amount of increase in the duration of life which has taken place during the twenty-three years specified is much greater than the above figures would seem to indicate. The death-rate having in fact undergone a gradual declension—with the exception of the interruption caused by the Irish famine, from 1838 to 1860, as may be seen by the subjoined figures—passing over the disastrous period referred to:—

	Total births.	Total deaths.	To 100 births.
1838	492,574	342,547	69.54 deaths.
1844	540,763	356,933	66.00 "
1851	615,865	395,396	64.20 "
1860	684,048	422,721	61.79 "

The difference between the first and last items in the last column of the preceding table is 7.75, which sum, in fact,

represents the real value of improvement in the duration of life which has been effected in this country during the twenty-three years ended 1860.

The year 1860 was remarkably healthy, the proportion of deaths having been lower in that than in any previous year on record, and probably as low as we need expect it to be for some time hence. It would be strange indeed were the duration of life to increase during the next quarter of a century in an equal ratio with that of the last, and would go far towards realising M. Flourens's estimate of man's natural term of life at 100 years instead of threescore and ten.

In producing a statement, therefore, of the death-rate at different ages, it may be well, instead of adopting the results furnished by this one very favourable year, to take the average of the three years ending with 1860, as follows:—

*Average Death-rate at Different Periods for 1858, 1859, and 1860.*

	Deaths to 100 births.		
	Males.	Females.	Total.
1st year . . .	8.55	6.74	15.29
2nd „ . . .	2.74	2.57	5.31
3rd „ . . .	1.38	1.36	2.74
4th „ . . .	0.92	0.93	1.85
5th „ . . .	0.65	0.67	1.32
5 to 10 years . . .	1.50	1.51	3.01
10 to 15 „ . . .	0.71	0.75	1.46
15 to 20 „ . . .	0.92	1.03	1.95
20 to 25 „ . . .	1.04	1.14	2.18
25 to 35 „ . . .	1.83	2.20	4.03
35 to 45 „ . . .	2.04	2.10	4.14
45 to 55 „ . . .	2.08	1.90	3.98
55 to 65 „ . . .	2.53	2.35	4.88
65 to 75 „ . . .	2.86	3.40	6.26
75 to 85 „ . . .	2.26	2.65	4.91
85 to 95 „ . . .	0.58	0.84	1.42
95 and upwards . . .	0.03	0.06	0.09
	32.62	32.20	64.82

Thus, for every 100 births during the three years ended 1860, there had occurred—

At the age of 5 years . . .	26.51 deaths.
„ „ 20 „ . . .	32.93 „
„ „ 50 „ . . .	45.27 „
„ „ 60 „ . . .	49.70 „
„ „ 95 „ and upwards . . .	64.82 „

The first and most remarkable feature noticeable in the preceding table is the high preponderance of male over female deaths during the first year; the proportions being 126.8 males to 100 females. In the second year the proportions stand at 106.6 to 100. From the end of the second to the fifteenth year these events occur in nearly equal proportions, fluctuating sometimes on one side, sometimes on the other, but on either side to a degree so fractionally small as to leave the general results almost equal—the widest variation between the two sexes, for the whole thirteen years, amounting only to .06.

From the age of fifteen to forty, the preponderance is very decidedly and unvaryingly on the female side, the proportions being—from fifteen to twenty years, 112 females; from twenty to twenty-five, 109.6; from twenty-five to thirty-five, 120.2; and from thirty-five to forty, 103 to 100 males respectively.

At forty, and often for two to five years later, the rates for the two sexes occur in nearly parallel order, after which they are reversed; the male deaths preponderating undeviatingly until about the age of sixty-eight, to an extent represented as follows:—From forty-five to fifty-five, 109.4 males; from fifty-five to sixty-five, 107.2; and from sixty-five to sixty-eight, 102 to 100 females respectively. After the age of sixty-eight the order is again reversed, the female death-rate being thenceforward, less or more, in excess to the end of life's limit.

In alluding once more to the popular notion respecting the high rate of infant mortality, it will be seen, on reference to the table, that the sum of deaths to 100 births at the age of fifty-five, stands at 47.26, and that at sixty years it is still .3 below 50 per cent. If, instead of the half of all born, it be meant that the half of all the deaths which happen occur before the age of five years, the assumption is still far wide of the truth. For instance:—The general death-rate being 64.82, it is evident that the half of this amount, namely,

32.41, will be found to have been completed at about the age of nineteen, as the sum of deaths up to twenty years—32.93—is only .52 in excess of the half.

(To be continued.)

## NECROSIS OF THE FEMUR AFTER FRACTURE — SUCCESSFUL OPERATION.

By ROBERT KNAGGS, Surgeon.

THE following case demonstrates that even under the most unfavourable circumstances Surgical operations may be attended with partial success:—

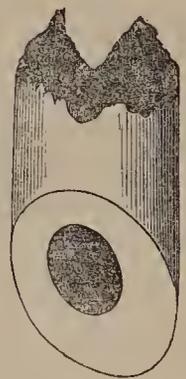

Michael K., aged 12, a pale, strumous-looking boy, of distinctly and decidedly serofulous parents, fell, in May, 1860, from the roof of a house at Baranquilla, South America, producing compound fracture of the shaft of the left femur. Part of the bone which extruded was sawn off, and the leg “set” after some fashion.

Early in the following year he came under my charge. There were two sinuses leading to necrosed bone; stiff knee (even allowing slight retroflexion); inverted foot, and dreadful deformity, which, of course, affected his gait (Fig. 1). I proposed to divide and reset the bone, at the same time removing the sequestrum, but owing to the difficulty of obtaining a chain-saw, I was unable to carry out my plan before August 13.

FIG. 1.

FIG. 2.

Assisted by Drs. Bleckley, of H.M.'s 14th Regiment, and Peschier, I made a longitudinal incision down to the bone, extending it from one inch below the trochanter-major to three inches above the external condyle. In doing this I liberated the sequestrum, of which I annex a sketch (Fig. 2). Natural dimensions, showing the sawn surface, whence bone was removed at the operation in May, 1860.

I then freed the adherent muscles of the thigh as much as possible from their morbid attachments to joined fractured portions and surface of the femur, passed the chain-saw in the line A B in the diagram (Fig. 3) around the point of union, severed it, sawed off a small portion of the upper fragment of the old fracture, to allow of its adjustment to the lower portion, brought the wound together, and treated the case as one of compound fracture.

In four months the sinuses had healed, the wound cicatrised, and the boy was on crutches, the foot being straight, the leg rather longer than prior to the operation, and flexible at both hip and knee-joints, and the femur straight, the point of union being apparently embedded in callus.

But after a few months one of the old sinuses re-opened, which I probed, discovering a small, movable necrosed wedge lying to the inner side of the junction. This I removed, and the sinus at once healed; but to this occurrence I date the lateral bend (which you see in the photograph) in the point of

union, producing deformity and comparative weakness of the limb.

FIG. 3.

FIG. 4.

In this case the gains (in spite of scrofulous predisposition) by the operation, were sixfold :—

1. Improved health and gait.
2. Satisfaction of patient.
3. Healed sinuses.
4. Removal of sequestrum.
5. Flexion of the knee-joint.
6. Corrected direction of the foot (Fig. 4).

He now walks without assistance. Trinidad.

## A MODEL HYSTERIC.

By ROBERT ELLIS,

Obstetric Surgeon to the Chelsea and Belgrave Dispensary.

I HAVE at length succeeded in permanently curing one of the most inveterate and obstinate cases of hysteria which I have ever known, or of which I have ever seen a record. As the lady has presented me with copious notes as to her previous history, which offers many points of interest, and some of practical value, I venture, with her consent, to offer a sketch of the case.

Miss A. B., an unmarried lady, in easy circumstances, in the winter of 1829 first became the victim of a disorder which, true to its protean character, assuming many aspects, never wholly left her for thirty years subsequently. She was at that time an excitable and impressible girl of eighteen; but I have been unable to discover any distinct emotional cause for the development of her hysteric disposition. She had a cough and pain in the right side, which was treated in the manner customary at that period,—by the repeated application of leeches. In the following spring she was taken to Dr. Abercrombie, who advised leeches again, followed by a blister, and this was repeated for several months, the purely hysteric element in her case never having been recognised. In 1831 she became a patient of the late Sir H. Marsh, who, recognising the real type of her disorder, prescribed, with a temporary relief, shower-baths and fresh air. But, her pain becoming very severe as winter approached, she again returned to Dublin, and this time was cupped on the side. From that moment a new symptom made its appearance in complete paralysis of the bladder. This was at first overcome by injections of turpentine and castor-oil and warm hip-baths. But in a short time these remedies lost all influence, and she was allowed to remain with the bladder unrelieved for thirty and forty hours. Sir Philip Crampton, who then saw her, and was apparently perplexed by her state, directed the catheter to be used twice daily. This, however, aggravated her distress from the excessive irritability of the urethra, to relieve which large

doses of laudanum were administered. She was now blistered on each side of the spine, and occasionally over the pubes, with but little good result. Issues were opened at intervals down the spine, and kept discharging for a considerable time. Thus the unhappy sufferer dragged on a painful life until 1834, when the hysteric cough came back, and was again attacked by repeated blisters. She had now fully learned the soothing influence of morphia, and was supplied with as much as she required. The disorder again returned to the bladder, and was this time overcome in a rational manner by the use of enemata of starch and opium into the rectum. So effectual was this remedy, that for many months the disorder did not recur; but the cough returned with its disappearance, and probably would have continued but for an intercurrent attack of diarrhœa, which left her quite free from all hysteric symptoms for several months.

In 1836, great domestic sorrow and anxiety prepared the way for a return of the old disorders. The bladder became as helpless as ever, and the old treatment of escharotics and issues to the spine was had recourse to. The hideous seams and numerous white cicatrices still visible on the back of this unhappy lady would almost suggest her having passed through some sanguinary field of battle. It was perhaps unfortunate for her that this violent treatment afforded a temporary relief, since it was persisted in to a most formidable degree. Suddenly the bladder acted as well as if nothing had happened, and now the patient got into a fresh trouble. She was taking pills with a minute quantity of strychnia. "I do not know whether the pills did me good or harm, but about this time I got a trick of falling down when I attempted to walk, and after a laudanum injection; but by keeping quite quiet came all right again." The hysteric paralysis had seized the voluntary muscles this time. Headaches and confusion of intellect now occurred, and offered a new and tempting opportunity for vigorous treatment. She was dry cupped again and again on the nape of the neck, and as soon as the glasses were removed a seton was inserted. Her dose of laudanum now reached two drachms.

In this state she became a patient of an eminent Physician at Leamington. There was now, instead of dysuria, a constant flow of pale urine. Her treatment commenced with calomel in cold gruel, and the laudanum was stopped. She became much reduced, and all her distresses were aggravated, especially at the menstrual periods. A tonic treatment was attended with a better result, and in a few months she became for a time tolerably well. Occasionally, however, the palsy of the bladder would recur, and was relieved by a dose of Jeremie's solution of opium. Then diarrhœa seemed to take its place, and I think there can be little doubt that this symptom had a purely hysteric origin. The old seductive influence of the opiates became again felt, and they were freely used.

In May, 1843, the bladder again giving trouble, suddenly, and without any previous warning, a severe attack of trismus ensued. The first invasion of this new malady was short, lasting only an hour or two at a time, and *invariably induced by irritation of the bladder*. Soon, however, it fully established its claim to a place in the chain of her morbid tendencies. The jaws would continue closed for a day, then for days, and at last even for months, with intervals of respite. In one of these the eyes suddenly closed and remained shut for a whole month! resisting all treatment and efforts to open them. During this period, the hysteric irritability being apparently at its height, she lost the use of every limb, and was perfectly helpless. The shock of being roughly carried down stairs and into a new house broke this spell, and in a tempest of hysterical passion she opened her eyes, and they only occasionally closed again for short periods. The trismus, however, would not let her go, and one long fit lasted for nine months, terminating, as usual, suddenly. She was taking much opium all this time. Sometimes she appeared comatose for eighteen hours, and then woke with an open mouth. If the trismus had lasted for days it was always at an end immediately on the occurrence of a fit of hysterics. Sometimes it yielded (as, indeed, might have been expected) on the sudden application of scalding water to the cheek.

Down to 1850 the state of this lady remained with little alteration, the trismus and the urinary difficulty only occasionally abating, and never wholly leaving her. In that year, during a period of home trial, the trismus relaxed, and was replaced by a violent spasm of the muscles on one side of the face, distorting the countenance in the most horrible manner,

and entirely preventing her swallowing even liquids. The inhalation of chloroform was then commenced, and proved effectual in subduing this spasm for a time. This new malady held its ground for a long time, and the chloroform became a necessity in order to enable her to take her meals. An attempt was then made to bring her under the influence of mercury, and she had the advantage of a scruple of calomel for a dose once a week! but no salivation ensued—in all probability the bowels and kidneys carrying out the drug. Profuse salivation was, however, at last the reward of a persevering inunction of mercurial ointment, with smaller doses of calomel often repeated. The spasm and trismus then vanished for two months.

An investigation into the state of the uterus was now made, and it was discovered that a small polypoid growth was hanging from the cervix. This was twisted off, but no change in her state ensued. She became rather worse, and used up at least a pound of chloroform every three weeks! Thus the case continued down to 1855, to the dismay of all who attended her. In the spring of that year a mimic paralysis agitans appeared on the scene, occurring with marked violence at the return of each menstrual period. In this state of hysteric oscillation, from the semblance of one disease to that of another, she came under my care. This was in the autumn of 1858.

The chloroform bottle, the opiate, and the catheter were now indispensable to her. She was sallow, haggard in expression, nervous and emotional in the highest degree. She still menstruated with great regularity, and her trismus and inability to empty the bladder remained as bad as ever. The teeth of the upper jaw, from constant pressure on the corresponding teeth below, were worn down in a remarkable degree, and the masseter muscles on each side had undergone a degree of hypertrophy very significant of their constant exertion during so long a period. A careful examination into her case, removed from it, with two exceptions, every trace of organic disease. The uterus was unhealthy. There was much congestion and some enlargement of the cervix and from its posterior lip hung down a small polypus, half the length of the little finger. There was in addition an unhealthy bunch of inflamed piles. After removing the polypus, and by repeated applications of nitrate of silver, and once or twice of stronger escharotics, the cervix was got into a perfectly healthy state. During this time a great amelioration took place in her state of general health. We had agreed to put the chloroform and the opiate on the shelf, and the catheter was also locked up. I then removed the piles, some by excision and some by ligature; "and from this," writes the patient, "I rose up in about ten days more free from pain than I had been for years." She then went into the country, and in a few months gained so much in strength and flesh as to be a wonder to herself and others—chloroform, opium, and the catheter were all disused and nearly forgotten.

It was certainly a triumph over the hysteria, but, as it proved, it was not of very long duration. The menstrual crisis was now approaching, and we were to have one more long struggle with this obstinate, often beaten, but unconquered foe. The monthly discharge beginning to occur irregularly, was at last attended on one occasion with much pain and discomfort and a feeling of bearing down, in fact a state of physiological congestion without relief by the usual flux. The old irritation appeared to leap back into its accustomed seat, and in April, 1859, this poor lady presented herself again as bad as ever, and, I am sorry to add, the opium had resumed its accustomed place on her dressing-table. I once or twice applied two or three leeches to relieve the uterine congestion, and always with benefit to her other symptoms, but as it was obvious this could not be repeated constantly, it became desirable, if possible, to overcome the hysteric disorder in some other way.

As there appeared to be some irritation in the canal of the urethra, relief was given to that by smearing the catheter with a little extract of belladonna. Hypodermic injections of morphia and other anodyne substances into the arm were then used, and invariably opened the mouth in a few minutes; occasionally also chloroform was given. In fact, the old routine was being gradually reopened, during the time I was awaiting the completion of one of Legendre and Morin's instruments for applying the electricity of induction, which Duchesne has called after the name of its discoverer Faraday. Upon the application of this remedial agent (the

only means as yet untried) my hopes of success were grounded, and, as the result showed, not without good cause.

I resolved to overcome the spasm of the muscles closing the jaw by throwing into action those whose function it is to open it, and which, in comparison with the former, were feeble and ill-nourished. Also it was determined to arouse the muscular contractility of the bladder, weakened by long abeyance of its activity and by the distension of its walls from long retention of urine. As the patient had been saturated with nervine tonics of every description for many years, she was to take nothing but a little tincture of sumbul in camphor-water occasionally.

The first application of the Faradising instrument to the depressors of the jaw was perfectly successful. The opposing muscles, oddly though it may sound, appeared taken by surprise, and yielded in a very few minutes with a sort of snap. I gave the patient a pretty strong dose of the electric current, and she was informed that it would continue to increase in its force every day until the mouth ceased to shut! Then with a moistened sponge on the conductors, the abdominal muscles were first acted upon. They were in a state of hysteric rigidity, and no doubt thus helped on the seeming paralysis of the bladder. On the right side there was much less contractility of these muscles—and, indeed, generally of the muscles of the body—than on the left, and this was developed in a striking manner by the varying tolerance of the electric current. There was also a most marked anæsthesia of the skin all over the right side of the body. By soldering on a small brass button of the size of a small pea to the end of a piece of brass wire, and then enclosing this in an elastic catheter, I manufactured an excellent instrument for carrying the electric current to the walls of the bladder itself without communicating it to the urethra, which would have been intolerably painful. By the moistened sponge conductor applied over the pubis, and by connecting the wire of the catheter with the other pole of the instrument, we succeeded in arousing the torpid muscular irritability of the bladder. This was the treatment on which I based my hopes of an ultimate victory over the bladder, and it proved in the end quite successful. At the same time, having removed the irritability of the urethra, I determined to overcome temporarily its contractility, by gently dilating it as in the removal of stone from the female bladder, and thus break the habit of retention of urine. This was effected under chloroform by Weiss's dilator, and excellent results ensued.

In a short time an obvious improvement took place in the patient's general state, and in her increased muscular powers. The depressors of the jaw acquired strength and a fuller increase of volume, and there was a very marked increase in the muscular power of the bladder, so that at last on using the catheter it projected a forcible stream, instead of the urine coming away in a mere passive flow. Occasionally a parenthesis of hysteric spasm would occur in the muscles of the face or of the neck. One morning my patient came to me with a mimic torticollis, and another time with her face drawn to one side in the most grotesque fashion. In the manner of a very decided rebuke for such unreasonable conduct, she received on each of these occasions so strong a dose of the electric current as to put an end to the difficulty as if by magic! We were thus gradually dislodging this martyring disorder, by, at the same time, giving her the muscular power to vanquish it, and calling out the will to that end. Much patience and a most determined resolution to conquer—at first wholly on my part, but afterwards very decidedly on that of the sufferer—brought this strange case to its close. The last thing done for her was on Saturday the 9th of June, 1860, and on Monday, 11th, she came, overflowing with gratitude, to announce herself set free from her disorder.

It is now nearly two years since this lady was discharged cured of her hysteria, and from that time to the present not even the shadow of any of her former annoyances has fallen over her history. Considering the long duration of her disorder—more than thirty years—its extraordinary pertinacity and obstinate recurrence, we may fairly conclude two years' absolute immunity to represent a complete cure. And as the menstrual function is now closed, and a source of irritation thus removed, we may fairly hope that this lady, who was called by some of the eminent Physicians who attended her the "Queen of Hysteria," has vacated her throne to some younger successor.

REPORTS OF HOSPITAL PRACTICE  
IN  
MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

NEURALGIA CONSEQUENT ON OLD FRACTURE  
OF THE LOWER JAW—EXTIRPATION OF A  
PORTION OF THE INFERIOR DENTAL NERVE,  
FOLLOWED BY SPEEDY AND COMPLETE RE-  
COVERY.

(Case under the care of Mr. WORMALD.)

[Reported by Mr. VERNON.]

J. F., aged 28 years, served in India before Delhi; during an engagement the right side of his lower jaw was broken by a blow from the butt end of a pistol. He was carefully treated in Hospital, but from time to time, at intervals, small pieces of bone became necrosed, and were thrown off by the mouth. Two years after the injury, when the fracture appeared repaired, he began to suffer intense pain around the seat of fracture. The pain was most agonising, fixed in one spot, not radiating up the face, much increased on eating or on any local pressure, and unaccompanied by any twitchings of the muscles. The pain came on for a short time nearly every minute, so that he would stop in the midst of a sentence, and seemed as if suffering most severely. He had not been free from pain for five minutes for the previous twelve months. He took large doses of quinine, of steel, and of various other drugs, with absolutely no relief. Morphia was injected into the gum, with almost no effect, on three several occasions.

On February 2, Mr. Wormald cut out a piece of the inferior dental nerve; he made an incision vertically through the lower lip immediately to the left of the symphysis; another incision, at right angles to the termination of the former one, was continued along the lower margin of the right side of the body of the jaw. This flap being turned up, the bone was exposed. With the exception of the loss of the molar teeth and their alveoli, there was nothing unnatural about the appearance of the bone, no signs of necrosis, no evidence of old fracture. The cancellous portion of the bone was freely opened with the saw and chisel, and the inferior dental nerve was exposed in its canal for about three-quarters of an inch, apparently natural in every way. This portion of nerve, with the neighbouring cancellous tissue, were freely extirpated with the gouge. Only one vessel required a ligature. The wound was stuffed with lint, and the edges accurately closed externally. The incisions healed almost by first intention. There was some little offensive discharge into his mouth, but after the operation an absolute cessation of his former pain.

He left the Hospital in ten days completely cured.

He presented himself at the Surgery on March 17; a small spicula of bone had been cast off into his mouth soon after he left the Hospital, but with that exception the operation had caused him no inconvenience, and had completely relieved his pain.

PARALYSIS OF THE LEFT LEG IN INFANCY—  
LIMB USELESS AND CUMBERSOME AT ADULT  
AGE, AND LIABLE, FOR SEVERAL YEARS, TO  
ULCERATIONS—AMPUTATION—EXAMINATION  
OF THE LIMB AFTER REMOVAL.

(Case under the care of Mr. PAGET.)

[Communicated by Mr. BAKER.]

A young woman, aged 23, was admitted into St. Bartholomew's Hospital in January, 1863, on account of paralysis of the left leg, from which she had suffered for more than twenty years. Her history is, shortly, that when she was 18 months old, her left leg became suddenly paralysed. No cause for the disease was known, and, so far as her parents knew, no convulsions, or other indications of disturbance of the nervous system preceded the paralysis. She regained only a very imperfect power of motion in the paralysed limb, and never walked out of doors without the assistance of crutches. For the last five or six years successively the lame leg has been ulcerated during the whole of the winter. Three years ago she was admitted into the Hospital, and on this occasion Mr. Paget divided the tendo-Achillis, and placed the foot in a

better position; so that with the help of an orthopædic apparatus she was enabled for a time to walk better, though not for any distance out of doors without crutches. But, some sores appearing on the foot, she left off the instrument, and her leg becoming again deformed, and being an incumbrance rather than any assistance to her in walking, etc., she was again admitted, and consented to undergo amputation. At the time of her second admission the leg was atrophied, cold, superficially ulcerated on its front, and almost absolutely powerless and useless. The foot was extended, and turned somewhat inwards. She looked pallid and rather weak, but there was nothing very evidently wrong in her general health beyond this. By her own account, she usually enjoys fair health, except in the winter months, when she is often much troubled, and she thinks weakened, by the ulceration of the leg occurring at this time.

Mr. Paget amputated the leg, through its upper third, on January 31. Excepting slight cellular inflammation about the stump on the first few days after the operation, and the formation of an abscess in the thigh a few weeks afterwards—both complications arising probably from defective nutrition of the limb—the patient has gone on satisfactorily, and is now (March 21) almost convalescent.

*Examination of the Leg after its Removal.*—The integuments on the front of the leg were superficially ulcerated over a small extent of surface, but in other parts apparently healthy. The subcutaneous cellular tissue was loaded with a large quantity of soft lobulated fat; and a layer of the same, about a quarter to half an inch in thickness, was beneath the integuments covering the inner side of the tibia, where the skin is generally so thin, and so rarely separated by much fat from the bone beneath. The gastrocnemius and soleus muscles were much atrophied, and their structure had undergone such utter degeneration, that they were scarcely, at first sight, to be recognised as muscles at all. A description of their condition will apply to all the muscles of the leg, with one or two partial exceptions to be noticed presently. To the naked eye, their colour, texture, and consistence were, on a superficial examination, hardly distinguishable from those of the common fat beneath the integuments and between the different muscles; but, on a closer examination, one could see, and more especially was this the case in the penniform muscles, that the original shape of each was retained, and that the changes which it had undergone had not destroyed the linear arrangements of the fibres and the characteristic shape at the same time with the colour and other external properties of the muscle. By dissecting carefully, too, the muscles could be separated with tolerable ease from each other, and their origin from the bones and insertion on their respective tendons made out as exactly as in their normal condition. The fat forming almost the whole of their substance was white or yellowish-white, and exceedingly soft, and easily torn. It was arranged, as before mentioned, in regular linear fasciculi, of the same shape and direction with those of the original muscular fibres, and quite separate from the common lobulated adipose tissue adjacent, unlike which it contained scarcely any connective tissue. The appearance was indeed exactly that of the original muscle, with the exception of the fasciculi composing it being rather atrophied, and composed of fatty instead of fleshy fibres. Here and there, in the calf muscles, and to a very small extent in the tibialis posticus and flexor longus pollicis were small patches of pink muscular tissue yet remaining. The flexor longus digitorum was in a much better condition than either of the preceding; very pale and fatty if compared with a healthy muscle, but having throughout a pinkish colour, and muscular fibres yet remaining visible in almost all parts of its substance. The muscles on the front and outside of the leg were in as complete a state of degeneration as the flexors. Those of the sole of the foot, though soft and greasy, were almost all of them less degenerated than those of the leg. A considerable quantity of soft lobulated fat filled the various depressions and interstices of the leg and foot, existing not only between the various muscles and ligaments, but dipping in, as it were, also amongst the fibres of the latter, so that it was impossible to clean them without cutting away a great deal of their substance. The tibia and fibula were very small and shrunken; their surfaces were white and smooth, and the markings of the attachments of muscles very few and indistinct. The appearance presented on examination of the muscles by the microscope were such as might have been anticipated

from the naked eye view previously obtained. In the parts of the muscle which were most degenerated no trace either of muscular striæ, or of the original shape or size of the fibre could be detected. All seemed converted into or replaced by a structure which, with the exception of the more irregular size and less definition of the oil-globules, could not be distinguished from common adipose tissue. In other parts, again, the original shape and size of the fibres could be traced, though in their interior no evidence of striæ remained. Instead, the fibre was filled by molecules and globules of oil of various sizes. In some of these fibres the larger oil-globules were in close apposition, and seemed in process of forming an imperfect kind of adipose tissue, similar to that just described,—a kind made up by the apposition of these, first, to others in the same fibre, and at last to those of neighbouring fibres, until all trace of the original size and shape of the fibre being lost, little but these fat-globules remained.

In some parts of the field the adipose tissue could not be distinguished from common fat, and it may perhaps be doubted how far this was formed out of the fatty elements produced in the degeneration of the muscle, somewhat in the manner of the more imperfect kind last described, and at a further stage of this process, or whether it was produced merely by increased formation of fat, which naturally existed around the muscle, and which, dipping in between its fibres, came at length to occupy their place, as they degenerated and disappeared. The portions of muscle which still retained their pink colour and general appearance of the original structure, contained some fibres, with well-marked striæ, and little if any appearance of fatty degeneration. Side by side, however, with these—and in many parts the change was very abrupt—were fibres beginning to break up; and from this stage it was not difficult to trace a more and more marked deviation from their healthy appearance.

### THE ROYAL ORTHOPÆDIC HOSPITAL.

#### CASE OF INFANTILE PARALYSIS—CLINICAL REMARKS.

(Under the care of Mr. HOLMES COOTE.)

ON January 8, a little girl, aged 6, was brought to Mr. Holmes Coote, at the Royal Orthopædic Hospital, suffering from talipes equinus of the right foot. The whole limb was cold, livid, and shrunken, and about one-third of an inch shorter than the opposite. As far as the knee this state of atrophy was strongly marked, and it extended, but in a less degree, to the muscles of the thigh and buttock. In walking, the child dragged the limb, or threw it clumsily forward, and seemed glad to cling to objects, such as the table, by which it gained support. In other respects it was well, but occasionally irritable. The mother stated that the child had had fair health, but had been subject to "terrors" at night. She never knew it have a fit; but once, after some nocturnal excitement, and whilst lying by her side, it fell back in the bed, and remained quiet for a minute or two. She thought this proceeded from exhaustion, and took no further notice. Shortly after this she remarked that the right limb was colder than the opposite, but the paralytic condition came on gradually. Mr. Coote divided the tendo-Achillis, and stated that, after having elongated the connecting material, so as to bring the foot flat on the ground, he should direct the employment of proper apparatus, by which the weakened limb might receive support.

Mr. Coote stated that infantile paralysis was the expression of a very serious lesion of the nervous centres, and that, although it was not so alarming as a paralytic stroke in the adult, this proceeded from the fact that in the former the disease was more limited to the spinal cord, the functions of the brain remaining unimpaired. The opinion so often expressed that in such cases there was no danger to life, was, in his opinion, an error. There were many degrees of these primary affections of the nervous centres, and the danger to life was in proportion to its extent and severity. The term *myogenic* paralysis appeared to him quite out of place. The disease belonged to the group of "convulsive affections of infancy."

Paralytic talipes equinus is never congenital; it appears sooner or later after birth, either after a violent convulsive fit, or one attended by only a momentary unconsciousness. The attack is usually preceded by thirst, restlessness, night-start-

ings, and other indications of cerebral disturbance. In many instances the primary attack is fatal. In others it leads to paraplegia, hemiplegia, etc., the power of movement usually returning to all except one limb, generally a lower extremity, which, in course of time, if the child lives, becomes withered and shorter than the opposite. The attack is usually associated with the first, sometimes with the second, dentition. It seems to affect boys and girls equally; equally also the right or left side. According to the sets of muscles paralysed, so is there produced talipes equinus, or calcaneus, or equino-valgus, talipes equinus being the most common. The arrest of development extends, in some instances, to the trunk, affecting the bones; thus there are cases in which one-half the pelvis is smaller than the opposite,—a serious complication in female children. If the attack be limited to one arm, the deltoid muscle is mostly affected.

The progressive muscular atrophy reduces the limb at last to a mere bag of fat, some few muscles, such as those of the foot, retaining some of their colour and consistence. The coldness of the limb rendered it liable to ulcerations and chilblains. But, again, there are cases in which, after a lapse of months, the muscular power unaccountably returns, and the limb grows more healthily, but still not *pari passu* with the other. As regards treatment, purgatives and small doses of antimony are indicated, but not tonics. The limb should be kept warm, and stimulating embrocations applied to the spine; the gums, when tense, should be lanced; electricity may be tried, but is usually unavailing; nux vomica is useless; sea air and bathing may improve the general health, but have no direct effect on the local malady. Very many cases are to be seen at the Orthopædic, 60 to 70 out of every 1000.

### THE LONDON HOSPITAL.

#### WOUND OF THE INTESTINES BY A STAB—PERITONITIS—DEATH—AUTOPSY.

(Under the care of Mr. COUPER.)

Ng A., aged 23, a Cantonese seaman, was brought to the Hospital on February 13, an hour after having been stabbed in the abdomen by a fellow-countryman to whom he had refused a loan.

When seen by Mr. Couper an hour and a half after the infliction of the injury, there was profound shock. The omentum, the transverse colon, and the greater part of the small intestine protruded through an oblique wound at the umbilicus rather more than a hand's breadth long. The lesser gut was wounded in three places. The edges of the wounds were strongly everted, and the mucous membrane protruded. One wound was a puncture half an inch long, and was plugged by the mucous membrane. The others were more extensive, and were directed across the gut. At one place the intestine was transfixed, so as to leave only two narrow portions of its circumference undivided. Four mesenteric arteries bled a little. Each was tied with fine silk, and the ligature cut short. The continuous suture, with minute intervals between the stitches, was employed in connecting the edges of the intestinal wounds. The ends of a piece of fine silk, each armed with a common sewing needle, were respectively passed from within outward through the edges of the wound and underneath the peritoneum only. They were drawn through until the middle of the thread corresponded with the wound. The needles were then repassed from within outwards in succession through the cut edges of the peritoneum, which was included to the extent of about two lines within each stitch. Preference was given to a double suture, which, acting as it did like a double boot-lace, enabled an assistant to tighten one end, and thus prevent the already inserted stitches from gaping while a fresh stitch was being made with the other. When all were tightened, the last was knotted twice, and both ends of the thread cut short. Each wound was thus treated, and the effect was to push the everted mucous membrane towards the interior of the canal, and to bring two peritoneal surfaces in contact. The line of suture formed a retiring angle, at the bottom of which the thread was hardly visible, and at the seat of the largest wound gave the appearance of annular constriction to the gut. The abdominal wound gaped widely, and there was some tension after its lips had been brought together by a metal pin transfixing the whole thickness of each, and by six silver wire sutures. The dressing of all the wounds occupied nearly two

hours, and the intestines were protected by warm flannels until they could be returned into the abdomen. The patient was kept under the moderate influence of opium, and was fed at first by the rectum, and after the fourth day by the mouth. Fluid nourishment only, and in small, frequently-repeated quantities was given. There was a natural evacuation of the bowels on the third day, and three or four liquid motions were passed on the fourth, fifth, and eighth days, notwithstanding the administration of full doses of opium. Peritonitis commenced at the end of the second day with some pain and considerable fever. The pain was completely neutralised by increased doses of opium, and the disease terminated in death on the fourteenth day. Inspection thirteen hours after death disclosed non-union of the wound in the abdominal parietes, from which the stitches had been removed thirty hours before death. The abdominal viscera were so agglutinated by abundant recent lymph, that all were matted into one mass, and no part of the peritoneal cavity remained. The edges of the intestinal wounds were thinned and ulcerated, and were not adherent. Their firm and broad adhesion to adjacent coils of intestine was the only barrier to the escape of fæces. Two small spots of lymph near the largest wound had an ochreous stain, which a stream of water failed to erase, but no fæcal matter had escaped either there or elsewhere. No suture was found at two of the intestinal wounds on slowly breaking down the adhesions. The orifices of these wounds had gaped considerably. The suture of the third and largest wound was in the act of separating, and was lightly held at one or two points only. Even this wound had gaped, and was filled up by the peritoneal surface of the adjacent coil, to which its edges adhered, and which must therefore have been in contact with the passing contents of the canal. The sutures fulfilled a twofold purpose:—In the first place, they prevented the escape of fæces during the time that preceded the agglutination of the peritoneal surfaces, while, in addition, they placed those surfaces in a position favourable for adhesion. In the second place, they helped to secure permeability of the intestine by repressing the everted mucous membrane, whose protrusion tended both to diminish the calibre of the gut and to enlarge the gap in the intestinal wall, which, had the patient lived, must ultimately have been closed by a slow process of cicatrisation.

### THE ROYAL LONDON OPHTHALMIC HOSPITAL.

#### AMAUROSIS OCCURRING IN A YOUNG MAN, AN IMMODERATE SMOKER OF TOBACCO.

(Case under the care of Mr. WORDSWORTH.)

G. A., aged 28, a butcher, residing in Essex, applied at the Royal London Ophthalmic Hospital, March 25, 1863, on account of partial loss of sight in both eyes.

He was a strong man, having every appearance of health. He stated that he had always had good health, that he had never indulged in liquor to excess, and that he had never had syphilis. His occupation had not been of such a nature as to fatigue his eyes. About eight or nine years ago, he began to smoke tobacco, and gradually smoked more and more, till he smoked about half an ounce of strong tobacco a-day. He had not apparently suffered in general health from smoking, but about nine months since his sight began to fail, and had gradually become worse to the time of his admission.

He can now scarcely read No. 18 test-type (canon) with his left eye, and No. 16 (2-line great primer) with his right. Distant large objects are also indistinctly seen. Both pupils are considerably dilated, the irides act slowly and imperfectly. Examined with the ophthalmoscope both optic nerve discs are partially atrophied; the apparent inner half of each is white, the outer being red and hyperæmic.

Mr. Wordsworth pointed out the case to the class as one of "tobacco amaurosis," of which he had lately seen several in excessive smokers, all being more or less attended by atrophy of the optic nerves. So far as he was aware, this form of amaurosis was quite incurable.

### GUY'S HOSPITAL.

#### OVARIAN DISEASE—STRANGULATION OF INTESTINE—DEATH—AUTOPSY.

(Case under the care of Dr. GULL.)

The following is an example showing rather a rare cause of

strangulation, and illustrating the difficulty of diagnosis in such cases. Dr. Wilks, at the autopsy, remarked that it would be seen that a case which was very difficult during life was of a very simple character as viewed after death. An ovarian cyst had long existed, although unknown to the patient; and, at the time of her fatiguing walk, a piece of gut had fallen in front of the tumour. This had caused the symptoms of pain, sickness, etc., the partial strangulation becoming afterwards complete.

The patient, a woman 74 years of age, was admitted on January 22. She said that, having walked a great distance, she was seized with pain in the abdomen and sickness. She then for the first time found that her abdomen was swollen. A few days later she came to the Hospital. There was then apparently a large ovarian cyst in the abdomen, but this, of course, was quite irreconcilable with the history she gave. Although the swelling did not decrease, she improved in health, and left the Hospital, but came again on March 18, having all the symptoms of strangulated intestine. She still persisted in her original story, and this rendered the diagnosis rather obscure. She died March 24. The following account of the *autopsy* is taken from Dr. Wilks' records:—

The abdomen was filled with a very large cyst of the left ovary. The parietes were adherent at one spot, and the omentum above. With these exceptions, the cyst was unattached, and, on lifting it up, a portion of intestine was seen passing round its pedicle, and, falling down in front, had become strangulated. Passing immediately behind the pedicle posteriorly was the commencement of the ileum. At about four inches from the cæcum it curled round the pedicle to its front part, and there lay as a distended coil in the pelvis. Thus posteriorly the first four inches of the ileum were contracted, empty, and of a pale colour, whilst the part immediately below, as seen in front of the tumour and in the pelvis, was distended with fluid matter, and of a dark red colour. By moving the tumour on one side, this piece of intestine could easily be lifted out, and, being brought round and behind the pedicle, was restored to its natural position. On examining the gut further, the constriction was seen to be tolerably tight, although not complete. The serous membrane was uninflamed. On cutting it open, the line between the two portions was well shown, and the mucous membrane was somewhat thin, as if a little more pressure would have destroyed it. The mucous membrane above was of a dark red colour from congestion.

### KING'S COLLEGE HOSPITAL.

#### LITHOTRITY IN A MAN SEVENTY-FIVE YEARS OF AGE—THREE OPERATIONS—RECOVERY.

(Under the care of Mr. FERGUSSON.)

[For this and the following case we are indebted to Mr. Smith, House-Surgeon.]

Ferdinand C., aged 75, and teacher of languages, a very corpulent but healthy-looking old man, was admitted into Albert Ward, under Mr. Fergusson, January 1, 1863, with symptoms of stone in the bladder.

He is an Italian, but has been for some years a resident in London. He had always had good health till about three years ago, when he began to pass small calculi by the urethra; these, however, caused him very little pain; he kept the stones which he passed, and found that at the end of two years they were more than one hundred in number. At the end of that time they began to disappear, and he was not troubled until the last month. He has noticed a great deal of gravel in his water, and felt pain at the neck of the bladder and the end of the glans penis, and after walking much or riding any distance in an omnibus, the urine becomes streaked with blood. His general health is good; he has a very fair appetite, and he sleeps pretty well at night. He was sounded by Mr. Fergusson before admission, and calculi were distinctly felt.

January 24.—The patient having been brought into the theatre, and chloroform given, Mr. Fergusson introduced a small lithotrite, and crushed three or four calculi. The instrument became clogged with *débris*, and it was with some difficulty that the blades were closed sufficiently to enable Mr. Fergusson to withdraw it. When this was at last accomplished, several small fragments were found adherent to the groove. Another lithotrite was then introduced, and the fragments further crushed, after which the patient was re-

moved. In the evening several small pieces were removed, and were found to be fragments of a lithic acid calculus.

31st.—Since the last date, the patient has passed a great many small fragments, but had very little constitutional disturbance after the operation. For a day or two afterwards the urine was much tinged with blood, but this soon passed off. To-day he was again operated upon under chloroform. A large lithotrite was first passed, and several stones crushed, after which some pieces were removed by a smaller instrument. One large piece slipped from the instrument, and stuck fast in front of the prostate, and was removed by an instrument with expanding blades, somewhat similar to one used by Mr. Brooke, of the Westminster Hospital.

February 3.—He has passed several fragments since last sitting. The urine has been very bloody, but is now clear. He has little constitutional disturbance, but complains, however, of much irritation about the neck of the bladder, and pain in making water.

7th.—The patient having been placed under chloroform, Mr. Fergusson introduced a lithotrite, and succeeded in crushing one large calculus, and removing seven fragments.

9th.—The urine has been quite clear since last sitting. He complains of very little pain, and no difficulty in micturition, and, in fact, feels quite well. During the day has passed six large pieces.

21st.—Was examined to-day by Mr. Fergusson, but no fragments could be detected by the most careful manipulation. Feels quite well, with the exception of some little amount of irritation about the neck of the bladder.

28th.—Discharged cured.

#### LITHOTRITY—THREE OPERATIONS—REMOVAL OF SMALL CALCULI BY THE LITHOTRITE—RECOVERY.

(Case under the care of Mr. FERGUSSON.)

Samuel C., aged 60, was admitted into Albert Ward, under the care of Mr. Fergusson, December 12, 1862, for stone in the bladder. He lives in Gloucestershire, and is a stonemason by occupation, is married. He had pretty good health up to about six years ago, when he began to complain of pain at the external orifice of the urethra during micturition. For this he applied at the Bristol Infirmary, where a calculus was detected in the bladder, and crushed. Since that time he has frequently passed fragments and small perfect calculi from the bladder.

Upon admission into King's College Hospital, a sound was passed into the bladder, and Mr. Fergusson diagnosed a collection of small calculi.

December 20.—The patient having been brought into the theatre, Mr. Fergusson first introduced the lithotrite and crushed a small stone, and afterwards by the lithotrite scoop extracted some fragments and several small calculi, six in number. In extracting one the orifice of the urethra requiring slitting with a bistoury. The stones were uric acid.

22nd.—He has been kept in bed since the 20th, but has had no bad symptoms. The urine after the sitting was very much tinged with blood, but is now quite clear. Has passed no fragments.

January 3, 1863.—He was again brought into the theatre, and twelve perfect stones were removed by Mr. Fergusson's small lithotrite. They varied in size from a bean to a cherry-stone.

5th.—Has felt very comfortable since last sitting; the urine is clear. Has passed no more fragments.

10th.—Again brought into the theatre, when four more stones were removed, two of which were much larger than those previously extracted.

12th.—Complains of irritability about the neck of the bladder, and a frequent desire to make water. In other respects he is well. Urine clear.

17th.—Mr. Fergusson carefully examined the interior of the bladder with a sound, but could detect no stone. Discharged cured.

**GARIBALDI'S WOUND.**—By a letter received in Paris a few days ago, it appears that the wound in General Garibaldi's ankle has again put on an unfavourable appearance. There is every reason to fear that some foreign body carried in by the ball still remains at the bottom of the wound, keeping up suppuration and preventing healing.

SATURDAY, APRIL 4.

#### MAN'S FRONTAL VERTEBRA.

OUR survey of the nasal segment of man was complicated by our knowledge of the fact that the division of the skull with which we were then dealing was the segment furthest removed from the vertebral centre. As, therefore, a peripheral segment of the vertebral column, we necessarily experienced the greatest possible difficulty in its recognition, under any circumstances, as the serial homologue of a true vertebra. If, instead of confining his researches to one single cranial segment, and that one *par excellence* the most difficult of comprehension, because the most peripheral, the student had extended his sphere of observation to the wider range of living structural forms, he would have been fully and satisfactorily aware of the fact, that there once existed a period when the whole vertebrate life on this planet was composed of those animals in which the polarizing forces tending towards irrelative repetition were strongly manifest. In the reptile which crept under the shade of the carboniferous forest, or trod the muddy sandstones of the Triassic shore, we see structures which exhibit the operation of this vegetative law, which, our readers will bear in mind, is the exact antithesis to the opposing principle which has produced the divergence of animals from the originally created type. The aphorism that "every animal is the resultant of two forces, the one teleological, and the other morphological," has been proved to be strictly and scientifically exact. And applying this principle to the examination of the individual skeleton of any animal, it will be easily seen that the polarizing force which regulates the adherence to type operates most powerfully in the segments of the body furthest from the extremities. The vertebral nature of any given segment is readily recognisable in the dorso-lumbar series; scarcely perceptible in the tip of the tail, or in the nasal vertebra. In these peripheral portions of the organisation, the teleological principle has modified each segment to fit it for the purpose to which it is applied. And without questioning in any way the fitness of such a structure, *e. g.*, as the nasal segment, for the reception of the olfactory ganglia, or the support of the upper teeth, we recognise in the relative degree of that fitness a subservience to the one great morphological law of "adherence to type," which regulates that the nasal segment in man shall be composed of answerable parts, in every one of the variously modified examples of the sub-kingdom *Vertebrata*.

In our examination, however, of the frontal segment of the skull, we have to deal with a far more simple organism, and one of which the vertebral nature has been often, and, we think, unfairly denied. The grounds of such negation are, however, so futile, that we shall not devote much space to their refutation.

If the description which we have already given does not

convince any one that the nasal segment is literally and entirely a vertebra, we despair of improving their perceptive faculties. We will endeavour to reply to the objection which has been made that there can be no true homology drawn between those segments of the skull which lie in front of the pituitary body and the trunk vertebræ. This is the old objection which has been made by the "practical men." Some accurate observers have, however, said that "in no instance, save *Amphioxus*, has the notochord, as yet, been traced through the whole of the floor of the cranial cavity. In no other embryo has it ever been yet seen to extend beyond the middle vesicle of the cerebrum, or in other words, beyond the level of the rudiment of the infundibulum and pituitary body. In the second place, the division into somatomes, in all known vertebrate embryos, stops short at the posterior boundary of the skull, and no trace of such segmentation has yet been observed in the head itself." John Müller, however, has virtually annihilated this argument. He has demonstrated that the notochord in the frog extends far in front of the basi-occipital bone; that "in *Mammalia*, including man, three cranial vertebræ are without exception discoverable in the basis cranii, either in the fœtus or in many cases even in young or middle-aged animals, the *occipitale basilare*, *sphenoidale*, *basilare*, *posterius*, and *anterius*; these also occur in fish. How far the chorda primitively extends in *Mammalia* is not yet made out; but even although it should not reach through the whole basis cranii, this, for the reasons which have been stated, would be no good argument." The opponents of the vertebral theory have alleged that a careful attention to embryology tends to overturn our belief in the actual vertebrate nature of the successive segments of the skull. Conscious, however, that a careful attention to the anatomy of the embryonic forms will establish the general truth of our conclusions, we will endeavour fearlessly to proceed in our investigations, with the sole object of attempting to render this obscure subject familiar to the tyro in human osteology.

Like every other cranial vertebra, the frontal segment is composed of two arches, the neural and the hæmal. The centrum, or remains of the primitive notochord, which in *Amphioxus* reached so far towards the periphery of the animal, is the bone termed "presphenoid." The lesser wings of the sphenoid, or orbitosphenoids, are the neurapophyses, through which the neural canal flows. Above these are the two bifid neural spines, or frontal bones. The external angular process, so termed in Human Anatomy, is, serially speaking, the "diapophysis," but actually the "post frontal." Knowledge of the form of the structure in man would never enable the student to perceive that it is veritably a distinct vertebral element; such, however, it appears in the bird, the fish, and the reptile. The pleurapophysis of the frontal vertebra, answering to the "rib" is the tympanic bone. Such, therefore, is the composition of the neural arch of the frontal segment.

We may for a moment call attention to the consideration of the hæmal arch, of the frontal segment, or maxilla, composed of two confluent elements; the *os articulare* (*hæmapophyses*) and the *os dentarium* (*hæmal spine*). Contrast this structure with that of the lower jaw of the crocodile, where the concave articular process is fitted over the tympanic bone (the reverse of the mammalian structure); where beneath the articular process extends a bone, the *angulare*, capped by another plate, the *surangulare*, and with a splint-like bone on the inside to support it, the *splenial*. The coronoid process in the reptile also forms a distinct ossification, while the dentary bone composes the "functional" part of the jaw, supporting the teeth. What do we recognise in this but a beautiful example of the operation of the law of "vegetative" or "irrelative" repetition, which gives to the scattered centres of ossification in the lower forms of *Hæmatocryan* vertebrata "a local habitation and a name?"

The frontal vertebra is, *ipso facto*, that segment which is most intimately connected with the optic sense. As the capsule defending the sense of smell is always placed in front of the nasal vertebra, as the nerves which regulate taste perforate the neurapophyses of the parietal vertebra, as the auditory capsule is continually lodged in the space, or otocrane situated between the parietal and occipital vertebra, in like manner is the eye associated with the frontal segment, and lodged in the orbital cavity between the frontal and the nasal vertebræ.

We shall not here enter into the vexed question of the development of the suspensory arch of the lower jaw, nor shall we venture, in the present state of knowledge, to identify the small bones of the ear, (*malleus*, *incus*, *stapes*, etc.), with the proximal elements of the mandible. We have perfect confidence that all they who carefully and diligently examine the structure and development of the mandible in the lower vertebrata, will experience no real difficulty in the actual identification of the mandible as the hæmal arch of the frontal segment, serially homologous with the maxillary arch, and, like it, being provided in man and the higher vertebrates with rows of more or less complicated teeth, whereby the food is seized, torn, or comminuted.

Hereafter we shall proceed with the investigation of the signification and homologies of the parietal segment of the skull.

## THE WEEK.

### CRIMINAL JUSTICE.

AN unprejudiced person, who has read the reports of the criminal trials which have taken place during the last few years, will certainly be led to the conclusion that the boasted British system of criminal jurisprudence is at least as imperfect as any, if not more imperfect than most human machineries. The patent absurdity of referring questions of recondite psychical and toxicological science to a panel of twelve persons, of whom nothing is previously known beyond the fact that they pay certain rates and taxes, has lately been insisted on in this journal, and we shall not here recur to it. But there is another imperfection, or, we should rather say, wrong, permitted by the English law, which is equally opposed to the dictates of humanity and to the first principles of justice. We refer to the unequal means of defence at the disposal of the wealthy and pauper prisoner. Let a poverty-stricken wretch be accused of a crime on evidence sufficient to satisfy a magistrate that he may possibly be guilty, and he is sent to gaol, there to lie powerless and unheeded. Meanwhile the most acute intellects in the town or country, men trained to the business of discovery, are employed to bring home the charge to his door. Incarcerated and penniless, he can collect no evidence to disprove the accusation; he cannot fee experts and counsellors; and, guilty or not guilty, he is virtually undefended. It is true that just before, or at the time of trial the judge may appoint an advocate for a prisoner who cannot otherwise obtain one. But however conscientiously the barrister may behave to his pauper client, whatever desire he may have to assist the prisoner, however skilfully he may seize the points of the case as they arise, it is not to be expected that he can rebut evidence which has been skilfully collected and arranged by men of practised sagacity and acuteness during the weeks or months that the man has been in prison. Suppose, for instance, that a penniless servant-girl is accused of putting poison into the family pudding. The case is brought to trial. Professor Taylor or Dr. Letheby, or some other toxicologist, appears for the prosecution. He describes symptoms, post-mortem appearances, analysis—in fact the whole scientific details of the case, as looked at under the assumption of guilt. But what scientific witness will be brought forward to test the validity of the expert's analysis, or to state whether it be not

possible that the scientific details are compatible with innocence? The pauper prisoner can obtain no such assistance, and it is therefore undeniable that she has neither the means of defence nor the chance of an acquittal which the money of a Palmer could purchase. Had Smethurst been a poor man, had he not been able to provide a defence which, at least, showed the weak points in the theory of the prosecution, what chance of life would he have had? It has been publicly stated that application was made to the judge who tried Burton that some Physician of eminence should examine him, and give evidence at the trial as to his mental condition. The answer said to have been returned was that there were no funds at the judge's disposal for such a purpose. Suppose Burton had been a millionaire who had murdered his valet, or a wealthy tradesman's wife who had killed her children, what would have been the array of skilled evidence in favour of insanity confronting the judge and jury? Lastly, it is a well-known fact that the man who can pay can obtain an advocate of higher standing and repute, and therefore, it is to be presumed, of greater experience and talent than the man who cannot. A great improvement was believed to have been made in the conduct of our criminal courts when the law first permitted a prisoner tried for a capital offence to have his defence stated to the court by his own advocate. Some of the most experienced lawyers nevertheless maintain that on the whole the accused person's interests were better represented under the old system. The judge himself was then the prisoner's counsel, and the jury heard from the bench all that could be fairly stated in his defence. But be this as it may, a glaring inequality in the position of rich and poor defendants in criminal actions is a blot upon the public administration of justice, and demands the interference of our law-makers.

#### THE NEW ARMY MEDICAL WARRANT.

THE following is the shape which the concession so long promised to the just demands of the Army Medical Officers has taken. The document, doubtless, removes some of the grounds of complaint, but it does not restore all that was granted by the original Warrant. Practically, Medical men can well dispense with the empty honour of "turning out the guard," and we can well suppose that our army brethren are not anxious for responsibility on courts-martial. But the reservations made by the House Guards demonstrate that jealousy and ill-feeling towards the department have not abated,—that the authorities have ceded under pressure as little as they possibly could, and that little with the worst possible grace:—

"Circular No. 808 (Relative Rank).

"(VICTORIA R.)

"Whereas we have judged it expedient to cancel our Royal Warrant of 28th March, 1861, which assigns the relative rank of junior major to certain staff and regimental Surgeons of our army, and to revise those parts of the several other Royal Warrants now in force, prescribing the privileges attaching to relative rank of officers of the Civil Departments and non-combatant officers of the Military Departments of our army; our will and pleasure is, that such privileges shall, from the date of this our Royal Warrant, be regulated as follows:—

"Relative rank shall carry with it all precedence and advantages attaching to the military rank with which it corresponds, and shall regulate the rates of lodging-money, number of servants, rations of fuel and light or allowances in their stead, detention and prize-money according to the regulations and upon the conditions in force from time to time; but such relative rank shall not entitle the holder to military command of any kind whatsoever, nor to the presidency of courts-martial, courts of inquiry, committees, or boards of survey, but when the president of such courts, committees, or boards shall be junior to the officer of the Civil Department, then such member of the Civil Department shall attend as a witness and not as a member. Choice of quarters shall be regulated by relative rank according to date of commission, except in the case of commanding officers'

quarters, and in cases in which special quarters shall be permanently appropriated with the approval of the Secretary of State for War.

"Relative rank shall not entitle the holder to salutes from ships or fortresses, nor to the turning out of guards, but it shall entitle him, if commissioned, to salutes by sentries or by individual soldiers.

"Honorary rank of paymasters shall carry with it all the privileges and advantages attaching to relative rank of corresponding degree.

"All commissioned officers serving with the troops shall be entitled to funeral honours according to relative military rank.

"Given at our Court of St. James's this 7th day of March, 1863, in the twenty-sixth year of our reign.

"By her Majesty's Command,  
" (Signed) G. C. LEWIS."

#### THE CASE OF STONE v. STONE AND APPLETON.

WE feel some difficulty in alluding to this case, in which a Medical man is alleged to have taken advantage of a patient during a swoon whilst he was in attendance upon her for disease of the womb. The circumstances are so unusual and so disgusting, the character of the unfortunate lady had been previously so good, and the evidence of her guilt so conflicting, for it depended principally upon an admission of guilt which she was alleged by some witnesses to have made—an assertion which was denied by others—also on the question of a few weeks in the age of a new-born child, that we cannot help entertaining a lurking hope that the jury were mistaken in the verdict which they gave for the plaintiff. One thing, however, we feel it our duty to notice. Medical men are liable to false accusations; they may be charged with improprieties committed in the absence of any other witness than the complainant, which it may be impossible to controvert by any direct evidence whatever. Considering how defenceless is the position of any man against whom such a charge has been made, it is especially necessary that the administration of justice should be as cool, temperate, and free from appeals to prejudice as possible. This, we are sorry to say, was not the case in the trial of Stone v. Stone and Appleton. There can be no doubt that the remark made by Sir C. Cresswell, in summing up, "that it was unnecessary for him to say what kind of damages should be awarded against a Medical man who had seduced a patient under his care," amounted, if correctly reported, to a flagrant misdirection of the jury. The Divorce Court is a civil, and not a criminal, tribunal. The object of damages, in civil cases, is simply to compensate the plaintiff for the injury he has sustained by the defendant's wrong or breach of contract, and the amount of them is perfectly independent of all extraneous circumstances connected with the defendant's position or conduct. The expression "exemplary damages" is frequently used by plaintiff's counsel, but the law knows no such term. In this case the petitioner's compensation ought to be estimated by the wrong he has sustained, and he is entitled to the same amount, whether the co-respondent be a Medical man or a footman. The contrary opinion is very prevalent among juries, and it is the duty of the Court to counteract any such notion. A judge who uses his influence in increasing the force of such prejudices incurs no ordinary blame.

#### PARLIAMENTARY.

THE late epizootic of foot and lung disease amongst horned cattle, and of ovine variola, will, it is to be hoped, produce some good by directing the attention of Parliament to the subject of the spread of contagious disease amongst cattle. On the 26th ult.,

"Mr. Holland gave notice that on an early day after Easter he would submit a Bill to amend the law for the prevention of contagion among sheep, cattle, and other animals."

The same evening, in Committee of Supply, the House voted—

"£1098, to complete the sum of £2098, for Quarantine Expenses."

And the following sums for Medical Charities in Dublin:—

"£1600 for the Lock Hospital; £700 for the Rotunda Lying-in Hospital; £200 for the Coombe Lying-in Hospital; £4600 for the House of Industry; £1500 for the Cork-street Fever Hospital; £600 for the Meath Hospital; £100 for St. Mark's Ophthalmic Hospital; £1300 for Dr. Steeven's Hospital; and £245 for the Board of Superintendence and Dublin Hospitals."

In the House of Lords on the 27th ult., on the motion for the third reading of the Irish Births and Deaths Registration Bill,

"The Earl of Bandon proposed an amendment, the effect of which was to assimilate the machinery of registration in Ireland to that of England.

"The Earl Derby thought that there might be an objection to limiting the choice of the guardians to Dispensary Surgeons, because in some cases, especially in large towns, those gentlemen might be too much occupied to be able efficiently to discharge the duties of the office of registrar. He would, however, suggest to his noble friend behind him that it would be as well he should not press his amendment, but that he should allow the Bill to pass as it had been agreed to in the House of Commons.

"The amendment was then withdrawn, and the Bill passed."

In the House of Commons,

"Mr. Blake asked the Secretary of State for the Home Department whether, in the case of the convict Burton, now under sentence of death at Maidstone Gaol for the murder of a child at Chatham Lines, an application was not made at the trial for the examination of the prisoner by Dr. Forbes Winslow, or some other Physician of experience in insanity, and refused by the judge; and whether taking into consideration the fact then stated of Burton's mother being confined in a lunatic asylum, and his brother not being of sound mind, it was his intention to order such an examination to be now made? He was informed that the prisoner's council applied to the judge to order that the evidence of eminent Medical men should be procured to show whether, when the prisoner committed the act, he was labouring under insanity or not. Mr. Justice Wightman, however, stated that he had no funds at his disposal for such a purpose. He trusted that the right hon. gentleman would satisfy himself whether this unhappy man was insane or not.

"Sir G. Grey was not aware that any application had been made to the judge of the nature described by the hon. member. The defence of the prisoner was his alleged insanity. Evidence was adduced on the subject, and the judge laid down the law in accordance with the highest legal authorities. The jury, after full and patient consideration, were of opinion that the prisoner was morally responsible for his actions. In answer to the second question, he had to state that no facts had come under his notice which would justify such an examination."

With all deference to Sir G. Grey, we should think that the fact of the hereditary nature of insanity would alone justify a Medical examination under such circumstances.

## REVIEWS.

*Points of Contact between Science and Art.* A Lecture delivered at the Royal Institution, January 30, 1863, by H. E. CARDINAL WISEMAN. London: Hurst and Blackett. 1863. Pp. 93.

WE gave so full an abstract of the Cardinal's Lecture immediately after its delivery, that we now need only announce its publication, and recommend our readers to peruse it for themselves.

*Experimental Essays.* I. *On the Motion of Camphor on Water.* II. *On the Motion of Camphor towards the Light.* III. *History of the Modern Theory of Dew.* By CHARLES TOMLINSON, Lecturer on Physical Science, King's College School, London. Illustrated with Engravings on Wood. London: Virtue and Co. Pp. 123.

THESE Essays are published in a shilling volume of "Weales' Series," which now appears to be in the hands of the Messrs.

Virtue. They are intended as *studies*; *i.e.*, investigations of single facts; first, with the view of ascertaining all that is known, and then of finding out something new. These Essays are well worth the shilling, and more; they completely explain the subjects treated on by simple laws; and the "Essay on Dew" shows that Wells was not so much the inventor as the popular expositor of that theory of dew which goes by his name.

*Waste.* A Lecture delivered at the Bristol Institution for the Advancement of Science, Literature, and the Arts, on February 10, 1863, by JOHN ADDINGTON SYMONDS, M.D., F.R.S. Ed., etc. London: Bell and Daldy. 1863. Pp. 51.

AN eloquent and suggestive lecture, as all Dr. Symonds' lectures are. He treats of waste, destruction, decay, and death; the wearing of the earth's surface; the destruction of animal and vegetable life; the extermination of species; the waste of man by war and pestilence, and the intrusion of stronger races; and the waste of his *potentiality*, of his intellect and powers. But out of death come new forms of life; the old passes away, and newer and better things take their place. "Order, growth, and development prevail in the midst of disruption, disintegration, and decay." Such is Dr. Symonds' creed, and such is our own.

*Heat Considered as a Mode of Motion.* Being a Course of Twelve Lectures delivered at the Royal Institution of Great Britain in the Season of 1862. By JOHN TYNDALL, F.R.S., etc., Professor of Natural Philosophy in the Royal Institution. With Illustrations. London: Longmans. 1863. 8vo. Pp. 466.

BEGINNING with the most homely facts relating to the production of heat by friction, and ending with the most sublime speculations on the constitution of the sun, the source of its heat, its rate of expenditure, and its effects, these admirable Lectures not only will introduce the student to the elements of one of the most important subjects of physical science, but will put the mature philosopher in possession of those more advanced doctrines of the unity and conservation of force which throw the charm of a romance over the dry matters of fact discovered by observation and experiment. The first seven lectures, as the Preface tells us, deal with thermometric heat, its generation and consumption in mechanical processes, such as friction, concussion, compression; how motion resisted becomes heat; and how heat disappears if *work*—*i.e.*, movement—be effected. It shows how the old theory that heat was a kind of fluid superadded to bodies, which they had various *capacities* for absorbing and holding, must be superseded by the newer theory that it is an accident or condition of matter, *viz.*, a motion of its ultimate particles. Not that this latter view is altogether new, for it had been presaged by Bacon and Locke, and held by Rumford and Davy; but scientific notions are like early asparagus and other "delicacies of the season," and as these at their first appearance are confined to the tables of the wealthy gourmand, but later are found in the barrows of the costermonger, so are these at first confined to the *élite* of the scientific world, till at last they find their way to the hawkers of popular lectures and compilers of popular manuals. That great idea, the "mechanical equivalent of heat," is fully developed, showing that "the quantity of heat which would raise one pound of water one degree F. in temperature is exactly equal to what would be generated if a pound weight after having fallen through a height of 772 feet had its moving force destroyed by collision with the earth. Conversely the amount of heat necessary to raise a pound of water one degree in temperature, would, if all applied mechanically, be competent to raise a pound weight 772 feet high, or it would raise 772 lbs. one foot high. The term 'foot pound' has been introduced to express in a convenient way the lifting of one pound to the height of a foot. Thus the quantity of heat necessary to raise the temperature of a pound of water one degree being taken as a standard, 772 foot pounds constitute what has been called the *mechanical equivalent of heat*."

The lectures proceed to develop the molecular theory of heat as explanatory of the solid, liquid, and gaseous states. Combustion is treated of as heat developed by the extinction of the motion of the particles of oxygen which rush towards the burning body, just as aerolites rush to the sun and feed his flames. As we go on we find described the vibrations

and tones produced by the contact of unequally heated metals; the ebullition of water, "specific," and "latent," heating the aerial currents generated by heat; the nature of glaciers; the refutation of the idea that the earth must have been chilled during the glacial period, and the demonstration of the contrary and the conduction of heat; and in the last five lectures, the history of radiant heat. It is not only the matter—the fact that so much is taught about heat, and about the processes in which it is concerned, and the grandeur of the views which show the unity of force, but the manner which we especially commend; the felicity of argumentation, and the exuberant ingenuity of experimental illustration, not to mention the bibliographical appendices, in which justice is done to Romford, Davy, Mayer, Holmholz, and other workers. Mayer is warmly eulogised, but not more than he deserves.

## FOREIGN CORRESPONDENCE.

### FLORENCE.

SIR,—In a comparatively primitive state of society, general belief or credulity attributed the discovery of mineral springs, or medicinal herbs possessing special virtues, to the well-disposed interposition of some celestial visitor, generally the patron saint of the district, who officiated as a modern cicerone, or referred it to some astonishing display of brute sagacity or instinct. The reported discovery of a cure for cancer, which has created some attention and interest in Northern and Central Italy, belongs to the latter category. The story is this:—Count Mattei, a wealthy nobleman of Bologna, possessed a favourite dog affected with cancer (I do not, of course, vouch for the accuracy of the diagnosis); this dog was observed to pay frequent visits to a particular locality, and there to partake of an herb of which there was an abundant supply. The evident improvement in the dog's condition, and its gradual recovery, is said to have provoked an examination and subsequent administration of the herb in cancer of the human subject, with, it is asserted, equally marvellous effects. Numerous are now the reported cases of cure. Without attaching any value to this statement, I must candidly admit that a case has come under my own observation which has somewhat surprised me. When an observer like Velpeau testifies to the great difficulty of establishing an accurate diagnosis in cancer, and admits the frequent errors of his own decisions, one must pause before admitting the positive existence or non-existence of cancer, even when supported by acknowledged authority. Seanzoni and Locock, on different occasions, unhesitatingly pronounced the disease to which I allude to be cancer, considerably advanced in one breast, less developed in the other. The two leading Surgeons of Florence endorsed these opinions. On one side it was open; the patient was unable to take any exercise, prostrated by pain, sleeplessness, and inability to take nourishment. Two months' use of a preparation from the herb was followed by comparative absence of pain, restored appetite, nights of refreshing sleep, and the power of taking a moderate amount of active exercise. The area of the cancerous sore has diminished two-thirds, and presents a healthy appearance. The patient had previously been attended by an homœopathic practitioner, who (*mirabile dictu*) admitted the helplessness of his art. This fact, to a sceptic like myself, might furnish some clue to the elucidation of the mystery. One may easily conceive a remedy possessing in a marked degree the properties of a sedative and tonic, producing such an improvement in the general health as to effect a corresponding amelioration in the urgent local symptoms, more especially in an individual not previously subjected to the influence of medicines usually employed by the rationalist or empiric under similar circumstances. After all, mitigation of symptoms or general improvement does not represent a cure. Even accepting this explanation, a remedy possessing such powers would prove a valuable addition to the Pharmacopœia, and increase the debt of gratitude which we already owe to our old friend the dog. The exploits of Dr. Fell in London, Dr. Noir in Paris, and a host of other pretenders, would, were other reasons wanting, excite in the educated mind of the experienced Surgeon, not only a doubt, but an indisposition to believe in the possible existence of such a remedy, and the loose, illogical reasoning not only of lay, but of Professional advocates does not tend to

allay a well-grounded suspicion of insincerity if not of wilful misrepresentation. Many, though perfectly honest, from defective mental training, or enthusiastic temperament, accept as fact that which a well-balanced mind would reject as founded on imperfect or unreliable evidence. Cases are adduced, but, as Velpeau remarked, there always remains the doubt as to the accuracy of the diagnosis. The public habitually attributes the salutary incredulity of the Profession to jealousy or obstinate reluctance to admit truth because at variance with ordinary reasoning and experience.

I may mention that Count Mattei refuses to divulge what he declares to be a remedy capable of effecting such marvellous results. One cannot purchase it; begging is as effectual as praying for the reform of Medical abuses before the British Legislature; and a man who would resent the epithet of unchristian or inhuman withholds that which he firmly believes would not only alleviate, but remove the cause of suffering to thousands of his fellow-beings. Another subject which has excited considerable interest in the Profession is the new operation for stone, recently introduced and practised by Dr. Aymini, of Turin, through the agency of electricity, which he calls "Lithomalakia Electrica." It appears that Dr. Aymini, who was for many years a Surgeon in the Piedmontese army, has for some time conceived the possibility of applying electricity to the destruction of urinary calculi; but from defective knowledge of its mode of application was unsuccessful, till he associated himself with a well-known electrician, Prof. Erchman, President of the Mediterranean Submarine Telegraph Company. I cannot give you the precise details, as Dr. Aymini has only supplied me with a general description. The operation is effected by the medium of the galvanic battery, from which the electric fluid is transmitted through a canula containing three platinum wires tipped with ivory, similar in construction to the lithotrite of Heurteloup. These wires are so arranged that by a mechanical contrivance the extremities may embrace the stone; when this has been seized, the wires are connected with the battery, and the transmission of the electrical current is followed by gradual disintegration of the stone, which is subsequently voided in the form of a fine powder. The operation necessarily requires repetition, the stone being divided into several fragments, which must be separately brought in contact with the wires. In three cases operated on successfully, each underwent three sittings of twenty minutes. Dr. Aymini, by experiments on himself, has been able to graduate the power of the agent. The point on which most stress is laid, which he has not communicated, is the nature of the solution with which the bladder is first injected; this, he asserts, must be modified according to the composition of the calculus, but how this knowledge is to be arrived at by a simple exploration is difficult to understand. The operation has already been performed in the presence of several Medical men, who testify to its complete success.

A friend of mine has seen the operation experimentally performed in a glass jar, and describes it as though the stone underwent a gradual process of fusion.

Dr. Aymini intends proceeding to Paris and from thence to London, when you will have an opportunity of witnessing the operation, of which I have only been able to furnish confused details.

M. C. P. L.

## GENERAL CORRESPONDENCE.

### RUSSELL v. ADAMS.

#### LETTER FROM MR. EDWARD COTTEM.

[To the Editor of the Medical Times and Gazette.]

SIR,—I feel that a just indignation at a system of persecution, and sympathy with a Medical brother, are sufficient motives for any man who has had a knowledge of the Russells to come forward and bear his testimony to their manner of life, previous to their making their atrocious attack on Mr. Adams. Thus actuated, I give mine as follows:—

I first knew Mrs. and Miss Russell by seeing them whilst I was attending the late Mrs. Crump at the house of her son, with whom, after her decease, they resided. I attended at an after period—viz., from January to July, 1860, both Mrs. and Miss Russell. During this period they were continually boasting of their noble connexions, claiming intimacy with the Earl of Shaftesbury, Lord Raynham, the Hon. B. Noel,

etc. I was often surprised at the greatness of their correspondence, and the number of letters I have seen ready stamped for the post, and was struck with the fact that all the persons of influence with whom they professed acquaintanceship were the promoters or upholders of philanthropic institutions. This impressed me with the idea of the nature of this large correspondence, and of their acquaintance with these noblemen, which both before the trial and during it, from the evidence of Mr. Toynbee, was fully confirmed.

During their stay with Mr. Crump they had the utmost kindness and consideration shown them by him, such as very few men would have shown; and it was only when he felt that he would be utterly ruined by the reckless manner in which they got into debt, he, after repeated expostulations, determined upon getting rid of them at any cost.

During the trial, Mrs. Russell swore her daughter had never before been engaged. I distinctly remember her telling me on one occasion, when her daughter complained of illness, that there was a circumstance I ought to be acquainted with, viz., that a short time before they came to the Hornsey-road, she (her daughter) had been cruelly betrayed by a gentleman on the very eve of marriage, after the wedding-dress was prepared, and every preparation made; and that, moreover, the betrayer was a minister of the Lord Jesus Christ.

I think the evidence which came out during the trial was enough to carry conviction to the minds of ninety-nine men out of a hundred. At all events, having been present, I feel confident the delay in the jury in finding their verdict filled with surprise a majority as large as this of those who were in court; yet the rejection of evidence then before the court on some points of law, prevented the base atrocity of the charge being fully recognised.

I am, &c.

EDWD. COTTEM, L.R.C.P. Ed.

Hornsey-road, Holloway, March 31.

THE APOTHECARIES' COMPANY OF IRELAND.  
LETTER FROM DR. C. H. LEET.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the last Number of your Journal there is an article under the foregoing head, which professes to have emanated from the King and Queen's College of Physicians of Ireland, relative to the Licence of the Irish Apothecaries' Company, in which the College, after quoting certain sections of the Act, 31 Geo. III., cap. xxxiv., goes on to state "that there is neither in these clauses, nor in any part of the Act, any authority given to grant any licence or certificate in Medicine; and on this point it seems requisite to observe that, in the case submitted to Sir R. Bethell, there is a mis-statement calculated to mislead counsel, where it is stated that, 'Such then, was the legal and recognised position of the Irish Apothecary, analogous in every respect to that of the Apothecary in England, when the Medical Registration Act (21 and 22 Vic., ch. 90) was passed,'" etc., etc.

Now, as regards the right construction of the Act referred to, Mr. Napier, Q.C. (ex-Chancellor of Ireland) states his opinion in the following words:—

"It is obvious that at the time of the passing of this Act, the Irish Apothecary was actually, according to usage and practice, and lawful under the common law, a Medical Practitioner, and such was he recognised to be by the legislature in previous statutes. That the statute recognised and did not originate the duties properly incident to the art and mystery of an Apothecary, is further evidenced by the constitution of the court of examiners under the 9th section.—This court is composed exclusively of Apothecaries, and they are to examine the candidates as to their acquaintance with the science and practice of Medicine, and ascertain their general fitness to act as Apothecaries. The qualification of the examiner for his duty flows from his skill and knowledge as an experienced Apothecary, and therefore the science of Medicine formed a part of that qualification."

Sir Richard Bethell (the present Lord Chancellor of England), also gives his opinion upon the same point, as follows:—

"By the Act, 31 Geo. 3rd, ch. 34, certificates are to be granted to persons who have been duly examined, entitling them 'to follow the art and mystery of an Apothecary in the kingdom of Ireland.' What was meant or denoted by these words, 'art or mystery of an Apothecary,' must be ascertained from the usage existing at and before the time of passing the statute, and thenceforth uninterruptedly to the

present time. If we refer to that usage, it is clear that from time immemorial before the Act, and at the time of its passing, the Apothecary in Ireland was a Medical Practitioner, attending the sick, and prescribing as well as supplying medicines for their relief. This status of the Apothecary is recognised by many statutes anterior to the Act of 31 Geo. 3rd, ch. 34; and it is therefore proved beyond a doubt that the Irish Apothecary was, at the passing of the Act, *de facto et de jure* a Medical practitioner. This well-known and universal habit and course of practice of the Apothecary is what the statutes denotes by the words, 'art or mystery of an Apothecary;' and ever since the passing of the Act such has been the admitted recognised interpretation of these words. The title of the Licentiate of the Apothecaries' Hall in Dublin to practise Physic has been uniformly treated as a clearly existing right. It has been acknowledged by the Legislature in several subsequent Acts, and recognised as a legal right in the courts of law."

As to the assertion of "a mis-statement" in the case submitted to counsel respecting the position of the Irish Apothecary, it is sufficient again to quote Mr. Napier's words:—

"The Apothecaries in both countries are exempted from serving on juries, a duty which would interfere with their calls to attend on the sick. On full consideration, therefore, of these statutes and authorities, I am of opinion that the legal rights and privileges of the Irish Apothecary are not inferior to those of the English."

It seems to be very remarkable, however, that the College should have omitted any allusion to that part of Lord Westbury's opinion which more especially bears upon the question at issue. He sums up his opinion in the following words:—

"These considerations would, in my opinion, be sufficient for the maintenance of the right of Licentiates of Apothecaries' Hall, Dublin, as duly qualified Medical Practitioners; independently of the Medical Act (21 and 22 Vic. ch. 90), but after the enactment of that statute there can be no doubt of the right of existing and future Licentiates of Apothecaries' Hall, Dublin, to be registered under that Act, and when registered as such Licentiates, to practise Medicine; this is plainly enacted by the 15 Sec. and 31 Sec. of that Act. These provisions entirely supersede the necessity of any inquiry into the constitution or rights of the Company of Apothecaries in Dublin, or its Licentiates; for they (the Licentiates) are by the 15th Sec. expressly entitled to be registered on producing their certificates from Apothecaries' Hall, Dublin, which are, by force of the Act, a statutory qualification for registration as Medical Practitioners.

"Should the Registrar refuse to register any Licentiate, a mandamus would lie to compel him to do so, and probably the applicant would be entitled to an action for damages.

"It is only necessary to observe, in addition, that the fact of being registered under the Medical Act as a Medical Practitioner, is 'such a certificate as qualifies a civilian to practise Medicine,' and that 'every person so registered has a good title to present himself at the competitive examination.'"

But the College article has this further statement:—

"The constitution of the Board of Governors of Apothecaries' Hall of Ireland, from whom the examiners must be selected, under the Apothecaries' Act, is not such as to insure a satisfactory guarantee that the examiners are competent examiners in the science and practice of Medicine."

The fact of the Board of Examiners being necessarily constituted of fifteen practising Apothecaries, who have undergone a course of Medical education, and whose successors must conform to the curriculum recommended by the General Medical Council, furnishes the answer to this statement of the College.

I am, &c.

CHARLES HENRY LEET, M.D.,  
Secretary to the Court of Examiners of the  
Apothecaries' Hall of Ireland.

Dublin, March 30.

IDIOTIC HUMAN BRAIN. — We learn that it is the intention of Mr. R. T. Gore, of Bath, to lay before the Anthropological Society of London, on Tuesday, the 7th inst., evidence of the brain of a female microcephale, aged 42, of which the brain weighed only 10 oz. 5 dr., a smaller weight than hitherto recorded.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 24, 1863.

RICHARD PARTRIDGE, Esq., F.R.S., President.

MR. PARTRIDGE, in taking the chair at the first meeting of the Society, thanked the Fellows for the honour they had conferred on him by electing him their President. He would attempt to show how highly he appreciated this honour by devoting his time and his utmost abilities to the duties of his post, and would endeavour to follow the example of the distinguished Physicians and Surgeons who had previously been Presidents of the Society. As the reputation of the Society rested mainly on its *Transactions*, he urged the Fellows to contribute papers.

A paper, by Dr. EDWARD HEADLAM GREENHOW, was read on  
DIPHTHERIAL NERVE AFFECTIONS.

The author began by stating that the epidemic sore-throat which, under the name of diphtheria, had latterly engaged so much attention, was well known to be followed by nervous phenomena of a peculiar kind. These consisted chiefly of impaired, excessive, or perverted sensibility, together with more or less complete paralysis of the muscles of the fauces, pharynx, tongue and lips, extremities, trunk, and neck; the frequency of the occurrence of these symptoms in the several sets of muscles being nearly in accordance with the order in which he had placed them, the first-named being the most frequently and the last the least frequently affected. The author had had the opportunity of watching the course of several cases of these diphtherial nerve affections in patients under treatment at the Middlesex Hospital, and the present paper was in a great degree based on those observations. He did not mean to infer that every attack of diphtheria was followed by some of these secondary nerve affections, for he had seen patients recover perfectly without experiencing any of them; nor to assert that their intensity was always proportioned to the severity of the primary disease, for he had sometimes seen them follow comparatively mild attacks of diphtheria. Nevertheless, as a general rule, he had certainly observed these nerve affections to be more frequent after the worst cases of diphtheria, and to bear some proportion even to the local severity of the attack; he had noticed, for instance, that the paralysis and anæsthesia were sometimes more complete on that side of the fauces which had been most severely affected by the primary disease. The author had found that a brief period of convalescence—generally not exceeding a few days, but in rare cases extending to weeks—almost always intervened between the disappearance of the sore-throat and the accession of the nerve symptoms; and cases had fallen under his notice in private practice in which patients who had recovered sufficiently from diphtheria to be sent from home for change of air, had subsequently fallen into a helpless condition from diphtherial paralysis. The fact of this interval seemed to him important, inasmuch as it went far to show that the paralysis could not be entirely attributable either to the albuminuria which so often accompanies the acute stage of diphtheria, or to the anæmia which closely follows it, as patients had often got rid of the former symptom, and had even begun in some cases to regain flesh and strength, before the accession of the paralytic symptoms. The author had observed that these nerve affections do not at once attain their maximum of intensity, but are progressive even in the same sets of muscles; and also that if several of the sets of muscles which he had enumerated should be attacked in the same individual, they do not become affected all at once, but in succession—the faucial or pharyngeal muscles being the first to suffer, and so on in the order in which he had placed them at the beginning of the paper—though it by no means followed that all of them should be affected in any one case. He had found the muscles of the fauces by far the most frequent, as well as the earliest, seat of nerve affections after diphtheria, and had seen them attacked in many cases in which the rest of the muscular system either entirely escaped or was very slightly affected. When the fauces were paralysed, the soft palate lost its natural action, the speech often became imperfect, and liquids regurgitated through the nostrils. These

symptoms should be discriminated from the hoarseness of voice and return of fluids through the nostrils which often occur during the acute stage of diphtheria, and arise, as in ordinary quinsy, from the swollen and painful state of the fauces impeding the natural action of the parts. Anæsthesia had co-existed with the paralytic affection of the fauces in all the cases that had come under the author's notice, so that these naturally very sensitive organs became altogether callous and insensible to touch. Next to the affection of the fauces, impairment of vision, probably due to paralysis of the ciliary muscle, appeared to be the most frequent of the nervous disorders consequent on diphtheria. The author had observed that the pupil of the eye became dilated, and acted sluggishly under the influence of light a day or two before the sight became sensibly impaired, and often remained so for a time after the sight had been regained; also that patients unable to read with unassisted sight could do so with the help of convex spectacles; and hence he attributed the impairment of sight to a temporary loss of adjusting power. The nerve symptoms which he had noted in the tongue and lips were, formication, or a sense of scalding, numbness, and impaired taste and power of movement. They began, for the most part, in the lips and the tip of the tongue, and gradually extended upwards towards the dorsum and root of the latter organ. The limbs had suffered more or less, in all the five cases which formed the basis of the paper, from paralysis and anæsthesia, besides tenderness and abnormal sensations, such as coldness, formication, and a feeling of constriction in the fleshy parts, as if they were tightly bandaged. These affections began either first in the upper, or at the same time in both the upper and lower extremities, and were at their commencement peripheral, extending gradually upwards from the tips of the fingers and toes towards the trunk, and in some cases affecting the lower part of the back and of the abdomen. He had found that pressure over the sciatic and median nerves was sometimes attended by acute pain, and that pressure of the instep between the finger and thumb sometimes caused convulsive starting of the leg and foot, as well as pain. He had observed that the paralysis in some cases assumed a more or less hemiplegic character, but had seen no instance in which, one side being paralysed, the other remained entirely unaffected. The author had seen nerve-affections after diphtheria of a graver character than any of those exemplified in the present group of cases, and several even fatal cases had fallen under his notice in private practice. In three of these latter, death was caused by failure of the action of the heart, and in one by exhaustion from vomiting. He believed, however, that such cases were fortunately exceptional, and that the great majority of sufferers from diphtherial nerve-affections, under good management, sooner or later recovered their usual health and strength. The author had satisfied himself that these cases were best managed on sound general principles. Generous diet, and a liberal allowance of stimulants, together with rest in bed, he believed to be always necessary. Tonics, especially steel and quinine, or the mineral acids, he had found useful from the first appearance of the nerve affections; and after the complete development of the paralytic symptoms, nux vomica and strychnia had proved in his hands most valuable remedies. Subjoined were the five cases on which most of the remarks in the paper were founded.

MR. ACTON said that as three of his children had suffered from diphtheria, he had thought a good deal on the disease. He was sorry that the author had not given any opinion as to its cause. He (Mr. Acton) considered that it arose from deficient drainage, and mentioned several facts in connexion with the disease occurring in his own family in support of this view. One of his children had been attacked without any evident premonitory symptoms. The first thing to notice was an offensive odour from the nose. Mr. Acton then went on to speak of other symptoms, as the want of power to write properly, especially to write on lines, and sudden falling in running. It seemed, he said, as if the power suddenly failed. All his children got well, and he considered that if, after a certain stage of the disease, the patients are sent into the country they will generally get well. He considered the change of locality a very important point, and believed that removal saved the life of one of his children. Mr. Acton referred to the peculiarity of pronunciation after recovery from the diphtheria. One of his children for nearly a year after could not say "ah," or pronounce the letter w.

Dr. WEBER related several cases of paralysis after diph-

theria, in which there had been much the same symptoms as in Dr. Greenhow's cases. He could not, however, agree with Dr. Greenhow as to the order in which the symptoms followed. He (Dr. Weber) had found that the first symptom was a great slowness of the pulse. This began during the persistence of the diphtheritic membrane, or just after its removal. It might be as low as 36. It was possible that this symptom might not be due to paralysis, as it had been shown that *irritation* of the pneumogastric caused retardation of the pulse. Still, the depression was so great, that he (Dr. Weber) thought it was a result, probably, of paralysis rather than irritation. He considered that the prognosis was generally favourable, but in two cases in his practice there had been a fatal result. In these, however, there were complications—viz., in one fatty degeneration of the heart, and in the other valvular disease. Dr. Weber then asked the question, whether the paralysis of diphtheria was to be looked on as a necessary part of diphtheria—as a “secondary” symptom of the disease? He did not give any opinion. He referred to other diseases, as scarlet fever, in which similar affections followed.

Dr. SANDERSON had seen a great many cases of diphtheritic paralysis, and believed that it depended not so much on a loss of muscular power as on a want of co-ordination. The different power of movement at different times showed this. Again, patients who could walk or use their arms for rough purposes could not do anything fine, as button a shirt. The defect of sight might be explained on the same principle. In all cases the defect of sensibility preceded that of motility.

Dr. WOOD related a case of paralysis which came on after diphtheria. It affected the fauces, the limbs and trunk, but not the sight. The paralysis was so great that the patient could not turn in bed, and could not feed himself. In another case there was no paralysis, but melancholia. The patient was an inmate of St. Luke's Asylum.

Dr. SIBSON suggested that the faucial paralysis might be the result of the local disease in the throat, the muscles being inflamed during the acute attack, and consequently their action would be afterwards impaired.

Dr. GREENHOW, in reply, said that his paper being exclusively on the secondary nerve-affections of diphtheria, he had necessarily abstained from all reference to the etiology of the primary disease. He might say, however, as the question had been raised, that in the course of his experience, which had been very extensive, he had altogether failed to discover any direct relation between diphtheria and the local impurities referred to by Mr. Acton. He must also dissent from that gentleman's remarks on treatment, for, on the one hand, he (Dr. Greenhow) had found rest a very important element in the treatment of the secondary nerve-affections; and, on the other, he had repeatedly found, as stated in his paper, that change of air had not the effect of warding off their accession. At a later period, however, when patients had begun to recover from these nerve-affections, their convalescence was undoubtedly accelerated by removal into a pure country air. Several questions had been proposed to him as to the pathological nature of diphtherial nerve-affections. He (Dr. Greenhow) could have wished that the gentlemen who put them had at the same time stated their own views on the subject, if they had formed any; for himself, he was unwilling to express any positive opinion on so obscure a question until further observation should have enabled him to verify what he could now only put forward as conjecture. He could not quite agree with Dr. Weber in regarding the slowness of pulse which he had so well described as one of the most frequent secondary symptoms of diphtheria; in his experience it had rarely occurred, and not oftener in the secondary than in the primary stage of the disease. Whenever it did occur, it was a serious and too often a fatal symptom, and he was disposed to think with Dr. Weber that it depended on some affection of the pneumogastric nerve. It was no doubt true, as Dr. Sanderson had suggested, that many of the phenomena of these curious nerve-affections were due to a want of co-ordinating power; but he (Dr. Greenhow) could not, like that gentleman, regard them as consisting entirely of paralysis of sensation; for although the loss of motor power only reached its climax *pari passu* with the muscular emaciation, there generally existed some degree of it from the beginning. The intense inflammation which had recently affected the superjacent mucous membrane might perhaps, as Dr. Sibson had suggested, partly account

for the paralysis of the muscles of the fauces, but could scarcely explain the paralysis of the tongue and cheeks which had been sometimes observed, and still less that of the muscles of the trunk and extremities.

## THE PATHOLOGICAL SOCIETY.

TUESDAY, MARCH 3.

Mr. PRESCOTT HEWETT, President, in the Chair.

Dr. OGLE showed

A LARGE EPITHELIAL WARTY GROWTH FROM THE VOCAL CORD  
—SUDDEN DEATH BY ASPHYXIA.

For the opportunity of exhibiting this specimen, Dr. Ogle was indebted to Dr. Stone, of the Brompton Hospital. It was removed from the body of a woman, aged 23, married. She applied for admission to the Brompton Hospital on July 15, 1862. She stated that her husband was a gravel-digger, that she worked in the fields, and had been subject to cough all her life, but dated her illness from twelve months previously. Her family were phthisical; her father and twelve brothers having died of this complaint. On first application she was examined by Dr. Sanderson, who ascertained the presence of tubercle on the apex of the right lung, but attributed the most urgent symptoms to some laryngeal affection. This latter had appeared four months before; since then there had been complete aphonia, great dyspnoea, especially at night, and uneasiness referred to the larynx. When seen, the act of inspiration was slow and difficult, there was croupy cough of a particularly shrill and vibratory character. A month later she was admitted into the wards, with no alteration in symptoms. She was very restless, and the act of swallowing caused dyspnoea. Respiration was deficient under the right clavicle, of a tubular character. Singularly enough, the resonance on percussion was good and equal on the two sides. Two days after admission she died suddenly, with symptoms of asphyxia. These began while she was standing in the ward, by gasping, struggling, and irregular movements of the arms. In a few seconds the face became livid; within a minute she was insensible; motion ceased, and the pupils gradually dilated; pulsation could be distinguished in the heart and carotids for some seconds longer. On post-mortem examination, a solid mass of tubercle, very defined, about the size of an orange, was found at the apex of the right lung: in the centre of it was a small cavity the size of a nut. The rest of the lungs were remarkably free from tubercular deposit; they were emphysematous at the edges, and contained much thin, frothy, serous fluid. The larynx contained the tumour shown, which consisted of a lobulated, warty, or cauliflower-looking growth springing from the whole length of the left vocal cord. About two-thirds of its bulk was above the level of the glottis; about one-third below, and in the trachea. Its size was such as completely to block the passage: a probe the size of a crowquill could, however, be passed along the posterior wall. In its largest diameter it measured four-fifths of an inch, and half an inch in breadth. Before the larynx was opened it reached nearly up to the base of the aryteno-epiglottidean folds. The other organs of the body were healthy. On microscopical examination of the growth, Dr. Ogle had found it to be one coming under the designation of epithelioma. It consisted of a vast number of epithelial cells of various sizes and shapes, some being of the character of so-called mother or parent cells, with a considerable quantity of fibrous tissue, mostly of a very firm consistence. The minute description of the various cells found would not differ from that of other similar growths found not occasionally in the same situation. Dr. Ogle observed that he had lately examined a somewhat similar specimen, which had been for some time in St. George's Hospital. The growth was much less in size, but its histological characteristics were almost identical with this specimen. It was removed from the body of a boy, aged 4 years, whose chief complaint during life was dyspnoea, with croupy inspiration, especially during sleep, which then was often stridulous. Dr. Ogle was informed by Dr. Stone that in his case laryngoscopy had not been resorted to, as it was feared the efforts necessary for such a procedure might bring on a fatal, or, at least, dangerous dyspnoea.

The PRESIDENT regretted that the patient had not been able to tolerate a laryngoscopic examination. There was present,

he remarked, a gentleman,—Dr. Gibb,—who had removed tumours of a similar kind, though not so large. He had no doubt but that Dr. Gibb would have been glad to have dealt with such a case.

Dr. GIBB thought that if the patient had been seen early the growth might have been removed. From inspecting many tumours of the larynx, he should judge that the specimen should be called “fibro-cellular,” rather than malignant.

Dr. OGLE explained that he did not call the tumour malignant, but epithelial. It contained epithelial cells.

Dr. BRISTOWE said that he had several times brought before the Society specimens of epithelial tumours which were not malignant. He considered that the tumour in the specimen exhibited was too extensive to have been removed during life.

Dr. GIBB said that he had then under his care a patient who had a warty growth in the larynx; it was the size of a pea. A few days ago he made an effort to remove it, but only got away a slice. He had since applied caustic to the cut surface, and under this treatment the mass was gradually getting smaller.

Mr. GAY showed to the Society an infant in whom there was

#### MALFORMATION OF THE GENITAL ORGANS.

The child was four months old. The scrotum was divided, and in each half was a testis. The penis was rudimentary, and the urethra opened at the lower part of the fissure. The corpus spongiosum was deficient on both sides. At the lower part there were two bodies, one vascular, which Mr. Gay thought was composed of the tissue of the undeveloped corpus spongiosum, and the other a rounded, polypus-like body. The child was brought to him in order that he might give his opinion as to the propriety of removing these bodies.

The PRESIDENT proposed that a drawing of the parts should be made for the *Transactions* at the expense of the Society.

Mr. PARTRIDGE asked if the case were not of a class not very uncommon, a split scrotum, rudimentary penis, and imperfect urethra, the two tumours being merely accidental. He referred to the case of a German who went about exhibiting himself, pretending to be of both sexes. He was really a man, though he had certificates from several distinguished foreign Medical men that he was a woman. His urethra was large, and this was taken for a vagina. It was said that the os tinæ could be felt in this so-called vagina; what was reached by the finger, however, was the prostate, and his urine could be drawn off through this channel.

The PRESIDENT said that he considered that the complications rendered it the more necessary that a drawing should be made. He agreed with Mr. Partridge that they were accidental.

In reply to Dr. Schulhof, Mr. GAY said that there was no instance of malformation in any other member of the patient's family.

Mr. THOMPSON suggested that the vascular growth might be removed by the ligature.

Dr. DICKINSON exhibited two specimens of

#### GRANULAR DEGENERATION OF THE KIDNEY.

They had both been taken from elderly people; dropsy had not been a prominent symptom in either case, and in other particulars each had been accompanied by a very characteristic history. The object in bringing forward these specimens, however, was not clinical, but had relation to morbid anatomy. The mechanism by which a granulated surface is developed upon the kidney was explained, and preparations and drawings were adduced in support of the views advanced. It was maintained that since the tubes of the kidney were of microscopic size, no mere dilatation of these structures could occasion any roughness of surface perceptible to the unaided senses. Granulations were made not so much by projection of the tubes of which they are composed, as by contraction of the intermediate spaces. This contraction was explained to be occasioned by a minute deposition of fibroid material upon the intertubular tissues, which subsequently contracted and drew in the surface. Granular degeneration of the kidney thus was made out to be exactly analogous to cirrhosis of the liver. In the earlier stages of the disease, fibrous processes could be seen passing into the kidney from the capsule at regular intervals. These worked their way into the kidney, travelling quite independently of the direction of the tubes. The tubes and their epithelium became subsequently affected. Dr. Dickinson expressed his dissent from the views of those pathologists who attribute all the diseases of the kidney to more or less desquamation of the epithelium.

Dr. WILKS said that the statement of Dr. Dickinson that the granular kidney was the consequence of an intertubular deposition of fibrous tissue was highly important if true, but it was so easy to confound the matrix of the organ, and even the wasted tubules themselves, with simple fibrous tissue, that much care was required in coming to a decision on the question. That the apparent adventitious material was nothing more than the wasted tubular structure was the opinion of many high authorities. As regards the similarity of the disease to that of cirrhosis of the liver, this held good under the more recently received opinion. In Bright's Disease the analogy was at once made, but disputed on account of the belief that the *hepatic* cirrhosis was due to the contraction of a plastic lymph, whereas there was thought to be an absence of such inflammatory product in the *nephritic* cirrhosis. On the supposition, however, that the granular kidney is caused by an intertubular nephritis, the two diseases have again been compared, and now they may with more justice than ever be considered as analogous conditions, on the theory that in neither case is there a deposition of lymph in the structure, but that the contraction and granulation are due to atrophy alone; in both cases the nodules or granulations being formed by little masses of the tissue itself.

Mr. SPENCER WATSON exhibited a specimen showing  
CONGENITAL DEFICIENCY OF THE RECTUM, AND IMPERFORATE URETHRA.

The child from which the preparation was removed was born probably at the full time, or nearly so, but was smaller than the average size. The mother, a tolerably healthy woman, had several other well-formed children. There was nothing on the surface to indicate the position of the anus or the course of the rectum. An umbilical hernia, covered only by the transparent integument of the cord, and talipes calcaneo-varus of the left foot, co-existed with the other deformities. An attempt was made to relieve the child by an incision from the perineum without success. No urine passed by the urethra. The belly became much distended, and the child died on the fourth day from its birth. On dissection a portion of colon, corresponding to the umbilical hernia, was found much inflamed, and recent lymph was effused on its surface. The whole large intestines much distended. The cæcum lying below the stomach, and the remaining portion of the colon took a very irregular course, a small portion of it only being attached to the left loin by mesocolon. The bowel terminated a little to the right of the inferior fundus of the bladder, and communicated with it by a narrow canal, a quarter of an inch long. The urethra was imperforate in the middle part of its course, and the bladder and ureters very much dilated. The dissection of the perineal region gave no indication of a sphincter muscle. The distance between the terminal portion of the bowel and the perineum was at least five inches. A cast of the left foot of the same subject, from King's College Museum, showed a variety of talipes having the characters of talipes varus and talipes calcaneus, the heel being depressed and the inner border of the foot raised.

Dr. GIBB exhibited a

#### PIECE OF NECROSSED CRICOID CARTILAGE EXPELLED IN THE ACT OF COUGHING.

The patient was a man of 47, who had been very ill with fever and rheumatism in India and China. He had been subject to sore-throat, was hoarse for months, and had had loss of voice some weeks. He could utter only the feeblest whisper. The breathing was stridulous and noisy. Expectoration was very profuse. Laryngoscopy showed a large tumour formed by the right false vocal cord, which nearly obliterated the glottic opening. The inner surface of the tumour was excavated like a crater. Under treatment the swelling and urgent symptoms subsided, and he was on the eve of discharge from the Hospital when he expectorated a portion of the ring of the cricoid cartilage. A few days after he had œdema of the right side of the glottis, with almost closure of the latter. Dr. Gibb scarified the swelling freely with an instrument he had devised, and introduced a large bougie (three-quarter inch diameter) into the larynx, to dilate the passage, by the aid of the laryngoscope. All the dyspnoea subsided, and he rapidly improved.

Dr. GIBB also showed illustrations of  
TUBERCULOUS AND FOLLICULAR ULCERATION OF THE LARYNX AND TRACHEA.

1. A female, aged 38, mother of four children. Tuberculous

ulceration of the larynx, especially involving the right vocal cord; hoarseness, partial aphonia and dysphonia for seven months; inflammation of the left thyro-hyoid ligament; in the third stage of pulmonary phthisis. 2. Pale, delicate, strumous lad of 17, in first stage of pulmonary phthisis. Loss of voice for sixteen months, and now a laryngeal whisper; larynx and trachea much congested, with ulceration of the follicles on true and false vocal cords, in the trachea, on the epiglottis, and aryteno-epiglottic folds. These were all healed up by two applications of a solution of nitrate of silver, and the voice improved. 3. A female, aged 24; has spoken in a whisper for fifteen months; in second stage of phthisis; great irritability of larynx, which was found to be finely ulcerated throughout, as in No. 2, conjoined with acute inflammation of the epiglottis. The aphonia was chiefly due to thickening of the true vocal cords and ulceration of their mucous covering, which had almost wholly stopped their action.

The PRESIDENT supposed that Dr. Gibb would agree that necrosis of the laryngeal cartilages was not rare, and that pieces of bone were not unfrequently coughed up. He had seen several cases in which this had occurred as regards the arytenoid. In one, the fragment got into the windpipe and nearly suffocated the patient.

Dr. GIBB said that he exhibited the specimen as it was rare to be able to see the exact point from which the bone came. This could only be done by the aid of the laryngoscope, and was represented in one of the drawings he brought forward.

Mr. OBRÉ then showed

#### PART OF THE TONGUE REMOVED FOR EPITHELIAL CANCER.

A gentleman, 42 years of age, had slight ulceration of the tongue from a false tooth. Induration followed, and the ulceration extended. There were no enlarged glands. Mr. OBRÉ removed it by the knife. There was a good deal of hæmorrhage, which was soon stopped; but afterwards secondary hæmorrhage ensued. There was evidence of tendency to cancerous disease on both sides of the patient's family.

Mr. HENRY THOMPSON referred to two specimens he had exhibited for Mr. Fiddes, of Jamaica. (See this Journal for May 18, p. 535, and June 1, p. 389, 1861.) In both the whole of the tongue was removed, and both patients recovered from the operation; but one of them died twelve months afterwards from recurrence of the disease, and the other, when he last heard from Mr. Fiddes, was suffering from recurrence. As to the removal of cancer of the tongue, he considered that if they were well isolated there was a good chance, and especially in some of a doubtful nature. There was no difficulty in applying the chain of the *écraseur* well behind the disease if the tongue were perforated. He doubted, however, whether it was desirable to remove parts of the tongue by this instrument, as, although there was little hæmorrhage at the time, many of them bled afterwards.

Mr. BARWELL referred to Mr. Nunneley's case of removal of the whole tongue. (See this Journal for December 21, 1861.) He (Mr. Barwell) believed that when cancer was seated near the tip of the tongue it was less likely to return when removed than when it was far back. This, he considered, depended on the nature of the tissue affected.

Mr. PARTRIDGE said that in all the cases in which he had operated the disease had invariably returned.

Mr. GAY said that he had seen a case of cancer of the tongue commencing in a position precisely corresponding to a decayed and roughened tooth, and he had no doubt but that such irritation was a frequent cause of the disease.

Dr. MONTGOMERY then showed a specimen of

#### PYÆMIC DEPOSIT IN THE LIVER.

He considered that it illustrated the mode of secondary deposits. There were clots blocking up branches of the portal veins, and these led to the part of the tissues of the liver which was diseased. These clots were exactly of the colour and appearance of the fibrine in the liver itself. On opening one of the deposits he found only *débris* of fibrine, and he believed that the so-called abscesses were not deposits at all, but coagulations in the capillaries, which afterwards softened and decomposed. Some of these were quite hard, and under the microscope showed the structure of ordinary clots. It occurred after an amputation, so that he could not understand that any material had been bodily carried and arrested in the capillaries.

Dr. DICKINSON said that the specimen looked like one of fibrinous clot.

Dr. MONTGOMERY replied that he thought so, but that the fibrine was being decomposed.

Dr. BRISTOWE considered that Dr. Montgomery meant that the so-called secondary deposits were not really secondary, but local deposits, which afterwards underwent softening. In the lungs blood was sometimes effused in pyæmia.

Dr. WILKS said it was true that such primary deposits would take place, but no one would deny that inflammatory changes would follow.

Dr. MONTGOMERY considered that very often there was no inflammation, at least none visible. He considered that the great bulk of the so-called deposits were decomposed fibrine.

Dr. WILKS and Dr. BRISTOWE explained that they were speaking of the first stage of the process.

Mr. BARWELL thought there was no evidence of actual carrying of pus. The condition of the blood was the important part of the diseased process.

The PRESIDENT thought that the theory broached as to the softening of fibrine would scarcely hold good as regards extensive deposits in the cellular tissue, in the joints, etc.

Dr. MONTGOMERY thought that if the substance from the localities mentioned were examined by the microscope it would be found to be softened fibrine, and would contain only a few pus corpuscles.

The PRESIDENT replied that he had found pus in the deposits in joints.

Mr. BROOKE exhibited a specimen of

#### CUTANEOUS TUMOUR

removed a week ago from the middle of the dorsal region of the spine. It had been growing for twenty years, but rapidly for the last three or four. It was soft, painless, and sessile. He could not decide whether it was a degenerated *nævus* or not, and he was not certain as to its malignancy. It contained large nucleated cells.

## OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, FEBRUARY 4, 1863.

Dr. OLDHAM, President, in the Chair.

The following gentlemen were elected Fellows of the Society:—W. Bannister, Esq.; A. P. Owen, Esq.; and Dr. G. Simpson.

After a short address from the President upon his assumption of office,

Dr. TYLER SMITH read a communication from W. W. Wiseman, Esq., and exhibited a part of the

#### FUNIS OF A STILL-BORN CHILD IN WHICH A DOUBLE KNOT WAS FOUND.

The knot was apparently the cause of death. It was the second child in a twin case, the first being born alive.

A paper, by I. BAKER BROWN, F.R.C.S., was read on VESICO-VAGINAL FISTULA, THE MODE OF OPERATING, AND THE RESULTS OBTAINED IN FIFTY-FIVE CASES AT THE LONDON SURGICAL HOME.

In the first part of the paper the author gave an account of the method at present followed by him in operating. The various steps of the same were illustrated by drawings. No bars or clamps are used. The knives employed are two—one for the right hand, and one for the left. The needles, of various curves, forming a series fourteen in number, are on the same principle as Startin's, but of rigid material. They are armed with wire, and thrust through the pared edges, great care being taken to avoid the mucous coat of the bladder. The two ends of the wire are simply twisted round and round, and so fastened. The patient is afterwards laid on the side, and a male elastic catheter, with bag attached, kept in the bladder. She is kept quiet ten or fourteen days, and the wires removed. The operation is often completed in ten minutes. The total number of cases of vesico-vaginal fistula admitted into the London Surgical Home since its foundation, four years and a-half ago, is 58. Of that number, 55 were submitted to operation, with the results as shown in an accompanying table. The remaining 3 were not operated upon in consequence of the bad condition of bodily health, the result of syphilis. Of the 55 cases treated, 53 were operated upon by the author, 1 by Mr. Nunn, and 1 by Mr. Harper. Of the total number of operations, 43 were followed by perfect cure, 1 was much relieved, 2 died, 5 were not cured, and 4 are still under treatment, with every prospect of cure. Of the 43 cures, in 24 this

result followed the first operation, including the cases of Mr. Nunn and Mr. Harper; in 8 the cure occurred after the second operation; in 5 after three operations; and in 6 after more than three operations. Of the other cases which were not cures details were given in tables exhibited. Of the 2 fatal cases, 1 died eighteen days after the operation, apparently from exhaustion, the age of the patient being 56; the other died seven days after from pyæmia. With regard to the causes of vesico-vaginal fistula. Of the 58 cases admitted into the London Surgical Home, 47 were over twenty-four hours in labour, and 39 were as much as thirty-six hours or more; 7 were two days, 16 were three days, 3 were four days, 2 were five days, 2 six days, and 1 seven days. In the whole number of cases, instruments were used in 29, exactly one-half; and in 4 only of these was the labour less than twenty-four hours, and with 7 exceptions the patients had been thirty-six hours, or more in labour before instruments were used. Of the 58 cases, in 24 only the injury happened at the first labour, in 7 at the second, in 5 at the third, in 4 at the fourth, in 6 at the fifth, in 2 at the sixth, in 5 at the eighth, in 1 at the ninth, in 1 at the thirteenth, in 1 at the fifteenth, and 2 not mentioned. In many of these cases, notwithstanding the existence of the fistula, the patient bore several children, apparently without inconvenience, before coming under treatment; and in a few of them, subsequent to cure by operation, other children have been born without recurrence of mischief. In a large proportion of the cases there is a history of the birth of a very large child; in some it weighed 15 lbs.; and in one, that of the woman in whom the lesion happened at the fifteenth labour, the child weighed 17 lbs. From the foregoing statistics it is evident that the cause of the lesion is protracted labour, and not the use of instruments or deformity of the pelvis; and, as a necessary conclusion to what has been stated, it follows that vesico-vaginal fistula would scarcely or never occur if a labour were not allowed to become protracted: this is a point for the careful consideration of the Society and of Practitioners at large. A printed tabulated statement as to the 55 cases operated on was handed round. Mr. Brown further stated that he had had 11 other cases under his care in St. Mary's Hospital, and 6 in private practice, making a total in his own experience of 58 cured; 34 by one operation, 11 by two operations, 5 by three, and 8 by more.

Mr. BRYANT remarked that the essential steps of the operation might be divided into two. First, to make a clean and even dissection of the margin of the fistula; and, secondly, to bring the edges together, and to keep them there. Both points were of equal importance; for if either was imperfectly executed, failure would necessarily follow. He differed from the author respecting the use of the forceps and scalpel in carrying out the first steps of the operation. He had been led to the formation of his pronged guide, a description of which would be found in the *Transactions of the Medical Society of London*. By this instrument a clean section of the margin of the fistula, however large it may be, is absolutely guaranteed. Every operation which he had undertaken since its introduction had been followed by immediate success. Respecting the second step of the operation, he generally preferred metallic sutures. He believed that it was unnecessary, as also injurious, to leave the sutures in after union had taken place. Failure had followed such a practice. Respecting the use of opium in the after-treatment, on which Mr. Brown had been silent, he was disposed to recommend that enough be given to keep the bowels at rest, but nothing more. He would inquire of Mr. Brown also how long the catheter was retained in the bladder after the operation? His experience had told him that a periodical introduction only was necessary.

Mr. NUNN believed that further observation would show, as it had shown in a case he referred to, that in some cases the retention of the catheter in the bladder was not always safe; that ulceration was liable to ensue. This was a point requiring careful consideration.

Dr. BRAXTON HICKS thought that, from what he had seen, more injury was done by long-continued pressure than by a more forcible one of short duration. It was impossible to lay down any rule as to the time the head could remain with impunity; for in a case of vesico-vaginal fistula he had seen the labour was of average duration, and never severe. Although he considered, in good hands, the forceps could be safely used, yet before we could assent to the inference drawn by Mr. Baker Brown, we must be certain that no other injuries would be produced by the forceps worse than vesico-

vaginal fistulae, injuries which might possibly prove early fatal, and thus not give time for the development of fistulae.

Dr. OLDHAM saw nothing in the communication made to the Society, valuable as it was, to induce him to vary a hair's breadth from the precautionary precepts for the employment of instruments in protracted labour which were recognised and advocated by the best British obstetric authors. He felt persuaded, from his experience of cases which had come before him, that the more frequent employment of instruments would result in the laceration of the structures at the floor of the pelvis, particularly the laceration through the sphincter of the rectum, an accident only second to that of vesico-vaginal fistula in its distressing results, and which involved a most painful and formidable operation.

Dr. TYLER SMITH observed that in laying down a rule of practice it was especially necessary to employ precise language. If Mr. Brown had employed the term labour with impaction, instead of protracted labour, he should have agreed with him. We might have protracted labour from many causes, some of them not necessarily injurious to the mother, but we could not have continued impaction of the head without the risk of injury to the soft parts of the mother, and impaction should therefore never be allowed to go on unrelieved. In performing the valuable operations which had been devised for these distressing conditions, he (Dr. Tyler Smith) thought it should be laid down as a principle, that in repairing one organ the integrity of the neighbouring organs should be respected. This applied, in the operations for vesico-vaginal fistula, to the rectum, ureters, and the os uteri. In some of the cases related the os uteri had been closed, and the menstrual fluid left to escape *via* the bladder, or the urine to pass per rectum. These evils were scarcely less than those they were intended to remedy. Fatal results had followed from closure of the os uteri. Very recently he had seen a remarkable case where the os uteri had been closed in a plastic operation, which seemed perfectly justifiable, for the relief of utero-vesical fistula. A perfect cure was the result as regards the urine for the time. Menstruation occurred through the bladder, but the patient in a few months became pregnant. The urethra was of moderate size, and there seemed no other explanation than that the spermatozoa must have passed from the vagina through the urethra and bladder to the uterus. The result of this and other cases satisfied him that it was not a safe practice to close the os uteri, or to invade other organs, but that the plastic operations should be limited as far as possible to the closure of the original fistulae.

Dr. ROGERS agreed entirely in the remarks made by the President and Dr. Tyler Smith. With reference to the mode of operation recommended by Mr. Brown, he thought it was undoubtedly the best. He considered Mr. Brown and other gentlemen were entitled to great praise for their untiring labours in rendering these formerly hopeless cases amenable to treatment.

Mr. BAKER BROWN, in reply, said that he supposed the prong mentioned by Mr. Bryant to be similar to that invented by Mr. Hilliard, of Glasgow. He had tried it, and found his old plan easier and quicker. In America, Drs. Sims and Bozeman did nearly all the denuding of the edges with scissors. This made the operation very long. But if the knife were first used to mark around the fistula how much was to be taken off, and then, by means of a fine pair of forceps, the edges were made tense, Mr. Brown said that the whole fistula might be denuded, taking out a complete ring—a matter of great importance. In regard to the sutures, Mr. Brown stated that he greatly preferred wire, although Dr. Hayward of Boston, U.S., used silk in preference. Mr. Brown had by this gentleman's advice used silk in one case with a good result. But they were more liable to slough, and the wires, from their stiffness, had the advantage of keeping the edges more in apposition, and so ensuring a greater depth of union. But the sutures to be used should, Mr. Brown thought, be silver, not iron, as recommended by Dr. Simpson, of Edinburgh. Mr. Brown expressed a very strong opinion in favour of keeping the sutures in long enough; never less than nine days. He believed no harm ever resulted from retaining them in longer; but in one case he had had, he removed them on the sixth day, at the patient's request. The fistula appeared quite healed. She got up next day, contrary to advice, and the whole burst open again. She was re-operated on; the sutures were left in a sufficient time, and a cure resulted. Mr. Brown had made experiments, and kept silver sutures in for six and nine months, and no trace

of ulceration appeared. Mr. Brown considered that opium should be given only in sufficient quantities to keep the bowels quiet. One grain immediately after the operation, and repeated night and morning, according to the circumstances of the case. Many patients cannot bear the catheter, especially the leaden one, but Mr. Brown had seldom found the male elastic catheter to cause irritation. Perhaps in time we might gain sufficient confidence in the operation to allow the patient to pass her urine as required, but at present it was better to retain a catheter, or, when that was not tolerated, to pass one when needful. He had purposely used the term protracted without reference to the cause of protraction, for it was very rarely that a Medical statement could be obtained. It was necessary therefore to take only the statement of the patient as to the duration of labour. When the head was impacted, Mr. Brown would deliver as soon as possible by forceps. He quite agreed with Dr. Tyler Smith as to the necessity of maintaining the integrity of the other parts in these operations. Of the two cases on which he (Mr. Brown) had operated, and where the patients subsequently menstruated per urethram, in one, the patient having been under many operations in other hands for some years, the os had already been interfered with either by sloughing or by the operation, and only one small opening, as described, remained to be closed. There was therefore nothing left to do but to close the opening, regardless of the menstrual flow. The patient had done well. No inconvenience had arisen, and she was grateful for the benefit received. In the other, that lately brought before the Society by Mr. Chapman, the os uteri was already closed by cicatrization, after extensive sloughing, and therefore Mr. Brown had nothing to do with its occlusion. He considered that the two terms, vesico-vaginal and vesico-uterine fistula, were not used with sufficient caution. Although the os uteri might often be involved in vesico-vaginal fistula, the true vesico-uterine fistula was when the hole was high up in the cervix, urine dribbling through the os uteri, although no aperture from the bladder was visible. This was the kind of which Jobert had related seven cases, Dr. Fleetwood Churchill one, and which had lately been so well described by Mr. James Lane, who had had one case. In all these the treatment had been to close the os, so that the patient menstruated per urethram. He (Mr. Brown) had never had such a case, but he thought that the treatment adopted was decidedly the lesser evil, and if the patient, on having the case laid before her, was of the same opinion, he considered it perfectly justifiable. The case Mr. Nunn had mentioned showed that, by leaving a vesico-vaginal fistula alone, other evil results, besides the inconvenience, would arise.

## MEDICAL NEWS.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—At a General Meeting of the Fellows, held on Monday, March 30, Thomas Watson, M.D. Cantab., was elected President of the College for the ensuing year. At the same meeting, the following gentlemen, having undergone the necessary Examination were duly admitted Members of the College:—

Henry Heanes Cruicknell, M.B., King's College Hospital; Octavius Sturges, M.B., 35, Connaught-square; Henry Llewellyn Williams, M.D., 9, Leonard-place, Kensington.

The following gentlemen passed the Preliminary Examination in the subjects of General Education on March 28:—

Robert Mark Bradford, Exeter; Walter Branson, Worthing; Henry Cheesman, 2, Finsbury-square; Frederick Churchill, Barkham-terrace, Lambeth; Arthur Bowes Elliott, Richmond, Yorkshire; Richard Hay, Bridport, Dorset; Walter Smith, Ringwood, Hants; Lytton Stewart Winslow, Caius College, Cambridge.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, March 26, 1863:—

John Page Julian, Durham; Henry Seekamp Ward, Horncastle; Thos. Lawson Craister, Leeds; Francis Blake Hutchinson, London; Frederick Page Atkinson, St. Thomas's Hospital; George Ireland Russell, Gravesend; Henry Charles Wine, Bristol; Thomas Baker, Birmingham; Samuel Lloyd, Smethwick; Robert Sidney Stone, Bath; James Allen, Hale, near Liverpool.

## APPOINTMENTS.

\* \* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BATT, EDGAR D., M.R.C.S. Eng., has been elected Coroner for County of Monmouth.

BENNETT, C. V. S., M.R.C.S. Eng., has been appointed Honorary Medical Officer to the Pembroke and Tenby Dispensary and Infirmary.

GOODCHILD, FREDERICK, M.D. St. And., has been elected Physician to the Warwick Dispensary.

HEAD, EDWARD, M.B. Lond., has been appointed Physician to the St. Pancras and Northern Dispensary, Euston-road.

HOLMESTED, T., M.R.C.S. Eng., has been appointed Resident Medical Officer to the Dispensary, Newport, Monmouthshire.

JONES, HENRY P., M.R.C.S. Eng., has been appointed Honorary Medical Officer to the Pembroke and Tenby Dispensary and Infirmary.

KEMP-TER, F. H., M.B., has been appointed a Resident Surgeon to the Melbourne Hospital, Australia.

KIRKMAN, WILLIAM P., M.D. St. And., has been appointed Medical Officer and Superintendent of the Kent County Lunatic Asylum, Barming Heath, Maidstone.

LITTLE, F., M.R.C.S. Eng., has been appointed House-Surgeon to the Loughborough Dispensary.

PAYNTER, JOSHUA W., M.R.C.S. Eng., has been appointed Consulting Surgeon to the Pembroke and Tenby Dispensary and Infirmary.

REID, DOUGLAS A., M.D., has been appointed Honorary Medical Officer to the Pembroke and Tenby Dispensary and Infirmary.

ROSS, D., M.D., has been elected Resident Medical Officer to the South Shields and Westoe Dispensary.

SUTTON, J. MAULE, M.D., M.R.C.P., has been appointed Consulting Physician to the Pembroke and Tenby Dispensary and Infirmary.

THOMAS, Dr. LYNCH, has been appointed Assistant Resident Surgeon to the Public Hospital of Demerara and Essequibo.

UTTERSON, E. V., M.R.C.S. Eng., has been appointed Consulting Surgeon to the Pembroke and Tenby Dispensary and Infirmary.

## DEATHS.

ALDIS, SIR CHARLES, M.R.C.S. Eng., at 13, Old Burlington-street, W., on March 28, aged 87, formerly one of the Surgeons at Norman Cross Barracks.

CASWALL, CHARLES, M.R.C.S. Eng., at Tuubridge, Kent, on March 27, aged 59.

EDGAR, THEODORE, L.F.P.S. Glasg., at Dalswinton, near Dumfries, on March 17, late of Birkenhead.

MAYOU, JOHN, M.R.C.S. Eng., at Monmouth, on March 17, aged 67.

ROWLEY, THOMAS, J.P. and M.D. Edin., at Lichfield, Staffordshire, on March 21, aged 73.

TREFFRY, RICHARD BARON, M.D. St. And., at Union-street, Kennington, on March 23, aged 31.

KAY, DAVID, M.D. Edin., at Bradford, Yorkshire, on March 20, aged 46.

HILSON, P. BROWN, Surgeon at Christchurch, Canterbury, New Zealand, on December 19.

BROWN, BENJAMIN WEBSTER, [M.R.C.S. Eng., of Wymeswold, Leicestershire, on December 23.

**CORRESPONDING MEMBER OF THE PARIS ACADEMY OF SCIENCES.**—M. Bouisson, of Montpellier, has been elected in the room of M. Maunoir, of Geneva by the suffrages of forty-five out of fifty-three voters present. The other candidates were MM. Ehrmann, of Strasburg; Landouzy, of Rheims; Gintroc, of Bordeaux, and Serre, of Alais.

WE are requested to state that it is Dr. Robert Meadows and not Dr. Alfred Meadows, of Cavendish-place, who is appointed on the Medical Staff of the Anglo-Chinese Expedition.

**THE CRIMINALS FOOKS AND PREEDY.**—These men were executed at Dorchester on the 27th ult. The *Times* states that Fooks, on hearing that the law was to take its course, was at first sullen, but afterwards expressed great sorrow for his crime. Preedy is said also to have been penitent, and to have signed a paper drawn up by the clergyman who attended him, in which he stated that during the whole time of his trial he was conscious of what was going on, and simulated madness in the hope of escaping punishment.

**THE GODARD PRIZE.**—M. Ernest Godard, one of the most active amongst the French scientific workers, has, by his will, left to the Paris Society of Biology 5000 francs. He directs that the interest accruing from this shall, every second year, form a prize for the best memoir on a subject relating to biology—the author being at liberty to choose his subject. If the memoirs sent in do not call for an adjudgment of the prize, the sum will be carried on to the next two years. The first prize will be awarded in January, 1865, and memoirs offered, which may be either printed or manuscript, must be forwarded to "M. le President de la Société de Biologie," 14, Rue de Londres, before November 1, 1864.

**ALKALI WORKS.**—The Government have laid before the House of Lords a Bill to carry into effect a recommendation made by the select committee of last Session on noxious vapours. The Bill proposes heavy pecuniary penalties for every alkali work (meaning every work in which muriatic acid is evolved) which shall not be carried on in such a manner as to secure, to the satisfaction of an inspector, to be appointed by the Board of Trade, the condensation of not less than 95 per cent. of the muriatic gas evolved in such work.

**THE LATE SIR BENJAMIN BRODIE.**—The will of Sir Benjamin Collins Brodie, Bart., D.C.L., F.R.S., F.R.G.S., of Broome-park, Betchworth, near Reigate, Surrey, was proved in the London court on the 11th inst., by his sons and executors, Sir Benjamin Collins Brodie, Bart., and the Rev. William Brodie, M.A. The personality was sworn under £18,000. The testator executed his will in October, 1861, and two codicils in August and September last. To his son, now Sir Benjamin Collins Brodie, Bart., F.R.S., and to his issue, he has devised his freehold estates; but, on failure thereof, should the same descend to any of the testator's family, except his daughter, Maria Eliza Hoare, the name of "Brodie" is to be used, by Royal licence, with his family arms. To his eldest son he also leaves his estate at New Sarum. His estate in Surrey—subject to the payment of an annuity of £100, bequeathed by the testator to his niece Blanche, the daughter of his brother, Mr. William Bird Brodie—is to be divided into three equal parts; one-third to his eldest son, one-third to his son William, and the remaining third to his daughter, Maria Eliza Hoare. The testator further bequeaths to his son, William, a legacy of £2500, and to his daughter, Mrs. Hoare, £500; appointing his son, Sir Benjamin, residuary legatee.—*Illustrated News.*

**PRIZE QUESTIONS OF THE PARIS ACADEMY OF SCIENCES FOR 1864.**—The Medical Prize of 5000 francs, "The History of Pellagra." A monograph, which, by elucidating the etiology and geographical distribution of pellagra, exhibiting the forms under which it is now known to exist, and imparting to the diagnosis and treatment more precision, will constitute a decided advance in pathology, and render a service to practice and public hygiene. The essays, written in French, to be forwarded by April 1, 1864. For 1866, the Medical and Surgical Prize of 5000 francs, "The Therapeutical Applications of Electricity. Indicate the apparatus employed, their mode of application and their physiological effects. Collect and examine critically the facts that have been published on the applications of electricity in the treatment of diseases, and especially affections of the nervous, muscular, vascular, and lymphatic systems. Verify and complete by new investigations the results of these observations, and determine the cases which are suitable for the application of intermittent or continuous currents." Essays, written in French, to be sent by April 1, 1866. *The Great Prize in Surgery*—"The Preservation of the Limbs by the Preservation of the Periosteum." The Academy, wishing to denote the importance it attaches to this question, fixed the prize at 10,000 francs; and the Emperor, appreciating the benefits which may result from so great a progress in Surgery has added a like sum,—so that the prize is now 20,000 francs. The essays are to be sent by April 1, 1866, and the candidates must make their names known. The Committee of Adjudicators consists of MM. Velpeau, C. Bernard, Jobert, Serres, Andral, J. Cloquet, Rayer, Milne Edwards, and Flourens, Reporter.

**RECENT POISONING CASES.**—Two cases of alleged administration of poison have been tried at the Lewes Assizes before the Lord Chief Justice. The first was a case of arsenical poisoning. William Sturt was tried for the murder of Mary Ann Day, by administering arsenious acid in a mince-pie. The evidence of Professor Taylor and Mr. Gear was conclusive as to death having been caused by arsenic. Three grains of white arsenic had been scraped off the mucous membrane of the stomach and were exhibited in court. The evidence, however, connecting the prisoner with the administration of the poison was not deemed by the jury, nor, it may be added, by the judge, sufficient, and the prisoner was acquitted. In the other case, a servant-girl was indicted for mixing corrosive sublimate in her master's beer. The taste and appearance of the beer were peculiar, and he did not drink it. Dr. Letheby proved that the remainder of the beer contained a large quantity of corrosive sublimate. A bottle was also discovered in a privy marked "lotion," "poison," which contained a small quantity of a saturated solution of the

same salt. Here again the evidence was not found sufficient to connect the prisoner with the alleged crime, and a verdict of "Not guilty" was returned.

**THE RETIREMENT OF AGED MEDICAL MEN.**—The question of the age at which a Medical man should retire from the active duties of his Profession, attracts as much attention in the United States as with us. A recent writer in the *American Medical Times*, in answer to the question at what age do successful Medical men in fact retire, replies, that, unless compelled by accident or disease, they do not do this until death overtakes them. They pursue their active and laborious duties long past the period at which men engaged in other pursuits seek the repose which is usually grateful to old age. The veteran is found clashing with the aspirant, and spares no effort to retain his families or even enlarge his sphere. If it be asked at what age should a man retire, it may be replied that he should do so when he ceases to improve his knowledge of Medicine by study and personal investigation and observation. When he neglects the teachings of contemporary science his period of utility has passed away, and he does not do full justice to his patients. This, however, is the age at which Physicians believe themselves most competent, relying upon their experience and grey hairs, the latter being often the more valuable of the two. The conclusions the writer comes to are:—1. Medical men do not retire at a sufficiently early age, struggling to maintain a practice after they have ceased to be competent Practitioners. In general a Physician at 65 is never as correct a Practitioner as at 40, and thereafter he rapidly degenerates with advancing age. 2. Old Medical men should not retain public positions. In France every Physician and Surgeon is compelled to withdraw from Hospital practice at 60. This is a most righteous regulation, and should be enforced in every Hospital. Aside from their incompetence, the old men do great injustice to the young who have time and talents to improve the advantage of Hospital practice. Age and decrepitude should not be tolerated in these responsible situations, which demand youthful vigour and strength.

**ROYAL SOCIETY.**—On Saturday evening last, General Sabine, the President, held his first *conversazione* at Burlington House, the meeting being very numerous attended. Amongst the various objects connected with the history and progress of the biological sciences we especially noted the following:—A collection of relics and memorials of Linnæus, arranged with great taste by Messrs. Bentham and Kippist. A portion of the Mediterranean cable, from a depth of 70 fathoms, between Sardinia and Africa, incrustated with coral-lines and other zoological specimens, exhibited by Mr. Jenkin; also some ova of the cuttle-fish, from 1000 fathoms depth, by the same gentleman. A case containing numerous tubes of the caddis-worm (larva of *Phryganea grandis*), which had been formed out of a variety of materials artificially supplied to the worms, exhibited by Mr. Smee. An apparatus, in full operation, for the artificial breeding of salmon, trout, charr, and other fish, fitted up by Mr. Frank Buckland. A series of war implements, dresses, and other articles employed by the natives of Nubia, from Dr. Gladstone's collection. Lastly, by Dr. Cobbold, an extensive collection of human and other *Entozoa*, which attracted considerable attention. The specimens were for the most part mounted in a solution of carbolic acid; this highly preservative fluid being the only medium in which preparations steeped in magenta will be found to retain their colour. So far as we are aware, this is an entirely novel, and, at the same time, a practically-important discovery. It is well known to many pathologists that for histological purposes there is nothing equal to this fluid for the preservation of tumours, soft deposits, and morbid growths generally. For weeks and months the most delicate cell-elements will retain their form and other natural characters. Dr. Cobbold's collection further illustrated the employment of carmine, ferrocyanide of potassium, and chloride of iron, tannin, glycerine, ultramarine, and other substances, in the preparation of moist anatomical specimens. Some of the parasites had their digestive and water-vascular systems injected, and several of the tape-worms had been reared artificially by the administration of cysticercus larvæ along with food. This unique series of *Entozoa* now forms part of the Pathological collection in the Museum of the Middlesex Hospital. There was a large attendance of the Medical Profession, amongst whom we noticed—Sir Henry Holland, Sir Ranald Martin, Dr. Garrod, Dr. Powell, Dr.

Bence Jones, Dr. Carpenter, Dr. Sharpey (Secretary Royal Society), Dr. Billing, Dr. Reynolds, Dr. Webster, Dr. Watson, Dr. Owen Rees, Dr. E. Smith, Dr. Francis, Dr. Gilbert, Dr. James Pettigrew, Dr. Spurgin, Dr. Phipson, Dr. Erichsen, Dr. Roget, Dr. Gull, Dr. Stewart, Dr. Babington, Dr. Lankester, Dr. Balfour, Dr. Bryson, Dr. Francis Hawkins, Dr. Miller, Dr. Odling, Dr. J. B. Hicks, Dr. R. D. Thomson, Dr. Eatwell, Dr. Cobbold, Dr. Jeaffreson, Dr. R. Bennett, Dr. Williams, Dr. Wilson Fox, Dr. Munro, Dr. Baird, Dr. Longstaff, Dr. Grant, Dr. Lloyd Birkett, Dr. Budd, Dr. Pavy, Dr. Handfield Jones, Dr. G. Johnson, Dr. Stenhouse, Dr. Granville, Professor Owen, Professor Fergusson, Professor Busk, Professor Partridge, Professor Miller, Mr. S. Solly, Mr. Shaw, Mr. De Morgan, Mr. Smee, Mr. T. Tatum, Mr. Curling, Mr. Paget, Mr. Arnott, Mr. Frank Buckland, Mr. Toynbee, Mr. Flower, Mr. Savory, Mr. Luke, Mr. Gulliver, Mr. Solly, Mr. F. Skey, Mr. Erasmus Wilson, etc.

**ANTHROPOLOGICAL SOCIETY OF LONDON.**—Tuesday, March 24.—Sir Charles Nicholson, Bart., Vice-President, in the Chair.—Twenty-one new members were elected. A paper, by Captain R. F. Burton, Vice-President, was read on "A Day Amongst the Fans." His account contained chiefly those first impressions which he was enabled to make, and it was distinctly stated that the Fans whom he visited were a comparatively civilised race, who have probably learned to conceal the customs which they have found distasteful to the civilised races. In the remoter districts they may still be determined cannibals. Captain Burton's paper leaves no doubt of the fact that cannibalism is habitually practised by them. After the fall of two or three warriors in battle, they are dragged off to be devoured, and their friends disperse. If the whole body cannot be removed, the victors content themselves with a "gigot" or two, to make soup. The cannibalism of the Fans is by no means remarkable, limited as it is to the consumption of slain enemies; the practice extends sporadically from the Nun to the Kongo, and how much further south Captain Burton cannot at present say. In the Niger and the Bross, the people do not conceal it; in Bonny he had seen all but the act of eating; it is execrated by the old Kalabarese, whilst practised by their Ibo neighbours to the north-west. The Duallas, of Camaroons, number it amongst their country fashions, and though the Mpongwe eschew the chimpanzee, the Fans invariably eat their foes. No joint of man is ever seen in the settlements; the sick are not devoured; the dead are decently interred, except slaves, who, as usual, are thrown into the forest. Prisoners are tortured with horrible ferocity. Children may be seen licking the blood from the ground. Cruelty seems to be with the African a necessary of life. All his highest enjoyments are connected with causing pain and inflicting death. His religious rites, different from those of the Hindoos, are ever causelessly bloody. Captain Burton cannot believe this abnormal cruelty to be the mere result of uncivilisation. It appeared to him rather the work of an arrested development which leaves to the man all the bloodthirstiness of the carnivore. A paper, by Professor Raimondi (translated by W. Bollaert), was read on "The Indian Tribes of the Great District of Loreto, in Northern Peru." Evidences of the cannibalism of these tribes were adduced, and the plans of the missionaries to Christianise the Indians commented on in detail. A discussion ensued, joined in by Messrs. Fraser, C. C. Blake, Burke, Tylo, Bollaert, Tagore, Dr Hunt, Sir Charles Nicholson, C. Blake, Drachaichis, Prideaux, and others. The next meeting will take place on April 7.

**JUNIOR MEDICAL SOCIETY OF LONDON.**—At a meeting of this Society, held at University College Hospital on the 19th ult., Mr. S. G. Freeman in the chair, the following pathological specimens were exhibited:—1. Head of a tapeworm found in dead body of a child. 2. Atrophy of a kidney and thickening and enlargement of the ureter, due to a calculus, by G. Howard Marsh, Esq., of the Hospital for Sick Children. 3. Large biliary concretion passed by the bowels, by Mr. Yeo, King's College. 4. Enlargement of the ends of the ribs in rickets. 5. Tuberculous enlargement of intestine from the same child. 6. Typical example of gouty deposit. 7. Polypoid growth in larynx, producing sudden death from suffocation, by Mr. Talfourd Jones, University College Hospital. Mr. Talfourd Jones, V.P., Medical Registrar to the Hospital for Sick Children, then read a paper on "Tuberculous Meningitis." The author, after having traced the history of the disease from the middle of the last century to the year 1830, showed how the more minute study of morbid anatomy

and clinical Medicine during the last thirty years had unravelled the true pathology of the disease. Following the arrangement adopted by Dr. Whytt, the author divided the disease into three stages, not based however merely on the variations in the pulse, but chiefly on a combination of certain special symptoms. He stated that although in many cases the first and second stages so merged into each other that it was almost impossible to attempt any accurate subdivision of them, yet in his experience he found the characteristic symptoms of the third stage almost always present. He laid great stress on the simultaneous occurrence of headache and delirium, and showed how, in the majority of cases in which these two symptoms were conjoined, they betokened intracranial inflammation. The author differed from the opinion commonly entertained that isolated masses of tubercle in the brain substance in cases of tuberculous meningitis were rare. He believed they were in numbers of cases overlooked, and not discovered simply because they were not carefully searched for; and he contended that convulsions, slight dragging of a limb, paralysis of one of the cerebral nerves, as the third, fifth, or seventh, described in books as irregular precursory symptoms, would commonly be found only in those cases in which such masses or nodules of tubercle existed. The author, after having described the intracranial pathological lesions he had met with, discussed the question of the cause of fluid in the ventricles of the brain, and of the central softening, and showed how in the majority of cases a mechanical explanation would account for both the fluid and softening, and he adduced instances showing how frequently measles, and next to that whooping-cough, proved to be the exciting cause of the acute tuberculization. The only necessary complication met with was a tubercular condition of the thoracic and abdominal organs, and this was so marked in all the cases he had seen, that he felt disinclined to speak of the acute hydrocephalus as a special disease, and considered the disease a general tuberculization, in which the brain was involved in company with other organs, and death ensued in consequence of a superadded intracranial inflammation. The author concluded by stating that a leech or two at the onset of certain cases, conjoined to the regular and repeated exhibition of purges, and continued application of cold to the head, were the only remedies which he had ever seen give even temporary relief. After an interesting discussion, the meeting was adjourned.

**THE ETIOLOGY OF PURULENT INFECTION.**—M. Flourens, in a note presented to the Academy of Sciences, gives an account of some experiments he has recently performed. He took some drops of pus from the dura mater of a dog and applied them to the perfectly healthy pleura of another dog. The dog died at the end of thirty-six hours, and a double purulent pleurisy was found to exist, the pleura being filled with pus, while no other viscus contained it. Pus was also applied to the abdominal muscles of a perfectly healthy dog. It died in four days, an enormous infiltration of pus having taken place amongst the different muscles of the abdomen. Moreover, pus transported from the dura mater to the pleura of the same animal, caused death on the fifth day, the left pleural cavity being filled with pus.

**HOMŒOPATHIC ANECDOTE.**—The late Baron Seutin, of Brussels, took it into his head to experiment with homœopathic remedies, and having procured a complete collection gave them into the charge of one of his *internes* at the Hospital. The *interne* assembled his assistants in solemn conclave in the evening, having provided himself with a large tumbler. Every phial of homœopathic remedies was emptied into the tumbler, and then filled up with distilled water. The operation completed, the *interne*, drinking a toast to the god Hahnemann and his prophets, drank off the whole collection just as if it had been so much sugar and water. Seutin next day commenced his treatment with the substituted distilled water, and all the affections capable of getting well progressed under its administration very satisfactorily. As to the *interne*, at first he felt no ill consequence from his bold adventure. Still homœopathy was doing its offices, and the longer he lived the more did the dilutions increase, and the greater was their energy. The case thus becoming serious, and not wishing to attain the laurels of Methusaleh, he resorted to energetic procedures, against which, strange to say, the globules were powerless. Joking apart, this lesson was of use to more than one, and Baron Seutin, informed afterwards of what had occurred, evinced hereafter considerably less enthusiasm with respect to mystical remedies.

**SUICIDES IN THE AUSTRIAN EMPIRE.**—Dr. Majer, who has already published a similar essay on "Suicide in Bavaria," enters in the present paper into a most elaborate statistical examination of the suicides which occurred in the Austrian Empire during the years 1852-57. They amounted during these six years to 9025, being 1504 per annum, in an average population of 30,093,918. The deaths from all causes amounted in the six years to 6,486,479, giving an average of 1 suicide to 704 deaths from all causes. Among the general conclusions which Dr. Majer arrives at are the following:—1. Suicide is least frequent in the non-German provinces of the empire, increasing in exact proportion with the density of population and to the activity with which industrial occupations are engaged in. On the contrary, deaths from murder or accident are more common in the non-German provinces. 2. With respect to *sex*, suicide takes place less frequently among women than men—the proportions being for the entire monarchy 1 to 4½. 3. *Age*.—Suicide occurs with more proportionate frequency in men than in women after the age of 40, in women oftener under 40. 4. Most suicides take place in the reformed and Protestant persuasions, and fewest among the Jews. 5. The greater number of suicides occur between the months of May and July, the fewest between December and February. 6. In the German provinces, suicide is most frequently accomplished by hanging and poisoning; in the non-German provinces, by drowning and shooting. In comparison with other countries, hanging is a very frequent form of suicide in Austria, drowning a rare one. The men, as a general rule, choose hanging and shooting, the women drowning and poisoning.—*Deutsche Zeitung für Staatsarz*, vol. ix., p. 96.

## NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon*.

*Milton*.—1. Communicate with the Registrar, Dr. Francis Hawkins. 2. We believe not.

*G. B.*—There is no fear that any fair comments on Mr. Probert's unexplained conduct to Mr. Adams will injure the Epsom College. Quite the reverse. We understand that an influential Committee is now in process of formation, in order thoroughly to sift the Russell and Adams case, and to adopt such further proceedings as may seem expedient.

*Blackwood's Magazine and Union Surgeons*.—The following malignant paragraph appears in *Blackwood* for March, in a review of a work by a Frenchman, in village life in England:—

"The 'Village Surgeon' is no longer an oracle. Railways have brought 'the first advice' (at any rate in the county town) within the reach of almost all his patients, and he has either disappeared altogether, or if he still exists, is the 'Union Doctor,' badly paid and little respected. He is seldom now a gentleman."

Pay and consideration always go together. The underpaid man is always treated as a drudge. Here is a solid reason for supporting Mr. Griffin, and for aiding in any reasonable attempt to do away with the system of unpaid or ill-paid Medical services. Yet, alas! the root of the evil lies with ourselves. So long as we are weak enough to scramble for these offices so long they will exist.

*Hotels at Nice*.—The following extract is from a letter which appeared in the *Times* of Wednesday, the 1st inst. :—

"There are several hotels in Nice, and large ones too. One may be a shade better than another, and one which I need not name, for it has sufficient notoriety, is so much worse than any other that I must be understood as excepting it altogether from the general remarks I may think justly applicable to the rest. In all these hotels the system is the same. When a traveller arrives, an attempt is made to induce him to engage his room or rooms for 'the season.' If he does not consent to do so, he is required to pay an extra rate,—as much as 5*fr.* or even 6*fr.* a day for a very indifferent room, and is, moreover, liable to be turned out of that as soon as any one can be caught for the season. If you consent to hire for 'the season,' you are, from the moment you sign the agreement, at their mercy. This agreement may be made to include the prices of the most obvious things, such as the 'table d'hôte,' breakfast, etc.; but there will always necessarily be many extras not contemplated at the time, and for all such you are made to pay in the most merciless and unconscionable manner. Your wood baskets are reduced to one-third the proper size, and charged three times the proper price. Eggs, which are sold at 1½*d.* a piece, figure in a bill at 7½*d.* If, tired of the thin and watered 'vin ordinaire,' you call for other, you get something with a fine name at a fine price, but in reality little better, and so on with everything. If you complain ever so mildly, the answer is ready,—'Oh, if you don't like the hotel you may leave it.' But if you go you forfeit the remainder of your lease, in the first place; and in the next, if you succeed in getting into another of these crowded hotels, you will find yourself no better off. At one hotel, a gentleman complaining to the mistress of the dinners, she replied, 'Oh! do not complain to my husband, or he will turn you out.' A French gentleman and his son who were in the same hotel with me had taken apartments for the season at 25*fr.* a day. The son was in delicate health, and the father, finding that the soup was hot water and the dinners anything but nourishing, took his son to some place where he could get better. But in two days he received notice that this could not be permitted. He

was bound by his agreement to live in the hotel, and that if he absented himself from the *table d'hôte*, his rooms would be taken from him. In vain he offered to pay any profit (*benefice*) there might be on his dinners. He was told he could not be allowed to absent himself from the *table d'hôte*, and, in short, he was obliged to return. Another instance. A gentleman died in a hotel, not of an infectious disease, but from the results of an operation. In the bill was a charge of 300*fr.* for damage to furniture—perhaps just enough; but there was a further charge of 300*fr.* 'for dying in the hotel,' and another of 600*fr.* for non-fulfilment of contract—that is, for not continuing to live to eat and drink in the hotel. In another hotel, a friend of mine, neglecting to make a bargain, was charged 10*fr.* a night for his bed; and a young couple, on their wedding tour from Paris, although they had only two very small and inconvenient rooms, found their bill for a week 700*fr.*! I asked them why they paid it—why they submitted to such open robbery, and was told that the formalities and expenses of law were great, and the redress it afforded small. At Cannes, at Mentone, etc., the system of pillage is the same, and prevails equally in the shops. A stranger, a traveller, is a fair subject of plunder.

"These are a few—a very few—of the facts I could state; but they would occupy too much of your space. These few will suffice, if you are so obliging as to publish them, to show the opening there is at Nice for an extensive proprietary hotel, like those of Paris or London, established by a company, with a printed tariff for everything. If some company, either in London or Paris, would undertake the thing, there is no doubt they would carry all before them, to the great comfort of strangers and benefit of the place. Your obedient servant, VIATOR."

"P.S.—A lady at an hotel with her maid is charged the immoderate sum of £25 a week. Hoping to make a better bargain by the year, she is told that, as a favour, they will charge her only £1000!"

It is with the greatest grief and shame that we notice, in the obscurest corner of our Journal, that distressing case of Mr. Evan Thomas, of Manchester, a Medical man of middle age, in large practice, a Fellow of the Royal Medico-Chirurgical Society, and Associate of King's College, who falls into a discreditable intimacy with a widow lady, who is pregnant by him. She comes to Manchester under conditions which raise the suspicion of a plan to procure abortion; but this idea was distinctly repudiated by the judge. The unhappy woman died suddenly, whilst Mr. Thomas was in her apartment, on the morning after her arrival at Manchester. A *post-mortem* examination was instituted, and an inquest held, at which Mr. Thomas swore to the existence of a tumour in the womb, and to congestion of the brain, and likewise that he had not known the deceased previously. The real facts were that the uterus contained a foetus of six months, and the brain was not examined. The defendant was found guilty, and the sentence was as follows:—

"His Lordship, in passing sentence, said: Prisoner, you have been found guilty, and in my judgment with the greatest propriety, of the offence of wilful and corrupt perjury, but the jury have accompanied their verdict with a very strong recommendation to mercy, and I shall act upon that recommendation so far as I am concerned in the sentence I am about to pass upon you, for I always feel inclined to favour a recommendation accompanying the verdict of a jury. I cannot but feel that the punishment I am about to inflict will be very small compared with the punishment which you will sustain for this crime, for no one can read that last letter which you sent to Mrs. Bell without feeling that you have been on intimate terms with this woman, and probably you were the father of the illicit offspring of which she was then pregnant. I will not say that there is any evidence to show that you used any instruments or other means to procure abortion; it is due to you to say that I have arrived at a different conclusion; but that you wilfully, and with the intention of deceiving the jury, made these statements as to the cause of the woman's death, is beyond all doubt. I am sorry that a member of one of the learned professions should now be before the court convicted of so serious an offence. It is not only a disgraceful thing, but I may truly say that it is a national misfortune, that a man in your position should have been guilty of this offence, for it is calculated to raise a serious doubt upon the value of Medical evidence given in our various courts of law upon assaults committed on railways, and in other places, for juries might justly remark, 'What reliance can we place on Medical testimony after the evidence of Mr. Thomas?' I repeat that I look upon the conduct of the prisoner as a national misfortune, because it will bring disgrace and discredit upon the Medical Profession. Giving effect, however, to the recommendation of the jury, I shall order you to be imprisoned for three months."

### DR. GIBB'S DEMONSTRATIONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your correspondent, Gobemouch, would do well to make his meaning somewhat plainer, so that the spectators of Dr. Gibb's demonstrations with the laryngoscope may know what kind of curiosity he wishes to collect. I would also recommend him to buy a copy of Murray's grammar, and read the chapter on composition. I am, &c.

March 30, 1863.

SPECTATOR.

### WHAT IS THE USE OF THE BRITISH MEDICAL ASSOCIATION?

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have known a good many mean things in my life, but nothing, I think, that could beat the cold shabbiness of an article in that ghastly periodical—the *British Medical*, of the 28th inst. The Editor (or some one to whom he has delegated the task of writing what probably he would not, as a gentleman, like to acknowledge) says that he has received communications from Mrs. Russell and Mr. Adams, but declines publishing them, on the plea that they would only foster the love of scandal; and sneeringly advises Mr. Adams to prosecute Mrs. Russell for perjury. Now, it is pretty evident that Mr. Adams is not the only person who has been victimised, though he has suffered more severely than any other; and an action of the kind proposed is clearly the function of an *association*, not of an individual. Of what use is the British Medical Association if it cannot investigate a matter so deeply affecting the honour and character of one of its members? Is the Editor enchained by this Irish Delilah? Does he believe her artless tale? If so, let him come forward like a man, and demand the investigation that shall clear up the character of the "lonely" ones, and blast Adams. On the other hand, if Adams comes out scatheless, let this pretentious set of talkers guarantee the law expenses of the action, which their journal sneeringly dares Adams to bring. I am, &c. ANTI-HUMBUC.

QUESTIONABLE PRACTICE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you please call the attention of your readers to the enclosed? The experienced Physician, I may remark, is Provincial Secretary to the British Medical Association. I am, &c.

A REGISTERED MEMBER, WHO SHOULD LIKE TO KNOW WHAT HE HAS PAID £2 2s. FOR.

Kent, March 26.

“J. H. Morton, Medical Hall, Upper High-street, New Brompton, respectfully invites attention to the superior quality of the medicines sold at his establishment, and solicits a trial of the following preparations, the large and increasing sale of which is a sufficient proof of their efficacy:—Morton’s Tasteless Antibilious Pills are the safest, most effectual, and decidedly the most agreeable ever introduced. Sample boxes, containing 3 pills, 1d., or in larger quantities 1s. and 2s. 9d. per box.—Morton’s Celebrated Powders for Children. To place these well-known powders within the reach of every mother, they may now be obtained in packets of six powders. Price 6d.—Morton’s Tasteless Castor Oil is entirely free from the rancid flavour of that usually sold, and will not produce nau-sea. In bottles at 6d. and 1s. each, or at 3d. per ounce. Trusses, Elastic Stockings, and all Mechanical Appliances in aid of Medicine at London prices.—An experienced Physician attends every evening. Advice gratis.—Urgent cases, Accidents or Midwifery attended at any hour.”

VISIBILITY OF THE TRAPEZIUS MUSCLE IN ADVANCED PHTHISIS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am desirous of placing upon record a curious physical sign which is now presented by one of my patients in the Hospital for Consumption and Diseases of the Chest, Brompton. It is of little practical value, yet it is worthy of being made known to your readers. The sign to which I refer is the visibility of the trapezius muscle in form and outline, by its colour, through the integuments of the back, shoulders, and neck. The figure of the muscle is perfectly symmetrical. The colour is faint blue, and much the same as that of the veins of the back of the hand.

The patient is a girl of fourteen years of age, suffering under far advanced tubercular disease of both lungs, much emaciated, and having a remarkably pale condition of face, with here and there a faint tint of blue.

On examining her for the first time a few days ago, I was struck with a symmetrical blue figure, extending from the lower dorsal vertebra to the neck, and spreading on either side to the scapula. I immediately perceived the correspondence between the figure and the trapezius muscle. When the muscle was put into contraction, a fulness or slight degree of swelling could be observed, exactly corresponding with the coloured figure.

In an experience of many years I have met with no other instance of a muscle rendered visible by its colour through the integuments. This phenomenon appears to depend upon four conditions: 1. Extreme tenuity of the integuments; 2. The absence of fat; 3. The dark colour of the muscle from the presence of ill-oxygenated, or almost venous, blood; 4. The superficial position of the muscle. The blue figure gradually terminates at the middle of the neck, where, it is to be remembered, the superficial fascia acquires additional thickness. The acoustic signs are highly interesting, and include well-marked metallic tinkle over a large area.

I am, &c.

March 25.

S. SCOTT ALISON, M.D., Physician to the Hospital.

REPORT IN REFERENCE TO THE CHARGE OF PLAGIARISM ADVANCED BY DR. MAYNE IN THE PREFACE TO HIS “MEDICAL VOCABULARY” AGAINST DR. FOWLER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Having been appointed referees in the questions in dispute between Dr. Mayne and Dr. Fowler, as to their works published under the title “Medical Vocabulary,” we beg to forward a copy of our decision, and would feel obliged if you would insert it in an early number of the *Medical Times and Gazette*. We are, &c.

THOS. B. PEACOCK.

A. MEADOWS.

[\*.\* We think it unnecessary to print the whole Report, but we call attention to the following conclusions:—]

“In conclusion we are of opinion:—

“1st. That the title of Dr. Fowler’s work was derived from the original ‘Medical Vocabulary’ of Dr. Mayne, and we do not consider that the anonymous publication of the original work, the long period which had elapsed since its first appearance, or the circumstance that no second edition had been announced prior to the publication of Dr. Fowler’s ‘Vocabulary,’ justify the appropriation, so long as the copyright of the original work existed.

“2ndly. On the other hand, we do not find anything in Dr. Fowler’s work which leads us to suppose that he has copied in his ‘Medical Vocabulary’ the plan of the work first published by Dr. Mayne, nor have we found such similarity in Dr. Fowler’s ‘Medical Vocabulary’ to Dr. Mayne’s ‘Expository Lexicon’ as would indicate that Dr. Fowler had availed himself of the use of that work in the preparation of his own. We are therefore of opinion that the charge of plagiarism against Dr. Fowler, implied, if not directly expressed, by Dr. Mayne in the preface to the second edition of his ‘Medical Vocabulary,’ has not in any degree been substantiated. (Signed)

THOS. B. PEACOCK.

A. MEADOWS.

“London, March 26.”

ELECTRICITY IN CHLOROFORM ACCIDENTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your Journal of last week, in a letter from Dr. Kidd on “Recovery from Chloroform Accidents,” he states that “pulling a pin out of his necktie, he stuck it into the region of the phrenic nerve, as it lies in the sterno-mastoid, another pin into the diaphragm, and quickly applying the wetted sponges of the ‘Paradisation’ current, the effect astonished himself and every one present.”

My reason for addressing you is merely to state that the pins are entirely unnecessary; that the moist sponges are all that are required. The following are the rules I have laid down in these cases:—

In drowning, chloroform accidents, suffocation, etc., if there is still warmth in the body, electricity should most certainly be given a fair trial, as it is really the only agent which has the power of re-awaking the vital energies, departing in the stagnation of the circulation and respiration. After placing the individual in the most favourable circumstances as regards temperature, ventilation, etc., for the return to life, place one moist conductor upon the left side of the neck, pressing it in behind the

middle of the sterno-mastoid, so as to get as near as possible to the phrenic nerve, then thrust the other moist conductor into the pit of the stomach, so as to cause the diaphragm to contract. Use the highest power of the apparatus, but only for two or three revolutions, or rather keep up the action, but remove the conductor, so as to pass a current for ten seconds at a time to the diaphragm. If there is any vitality remaining in the system, the diaphragm will soon contract, causing a sobbing inspiration. Each of these prepares the way for life; they must be continued until natural respiration is established; then the lower conductor may be removed, and gently passed over the chest generally. A conductor better adapted for this purpose may be obtained, having two terminals, to press on either side of the neck, upon the roots of the phrenics.

I am, &c.

70, Brook-street, March 30.

APPOINTMENTS FOR THE WEEK.

April 4. Saturday (this day).

Operations at St. Bartholomew’s, 1½ p.m.; St. Thomas’s, 1 p.m.; King’s, 2 p.m.; Charing-cross, 1 p.m.

6. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark’s Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.

EPIDEMIOLOGICAL SOCIETY, 8 p.m. Dr. Swarbreck Hall, of Hobart Town, “On the Epidemic Diseases of Tasmania.”

MEDICAL SOCIETY OF LONDON, 8½ p.m. Clinical Discussion.

ODONTOLOGICAL SOCIETY OF LONDON, 8 p.m. Meeting.

ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

7. Tuesday.

Operations at Guy’s, 1 p.m.; Westminster, 2 p.m.

ANTHROPOLOGICAL SOCIETY OF LONDON, 7½ p.m. R. T. Gore, Esq., “On the Brain of a Microcephalic Female Idiot.” Dr. Julius Schwarcz, “On Permanence of Type.”

8. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary’s, 1 p.m.; Middlesex, 1 p.m.

HUNTERIAN SOCIETY, 8 p.m. Dr. Fowler, “On a Case of Laceration of the Vagina during Labour—a Medico-legal Question.”

9. Thursday.

Operations at St. George’s, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.

10. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

TRADE MARK

# CHLORODYNE

WAS DISCOVERED AND INVENTED IN THE YEAR 1848 BY  
**DR. J. COLLIS BROWNE, M.R.C.S.L. EX. ARMY-MED. STAFF.**  
 AND IN 1856 HE CONFIDED  
**THE ORIGINAL AND ONLY FORMULA**  
 FOR ITS MANUFACTURE  
 SOLELY TO **J. T. DAVENPORT, PHARMACEUTIST,**  
 33, GREAT RUSSELL ST. BLOOMSBURY SQUARE, LONDON.  
 REGISTERED, 1856

## NOTIFICATION.

The attention of Medical Men is directed to the Piratical application, by some parties in the Trade, of the term "Chlorodyne" to various mixtures compounded of Chloric Ether Opium, Indian Hemp, and Peppermint, in Imitation of the ONLY Genuine preparation of this name.

The dangerous expedient of encouraging or advocating the assumption of a name specifically indicating a particular property or remedy—such as *Chlorodyne* is to spurious imitations and substitutions—ON THE GROUND OF CHEAPNESS, is a subject of surprise and grave reproach, supremely so, when the adulteration, sophistication, and tampering with Drugs, becomes so serious and important a consideration in the successful practice of Medicine.

The fact of these Piracies must fully convince the Profession of the extraordinary efficacy of the Genuine Chlorodyne; whereas the sad results and disappointment arising from the use of spurious compounds cannot be expressed.

Each Genuine Bottle bears a Red Stamp, with the words, "Dr. J. COLLIS BROWNE'S CHLORODYNE," in White Letters.

To be obtained from all Wholesale Druggists in 1oz., 2oz., 4oz., and 8oz. Bottles.

**NOTICE. — REDUCTION OF PRICE TO THE PROFESSION.**

In Bottles, 1oz., 3s.; 2oz., 5s.; 4oz., 8s.; 10oz., 15s. To Hospitals and Charities in large quantity, a Liberal Discount.

## *Pulvis Jacobi ver, Newbery*

is the ORIGINAL & GENUINE, was ESTABLISHED A.D. 1746,

And is Prescribed, with the greatest success, "by the highest authorities," for Fevers, Ague, Cerebral Congestion, Rheumatism, Chills, Influenza, &c. &c.

**FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.**

Prices for Dispensing—1 oz., 9s.;  $\frac{1}{4}$  oz., 3s. 4d.

## TOWLE'S CHLORODYNE.

Medicinal Properties:—

Anodyne, Diaphoretic, Sedative, Astringent, and Anti-Spasmodic.

**CAUTION.**—For the convenience and safety of prescribing Chlorodyne, in combination with other ingredients, so as to avoid decomposition (a result known to have taken place) through the use of SECRET COMPOUNDS, Mr. TOWLE begs to call the attention of the Profession to the following component parts in his Preparation:—

CHLOROFORMYL  
ETHER.

OL. MENTH. PIP.  
ACID. PERCHLOR.

TINCT. CANNABIS INDICÆ.  
ACID. HYDROCYAN.

TINCT. CAPSICI.  
MORPHIA & THERIACA.

The proportion of Morphia— $\frac{3}{4}$  gr. inf. ʒj. Dose—Five to Twenty Drops.

Letter from ALFRED ASPLAND, Esq., F.R.C.S. Eng., J.P. Chester and Lancaster, Surgeon 4th Che-hire Batt. V.R., Surgeon to the Ashton Infirmary.—"After an extensive trial of your Chlorodyne in Hospital, Infirmary, and Private Practice, I am able to state that it is a valuable medicine. I have found its action peculiarly serviceable in Bronchial, Spasmodic, and Neuralgic Affections. I have never found it produce headache or feverish disturbance, results which not unfrequently occur from other forms of Chlorodyne. As a sedative to allay excitement arising from the abuse of intoxicating drinks, so commonly witnessed in our Barrack Hospital, I have been perfectly satisfied with it. Its known composition will doubtless prove an additional recommendation to the Profession."

Sold by Wholesale Houses in bottles, 1 oz., 1s. 6d.; 2 oz., 2s. 6d.; and 4 oz. to 20 oz., 1s. per fluid oz.

Sole Manufacturer—A. P. TOWLE, CHEMIST, &c., 99, STOCKPORT-ROAD, MANCHESTER.

## CHLORODYNE.

"INVENTED AND DISCOVERED, IN 1844, BY RICHARD FREEMAN."

(Extract from Affidavit made before S. C. WARD, Esq., Chancery Record Office, Chancery-lane, London, June 16th, 1862.)

The Inventor begs to thank the Medical Profession for the liberal support he receives from them, and to assure those who have not yet tried his Chlorodyne that it is superior to any other maker's, being more certain and more lasting in its effects; and the low price which he charges for it allows the poorest sufferer to enjoy its extraordinary beneficial influence. The immense demand for it by the Profession is a convincing proof that they find it a most valuable therapeutical agent. The following are a few out of many voluntary Medical Testimonials:—

From W. VESALIUS PETTIGREW, M.D., Hon. F.R.C.S. Eng., formerly Lecturer upon Anatomy and Physiology at the St. George's School of Medicine.

"I have had the opportunity of trying the effects of Mr. Freeman's Chlorodyne, and find it an excellent Anodyne and Antispasmodic medicine."

From H. J. O'DONNELL, M.R.C.S.E. and L.M., &c. &c.,  
Albert-terrace, London-road, S.

"I can with much confidence bear testimony to the efficacy of Mr. Freeman's Chlorodyne as a Sedative and Antispasmodic, having used it for some years in Colic, Neuralgia, Phthisis, and Asthma. I daily administer it in after-pains, and in all cases find it infallible. It is the most valuable medicine we have in Labour cases. I find, since I have used it, the pains

seldom or ever exceed the third day, while with the former remedies my patients suffered eight or nine days. In fact, I cannot speak too highly of it."

From F. W. HOOPER, M.D., M.R.C.S. Eng., &c., &c., Medical Officer,  
Christ Church District, Camberwell.

"I have much pleasure in stating that, after a sufficient trial of Mr. Freeman's Chlorodyne, I am fully persuaded that it is superior to any preparation of the kind, and, from its moderate price, is a great boon to the suffering poor, who daily acknowledge its salutary benefit."

From W. G. KING, M.D., M.R.C.S. Eng., Hackney.

"I have used your Chlorodyne for some time, and can bear testimony to its efficacy and value in all cases in which a Sedative has been indicated."

Manufactured by RICHARD FREEMAN, Pharmacist, Kennington-road, London, S.;  
And Sold by all Wholesale Houses, in bottles, 1 oz., 1s. 6d.; 4 oz., 5s.; and 8 oz., 10s. each.

PROFESSOR HUXLEY'S LECTURES  
AT THE  
ROYAL COLLEGE OF SURGEONS.

LECTURE IV.

(Being the Third of Six Lectures on Classification.)

MR. PRESIDENT AND GENTLEMEN,—Hitherto, it has not been a matter of very great difficulty to discover the characters in which the members of the various classes, which have passed under our notice, agree with one another and differ from the members of all other classes. But to-day we shall be met, at the outset of our studies, by a large series of organisms which present us with much greater obstacles,—the result, in a great measure, of imperfect knowledge.

The first group on the list—the *Echinodermata*—comprises the star-fishes, sea-urchins, sea-cucumbers, trepangs, and feather stars—known technically as *Asteridea*, *Echinidea*, *Holothuridea*, *Ophiuridea*, *Crinoidea*, etc.,—marine animals which differ vastly in external appearance, though they all, in the adult state, present a more or less definitely radiate arrangement of some parts of their organisation.

That which most remarkably distinguishes the *Echinodermata* is the nature of the embryo, and the strange character of the process by which the adult form is originated by a secondary development within that embryo.

In the great majority (a) of the *Echinodermata*, the development of which has been examined, the impregnated egg gives rise to a free-swimming, ovoid, ciliated embryo, the cilia of which soon becomes restricted to, and, at the same time, largely developed upon, one, two, or more bands, which are disposed either transversely, or more or less obliquely to the longitudinal axis of the body, but are, in any case, bilaterally symmetrical (Fig. 1).

FIG. 1.

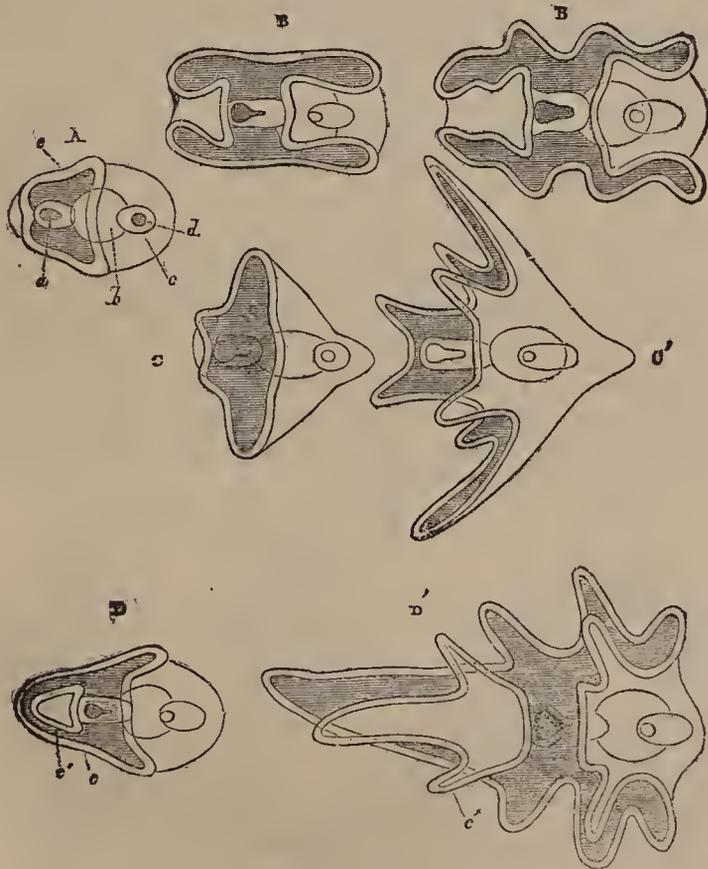

Diagram exhibiting the general plan of the development of the *Echinoderms* (after Müller).—A, Common form whence the *Holothurid* (B, B') and *Ophiurid* or *Echinid* (C, C') larvæ are derived. D, D'. Younger and more advanced stages of the *Asterid* (*Bipinnaria*) larvæ. a'. Mouth. b. Stomach. c. Intestine. d. Anus. e. Ciliated band. e'. Second or anterior ciliated circlet.

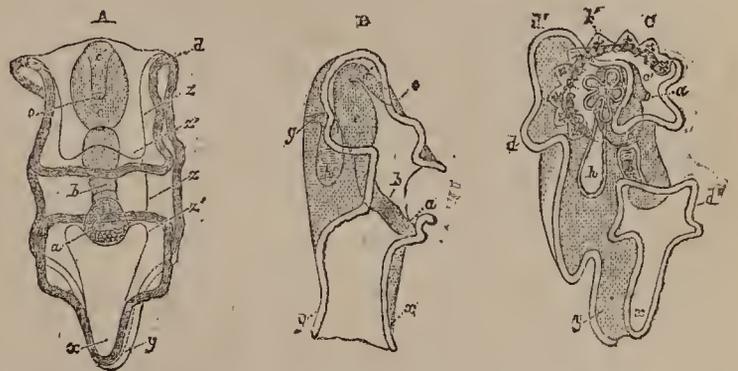

(a) In *Ophiolepis squamata* and *Echinaster sepositus*, the larva appears to attain only a very imperfect state of development before the appearance of the echinoderm body; and careful re-examination is required to decide how far the larvæ of these animals are truly bilaterally symmetrical.

The parts of the body which carry the ciliated band or bands often become developed into processes, which correspond upon each side of the body, and thus render its bilateral symmetry more marked. And in the larvæ of some *Echinidea* and *Ophiuridea*, other bilaterally symmetrical processes are developed from parts of the body which do not lie in the course of the ciliated bands.

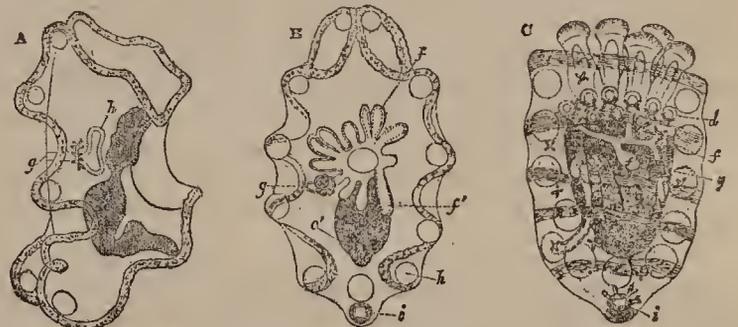

The larvæ of *Asteridea* and *Holothuridea* are devoid of any continuous skeleton, but those of *Ophiuridea* and *Echinidea* possess a very remarkable bilaterally symmetrical, continuous, calcareous skeleton, which extends into, and supports the processes of the body (Fig. 2).

A distinctly defined alimentary canal early makes its appearance in these *Echinoderm* larvæ. It is divided into a well-marked oral and œsophageal portion, a globular stomach, and a short intestine terminating in an anal aperture (Figs. 1 and 2). All the parts of the alimentary canal are disposed in a longitudinal and vertical plane, dividing the larval body into two symmetrical halves; but the œsophageal and intestinal portions are so disposed as to make an angle open towards the ventral side with one another. No nervous, or other, organs besides those indicated have as yet been discovered in these larvæ.

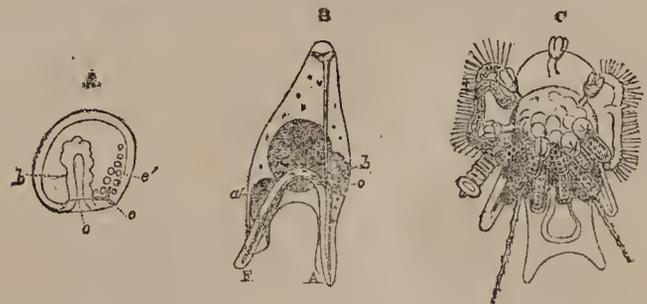

FIG. 2.

A young *Asterid* larva (after Müller).—A. Ventral. B. Lateral views of the larva. C. Commencing development of starfish. a. Mouth. b. Œsophagus. c. Stomach. d. Intestine. e. Anus. x. Anterior, and y. principal ciliated band. h. Cœcal diverticulum, forming the rudiment of the ambulacral vascular system, and opening externally by the pore g. k. Porisoma of starfish.

Development of a *Holothurid* (after Müller).—A. Early condition of larva. B, C. Later stages. f, g, h, the ambulacral vascular system.

Development of an *Echinid* larva (after Müller).—A. Earliest, and B. later condition of larva. C. The *Echinus* imago developed within and nearly obliterating the larva.

After swimming about in this condition for awhile, the larval *Echinoderm* begins to show the first signs of those changes by which it is converted into the adult form. An involution of the integument takes place upon one side of the dorsal region of the body, so as to give rise to a cœcal tube, which gradually elongates inwards, and eventually reaches a mass of formative matter or blastema aggregated upon one side of the stomach. Within this the end of the tube becomes converted into a circular vessel, from which trunks pass off radially through the enlarging blastema. The latter, gradually expanding, gives rise in the *Echinidea*, the *Asteridea*, the

*Ophiuridea* and the *Crinoidea*, to the body of the adult, the larval body and skeleton (when the latter exists), with more or less of the primitive intestine, being either cast off as a whole, or disappearing, or becoming incorporated with the secondary development, while a new mouth is developed in the centre of the ring formed by the circular vessel. The vessels which radiate from the latter give off diverticula which communicate with the cavities of numerous processes of the body—the so-called feet—which are the chief locomotive organs of the adult. The radiating and circular vessels, with all their appendages, constitute what is known as the “ambulacral system,” and, in Asterids and Echinids, this remarkable system of vessels remains connected with the exterior of the body by canals, connected with perforated portions of the external skeleton—the so-called “madreporic canals” and “tubercles.” In Ophiurids the persistence of any such communication of the ambulacral system with the exterior is doubtful, and still more so in Crinoids. In Holothurids no such communication obtains, the madreporic canals and their tubercles depending freely from the circular canal into the perivisceral cavity.

Whether the larva possessed a skeleton or not, the adult Echinoderm presents one which is developed quite independently of that of the larva. This skeleton may be composed of mere detached spicula or plates, as in the Holothurids, or of more or less definitely disposed ossicula, or plates, as in other Echinoderms. In the latter case its parts are always disposed with a certain reference to the disposition of the ambulacral system, and hence have a more or less definitely radiate arrangement. It might be expected, in fact, that the arrangement of the organs of support should follow more or less closely that of the chief organs of movement of the adult Echinoderm, and it is not surprising to find the nervous system similarly related. It is, in all adult Echinoderms, a ring-like or polygonal ganglionated cord, situated superficially to that part of the ambulacral system which surrounds the mouth, and sending prolongations parallel with and superficial to the radiating ambulacral trunks.

The reproductive organs of the Echinoderms, which usually open upon, or between, parts of the radially disposed skeleton, commonly partake of the radial symmetry of that skeleton; but they have no such radial symmetry in the *Holothuridea*.

The alimentary canal of the adult Echinoderm is still less connected with the skeleton, and exhibits anything approaching a radiate disposition only in one group, the *Asteridea*.

The vascular system which exists in many, if not all, adult Echinoderms, but the true nature of which is by no means understood at present, is closely related both to the alimentary and to the ambulacral systems, and partakes of the disposition of both.

No Echinoderm whatsoever has its organs, internal or external, disposed with that absolute and perfect radial symmetry which is exhibited by a Medusa, the tendency towards that kind of symmetry being always disturbed, either by the disposition of the alimentary canal, or by that of some part of the ambulacral apparatus. Very often, as in the Spatangoid sea-urchins, and in many *Holothuridea*, the ambulacral and nervous systems alone exhibit traces of a radial arrangement; and in the larval state, as we have seen, radial symmetry is totally absent, the young Echinoderm having as complete a bilateral symmetry as have Annelids, or Insects.

Nothing can be more definite, it appears to me, than the class *Echinodermata*, the leading characteristics of which have just been enumerated; but it is a very difficult matter to say whether the seven groups, some of considerable extent, which are massed under the next head, that of *Scolecida*, are rightly associated into one class, or should be divided into several. The seven groups to which I refer are the *Rotifera*, the *Turbellaria*, the *Trematoda*, the *Taniada*, the *Nematoidea*, the *Acanthocephala*, and the *Gordiacea*; and of these, five are composed of animals parasitic upon others, and exhibiting the anomalies of structure and of development which might be expected from creatures living under such exceptional conditions.

There is one peculiarity of organic structure which the first four of these groups certainly have in common; they all present what is termed the “water-vascular system,”—a remarkable set of vessels which communicate with the exterior by means of one or more apertures situated upon the surface

of the body, and branch out more or less extensively into its substance.

In the *Rotifera* the external aperture is single, and situated at the hinder end of the body; it communicates with a large rhythmically contractile sac, whence two trunks proceed, which usually give off short lateral branches, and terminate in the ciliated “trochal disk” of the Rotifer. Both the lateral offshoots and the terminal branches contain vibratile cilia. The Trematode and Tænioid worms have a similar, but usually much more ramified apparatus; and it is interesting to observe that in these animals, as in the *Aspidogaster conchicola* (Fig. 3), the water-vascular system becomes divided into two

FIG. 3.

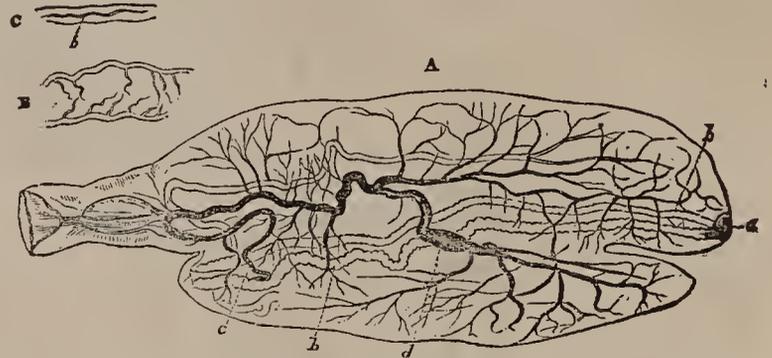

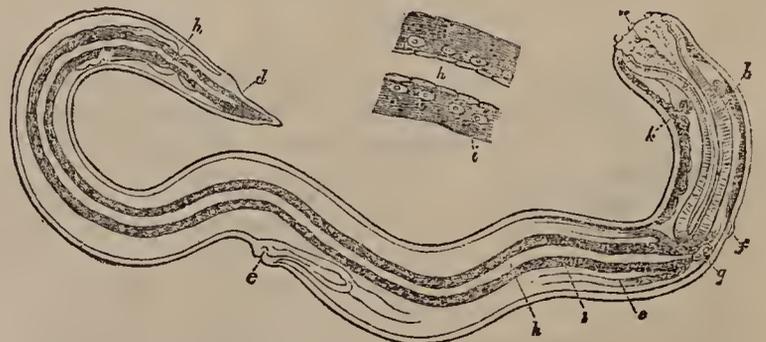

FIG. 3.—A. Water-vascular system of *Aspidogaster conchicola*; a, terminal pore; b, lateral contractile vessels; c, lateral ciliated trunks, that of the left side shaded; d, dilatation of this trunk; B, one of the larger, and C, one of the smaller, ciliated vessels.

distinct portions, one with contractile and non-ciliated walls, the other with con-tractile and ciliated walls. In some *Turbellaria* the apertures of the water-vascular apparatus are multiple, while it would seem that in others, as the *Nemertidae*, the apparatus becomes shut externally in the adult state, and consists mainly, if not exclusively, of contractile vessels. The difficulties of observation are here, however, very great, and I would be understood to express this opinion with all due caution.

In none of these animals has any other set of vessels than those which appertain to the water-vascular system (if I am right in my view of the vessels of the *Nemertidae*) been observed, nor has any trace of a true heart been noticed. The nervous system consists of one or two closely approximated ganglia.

This sum of common characters appears to me to demand the union of the *Rotifera*, *Turbellaria*, *Trematoda*, and *Tæniada* into one great assemblage. Ought the *Nematoidea* worms to be grouped with them? If the system of canals, in some cases contractile, which open externally near the anterior part of the body (Fig. 4), and were originally observed by Von Siebold, and since by myself and others, are to be regarded as homologous with the water-vessels of the *Trematoda*, this question must, I think, be answered in the affirmative. In it is almost the only system of organs in the *Nematoidea* which gives us a definite zoological criterion, the condition of the nervous system in these animals being still, notwithstanding the many inquiries which have been made into the subject, a matter of great doubt.

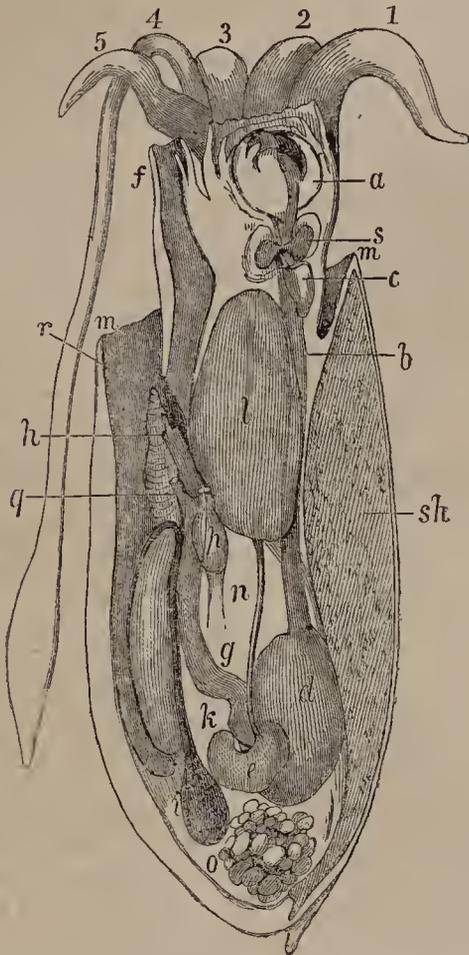

FIG. 4.

*Oxyuris*.—a. Mouth. b. Pharynx. c. Commencement of intestine, and d. its termination. The intermediate portion is not figured. e. Genital aperture. f. Opening of vessels. g. Their receptacle. h. One of the vessels. i. Cellular matter enveloping them. A portion of one of the contractile vessels is represented above, more highly magnified.

In habit and feature, the *Gordiacea*, filiform parasites which inhabit the bodies of insects, and leave their hosts only to breed, resemble the *Nematoidea* so much that I can hardly

doubt that their systematic place must be close to that of the latter; but positive evidence is almost wanting on this head, the extant accounts of the minute anatomy of these animals not having received that kind of confirmation which is desirable.

Diagrammatic section of a female Cephalopod (*Sepia*) omitted in the last lecture. *a*, Buccal mass surrounded by the lips, and showing the horny jaws and tongue; *b*, oesophagus; *c*, salivary gland; *d*, stomach; *e*, pyloric caecum; *g*, the intestine; *h*, the anus; *i*, the ink-bag; *k*, the place of the systemic heart; *l*, the liver; *n*, the hepatic duct of the left side; *o*, the ovary; *p*, the oviduct; *q*, one of the apertures by which the atrial system, or water-chambers, are placed in communication with the exterior; *r*, one of the branchiae; *s*, the principal ganglia aggregated round the oesophagus; *f*, the funnel; *m*, the mantle; *sh*, the intercal shell, or cuttle-bone. 1, 2, 3, 4, 5, the produced and modified margins of the foot, constituting the so-called "arms" of the *Sepia*.

## ON OBSERVING AND JUDGING AS TO THE EFFECTS OF REMEDIES.

BEING REMARKS INTRODUCTORY TO THE SPRING TRIMESTRE OF CLINICAL TEACHING

AT THE

ROYAL INFIRMARY, EDINBURGH,  
By THOMAS LAYCOCK, M.D.

Professor of the Practice of Medicine and Clinical Medicine;  
and Lecturer on Medical Psychology and Mental Diseases in the  
University of Edinburgh.

*Fashions in Physic—Difficulties in the Way of Observing—No Other Guide than Experience—Rules to be drawn therefrom—Nature and Mental Influences as Curative Means—Relation of Science to Medical Practice—Importance of Prognosis to Treatment, founded on a Knowledge of the Natural Order of Phenomena—Neglect of the Dies Indicantes, or Critical Days; and the Causes.—Bad Influence of Theories on Medical Art—Humoral Theories—Zymosis—Uræmia—Gouty Deposits—Exudations in Inflammation—Theory of Elimination—Theories as to Drugs—Dangers of Carbonate of Soda as a Dietetic Drug, and in Routine Practice—Chloroform—Magnesia.*

GENTLEMEN,—We shall shortly have an imperial Pharmacopœia with new drugs and new formulæ, commended to us by experience of their value on the part of eminent Practitioners. And we have almost a new non-official Pharmacopœia already, in the lists of new remedies, sent to us from time to time, in which various drugs and compounds, chiefly of American

growth or French manufacture, are strongly commended to our notice. There is a fashion in physic as in everything else, and arising like others from a love of change. Remedies and modes of treatment rise into popularity, and sink into oblivion in succession, and carry with them their appropriate theories and fallacies. But fashion in physic is not to be admired, for it is too apt, like all fashions, to trifle with weighty interests. You will have to judge for yourselves as to the real value of vaunted remedies and drugs in the treatment of disease; and I therefore think that the half-hour I devote to this introductory lecture cannot be better occupied than with the difficulties of observing and judging as to remedies.

At the close of the last summer's clinic, I remarked on some of these. In particular, I said that, although practical therapeutics have, in fact, kept pace with other departments of Medicine, the first aphorism of Hippocrates, so often quoted, is as true now as ever, and we can still say, "Life is short, and the art widely extended; the opportunity fleeting, experiments dangerous, conclusions difficult. For the Physician must be not only prepared to do what is best himself, but also to make the patient and nurses and all around co-operate." Supposing the *modus operandi* of a given drug in the cure of any disease or relief of a symptom were exactly known, what difficulties in the way of exact and successful treatment arise on the side of the drug merchant, the dispenser, the nurse, the patient, and from a multitude of unnameable collateral things, which influence the administration and effect of remedies! Every time we direct curative means we aim at what scientifically is the performance of a physiological experiment; if, then, we conceive an experimental physiologist making researches or experiments with a well-known drug, on a living being under circumstances like those which meet us when prescribing, we shall attain to something like a conception of the difficulties which surround exact therapeutics, and learn, at least, the practical truth, that such exactness is unattainable. But let us carry the comparison further, and suppose there is no exact knowledge of the *modus operandi* of the remedial agent, and that this knowledge has to be obtained by observation and research under the circumstances mentioned (which are, in fact, those of ordinary practice), and we have at once an explanation of the uncertainties and contradictions of therapeutical science. It is seen that scientific research, in the proper sense of the term, is, in truth, simply impossible in ordinary therapeutics. The *modus operandi* of drugs has, however, been investigated in a scientific manner by experimental researches, either on the person of the experimenter, or on lower animals; and in this way some positive knowledge is acquired. But when, by isolation from all disturbing causes, by a strict exactitude as to the purity of the drug, the doses, the times and mode of administration and the like, such knowledge is attained, it is by no means readily applicable to practice. And this for the obvious reason, that the conditions are not the same. The patient is not a lower animal, if the knowledge was acquired by researches on the lower animals, nor is he in health, if the experiments were made on persons in health. Then, again, persons both in health and disease differ much from each other as to the vital changes induced by disturbing agents; nay, the same person differs as much from himself, from time to time, as he differs from others. These differences are so great, even as to articles of diet, that it is embodied in proverbial philosophy;—"What is one man's meat is another man's poison." Perhaps, of all drugs, opium is the most uniform in its operations. Yet, there was a man admitted into ward X. last summer, who assured us he could chew one ounce of opium in a day, and smoke a pipeful, without any other effects (as he said) than those of a moderate dose of liquor. On the other hand, doses of laudanum as small as a minim or two, given to infants, cause serious symptoms; and even in adults, opium in small quantities is sometimes wonderfully mischievous. I had a young lady under my care, in whom erysipelatous inflammation was invariably induced by the external application of an opiate. These are called peculiar constitutions, or idiosyncracies, as if the term explained the phenomena; but the practice of Medicine is full of such idiosyncracies and peculiarities.

What then, you will ask, is to be relied upon in therapeutics? Is there no guide to the administration of remedies? Most assuredly there is, and a sure guide, too—namely, that *experience* of remedies which is founded on long and careful observation, and enlightened and corrected by physiological

knowledge. I say, long and careful observation; for I am satisfied, after more than thirty years' experience of drugs like calomel, colchicum, and opium, that the therapeutical uses of things can only be learnt in that way, because only in that way can we attain to a knowledge of those varied and numerous conditions which modify their action in individuals. And, when I reflect upon this, I am astonished at the positive manner in which opinions are expressed as to the value and uses of leading remedies by those who, in the same breath, declare they seldom or never prescribe them. It is sufficient for these therapeutists to criticise the contradictory statements of observers, or to advance ingenious *d priori* objections founded on purely hypothetical data. Such criticism on the recorded results of experience is easy enough, but is just as worthless as it is easy. Physic, in general, we all know, is uncertain and contradictory; but in therapeutics, more especially, not a single theory (of which it is full) is really tenable—is, at the best, only plausible.

Our safety is, in truth, in the multitude of our observations; by these, all the variously modifying conditions are disarmed, as it were, of their modifying power over our conclusions. Just as in constructing life-tables, with the greatest uncertainty as to the duration of life of each of 1,000,000 persons born, we can determine, with fair accuracy, the number that will die at successive ages until not one survives; so it is with our conclusions as to the operation of drugs and remedial means. Although there may be, and is, great uncertainty as to each individual case, the general conclusions from a multitude of cases have an element of certainty; and these form a guide and standard of comparison as to the effects of treatment in individual cases. Thus, while experience shows that opium in two-grain doses may, in the majority of persons, be expected to produce torpor, insensibility, and other changes indicating its influence on the nervous system, we know by experience also, that in a certain class of diseases of the nervous system, as tetanus, or some forms of mania and delirium tremens, those results will probably not follow, but even the contrary.

What rules may be drawn from experience as to the observing the effects of remedies? Clearly, it is necessary to know, primarily, that the remedy has actually been used or applied in the prescribed mode. This first rule, so obvious, is, however, too often neglected. Secondly, as to any particular mode of treatment of a special group of symptoms: if we find that like general conclusions have been drawn as to the success of other modes of treatment; or, in other words, if various and very differently-acting remedies have been found equally available in the cure of a disease, we may infer that there is an element common to all, but not recognised, upon which the curative result depends. Close a wound carefully, and rest the wounded part, and to that you might add a hundred remedial things, besides salving the wound that inflicted it, with equal success. The natural result would follow, namely, healing of the wound under any circumstances which did not interfere with the natural processes. It is, therefore, of primary importance in therapeutical investigations to determine the natural history of morbid states, or the order in which they rise and terminate. The two chief things to this end are etiological diagnosis and prognosis. It is for this reason that the older Physicians cultivated prognosis so strenuously; for, to use the very words of Hippocrates, "Our natures are the Physicians of our diseases." So that what *these* Physicians are doing, and are likely to do, is a question of very vital importance to both the Physician and his patient. Skill in prognosis is, therefore, the first qualification of the true Physician: by this he is enabled to attain to the highest knowledge of all in Medicine—the knowledge when to do nothing, but watchfully wait on nature, and firmly resist all temptations to perturbative treatment. The therapeutics of two very common diseases may illustrate these views: Acute pneumonia is one of those diseases in which our natures are often our physicians. Hence, the success of so many and such different modes of treatment; hence, the real value of the rational and expectant method of treating pneumonia you have seen me adopt in the wards, founded on this principle of experience. Epilepsy, on the other hand, is not, like pneumonia, a self-limited disease; but it is essentially an affection of the encephalon, and is, therefore, more or less amenable to all those influences which alter the vital activity of the encephalon. Now, nothing is so certain in this respect as mental or moral influences. So that of the hundreds of

remedies and remedial means which have been found useful in epilepsy, and the mere list of which would fill a quarto volume, in a certain class of cases there are few which operate independently of these mental changes. Hopeful anticipation may be said to be the best remedy for these kinds of epilepsy, as for emotional hysteria, and other encephalic affections of the same class. It is probable therefore for this reason, that mesmeric passes, prayers for recovery, novel and striking remedies, and even a simple change in treatment, are all so often followed by beneficial results in hysterical paraplegia and epileptiform diseases.

In observing and concluding as to the results of treatment, we must carefully distinguish between the science and the art of healing. It is admitted generally that the science can only have a solid foundation in Medical etiology, or the science of causes of disease. But, then, such science involves an anterior science of very wide extent, which may be fitly termed Biology, or the science of life, because, to know scientifically how disease begins, it is necessary to know how life arises and continues. At present this is impossible. The art is more attainable, because it is limited to a comparatively narrow field of research into causes and effects, and uses science chiefly as a means of enlightening experience than giving principles to art. So that there may be a highly advanced therapeutical art if founded and directed thus. And even with little science, much art of a kind is attainable. The ancient Physicians, although greatly in the dark as to the causes of disease and as to biological science, were better informed than we are as to the order of morbid changes, and that simply by the force of empirical observation. It is plain they watched this order very closely in fevers and acute diseases, and came to conclusions of great importance to practice. These constituted the foundation of the theoretical doctrines of crises and critical days. But they also constituted the basis of a method of prognosis which was distinct from the mere theories, and which, because of the theories, has undeservedly become almost obsolete. To understand it rightly, it is necessary, therefore, to distinguish between the generalisation from the facts of experience, and the theories which were invented to explain them and apply them to pathology and therapeutics. The facts are amongst the most certain in medicine; no one doubts, for example, that intermittent and remittent fevers run a regular course, and, that certain data being known, the course of such a fever can be anticipated. It is, in truth, this knowledge of the order of events in agues which enables us to anticipate and prevent a fit.

The exact punctuality of recurrence and alternation of the paroxysm sometimes observed in cases of ague and intermittent nervous affections is very striking. I have known a fit of neuralgia recur daily at the same hour within a minute or two. This curious exactness is not, I think, due to the disease, but to the same kind of mental state which interferes so much with an accurate estimate of the effects of remedies; nevertheless, it is very certain that vital events do occur and recur in health at measurable periods. All those of incubation, menstruation, and utero-gestation are of this kind; and so, also, the successive stages of fevers and other acute diseases. Several years ago I endeavoured to bring the laws of periodic recurrence of vital changes, in general, into relation with the laws of recurrence of periodic morbid changes.<sup>(a)</sup> The entire class of phenomena can be resolved, I think, into one or two simple laws of chronometric nutrition; and I am very sure one of the next large advances in the science of life and the practice of medicine will consist in the development and practical application of these chronometric laws. Without a knowledge of them, indeed, we are much in the same condition as to diseases in general as the cattle-breeder or obstetric Physician would be if he were ignorant of the chronometric laws of conception, utero-gestation, and parturition; and which are, in truth, illustrations of the fundamental laws, because they can be resolved into periodic laws of nutrition and development. The mode in which simple experience of these laws in disease was formerly made available to practice is very well shown in two chapters of *Ætius* on the "Method of Prognosticating the Day and Hour of a Patient's Death." The day, he says, is to be ascertained by observing on what critical days the attacks are most severe; the hour by noting at what time of the day the exacerbation comes on, and at what period of it the patient is most

(a) *The Lancet*, 1842-43.

depressed; "for at that hour at which the pulse is most depressed, death will take place." Such a prognosis might have been further helped by a knowledge of the hours of the day at which the heart's action and the vital powers generally are most depressed. Experience shows that death takes place at the early morning hours more frequently than at any other. I had the hour of 3000 or 4000 deaths tabulated some years ago, and found this the fact. It is clear that this method consisted in nothing more than the formation of an opinion as to the probable future course of a disease from the data of experience in like cases, and was therefore identical in principle with that which enables us to anticipate the probable effects of drugs. From this simple method arose also the technical terms which have long indicated the periodic changes in disease, for the primary and proper meaning of the Greek word "crisis" is "opinion," or "judgment;" so that a "critical" day was at first simply a day on which a Medical opinion or judgment as to the course of the disease could be made or would be confirmed. Hence critical days were termed in Latin, "*dies indicantes, dies judicatorii,*" and the like. In the words "critic," "critical," and "criticism," as applied to literature and art, this primary meaning is still expressed. It is only by an abusive and restricted use of the terms that critical is used in the sense of dangerous, and "*κρίσις*" and "judgment" in the sense of condemnation. So fundamental a branch of art can never go out of use, and we still practice this old method of prognosis, but in a limited and imperfect way; as, for example, when we anticipate what will happen at a menstrual period in certain feminine diseases, or when we form a judgment as to the course of an exanthematous fever from the date of the eruption and other symptoms. But the want of definite knowledge and training in exact observation renders even this simple application of the method very imperfect. Thus, a Practitioner, relating the result of his experience in the treatment of small-pox by the *saracenia purpurea*—an alleged specific—informs the professional public that, although it had failed to cure the patient (for the disease was rapidly fatal), it had caused an abortive eruption, or, in other words, had prevented the development of the cutaneous inflammation. Now, in a case of variola, the delay or "abortion" of the eruption usually coincides with a dangerous kind of fever, and is a *malum signum* in prognosis for this reason; and is not, unfortunately, to be modified by very potent drugs. If the *saracenia* had any influence on the eruption, as alleged, we must conclude that it was rather injurious than beneficial. Other Practitioners relate its effects in cutting short or modifying varioloid, not aware, apparently, that that which they attribute to the drug is the ordinary course and termination of the fever. Without a regard, then, to this natural order of events, no therapeutical observations can be made of any practical value.

One chief reason why the periodic changes in disease are not better observed, and rendered more available to prognosis and the correct observation of the action of remedies on the course and termination of a case, is to be found in the fact that few, if any, of our modern writers discriminate between the facts and the theories. The older Physicians, like us moderns, were not content with observing the facts and founding their judgment thereupon, but they invented a theory to explain them. Thus, there was an elaborate humoral theory generally accepted, which affirmed that the sweats, diarrhoeas, and other discharges which are observed to take place on certain days, are critical in the sense of curative. The "*materies morbi,*" or "acid," or "peccant humours" it was thought were thereby eliminated, and thus health restored, so that it became part of the business of the Physician to watch for and encourage these "efforts of nature," as they were termed, to throw off the morbid "humours." Then, again, a theory was grafted on this as to the mode of elimination. It was maintained there was a zymosis, or fermentation going on in the blood; and thus terms, such as coction, despumation, and the like, derived from the brewhouse, became technical. So completely have these theories usurped the place of the facts of experience, which they were invented to explain, that I believe very few modern Physicians recognise the facts at all. So that a very eminent and able writer on fever only represents current opinions when he discusses the doctrine in his recently published work in no other sense. He observes, "It has been a very common opinion from early times, that in fevers the decline and disappearance of the symptoms are accompanied or preceded by a *crisis* (a term implying *separation from the body*)," etc. Some

of the old Greek writers, as Galen for example, had a theory of the facts founded on a semi-mystical doctrine of numbers, and I remember when a Physician of great intelligence and acuteness gave a lecture on the doctrine of critical days in Edinburgh, he specially undertook to show that this and the other theories were incompatible with the facts, but he did not inquire into the facts, because confounding them with the theories, nor attempt any explanation of those periodic changes which confessedly do occur in both healthy and morbid conditions.

And yet, for all this, we have still our humoral hypotheses and theories, exercising the same injurious influence on Medical art. Thus, for example, authors write of uræmia and uræmic poisoning, as if the theories these terms imply are well-established pathological truths; so that when a patient who has a structural disease of the kidneys which interferes with their proper function, dies, and has also certain symptoms indicating a cerebral disorder, it is said he dies of that because his blood is poisoned with urea. But, in fact, this explanation of the order of events is hypothetical, and in some cases is certainly wholly inapplicable. So, again, salts of uric acid are found in the tissues in certain cases termed gouty; urates are also found in the blood, and it is thence concluded that the urates found in the tissues are deposited from the blood. Now, as to some tissues, at least, it is much more likely that they are formed where they are found, and have never been in the blood at all. We have a like theory in the current doctrine of certain diseased states termed inflammations. Abundant fibrine is found in the blood: it is also found at the same time in or on the tissues of an inflamed part. Hence the conclusion that it exudes from the vessels into the inflamed tissues. This may be true as to some tissues, but as to others it is at least equally probable that the plasma is formed where it is found, and not exuded. A like fallacy is at the root of the current, albeit modified, humoral doctrine of critical days: a patient is observed to be better after a copious sweat or diuresis or diarrhoea, and it is concluded that the evacuation is the cause of the improvement in the health, while, in truth, it is more probable it is only the effect, and therefore a sign of a general change for the better. I do not mean to say that a return to any healthy function in any organ is not beneficial generally; what I affirm is, that that return to healthy function—as, for example, the return of appetite and digestion of food—must itself have been preceded by some other change for the better, and is therefore a *result* of an improvement, as it, in its turn, may be the *cause* of further advances to health. So that any therapeutical theory founded upon the supposed curative power of these so-called critical or judicatory discharges, must of necessity have an element of error, and thereby confuse observation as to the effects of remedies and of the natural processes.

I am well aware how satisfactory it is to us all, whether student or Practitioner, to have some simple, easily intelligible, and at the same time apparently safe theory, to rest upon, when studying and treating the intricate phenomena of disease. But be assured all such theories will prove but broken reeds if relied upon exclusively; a well-formed habit of careful, accurate observation is a far surer source of satisfaction, for you thereby gain that knowledge of things as they are which constitutes solid experience, and which an adoption of theories, except for merely temporary purposes, inevitably vitiates. And if you bring to the bedside those habits of close observation which have already done so much for physical diagnosis, you will, in fact, do all that is needed for improved clinical research into the natural order of morbid changes, with a view to an estimate of the effects of remedies. Date—weigh—measure—number; this is the rule for true clinical inquiry—not easily to be followed, I readily admit, but still the rule.

There are equally mischievous theories as to the properties of drugs. We are told that drugs are diuretics and diaphoretics, and narcotics, and astringents, and antacids, until we get to believe that they have some peculiar property or quality, and we lose sight altogether of the fact that they must exercise very various influences on vital changes. Thus the sesquicarbonate of soda is found very useful in relieving those various uncomfortable sensations which the action of an acid stuff on the mucous membrane of the stomach causes, and, in consequence, has passed into such popular use that our very food is drugged with it. We are offered soda bread, soda cakes, "scones" made light with soda; beer, if hard, is made more injurious by soda; nay, I think some one has

invented a "baking powder" which has a soda salt as its basis. Yet carbonate of soda has on some persons, as I know, a pernicious influence, and perhaps, in many, it causes bad effects not recognised, because not looked for. A few years ago, I saw a curious example of the influence of these theories in practice. A lady, the wife of an eminent Practitioner, had a morbid condition of the nervous system, such that she could not sleep, for just as she was falling asleep she was attacked with peculiar convulsive movements. The only theory of causation I could make out was that some poisonous agent was at work, but nothing further, until a close inquiry into the dietetic habits of the patient elicited the fact that she held the conviction that she had an hereditary tendency to ossification of the arteries of the brain, and that acids would carry off the bone-earth. She therefore drank freely of sour French wines, and, to remedy the gastric disorders they induced, took equally freely the sesquicarbonate of soda. Having observed somewhat similar effects once before, I advised that the treatment should consist simply in drinking diluent fluids, and discontinuing the sour wines and the soda. The result was the entire relief of the morbid state. Again, a gentleman to whom I had recommended this drug told me that he always had peculiar sounds in his ears after taking it, and that they sometimes ended in what appeared to be a loud explosion in his head. Another patient can rarely take thirty or forty grains without feeling a pain in the back, exactly in the region of the kidney, and which organ is doubtless the seat of the pain. So that if he chanced to take large doses of the alkaline carbonates the result would probably be a serious renal affection. Other apparently simple drugs have also their action upon distant organs, and their morbid sequelæ. We hear of the *deaths* from chloroform, but rarely, if ever, of the diseases. Men will carry cakes of magnesia in their pockets as if it were a harmless antacid like chalk; but it acts upon the genito-urinary system of some persons in a way which shows that it is something more—possibly because it forms a soluble salt with some of the acids.

Thus, then, whether we look at practical therapeutics from the side of pathology or *Materia Medica*, we find the strongest grounds for close and careful observation and cautious conclusion.

## ORIGINAL COMMUNICATIONS.

### CLINICAL MIDWIFERY.

By FRANCIS H. RAMSBOTHAM, M.D.

Physician-Accoucheur to the London Hospital, etc.

(Continued from page 289.)

THE following four cases of lingering labour under head presentation, in which instruments were not employed, occurred in my practice during the five years between January 1, 1840, and December 31, 1844:—

#### *Lingering Labour.*

*Case 188.*—On June 7, 1841, at 6 p.m., I was sent for by a Medical friend, to Mrs. S., Effra-road, Brixton, aged 30, in labour of her first child. The membranes broke on the night of the 5th; the first part of the labour had been very painful, and she had been very restless and unmanageable, screaming loudly through the whole night of the 5th and the whole day of the 6th. The child's head was just expelled when I arrived,—very putrid. The vagina and external parts were very rigid and dry, and there was a sensation of crepitation imparted by them to the finger, which made me apprehensive they would slough. I extracted the body of the fœtus with some difficulty, and in thirty minutes removed the placenta by introducing the hand into the uterus. It was partially adherent, and the adherent portion was covered on the maternal face with a thick layer of coagulable lymph. There was no hæmorrhage either before the placenta was taken away or after; as the bladder was distended, I emptied it by the catheter. In the evening she was free from pain, but the bladder had not acted. The catheter was again used, as also next morning. After that she passed water naturally for a few days, and then it began to run away involuntarily. She suffered no pain at all, but lost flesh rapidly, and without any very prominent symptoms, except those two just mentioned, she sank, and died on July 8.

N.B.—This is a case where chloroform might probably have

been of service, both because for many hours the advantage gained was not at all equivalent to the suffering endured, and because chloroform would most likely have lessened the rigidity existing in the vagina and perineum by paralysing the muscular tissues which enter into the composition of those organs, as it does most of the other muscles of the body. It is probable also that this patient's life might have been saved if instruments had been had recourse to some hours before my arrival.

#### *Lingering Labour.*

*Case 189.*—On July 5, 1842, at 11 a.m., a Professional friend called me to Mrs. H., High-street, Shadwell, a stout young woman, in labour of her first child. The membranes broke about thirty hours before. She had been most unmanageable throughout her labour, screaming violently, and throwing herself about the bed. I found the head on the perineum, and it passed in half an hour; the child was alive; the placenta was soon expelled, and she recovered well.

#### *Lingering Labour—Prolapsed Bladder.*

*Case 190.*—On August 8, 1842, at 7 a.m., I was requested by a Professional friend to see Mrs. B., in the Borough, in labour of her fourth child. I had delivered her in her first labour by the forceps, there being a slightly contracted pelvis. The membranes broke about twenty-four hours before I saw her; the pains had been strong and active; my friend had attempted to deliver her by the forceps, but had not succeeded. I found the cavity of the pelvis almost entirely filled by a fluctuating tumour, and I had no difficulty in determining that it was the bladder prolapsed. The head could be felt distinctly above it, partly engaged in the brim. I removed the urine at once by the catheter, the tumour disappeared, and the head speedily took possession of the pelvic cavity. The child was born in half an hour—living; and she did well. It appeared quite evident to me that the prolapsed bladder was the cause of the head not descending, for, although it had remained stationary for some hours before my visit, it came down directly the urine was withdrawn.

#### *Lingering Labour attended with powerful Uterine Action.*

*Case 191.*—On November 7, 1842, at 8 a.m., I was sent for by a Medical friend to Mrs. A., New-road, Whitechapel, in labour of her first child. The first stage of labour went on very slowly; the membranes broke six hours before. I found the os uteri almost entirely dilated, the head passing through the brim, neither impacted nor arrested; and, although the uterus had been acting very powerfully ever since the membranes broke, there was not the least distress in the system. I recommended that no means should be taken to deliver then; and the child was expelled at 11 a.m. The patient made a good recovery. The anxious state of the friends was the sole cause of my being sent for.

#### *Sudden Arrest of Labour Pains from Fright.*

*Case 192.*—On October 18, 1841, at 9 p.m., a Medical friend called me to Mrs. C., Commercial-road, in labour of her second child. She was progressing exceedingly well through the first stage of labour, when, at 11 a.m., the membranes broke with a report so loud as to alarm every one in the patient's chamber at the time, and to be heard distinctly by my friend in the adjoining room. The patient was so frightened by it that the pains, which were strong and frequent before, ceased entirely; and when I arrived there had not been a single one since the occurrence. The os uteri was almost entirely dilated, and the head was partly occupying the pelvic cavity. I gave a dose of ergot immediately; this caused the uterus to resume its action in about ten minutes, and the woman was delivered of a live child in an hour; the placenta soon passed, and she did well.

N.B.—I never myself heard any noise when the membranes broke, as far as I can recollect, and I should not have credited this story had it not been for the effect upon the patient herself as well as for the unanimous testimony of three or four women who were in her room at the time, and of my friend who declared he heard it quite plainly, and that it sounded like a distant pistol-shot.

#### *Dropsy of the Ovary.*

*Case 193.*—On June 27, at 7.30 a.m., I was requested by a midwife to the Royal Maternity Charity to see Mrs. G., in Whitechapel, one of the patients, who had borne many children. She had been under my care for six or seven weeks with œdematous legs and an abdomen immensely

distended. When I first saw her, she thought herself between seven and eight months advanced in pregnancy, but for some time I doubted that she was pregnant, in consequence of her enormous size, which was rapidly increasing, and the very evident abdominal fluctuation, which was as distinct as in most cases of ascites. However, on June 25, I made a vaginal examination. I then found the os uteri dilated to the size of a half-crown piece, and I could detect the head presenting. When I was sent for on the 27th, I found that she had been in labour all night, but that the pains had been slight and infrequent. I immediately ruptured the membranes, and we caught in basins more than a gallon of liquor amnii; besides this quantity, there was *in utero* about half a gallon more, which flowed away. The pains came on strongly after the escape of the liquor amnii, and she was delivered naturally at 9 a.m. The child was alive, but its abdomen was distended with water. Soon after it was born it became perfectly livid; it never cried, and died at 1 p.m. As the parents were of the Jewish persuasion, an examination was not permitted. It would have been interesting to know whether there was any fluid in the chest, and whether the foramen ovale was open or not. I have almost invariably found, when the fœtus has been hydrocephalic, or otherwise dropsical, that there has been an excessive quantity of liquor amnii, as also with acephalic fœtuses, which condition, indeed, has its origin in hydrocephalus.

Besides the three cases of face presentation which I have already detailed, one of which I delivered by the forceps, and two by craniotomy, two others occurred in my practice during these five years.

*Face Presentation—Prolapsed Bladder.*

*Case 194.*—On March 23, 1840, at 2 p.m., I was called by one of the Surgeons to the Royal Maternity Charity to Mrs. B., living in the Borough, in labour of her sixth child. I had delivered her of her last by the long forceps about two years before, in consequence of diminished space at the brim. The membranes broke at six the evening before, and the pains had been strong and frequent ever since. The head was almost entirely above the brim, the anterior fontanelle was presenting, the crown of the head was looking towards the left sacro-iliac symphysis, and the face necessarily directed towards the right groin. The bladder was distended and prolapsed, filling up the greatest part of the pelvic cavity, as a fluctuating tumour. I drew off the urine, and applied the long forceps over the face and posterior part of the head, without, however, much hope of being able to deliver with them. Nevertheless, I brought the head a little lower; but the chin came down, and then the case was converted into a complete face presentation. Fearing to use any more exertion than I had already made, as the uterus was acting well, I took off my instruments, and the head was expelled in an hour, the chin appearing under the symphysis pubis. The child was living. The placenta was soon expelled, and she recovered favourably.

*Face Presentation.*

*Case 195.*—On January 23, 1843, at 4 p.m., I was sent for to a patient of my own, at Leyton, in labour of her fourth child. There had been pains coming on every fifteen minutes since twelve the night before. I found the os uteri very high, soft, and thick, not dilated to a larger size than a six-penny piece. The pains continued, though not strong; and at 2 a.m. of the 24th the os uteri was the size of a crown, and quite thin. I then detected that the centre of the brow was presenting,—the middle indeed of the frontal suture. I could feel the nose quite distinctly, and the chin was towards the right sacro-iliac symphysis. I made some counter pressure, hoping to raise the face, and bring down the posterior part of the head; but in this I was foiled; for although, the membranes being unbroken, I succeeded in pushing up the face somewhat, it always returned to the same position as soon as the counter pressure was removed. I therefore desisted from any further efforts; for, knowing that the lady possessed a very roomy pelvis, I hoped the head would be expelled with the face foremost without any injurious exertion. The membranes broke at 3.15, and the head was born at 3.30, the chin under the pubis. The child was living, the placenta passed soon, and she made an excellent recovery.

N.B.—When the face comes down into the pelvis foremost, in whatever position it is placed as regards the pelvic brim, in its exit through the outlet I believe it invariably passes with the chin underneath the symphysis pubis, pro-

vided no interference either by instruments or otherwise is used. Dr. Meigs, indeed, gives an illustration, in which he shows the head passing with the chin sweeping the sacrum, and details a case in point; but he had brought the head into the pelvis by the forceps: and Dr. Lee also gives a cut of the same kind. I can only say that no such case ever came under my observation.

8, Portman-square.

(To be continued.)

NOTES ON CAUSES OF EARLY MORTALITY.

By J. WHITEHEAD, M.D.

No. V.

GENERAL DEATH-RATE.

(Continued from page 340.)

As already intimated, the general rate of mortality for France is considerably higher than that for England. Such has been the case for many years past, even when the average duration of life in this country was far lower than it is at present. The following table exhibits the fatal results for 1856, the most favoured year, in this respect, of the last seven:—

*General Death-rate at Different Ages in France for 1856.*

	To 100 Births.		
	Males.	Females.	Total.
1st year	9.24	7.48	16.72
1 to 5 years	5.36	5.22	10.58
5 to 10 "	1.70	1.74	3.44
10 to 15 "	1.02	1.13	2.15
15 to 20 "	1.33	1.44	2.77
20 to 30 "	2.49	2.95	5.44
30 to 40 "	2.55	2.74	5.29
40 to 50 "	2.84	2.72	5.56
50 to 60 "	3.95	3.60	7.55
60 to 70 "	4.56	5.39	9.95
70 to 80 "	5.33	5.79	11.12
80 to 90 "	2.10	2.77	4.87
90 to 100 " } and upwards }	0.2	0.30	0.50
Total	42.67	43.27	85.94 (a)

From the preceding table it appears that for every 100 births in France in 1856, there had occurred,—

At the age of 5 years	27.30 deaths
" 20 "	35.66 "
" 50 "	51.95 "
" 90 " and upwards	85.94 "

The comparative results of the last two tables (English and French) present two or three notable points of difference. Although the rate of mortality during the first five years of life is constantly higher in France than in England, yet is the value of life during nineteen-twentieths of this term considerably and as constantly lower in the latter than the former country. The excess in the French table for the first 5 years is occasioned by a remarkable preponderance of deaths during the first three months, which, in this instance, amounts to 2.61, but in many others to 3 or 4 per cent.; while, for the rest of this period—from three months to five years—it is below the English estimate to the amount of 1.82, and in some years considerably more,—in 1857, 2.40.

These relations for 1856 are exhibited in the subjoined statement:—

	Deaths to 100 births.		
	First 3 mos.	3 mos to 5 yrs.	Total to 5 yrs.
France	19.26	1.04	27.30
England	7.65	18.6	26.51

Hence the conclusion, that while in England a more favourable condition is secured for the infant during the first three months, owing, in all probability, as already suggested, to the more frequent practice of breast-nursing during this early period, the credit of a more judiciously-adapted hygiene for young children must be accorded to the French.

(a) This item in the official return stands at 87.06, that is, 1.12 higher than is here represented. The error, if on my part, is due to a deficiency in the decimal numbers of the component items, which might possibly be rectified by re-calculation, but it is equally likely to be on the other side.

In England it is too much the custom to feed infants, immediately after weaning, even so early as eight or ten months, with foods which are suitable only for labouring men. For instance, in the families of successful artisans and wealthy shopkeepers, one commonly sees the young children, down to that on its mother's lap, seated at the dinner-table, partaking of each article which the parents themselves use. They are especially supplied, not only at dinner, but at other times, with concentrated soups, strong beef-tea, eggs, fish, bacon, tea, coffee, and rich cakes and puddings, with any other hard and savoury article that may be in vogue, not excepting a taste of beer or other strong beverage,—a species of diet assimilable only by those of ripe age who are able to take vigorous physical exercise. The offspring of the needy peasant, who has nothing to spare for them but bread-and-milk and oatmeal food, grow up vigorously healthy and robust, and are consequently often inconveniently numerous; they are not seldom seen pursuing their ordinary play, in and out of doors, while experiencing an attack of some of the much-dreaded children's ailments, which generally visit them but lightly; while those of the other class are thinned in number at every such visitation. These observations do not, of course, apply to the educated classes generally; although, amongst them, there are exceptions. They are more especially applicable to those who possess a greater abundance of means than of knowledge or judgment in their application.

It is remarkable that the rate of infant mortality for the Seine department is lower than the general estimate, and still lower for Paris than for the rest of its department. This may possibly be accounted for by the fact that a considerable number of the children born in Paris are sent out beyond its precincts for nursing, and doubtless, also, the abundance of resources available in the capital for the treatment of children in times of sickness must be taken into this account.

The general death-rate for Paris and the department of the Seine is considerably below that of the whole country, the average mortality for 1856 and 1857 being 75·53, or 10·41 per cent. below that for the whole of France. In a commercial point of view, the value of life of the Parisian citizen is at least 10 per cent. higher than that of the rural inhabitant. This result tells favourably for a city whose population is, perhaps, more densely packed than that of any other large city of Europe (b), and is probably due to the improved sanitary condition of the capital, effected under the auspices of its present enlightened ruler.

With this one exception, namely, the more prosperous condition of the infant from the age of three months to that of five years, the French death-rate exceeds the English at every subsequent stage, being higher at fifteen years than the English is at twenty, and as high at fifty as the English at sixty-two. It arrives at 50 per cent. in France at the age of forty-eight, while in England not until upwards of sixty.

The wide and persisting difference in the relative healthfulness, as indicated by the respective death-rates of two countries so nearly alike in geographical position, the staple products of the soil, the industrial pursuits of the people, and in other points, may appear somewhat paradoxical. In most of these respects France would seem to be more favourably circumstanced than England. Its climate has a geniality far surpassing that of this island. Its alternations of temperature, albeit more widely varying at some seasons, are not nearly so frequent or so sudden, and the atmosphere, of the towns especially, is much purer.

With a limited exception, France lies within the more moderate portion of the temperate zone, between the isothermal lines of 50° and 60°, and consequently with a mean annual temperature, the difference of which, at its north and south extremities, does not exceed 10° or 12°. The extreme climatic severities are experienced in the N.W., where the prevalence of winds from that direction, loaded with the exhalations of a wide expanse of seas, produces a superfluity of moisture, with mists and heavy falls of rain, representing the type of the English climate generally; and in the opposite, the S.E. quarter, where, on the contrary, a sultry, stifling heat sometimes prevails, giving origin at certain seasons to malignant fevers. But setting these aside, more than four-fifths of the

(b) Before the annexation of the Banlieu in 1860, Paris contained 1,174,346 inhabitants, crowded into a space of 6804 acres, or 140 to the acre; and with its present boundaries, now numbering 1,525,942 inhabitants, there are about 80 to the acre; while London has a little less than 36 to the acre.—*Ten Years of Imperialism in France*, p. 32. Impressions of a "Flaneur." 1862.

surface remains under an atmosphere remarkable, especially in the central districts, for salubrity, serenity, and brightness (c).

The labouring population of large towns in France are not usually so crowded in their dwellings as the corresponding class in England. For, although a far greater number of people are found occupying a given extent of surface, yet, as the houses are generally much loftier, the space of ground covered by an English cottage of two stories high with four apartments, being made, in French towns, by reason of additional stories, to afford three or four times as many rooms, the accommodation as to breathing space is consequently much more ample. The upper stories of such dwellings are far healthier than those below, especially than those of the ground floor and that next above it, from being elevated beyond the reach of the surface stratum of the atmosphere, which during the prevalence of still weather, in some seasons continuing through a considerable period, remains stagnant and for a long time unrenewed, and at all times loaded with noxious effluvia.

French towns possess, moreover, the advantage of large open spaces planted with trees and well-tended flower gardens, especially provided for the recreation of the populace, and the working classes have generally more leisure for the enjoyment of these privileges. In garrison towns also an additional attraction to these resorts is afforded by the presence of military bands at stated hours in the evening, a graceful and highly appreciated tribute which it has become a part of the duty of these professionals to render in times of peace. The omission of this kind of gratification in England is doubtless a mistake which the municipal authorities have it in their power to rectify. Open-air performances of good music, gratuitously afforded, might prove a powerful inducement to the cultivation of this humanising accomplishment among the working classes at their own homes, instead of resorting to places of intemperance, where demoralisation and waste of means are inevitable.

In regard to habits of cleanliness and temperance, in their influence upon health and longevity, it may be remarked that inattention to the practice of these moral virtues can have had but little share in elevating the rate of mortality in France so much above that in England; for the French of all classes are not less observant of personal neatness in every sense, nor less alive to its sanitary importance; and they are decidedly more temperate in their habits than the English.

Peculiarity of race and quality of diet may not unreasonably be assumed to have had an influence in determining the disparity; but the latter, in my belief, much more largely so than the former. Indeed, it is tolerably manifest that the duration of life is not necessarily lower among the Celts than the Anglo-Saxons, as may be oppositely illustrated by an example to be found amongst our own population. The Welch, for instance, as a race, are not less purely Celtic than the French, and yet the duration of life presents as high a value throughout the Welch counties as in the other English districts.

Diet and exercise have probably a more potent agency. A sufficient supply of wholesome food of a sustaining quality, and a daily well-apportioned measure of labour—whether pursued as a means of earning a livelihood or as pleasurable exercise—contribute much more largely to the development and maintenance of a healthy and enduring physique than either climate, or the particular nature of occupation, or personal cleanliness, or race, or the mere abstinence from vice in any shape, except intemperance. To the possession and temperate use of the first of these, and the due performance of the other, is man chiefly indebted for his efficiency as a citizen during the longest period allotted to him to live.

The diet of the English peasant, though generally more simple, is everywhere more substantial and of better quality than is found elsewhere; and this, together with the tonic nature of the atmosphere, which, dense though it be, is always more or less of marine character, even in the most inland situations, and especially so during the prevalence of high winds, which are never long absent, predisposing to vigorous open-air exercise. This is sufficiently exemplified in the nature of the prevailing sports and pastimes, spontaneously adopted, and therefore national, all or most of them being of a kind calculated to strengthen and invigorate the physical tone, and to fortify the system against the assaults of disease.

## REPORTS OF HOSPITAL PRACTICE

IN

## MEDICINE AND SURGERY.

## CASES OF PURPURA AND SCURVY.

PURPURA is frequently ranked amongst cutaneous affections as a distinct disease, but, as Dr. Watson remarks, incorrectly, even in the "loose sense in which that epithet is sometimes applied to affections which are really *beneath* the skin, but visible through it," as,—“the spots are not peculiar to the skin nor to the subcutaneous tissues, but are found occasionally upon all the internal surfaces also, and within the substance of the several viscera.” It is often used to imply “a diseased condition of the blood, whereby it exudes through the textures.” It is a hæmorrhage, and may occur in any part of the body, and is a symptom of many diseases, and of diseases very different. It occurs in small-pox, scarlet fever, typhus, pyæmia, and in the form of splenic disease associated with enlarged lymphatic glands. It is met with, too, in artificial poisoning, as by arsenic, as well as in the so-called blood-poisoning of disease. Still, there is a disease to which the epithet purpura may be applied with convenience, if not with scientific accuracy, although, no doubt, in time it will be more convenient to substitute some name expressive of its cause, or of the conditions of the blood which give rise to it. Dr. Wilks writes—“Purpura is a term denoting a disease in which the cause of the affection is not evident, and therefore we adopt it as denoting a substantive affection, originating probably in the blood itself. The same condition, however, or a similar one, we know may arise from various causes,—as from improper food inducing scurvy; or in fevers of all kinds, when the rashes becomes petechial; in artificial poisoning, as by arsenic, where ecchymoses have been met with on the endocardium and other parts; also in visceral affections, renal, hepatic, or splenic, where a purpura is not uncommon.” Perhaps the condition of the blood which gives rise to the hæmorrhage may be pretty much the same in all these affections. We shall now give the details of several cases, which show most clearly that purpura is often but one symptom in various disorders, and scarcely in itself sufficiently an entity even for nosologists. The case under the care of Dr. Barker, however, is one of those to which it would be difficult to give for the present a better name.

Of purpura in connexion with pyæmia we have in this Journal, July 27, 1861, reported a well-marked instance. The first symptom was purpurous spots, and then glossitis. The lungs and other viscera showed evidences of pyæmia, the starting-point of which was doubtless suppuration of the kidney and bladder from old calculous disease. In reference to this case, Dr. Wilks says, there being no history of scarlatina or other exanthem, we must consider the case as one of pyæmia commencing in the bladder and kidney, the purpura being but a symptom.

In reference to purpura as a symptom of poisoning by certain substances, we may refer to a discussion at the Pathological Society, reported in this Journal January 18, 1862. Dr. Wilks said that in all the cases of poisoning by arsenic which he had examined after death, he had found ecchymosis of the endocardium. Dr. Harley remarked that the poison of the African puff adder produced ecchymosis extensively under the skin, in the muscles, under the periosteum, and, in fact, in nearly every part of the body. We heard Mr. Hulke remark, at the Royal London Ophthalmic Hospital, that he had under his care in the Crimea a man who nearly died from hæmorrhage from a small scratch on the cheek. The patient had salivated himself profusely for some illness or other, and it was to this, and not probably to any permanent “hæmorrhagic diathesis,” that the severe bleeding was due. Although there was no purpura in this case, it is worth noting as an instance of poisoning of the blood allowing of great hæmorrhage on slight mechanical injury. These and other similar facts tend to show that purpura, although it occurs in many diseases, depends probably on some common condition of the blood.

Scurvy is a disease somewhat allied to purpura, but there are important differences, at least clinically. These differences

are well set forth by Dr. Ward in his remarks on the cases under his care, reported at page 373.

As to the direct cause of the local phenomena in scurvy and purpura, it has been shown by Dr. Richardson that a super-alkaline condition of the blood, producing abnormal fluidity, and a tendency in the corpuscles to disintegrate, is present in many diseases, as typhoid fever, and it is possible that to this may be due also the almost universal purpura occurring in some fevers and in pyæmia. He thinks that typhoid symptoms may be set up by the absorption into the blood of poisons generated in the body, as for instance in gangrenous abscesses. In proof, as one link in the chain, he found that in a patient who had fœtid breath from a cavity in the lungs the fœtor was due to sulphide of ammonium, which, by experiment on animals, he found capable of producing symptoms of blood-poisoning. A case of scurvy lately under the care of Dr. Johnson, in King's College Hospital, seems to favour this view. The patient, a woman, who had a cavity in the lung, in spite of good diet, with plenty of vegetables, had purpurous spots. Dr. Johnson “believed that a morbid state of the blood was kept up by the horribly fœtid gases which continually escaped from a cavity in the lungs.” In none of the cases of purpura or scurvy we are about to relate was there any evidence of blood poisoning from so evident a source; but in purpura in pyæmia, to which we have already alluded, it may be on symptoms of an over-alkaline condition of the blood from some form of ammonia, “one of that numerous family of volatile alkaline principles coming from the death of the organic world, of which the common ammonia forms but a type.” (Richardson.)

Dr. Richardson has shown that the fixed alkalies may produce symptoms analogous to those of ammonia. He says “the possible influence of common salt in the production of scurvy is not difficult to understand, when the effect of the chlorides of potassium, sodium, and ammonia in rendering the blood fluid is fully comprehended.”

## GUY'S HOSPITAL.

## CASE OF VARIOLA FATAL ON THE FIFTH DAY, WITH PURPURA AND HÆMATURIA — DIAGNOSIS FROM SCARLATINA AND MEASLES DIFFICULT—CLINICAL REMARKS.

(Under the care of Dr. GULL.)

[Reported by Mr. FREDERICK LONG.]

THIS case caused a good deal of discussion in reference to its diagnosis. The roseola variolosa coming on so soon after the onset of the premonitory fever suggested to the gentleman who first saw her that it was a case of scarlatina. It was not until the beginning of the third day, *i.e.*, Sunday night, that the features began more distinctly to swell, and on Monday at midday there was a difference of opinion as to the character of the rash, it being supposed by some to be a case of rubeola. Dr. Gull, under whose care the case was, declined to give an opinion at this time. From the duration of the premonitory fever, he considered it would be one of variola though the crescentic disposition of the papules and their tint gave rise to some doubt. He took occasion, however, to remark at the bedside, that in such cases the surest ground of diagnosis is from the duration and character of the premonitory fever, before the rash appears. The case, he remarked, was plainly not one of scarlet fever, the hyperæmia of the skin (roseola) being attended in this case by general swelling, giving a rounded character to the features, and a puffy appearance to the face, and he much insisted on this being the distinctive characteristic of roseola preceding the rash of confluent small-pox. It clearly then differs from the scarlatinal rash, as the latter is a simple hyperæmia. The occurrence of the rash in this case at so early a period was contrary to what occurs in measles, the premonitory fever being almost universally at least four days. Dr. Gull also remarked that the occurrence of purpura and hæmaturia more often complicates the onset of small-pox than it does the onset of scarlet fever or measles, and would in itself, in a doubtful case be of value in diagnosis. Nor is there either in measles or scarlet fever a severe aching pain in the loins or the tendency to vomit which usually characterise the premonitory fever of small-pox. These things duly considered, Dr. Gull is of opinion, would lead to a safer diagnosis in a different case than the appearance of the rash. As we have seen, there was an actual difference of opinion as to the rash,

but duration of the premonitory fever is one of the most definite facts in the history of exanthematous fevers.

Elizabeth G., aged 26, admitted March 15, 1863, into the clinical ward, under the care of Dr. Gull. She was a single woman, and had been employed at the bar of a public-house. When a year old was inoculated (sic.) for small-pox, and a large, thick cicatrix was found on the left arm. At the age of ten she had an attack of measles, since which she has had very good health. During the last week or so she has been suffering from a bad cold, but has had no cough; except this, she was perfectly well up to Friday, the 13th, when, in the morning, she had an attack of vomiting, but with this she never complained of any cold or shivering. Towards evening she began to suffer severe aching pains across the loins, which continued all the next day, but she did not keep her bed.

On Saturday, the 14th, her friends just noticed a reddening and a general swelling of her face and arms, and she then complained of a sense of itching over the whole surface. Slight cough came on.

On the 15th, the redness was not more intense, but the cough was a little worse, and the face continued puffy. In the afternoon she was brought to the Hospital, and was taken in as a case of scarlet fever. At night she was seen by Mr. Stocker, who ordered—Pulv. jalap. c. hydr., ℥j.; statim haust. effervescens, 4tis hôris. There was no history of contagion, but in the same house there was "gastric fever."

The reporter of the case continues:—

16th.—At first sight she has the aspect of measles; the face is puffy, and covered with a bright roseolous rash; over the rest of the body an eruption has shown itself to-day. On the hands and fore-arms, which are swollen and of a deep, dull red colour, the epidermis is raised, as if from a number of vesicles in an early stage, some larger than others, and closely aggregated together; but on the chest and abdomen there is a distinct mottled rash, with here and there a few papules and vesicles scattered about; at the lower part of the abdomen, about the groins and upper part of the thighs, the papules are numerous, and at their bases purpura. Lower down the legs, especially by the knees, the eruption is more like that on the chest, and has the crescentic distribution and tint of measles. There is extravasation of blood beneath the conjunctivæ of both eyes, which water slightly. There is a patch of purpura on the lower lip, which is swollen and dry. Tongue soft, moist, and pale; in the centre are three or four ecchymoses raising the papillæ from the surface, and on looking at the fauces, raised spots of purpura are seen scattered over the soft palate, uvula, and tonsils, and the mucous membrane is rather injected. Has a dry, hacking cough, but no expectoration. Feels the throat rather sore. On listening to the heart, a slight systolic bruit is heard over the aortic valves. Urine is high-coloured, from a large admixture of blood; sp. gr. 1018. Pulse 120. Was seen by Dr. Gull for the first time, who refused to give any decided opinion as to the nature of the case, and ordered—℞ Ammon. sesquicarb., gr. iv.; inf. serpentariæ, ℥iss., 4tis hôris.

17th.—Slept last night, and this morning says she feels very well. There is no such nervous prostration as corresponded to the severity of her illness, but she lies on her side, and moves her limbs about quite well, and even got out of bed once with as much strength as if nothing were the matter. No drowsiness, and her voice is quite strong. There is nothing more definite about the face, which is still roseolous; the eyelids are more puffy, and the extravasation is much increased in the left eye, producing almost a state of chemosis. The vesicles on the arms seem rather more distinct, but none show any depression. The mottled eruption on the chest and abdomen is now more papular, and above the left breast is a single vesicle with a well-marked central depression; others can be faintly made out. On the legs the papules are very distinct, and the thighs are thickly covered, and all more or less purpuric at the bases; the summits of some are vesicular; spots of purpura on the lips, which bleed; no headache; cough dry and hacking; the hæmaturia continues profusely; pulse 128, compressible.

18th.—The face continues uniformly puffy and roseolous, without any trace of distinct papular eruption upon it; eyelids more swollen; lips bleed; expectorates a quantity of bloody mucus with the cough. The eruption about the body is still very obscure, though here and there is a vesicle showing a central depression. The surface of the skin is almost universally purpurous, especially about the thighs; on the

roof of the mouth are some vesicles very distinct; urine loaded with blood; no distinct malæna, but the stools are rather of a slate colour, probably due to blood. Takes milk and bitter beer. Pulse 136, weak.

19th.—The face is very much swollen, and blood oozes everywhere from the surface, giving a most frightful appearance; the eyelids are closed and black from extravasation; she is *perfectly sensible*, puts out her tongue, and answers quite clearly when spoken to. There is no stupor, and she does not seem to be sensible of her prostration; lies chiefly on her side. The whole body, especially the legs, are quite purpuric, and have a horrible look; what vesicles can be made out are filled with a bloody serum. Blood is constantly escaping from the vagina, saturating the bed-clothes, but none comes from the rectum; cough easier; tongue flabby, whitish; pulse 140, feeble. As the nurse was holding her up to take some milk and eggs, which she drank greedily, she suddenly fell back dead. A few hours before death the skin over the hands and fore-arms had become white, and had the appearance somewhat of one enormous bleb.

#### DOUBTFUL ERUPTION WITH PURPURA (SMALL-POX?)—HÆMATEMESIS AND MALÆNA—DEATH NEXT DAY.

A boy, 14 years of age, was admitted into Guy's Hospital on December 24. He had pain in the back, and said that he had received a blow on it. He was therefore taken into the Surgical Ward. He appeared to be very ill, and very soon an eruption was observed, somewhat like that of scarlet fever, but there was no marked sore throat. Towards evening the rash became purpuric in character. In the night he vomited blood, and passed some by the bowels. On the following morning, December 25, he died.

*Autopsy Thirty-two Hours After Death.*—The body was that of a boy who had died of acute disease. On the chest and upper part of the body a purpuric or petechial rash was present. The spots were very small, as if corresponding to some rash. The brain was healthy, with the exception of some purpuric spots in parts of the medullary substance. Spots of ecchymosis were present on the surface of the lungs, and a few on the pericardium, and they were observed on various parts of the peritoneum. The stomach was highly congested, or rather of a purple colour, partly from congestion and partly from staining; the stomach also contained some fluid blood. The small intestine was healthy, large, of a dark colour like the stomach, and contained blood. The kidneys were congested, but apparently healthy. The bladder contained a little urine, which was not albuminous.

Dr. Wilks, from whose post-mortem records we extract this case, adds the following remarks:—

This case was involved in obscurity. There was no proof that the blow was a severe one. The boy evidently died of purpura, but whether this was only one symptom, or whether (as in the other case we have detailed) small-pox, was not very evident. Mr. Stocker, who saw him during life, rather inclined to the latter opinion. A few days afterwards a man who lay in the next bed in the ward was seized with small-pox.

#### THE LONDON FEVER HOSPITAL.

##### HÆMORRHAGE INTO THE URINARY PASSAGES, FROM A CASE OF SCARLET FEVER AND PURPURA—DEATH—AUTOPSY.

(Under the care of Dr. MURCHISON.)

JOHN B., aged 19, belonging to the Shoe Brigade, died on January 18, 1863, thirteen hours after his admission into the London Fever Hospital. The patient had been ill four days before he was brought to the Hospital, and the Medical man who saw him pronounced him to be suffering from scarlet fever. On admission there was no sore throat, and the tongue was pale, the papillæ not being enlarged; the whole of the trunk was covered with a dusky purple, slightly elevated eruption, mixed up with numerous petechiæ and purpura spots. There were also numerous purpura spots on the extremities. The pulse was 120, and small. Viscid mucus, stained with blood, run from the mouth, and petechial spots could be seen on the palate. Blood was also passed from the urethra and rectum. Thirteen hours after admission the patient was found dead lying in a pool of blood, which had passed from the bowels and urethra.

At the autopsy blood was found extravasated in almost every organ of the body. The lower part of the ileum and the whole of the large intestine contained a quantity of dark-coloured blood. There were small extravasations in the sub-pleural and sub-peritoneal tissues, and extensive extravasations in the areolar tissue surrounding both kidneys and ureters. The infundibula and calices of both kidneys and both ureters were distended with firmly coagulated blood, and a large coagulum was also found in the bladder. In the submucous tissue of the bladder were numerous extravasations, from the size of a pin's head up to that of a sixpence; some of them considerably elevated above the surface. Similar ecchymoses of a smaller size were seen in the submucous tissue of the ureters and infundibula of the kidneys, but no laceration of the superimposed membrane could anywhere be discovered. The kidneys were large and smooth; the right weighing six ounces, and the left five. The cortical tissue was hypertrophied and pale, and the uriniferous tubes were loaded with epithelium. The left kidney contained a cyst about the size of a cherry, communicating with one of the calices; and a calculus, the size of a hazel-nut, was found in the bladder. With the exception of extravasations, the remaining organs were healthy.

It is worthy of note, in reference to the pathology of purpura, that well-formed red blood corpuscles were found in the extravasated blood.

### ST. THOMAS'S HOSPITAL.

#### PURPURA OCCURRING IN A WOMAN OVERWORKED AND UNDERFED.

(Case under the care of Dr. BARKER.)

ELIZABETH G., aged 35, a married woman, without children, was admitted November 20. She said that she had been ailing for the last two years, during which time she had had cough and general weakness. She said that she had worked very hard, remaining up until one and two o'clock in the morning at washing, and also that she had eaten but very little, on account of her appetite being very bad.

When admitted, she had on the legs, above the ankles, and on the right thigh, a number of spots of a dull red colour, about the size of a millet-seed; some were distinct, others ran together, forming a patch the size of a fourpenny-piece. They were not elevated above the skin, and did not disappear on pressure. There was also effusion of blood into both the upper eyelids. There was swelling and puffiness, much resembling rheumatism, in the right hand and in both elbows, and much pain in these parts. She vomited after taking food or medicine, a light-brown fluid being thrown up. The bowels were costive, the tongue was coated with a thick, creamy fur, and her appetite was very bad. Pulse 65, very feeble.

Dr. Barker ordered her to take:—℞ Quinæ disulph., gr. j; tinct. card. comp. ʒj.; mist. camph. ʒj.; ter. die.

Under this treatment, and a gradually improving diet, together with the quiet and good hygienic arrangements of the hospital, the patient quickly recovered, and was discharged well on December 15.

### SEAMEN'S HOSPITAL, "DREADNOUGHT."

#### CASES OF SCURVY—CLINICAL REMARKS.

(Communicated by Dr. WARD.)

*Scurvy, although extinguished from the Navy, still frequent in the Mercantile Marine—Diagnosis of Scurvy and Purpura—Treatment of Scurvy.*

THE following cases, although not reported at any length, very well illustrate the conditions under which scurvy is developed, its characteristic symptoms, and the features in which it differs from another disease of the blood, in some respects allied to it, namely, purpura:—

Scurvy, for some years extinguished in the navy, save under exceptional and unavoidable circumstances, still occurs, far more frequently than is generally supposed, in the mercantile marine. From seventy to eighty cases are annually admitted on board the *Dreadnought*, and these form but a portion of all that are brought into the port of London. In justice, however, to London shipowners, it must be stated that nearly all the cases admitted into the Hospital have come from ships belonging to owners in the north of England or in Scotland.

The ships have generally come from off long voyages, and have sailed from different ports in India, China, and Australia, badly furnished in regard to essential dietetic arrangements; so that a long continuance upon salt provisions, without vegetables, decomposed or deficient lime-juice, and bad drinking-water, has developed in some or all of the crew that state of nutrition and blood which results in the disease under consideration.

Scurvy has been regarded by some pathologists as identical with purpura, and in all classified arrangements of disease is placed side by side with it; exhibiting in common a tendency to hæmorrhage beneath the skin and from the mucous surfaces. These affections in other respects differ. The hæmorrhagic spots on the skin have a less vivid colour in scurvy than in purpura; the hæmorrhagic tendency in the latter affection being often of an active character, and associated with a plethoric state of system. The swollen, spongy state of gums, the contracted, painful joints, periosteal swellings, and brawny state of the fleshy parts of the lower extremities which characterise scurvy, are wanting in purpura. The aspect also of the sufferer from the former affection tells of a far more damaged state of blood than is met with in the latter. The diseases also differ in their exciting causes, and very often, too, in the appropriate treatment—remedies that give relief in some forms of purpura being such as would prove fatal, or at any rate aggravate the symptoms, in scurvy.

The treatment adopted at the *Dreadnought* for the cure of scurvy consists in the free use of lime-juice, vegetable soups, potatoes, beef, bread, and stimulus where there is much prostration. In severe cases the recumbent position is strictly enjoined, as the principal risk is fatal syncope from suddenly giving the heart more work than it can accomplish. Chlorate of potash is certainly useful for the relief of the gums, but does not seem to have any effect upon the other symptoms. Under the above plan the patients get rapidly and certainly well.

*Case 1.—Scurvy coming on during a Long Voyage from Bad Lime-juice and Bad Water—Great Prostration—Examination of the Blood by the Microscope—Treatment—Recovery.*

John K., aged 22, was admitted into the *Dreadnought*, under the care of Dr. Ward, on October 15. He had just arrived in a Glasgow ship from Singapore, and had been four months and a-half on the passage. Prior to leaving Singapore, he had been under treatment for rheumatism. For the last six weeks he had been suffering from scurvy. The crew had had lime-juice served out once a week, but it was very bad, having the taste of rotten apples. They had been living entirely upon salt provisions, without any vegetables, and the water was very bad.

On admission he presented the following symptoms:—The complexion was very characteristic, being of a uniform pale, earthy, and dusky hue, with clear conjunctivæ and bright expression of eyes. He was much emaciated, and the breath emitted what may be called the scorbutic odour; the right knee was thickened, and somewhat contracted from fibrinous effusion, and there was marked induration of the ankles and calves of both legs. There were also a few hæmorrhagic, purpurous spots scattered over the thighs and legs. The gums were spongy, but not to any marked degree. The following general symptoms were also recorded during the first few days after admission:—Tongue very pale, clean, and smooth; bowels open once daily, with healthy character of stools; urine, specific gravity 1022, slightly acid, free from deposit, and also from albumen, the pulse was weak and compressible, and varied in frequency from 100 to 140; the skin dry during the day, freely perspiring at night; he had but very little sleep, owing to the pain; once or twice there was slight hæmorrhage from the mouth and also per anum.

The treatment of the case was as follows:—On his admission, in consequence of his great prostration, he was ordered an ounce of *mistura vini Gallici* every two hours. Strong beef-tea, milk, and three ounces of lime-juice daily were also ordered, and a mixture of fifteen grains of chlorate of potash in an ounce of decoction of bark, three times a day. When his gums were well enough to enable him to masticate with comfort, he was put upon the ordinary diet of the Hospital, which consists of fresh meat, with vegetable soups, and a fair supply of potatoes and greens.

October 26.—He reports himself as having slept well for the last two or three nights, although last night he had sweated very profusely. His bowels are acting once in the

twenty-four hours, and his urine is free and clear. He is gaining flesh and strength, his complexion is healthier, the fibrinous effusion in the knee and legs is becoming rapidly absorbed, and the hæmorrhagic spots are getting fainter. From this time he continued to improve, and was discharged convalescent on November 7.

The blood was examined under the microscope once or twice soon after the patient's admission, and with the following result:—The red corpuscles cohered together into irregularly-shaped masses; some of the corpuscles had a shrivelled appearance, the others did not fringe by exposure at the edges; the white corpuscles varied in size, and seemed to be more numerous than usual.

The subjects of the following cases, reported by Mr. Leach, belonged to a Liverpool ship, which arrived in the Thames in the early part of January, 1863, having made a passage from Tuticorin and Bombay of 127 days. The meat and other provisions served to the crew were all good of their kind; the lime-juice is said to have been good, regularly given and taken; but, in spite of the facilities for obtaining good water at Bombay, the supply for the passage home was taken from Tuticorin, where the quality of the water is always notoriously bad.

*Cases 2 and 3.—Scurvy occurring from want of Good Water, Provisions and Lime-juice being good—Extreme Prostration—Treatment—Recovery.*

B. Q., aged 19, ordinary seaman, admitted January 3, 1863, under the care of Dr. Ward. He had been confined to his berth during the last thirty-five days of the passage. He was hoisted on to the deck of the *Dreadnought* in a state of extreme prostration, with feeble pulse, anxious aspect, and sunken, hollow eyes. The gums were in some places so much inflamed, and so spongy, as almost to hide the teeth. There were purpurous spots about the anus, thighs, and legs, with much fibrinous deposit about the tendons of, and generally around, the left popliteal space. There were two or three small bed-sores on the back, and the skin over most of the bony prominences was threatening to break. The bowels had been confined for two or three days. He was placed on a water-bed, and ordered lime-juice, strong beef-tea, and six ounces of wine daily, with the following mixture:—℞ Potassæ chloratis, ʒss.; decoct. cinchonæ, ʒj., ter. die.

6th.—The treatment was continued up to this day, with occasional opiates to relieve the pain and restlessness at night. The quantity of wine was now increased to eight ounces, and a diet of beef and potatoes substituted for the beef-tea. There was a great amount of swelling and tenderness in the left groin, which was relieved by hot fomentations and poultices. The bowels also required frequent assistance.

10th.—Still weak, but takes animal food well; the pain and stiffness of joints greatly diminished. Wine increased to 12 oz.

14th.—Placed on full diet to-day with a pint of porter. He continued to convalesce, though slowly, without an untoward symptom, and was allowed to get up on the 24th. He was discharged on February 6, in order that country air might complete the cure.

B. D., able seaman, aged 54, admitted also on January 3, 1863. Was attacked with scurvy seventy-seven days after the commencement of the passage home, but did not give up work for some time after.

*Symptoms on Admission.*—Great general prostration; spongy gums, and hæmorrhagic spots about the lower limbs; complaints of great pain and stiffness in the lower joints. Heart's action feeble. Has had some diarrhœa during the last eight days. His aspect is dusky and anæmic, denoting a damaged condition of blood. Strong beef-tea, lime-juice, and six ounces of wine daily were ordered, and a mixture of bark and chlorate of potash.

4th.—The diarrhœa continuing, five minims of tincture of opium were added to each dose of the mixture.

6th.—From this day he improved quickly; was placed on ordinary, and afterwards on full diet, and was discharged cured on the 20th of the same month.

Both these patients spoke independently as to the good quality of the lime-juice, and both had previously enjoyed good health. In six other cases admitted at about the same time the passages had been long, the quality of the meat, lime-juice, and water was bad, and, with one exception, the patients had come from north country ships.

## ST. BARTHOLOMEW'S HOSPITAL.

### SEVERE CASE OF SCURVY—DEATH—AUTOPSY.

(Under the care of Dr. JEAFFRESON.)

Alfred C., aged 16, a sailor, was admitted April 17, 1862, with purpurous spots on the legs and ankles, with some swelling of the joints, and slight pain and tenderness. His gums were slightly swollen and vascular. Urine, specific gravity 1025, containing a small quantity of albumen. There was a systolic murmur heard all over the cardiac region, loudest at the apex, and heard posteriorly. The second sound was loud. He had been in the Navy since July, 1860, and had been on the sick-list at intervals almost ever since. He had lived on meat and biscuit, but very few vegetables. He could not say when the purpura appeared, but had had several attacks of pain and swelling of his joints. He knew nothing of his family history. He was ordered a tablespoonful of lemon-juice three times a-day, and on April 25 a grain of acetic extract of colchicum every night.

28th.—The pain and swelling of the knees and ankles has increased, the spots remaining as before. There is cough and some mucous expectoration. ℞ Potassa bicarb., gr. xv.; acidi hydrocyanici, dil., mʒj., 6tis horis.

May 5.—Better in every respect. No spots, no swelling of joints; knees painful at night. ℞ Ferri ammon. citrat., gr. v., ter. die.

12th.—He has been up, and the purpura has returned. ℞ Potass. chlorat., gr. xv., ter. die.

From this time he continued much in the same condition, the purpura disappearing when he was in bed and reappearing on his getting up, till August 2, when he was attacked with erysipelas of the face. This passed off, but he had an increase of pain and swelling of limbs, dyspnoea, and extreme exhaustion, and died August 17.

*Autopsy on August 18, by Dr. Andrews.*—Body poorly nourished; lower extremities œdematous; spots of purpura on trunk and limbs. Heart weighed eleven and a-half ounces; right cavities filled with soft, watery fibrinous clots; both greatly dilated. Walls of right ventricle somewhat increased in thickness; walls of left ventricle also somewhat hypertrophied. Mitral valve scarcely, if at all, thickened, but along the free edge of the auricular surface was a dense row of long, filiform vegetations, some as much as an inch in length, projecting into the cavity of the ventricle. The chordæ tendineæ were somewhat matted together and short, the muscular portion of the papillæ coming close up to the valve. Soft globular vegetations were attached to the ventricular aspect of the aortic valves. There were slight patches of atheroma in the first two inches of the aorta. Under the microscope, a few of the fibres showed slight fatty degeneration, but the transverse structure was nowhere entirely lost. Liver: capsule normal, surface mottled with dark red patches; its section was nutmeggy. Kidneys: capsules separate readily, leaving surface smooth, intensely congested, and ecchymosed. On section, cortex much diminished in amount, especially the peripheral portion; slightly granular. Other organs normal.

ROYAL INSTITUTION OF GREAT BRITAIN.—At the General Monthly Meeting, Monday, April 6, 1863, the Rev. J. Barlow, Esq., M.A., F.R.S., Vice-President, in the chair, Levcon Francis Vernon Harcourt, Esq., B.A., William Harvey, Esq., F.R.C.S.L., Joseph Norman Lockyer, Esq., F.R.A.S., Paul Julius Reuter, Esq., Octavius Sturges, Esq., Frederick Thompson, Esq., and Robert Wigram, Esq., were elected Members of the Royal Institution. Colonel Dickens, Abraham Pope, Esq., John R. Russell, M.D., and John Rivington, Esq., were admitted Members of the Royal Institution. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

POISONING BALLET-DANCERS.—A few days since the dancers in a new *ballet* performed at Hamburg, who represented the water-nymphs, were clothed in a green costume. These dresses first nearly cost the lives of those who made them, and then of the girls who wore them. So large was the quantity of arsenic contained in the fabric, that some of the dancers fell ill, and others exhibited unequivocal signs of poisoning even during the representation.

SATURDAY, APRIL 11.

BROMWICH v. WATERS.

It has been our duty on many occasions of late to comment on actions brought against Medical men accused of misconduct with female patients. In such actions, the naked testimony of any woman whatever may cause (as Mr. Baron Bramwell observed of the case of Bromwich v. Waters), a Physician, a married man, the father of grown-up children, to be put on trial, and to have his character, position, fortune, nay, even his very life dependent on his being able to rebut by accidental and indirect testimony facts directly and positively sworn to by the complainant. The whole features, statements, details, and complexion of such cases cannot, then, be too closely scrutinised by the Medical journalist. In another column will be found an abridged report of the trial from the notes of a Professional gentleman who was in court the whole time. Here we will offer a commentary on the facts, and on the conduct and testimony of the chief persons concerned, in doing which we would record our admiration at the conduct of Mr. Baron Bramwell, whose charge to the jury consisted of the most lucid and unmistakeable vindication of the defendant, and through whose firmness and good sense it was that the jury were prevented from yielding to the weakness and mental confusion of one of their number, and so frustrating justice by being discharged without giving a verdict.

Of the plaintiff, Miss Bromwich, we are willing to agree with the judge in believing that she brought the action under a firm conviction of the innocence of her servant, although she fully deserved the censure which his Lordship passed upon her for her levity and unfairness in allowing her servant's illegitimate child to be baptised in Dr. Waters' name.

Yet there is a singularity in the circumstance that a middle-aged lady, living in a country town, whose counsel remarked that she was of no great means, and that the expenses of a lawsuit must be seriously inconvenient to her,—to say nothing of the worry and turmoil,—should think of going to the enormous expense of such an action as this. It would interest us all very much if all the motives and advice, legal and otherwise, which prompted a step so momentous could be fully known and analysed.

As for the girl Whalley, her whole statement bears, to our eyes, distinct internal evidence of the entire innocence of Dr. Waters. There were, to begin with, symptoms of uterine irritation, followed by very decided hysteria. It is the misfortune of our Profession, in cases like the present, that the jury neither can know beforehand nor be taught adequately, how much of physical and moral aberration may be involved in that simple term hysteria. According to her own statement, Dr. Waters used her coarsely and indecently when he first examined her; often made use of disgusting expressions,

and once exposed himself indecently; and yet for all this, she never complained to any one, but continued her visits to his house without the protection of any other woman as a companion and witness. Moreover, as the judge said, during all the twelve months during which these alleged occurrences took place

“Nothing happened—they did not hear of his taking liberties with her, even according to her own testimony; and he would again remark that if Dr. Waters was desirous of getting possession of her person, how strange it was for him to recommend her to have a husband, which would diminish his own chances. If he had got his trousers open at one time, it was remarkable that they heard of no blandishments—no kissing, no feeling of other parts of her person, as her bosom, or her throat, or doing anything to excite her passions. On the other hand, Mr. Serjeant Shee had replied that if her story were false, she would have said he had done these things. But this created a greater difficulty for the plaintiff. If he had made such indecent overtures, as a decent woman she ought never to have gone again—she ought to have told her mistress. On the contrary, she did go from time to time. Was it not a strange thing that, if the defendant began this course, and persevered in it for a year, that she could only impute to him one single act of indelicacy—his trousers being open; and two or three trivial remarks, such as ‘You want a husband;’ ‘Supposing I were your husband.’ From that they were asked to infer that he wanted to debauch her. But it was very curious that, during the whole of that time, he, to use a vulgar expression, never ‘tried it on.’”

At last, as she swore, on Saturday, November 9, she arrived at his house faint and ill; she took from his hands a glass of some liquid like wine, immediately after which she became insensible, continued so for two or three hours, and woke up, finding herself sick upon the hearth-rug in a different room, and with an obscure recollection that part of her dress had been opened. She went home in a cab. From this day she dates her pregnancy. As the learned judge well put it:—

“The woman's statement was this, ‘I never had connexion with any man, or had anything done to me which could by any possibility have made me the mother of that child, except when I was in a state of insensibility in company with the defendant; therefore he must be the father.’ This statement, it was obvious, depended entirely upon the woman's own oath. The charge was substantially one of rape; and it had been said by learned judges who lived long ago, that if there was one charge more easy to make and more difficult to refute than another it was that of rape. Most crimes left a trace behind them; if a murder had been committed, there was the dead body; if a forgery, there was the document and the man who swore it was not his handwriting; if a sheep had been stolen, it would be found elsewhere. There would be a physical indication of a wrong done. But not so in a case of rape. In such a case the man's guilt or innocence depended solely upon the inclination of the woman's mind, which could leave no trace behind. Those remarks applied with more force to the present case, because in it there was insensibility.”

There are just two circumstances, and no more, to corroborate Mary Whalley's statement. She had been insensible before, therefore might be again; and her whole conduct, up to the time of her delivery, seemed that of an innocent woman,—courting examination, and apparently quite unconscious of her situation. But in every substantial point which admitted of contradiction her statements were negatived by many independent witnesses; and we call especial attention to these points:—

1. There is the moral contradiction involved in her account of Dr. Waters' indecent conduct, and in her continuing to visit him.
2. She swore that the alleged outrage took place on November 9. It was proved by the oaths of four witnesses that it could not have been on the 9th, but that it must have been on November 30.
3. She swore that she received the wine from the hands of Dr. Waters; that she immediately became insensible; and that

she was wakened up between two and three hours afterwards in another room. On the contrary, Dr. Waters' servants swore that they gave her the wine; that she went into the other room before she had the wine, and that she was not insensible. As the learned judge put it—

“According to Whalley's account, she went into the study on the day she went there, and the Doctor at once gave her a glass of wine; stupefaction immediately followed, and continued two hours, and when she came to herself she was in another room. The interview being identified by the cab, it was immaterial for this purpose whether it occurred on the 9th or the 30th of November, because both the servants contradicted her as to this. They stated that it was not true that she was insensible in the study; it was not true she continued insensible for two hours; and they had sworn that she was in the little room sitting on a chair before the fire, and that she was in a sensible and coherent condition the whole of the time. This was a contradiction which did not depend on the day. Were it the 9th, or the 30th, or any Saturday, it was not true that she had the wine in the study, or that she was unconscious two hours, because she remained in the little room with her shawl and bonnet on in a state of perfect sensibility, and conversing.

4. She swore to her own good conduct and integrity. At least three if not four witness swore to acts of indecent familiarity with men, and Dr. Waters swore that she was not a virgin.

5. She was delivered of a child—which the plaintiff's counsel admitted to be “full-grown”—on July 26, 1862. According to the plaintiff's case, which dates her “insensibility” on November 9, this full-grown child was born on the 259th day after impregnation; but according to the irrefragable testimony of half-a-dozen independent witnesses, which dates the alleged occurrence on the 30th, it was on the 238th day. A statement which the learned Judge called a “clumsy invention.”

In the next place we will turn to Dr. Waters, the defendant. It is, we believe, indisputable that he is a Physician of unblemished character and great scientific attainments, a grey-headed man, the father of a large family. Baron Bramwell said:—

“Dr. Waters was a married man, and had arrived at a tolerably sedate time of life. But an old judge had said, ‘There is no wisdom below the girdle,’ and he would quote from an old author, who had truthfully said, ‘A man will leave an angel's feast to prey on garbage.’ But they would hope it was not common. In the box they had had the defendant's oath—that would carry the case very little further, but they had seen the demeanour of both parties, which they must judge of. Mr. Welsby had said that the woman's conduct in the box had displayed a want of modesty, and an extraordinary acquaintance with Medical terms. On the other hand, there was no fault found by Mr. Serjeant Shee with the manner in which Dr. Waters gave his evidence, and it was a trying thing for a man thus to undergo the cross-examination of Mr. Serjeant Shee, for if a man had any untruth in him it must come out. If they thought Dr. Waters had stood that cross-examination well, it was very much in his favour. . . . If Mary Whalley had been a particularly inviting person, one could have easily understood that the defendant might have fallen a prey to her attractions. If he were a generally lascivious man, he might have caught at the opportunity. But was she an attractive person? They had seen her in the box, and they were to judge of that. Her complaint, too, would be anything but stimulating to a man who had to deal with her in the way the defendant had. Then the Doctor had never been charged with such an offence as this before, and up to this time, as acknowledged by Mr. Serjeant Shee, his reputation had been unimpugned. He had conducted himself as a gentleman of education, and had occupied an honourable position in Society.”

Passing on from the probabilities of the case, we would next call attention to the utter absence of all proof that Dr. Waters was alone with the complainant at all on the day of the alleged outrage; and to the positive testimony of two of the servants, that they saw the complainant frequently during the time she was in Dr. Waters' house; that she was

not insensible; that he was busily occupied in selling a pony, and could not have been alone with her, unless they had observed it. Really, there never was a case less supported and more contradicted by positive evidence.

But, as honest commentators, we are next bound to inquire, for the instruction and warning of our brethren,—supposing there was no misconduct,—were there any indiscretions, any want of prudence in Dr. Waters that could have laid him open to this charge? Alas! yes. He was guilty of giving gratuitous advice; of attempting not merely to relieve the bodily illness of a poor wretch, but also of sparing her feelings, of admitting her to his house, and giving her the privileges of a private patient, without fee or reward. Verily, here is a warning to any one against similar offences, unless he has a cool thousand at his banker's to conduct a defence against an action on an hysteric patient.

Dr. Waters deposed that the patient on one occasion behaved to him with offensive familiarity. It is to be regretted that, after this, he allowed her to repeat her visits.

But he may be open to the charge of imprudence, or of mistaken practice in using the speculum at all. On this point, generally, we re-echo the sentiments of the best members of our Profession when we reaffirm the statements made by our Reviewer in another column as to the possible abuse of that instrument. But, as it is there laid down, no Medical attendant is justified in neglecting to ascertain the state of the uterus in any case of obstinate illness, even though of clearly hysteric origin, provided that the health is seriously compromised; and if there be local disease, the Physician must determine whether there be just grounds for local treatment. Moreover, there is just one point which makes all the difference. Was Mary Whalley a maid? If, as Dr. Waters has sworn, she were not, all the moral and sentimental objections to local treatment are withdrawn, and Dr. Waters may fairly rely, as Dr. Ferguson so well puts it, on his character, position, and scientific attainments to justify his treatment in the eyes of society and of the Profession. We have the best private information that Dr. Waters is not a “speculum man,” and not given to the over-use of that instrument in his practice.

This brings us to the last part of the case, in which we shall consider the conduct of the three Professional witnesses, Drs. Lee, Ramsbotham, and Taylor. We take the liberty of referring to articles in the *Medical Times and Gazette* for 1862; vol. i., on the case of *Rich v. Pierpoint*, in which it is shown that the attendance of witnesses to give *opinions* is quite voluntary, and that they may refuse if they please; and in which we denounce that most monstrous and uncharitable doctrine, that because A. and B. may differ in treatment, therefore A. is justified in coming into a court of justice and swearing that B.'s treatment is wrong. We again point to the emphatic *dictum* of Justice Erle, that it is “a pity that one Medical man should be ready to come forward and condemn the treatment of a brother in the Profession, and say that *they* would have done *this* or *that*, when probably, had they been in a position to judge of the case from the first, they would have done no better.” Every man who does so is putting a rod into the hands of the public by which himself may be scourged.

As for Dr. Taylor's evidence, it was to the indisputable fact that impregnation may take place during unconsciousness. This was no injury to Dr. Waters; whilst, in repudiating the notion that any poison could have produced sudden unconsciousness followed by sudden recovery at the end of three hours, Dr. Taylor's evidence was on the side of truth and justice.

Drs. Lee and Ramsbotham (if we are rightly advised) were compelled to attend, because they had to depose to matters of fact, viz., to the state in which they found the cervix uteri of Mary Whalley when they examined her in the early part of 1863. They deserve great credit also for having strongly

advised the plaintiff's attorneys against bringing the action into court. But, for all this, Dr. Waters' friends complain most bitterly of their presence in court, and affirm that their evidence on a matter of *opinion* and not of *fact* was of material service to the plaintiff; we are therefore compelled to see what that evidence was, what its drift was, and how far it was justified.

The *fact* was that Mary Whalley was examined by these gentlemen in January (Dr. Lee said that he was two hours so engaged on her cervix uteri!), and that no mark of *ciatrix* could be discovered. A very simple matter of fact. But see the momentous chain of inferences! If there were no *ciatrix*, it is pretended that there was never an ulcer. Dr. Lee is reported to have deposed that no ulceration had ever existed at all; and Dr. Ramsbotham, that had there been an ulcer there would have been a *ciatrix*. Therefore it is argued the use of the speculum and caustic was unnecessary and wrong; and from this the further inference would be drawn by the plaintiff's counsel, that the use was merely colourable, prompted by base motives, viz., in order to indulge in filthy propensities, and give the defendant the opportunity of gratifying his base lusts.

As to the possible existence of "superficial ulceration," or excoriation, which may be benefited by nitrate of silver, and heal without a scar, we believe that most of our readers will not question it. They will therefore question the right of Drs. Lee and Ramsbotham to give such a dictum as we have ascribed to them.

In the next place, they may refer to Dr. Lee's own book, published in 1853, and there see the identical treatment advised; and they likewise will see from Dr. Ramsbotham's evidence a vindication of the same practice, under certain circumstances.

The whole Profession agrees that there are cases in which the "speculum and caustic" are justified, and others in which they are not. We claim for Dr. Waters the right to judge to which class Mary Whalley's case belonged. We do not say whether he was right or wrong, but we affirm that mistaken practice, on a point where opinions differ, is not to be visited as a crime. Baron Bramwell said:—

"But was it made out that the treatment was improper? They had had Medical evidence in favour of the plaintiff's case. There was Dr. Lee, who was not altogether a satisfactory witness, although, doubtless, a very learned man. There was Dr. Ramsbotham, who gave his evidence in a very satisfactory manner, and who also expressed his opinion that the treatment was improper. There was Dr. Taylor, to whom the learned Judge paid a very high compliment, who would scarcely express an opinion on that part of the case, and in fact declined to say whether the treatment was proper or not, he having no practice as an accoucheur. Against their testimony, they had on the other side Dr. Simpson, of whom Mr. Serjeant Shee had spoken in the most eulogistic terms, and who no doubt was one of the most eminent men in the world in that department of his profession; Dr. Keiller, who gave his evidence in a most satisfactory manner; also, they had had called before them Mr. Brittain and Dr. Fyfe—all four gentlemen of position and intelligence—who had told them that the treatment exercised by Dr. Waters was not improper, but, on the contrary, was perfectly correct. One observation on this point might be fairly made; that these four gentlemen would have done precisely the same thing as Dr. Waters had done, under the same circumstances; that is to say, they would have treated the case in the same way. *They might have been wrong, but it would only amount to a mistake*, and Dr. Waters might merely have fallen into the same Medical error, and in that case his improper treatment would be no assistance to the plaintiff's case. And here it might fairly be said that the recommendation of a husband had turned out to be a correct prophecy."

In conclusion, we can only say that we heartily regret the evidence given by Drs. Lee and Ramsbotham. We would speak of neither without the sincerest respect; we would faintly believe that they can represent themselves as misled, or drawn in against their will, but justice to our whole Pro-

fessional brethren—any one of whom may be the victim of an ungrateful and unprincipled patient—forces us to say that we wish, before consenting to attend as witnesses, they had put themselves in the defendant's position, and imagined the long and fearful agony of such a lawsuit.

#### ARMY MEDICAL DEPARTMENT.

THE authorities now find themselves very much in the position of the uninitiated who took the Magician's Wand and found it easy enough to raise up spirits, but impossible to manage or dispel them afterwards.

At the time of the appearance of the Warrant of 1858 the Medical Department was contented! Now the case is altered, and we do not think this new Warrant likely to dispel the cloud of discontent which a more judicious and honest course a few years ago would have prevented altogether. (a)

It is all very well for the Secretary for War—knowing little and caring less about the Department—to usher in this Warrant with the promising words "that it would satisfy all parties."

The Profession may congratulate itself that the authorities have been forced into conceding something. A Surgeon will henceforth take his relative rank, and the advantages attending it, according to the date of his commission. We cannot believe, however, that all the recommendations of the late commission are embodied in this concession, or that it will prove sufficient to attract the promised redundancy of candidates. No earlier retirement has been granted, nor any means taken to ensure a more reasonable rate of promotion, or to overcome the dead-lock at present existing.

The candidate for a Medical appointment in Her Majesty's army will still find himself an Assistant-Surgeon until he attains his step in rank as Surgeon Major; and this very long service in a subordinate position will be still further increased by his being placed upon half-pay whenever he may be invalided from a foreign station.

However, the official hook has been supplied with a tentative bait, and we shall see whether it takes!

The Department can scarcely be blamed for having learned the lessons taught them by the Horse Guards; it is quite possible that something in the shape of a confidential Circular may have emanated to interpret the meaning and nullify the effect of the present meagre concessions.

We still hold that further and more radical changes are required in the Department before the best men can be tempted to enter it.

Military authorities and journalists alike seem to ignore the fact that Medical Science and the Medical Profession are quite different from what they were a few years ago. The course of education has been widely extended, and rendered far more expensive than formerly, and a student of the present day will do well to calculate what prospects and remuneration the service offers him in return.

For our part, we advise him yet to hesitate before he commits himself for life to the tender mercies of Government officials.

#### THE WEEK.

##### MEDICAL PROVIDENT ASSOCIATION.

WE wish to call special attention to a letter from Mr. R. B. Carter, of Stroud, Gloucestershire, which we publish in another part of the journal. The subject of the letter is the establishment of a Medical Provident Society, to provide support for its members during sickness. If such an Association be formed and supported by the whole mass of the profession, the wealthy who may not be likely ever to require its aid, as well as those of seantier means, it must be a source of

(a) The loss to the service by the resignation of its best men is lamentable. We had to regret the resignation of Dr. Frank, and now we hear Mr. Buckland retires!!

incalculable good. We would suggest that a Mutual Protection Fund, to secure Medical men against the ruinous expenses of unjust lawsuits incurred in the practice of their profession, should be included in the scheme.

THE SECOND CHATHAM TRAGEDY.

THAT great crimes occur in clusters has been often observed. Our forefathers accounted for moral epidemics by planetary, or other occult but all-pervading influence. We ascribe them to imitation, an instinct shared by man with the brutes which approach him nearest, and most powerful in man when the higher faculties of reason and volition which distinguish him from those brutes are least educated and exercised. The second horrible child murder which has taken place at Chatham is clearly an imitation of the first. A soldier, of previously good character, and mild, inoffensive disposition, because he is piqued by a reprimand from a sergeant, makes up his mind to "get rid of the world." But his wife, with whom he has lived on the best terms, in case of his death, would have to provide for their child. He therefore kills the child with the intention of being hanged himself. Without expressing any opinion on the case before it has been tried, we may state that the morbid train of thought thus indulged by a man of previously good character strongly suggests insanity. And this probability of insanity is supported first by the fact that the man's brother committed suicide by hanging, and that the murderer appears to have been labouring under a dominant idea that a similar fate awaited him; and secondly, by the circumstance that after a total abstinence for six months he had drunk freely during the week before the murder. We do hope, in the interests of humanity, that Alfred Holden's mental condition will be carefully investigated by a Physician of acknowledged skill in mental affections before his case is submitted to a jury.

WEISS v. MACKENZIE.

THIS was an action by the plaintiff, a Medical agent in London, to recover commission upon the introduction of the defendant as a partner to Mr. Margetson, a Surgeon, practising in George-street, Hanover-square. The plaintiff had been employed by Mr. Margetson to find him a partner, and Mr. Margetson had already paid him commission; but the plaintiff claimed to be entitled, under the terms of his printed circular—which he said he had shown and explained to the defendant—to receive commission from the defendant also. The defendant, on the other hand, stated that he never employed the plaintiff to find him a partner, and only called at his office in consequence of seeing the plaintiff's advertisement of the partnership in the *Lancet*, and denied that he ever saw the plaintiff's circular until the plaintiff sent one to him after the partnership had been completed. The jury found their verdict for the defendant. In this case the defendant was fortunate enough to avoid being saddled with any alleged contract between him and the plaintiff. We have reason to believe that it is often otherwise. The agents, knowing that they have no chance of recovering against a person who never employed them, no doubt endeavour if possible to get both parties on their books before they bring the arrangement to a conclusion. It is probably not uncommon to issue an advertisement on behalf of an imaginary party, for the sake of getting the names of persons seeking such an opening as that held out, and then obtaining, as it were, retainers from them, in order, when the occasion offers, to pocket a commission for introducing them to what they desire. The frequency of such actions shows that it is advisable either to abstain altogether from answering agents' advertisements, or to guard in every way against what might be construed into taking the agent into employ, or contracting to remunerate him if that be not the intention of the applicant.

REPORT OF THE TRIAL, BROMWICH v. WATERS.

(From a Correspondent.)

A CAUSE was tried at Chester last week, occupying the whole of Thursday and Friday, before Baron Bramwell, not only of the greatest possible importance to the highly respectable Physician whose character was arraigned, but also to every individual member of the Medical Profession—Bromwich v. Waters. It was ostensibly to assess damages for loss of service, but it really implicated the honour and Professional conduct of the gentleman we have named. The charge against him was as follows:—The plaintiff, Caroline Bromwich, is an elderly maiden lady, who with her sister, also a maiden lady, near her own age, reside at Boughton, in Chester. They had a servant, Mary Whalley, now 28 years old, who had been in their service fifteen or sixteen years, who had nursed both themselves and a brother in his last illness, in whom they implicitly relied, and to whom they were deeply attached. Dr. Waters had attended their brother, and occasionally themselves; and Mary Whalley applied to him for advice, at the suggestion of the plaintiff, in February, 1860, for vomiting, and other symptoms of gastric derangement. Getting no better, she was taken by her mistress to Llandudno, and thence to the Isle of Man, and returned to Boughton in July, 1860. Being still ill, she again applied to Dr. Waters, who saw her in bed at her mistress's house, recommended her to go into the Infirmary, where she would be under his care; and, on her evincing great repugnance to do so, told her she might come to see him at his own house, for which he would charge her nothing, as the expense of medicines would be as much as she could afford. She used always to go to him on a Saturday. On the first Saturday in December, 1860, he made a vaginal examination, told her she had ulcers in the womb, and on the second Saturday applied lunar caustic, and this he continued to do at intervals of a week or fortnight, according to her account, for more than a year; according to his, five or six times, certainly not ten. In April, 1861, her mistress took her to the Isle of Man again, where she became the subject of aggravated hysteria. In August she again saw Dr. Waters at his own house, having often seen him at her mistress's during the summer, as he was attending Miss E. Bromwich under illness. No examination by the speculum was made in her mistress's house; but, on her resuming her visits to him, he began again to apply the caustic, and continued to do so until Saturday, November 9, 1861. On that day, according to her account, she walked to Dr. Waters' house, rather more than a mile, having been very ill all the morning, and taken nothing all day but one cup of tea. On seeing her so faint when she arrived, he gave her a glass of wine, almost immediately after drinking which she became insensible, remained so for more than two hours, and was unconscious to everything until between five and six o'clock, when she "was awoke by the Doctor," lying in another room, and found she had been sick over the hearth-rug. He got a cab for her, and she went home in it. After this he saw her at her mistress's once or twice, and two or three times at his own house, but did not use the speculum. Her menses had appeared regularly until November, 1861, after which they ceased. The last appearance having been the last week in October, and one or two days in November. On April 2 her mistress took her to Malvern, having previously consulted Dr. Waters as to how she should treat her, and whether she should call in Medical advice there. This latter he dissuaded her from doing, saying it would be of no use. At this time Whalley's person began to enlarge, and according to her account, Dr. Waters, after an examination of the abdomen, told her her liver was enlarged, that she must take wormwood tea, walk up the Malvern Hills as much as she could, and that she would be better when her menstruation returned.

On May 22, Dr. Gully, of Malvern, was consulted, and pronounced the case one of tumour of the womb. The patient went through all the formula of the water treatment, and on July 26, after evidently a good many hours' suffering from labour-pains, a boy was born. It was acknowledged on all hands that the girl conducted herself as though she had no idea she was pregnant, nor that the pains were those of labour until after the child's birth. Dr. Gully was sent for when she was under expulsive pains; his assistant, Dr. Badgley,

came, but the child was born before his arrival. She alleged that she must have been taken advantage of by Dr. Waters, while she was insensible at his house for more than two hours on November 9. She did not charge Dr. Waters with any other indecent conduct, except once, when she being on her back, and he striding across the lower end of the couch on which she lay, while the speculum was being used, a knock was heard at the study door; she then hastily removed the handkerchief with which she was accustomed to cover her face while under examination, and saw his trousers unbuttoned, and his shirt protruding. He turned from her, adjusted his dress, and opened the door, and another time when he pressed heavily upon her while making his examination. But she swore to his having made use of the following expressions at different times:—"There are only two things to be done, either I must apply caustic, or you must have a husband." "You want something doing to you." "You want a husband; now how should I do for your husband?" "You have a beautiful colour, and if you could see yourself in a glass, you would think yourself fit to be a bride." She also swore that he requested her not to tell her mistress he had used caustic, "as that was a Surgeon's business." All this, as might be supposed, was denied by the defendant, Dr. Waters, except that he recommended to her marriage, which he acknowledged, as well as telling the same to Miss Bromwich, her mistress, and that he did do this Miss Bromwich corroborates.

To sustain her story, Miss Bromwich was called, but she could only of course speak to the girl's general state of health, the journeys undertaken, and dates.

Dr. Badgley pronounced the child well developed.

Dr. Robert Lee had examined her most carefully with the speculum twice, and found the uterus perfectly healthy; he could detect no signs of previous ulceration, which must be evident had ulceration ever existed; he thought the speculum had been grossly abused.

Cross-examined by Mr. Welsby: The speculum has been very largely employed in exploring diseases of the uterus all over the world.

Mr. Welsby: Would the use of the speculum be proper in inflammation of the uterus?—Witness: I don't understand you.

Mr. Welsby: Inflammation of the orifice of the uterus?—Witness: I don't understand that.

Mr. Welsby: Do you understand by it irritation of the uterus?—Witness: That is a term with no meaning. (Laughter.)

Mr. Welsby: Do you understand by it superficial ulceration?—Witness: No, I do not.

Mr. Welsby (holding up a book): Are you the author of "Clinical Reports of Ovarian and Uterine Diseases?"—Witness: Yes.

Mr. Welsby read an extract from this volume, which stated that the speculum in exploration of diseases of the uterus was much employed on the continent. (a)

The witness said he had published two books. There was another publication.

Mr. Welsby: Do not the words inflammation of the orifice convey to your mind any specific idea?—Witness: No; very different.

(a) Extract from Dr. R. Lee on "Ovarian and Uterine Diseases." Churchill. 1853.

"An examination of the physical condition of the uterus in unmarried women, either with or without the speculum, I have always refused to make, even when requested to do so, unless pain, severe, and almost constant, in the region of the uterus, existed; leucorrhœa or hæmorrhage which did not yield to treatment; and where the symptoms did not make me strongly suspect the presence of some displacement or organic disease. In unmarried women, whatever their rank or condition in life may be, the integrity of their structure should not be destroyed with the speculum, nor their modesty wounded by an examination of any kind, without a necessity for such a proceeding being clearly shown. Even in married women it is unjustifiable, on the grounds of propriety and morality, to institute an examination of any sort unless the symptoms warrant the supposition that the uterus is displaced, or is in a morbid condition, the nature of which cannot be determined by the symptoms alone."—P. 135.

"The os uteri, . . . and its red, swollen, hypertrophied granular state, often indicates morbid conditions of the constitution of the glands, mucous membrane, and walls of the uterus, on the nature, diagnosis, and treatment of which little or no information is derived from the use of the speculum. In these cases I have known leeches, scarifications, caustic, and the speculum employed upon a great scale; and sometimes, I admit, (if the reports of patients are always to be trusted to) with apparent temporary relief. Gently rubbing the os uteri with lunar caustic through the speculum, a few times at long intervals, has appeared to effect all the good which such local treatment can accomplish."—P. 137.

N.B.—The italics are our own.—Ed.

Mr. Welsby: What information do you wish to convey to the Profession, that in cases of inflammation of the orifice it is important to use the speculum?—Witness: It is an expression of opinion generally received on the Continent, and if you ask my opinion at the present moment, I will tell you that ulceration is very rarely met with. That book was written a long time ago.

Mr. Welsby: In 1853. Am I to understand that it is unintelligible from the fact that it was written ten years ago? How old are you now?—Witness: I am ten years older than I was then. (Laughter.)

Mr. Welsby: What is your age?—Witness: You would have some difficulty in finding it out. (Renewed laughter.)

Mr. Welsby: Would I. I ask you again, how old are you?—Witness: I don't know.

Mr. Welsby: You won't tell me?—Witness: I cannot tell you.

Mr. Welsby: How long is it since you began your studies?—Witness: My whole life has been devoted to it.

Mr. Welsby: How do you know that? This is not a farce we are now acting, nor a comedy. Just tell me honestly, like a gentleman, how long you are experienced in these diseases.—Witness: These diseases have occupied my attention since I was a student in Edinburgh.

Mr. Welsby: In what year?—Witness: Twenty years ago I studied everything that could be found in Edinburgh.

Mr. Welsby: When did your practice begin?—Witness: I studied on the continent for four years.

Mr. Welsby: In what year did you begin to practise? Why do you not give me a direct answer?—Witness: I was two years with Prince Woronzoff in Russia, when I returned to London, and I have not got a holiday since 1827.

Mr. Welsby: You have got one now, at all events.—Witness: I am bound to say that I have not known an idle hour in my life; and if I am ignorant it is not my fault.

Dr. Ramsbotham had examined her with the finger and the speculum on February 6 last. The uterus was then perfectly healthy, there was no cicatrix at the os uteri, which there would have been had there ever been present an ulcer that had destroyed the substance of the uterus extensively; but if the ulcer had been merely superficial, only destroying the mucous membrane, no trace might be left at such a distance of time, because that membrane possesses such restorative powers in itself, that all marks of previous ulceration on it alone are soon effaced. To require so many applications of caustic for so long a time would generally imply that the substance of the mouth and neck was deeply implicated, because the superficial ulceration mostly gives way to six or eight applications at the farthest; but this superficial ulceration has a great tendency to recur, so that a return of the complaint may require a return to the caustic, and thus the same kind of treatment off and on may be necessary for many months. The speculum is most extensively used in this country and all over the world. He himself never uses it in the case of an unmarried woman of good character, unless it has previously been employed by another Practitioner in the same case. From the description Whalley gave of the attack she had on November 9, 1861, he should call it cataleptic hysteria, or hysterical coma. Very distinguished authors both in England, France, and Germany, have expressed their conviction that a woman might be impregnated while in a state of insensibility, and he was of the same opinion. He thought if attacks of hysteria such as Whalley experienced could be distinctly referred to the use of the speculum or the application of caustic, that the application should be discontinued as soon as they appeared. Patients with ulcerated os uteri are generally separated from their husbands while under treatment. The recommendation of marriage in hysteria, where no ulceration exists, would be proper, inasmuch as connubial intercourse often cures hysterical complaints.

Dr. Alfred Swayne Taylor knew that caustic was applied to the os uteri by Physicians as well as Surgeons, and it could not be considered wholly a Surgeon's business. He agreed with Dr. Ramsbotham respecting the character of the attacks to which Whalley became subject, and his remarks about marriage in cases of hysteria. He knew of no drug which would produce perfect insensibility immediately it was swallowed, and continue to affect the person in the same way for two or three hours, its effects after that time passing off. Any drug with such power would produce death.

Dr. Waters, as above said, denied using such expressions as were attributed to him; denied his trousers were ever un-

buttoned in Whalley's presence; was sure from the first examination he made that she was not a virgin; had certainly not used the caustic more than ten times; considered the girl of a lascivious temperament; and on the first occasion of his seeing her at his own house, she put her arms round him when he was examining with his ear the action of the heart, and drew him towards her in a caressing manner. He then told her that was wrong, he had a family, and nothing improper must take place between them. This she was called afterwards to refute.

Besides Dr. Waters' denial, the defence was based upon two circumstances,—the first, that the day on which Whalley got a glass of wine and was sick was not November 9, but the 30th, on which day the Doctor, though at home, could not have been with her for many minutes together, because he was selling a pony in the paddock at some distance from the house; the second, that the girl was of a disreputable character, used to talk about her sweethearts, etc., and was often seen kissing a certain Joe Smith, and other men.

Joe Smith was called, and swore he never kissed her except once, ten years ago, and that was for a wager.

One of her fellow-servants, indeed, deposed to her very often having seen her straddling with her legs across a boy who was kept in the house, of 14 years old, while he was sitting in a chair, so that her naked legs could be seen, and he had his breeches down at the same time. This always happened in the kitchen, and at dinner time. She never told her mistress of the misconduct.

Mr. Serjeant Shee, however, drew out of this witness that she had a great hatred to Mary Whalley.

The boy was examined, who swore it was false.

Mr. Brittain, Dr. Fyfe, and Professor Simpson, of Edinburgh, all concurred that the treatment pursued by Dr. Waters was correct; and Dr. Simpson told the court that a child born three weeks before its time would not be fully developed.

The jury, after six hours' deliberation, found a verdict for the defendant. This announcement was received outside the Court with tremendous cheering.

On the next day, Saturday, an action for slander was brought by Dr. Waters against Miss Bromwich. The plaintiff's case having been proved, it was proposed by the defendant that a juror should be withdrawn, upon which his Lordship remarked, "This case was most satisfactorily investigated yesterday, and if I were the plaintiff's counsel I certainly would not permit him to consent to the withdrawal of a juror." A verdict (by consent) was then taken for the plaintiff, damages 40s. and costs. His Lordship remarked, "I think it is most correct for the defendant to express her satisfaction with the jury's decision yesterday, in which I most heartily and entirely concur."

In another action against a Mrs. Arthur Potts, a juror was withdrawn.

For the honour of the Profession, as well as for his sake, we rejoice that this trial has resulted in the acquittal of Dr. Waters, but we sincerely wish the advice given early in the case by Dr. Robert Lee, but especially by Dr. Ramsbotham, that it should be withdrawn, and not allowed to proceed, had been taken; much scandal would have been avoided, and a degree of perhaps very natural, but certainly unseemly, excitement in which the city of Chester and its neighbourhood have been kept for many weeks, would have been prevented.

We must say, however, that nothing could have been fairer or more temperate than the speech of Mr. Serjeant Shee (who was specially retained for the plaintiff), and that the evidence of both Dr. Ramsbotham and Dr. Taylor told for, rather than against, the defendant, which, indeed, the plaintiff's counsel and solicitor knew well they would do long before they were put into the witness-box.

\*.\* The Editor of the *Chester Courant* writes:—

"It will be seen from the above trials that the jury in the seduction case were unanimous. The delay in giving the verdict arose from the fact, that originally there was one dissentient. Eleven of the jury were in favour of the defendant (Dr. Waters) five minutes after the judge had concluded summing up. It is the privilege of an English jury that each should be satisfied and agree. But we may safely say that in this case the verdict has given unmixed satisfaction in this city; and we heartily congratulate the Doctor on the result. With respect to the verdict for 40s., in the action brought by Dr. Waters against Miss Bromwich for slander, in conse-

quence of an intimation from the judge that "the verdict in the seduction case had his hearty and entire concurrence," the counsel of Dr. Waters stated that his client had no wish to be vindictive—the object was not to extort money, but the clearance and vindication of reputation, and these would be sufficiently attained by a consent-verdict for the above amount."

## REVIEWS.

*A Handbook of Uterine Therapeutics.* By EDWARD JOHN TILT, Member of the Royal College of Physicians, etc. London: Churchill and Sons. 1863. Pp. 309.

THE sexual organs of women are liable to two classes of maladies, which, though they may be mingled in certain cases, yet are in most instances very distinct one from the other. One class is that of the structural—the changes to which the womb is prone in common with every other part of the body—inflammation from cold, gout, rheumatism, and the like, morbid growths, as cancer, hypertrophy, and the like. The other class consists of certain changes determined by aberrations in those passions, emotions, sensations, and functions, which distinguish woman, as a sexual being, endowed with the desire and the aptitude for maternity, from a creature passionless and sexless, as a child, an old woman, or a eunuch would be. Periodic congestion of the womb and ovaries, even turgidity, and bursting of blood-vessels, rupture of vesicles, and exfoliation of membranes, are parts of the very life of woman, during thirty years and more, by virtue of her sex. Any influence whatever which tells unfavourably on mind or body, even hereditary diseases, blood tainted by gout or rheumatism, debility, unwholesome occupations, depressing passions, and, above all, that unsettled condition of mind and body which arises from a latent consciousness of fitness for maternity, when the conditions for it are denied, are of necessity attended with changes in the distribution of blood to the sexual organs, and may transform the natural processes into nearly allied morbid ones. Abnormal states of nervous and vascular supply are followed by pains, discharges, engorgements, irritability, superficial abrasions, perhaps some infiltration or hypertrophy, or by ulceration.

That such maladies should be difficult or tedious in their cure, is no more than must happen from the circumstances which give rise to them, which usually are of long and deep growth, and often impossible to remove by any means whatever. Maladies of the first class, that is to say such as spring from the wear and tear of life, such as the enlarged and suppurating womb of the woman who rises too soon after parturition or miscarriage, should doubtless be treated just as maladies of an analogous sort when situated elsewhere. As an ulcerated cornea is touched with nitrate of silver, and as a suppurating conjunctiva or congested retina may be treated by astringent washes, citrine ointment, cupping, belladonna, and the like, according to the nature of the case, so should analogous uterine maladies be treated by leeches, nitrate of silver, injections, and the like. But not so those maladies which have their source in mental or sexual disturbance. For, in the first place, they are like Proteus—they have no fixed form nor local habitation. That which is believed to be abrasion or engorgement of the "uterine neck" in January, becomes endometritis, or ovaritis, or pelviperitonitis in June; and, secondly, when the alleged local condition is removed, the whole mass of symptoms may be aggravated, or may crop up in another totally different and worse form. But further, the use of local remedies is not only utterly unable to reach the main source of the illness, but is, in itself—if used in the wrong set of cases—a poison of the worst kind to the mind and body of the unfortunate victim. We cannot too strongly advise our readers, especially the younger part of them, to study Dr. Ferguson's introductory essay on "Irritable Uterus," in his edition of Gooch on "Diseases of Women," published by the New Sydenham Society. They will find this physician—a man of the greatest attainments and of the widest experience amongst that class of patients who are most strongly disposed to hysteric, uterine, and nervous diseases—affirming that "in this malady of the irritable uterus, the greatest amount of benefit is attained from general, and the greatest risk of mischief incurred from topical, treatment." Dr. Ferguson shows how the passion of

fear, and especially the desire of sympathy, induces women to be dissatisfied with any "but such modes of cure as they think are commensurate with the magnitude of their malady, and worthy of the spirit of martyrdom within them, which makes the most heroic measures the most welcomed." They therefore urge on the Physician to the use of remedies which his inner soul disapproves, but which he consents to adopt lest his patient should be tired of waiting, and go to some more "active" practitioner. It is impossible not to gather from Dr. Ferguson's remarks the conclusion that *local* remedies—that is, the speculum and caustic—have been frightfully abused in the case of single women. For our own parts, we do not hesitate to say that the abuse of such measures in such patients has been the crying sin of the age, and that we have little to boast of in having abolished the custom of draining patients of their blood, and in that improved diagnosis which enables us to distinguish organic disease from that which simulates it, if we have introduced or sanctioned a plan of treatment both cruel and immoral, and calculated to exasperate or perpetuate the worst of the patient's morbid conditions.

Let us not be understood as condemning *all* local treatment in *all* hysteric cases. As organic disease is no bar to hysteria, so may a disease of hysteric or sexual-sensitive origin be complicated with organic changes which require local treatment. *If general health be giving way*, no Physician who treats an hysteric-uterine case can be absolved from the necessity of ascertaining the absence of serious organic disease, which, if found, must be treated according to discretion. If the practitioner believe that the local disease is one which will not get well with merely general treatment, and that the whole case will be benefited if the local malady be removed, he will put to himself the question, whether he should resort to the particular treatment were the patient his own daughter or sister. "The answer," to use the emphatic words of Dr. Ferguson, "must be left to each man to make before his own conscience, and to justify to society by his scientific attainments."

We have been wandering away from Dr. Tilt's book, which has thus set us thinking on paper. He says, "that for many years he has sought to determine the real value of those various modes of treating inflammatory affections of the womb that have been more or less exclusively advocated by eminent Practitioners during the last fifty years." (Or in another place, p. 3), "In the present work my principal object is to discuss the many ways of treating the various forms of uterine inflammation." "It would be singularly incorrect to suppose" (he continues), "that most diseases of women originate in inflammation of the neck of the womb; but besides the fact that many do, it must be borne in mind that the neck of the womb is its only accessible portion, and that the application of remedies to the cervix is often the best way of curing inflammation of the body of the womb and of the ovaries." On which programme of Dr. Tilt's the reasonable commentary is, and it is one which recurs to the mind on reading the whole of the book, that this "inflammation" of the womb is nowhere defined. Be it remembered, that the term "inflammation" of the womb, *per se*, is one of the most indefinite in existence. It may be applied to a state which will kill in six hours, or to one which may get well in an hour on the receipt of good news. It may be anything or nothing—a state in which leeches or marriage may be a remedy. "I have seen women," says Dr. Tilt, "so suffering from chronic uterine inflammation that I should have been very sorry to have sanctioned their marriage, yet who certainly improved by it. I have under my care," continues Dr. Tilt, "a patient who suffers severely from *ovaritis* and *internal chronic metritis*, and the neck of the womb is *soft, swollen, and exquisitely sensitive to the finger*, nevertheless she has no pain on connexion; it does not make her worse, and in fact relieves many of her distressing nervous symptoms. Another lady suffered much from *hystericalgia* on the loss of her husband; *everything* was tried without success," till, after some years, another husband cured her, *tuto, cito, jucundè*. The italics in the passages quoted are our own, and we insert them with a view of showing, that whereas, on the ordinary principles of Medicine—as Dr. Tilt himself says just before—you might as well let a man with a broken leg walk, as let a woman with inflamed womb have connexion; yet that in some "chronic affections of the neck of the womb" in patients of "*strong temperament*" and those "*subject to hysteria*," it is "rather beneficial than otherwise!"

We have not a doubt of it; but we should demur to calling such cases "inflammatory," or even speaking of them in the same category with cases which require leeches, speculum, caustic, and all the other implements of the sort, humane and necessary in the right cases, cruel and disgusting in the wrong ones. Pray let us ask what does Dr. Tilt include under the term "everything," in the case of the poor woman who lost her husband and suffered "hystericalgia" till she married again? Was all the uterine artillery employed against her?

If a proof were wanted of the possible confusion that may exist of the organic with the hysterical form of uterine malady, even in the mind of so able and industrious a writer, and one so habituated to the consideration of them as Dr. Tilt, we might adduce the following passage. Dr. Tilt says, and no one will deny the truth of it, page 270:—

"When the body of the womb is inflamed, connexion is very painful."

Here we have a *dictum*, short, precise, incontrovertible, like an aphorism of Hippocrates, or one of the laws of whist.

But the author goes on to say, "when connexion is not painful"—What? Why of course the womb can't be inflamed, is the irresistible conclusion! Alas for logic, Dr. Tilt says, "when connexion is not painful it is rather beneficial than otherwise!" and he is "much less particular" in restricting it than he was when he began practice! Well, there is such a thing as living and learning; and we may learn, as well as Dr. Tilt, that a good many cases which have been considered as "inflammation," were not inflammation, in any real sense of the word, but were instances of that state, call it what you will, for which marriage is a remedy.

If our time permitted we could show from Dr. Tilt how pregnancy cures what he calls "those little-understood conditions of the ovaries to which I have drawn attention, as ovarian irritability and subacute ovaritis." A curious hallucination of Dr. Tilt's, if he imagines that the existence of this ill-understood condition was discovered by himself, although we do not wish to give him the credit of the name "ovaritis," which we affirm to be mistaken and mischievous. Hypertrophy, too, chronic inflammation, and some displacements, are cured by the same magical remedy.

The great defect of Dr. Tilt's book is, as we have said, the confounding together, or the want of distinction between, the two great classes of uterine maladies which we have pointed out, and the sanction which it gives to "local," that is, speculum treatment and caustic to the neck of the womb for these "ill-understood conditions," which have been, by the most grievous abuse of words, called inflammatory "ovaritis," etc. What would be safe in Dr. Tilt's own hands, might be misunderstood or abused by others.

Dr. Tilt does repudiate many local remedies, such as the intra-uterine pessary, which have much better claims to respect than the everlasting caustic, but still the great fault of the book is the exaggeration of local treatment, and want of caution against its misapplication. But it is fair to say that there is a large amount of useful information scattered throughout the book, available for those cases in which local treatment is useful, and that we thoroughly believe in Dr. Tilt's good faith. The very passages we have quoted as examples of inconsequent reasoning and inconsistent statements, are proofs of the writer's sincerity. All details respecting injections, suppositories, incisions and dilatations (on which the author looks with no favour), pessaries, leeches, diet, etc., are here to be found in abundance.

We must say that, in one respect, Dr. Tilt is like a careless player, and shows too much of his hand. He instructs the young Practitioner to "listen to his patient with eyes bent down, or seemingly bent down, to all she may say." But we would rather advise the young Practitioner to be natural, and be a gentleman, and never to resort to any such histrionic dodges.

*On Diseases of the Chest, including Diseases of the Heart and Great Vessels: their Pathology, Physical Diagnosis, Symptoms, and Treatment.* By HENRY W. FULLER, M.D. Cantab., Fellow of the Royal College of Physicians, London, Physician to St. George's Hospital, etc. Demy 8vo. Pp. 763. Price 12s. 6d. London: Churchill and Sons. 1862.

THE great bulk of this volume, and the didactic dryness of the author's style, may possibly scare away lazy and dilet-

tante readers, but it will nevertheless be welcomed by the Profession as a good sound text-book on diseases of the chest, satisfying every real want of the student and of the practitioner. It is by no means a mere compilation of what others have written. Both in form and in matter every portion bears traces of originality. While availing himself freely of the labours of his predecessors and contemporaries, Dr. Fuller does not fail to contribute rich fruits of his own observation and matured experience. He has evidently mastered every portion of his subject for himself, and is able to make his statements, not at second-hand, but as an independent and weighty authority. An adequate summary of the contents of this most excellent book is impossible in the space at our command. We can merely notice a few of its more important and characteristic features.

A considerable portion of the work (over 200 pages) is explanatory of the general principles of physical diagnosis, and their application to the investigation of diseases: 1. Of the lungs; 2. Of the heart and great vessels. Those who are commencing the study of auscultation, as well as advanced students who are aspiring to its greater niceties, will here find real and welcome assistance. Its principles are set forth in plain, unmystified language, so as to be intelligible to the most ordinary capacity. In his explanation of the mechanism and true significance of ægophony and a few other abnormal sounds, Dr. Fuller does not hold with the generally received opinion. Wherever this is the case, the grounds of his dissent are fully stated. Interspersed with the text are some capital tables, showing at a glance the different sounds audible in the lungs in health and disease, their character, mode of production, usual seat, and also the forms of disease with which the morbid varieties are usually associated. This last is a point on which Dr. Fuller lays great stress. It is by endeavouring, he says, to interpret auscultatory sounds without reference to the morbid condition and consequent altered mechanism in which they take their origin, that students "so often find themselves bewildered and ready to discard the stethoscope, as, to them at least, a hopeless mystery."

To facilitate the diagnosis of the different diseases of the lungs, Dr. Fuller adopts the excellent plan of placing the morbid anatomy and corresponding physical signs of the several stages of each disease in parallel columns. The following partial extract will give an idea of the nature and value of such an arrangement (p. 253):—

*"Chronic and Passive Œdema.*

*"Morbid Anatomy.*

"Lung of a pale greyish colour; collapses slowly and imperfectly; is inelastic, doughy, pits readily on pressure, and scarcely crepitates on being handled. On section, a large quantity of almost colourless serum, unmixed, or nearly so, with air, oozes from the surface; the lung tissue is tough and resistant, and portions of it sink instantly in water without being previously subjected to pressure. The lining membrane of the bronchi is often of a dark, livid colour, consequent on chronic vascular congestion."

*"Physical Signs.*

"Inspection affords no information.

"Palpation is said sometimes to disclose increased vocal fremitus. This has not been the result of my experience.

"Percussion sound duller than natural, and parietal resistance increased. Skoda speaks of a tympanitic sound on percussion, but I have never met with it.

"Auscultation. — Respiration weak, or almost absent, or else harsh and coarse, and accompanied by bubbling râles, according to the precise degree of infiltration of the portion of lung auscultated. If, as often happens, bronchitis co-exists, sonorous and sibilant rhonchi will be heard."

The same method (of tabular juxtaposition) is adopted to contrast the salient diagnostic features of diseases liable to be confused, as, for instance, pleuritic effusion and pneumonic consolidation, bronchitis and incipient phthisis. The tables are well constructed, and much enhance the usefulness of the book.

Dr. Fuller's account of the various diseases of the lungs and heart will be found quite up to the level of the most recent researches. The several varieties and complications (as well as the ordinary typical form) of each disease receive full consideration. Disputed questions are impartially weighed, and the reasons for his own conclusions thereon definitely stated. On certain points his opinions are more or less at variance

with those ordinarily entertained in the Profession, and, we are bound to add, have very weighty evidence adduced in their support. Some of these we will very briefly notice.

He disbelieves that exposure to cold has that agency in the causation of pleurisy which is generally attributed to it. "Cold," he says, "however intense, and however applied, will not produce pleurisy in a healthy person; and when exposure to cold is followed by inflammation of the pleura, the disease is due to some morbid condition of the blood, and not merely to cold. . . . Cold is a mere accessory cause of the disease; a predisposing or exciting, but not the proximate or essential cause. . . . Experience has long since proved that a tuberculous, scrofulous, or cancerous diathesis, and the cachectic condition of the blood which results from Bright's Disease of the kidneys, intemperate habits, syphilis, pyæmia, gout and rheumatism, are amongst the more active provocatives of pleurisy, and equally so of serous inflammations, and that we should at once suspect and search for one of these when called to a case of pleurisy in which 'cold' is the only apparent cause of the attack."—Pp. 177-8.

He is at variance with the opinion so generally entertained that warm climates are preventive and arrestive of phthisis, and that cold ones have the contrary effect. The consideration of certain facts of every-day life, and the results of recent statistical inquiry, have satisfied him that "not only is cold not productive of phthisis, but that in many instances it invigorates the animal economy, and thus proves antagonistic to the accession and subsequent progress of the disease. And, if this be so, it follows that, in certain instances at all events, warmth must not only enervate the patient, and thus expose him to an attack of phthisis, but, when the disorder is once developed, must have a prejudicial effect on its progress."—P. 418. Dr. Fuller's remarks on the influence of climate in phthisis are most valuable. In a very few pages—discarding theory and making facts alone the basis of inference—he gives all that is really known on the subject in the present state of medical science.

He maintains that permanent recovery from pulmonary consumption, provided the disease be not hereditary but merely the result of temporarily impaired nutrition and deterioration of the blood, is not only possible, but, in a considerable proportion of cases, a matter of actual occurrence. We wish we had space for a summary of his arguments in support of this opinion. We must refer our readers to pages 403-412 of his book, in which he endeavours to show that so cheery a prognosis of this gloomy malady is not only consistent with *a priori* considerations, but further justified by the facts of clinical observation and pathological research.

The latter part of the work is devoted to diseases of the heart and great vessels. The account of these is full, at the same time simplified to the utmost, and thoroughly practical. The remarks on the prognosis of the various forms of disease of the heart, on its dilatation, fatty degeneration, and functional derangement, and on the means of distinguishing symptoms of functional derangement from those of organic disease, will be appreciated by those who have felt the difficulties of this class of diseases. The commonly received views of the action of digitalis he holds to be "utterly inconsistent with fact." He appeals to experiments and observation in proof that "digitalis stimulates the muscular fibre of the heart and augments the contractility of the capillaries. When it kills, it does so not by producing paralysis of the heart, but by giving rise to tonic contraction and spasm of that organ. Such being the case, it is a most valuable remedy in the treatment of dilatation, and is dangerous only when administered in hypertrophy. Whenever the pulse is feeble and irregular, and more especially when from any cause its feebleness and irritability are temporarily increased, digitalis is, of all known remedies, the most useful."—P. 592.

In discussing the treatment of chest diseases, Dr. Fuller makes no mention of remedies which experience has proved to be valueless, and contents himself with pointing out those particular methods of treatment "which have appeared to him most successful and based upon the soundest physiological principles." In this he has certainly acted wisely; but we think it would have been better in several cases if his methods of treatment had been a little more detailed. Well-approved formulæ of medicines, available for the treatment of different diseases, might with advantage have been given either in the text, at the foot of the page, or in an appendix.

The book has an index and an analytical table of contents, but it wants yet more facilities for casual reference. In long

chapters, as, for instance, that on Pulmonary Consumption, there should have been running titles, or else such slight change either of type or textual arrangement as would indicate at a glance the particular portion of the subject under discussion.

*Klimatographische Uebersicht Der Erde: Climatographical Survey of the Globe.* By A. MÜHRY, M.D. Leipzig and Heidelberg. 1862. 8vo, pp. 744.

Dr. MÜHRY speaks of climatology as a science of modern origin and of youthful attainments, nevertheless as a science of warm and lofty aspirations. This is not the first-fruit of the author's laborious investigations into the subject of which he treats. In 1856, he published his "Nosogeography," and in 1860 appeared his "Investigations into the Influence exerted by the Elements of Climate upon the Sanitary Condition of different Countries." The former consists of two parts, the one explanatory of Medical geography, the other comprising a general description of the climatology of the several regions of the earth. The latter also is divided into two distinct parts, in the first of which is given a treatise upon general, in the second one upon special climatology. Besides these, other works of considerable interest have proceeded from the pen of the author now before us.

The present volume may be regarded perhaps as a third part of the author's scheme, being in its general character similar to its predecessors, but containing information of a more diversified nature concerning the climate and statistics of our own and foreign countries. The author does not profess to comprehend every place in his volume, but such only as are of chief interest to Europeans; and concerning these he does not confine his observations to bare climatological facts, but supplies also such other information as may be of service in a Medical, agricultural, or commercial point of view, thus rendering his work valuable alike to the emigrant and colonist, to the missionary and the commercial traveller, as well as to the health or pleasure seeker.

The body of the work is divided into five larger and upwards of twenty smaller sections. The first larger section—the torrid zone—comprises descriptions of the Andes and their vicinity, the east coast of South America, the West Indies, and those portions of Africa which occupy the corresponding parallels of latitude, India and its Archipelago, Australia, and the South Sea Islands. The second section—the north temperate zone—comprises middle and southern Europe, northern Africa, and mid-Asia. The third section—the south temperate zone—comprehends the southern portions of South America and Africa, Southern Australia, and New Zealand. The fourth section—the North Polar zone—comprises the Arctic portions of America, Europe, and Asia. The fifth section—the South Polar zone—completes the survey, by a glance over the seas of Antarctic regions. The volume concludes with an appendix, which is also divided into five parts. The first of these contains a description of the meteorology of the North Polar zone, with its bearing upon the wind-systems; the second relates to the influence of the trade-winds; the third to some peculiarities in the meteorology of the South Polar zone; the fourth to the description of an atmometer; and the fifth to the principal ocean currents. Lastly, there is a short supplement consisting of a paragraph upon monsoons; one upon the vital statistics of Sweden; a third concerning peculiarities in the summer of 1861, bearing upon the same subject as the second part of the appendix; and finally, a few remarks upon the distribution of rain.

In a work of this kind it would be impossible for the author to exhaust the subject at any point, since it is quite obvious that a single country would of itself have afforded ample materials, not for one only, but for several volumes. Dr. Mühry tells us that he collected his notes originally for his own use, and not for publication; and that he was led into the latter procedure from a desire to put others in possession of knowledge which he found to be so useful to himself, and, moreover, with the view of encouraging the pursuit of cognate researches. To follow the author through his descriptions is beyond our space. In some instances we think perhaps more recent information might have been made available to the reader, and in others we should have been glad of information upon matters of practical utility which are passed over in silence. But the limits of the volume are too narrow to permit of much extension into detail, and we owe our thanks to Dr. Mühry for the instruction which his work contains. It

is a book which cannot fail to be of use to all who are interested in the climatic characteristics of foreign countries, and one which, especially they who contemplate a sojourn abroad, would find it greatly to their interest to consult. The previous volumes, to which we have adverted, were dedicated respectively to Baron Humboldt and Sir John Herschel; the dedication of the present volume is equally graceful on the one part as it is well merited on the other; it is made to Sir James Clark, whom the author mentions as one of the founders and supporters of the science of climatology.

*Memoir of the Life and Writings of Robert Whytt, M.D., Professor of Medicine in the University of Edinburgh from 1747 to 1766.* By WILLIAM SELLER, M.D., F.R.S.E. Pp. 33.

Dr. Whytt was born in Edinburgh in 1714, studied general literature at the University of St. Andrew's, attended Medical lectures at the Medical school of the University of Edinburgh, under Monro and others, thence proceeded to London, about 1734, and became the pupil of Cheselden, and afterwards went to Paris, where he attended the lectures and dissections of Winslow. He next repaired to Leyden to hear Boerhaave, who was then very old, and Albinus (the Latinized name for White or Weiss), who was in the prime of life; and, after six years employed in the study of Medicine, he took the degree of M.D. at the University of Rheims, which seems to have been much frequented in the eighteenth century for Medical degrees, but which was suppressed altogether at the first French Revolution. The same degree was conferred upon him by the University of St. Andrew's, and he afterwards joined the Royal College of Physicians of Edinburgh, and entered into practice, in which it appears he was very successful. He published a considerable number of papers on scientific subjects, and, among other minor controversies of the period, he entered into one with the illustrious Haller, on the "Nature of the Contractility of Muscular Fibre," Unzer and Prochaska ranging themselves on the side of Whytt. In 1747, Whytt was appointed Professor of Medicine in the University of Edinburgh; in 1752, he was elected a Fellow of the Royal Society of London, to the *Transactions* of which he contributed several papers; in 1761, he was made first Physician to the King in Scotland; and, in 1763, he was elected President of the Royal College of Physicians of Edinburgh, which office he retained until his death, which took place in 1766.

The claims of Dr. Whytt as a great pioneer to the discovery of physiological truths, if not a great discoverer himself, are too little regarded in the present day; and Dr. Sellar deserves credit for rescuing his name and his works from the neglect into which both have rather unjustly fallen. One of his earliest essays was a paper on the "Virtues of Lime-Water in the Cure of Stone," the attention of the public as well as the Profession being much attracted to this subject in the middle of the last century by the great success of a secret remedy for calculous disorders invented by a Mrs. Stephens, who received a grant of £5000 from Parliament for the discovery. It appears that the ingredients were chiefly egg-shell powder and soap, the latter, from containing an alkali, being, in all probability, the real solvent of the calculus, especially when it consisted of lithic acid. Whytt, however, thought that the lime was the solvent, though he always gave it in practice combined with soap, and, in some experiments on the solution of calculi out of the body, he hit upon the real nature of the chemical action, for he put some grains of a calculus (consisting, no doubt, of uric acid) into a mixture of carbonate of potash and quicklime, and he actually explained the results, foreshadowing the more accurate and brilliant discoveries of Scheele, who first described uric acid, and of Black, the discoverer of carbonic acid. But still more important in their nature and in their effects on Medical science were the other papers of Whytt, particularly his "Essay on the Vital and other Involuntary Motions of Animals," published in 1751, his "Inquiry into the Causes which Promote the Circulation of the Blood in the very Small Vessels of Animals," his "Observations on the Sensibility and Irritability of the Parts of Men and other Animals," and his "Account of some Experiments Made with Opium on Living and Dying Animals." The three latter papers all bore upon the question of his controversy with Haller, who maintained that muscular fibre owed its property of contraction to a power inherent in itself, while Whytt attributed it to an influence derived from the nerves. Whytt also maintained that the circulation in the

capillaries was due to the action or oscillation of the small arteries, and not to disturbances of the blood itself, as was argued by the humoral pathologists of the day, nor exclusively to the action of the heart. Whytt's views on the nervous system are generally supposed to be founded upon, if not identical with those of Stahl, but such is not the case, for, instead of the soul, or anima, or archeus of Stahl, Whytt supposes the nerves to have properties and powers independent of the mind or thinking principle, and, in fact, he may be considered as agreeing with those, who, like Unzer and Prochaska, paved the way for the full development of the theory of reflex action, by which Marshall Hall has placed himself among the first ranks of modern physiological discoverers. The sum of Whytt's doctrine on this subject is, that an impression conveyed by nerves to the central nervous organs excites involuntary animal movements by a physiological necessity, without reason, intention, or consciousness; and we agree with Dr. Sellar in thinking that these views contain the nucleus of the modern theory of reflex action in the spinal cord and brain.

This brief memoir of Dr. Whytt's life and writings will amply repay perusal.

*Familiar Letters on the Diseases of Children.* Addressed to a Young Practitioner. By JAMES BOWER HARRISON, M.D. London: Churchill and Sons. 1862.

IN itself an inoffensive, innocent little book; a well-watered reproduction of the ordinary practical teaching in children's diseases. For Medical men we do not see its use, for, unless unusually ignorant, they know all that it contains, and, if not, they have already the information within reach in a hundred different forms. To mammas and nurses, for whom, from its popular style, we suppose it principally written, it offers a proverbially dangerous thing—a little knowledge.

## FOREIGN CORRESPONDENCE.

### ITALY.

FLORENCE, March 5.

THE Italian universities are indebted to the late minister of public instruction, Professor Matteucci, for two valuable acquisitions from Germany—that of Professor Moleschott for Turin, and that of Professor Schiff for Florence. The exchange may be advantageous to both countries; not only could Germany spare some of her physiologists while Italy stood sorely in need of them, but the undue and unduly fostered predilection with which physiology is cultivated by the German student is far from being favourable to his clinical training, while the comparative indifference with which this gigantic (though only nascent) science has hitherto been treated on this side of the Alps, was of course still more objectionable than the German excess of zeal. Florence has no University, nor, strictly speaking, a Medical faculty, but it has much of the auxiliary apparatus for the student of Medicine. It has three *cliniques*, a botanical garden, and the celebrated museum for natural history, and it is in this last named establishment, that Professor Schiff delivers his lectures on Physiology. Should they continue to be as numerous attended as hitherto, it may be hoped that the Italian taste for physiological researches will soon rise to a healthy level, and propagate itself over the rest of the Peninsula.

Independently of these lectures, Professor Schiff continues his interesting researches on the "Function and Distribution of the Vascular and Calorific Nerves," and he has quite recently published a paper on the "Influence of Reflex Action on the Vaso-motor Nerves," which adds new and somewhat unexpected results to those of his former experiments published last autumn. For the reader's convenience, I will endeavour to recapitulate the latter, before mentioning the new additions contained in Professor Schiff's last pamphlet. For the details concerning the vivisections themselves, I must refer the readers to the September numbers of the *Comptes Rendus* of the French Academy. The results may be briefly summed up as follows:—

The vaso-motor fibres, *i.e.*, the fibres whose section or paralysis produces dilatation, and whose irritation produces contraction of the corresponding blood-vessels, have their origin

neither in the ganglia nor in the spinal cord, but in the *medulla oblongata* itself. Nor can their origin be higher, since lesions of the pons Varolii do not disturb the state of vascularisation in any part of the body. Only the vaso-motor nerves of the abdominal viscera can be physiologically (not anatomically) traced as high up as the *thalami optici*. Part of the fibres originating in the *medulla oblongata* remain, throughout their course on the same side, while others cross over to the other side. The crossing seems to take place (at least in the lower half of the spine) close to the level of the anterior spinal root, with which, and through which, the vaso-motor nerve leaves the cord. Hence, Professor Schiff assumes two distinct systems of vaso-motor fibres, the one consisting of one-sided fibres, the other of crossing fibres. The former go to the face, the hand, and the foot, and the lower third of either extremity; the latter (the crossing fibres) go to the upper two-thirds of the leg and arm, and also to the integuments of the thorax and the abdomen. The former leave the cord together with the anterior roots of the fifth, sixth, seventh cervical, and first dorsal above, and of the four lower lumbar and the sacral pairs below. They thus enter into the brachial and lumbo-sacral plexuses respectively, and join the great nervous trunks of both extremities. The crossing fibres, issuing from the spine by the anterior roots of the second, third, fourth, fifth, and sixth dorsal pairs above, and of the last three dorsal ones and first lumbar pair below, spread partly over the thoracic and abdominal integuments, partly on the parietes of the blood-vessels of the arm and leg respectively, but they reach these vessels straightways, only joining on their way the axillæ and pelvic plexuses, but not the chief nervous trunks of the extremities. Hence, a lateral section of the cord just above the roots of the sacro-lumbar plexuses would produce an increase of heat in the foot and lower third of the leg of the *same* side; and a lateral section just above the tenth dorsal vertebra would produce the same effect as the former section (*viz.*, increase of temperature in the foot and ankle of the same side), *plus* an increased vascularisation of the thigh and knee of the opposite side. A lateral section of the *medulla oblongata* would produce vascularisation the facial half in the hand and foot of the same, and in the humerus, thigh, and abdominal integuments of the opposite side, etc.

These results were published soon after Mons. Claude Bernard's beautiful experiments on the sub-maxillary ganglion, showing that this ganglion, as long as its sympathetic root is intact, can become the centre of reflex actions between the tongue and the sub-maxillary gland, after its connexion with the brain has been destroyed by the section of both the lingual nerve and the *corda tympani*. While Prof. Schiff's results have greatly reduced the importance of the sympathetic nerve, by showing that it is a compound nerve, containing motor, sensitive, and vaso-motor fibres, and giving origin to none, not even to the vaso-motor ones, yet there is nothing in them that would militate against M. Bernard's conclusions, who vindicates for the ganglia the honour of being real, though only auxiliary, central organs for reflex actions.

If we add to all this Budge's discovery of the cilio-spinal region (more justly called oculo-pupillaris by Bernard) and the more recent discovery of the direct connexion of the heart with the four upper thoracic ganglia (a), it would appear as if every province of the nervous system had been searched and explored, and as if this branch of physiology had attained something like completeness. Yet, how much still remains to be done, and how many phenomena to be explained, may be seen by Mons. Collins' late experiments on the sensibility of the blood-vessels, and still more by the experiment which forms the subject of Prof. Schiff's recent publication.

Prof. Schiff found that slight tickling caused the central artery in a rabbit's external ear to dilate, and this dilatation was prompt, very considerable, and strictly confined to that part of the artery which had been touched by the tickling finger (through the integuments, of course, which are exceedingly thin in that part of a rabbit's ear). Above and below this region the calibre of the artery remained unchanged. The section of the cervical sympathetic (on the same side) and the extirpation of the first cervical ganglion altered nothing in these phenomena. But when all the sensitive nerves of the ear were cut, the tickling had no further effect on the vessel, which, however, could be caused to dilate again, when friction was used instead of tickling; while, lastly,

(a) See *Medical Times and Gazette* for 1862, October 4, p. 365.

the opposite effect, or contraction, took place on further increasing this friction.

One is almost bewildered by these apparently contradictory phenomena. We see, in the first place, that the dilatation is a really active one, not preceded by any contraction, so that it cannot be explained by some passive relaxation after previous over-action. Nor can this dilatation be the mechanical effect of an increased afflux of blood, which would swell the calibre of the artery more uniformly and far beyond the part touched by the finger. The phenomenon being independent of the sympathetic, but depending entirely on the sensitive nerves, may therefore be explained either by a reflex action propagated by yet unknown ways and means, or else, according to Professor Schiff himself, by the idio-muscular action of the circular fibres of the muscular coat of the artery. Such an action being proper to all muscles, even when they are separated from their motor nerves, or from the living body altogether, it would not be wrong, even *à priori*, to attribute the same force to the muscular fibres encircling the arteries. Moreover, the alternation of the two opposite effects of dilatation and contraction, after the application of the same irritation in different degrees, may be seen in a prepared muscle as perfectly and as regularly as in the circular fibres of the rabbit's auricular artery in Professor Schiff's interesting experiment.

It is evident that pathology must sooner or later be benefited by these researches. The phenomena of congestion, erection, inflammation, and fever, as well as those of aneurism and other diseases of the vascular system, will be traced to their proper causes. And we may fairly expect some indirect advantages even to therapeutics. Professor Schiff, in one of his former publications, points out the curious fact, that the regions of the body, which in feverish diseases are of the greatest semiotic importance, viz., the face, hand, and wrist, are precisely those which derive their vaso-motor innervation from the system of one-sided fibres.

## GENERAL CORRESPONDENCE.

### EPIGASTRIC VENOUS MURMUR.

LETTER FROM DR. HERBERT DAVIES.

[To the Editor of the Medical Times and Gazette.]

SIR,—The subject of venous murmur is one of sufficient interest, that no apology will, I believe, be necessary for troubling you with a few notes of a case in which the above unusual sound was distinctly evident.

Charles J., aged 46, a brewer's man, much addicted to drinking beer and gin, was admitted in the early part of this year under my care into the London Hospital. His sallow and jaundiced aspect, wasted frame, and distended dropsical abdomen clearly pointed to cirrhotic degeneration of the liver as being his predominant disease—a diagnosis fully confirmed by the post-mortem examination.

On applying the stethoscope to the upper part of the abdomen, a loud continuous, almost roaring murmur, rising and falling in intensity with the inspiratory act, was distinctly audible. It could be heard right and left of the mid-line, and as far as the level of the umbilicus, and pressure on the superficial epigastric veins arrested it. There could be no doubt of its source being in these vessels which were large and greatly distended.

The marked cirrhotic state of the liver observed on post-mortem sufficiently indicated the great impediment which must have existed to the portal circulation, and the absolute necessity of a collateral and regurgitant current being established from the hæmorrhoidal plexus through the epigastric veins to the vena cava superior.

These veins did not elucidate on examination the physical cause of the sound, beyond the fact of their abnormally increased size. The murmur probably arose from their valves being insufficient to arrest the backward current, which therefore set their edges into vibrations capable of producing sound. The deficiency of blood discs which characterises chronic alcoholic cachexia, would also, by causing diminution in the specific gravity of the blood, favour the production of murmur in the regurgitant current.

I am, &c.

HERBERT DAVIES, M.D. Cantab.

23, Finsbury-square, March 28.

## ACUPRESSURE AS A MEANS OF ARRESTING ARTERIAL HÆMORRHAGE AFTER OPERATION.

LETTER FROM MR. EDWARDS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to offer three cases of operations in which, within the last three weeks, I have made use of acupressure, stated as shortly as possible.

*Case 1.*—J. S., aged 25, applied to me with his right arm stiff and straight. He had suffered a compound fracture some months before, and met with other severe injuries at the same time. Thanks to the skill and attention of my friend Dr. Braine, now of Bayswater, he had so far recovered. Portions of bone had been removed from the elbow from time to time, but since Dr. Braine left Edinburgh the patient preferred keeping the arm straight and motionless,—hence its present condition. I advised removal of the ends of the bones, and he accordingly called the next day to have the operation performed. The parts were unusually vascular, and somewhat altered in their relative positions. Although I kept as close as possible to the bone, I divided a large artery which lay in the thickened tissue, a large vein, and several smaller vessels. An artery spouted from the cut end of the bone, and required a wooden peg to arrest it. To all the others I applied short sewing needles, threaded with twisted iron wire. After the wound was dressed, and the arm placed in a sling, the patient awoke from the chloroform, and walked to his home in a neighbouring street. I saw him about half an hour afterwards, and found that there had been slight oozing, as there generally is after any operation, but no arterial bleeding. All the needles and wires were removed in twenty-two hours. The peg was not removed until next day. The patient has since done well.

It will be seen that in this case there were three classes of vessels bleeding—arteries, veins, and a vessel in the osseous tissue. The plan of pegging an artery in bone is very ancient, the bleeding from the vein would probably have ceased spontaneously very soon, but still was likely to pour out a considerable quantity of blood before stopping. I should have been unwilling to tie this vein, and being also reluctant that the patient should unnecessarily lose blood, I applied the needle and wire; all the arteries cut in the soft parts were of such a size as to require ligatures, had the latter been used and they would have stopped the bleeding equally well with the needles, but have remained in the wound for a week perhaps. Now, all the foreign bodies necessary for arresting hæmorrhage from the soft parts were in this case removed in the twenty-second hour. Surely an advantage.

*Case 2.*—*Amputation of the Left Arm.*—Miss M. S., aged 15½. I was called to this girl by Dr. James Sidey. He had only seen her once before, when her timidity prevented any examination being made. The history was that of an ordinary case of diseased elbow-joint of two years' duration, apparently set up by an injury. Latterly she had suffered severe pain, and moving the limb was scarcely possible. When I saw it the elbow was packed in large heavy poultices, the weight of which had, during some moment when the arm was left unsupported, broken the humerus about two inches above the joint. The fractured ends threatened to pierce the skin. The joint was evidently disorganised. She was not a favourable subject, being thin and feeble; a large swelling, apparently a chronic abscess, over the left side of the thorax; but she was suffering so acutely from the fractured arm that I thought it my duty to amputate, which I accordingly did the next day, having to go close under the tuberosities, so as to secure tolerably healthy soft parts. All the vessels, including the brachial, were secured with needles and wires by Professor Simpson; they effectually prevented hæmorrhage, and were all removed in twenty-two hours; the flaps adhered, and, except a little pouting at the skin margins, the stump was healed in five days; on the fourth she was out of bed, and was able to walk to my house on the eighth day.

In this case it was a great object to get the patient out of the close air of a sick room, with its other depressing influences, and I cannot help thinking that the use of acupressure, inasmuch as it enabled us to remove all foreign bodies from the wound in such a short period, greatly assisted us, and hastened the recovery of the stump.

On examination, the joint was found to be necrosed. The fracture was situated above the apex of the olecranon fossa.

*Case 3.—Excision of the Elbow.*—Miss K., recommended to my care by Dr. Alexander Wood, has suffered from disease of the right elbow-joint for two years; believes she can trace its history to a fall. She has seen various Surgeons, and undergone all the usual forms of treatment. As she suffered much with nocturnal paroxysms of acute pain, and a probe passed into the joint, I advised excision of the latter, which was accordingly performed. Only two vessels of any importance bled; they would have required ligatures, but I preferred needles and wire. I called four hours after, and drew out one of the needles, the other I left in until next morning. There was no hæmorrhage, and the case has done well hitherto.

It may be objected that in most of these cases the arteries were small. So they were, but large enough to require something to secure them. Formerly, I would undoubtedly have tied them; now, I should prefer the temporary compression of a wire on one side and a needle on the other. Besides, the brachial in the upper arm is not a small artery. What has always appeared to me somewhat tantalising in operations, especially amputations, is that the largest and the smallest vessels are treated alike; for, how seldom is torsion practised. The only difference is, that the ligature round the most important vessel is marked by a knot. I know that great authorities affirm that ligatures are not in the way of the healing of a wound, and some even do not follow invariably Mr. Veitch's suggestion of removing one end of the thread. But although I have heard many Surgeons declare that ligatures were no impediments, and others say they actually did good and were favourable to healing, I cannot remember a single instance (except, of course, where bleeding followed) where a Surgeon expressed anything but satisfaction when his ligatures came away.

It will be seen from the manner in which I have reported these cases that I bring them forward only as additional evidence in favour of acupressure. I can only hope that other Practitioners will do likewise. I am, &c.

Edinburgh, March 9.

A. M. EDWARDS.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a Meeting of the Court of Examiners on the 7th inst., and, when eligible, will be admitted to the Pass Examination:—

Messrs. F. H. Appleby, Alfred Ensor, Henry Clothier, and George Grewcock, Students of the University College; B. L. Powne, G. V. Langworthy, A. H. Brewer, and H. M. Brewer, of St. Bartholomew's Hospital; W. P. Knott, E. F. Turner, and R. R. Daghish, of Guy's Hospital; Thomas Edgelow, George Edgelow, and John Cavafy, of St. George's Hospital; J. E. Adams, and J. H. Craigie, of the London Hospital; H. V. Bertin, and W. T. B. Hamlyn, of St. Mary's Hospital; Joseph Snape, and M. A. Wood, of King's College; J. W. Jones, and W. B. Shorto, of Charing-cross Hospital; E. J. Armstrong, of the Middlesex Hospital; C. J. Cullingworth, and C. W. E. Foster, of Leeds; Edward Mackey, and John Lloyd, of Birmingham; Joseph Moorshead, of Belfast, and J. M. Fisher, of Hull.

The following passed on the 8th inst., viz.:—

Messrs. Henry Rayner, J. B. Liddall, F. J. Wadd, Edward Bellow, A. J. Freeman, W. N. Heygate, W. H. Reed, and Francis Snaith, Students of St. Thomas's Hospital; Thomas Bond, John Grimes, T. P. Pothergill, and T. C. Shard, of King's College; J. W. Hayward, N. H. Lower, R. W. S. Barraclough, and E. C. Roberts, of Guy's Hospital; Llewellyn Powell, John Powdrell, and F. W. Richards, of St. Bartholomew's Hospital; W. V. Snow, Griffith Griffiths, and Marshall Hooper, of University College; W. N. Symonds, H. C. P. Masser, and G. E. L. Pearse, of the Westminster Hospital; Henry Cribb, and Robert King, of the Middlesex Hospital; E. F. Brockman, and William Leigh, of St. George's Hospital; Henry Willson, of the Charing-cross Hospital; G. W. Mackenzie, of the London Hospital, and F. J. Marshall, of St. Mary's Hospital.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, April 2, 1863:—

John Prior Purvis, Blackheath, Kent; Horatio Bate Gould, Gosport, Hants; Francis Wm. Slow Wicksteed, St. Bartholomew's Hospital; Matthew Trevan, St. Bartholomew's Hospital; George Jenkyn Thomas, Haverfordwest; Wm. Adolphus Fred. Bateman, Richmond, Surrey.

The following gentlemen also on the same day passed their First Examination:—

James Mare Taylor, Queen's College, Birmingham; John Henry Ashton, St. Bartholomew's Hospital; Alfred Square Cook, St. Bartholomew's Hospital; Panlin Martin, St. Bartholomew's Hospital; Thomas Clay Shaw, King's College; Ralph Gooding, King's College.

## APPOINTMENTS.

\* \* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BOOTH, SAMUEL, JUN., M.D., has been elected Medical Officer and Public Vaccinator for the South Salford District, Manchester.  
 COCKS, BENJAMIN, M.R.C.S. Eng., has been appointed Certifying Surgeon under the Factory Act to Wigston Magna, Leicestershire.  
 MCINTOSH, W. CARMICHAEL, M.D. Edin., has been elected Medical Superintendent of the Perth District Lunatic Asylum, Murthly.  
 MIDDLEMIST, ROBERT P., M.R.C.S. Eng., has been elected Surgeon to the St. Pancras and Northern Dispensary.  
 PLAYFAIR, Dr. WILLIAM S., M.D. Edin., F.R.C.S.E., has been appointed one of the Physicians to the Margaret-street Infirmary for Consumption and Diseases of the Chest.  
 SPENCER, THOMAS, M.R.C.S. Eng., has been appointed Certifying Surgeon under the Factory Act to Earl Shilton, Leicestershire.  
 SWANN, H. J., M.R.C.S. Eng., has been appointed Certifying Surgeon under the Factory Act to Barrowden, Rutlandshire.  
 THOMPSON, Mr. E. SYMES, M.D., has been appointed Assistant-Physician to the Hospital for Consumption, Brompton.  
 TOULMIN, FREDERICK J., F.R.C.S. Eng., has been appointed Consulting Surgeon to the Stamford-hill and Stoke Newington Dispensary.

## DEATHS.

BROWNELL, THOMAS F., F.R.C.S. Eng., at the Crescent, Salford, Manchester, on March 26, aged 51.  
 BRYDGES, W. H., at Aylton, near Ledbury, on March 13, aged 83.  
 DAVEY, JAMES S. ENGLEDDUE, M.R.C.S. Eng., on his passage home from the West Coast of Africa, on January 8, aged 24.  
 FOGARTY, THOMAS T., M.R.C.S. Eng., at Lawrence-street, Drogheda, on March 21.  
 MCARTHUR, ANDREW, L.A.H. Dub., at Shinrone, King's County, lately.  
 MARTIN, R. E., M.R.C.S. Eng., at Ipswich, on March 25, aged 45.  
 PARKER, WILLIAM, M.D., of the London Mission, at Ningpo, China, on February 2.  
 PATERSON, Dr. COLIN, Deputy-Inspector-General of Hospitals, at Nagpore, India, lately.  
 WATERMEN, HENRY, at Saigon, China, on January 14, aged 45.

**ACADEMIE DES SCIENCES DE FRANCE.**—The Academy, in two successive weeks, has made two elections into the Section of Medicine and Surgery,—that of M. Bouisson, of Montpellier, as we have already recorded, and last week that of M. Ehrmann, of Strasbourg (in place of M. Bretonneau) who obtained thirty-six suffrages, fifty-six voters being present.

**ROSE-COLOURED TEETH.**—Professor Moritz Heider, of Vienna, gives an account of two twin children who had red teeth, this not being explicable by hereditary influence or any peculiarity of diet. The permanent teeth, when they succeeded the milk teeth, assumed the same colour, and only became paler at the end of some years, without even then entirely losing their rose tint.

**BIRTHS AND DEATHS IN VIENNA IN 1862.**—The births amounted to 22,853 (11,620 boys and 11,233 girls) being 514 less than took place in 1861. The deaths, exclusively of those which took place in the military Hospitals, amounted in 1862 to 19,662. Of these 4536 were caused by tuberculosis, 1277 by inflammations of the respiratory organs; 855 by diseases of the abdomen; 840 by typhus; 636 by scarlatina; 412 by small-pox; 151 by apoplexy; and 116 by pertussis. Of the deaths 4056 occurred before the first year.

**THE PATHOLOGICO-ANATOMICAL DEPARTMENT OF THE VIENNA HOSPITAL.**—According to the report for 1861 of this Department, of which Professor Rokitansky is the Director, there were during that year 1464 autopsies executed. It may be of interest to refer to the proportionate frequency of certain affections. Among the 1464 autopsies, 23 were cases of meningitis, 52 of atrophie cerebri, 40 of cerebral hæmorrhage, 9 of encephalitis, 5 of abscess of the brain, and 12 of œdema of the brain. There were 12 cases of myelitis, 6 of œdema of the glottis, 20 of pleurisy, 120 of pneumonia, 11 of gangrene of the lung, 13 of pericarditis, 105 of disease of the heart, 67 of peritonitis, 15 of granular liver, 4 of acute atrophy of the liver, 7 abscess of the liver, 178 of typhus, 57 of dysentery, 30 of Bright's Disease, 9 of atrophy of the kidney, 14 of nephritis, 105 of puerperal disease, 19 of anæmia, 4 of lukæmia, 30 of pyæmia, 9 of scorbutus, 10 of delirium tremens, 7 of variola, 14 of syphilis, 255 of tuberculosis, and 104 of carcinoma.

**NEW PROCESS FOR RECOGNISING SUGAR IN DIABETIC URINE.**—MM. Trousseau and Dumontpallier have been recently making some experiments with *tincture of iodine* as a test. This tincture when added to urine which is acid, imparts a deep colour to the fluid, and if the urine in jaundice be treated by some drops of the tincture, the green matter, termed *biliverdine*, is rendered very manifest. During the trials which produced the above results, some diabetic urine was treated with some drops of the tincture. The urine, almost colourless at first, after the addition acquired the colour of barley-sugar; but this colour gradually disappeared, the urine again becoming completely colourless at the end of a few seconds. The experiment was repeated again and again with the urine of various diabetic patients, and always with the same results,—the power of this urine in producing the discoloration of the tincture being in proportion to its density. Tried with urine from various sources, the conclusion has been arrived at that diabetic urine alone possesses the power of rapidly rendering the tincture colourless. The researches are still being carried on with the hope of being able to measure by means of the tincture the exact amount of glycose contained in given urine.—*Union Médicale*, March 31.

**DREADFUL DEATH.**—The *Huddersfield Examiner* contains the following:—"An accidental death, attended by circumstances of an unusually painful character, occurred at Longwood, at the commencement of the present week. The unfortunate subject was a girl of 17, named Anna Maria Balmforth, daughter of Joseph Balmforth, joiner, residing at Cliffe-end, Quarmby. Death took place on Monday morning, and the inquest was held by Mr. Dyson on Tuesday. It appears that the girl had been suffering from a cold, which defied ordinary remedies, and her mother, by the advice of a neighbour, resolved to administer a hot vapour-bath. This resolution was carried into effect on Sunday last. The deceased was enveloped in blanketing in the usual way, the hot brick, according to custom, was placed beneath her, but instead of being put in cold water to produce the vapour, it was placed in water at the boiling point. The result may be easily imagined. The girl soon began to feel the vapour unbearably hot. She was told, however, to bear it; and this she did with noble endurance as long as she could. The heat, however, grew more intense, until at last it was unendurable. The girl cried out to be released, but, unfortunately, the old woman left in temporary charge was deaf, and did not hear her entreaties; and, after one or two vain appeals, the girl sprang from her trammels with a shriek, and rushed to bed. It was then found that her whole body was dreadfully scalded, so much so that the skin came off with the slightest touch. She lingered in great pain till Monday morning at seven o'clock, when she died, to the great consternation of the family." The only reflection which this case suggests is, that in the hands of ignorant people the simplest and safest remedies may be rendered dangerous. Had the poor girl obeyed her sensations, and retreated from the bath when it became painful, no harm could have happened. She fell a victim to her own fortitude.

**ANTHROPOLOGICAL SOCIETY OF LONDON.**—April 7, 1863, Dr. Hunt, F.S.A., President, in the Chair. Seven new members were elected. J. F. Collingwood, Esq., F.G.S., was elected Hon. For. Secretary, in the place of E. Burnet Tylor, Esq., resigned. A paper was read by R. T. Gore, Esq., F.A.S.L., "Notice of a Case of Microcephaly." The individual in question was for a long time under his observation. She was a female, the offspring of healthy parents, and without any known instance of idiotcy or defective intellect in the family. She lived to her 42nd year, and died of phthisis; her height was about five feet; her figure slight, and rather well proportioned. The intellect was infantine, *i. e.*, corresponding to that of a child three to four years of age beginning to talk. Her habits were decent and cleanly; her gait unsteady and tottering. Accurate photographs and casts of the brain were exhibited. The occipital foramen was situated far back, at a point corresponding to one-fifth the antero-posterior diameter of the basis cranii; the anterior lobes of the brain were much narrowed towards their apex; the posterior lobes left a large portion of the cerebellum uncovered. The weight of the brain is remarkably small. Carefully weighed when recent, after the membranes and vessels had been removed, it weighed 10 oz. 5 gr. avoirdupois (=283.75 grammes). The smallest case previously known was "Theile's case," men-

tioned by Wagner, in which the brain weighed 300 grammes. The idiot's brain in St. Bartholomew's Hospital, described by Owen, weighed 332 grammes. There is no evidence of any disease having been concerned in the production of the microcephaly in the present case. The mental phenomena were very similar to those of early infancy, contrasting strongly to those exhibited by ordinary idiots. Professor Owen, F.R.S., remarked that instances of analogous arrest of development had been recorded in the different varieties of the human species, as, *e. g.*, in the negro variety, called by her showman the "Hottentot Venus," and by the hybrid Spanish and Indian children from St. Salvador, termed "Aztecs;" likewise in the brain weighing 1 lb. 4½ oz., described by Dr. Todd, and by the present instance. So far as Professor Owen's researches extended, the present instance exemplified the smallest instance of a brain, otherwise of sound structure, in which the individual has lived in health beyond maturity to middle age. The brain so arrested was, however, widely different from that of the quadrumane. Professor Owen entered into an extended description of the psychological characters associated with the cerebral modifications in those idiotic brains which had been observed by him. Mr. Carter Blake read extracts from Rudolph Wagner's "Vorstudien," and from the valuable tables compiled by Dr. Peacock (St. Thomas's Hospital), respecting the average cerebral development, and the occasional abnormal departures from it exemplified by microcephalic and macrocephalic brains. He also urged the advantages which would accrue to science if translations of the works of Wagner and Gratiolet were in the hands of every student, and stated that the preparation of such works were in contemplation by the Society. An animated discussion ensued, joined in by Professor Owen, Mr. Robert Dunn, Mr. Carter Blake, Mr. Prideaux, Dr. Drachaichis, Mr. Burke, Mr. Mackie, the Duke of Roussillon, and the President. The Rev. H. F. Rivers presented to the Society the remains of two human skeletons, discovered in brick earth at Chatham, and which exhibited a low frontal development, rather large frontal sinuses, and well-marked muscular impressions on the limbs.

**THE NEW METAL THALLIUM.**—At the Royal Institution, on Friday, March 27, 1863, Mr. William Crookes gave a highly interesting lecture to a small audience on the "Discovery of the Metal Thallium." During the last century philosophers record the discovery of thirty-two new elements. The importance attached to the three latest is due more to the means by which they have been brought to light than to the metals themselves. Previous to the discovery of these elements the number known was seven, which we may call the seven ancient elements. Sir Humphrey Davy separated, by means of voltaic electricity, the metals of the alkaline earths. The discovery of the metal thallium is inseparably connected with the spectrum. There is a curious historical parallel between the discovery of thallium and that of selenium. Berzelius, while searching for tellurium in sulphuric acid deposits, found selenium. The lecturer, while examining SO<sub>3</sub> deposits for the same element, found thallium. He examined it through the spectroscope, and, by the appearance of the green line, he suspected some new feature. The great care required in these operations may be seen when we say that there were only three grains of thallium in three lbs. of seleniferous deposit obtained from oil of vitriol works. One grain to the lb. distilled from copper pyrites. The name was given from the Greek *θαλλός* = a budding twig. It was in September, 1862, that the lecturer first obtained the metal precipitated in crystals. This precipitate squeezed in the fingers and pressed well in a small steel mortar and placed in a powerful vice, then melted in a manner to prevent the oxygen of the air acting upon it. Up till now the investigation has been carried on under very great difficulty, in consequence of the very poor stock of accessible working material. Arrangements have now been made with sulphur manufactories to alter the condensing flues. Only yesterday one ewt. of deposit was sent up, from which the lecturer expected to obtain one or two lbs. of thallium. In a short time thallium will be a very common metal. One ton of pyrites contains about ten ozs.; hydrochloric acid three or four grains to the cwt. *General Properties.*—1. Heavy. 2. Ductile. 3. Malleable. 4. Very soft—the softest heavy metal. Lead scratches it with the same facility as steel will scratch lead, the finger-nail will make a very deep mark upon it, and a knife will cut it as if it were cheese. 5. Its property of being welded together in a mould as perfectly as if it were melted is peculiar. 6. Easy

way in which it marks upon paper.—This mark upon paper has a gold-coloured reflection, and in a few hours it will almost completely fade away, but can be revived by passing over the characters a solution of the sulphide of thallium. 7. Electrical power of thallium.—Mathieson discovered that thallium conducts almost as well as lead. 8. Its behaviour between the magnetic poles.—It stands next to bismuth as a diamagnetic body. 9. Volatility.—It is one of the most volatile metals; burns with a beautiful green flame. Has a great affinity for O. The oxide of thallium has the property of dissolving in water; has an acrid, biting taste, and colours turmeric paper as strongly as caustic potash would. When thallium is melted in the air it forms an oxide. An alloy of thallium and silver can be cupelled. 10. Chemical properties of thallium.—It forms a beautiful series of well-defined crystalline salts. 11. The position of thallium in the scale of elements.—The general opinion on the Continent is that it is an alkaline metal. The lecturer gave his reasons for supposing it to belong to the lead and silver group, and exhibited the tests which supported his view. The only uses to which it seemed capable of being applied were for making bullets and fireworks for pyrotechnic displays; its beautiful green colour while burning would make it useful, and its density and property of being easily moulded would bring it into requisition for bullet manufacture.

**ST. BARTHOLOMEW'S HOSPITAL.**—The great old charities of London know nothing of those shocks and alarms felt by younger institutions, when cotton famines, and money panics, and seasons of dear bread arise. The cause of the difference is not occult; it is, in fact, all resolvable into the question of endowment on one hand, and voluntary support on the other. The income of St. Bartholomew's Hospital amounted last year to £54,767, towards which there was contributed in benefactions only £599. Of course it is well understood that the safety of the Institution, which derives its increasing income from estates, prevents the extension to it of individual voluntary aid, or rather, as the income is secured, the charitably disposed find other ways for doing good with their surplus means, and there is no stint of personal charity because of ancient endowments. There was a balance of £2989 brought forward from last year's account, and there is a balance carried on from the account closed the 31st of December last of £4196; so that the income appears to gain upon the expenditure. The principal item in the receipts is the sum of £29,260, received on account of rents; dividends on stock produced £4870; and another sum of £4476 resulted from the sale of Consols. The most interesting item on the debtor side of the accounts is a temporary loan of £5000 from the Bank of England, required for the recent improvements effected in the Hospital. On the creditor side we see an entry of £10,000 temporary loans repaid; and observing also that the balance carried on amounts to £4196, it is obvious that the incurring of a small amount of debt would have obviated the borrowing of the £5000 which comes into this account. But as moneys prospective and uncertain are of less value than moneys in hand, we make no complaint, though we cannot but think an institution of this kind ought to improve and extend itself without borrowing at all. The total outlay last year, on account of Hospital management and managing estates, that is, inclusive of "extra expenditure," was £40,546. Looking down the long list of payments, it is not easy to determine the necessity of all, or the non-necessity of any; but it is worth while to note that the total amount paid for "diet for the poor patients and nurses," and for "drugs, chemicals, etc.," was £13,101, that is, a trifle over one-third of the whole expenditure, the remaining nearly two-thirds being wholly absorbed in management. Tradesmen's bills amounted to £6129 salaries to £9903; there are other payments for annuities and liveries, and the rest of the account consists of entries for insurances, rates, lighting, law charges, rents, printing, and other such items. The entry for Hospital dinners is only £219, and for viewing estates, £88; these, then, are not the causes of the distribution of so large an income. Perhaps a statement of assets might explain the matter, by showing that some of the entries on account of extra expenditure will result in an increased future rental; such, indeed, we should expect, as most of these payments are for purchases and improvements, which are always supposed to insure a good return.—*City Press.*

**TASTE OF MEDICINES DISGUISED BY CHLOROFORM.**—M. Grave has shown that the taste of bitters may be entirely disguised by the addition of chloroform, as, e.g., in the tincture

of aloes or gentian and a solution of quinine. M. Lamou also states that chloroform instantly and completely annihilates the odour of assafœtida. It remains, however, to be seen whether the chloroform does not also deprive these substances of the whole or part of their therapeutical properties.—*Journal de Pharmacie*, vol. xlii., p. 338.

## BOOKS RECEIVED.

The Glasgow Medical Journal, No. XLI., April, 1863. Quarterly. Mackenzie, Glasgow.

\* \* \* Contains a full and very interesting Medico-legal Report of the Trial of Jessie M'Lauchlan for Murder, a very scholarly article on Malformations of the Aorta, by Professor Allen Thomson, M.D., a Case of Ovariectomy, by Dr. Lyon, and much other interesting matter. A paper on Bathing, by Dr. Hatrick, is a curious *omnivium gatherum*, which contains at least one amusing passage. The writer deprecates daily bathing. "Its expediency is less obvious among those who are accustomed to change their under-clothing regularly. . . . Daily immersion of the entire skin in water tends to injure its tone, and, along with the subsequent friction in drying, debilitates and leaves the pores exposed by removing too rapidly the sebaceous secretion and loose external scales of the epidermis. . . . Too assiduous washing of the head and body may not improbably induce premature grey hairs. The almost innumerable sebaceous glands were implanted in the skin for a purpose, which was scarcely in order that their oily exudation might be removed every day." O happy Glasgow! whose citizens need to be thus cautioned by a learned Physician against excessive cleanliness! How times must be changed!

The Westminster Review (New Series), No. XLVI., April, 1863.

\* \* \* The politician will find an elaborate article on Austria, the Biblical critic will regale himself with a defence of the everlasting Bishop Colenso, the man of material good sense will turn to an article on the Resources of India, the Ethnographer will be interested in an account of the Jews in Western Europe, idle old women will read about Lady Morgan, disputatious young men about "Truth v. Edification," and the curious young lady may set her soul on fire by speculations on the Antiquity of Man, and his co-existence with the huge extinct pachyderms of Northern Europe. The original articles are accompanied by the accustomed bibliographical notices, with short critical comments.

A Hand-book of Uterine Therapeutics. By Edward John Tilt, M.D. London: Churchill and Sons. 1863. Pp. 310.

The Quarterly Journal of Microscopical Science. Edited by Lr. Lankester and Mr. Busk. New Series. No. X., April, 1863. Churchill and Sons.

\* \* \* This number is full of articles of interest. Amongst them is a paper by Dr. Greville, on the genus *Auliscus*, a genus of Diatomaceæ, introduced by a discussion on the vexed question of "What is a Species?" Lines of specific separation are very hard to find in the Diatomaceæ. Dr. Ciaccio, of Naples, publishes a paper in support of Dr. L. Beale's observations on the Anatomy of Nerve Fibres and Cells. The Editors reprint from Silliman's Journal Professor Wyman's Experiments on the Formation of Infusoria in Boiled Solutions of Organic Matter enclosed in Hermetically-sealed Vessels and supplied with Pure Air. The experiments are of the highest interest, but they are open, like all others of the same kind, to objections founded on the observations of De Quatrefages, Robin Pouchet, and Pasteur.

The Edinburgh Medical Journal, No. XCIV., April, 1863. Oliver and Boyd.

\* \* \* Contains a good lecture by Mr. William Turner, M.B., on Cellular Pathology, erring perhaps on the side of exclusiveness. The conclusion supported is that pus, cancer, and tubercle all originate in the same way from pre-existing cells of healthy tissue; that up to a certain time they appear the same, and that their ultimate difference is one of the mysteries of organisation involved in the question, "What is disease?" Dr. Keith publishes two instructive cases of ovariectomy, one fatal, the other successful.

The Madras Quarterly Journal of Medical Science, No. XI., January, 1863. Gaultz, Brothers, Madras.

\* \* \* This Journal loses nothing by comparison with our home productions. One of its most attractive papers is by a native Doctor, W. Venkataswamy Nardoo, Medical Subordinate of the Madras Establishment, proposing a scheme for establishing European Medical Practice and sanitary measures amongst the native population. It gives a curious account of native quackery. The village quack, like Sir W. Scott's friend, the blacksmith, who treated all his friends with two simples, laudamy and calamy, has two remedies—black medicine (opium), white medicine (mercury). The results may be conceived. The writer naïvely recommends that all respectable natives who contract syphilis should be compelled to pay double for their medicines. He supposes that half the population in the towns are under the influence of syphilitic poison. Amongst other valuable papers are those by Mr. Wood and Mr. Lowe on Tetanus, and Mr. Blacklock on Delirium Tremens.

The Edinburgh Veterinary Review, No. XXXVI., April, 1863. Maclachlan and Stewart.

\* \* \* Professor Gamgee's paper, on the Anatomy of the Horse's Foot, is worth reading. We commend it to our country friends, whose horses' soles are periodically pared away by the village blacksmith's apprentice. Professor Ferguson publishes a Report on Rot in Sheep, and Mr. J. McGillwray a paper on Diseased Joints in Cattle and Sheep. Mr. Rarey's mode of horse-taming is found to produce curb, spavin, and enlarged fetlocks.

Irish Facts and Wakefield Figures in Relation to Convict Discipline in Ireland. Investigated by the Rev. John T. Burt. Longmans.

\* \* \* The main conclusion of the writer seems to be that we are all wrong in ascribing garrotting, etc., to the present "convict system." This doctrine is supported (like most others) by statistics.

The York Star, Vol. III., No. 2.

\* \* \* Very creditable both to the inmates and managers of the York Asylum.

An Account of the Medical Evidence connected with the Trial of Jessie M'Lauchlan. By G. H. B. Macleod, M.D., etc. Glasgow: Mackenzie. 1862.

\* \* \* A temperate statement of the conclusive evidence against the prisoner.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

*Medicus.*—We believe he can refuse to give evidence unless his fee be previously paid.

*W. C. L.* will find papers on Faradisation in the *Medical Times and Gazette* of August 30 and September 13, 1862.

Nothing can exceed the ability and good feeling which mark the reports of the *Chester Chronicle* and *Courant* in Dr. Waters' case.

*Morgan v. Lingen.*—An action for libel in which a member of the Medical Profession, Dr. Lingen, of Hereford, is defendant, stood over from the late assizes held at that town. It will be satisfactory to the professional brethren of the defendant to know that the action—should it be proceeded with, which may be doubtful—is in no respect likely to affect his reputation as a Medical man. We may add, that a statement which has appeared in the Supplement to the *Hereford Times*, to the effect that a compromise and apology had been offered by the defendant, is unfounded, and has or will be contradicted by his counsel. We are informed that the Judge wished the matter settled out of Court, as being a trifling affair, but that such a course will not be adopted.

*Erratum.*—The writer of the letter on the case of *Russell v. Adams*, published in the last number of the *Medical Times and Gazette*, p. 350, is "Mr. Edward Cottew, L.R.C.P. Ed., not "Mr. Edward Cottem."

THE APOTHECARIES' COMPANY OF IRELAND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Dr. Lect, in his letter published in the *Medical Times and Gazette* of the 4th instant, has omitted to inform your readers that the opinions of Mr. Napier (ex-Chancellor of Ireland) and of Sir R. Bethell (Chancellor of England) were submitted by the Poor-law Commissioners to the Attorney-General and the Solicitor-General for Ireland, who gave the following opinion, February 11, 1863 :—

"We think that the Apothecaries' Hall, Ireland, has no power to grant a diploma or license to practise Medicine.

RESTORATION FROM CHLOROFORM ACCIDENTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you allow me to make a few practical observations on restoration from chloroform accidents. It was stated in your impression for March 28 that "the great desideratum in such cases is to re-establish the action of the diaphragm and respiratory muscles. May it not be of the first importance to remove as quickly as possible the chloroform from the patient's lungs—to get rid of the exciting cause of the asphyxia?"

The first thing to be done in the case of the apparently dead from chloroform is immediately and suddenly to compress the front and sides of the chest by the patient's own arms, the compression to be continued for about two seconds. By this means the poisoning vapour is expelled; and upon the pressure being suddenly relaxed, the elastic parietes of the chest recoil, and give the primary impetus to inspiration. This should be taken advantage of, and the ribs drawn up by means of the pectoral muscles, as I have elsewhere described. The chest may be made to draw in and again expel air mechanically as a pair of bellows. What is chiefly required is dexterity in the operator. A forcible expiration not only serves to remove the poisonous vapour, but is the first step towards the succeeding inspiration.

Clapham-common, April 7.

I am, &c.

HENRY R. SILVESTER.

FARADISATION IN CHLOROFORM ACCIDENTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am very pleased that such a practical man as Mr. Lobb approves of the "Faradisation" current through the respiratory nerves in cases of apparent death from chloroform. I was previously aware that the needle or pins into the sterno-mastoid or diaphragm was not indispensable, still I think, in the hurry of the moment when these appalling miseries occur, not especially in hospital practice, but elsewhere, that it is a good plan, first to stick a needle at once into these parts; a needle into the diaphragm alone will do no harm, and may sometimes save a valuable life; and the magnet or cell battery is not always at hand. This subject is perfectly new, or I should not dwell on it; the "Faradisation" current alone seems to answer, and through the phrenic, but no other nerve. It is only necessary to read a report of my excellent friend Dr. Richardson in the current number of the *Medico-Chirurgical Review* to see what deplorable ignorance exists in all our standard and severely genteel classic journals on this point. I could not help smiling, sitting at the College of Physicians at the collected wisdom of Sir Charles Hastings' Association, when this old world lore was read by Dr. Richardson, viz., that we had no hope in Chloroform accidents from electricity, but if one passed a galvanic wire into the right auricle, and slit open an unfortunate patient's pericardium, then the "Association" would have reason to see something very miraculous; the battery being applied also to the nape of the neck or heart! "This orthodox plan," as Dr. Richardson says, only assisted to kill the patient more completely. I can corroborate this in a chloroform case I saw at Guy's, and I have asked at least a dozen men who are in the habit of administering chloroform how electricity should be used, but they invariably gave the wrong plan, the "orthodox plan," as saith the *Medico-Chirurgical Review*.

I am, &c.

CHARLES KIDD, M.D.

Sackville-street, April 3.

P.S.—We have had three deaths from chloroform very recently in the London Hospitals, no notice taken of them in the Journals. This new

plan of Mr. Faraday's is known over a year and a-half, it has been tried in thousands of experiments on the lower animals poisoned by chloroform with the same beautiful and marvellous result. This was the first case of such accident in the human subject in which it was tried.

EXPERT SWEARERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Dr. Edward Waters, more than 50 years of age, with grown-up children, and enjoying a most extensive practice and a high character as a Physician in the city of Chester," has just had to rebut a charge of seduction, with Serjeant Shee (specially retained) and a string of counsel against him.

Dr. Waters fortunately vindicated his character from this most serious charge, and also gained a verdict in two subsequent actions for slander therein; so that the Profession has nothing to regret upon his account; but it is astonishing to find Drs. Lee and Ramsbotham down from London to sustain the charge by swearing that "the use of the speculum is improper where there are symptoms of hysteria." Now, is this a fact? Can anyone rightly affirm that in a troublesome and anomalous case of "cataleptic hysteria," with evidence of uterine irritation, a Physician is acting improperly in searching for ulceration of the os uteri, and in using the speculum for the purpose of applying caustic thereto? If the Profession think as I do on this question, they will hasten to reprobate the conduct of Drs. Lee and Ramsbotham for risking the credit of the Medical Profession by dogmatizing upon a point whereon they had not the means of judging, and for doing this in such a way and at such a time as to jeopardise a fellow-practitioner of high position and reputation.

A charge of seduction may be brought against anyone; and how many of us are in a position to *disprove* a charge of having taken liberties with a patient in our consulting-room some eighteen months ago? Yet, had Dr. Waters not sold a pony on the day of the alleged misconduct, and had the purchaser not been at hand to furnish the date of the sale, and so contradict material points in the plaintiff's case, Dr. Waters would very probably have left that court mulcted of £1000, and blasted for the rest of his life, and chiefly in consequence of the unwarrantable assertions of these two obstetric specialists.

A short time since, in a trial for malpraxis in a forceps case, Dr. R. Barnes, I believe, deposed on oath "that the forceps should never be used without a consultation," and this also against a brother-practitioner.

I am, &c.

JAMES EDMUNDS, M.D.

35, Finsbury-circus.

MEDICAL PROVIDENT ASSOCIATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg leave to inform you that, in consequence of the various letters that have appeared in the Medical journals on the subject of Health Assurance, a meeting of Medical Practitioners was held at Cheltenham on the 31st ult., for the purpose of taking the matter into consideration. The meeting was held at the house of Wm. Dalton, Esq., F.R.C.S., under the presidency of Dr. Abercrombie, F.R.C.P. It was convened by circulars signed by the above gentlemen, as well as by Dr. Colledge, Mr. Rumsey, Dr. Eves, Dr. Rooke, and myself.

I will not attempt to give anything like a verbatim report of the remarks of the various speakers, but will only say that the meeting regarded the question under a threefold aspect:—Wishing to ascertain, first, whether a Medical Provident Association, for the purpose of giving its members an income during sickness, would be generally acceptable and useful to the Profession? Secondly, what would be its proper scope and aim? Lastly, what would be the cost of maintaining it in operation? It was the opinion of the meeting that the two first questions must be satisfactorily answered by the Profession, as a necessary preliminary to the solution of the third by an actuary.

It was therefore moved by Dr. Eves, seconded by Mr. Dalton, and carried unanimously,—"That the proposition for the formation of a Medical Provident Association is one entitled to the best consideration of the Profession."

It was moved by Dr. Hobson, seconded by Dr. Philson, and carried unanimously,—"That the editors of the Medical journals be requested kindly to give publicity to the following questions, and that individual Practitioners be requested to reply to them:—

- "1. Do you think such an institution desirable for the Profession generally?"
- "2. Should you be inclined to become a subscriber?"
- "3. What has been, in weeks, your own annual average of sickness sufficiently severe to disable you from practice?"

Having intimated to the meeting that I was prepared to receive and arrange the answers to these questions, I was requested to undertake the task. I hope that all gentlemen who feel interest in the matter will favour me with early communications; and, in a fortnight from the publication of this paper, I propose to commence an analysis of the letters I receive. If the scheme should be generally approved, a second meeting will be in a position to make public an outline of the scope and aim of the association, as a basis for the discussion of details into which it would now be premature to enter. As soon as this can be done, it would be advantageous to hold meetings in various parts of the country; but, at present, in the absence of further information, such meetings would hardly produce benefit equivalent to the trouble and inconvenience of holding them.

Having said thus much as the mouthpiece of the meeting, I would beg leave most earnestly to urge the matter upon the attention of my Professional brethren. If a Provident Association can be carried out at a moderate cost, it will be a great benefit to a large number of Practitioners; and, on the contrary, if there be insuperable difficulties or objections in the way, they may now be brought to light, and the question set at rest for ever.

I am, &c.

Stroud, Gloucestershire, April 4.

R. B. CARTER.

THE SO-CALLED "TOBACCO AMAUROSIS."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The *Medical Times and Gazette* for the 4th instant contains a report of a case of atrophy of the optic nerve seen at the Royal London Ophthalmic Hospital, and attributed by Mr. Wordsworth to the influence of tobacco. In similar cases I have heard a similar opinion expressed by some of Mr. Wordsworth's colleagues, but I am not aware upon what kind of evidence it is based.

I do not by any means wish to deny that tobacco-smoking may be among the causes of the disease in question; but I do not know of any

facts that justify a positive statement in the matter. In this country a very large proportion of adult males are habitual smokers; and the mere coincidence of white atrophy with the use of tobacco proves nothing whatever. Moreover, a hasty, and possibly erroneous assumption, may tend to shut our eyes to the influence of other causes that ought not to be overlooked.

By "white atrophy" I mean a disease that is attended by gradual and painless loss of sight, and commonly by sluggish and rather dilated pupils, upon which atropine exerts less than its usual influence. The optic nerves are at first invaded by white patches, generally wedge-shaped—the rest of the nerve circle being either slightly hyperæmic, or appearing so by contrast with the altered portions. Gradually the white colour spreads over the whole nerve, the central vessels dwindle, and the blindness becomes complete. It is not uncommon in the progress of the disease to see slight capillary apoplexies at various points of the *fundus oculi*.

In this description I wish to include only those cases in which there is no evidence of cerebral mischief, and no physical obstruction, such as an orbital or intracranial tumour to the blood supply of the nerve.

I have seen this white atrophy in persons whose circumstances and habits differed so widely, that I have been much puzzled to find any cause common to them all. I have seen it several times in young women, none of whom used tobacco in any form. The last four cases that I remember were:—1. A lace manufacturer, about 50 years old, of regular life and habits, not a smoker. 2. A young countryman, of 24, a great smoker and hard spirit drinker, but whose powerful constitution seemed scarcely injured by his excesses. 3. A cavalry sergeant, aged 34, a steady man and moderate smoker. 4. A young girl of 18, a dressmaker, in comfortable circumstances and of regular life, who had never smoked. All these patients suffered in health by the depression incidental to impending blindness, but none of them presented any disease to which the atrophy could be clearly traced.

Upon the assumption that nineteen-twentieths of Englishmen smoke tobacco, there is hardly any disease that might not be attributed to its baneful influence. If Mr. Wordsworth is in possession of any better evidence than a coincidence that is necessarily frequent, I for one should be grateful to him if he would make it public. Perhaps he may know something about the proportionate frequency of the disease in males and females, or in Germans and Englishmen respectively; or about its occurrence in the classes that use tobacco largely. Perhaps he may have some hypothesis as to the *modus operandi* of the nicotian herb. Perhaps he may possess statistics that place the accuracy of his opinion beyond question. But the Profession has a right to expect from Moorfields something more than a barren statement; to expect, indeed, either philosophical caution or satisfactory evidence. To my judgment, the etiology of white atrophy opens some of the most obscure questions in pathology, and I shall gladly welcome any information tending to elucidate them.

I am, &c.

Stroud, Gloucestershire, April 5.

ROBERT B. CARTER.

#### HEMICRANIA AFTER INFLUENZA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In "Notes and Queries" of last week's *Medical Times and Gazette* I observe a letter from Dr. Norris, of South Petherton, remarking on the frequent occurrence of hemicrania, etc., as a sequence to the very severe epidemic of influenza which has visited his neighbourhood, and asking for information as to its frequency elsewhere. I believe I have never before known so severe an attack of the kind as that which visited this neighbourhood also, and I have also remarked with surprise the very common occurrence of cephalalgia of an intermittent type (generally quotidian) on the decline of the disease. Some of the cases have proved very troublesome, but they have all yielded after a time to the exhibition of the ordinary antiperiodic remedies. Sulphate of zinc has proved very useful.

I have frequently noticed during the last three years (the wet seasons) the peculiar and well-marked tendency of almost every kind of febrile disease to assume the intermittent type, and even chronic disease has often partaken of the same nature. Intermittent fever being, up to that time, a comparatively rare disease in this neighbourhood, I accounted for the tendency towards its manifestation by the excessive quantity of moisture in the air, and the almost constantly sodden state of the ground during that period. About this time last year, during a severe attack of influenza, I experienced in myself a very severe attack of cephalalgia coming on every morning about nine o'clock, and lasting till 5 or 6 p.m., during which time I was almost incapacitated for either mental or bodily work. This lasted a fortnight, unchecked by quinine, zinc, or arsenic. At last, almost in despair, I tried chlorodyne, in a dose of thirty drops. The relief obtained was almost magical, being quite free from pain in half an hour. A smaller dose next morning warded off another attack which was evidently approaching, and the complaint passed off without a recurrence. I have obtained relief in the same way from a similar attack once since.

Whilst writing, I wish to make an observation as to the very great utility of subcutaneous injections in neuralgic and other affections, in which too often opium in any form fails to afford relief, when administered by the mouth. I allude particularly to sciatica, several cases of which I have completely cured by subcutaneous injections of morphia in doses of three-quarters to one grain, after all other treatment had proved unsuccessful. In one case of delirium from fever it proved quite successful after opium and morphia, to the extent and equivalent to six grains of the former, had completely failed to procure sleep. I have a patient still under treatment who was sleepless for five nights. On Friday last he was much worse, and delirium tremens had set in. Opium to the extent of three grains, in divided doses during the night, only caused increased restlessness. At 11 a.m. the following day I gave him thirty-five minims t. opii., and at 1 p.m. fifteen minims more, all to no purpose. At 7 p.m. he was worse than ever. I then injected about half a grain of morph. hydrochlor. which made him quieter, and at 8 p.m. I injected a quarter of a grain more. This was followed by refreshing sleep in naps of from half an hour to two hours in duration during the night, the following day and night, and no opium has been given since. Consciousness has gradually returned, and he is now progressing favourably. I do not assume to any discovery, knowing that the plan has been adopted by others before me, but I do not think its value is sufficiently appreciated, which I believe would be the case if a more extensive trial were made of it, its convenience and facility of use being most important features among its peculiar advantages.

Apologising for the length of this communication, so much of which does not bear upon the subject which induced me first to take my pen, but the importance of which seemed so urgent upon me, I am, &c.

Milton Abbas, Blandford, April 1.

### APPOINTMENTS FOR THE WEEK.

April 11. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.

13. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.

MEDICAL SOCIETY OF LONDON, 8½ p.m. Mr. Gay, "On Intestinal Stricture."

14. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ETHNOLOGICAL SOCIETY, 8 p.m. John Crawford, Esq., "On the Antiquity of Man."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. Henry Thompson, "On Treatment of Severe Stricture of the Urethra by Gradual Distension at a Single Sitting." Dr. H. Weber, "Pathology of Crura Cerebri."

ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Mechanics."

15. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.

16. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.

HARVEIAN SOCIETY, 8 p.m. Dr. Cock, "On Rickets, and the Connexion of Laryngismus Stridulus, or False Croup, with that Disease."

ROYAL INSTITUTION, 3 p.m. Prof. D. T. Ansted, F.R.S., "On the Relations of Geology with Allied Sciences."

17. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 8 p.m. Frank Buckland, Esq., "On the Culture of Fish."

WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON, 8 p.m. Practical Evening, for the Narration of Cases and the Exhibition of Specimens.

### EXPECTED OPERATIONS.

King's College Hospital.—The following Operations will be performed on Saturday (to-day) at 2 p.m. :—

By Mr. Fergusson—For Vesico-Vaginal Fistula (two cases); For Lacerated Perineum; For Anchylosis of Elbow-joint; For Lithotripsy.

By Mr. Henry Smith—For Prolapsus Ani.

hand, pretty clearly made out. They are vermiform parasites, like the *Teniada*, devoid of any mouth or alimentary canal, but provided with a proboscis armed with recurved hooks. The proboscis is supported within by a sort of rod-like handle, whence a cord is continued, to which the reproductive organs are attached. A single ganglion is seated in the "handle" of the proboscis. Immediately beneath the integument lies a series of reticulated canals containing a clear fluid, and it is difficult to see with what these can correspond if not with some modification of the water-vascular system.

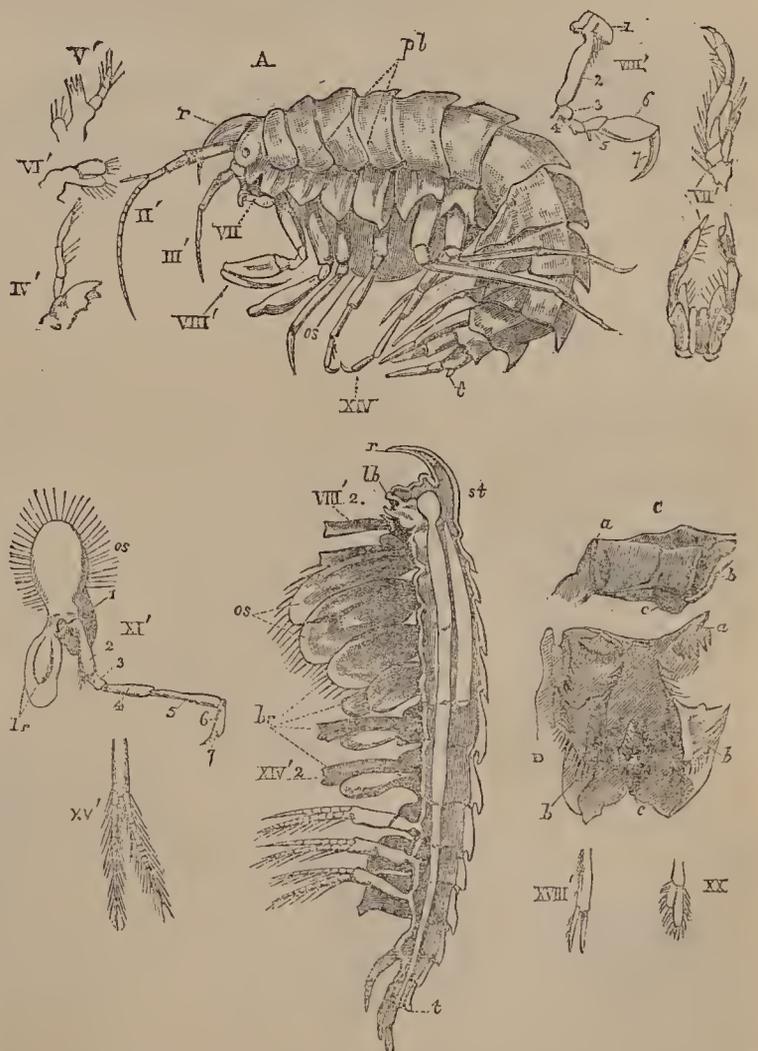

Leaving the division provisionally termed "Scolecida" in this confessedly unsatisfactory state, I pass on to the *Annelida*, a class of large extent, containing the leech, the earthworm, the *Sipunculus*, the lobworm, the scamouse and *Polynoe* (Fig. 6), the *Serpula*, and the *Spirorbis*.

All the members of this class possess a nervous system, consisting of a longitudinal series of ganglia, situated along one side of the body, and traversed anteriorly by the oesophagus, the præ-oesophageal, or so-called "cerebral" ganglia being connected by lateral commissural cords with the post-oesophageal ganglia.

In many of these animals the body is divided into segments, each of which corresponds with a single pair of ganglia of the chain, and each of these segments may be provided with a pair of lateral appendages; but the appendages are never articulated, and are never so modified, as to be converted into masticatory organs, in the cephalic region of the body.

No Annelid ever possesses a heart comparable to the heart of a Crustacean, or Insect, but a system of vessels, with more or less extensively contractile walls, containing a clear fluid, usually red or green in colour, and, in some rare cases only, corpusculated, is very generally developed, and sends prolongations into the respiratory organs, where such exist. This has been termed the "pseudo-hæmal" system; and I have thought it probable that these "pseudo-hæmal" vessels are extreme modifications of organs homologous with the water-vessels of the Scolecida. As M. de Quatrefages has clearly

shown, it is the perivisceral cavity with its contents that, in these animals, answers to the true blood-system of the Crustacea and Insects.

The embryos of Annelids are very generally ciliated, and vibratile cilia are commonly, if not universally, developed in some part or other of their organisation. In both these respects they present a most marked contrast to the succeeding classes.

In the Crustacea the body is distinguishable into a variable number of "somites," or definite segments, each of which may be, and some of which always are, provided with a single pair of articulated appendages. The latter proposition is true of all existing Crustacea; whether it also held good of the long extinct Trilobites, is a question which we have no means of deciding. In most Crustacea, and, probably, in all, one or more pairs of appendages are so modified as to subserve manducation.

A pair of ganglia is primitively developed in each somite,

and the gullet passes between two successive pairs of ganglia, as in the Annelida.

No trace of a water-vascular system, nor of any vascular system similar to that of the Annelida is to be found in any Crustacean. All Crustacea which possess definite respiratory organs have branchiæ adapted for respiring air by means of water, the terrestrial Tropods, with their curious rudimentary representation of a tracheal system which some exhibit, forming no real exception to this rule. When they are provided with a circulatory organ, it is situated on the opposite side of the alimentary canal to the principal chain of ganglia of the nervous system, and communicates by valvular apertures with the surrounding venous sinus, the so-called "pericardium."

The Crustacea vary through such a wide range of organisation that I doubt if any other anatomical proposition, in addition to those which I have mentioned, except the presence of a chitinous integument and the absence of cilia,

FIG. 10.

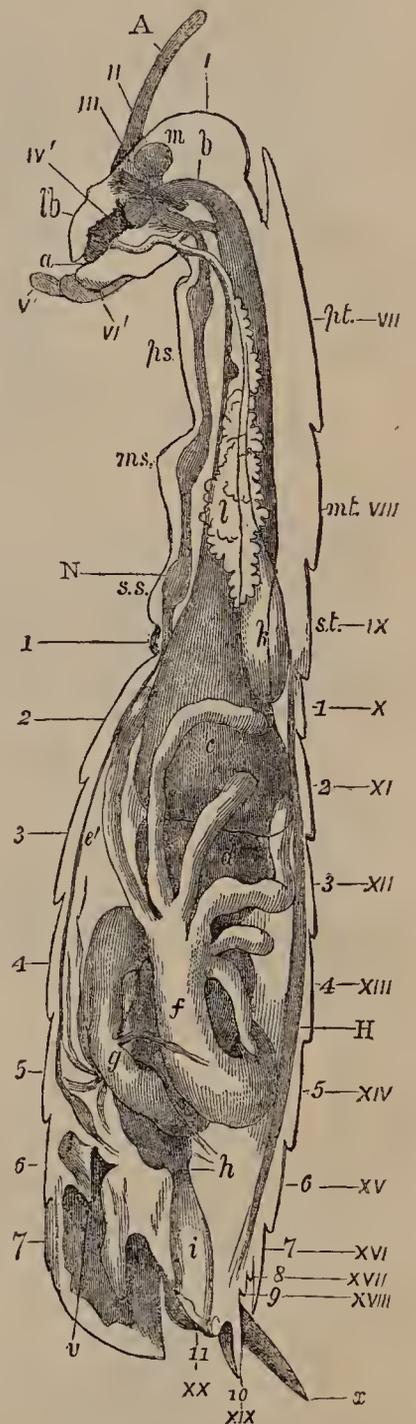

FIG. 10.—Longitudinal and vertical section of a female Cockroach (*Blatta*). 1 to 22, Somites of the body; 1 to 11, somites of the abdomen; *A*, antenna; *lb*, labrum; *a*, mouth; *b*, œsophagus; *c*, crop; *d*, stomach; *e*, pyloric cæca; *f*, *g*, *h*, intestine; *i*, rectum; *v*, vulva; *k* *l*, salivary gland and receptacle; *H*, position of heart; *m*, cerebral ganglia; *N*, thoracic ganglia; *x*, palp-like appendage.

can be enunciated, which shall be true of all the members of the group.

It is this extreme elasticity, if I may so speak, of the crustacean type which renders the construction of any definition of the *Crustacea* which shall include all its members and exclude the next class, the *Arachnida*, so difficult. For the Spiders, Scorpions, Mites, and Ticks, which constitute this class, possess all the characters which have been just stated to be common to the *Crustacea* save one; when they are provided with distinct respiratory organs, in fact, these are not branchiæ adapted for breathing aerated water or moist air, but are tracheal tubes, or pulmonary sacs, fitted for the breathing of air directly, and not by the intermediation of water. But then many of the lower *Arachnida*, like the lower *Crustacea*, are devoid of special respiratory organs, and so the diagnostic character fails to be of service.

The following common characters of the *Arachnida*, however, help out our diagnosis in practice. They never possess more than four pairs of locomotive limbs, and the somites of the abdomen, even when the latter is well developed, are not provided with limbs.

In the higher *Arachnida* (Fig. 8), as in the higher *Crustacea*, the body is composed of twenty somites, six of which are allotted to the head; but in the former class one of the two normal pairs of antennæ is never developed, and the eyes are always sessile, while, in the highest *Crustacea*, the eyes are mounted upon movable peduncles, and both pairs of antennæ are developed.

The *Myriapoda* (Fig. 9) have the chitinous integument; the body divided into somites, provided with articulated appendages of the former groups, and nervous and circulating organs constructed upon a similar plan to theirs. The body consists of more than twenty somites, and those which correspond with the abdomen of *Arachnida* are provided with locomotive limbs.

The head consists of at least five, and probably of six, coalescent and modified somites, and some of the anterior segments of the body are in many genera coalescent, and have their appendages specially modified to subserve prehension. The respiratory organs are tracheæ, which open by stigmata upon the surface of the body, and the walls of which are strengthened by chitin, so disposed as readily to pull out into a spirally coiled filament.

The *Insecta*, lastly, have respiratory organs like those of the *Myriapoda*, with a nervous and a circulatory system disposed essentially as in this and the two preceding classes. But the total number of somites of the body never exceeds twenty. Of these five certainly, and six probably, constitute the head, which possesses a pair of antennæ, a pair of mandibles, and two pairs of maxillæ, the hinder pair coalescent, and forming the organ called the "labium."

Three, or perhaps in some cases more, somites unite and become specially modified to form the thorax, to which the three pairs of locomotive limbs, always present in insects, are attached.

An additional two pair of locomotive organs—the wings—are developed in most insects from the tergal walls of the second and third thoracic somites. No locomotive appendages are ever developed from the abdomen, but the ventral portions of the abdominal somites, from the eighth backwards, are often metamorphosed into apparatuses ancillary to the generative function (Figs. 10 and 11).

## A CLINICAL LECTURE

ON

### MENORRHAGIA DEPENDING ON MORBID CHANGES IN THE OVARIES.

DELIVERED AT

The Middlesex Hospital,

BY

W. O. PRIESTLEY, M.D.

GENTLEMEN,—The term "Menorrhagia" is very commonly applied to all cases in which unusual and profuse losses of blood take place from the unimpregnated uterus. And yet, strictly speaking, "menorrhagia," which means over-profuse menstruation, is applicable only to a limited number of such instances. Abnormal uterine hæmorrhage is, in truth, but

one of the symptoms which give evidence of some probably existing morbid state in the uterus and its appendages, and it may be produced by several separate and distinct pathological conditions. It is, for example, the common attendant of uterine congestion and hypertrophy, of fibroid tumours, of the various forms of polypi, and of cancer; and when it is caused by these diseases, however convenient it may be to speak of it as menorrhagia, the bleeding cannot then be regarded as an abnormal form of menstruation, inasmuch as the function of menstruation is in no way concerned in the appearance of the discharge.

The form of uterine hæmorrhage to which I propose to direct your attention to-day may, without any lack of precision, be designated "menorrhagia," because the ovaries are supposed to take the initiative in the production of the morbid flow of blood from the uterus, much in the same way that they take the initiative in the order of events which results in the production of the catamenia under healthy circumstances. It is, I believe, of common occurrence, and yet the subject is involved in much obscurity, not only because the ovaries, when situated in their natural anatomical position, are in most cases with difficulty accessible to our methods of examination, but also because the exact relation between the physiological processes which take place in the ovaries and the functions performed by the unimpregnated uterus are yet very imperfectly understood. What we *do* know, however, of the anatomical changes which take place in the organs of generation at the menstrual periods in women, greatly aids us in arriving at intelligent conclusions as to the pathology of this morbid condition. It is now well ascertained that as each catamenial period comes round, the ovaries become swollen, and one or more of the Graafian vesicles imbedded in their substance become matured, and approach the circumference of the organ for the purpose of being discharged subsequently into the trumpet-shaped extremity of the Fallopian tube. Coincident with these active changes in the ovaries, the uterus and the pelvic organs generally receive an increased supply of blood, and the congestion thus produced results in the catamenial flow. Menstruation being completed, the congestion subsides, and in the unimpregnated and healthy woman the generative organs resume their original quiescence.

Various circumstances may, however, conduce at the catamenial periods to excite a state of hyperæmia in the ovaries and uterus, which proceeds beyond the limits associated with normal menstruation; or the hyperæmia, without being excessive in degree, may be prolonged beyond the time when the menstrual molimen ordinarily passes away. In the one case it probably gives rise to excessive loss of blood, which is confined to the ordinary number of days occupied by the catamenia; in the other, the menstrual discharge is prolonged beyond the usual number of days. In some cases, again, by a combination of the two conditions, the menstrual discharge is not only extremely profuse during the usual period, but also prolonged much beyond the time at which it ought to cease. But I may go farther than this, and state what I believe to be the fact, that uterine hæmorrhage may be provoked at any time in the interval between the catamenial periods, if the ovaries become the seat of morbid changes which assimilate themselves to those active processes which take place at the menstrual times. If one or both ovaries become congested, whatever be the cause, the excitement in the ovaries may be followed by uterine congestion, and the congestion be relieved by uterine hæmorrhage.

In this way we may have an irregular and morbid form of menstruation, and yet the phenomena occurring, so far as anatomical conditions are concerned, in the same order as during healthy menstruation.

Congestion and inflammation of the ovaries are not, however, invariably accompanied by menorrhagia, and it is not always easy to disentangle the evidence such cases afford, and to trace with precision the primary cause of the hæmorrhage. Apart from the presence of organic disease, loss of blood takes place from the uterus as the result of various causes, and in many of these instances the ovaries are not at fault, and there is no coincident turgescence of these organs. When no fibroid tumour is present, when there is no polypus, no cancer, or other of the graver diseases which are commonly attended by hæmorrhage, the uterus may become congested, because there is some derangement in the chylo-poietic viscera, and loss of blood from the uterine mucous membrane is the consequence. Or the general condition of the blood may be so deteriorated and impoverished by kidney disease, or some

other debilitating cause, that it can scarcely be retained in its customary channels, and it escapes more readily from the uterus than elsewhere, because, in addition to the influence of gravitation, its mucous membrane is so constructed that blood can be poured out easily on its surface, as we see it in the performance of its ordinary periodic function. Moreover, such attacks of ovarian irritation as lead to uterine congestion and hæmorrhage cannot be frequently repeated without leading to persistent congestion and even hypertrophy of the uterus. This, of course, increases the tendency to hæmorrhage from slight causes, and so far complicates the diagnosis, that it is often extremely difficult to trace out accurately whether the malady originally began in the uterus or ovaries. In many instances, nevertheless, the evidence is sufficiently clear to lead to correct inference. The diagnosis is often facilitated by the ovary or ovaries being so displaced downwards that they are within reach, and their condition can thus be ascertained by the touch. The tendency of ovarian congestion is to produce increased weight of the ovaries, and by its long continuance the ovarian ligaments become so elongated that the ovaries themselves lie in the retro-uterine cul-de-sac of peritoneum, where they can be felt both by the vagina and rectum.

The following is the short history of a patient whose presence in Prudhoe Ward has led me to bring this subject before you. The case is abridged from the notes of Mr. Spanton, the obstetric assistant:—

*Case 1.*—E. K., 21 years of age, unmarried, and a lady's-maid, was admitted into the Hospital nearly two months ago. The patient was of middle height and well proportioned, with dark hair and eyes. Her countenance was anæmic, and her lips, gums, and conjunctivæ very pale. She said she had been almost constantly unwell for six weeks, and complained of great weakness, aching pain in the loins and right iliac region, great depression of spirits, and inability to follow her occupation. The tongue was clean but very pale, and her pulse was slow, weak, and easily compressed. There was no distension of the abdomen, and pressure only caused slight pain in the hypogastric and right ovarian region. She had no tenesmus and no dysuria. It was elicited with some difficulty that the patient had an illegitimate child at the full period about a year before. The labour was natural, and convalescence up to a certain period satisfactory. On beginning to go about afterwards, she experienced pain in the uterine region, which sometimes extended over the whole abdomen. At this time there was no history of rigors, fever, or sudden accession of pain, and she went to Brighton in the hope of improving her general health. The catamenia recurred regularly after the confinement, but the discharge was too profuse, lasting eight or nine days, and was accompanied with unusual lumbar pain and lassitude. The last two or three regular periods had been attended by much more severe pain, localised in the right iliac region, and for nearly two months the catamenia had not ceased to flow for more than a day or two at a time, and had sometimes been very profuse.

On examination by the vagina, the uterus was found somewhat swollen, but otherwise healthy. Both ovaries could be reached by pushing the finger up behind the uterus, but the right ovary was so prolapsed that it was on a level with the os uteri; it was considerably enlarged and rounded in its outline, and very sensitive to the touch. A copious discharge of fluid blood poured from the os uteri.

The patient was ordered to be kept in bed, to have simple diet, and to take a mixture containing dilute sulphuric acid every six hours, with an occasional opiate to soothe the pain when severe.

Great care was taken to regulate the bowels, which were inclined to constipation, and to keep the patient in the horizontal posture. In four days after admission the menorrhagia ceased and the pain abated, but the ovary, when examined from time to time, was still swollen and tender. Subsequently she was ordered a more liberal diet, with port wine, and to take the following draught three times a day:—℞ Ferri sulph., gr. iss.; magnes. sulph., ʒj.; acid. sulph. dil., mʒ.; infus. quassia, ʒj. mft. haust.

Three weeks later the sanguineous discharge returned in moderate quantity, like a regular period. It was unaccompanied by much pain, and lasted about six days. In about six weeks from the time of admission she left the Hospital much improved; she was weak and pale still, but free from pain, and had no hæmorrhage. The uterus was healthy, and the right ovary, though still prolapsed, was but

slightly tender; it was much diminished in size, and its surface could be felt distinctly corrugated, like the shell of a walnut.

The detection of the enlarged and tender ovary, and its association with the pain experienced in the right iliac region, the absence of any sufficient cause for the continued loss of blood either in the uterus or in the constitutional condition of the patient, sufficiently justifies the inference that the symptoms described were produced by undue and prolonged excitement in the ovary. The case is a mild one of its kind, the pathological condition readily subsiding under the influence of rest and appropriate treatment. But instances are not infrequent in which the symptoms are much more aggravated in their character, and in which pain and uterine hæmorrhage are present in a much greater degree. Few cases indeed are exactly alike in their various phases, and they differ not alone in the intensity of their symptoms, but in various other points. In some patients, ovarian irritation manifests itself as one of the forms of dysmenorrhœa, severe pains being experienced in the ovarian region, chiefly about the time of the regular menstrual periods, which are attended by large losses of blood; but yet the hæmorrhage occurs only at those times, and subsides when the period is past. In these cases there is ordinarily no sufficient cause for the symptoms to be found in the condition of the uterus, but one or other ovary is frequently felt prolapsed into the retro-uterine cul-de-sac, enlarged and sensitive to touch even during the menstrual interval, but more swollen and sensitive still before and during a menstrual period. Sometimes the discharge is mixed not only with coagula, but also with distinct membranous shreds. The late Dr. Edward Rigby, to whom we are indebted for various useful contributions to our knowledge concerning these morbid changes in the ovaries, held the opinion that the variety of painful menstruation which is characterised by the formation and expulsion of the so-called dysmenorrhœal membranes had its origin primarily in the ovary, and that those membranes which are now known not to be inflammatory exudations, but the separated mucous laminae from the interior of the uterus, were formed in sympathy with morbid changes going on in the ovary, just as the true decidua is formed in consonance with those physiological changes which take place as the result of impregnation. Some obstetrical writers regard membranous dysmenorrhœa rather as the result of uterine congestion which has not been primarily and essentially provoked by ovarian irritation. A beautifully injected preparation in this museum, taken from the body of a woman who suffered during life from membranous dysmenorrhœa, and who died menstruating, apparently affords some confirmation of Dr. Rigby's view. A dysmenorrhœal membrane is present in the uterine cavity, and both ovaries are swollen to double their normal size, without cystic degeneration. In other patients some accident determines a sudden accession of ovarian congestion in the interval between two periods. Severe pain of growing intensity is experienced in the lower part of the abdomen, but chiefly referable to the iliac region and sacro-iliac synchondrosis of the side affected. General febrile symptoms may be added, and at length uterine hæmorrhage appears, probably bringing with it an amelioration of suffering. In other patients, again, repeated attacks occur of an irregular character, separated by weeks or months, are not traceable to any immediate exciting cause, and are attended by variable symptoms. I have remarked that women who are the subjects of these repeated attacks often menstruate profusely and painfully as a habit, and in more than one instance in which sudden accessions of ovarian pain, followed by uterine hæmorrhage, have been repeated, I have found evidence of inflammation extending from the ovary to contiguous parts,—pelvic cellulitis or local peritonitis being lighted up around the ovary, which was the centre of the mischief. The following case is an illustration in point:—

*Case 2.*—Mrs. L., a married lady, of 35 years of age, who had borne no children, and who menstruated regularly, but always very profusely, some periods almost amounting to flooding, was seized during a menstrual interval with what she considered to be a severe bilious attack, having previously had several illnesses of a like character. When I saw her she complained of severe pain in the lower part of the abdomen, most intense in the left ovarian region, and there increased by pressure. There was violent bilious vomiting, and some uneasiness in the epigastrium and right hypochondriac region. The attack had been ushered in by rigors, frequently repeated, and the pulse was full and bounding,

and beating at the rate of 130 in the minute. There was an intense febrile condition of general system, and retention of urine, the bladder being full, and requiring the use of the catheter, which for several days subsequently had to be employed. Hot fomentations were applied to the abdomen, and calomel and opium, with effervescing saline draughts, were prescribed. On the third day a sanguineous discharge, like the catamenia, began to flow from the uterus, and a day later it was so profuse as to amount to flooding. Relief of pain and diminution in the frequency of the pulse soon followed, and there was no longer necessity for the use of the catheter. Copious menorrhagia continued for ten days, and then gradually subsided. At the end of three weeks from the beginning of her illness she was well, and going about as usual. In three months the patient had another attack, characterised by almost the same symptoms, but with suffering even more intense, and only subdued by large and often-repeated opiates. I made a vaginal examination early on this occasion, my experience of the previous illness leading me to suspect some morbid change in the womb or its appendages. The uterus was somewhat enlarged and depressed in the pelvis, but not very sensitive to pressure. Behind the uterus and to the left side, in the direction of the ovary, there was decided fulness, and pressure with the index finger produced acute pain, which was compared to the stabbing with a knife. Menorrhagia came on five or six days later, and brought with it amelioration of all the symptoms, and ultimately convalescence.

I had an opportunity of seeing this patient two months later in a third attack of like character, but more severe than either of the two immediately preceding. On the third day I found the uterus more tender than before, and there was a distinct irregular swelling, most tender to the touch, in the direction of the left broad ligament and ovary. Menorrhagia came on as usual in the progress of the attack, although the regular period had only ceased a week before. The patient was much reduced on this occasion, recovering more slowly and less perfectly. On examination afterwards, I ascertained that the uterus was fixed to the side of the pelvis by inflammatory deposit about the left ovary and in the left broad ligament, which eight or nine months of careful treatment subsequently did not entirely remove. Since the attack last mentioned, others have occurred to the same patient, and indeed they are easily provoked by fatigue or cold at any time; but I need not go into further details; suffice it to say that, on the whole, the patient's health is recently more satisfactory, her illnesses less frequent, less severe when they do occur, and the catamenia have been much more moderate in quantity for two or three months past, which I am disposed to regard as a very favourable point in the prognosis.

(To be continued.)

## ORIGINAL COMMUNICATIONS.

### AN ACCOUNT OF THE PHYSIOLOGICAL RESEARCHES OF THE REV. PROFESSOR HAUGHTON, M.D., TRINITY COLLEGE, DUBLIN.

(Continued from page 237.)

THE theory of the Rev. Professor Haughton with regard to the relation between work done and urea is, that the animal excretions significant of work done are three in number—

1. Carbonic acid.
2. Water (in part).
3. Urea.

Before developing this theory, it is necessary to show why the Professor specially connects the work done with the nitrogen eliminated by the kidney.

If the total excretion of carbonic acid for twenty-four hours, under ordinary every-day conditions of life, were known, this excretion would be gladly assigned its proper place, whatever it be, among the representatives of work done; but this is a question which yet remains to be solved. Prout of old discovered daily and hourly variations in the quantity of carbonic acid evolved by the lungs; Barral, Vierordt, and Dr. Edward Smith have ascertained monthly and seasonal

differences in the excretion of this gas. Temperature, barometric changes, atmospheric moisture influence its formation; internal conditions of the organism, the chemical nature of the food, and, above all, the rhythm of the respiration affect its production. The methods adopted with a view to experiment on this excretion have been inadequate to overcome the great difficulties in the way of a correct estimate of the total quantity evolved in twenty-four hours by an individual in routine life. Coathupe and Prout sought only the percentage amount of carbonic acid in a few cubic inches of expired air, and the total quantity of air expired was not ascertained. Dr. Smith's elaborate observations cannot be regarded as solving the problem, though adding many new facts to our previous knowledge, the gas being collected for short periods of each hour, and the conduct involved by the carrying out of the investigations certainly not coming under the category of the ordinary every-day condition of life. The experiments of Pettenkofer and Voit with their air-chamber at Munich have surpassed all previous ones in accuracy and attention to minutiae, but the Professor still objects that the ordinary "*opus mechanicum*" of a labouring man cannot be fairly performed in a room of the dimensions of eight cubic feet.

The objections raised against the percentage mode of estimating the excretion of carbonic acid apply with equal force to the means employed to determine the excretion of pulmonary and cutaneous water—the urinary water being of course observable by direct measurement—and, moreover, another difficulty presents itself to those who would discover what relation the water which leaves the animal body has to the work done, namely, how much of the water was formed in the body—a question in vital chemistry not yet answered. The greater part of the water excreted entered the body as such, and therefore, as it leaves the body in the same condition as it entered it, it represents no work done; the two difficulties, then, with regard to the excretion of water by the skin and lungs are, first, to find the total quantity, and then how much of this quantity was formed in the body. The Professor has felt himself inevitably forced by the difficulties attending the correct estimation of the excretions of carbonic acid and water to regard the excretion of urea, which is easily measured, as an exponent of the whole work. He reluctantly adopts a partial solution of the problem of work in the absence of any better one, not under-estimating the significance of the other excretory products, but regretting that in the present state of our knowledge we are unable to appreciate them.

As before mentioned, the division of work adopted by Professor Haughton is fourfold.

- a. *Opus vitale.*
- b. *Opus calorificum.*
- c. *Opus mechanicum.*
- d. *Opus mentale.*

The first two of these divisions are correlated, and are necessary to the life and health of the individual, but the at present unknown quantity of carbonic acid eliminated by lungs and skin, when determined, will probably fully account for the *opus calorificum*, so that there remain three descriptions of work, the equivalents to which, in grains of urea, are sought for.

For examples of *opus mechanicum* were taken the work done in pedestrian exercise; shot-drill, common drill, oakum picking, in the military prison, and the labour of paviers employed in the streets. The mode of estimating the work done by a person of a given weight walking is to find what the one-twentieth part of the weight of the body lifted through the distance walked amounts to. By No. 1, in table B (see former number), who walked three miles daily, and weighed 173 lbs., the work done in walking was equal to 61.1 tons lifted through one foot; the work done by the prisoners employed at shot-drill is estimated at 160.7 tons lifted one foot; at common drill, 66.5 tons; and at oakum picking, 83.1 tons lifted one foot. By equations deduced from these facts (for which we refer to the Professor's original papers), he finds that the amount of urea equivalent to the pedestrian exercise, or mechanical work done by No. 1, table B, was 24.2 grains, and the amount, representing the mechanical work done by the prisoners at shot-drill, common drill, and oakum picking was 120 grains a man, and comparing together the individuals who differ only in the labour they perform, by some other equations, he finds that the *opus vitale* of a man of 150 lbs. in weight is represented by 297.7 grains of urea per pound weight of body.

This is the excretion of urea necessary to keep 150 lbs. weight of man alive for four-and-twenty hours, and may in round numbers be called 300 grains; from which it follows that each pound weight of living man requires an expenditure of work, represented by two grains of urea per day to keep it alive, and prevent it from becoming subject to the ordinary chemical laws of inert matter. This calculation does not include the *opus calorificum*, or work necessary to keep the skin at a constant temperature of 90° F., nor the additional force requisite to vaporise the perspiration from a fluid to a gaseous condition, during which vaporisation 1000 times more heat is absorbed and rendered latent than the perspiration held as a fluid.

The remarkable result that the minimum excretion of urea absolutely indispensable to health is two grains per pound weight of living man, deduced from observations made on persons in perfect health, has since been confirmed by the determination of the discharge of urea in diseased conditions, the excretion of a less quantity entailing the symptoms of uræmia or ammoniæmia.

The subjects experimented on, who worked their minds, either did so at "office work" or high class teaching, with severe study preparatory to it. Nos. 2 and 4, table B, were employed in "office work" three and six hours respectively; Nos. 1, 5, and 6, studied five, four, and four hours severally. Both kinds of mental labour indicate a waste of tissue of a higher order than that involved in the common *opus mechanicum*, as seen by a comparison of the equivalent excretion of urea during a day's labour in each.

- |  |                           |
|--|---------------------------|
| 1. <i>Opus mechanicum</i> , or 150 lbs. lifted one mile, | } = 136.5 grains of urea. |
| 2. <i>Opus mentale</i> , or five hours study,            |                           |
| 3. <i>Opus mentale</i> , or eight hours office work,     | } = 217.0 grains of urea. |
|  |                           |
|  | } = 221.7 grains of urea. |
|  |                           |

The waste of tissue here demonstrated to be involved in the *opus mentale* required in teaching and in the preparation for it, is a scientific explanation of our dearly-bought experience as to the results of overtaxing the powers of mental labourers, and a corroboration of the fact that the finer operations of the animal machine require superior food. Men employed only in manual or routine bodily labour are sufficiently well fed on vegetable diet, and discharge on an average 400 grains of urea per day, of which 300 grains are spent in vital, and 100 in mechanical work; a statement in conformity with the experience of the mass of mankind employed in manual labour in all ages and countries; but when the work is of a higher order, a better pabulum must be supplied, sufficient to allow of a discharge of 533 grains per day of urea, of which 300 grains, as before, are spent in vital work, and 233 in mental work and the mechanical work necessary to keep the body in health.

The following Table exhibits the Work done, expressed in Urea Grains, and divided into its Component Parts:—

No.	Total urea.	Opus vitale.	Opus mechanicum.	Opus mentale, etc.
Table B, No. 1 . . . . .	367.5	343.3	24.2	—
„ Nos. 2, 3, 4, 5 . . . . .	400.6	279.8	120.8	—

## A CASE OF REMARKABLY PROLONGED AND PROFOUND SLEEP, WITH REMARKS.

By JOHN WARD COUSINS, M.D. Lond., F.R.C.S.,  
Surgeon to the Royal Portsmouth Hospital.

J. C., a farmer, aged 43, has been subject at intervals during the last twenty years to attacks of deep and prolonged sleep. He has never suffered from any disease of the brain, or any other illness. The disorder commenced without any assignable cause in the year 1842, and continued nearly a whole year. It returned again in 1848, and having persisted without interruption for eighteen months, it left him entirely for the space of twelve years. The present attack commenced on May 19, 1860. Since that time he has not slept naturally.

He retires to bed at night soon after 10 p.m., and almost immediately falls into a profound sleep, from which all the means at present adopted have failed to arouse him. He generally sleeps on his side, and appears like a person in refreshing slumber. His face and ears are pale; skin generally warm; but the feet are often cold and livid. Pulse slow and feeble; pupils generally somewhat dilated; respiration very gentle and shallow. He seldom moves, but occasionally he turns over from one side to the other. He never snores or moans. He awakes suddenly, without giving any warning, and he always seems refreshed, just as if he had slept naturally. Occasionally he complains of a slight pricking sensation in the forehead.

The longest period he has ever passed in profound sleep is five days and five nights. Lately, he has frequently slept three days, and occasionally four without waking, but the average time is nearly two days. He is awake about four or five hours out of forty-eight. During these remarkable sleeps he never dreams, and the contents of the bowel and bladder are always retained. Before he falls asleep, he says that he "sometimes feels stupid;" but this is the only head symptom he ever complains of. His memory is good. When he awakes he remembers everything that happened the day before he began to sleep, and always asks, "How long have I slept?"

Lately, he has looked pale, and has lost flesh. His appetite is good, and the bowels are active. His manner is quiet and his disposition amiable. He is a good man of business, and is fond of reading. In intellectual power he is by no means deficient, but his early opportunities have been limited.

During the attack in the year 1848, he frequently suffered from spasmodic trismus, which generally commenced soon after he awoke, and persisted for many hours. His jaws were always firmly locked, and at the same time he complained of pain in the back and neck. This affection, however, has never reappeared.

*Remarks.*—There are many authentic cases of prolonged sleep on record, and they admit of a division into three classes—1. It occurs as a primary affection arising from an altered state of the cerebral circulation; this is very rare. 2. As a secondary disease depending upon organic changes within the brain. 3. It occasionally happens from an overdose of alcohol or opium. After an analysis of the case above, it appears to me that it may be fairly placed under the first division. It consists essentially in a modification of ordinary sleep, depending upon an anæmic and faulty nutrition of the brain. From some condition of this central organ or its blood-vessels those changes are deficient which are necessary to a due supply of nervous force; hence there is a persistent torpidity or suppression of the cerebral functions. This explanation of the phenomena of the case is based upon the following considerations:—

1st. The general condition of the body during sleep. The limbs are relaxed, the surface generally pale, and the extremities often cold and livid. The pulse is soft and slow, respiration almost imperceptible—about eight or nine inspirations in a minute. He looks like a person in a refreshing slumber. The secretions are always scanty, which clearly proves the torpidity of the organic functions of the whole body.

2ndly. The characteristic condition of the external ear. Dr. Laycock has shown by his interesting investigations that the state of the circulation and nutrition of the external ear is very commonly associated with a similar condition of the brain, or, in other words, that the vascular activity and nutrition of the brain is indicated by the vascular activity and nutrition of the external ear. Now the ears of my patient are both habitually flaccid and pale, and very remarkably so during a long sleep. This is therefore additional evidence of the very imperfect vascular energy and faulty nutrition of the encephalic tissues.

3rdly. The profound and prolonged character of the sleep. During healthy slumber, an impression upon a peripheral nerve may unconsciously influence the brain and give rise to an unconscious movement; thus an uneasy sensation often does occasion a change of position. Now, although these actions, as Dr. Carpenter says, "are purely consensual, being as automatic as if they were reflex movements," still they are sufficient to prove that the nerve centres are just capable of receiving an impression, and therefore cannot be wholly dormant; moreover, strong impressions upon the various organs of sense are always sufficient to rouse the brain, and produce a return of consciousness. My patient, on the other hand, when asleep, lies profoundly still,

and seldom moves a limb. The special senses are likewise insensible to the strongest stimuli. A bright light has been poured upon the eye, and an alarm bell rung over the head; he has been dashed with cold water, and then rubbed generally over the body, but without the slightest indication of awakening. This is strong evidence of the entire dormancy of the cerebral organs; the spinal cord and medulla being alone active, by which the reflex actions are slowly carried on.

Again, the brain during natural sleep is often completely inactive, yet there are few, if any individuals, who do not in ordinary health either habitually or occasionally dream. Often the various grades of sleep occur during the same night—the first hours of repose are profound, but when the brain has reached a certain stage of reparation and nutrition this is succeeded by a less perfect slumber attended with dreams, until at length a state of half sleeping is reached. Dreaming is due to a partial or irregular activity of the hemispheric portions of the brain, so that mental manifestations are not completely in abeyance. It can be induced by whatever promotes congestion and increased circulation through these organs. From these considerations, it appears highly probable that the various grades of sleep are directly connected with the various states of cerebral nutrition and circulation, and that habitually profound sleep, and an entire absence of dreaming, are associated with deficient supply of blood and extreme vascular inactivity.

After six or eight hours, healthy sleep terminates spontaneously. Consciousness returns after the exhaustion and waste of the body has been silently repaired, and a fresh supply of nervous force developed. The nourished condition of the nerve centres rouses the body again into activity, by sending a spontaneous rush of nervous power to the muscles,—the limbs are stretched, eyes opened, features expanded, and thus the senses are exposed once more to the influence of the outer world. That spontaneous waking must be due, then, to a change within the nerve centres themselves, is proved by the fact that movement precedes sensation. The application of these remarks to my case is apparent. The sleep is prolonged just because the nerve centres are charged so slowly with that mysterious nervous power, in consequence of the languid cerebral circulation, and the imperfect nutritive changes in the ultimate nervous tissue. The act of awakening is thus delayed for the want of that burst of nervous force which is essential to a spontaneous revival of consciousness.

4. There is an entire absence of any head symptoms, and the general health is fairly sustained. Before going to bed, he experiences only the common sense of fatigue after a day's exertion. He awakes refreshed, and with every mental faculty entire.

Now, when these prominent features of the case are placed together, viz., the general condition of the body, the habitual state of the external ear, the insensibility of the organs of sense and seats of sensation, the profound character of the sleep, and the absence of all other nervous symptoms, they appear to me plainly to indicate that the prolonged suppression of all the mental faculties is dependent upon anæmia and faulty nutrition of the brain. We may suppose either that there exists some change in the minute structure and capillaries of the nervous substance, or that the diminished vascularity and imperfect nutrition may arise from an alteration in the calibre of the larger vessels which supply the head; as in a case of coma from narrowing of the carotid arteries, referred to by Dr. Copland in the first volume of the "Medical Dictionary," page 392.

It is a well-established physiological principle, that the circulation of arterial blood through the various organs of the body is increased and diminished in direct proportion to the functional changes taking place within them; therefore we have much reason to believe that the brain has a less vigorous circulation during healthy slumber than in the waking state, when it is the seat of all the exalted phenomena of mind. This view is supported by the important observations of Durham, Brown, and Ackerman, who have found that the blood-vessels of the brain are empty in the sleeping state compared to their fulness during waking hours. Very lately this opinion has been corroborated by Dr. Hughlings Jackson, who has shown, by examining the eye during sleep, that the optic disc and retina are paler and the arteries smaller. I hope before long to have an opportunity of making an ophthalmoscopic examination in my case.

The occurrence of trismus during the attack of 1848 appears to have been a subordinate symptom, and by no means an essential part of this singular disorder of the nervous system,

for it was entirely absent in the first attack, and has not yet reappeared in the present one. It probably originated in some eccentric irritation, which, in consequence of an increased reflex excitability of the medulla oblongata and pons Varolii, was reflected upon the muscles of the lower jaw. But, although the associating links between this and the other facts of the case are very obscure, still it is possible that all of them may have had a common cause in reflex action,—as contraction of the blood-vessels of the brain, and consequent alteration in the nutrition of its substance, may be generated by an irritation of some centripetal nerve.

My patient resides many miles in the country, so that I have been prevented from adopting a satisfactory course of treatment. The indications are,—1st. To improve the nutrition of the nervous system by general tonics (especially quinine and iron), generous diet, and moderate exercise. Belladonna deserves a trial theoretically, as it appears to possess the power of producing dilatation of the capillaries of the brain. 2nd. During sleep the body should be kept warm, and stimulating and nutritive enemata freely administered; and, after twelve hours, a persistent effort should be made to arouse him by general friction and galvanism.

## BRIEF NOTES OF TWO CASES OF VESICO-INTESTINAL FISTULA,

ONE OF WHICH WAS COMPLICATED BY AN EXTERNAL FISTULOUS OPENING THROUGH THE ABDOMINAL PARIETES.

By F. BAINBRIDGE, of Harrogate.

THESE cases I should have offered for publication at the time they came under my care, had any points of interest occurred in the treatment likely to have resulted in benefit to others who might be similarly afflicted; but as this was not the case, the record of these and similar cases tends to prove only what an extensive amount of disease the human constitution can tolerate for years without giving way, or even indicating the mischief to which that constitution must ultimately succumb; and, as it appears to me, it is this tolerance of the system in slowly-developed disease which constitutes the chief point of interest in these rare and incurable complications of disease. But, without further preface, except to state that it was the report of Mr. McWhinnie's case in No. 654 of the *Medical Times and Gazette* that tempts me now to add these two to his and any similar cases which may be published.

Mrs. L., aged 43, has been married twenty years, but without issue. Catamenia ceased several years since. Has occasionally for three years previously been under my care for dyspepsia, with disordered urine, and has as often obtained relief. On the present occasion, however, February 24, 1851, she called on me, and described her symptoms as unusually urgent; dull aching about the loins, and under pressure deeply-seated pain above the pubes; pain also and scalding during, previous to, and after micturition, at which time small quantities of urine only are voided. She speaks of a thick deposit from the urine, and insists that it contains bits of her food, such as potato, meat, and gooseberry seeds from the jam, of which she is fond. Upon this point I imagined that she might be deceived; for how, I asked myself, could her system be so tranquil under such a source of irritation as a communication between the bladder and the bowel allowing of half-digested food and free bile to pass into the former organ. Her pulse was 66, and feeble; tongue watery, glossy in the centre, and pointed; bowels rather costive. Enemata of soapy water were ordered, and henbane and sodæ sesquicarb. given internally. According to request, my patient brought me next morning six ounces of her urine, passed between the hours of one and six in the afternoon, in which, as she had stated, portions of comminuted food were visible, mixed with and partially suspended in a thick cloud of mucus, which speedily subsided when set at rest; specific gravity 10·22, feebly acid. So evident were the portions of food as to enable me to tell my patient that she had dined on boiled beef and brown bread.

February 26.—I visited her at her own house, and found her better; less deposit in the urine, on voiding which the pain and scalding were diminished. She states that she is losing flesh, but that this is usual in the winter months, being always better when engaged in her occupation of washer-woman by our summer visitors.

It will not surprise those who have many dealings with the

uneducated part of the community when I record the difficulty encountered in obtaining the history of her disease, and that the fact of her having suffered from a large abscess twelve years previously, which remained open for two years, discharging its contents through an external aperture midway between the umbilicus and pubes, and which healed of its own accord, was one of the last discovered, and yet one of the most leading symptoms tending to throw light upon her malady.

I saw the patient repeatedly up to March 22, on which day at my request Dr. Bennett visited her with me, and came to the obvious conclusion that an opening, either direct or fistulous, existed between the small intestine and the bladder; moreover, that as the disease was incurable, the indications to be fulfilled were to keep the bowels soluble, avoid crude ingesta, and support the strength.

January 1, 1853.—Since the last date the subject of these notes has consulted other Medical men, but without any alleviation of her symptoms or suffering, and came back to me, as having given her more relief than any one else. She then stated that for several months an abscess had existed nearly in the site of that formerly named, on examining which I found an opening the size of a goose's quill, through which were discharged bile, purulent and faecal matter ex-coriating the abdominal parietes for several inches around the aperture. On examination of the urine, I found that it contained pus, albumen, bile, and portions of food. Her suffering was at times very great, obliging me to use morphia in large doses, a combination of that salt with carbonate of magnesia proving the most serviceable of anything I tried. Her life was protracted till May 12, on which day she expired from sheer exhaustion.

With much difficulty I obtained an examination of the body, on condition that I would confine my attention to the abdomen. The system was so much wasted as to be absolute skin and bone; the abdominal parietes like parchment, totally devoid of fat, and adherent in many places to the peritoneal coat of the intestines, which in their turn were so completely massed together as to be quite inseparable except by prolonged dissection, which I had not time for. It was thus impossible to trace the exact portion of intestine from which the fistulas led; neither the opening through the wall of the abdomen, nor that into the bladder, but I satisfied myself that both communications were from the ileum. The urinary bladder was nearly empty, somewhat thickened, and opaque; the abnormal opening was situate at the antero-posterior portion, rather to the left side; this opening surrounded by a thickened margin like a ring, from which I was able to inject water, which, by a tortuous course, reached the abdominal surface, thus proving the connection between the two apertures. The bladder was perfectly adherent to the uterus, which was itself perfectly schirrus, together with the ovaries, that on the right side being adherent to the fundus vesicæ. An old abscess, containing degenerated pus, existed between the muscular layers above the pubes. The stomach was thin and congested; the kidneys and liver congested; the gall-bladder full.

Case 2.—April 16, 1854, I was sent for in haste to Robert Chapman, aged 56, with a statement that he could not pass his water; I therefore took with me a box of catheters, and on arrival found him straining over a chamber-vessel, into which at brief intervals fell pipe-shaped pieces of yellow faecal matter, which he urged along the urethra at the rate of an inch per minute. I waited until about half a wine-glassful was extruded, when, from a sudden exclamation of pain and a stoppage of the flow, I at once introduced a catheter, which I kept pervious by repeatedly introducing the stilette. The process was tedious, but effectual in draining off about six ounces of turbid faeculent urine, which for that time relieved him. This was the first time I had attended the poor fellow, though I had frequently observed him standing near his home, as I then thought from indolence, but as I now learnt from disease, he being afflicted with mitral disease, asthma, and ascites, and, according to his own account, had had inflammation of the bowels some few years since, to which account he added that he had passed small, rough stones with his urine. My attendance was continued to May 19, 1854, on which day his wretched existence terminated by rapid peritonitis which had set in but a few hours previously.

Note.—From the faeculent matter which was voided by the urethra being identical in consistence and colour with that passed *viâ* ani, I conclude that the fistula existed between the *rectum* and bladder.

## REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

### ST. THOMAS'S HOSPITAL.

#### CASE OF OVARIOTOMY.

(Under the care of Mr. SIMON.)

A. W., aged 22, single, in service, observed about four years and a-half ago a slight but persistent swelling on the right side of the abdomen, the periodical return of the menses ceasing about the same time. From that date the tumour slowly but progressively increased, its development being unattended by constitutional symptoms, and the patient continuing to enjoy tolerable health. She was received as an in-patient at St. Thomas's Hospital, under the care of Dr. Bennett, November 2, 1861 (nearly three years after she had noticed the first appearance of the tumour). The case being diagnosed as one of ovarian dropsy, the patient was shortly afterwards tapped, though about half-a-pint only of clear fluid was evacuated. The size of the abdomen was not appreciably diminished by the operation, and the patient left about a fortnight afterwards, being still in a fair state of health, and promising to return at the end of a month or six weeks to undergo the operation of ovariectomy, this measure being considered advisable by Dr. Bennett.

Circumstances, however, prevented her returning until November, 1862, when she came under the care of Dr. Brinton, suffering at the time from an attack of chronic diarrhoea, by which she was considerably reduced in strength. The condition of the tumour was not much altered since the time of her first admission, the size of the abdomen being, however, decidedly, though not greatly increased. With tonics and astringents her condition gradually improved, the diarrhoea ceasing, and her strength partially returning. Under these circumstances it was decided by Mr. Simon, to whose care the patient was now transferred, to operate on February 27.

Previously to operation, the girth of the patient, measured at the widest part, was about forty-eight inches, the distance from the umbilicus to the pubes being rather more than a foot. Before the patient was removed from her bed, the bladder was emptied, and she was placed under the influence of chloroform, as small a quantity being given as was consistent with the production of its anæsthetic effects. She was then removed to the theatre, the temperature of which had been raised to 75°, and the operation commenced. An incision was first made by Mr. Simon, from about two inches below the umbilicus downwards in the median line to the extent of four, the tumour being readily exposed by a few touches of the knife. He then introduced two fingers of the left hand at the upper margin of the incision, carried them upwards between the tumour and the abdominal parietes, and introducing the knife in the interval, extended the incision upwards through the umbilicus to the extent of three inches, the total length of the wound being about seven and a-half. The margins of the opening were then separated, and the tumour grasped and drawn forwards by the forceps. Its walls, however, possessed such little tenacity that they were torn through by the tension exercised upon them, and the fluid contents began to pour out, but were prevented from entering the abdomen by heated flannels, with which all access to the general peritoneal cavity was shut off. Mr. Simon then introduced his hand into the wound, passed it rapidly round the tumour, and turned it out upon the abdomen. Two omental adhesions at the upper part of the tumour, the only ones which existed, were ligatured with silver wire, cut through, and returned into the abdomen. The pedicle, of considerable size, and containing several large vessels, was drawn forward, tightly included in a clamp, and divided. The tumour, being thus severed from its connections, was removed, the pedicle drawn downwards and forwards to the lower extremity of the incision, and the edges of the wound brought together by silver wire sutures. Some pads of lint were placed upon the line of incision, and over the pedicle; two or three broad pieces of strapping were passed with some degree of firmness round the now greatly diminished abdomen, and the operation was completed.

On examining the diseased ovary, it was found to consist of three large cysts, one of which only had been emptied

through the canula; of the remaining cysts, one contained a glutinous fluid of much greater consistency than the liquid in the others. The tumour itself was about a foot in diameter, its total contents being nearly three gallons. The patient appeared somewhat but not greatly exhausted by the operation, her pulse, which previously stood at 80 per minute, having now risen to 90; she vomited three times during the next two hours, seeming at the end of that time more comfortable and inclined to sleep; shortly afterwards she fell into a doze, and remained so for about an hour, her pulse having fallen during that period to 80. A small quantity of brandy or beef-tea was occasionally administered to her during the course of the afternoon, and she dozed a little from time to time, expressing herself tolerably easy and free from pain. At about 7 p.m. the patient's pulse stood at 80, the temperature of the apartment being 70°. At 10 p.m. she became restless, tossing her arms about, but expressing a desire to sleep. Her pulse at this time was still 80 to the minute, but rose slightly during the next three hours. She vomited once between 12 and 2 a.m., but, at the end of that time fell asleep, awaking refreshed, and free from nausea in about an hour. During the remainder of the night she was more comfortable, not being again attacked with sickness, and dozing frequently, although she only remained asleep for about half an hour at a time.

February 28.—Remained comfortable during the day, taking a little beef-tea, milk or egg, and brandy at intervals, and being free from peritonitic pain or tenderness. Towards evening, however, she became a little restless and feverish, her pulse standing at 96 per minute at 7 p.m. Subsequently it declined again, her restlessness also subsiding during the night.

29th.—Slept fairly last night, feeling refreshed, and free from pain or uneasiness in the morning. At 9.30 a.m. the clamp was removed and the wound dressed, the edges appearing to be adherent through the greater portion of their extent. A small portion of the margin of the pedicle was temporarily included in a ligature, which, being drawn forwards and attached to a roll of lint, prevented the former from retracting. From this period the progress of the patient towards recovery was rapid, and unmarked by a single adverse symptom. The sutures were all removed on March 4, with the exception of one near the pedicle, which was allowed to remain until the 5th, and the pedicle itself lightly covered with charcoal, a small piece of muslin being interposed. This mode of dressing was shortly after rendered unnecessary by the healthy condition of the part. At the present time the patient is still in the Hospital, but is quite convalescent, and will shortly be in a fit condition to return home. One of the most noticeable points in this case was the small amount of constitutional disturbance which followed an operation of so severe a character as that of ovariectomy.

## THE LONDON HOSPITAL.

### CASE OF PHLEBITIS SIMULATING PHLEGMASIA DOLENS—DEATH—AUTOPSY—CLINICAL REMARKS. (a)

(Under the care of Dr. FRASER.)

For the notes of this case we are indebted to Mr. Weller.

Sarah N., aged 56, a washerwoman, was admitted into the London Hospital, February 24, 1863. She was a short, stout, muscular woman, of lymphatic temperament, and has had very good general health. She has had four children, the youngest 23 years of age. She has always had good times during her labours, and no hæmorrhage. She has had varicose veins of both legs ever since her marriage. Always after a day's hard work at the wash-tub they have swollen to a great size. For many years she has been troubled with dyspnœa.

About a week before she entered the Hospital, while attending to her domestic duties, she felt a slight tingling sensation in the calf of her left leg. Upon rubbing it a little the pain disappeared. Five days later a similar sensation recurred, and from that time the leg began to swell rapidly, commencing from the thigh, and ascending as far as the groin, and then descending to the foot. During the time the leg was swelling she suffered great pain in the limb, and also in her head, with giddiness and sickness. Upon auscultation, a slight mitral murmur could be heard. The urine since the leg began to swell has been scanty.

(a) See similar case in the "Rapport de la Société Anatomique" for August, 1834.

When admitted, the left leg was as large again as the right. It had a white, shining, and glazed appearance, was tense and elastic to the touch, perfectly cold, and no pulsation could be felt in the posterior tibial artery. She was put to bed, and was ordered a scruple of the calomel and jalap powder; warm fomentations were applied to the leg, and a hot-water bottle to the foot. On examining her at night, a very slight pulsation could be felt at the femoral artery, the leg and foot were much warmer, and the swelling had gone down a little. No enlarged glands could be felt in the groin. The leg was ordered to be wrapped in cotton wool, and enveloped in oil-skin. An effervescing ammonia mixture was ordered, and also twenty minims of the liquor opii to be taken at bed-time. To have for diet, milk, beef-tea, two eggs, and six ounces of wine.

February 25.—The leg is still very much swollen, the urine acid, and loaded with lithates. To have ten grains of the bicarbonate of potash every hour, and a large common enema to be injected. A free motion, but no scybala came away.

26th.—The leg still very much swollen. She complained of pain on pressure in the groin; no pulsation of the femoral could be felt; the pulse 90.

27th.—Much the same; she still complained of pain in the groin. Eight leeches were ordered to be applied over the spot. A dose of castor oil to be taken every morning, so that the bowels should act regularly once a day. A local vapour bath every night to the leg.

March 1.—Better; she was ordered a chop.

3rd.—The swelling much reduced.

4th.—She has passed a comfortable night. To have the local vapour bath at night and in the morning, and continue the other remedies.

On the morning of Friday, March 6, there was little or no swelling in the leg to be seen. She appeared much better, and ate her breakfast with a relish. About one o'clock the same day she was observed to struggle, as if for breath, assistance was called, but before the nurse could communicate with Dr. Powell, the resident Medical Officer, she was dead.

*Autopsy, Twenty-one Hours after Death.*—Lungs healthy. Considerable deposit of fat on the surface and around the base of the heart; all its cavities were dilated; the mitral valve thickened and opaque. In the right (b) auricle was a pale clot, adherent to the appendix, and extending thence into the right ventricle and pulmonary artery, occupying rather more than half the calibre of that vessel, and surrounded by loose and dark coagula. The muscular substance was pale, easily lacerable, and at parts had undergone fatty degeneration. The kidneys pale, but apparently healthy. The liver fatty, weighed 5 lbs. The affected leg was found of normal size. The femoral, popliteal, and saphena veins were distended, hard, and cord-like to the touch, the external coat was thickened, vascular, and infiltrated by plastic deposit. The inner coat was softened, and stained of a deep purple colour. The veins were filled by coagula, the latter externally pale and of tolerably firm consistence, and partially adherent in several places to the lining membrane of the vessels. Towards the centre the clot was soft and dark-coloured, but there were no appearances of suppuration. The other veins of the limb were larger than those of the opposite limb, showing an attempt to form a collateral circulation.

*Clinical Remarks by Dr. Fraser.*—Mr. Weller headed this case "Phlegmasia Dolens," and that he had reason for so doing those of you who saw the case will freely admit, the more so as the swelling was in the left leg, the member said to be the most frequently attacked by phlegmasia dolens; but, when we reflect that twenty-three years had elapsed between her last confinement and the present illness, the idea is dispelled that it had any connexion with parturition. On the other hand, the feeble arterial, femoral, and tibial pulsations raised the question of arterial obstruction; but this view of the case was dismissed on reviewing the other symptoms, and by the simple explanation that the swelling of the parts was sufficient to explain this apparent feebleness. It was therefore placed as a case of "phlebitis," and, as afterwards revealed, a case of "adhesive" phlebitis, as no sign of suppuration appeared. The question now is, was the coagulum primary? and therefore acted as a foreign body, and thereby caused the inflammatory action; or, was the coagulum

(b) An exactly similar case is given by Dr. Richardson (page 405), on "Coagulation of the Blood."

secondary, and the effect of antecedent inflammatory action? From the fibrinous deposit found in the heart—not an offshoot from the deposit in the affected veins—I am inclined to think that the coagulum found in the veins was a consequence of that state of the blood favouring fibrinous deposits, arising from an excess or deficit of fibrin, the presence of septic matters, and greatly aided in this case by a languid circulation through enlarged varicose veins. This subject is too extensive for present notice, and I shall merely observe that the alkaline treatment, and local vapour baths seemed to be most beneficial in reducing “the swelled leg,” and conclude by drawing your attention to a most important feature in the history of the case—viz., the sudden, and, to the bystanders, most unexpected death. The disease was apparently cured, the swelling of the leg was gone, all pain had passed away, the woman was cheerful, hopeful, and looking forward to a return to her domestic circle, when in a minute she is struck with death. The fibrinous deposit in the right heart gives the explanation. The formation of this clot may have been going on for an indefinite time, and it was only when the pulmonary artery became nearly, if not completely, blocked up that the fatal event arrived. The moral is, that we must give in similar cases a guarded prognosis, and especially if there be the slightest cardiac *bruit* in either side, the slightest dyspnoea, or any indication of a tendency to fatty degeneration of the tissues and organs of the body.

### GUY'S HOSPITAL.

#### TUBERCULAR DISEASE OF THE LUNG — ABSCESSES IN THE BRAIN (PYÆMIC?)—SUPPURATION OF THE FALLOPIAN TUBE.

(Under the care of Dr. PAVY.)

ANN H., aged 31. This patient, a strong Irishwoman, was a respectable married woman, and had had one child eight months before. Until the disease of which she died, she had never had a day's illness. She was admitted into the Hospital on February 18. For two weeks before this she had been attending as an out-patient for severe pain in the head. She complained bitterly of the pain. She kept a wet rag on it constantly. The pain in the head was, on admission, the principal symptom, but the breathing became difficult, and she had cough. The pain used to come on ten or twelve times in the day, and was very intense. There was pain in the left psoas region, and she had difficulty in moving this leg.

*Autopsy.*—The following is copied from Dr. Wilks' records: There was no disease of the bones. On removing the dura mater, a small tumour was found growing from its posterior part near the longitudinal sinus; it was imbedded into the posterior edge of the hemisphere; it was firmly attached to the dura mater, and its surface was vascular, as if covered by arachnoid; it was the size of a grape, and when opened was found to contain liquid pus, which poured out, leaving a thick cyst wall. There was no appearance of scrofulous disease about it. In the brain substance were three other abscesses exactly like the one described, each having a thick cyst wall, which could be easily turned out, and which was vascular on its surface. The interior contained fluid pus, which flowed out. They were all close to the surface, and projected slightly, so that their position was indicated from without. They also seemed, in two places, to have pushed the grey matter before them, as this was seen on their inner side. They were about the size of small chestnuts, and quite round. One was situated near the vertex, in the right hemisphere; another on the under surface of the left anterior lobe; and the third partly in the cerebellum and partly in the crus cerebelli. The only approach to tubercular matter was a small patch of yellow matter which closely adhered to the surface of the right hemisphere. This was nearly as large as a pea. The *lungs* were filled with tuberculous matter from apex to base. The tubercle was yellow and soft. There was no abscess and no disorganisation. The left *Fallopian tube* was very much distended and tortuous, its extremity being attached by adhesions. When opened, some mucus flowed out at its end, but nearer the uterus it was filled with soft, tuberculous, purulent matter. When the fluid part was removed, the interior was seen to be covered with tuberculous matter, and this proceeded to the uterus, the interior of which contained a similar material as the mucus near the opening of the tube.

#### DISEASE OF THE TEMPORAL BONE—PYÆMIA—DEATH—AUTOPSY.

(Under the care of Dr. REES.)

THIS case is similar to the one related in our Hospital Reports, February 21, in that acute cerebral symptoms followed on caries of the cranial bones. In that case the caries (of the frontal) followed an injury, but in this it was the result of disease of the ear, extending to the temporal bone. As will appear by many cases related by Mr. Toynbee, a patient who has discharge from the ear is not to be considered safe, although he may have escaped ill consequences for many years. In Dr. Rees' case there is unfortunately no history. The most frequent cause of otorrhœa, and, in neglected cases, of disease of the temporal bone, is scarlet fever.

Not long ago a patient, who had been for some time subject to epilepsy, was brought as an out-patient to Dr. Brown-Séquard at the Hospital for the Epileptic and Paralysed. He had discharge from one ear, and was slightly feverish. He died of pyæmia about a fortnight later. There was no post-mortem.

Dr. Wilks relates four such cases in his article on Pyæmia in Guy's Hospital Reports for 1861. “It (pyæmia) may occur,” he says, “by two channels—through the vessels of the affected bone, or more immediately through the blood of the lateral sinus, which is involved by contact.” In the cases he gives, as in the following, the latter was the way in which the affection occurred.

Whilst pointing out the grave results following what is often, to the patient, a trifling disease in the ear, we may draw attention to a paper by Mr. Toynbee on the “Means of Preventing Caries of the Petrous Bone and the Formation of Abscess within the Brain in Cases of Disease within the Ear,” *Medical Times and Gazette*, March 16, 1861; and one by Mr. Wilde, on “Aural Diagnosis and Diseases of the Mastoid Process,” in the same volume, May 11, 1861. In these papers the various methods of treatment are discussed.

D. J. C., aged 22, was admitted, under the care of Dr. Rees, on September 3. He died on September 15. This patient was brought to the Hospital with no history, and he was too ill to give a detailed account of his symptoms. He was in a high state of fever, with furred brown tongue, but no eruption. In the absence of all local symptoms it looked like a case of fever. Salines were ordered. Afterwards, it was noticed that he had rigors, and quinine was ordered. He continued in a uniform listless state, making no complaint, until three months before death, when it appeared that he had pleurisy.

*Autopsy, by Dr. Wilks.*—On removing the brain, the right lobe of the cerebellum was seen to be slightly discoloured; the dura mater corresponding to this was of the same colour. On lifting up the dura mater, the lateral sinus was found to be obstructed, its walls thickened and suppurating. On opening it, it was found to be nearly closed by fibrin adherent to its walls, the latter also being softened and infiltrated with pus. The adjacent sinuses were obstructed by coagula of recent formation, the longitudinal being completely blocked up by it. The surface of the bone was carious, and a probe, passed into the ear, came against dead bone. The right jugular vein was affected in its whole course in the same manner as the sinus. Its walls, as well as the cellular tissue around, were thickened. The interior was covered by adherent fibrin, and almost closed thereby. The right side of the chest contained a dirty-coloured serum and air, from rupture of an abscess in the lung. The right lung was collapsed, from rupture of an abscess in the lung.

### MIDDLESEX HOSPITAL.

#### DISEASE OF THE TEMPORAL BONE—MENINGITIS—DEATH—AUTOPSY—OBLITERATION OF THE LEFT LATERAL SINUS.

(Under the care of Dr. HENRY THOMPSON.)

A WOMAN, 25 years of age, stout and well-developed, was admitted, under the care of Dr. Henry Thompson, December 9, 1862. Seven weeks before she had severe pain in the head, chiefly about the left ear. An abscess formed behind the ear, and broke about two weeks before admission, and at the same time discharge began to flow from the meatus.

When admitted, she was scarcely conscious; her aspect was

vacant and wild; she resisted attempts to move her, and moaned. The tongue was coated, but moist; pulse 120, soft and compressible. There were no abnormal chest or heart sounds. There was a small red cicatrix with a slight sinuous opening behind the left ear, emitting a slight discharge, and there were also signs of a recent discharge from the meatus. Her head was shaved, and a blister was applied over the scalp; an aperient was given, and two grains of iodide of potassium with citrate of potash were ordered every six hours. Subsequently, the symptom of meningitis becoming more developed, purging, leeches, and cold lotions were ordered. Next day she had vomiting, and a well-marked and severe rigor. On the 11th she appeared sinking, and had a difficulty in swallowing; enemata of beef-tea and brandy were therefore ordered. She made no real improvement, and died on the 13th.

It was found at the autopsy that the left lateral sinus was obliterated by a large, nearly white, firmly-adhering clot. The walls of the sinus were thickened in the whole of its extent, and this condition of the walls extended a little way into the superior longitudinal sinus, and towards the anterior part of the latter the walls were again thickened. The lateral sinus communicated by a small opening with a cavity, the size of a pea, in the mastoid process, containing pus and débris of dead bone. Puriform lymph was effused in various parts of the surface of the brain, and the ventricles contained a large quantity of reddish and rather thickened serum, and at the bottom of each of the posterior cornua was a slight purulent deposit.

### HOSPITAL FOR SICK CHILDREN.

#### CASE OF PYÆMIA IN A CHILD A FEW WEEKS OLD—LACERATION OF THE VAGINAL MUCOUS MEMBRANE DURING BIRTH—RECOVERY.

(Under the care of Mr. THOMAS SMITH.)

A FEMALE child, fourteen days old, was brought to the Children's Hospital with erysipelatous inflammation about the vagina and external genitals. The vaginal mucous membrane had been lacerated in the birth.

The local inflammation subsided under treatment, but was in a few days followed by the appearance of abscesses in various parts of the body. These collections of matter were large, baggy, and without tension or redness. Two appeared on the back, three on the abdomen, one on the thorax, one on the shoulder, one in each of the calves, and one in the elbow-joint. The largest were about the size of oranges. They were all opened when the skin became very thin over them, as the child could bear it. She took wine freely, and small doses of cinchona. She, however, became extremely emaciated and feeble. For some weeks the bones of the elbow-joint remained exposed from ulceration of the integuments and soft parts covering them. Finally, all the abscesses closed. The joint has covered in by granulations, and when Mr. Smith saw the child six months after she was fat and well, and had regained perfect movement in the elbow-joint.

This case, Mr. Smith remarks, is instructive, as illustrating (1st) not an infrequent cause of pyæmia, viz., injury during labour. (2.) The power in children of bearing up against prolonged suppuration, and (3.) the advantage of delay in opening abscesses that are chronic. Of the latter there was another instance on February 28, 1863.

#### PYÆMIA FOLLOWING AN INJURY RECEIVED DURING BIRTH—SUPPURATION IN THE HIP AND WRIST JOINTS — PLEURISY — DEATH — AUTOPSY.

(Under the care of Mr. THOMAS SMITH.)

A CHILD, who had been turned and delivered by the leg, one week after birth showed a swelling of the right hip, which quickly suppurated, was opened, and disclosed a disorganised hip-joint. A week afterwards a secondary abscess formed over the wrist-joint. This was followed by pleurisy; and four weeks after birth the child died.

The autopsy showed the right pleura full of purulent effusion. The capsule of the right hip-joint widely open; the head of the femur absorbed; the bones of the acetabular cavity were deeply eroded; the upper end of the femur was apparently necrosed.

The advantage of delay in the opening of chronic abscesses is well shown by the case of a little girl, aged 11, now under

Mr. Smith's care. Fourteen months ago she came to the Hospital with a large, tense, thin-walled abscess in the front of the left thigh, just below the groin. There was no redness over it, and but little pain on pressure. It was at first treated by rest, until the danger of immediate bursting had passed away. Since that time the child has used a crutch, and has taken tonics, and has had gentle pressure of supports applied to the abscess.

On March, 1863, the swelling was about one-third its former size. Its walls are thick and more flaccid; it had travelled down the thigh, and was about half-way between Poupart's ligament and the knee.

SATURDAY, APRIL 18.

### FATHERS OF THE PROFESSION.

In another column we print a letter from a most experienced Physician and valued contributor to our Journal, Dr. Ramsbotham. We invite the particular attention of our readers to that letter, and we take leave to say that, widely as we differ from Dr. Ramsbotham on the point at issue, we hope to state our side of the question in such a manner as becomes the respect due to the personal and professional position of those whose actions we presume to censure.

We respectfully maintain that Dr. Lee and his coadjutors, Dr. Ramsbotham and Dr. Taylor, were not obliged to appear at Chester in the trial of Bromwich v. Waters. It is now well enough known that a man may decline to attend if subpoenaed to give "his opinion;" and these gentlemen cannot plead compulsion. We affirm that the solitary matter of fact to which Drs. Lee and Ramsbotham were able to depose, viz., the absence of a cicatrix on the cervix uteri of Mary Whalley, in February, 1863, was a fact which, if fairly stated, could be shown to have had nothing whatever to do with the case. Whilst the opinions which Dr. Lee in particular delivered, though absolutely contradicted by his own writings, were decidedly hostile to Dr. Waters.

These gentlemen cannot with fairness plead that they went because they relied on a statement made by a woman who afterwards turned out to be a deceiver. They ought to have known that every tale is plausible until the other side is heard. But there is a point of Professional conduct involved here. If these gentlemen thought fit to believe that Dr. Waters had been guilty of rape—if they believed in his profound immorality as a man—they should have recollected the courtesies due to him as a legally qualified Practitioner. If there be one truth more certain in Professional ethics than another, it is, that no one Practitioner has any right to assume, on lay testimony, that another has been guilty of malpractice. Dr. Waters ought to have been credited with skill sufficient to guide him in the treatment of disease. To denounce any other man's diagnosis or treatment, without seeing the patient, is contrary to the whole rules which regulate the intercourse of Medical Practitioners.

Now, be it observed that what made the voluntary and spon-

taneous, and, as we think, not to be justified, testimony of the three Medical experts so injurious and cruel to Dr. Waters, was, that it was clearly the hinge on which the whole case turned. Every one acquainted with legal proceedings knows that the first point of the lawyers is to nail a man with a fact; then to clinch him with the inference. And so cunningly do they work upon juries, that if they can get them to swallow the fact, the inference usually slips down without further ado. Was, or was not, Bill Sykes in that lane at eight o'clock on that dark night? He denies it, just as he denies that he committed a burglary on the house close by at eleven; but if he can be proved to have been in the lane, the jury will have no difficulty in finding him guilty of all that follows. Still more, if a man can be proved guilty of any one unlawful act, is he liable to be thought guilty of any other connected therewith. If a Physician can be proved to have treated a woman wrongly, and to have pretended that she had a complaint which she never had, then the jury are called upon to believe any further offence that is alleged against him, and most likely will believe it.

This was just the nice point in Dr. Waters' case. Of course the plaintiff had the first innings, and her witnesses were able to make a score, which the defendant had to rub out next day. During this time the minds of the jury could not help being impressed with the fact that three grave and reverend seniors had been fetched from London at great expense, and were there swelling the "imposing" array of plaintiff's witnesses, and adding to the look of solidity and respectability of her case. These witnesses were put into the box to tell the jury that the treatment was wrong, and that no ulcer had existed to justify it. It is but just to Dr. Ramsbotham to say that his evidence, if carefully perused by anyone who understands the matter, contains not much that is condemnatory of Dr. Waters. He said, that if there had been destruction of tissue to any extent, there would have been a cicatrix left; but if only a superficial ulcer or abrasion, the membrane would have restored itself to a healthy condition, and no cicatrix would be visible. He also said, that although it must have been an obstinate ulcer to require continuous applications of caustic for fifteen or sixteen months, once a week or once a fortnight, still that the superficial ulceration had such a tendency to return, that a return to the treatment might be necessary more than once during the interval.

But in vain these qualifications. The fact remains that Dr. Ramsbotham did give an opinion on Dr. Waters' treatment, on an *ex parte* and false description of that treatment, and that the general impression of his evidence on the judge's mind was, "that he had given his evidence in a satisfactory manner, and had expressed an opinion that the treatment was improper." A rare compliment for the clear-headed Baron Bramwell! He describes the evidence as given in a satisfactory manner, and draws from it the opposite inference to what the witness meant. Of course he did.

As for the distinction between "superficial" and "deep" ulcers, that would be beyond the judge and jury, who never would believe that such witnesses could be put up to depose to what was not material to the plaintiff's case.

We again say that Drs. Lee and Ramsbotham formed an opinion on an *ex parte* statement, which they now admit to be false, and that they appeared in the witness-box, and lent the weight of their names and reputation to a most cruel and odious prosecution of one of their brethren. If it is against the rules of Professional taste to listen to the stories which patients sometimes tell against other Medical Practitioners—if no man would venture to say of a case which he did not see, that there was no ulcer, and no need of treatment a year ago—how much less ought he to get into a witness-box and give an opinion about it on oath, to the jeopardy of the very life and character of an innocent neighbour; and how deplorable that this should be done by men who claim to be fathers of the Profession?

## MR. PROPERT AND MR. ADAMS.

EVERY member of the Profession will regret to hear that Mr. Propert maintains the same obstinate silence as before, and steadily refuses all explanation of his conduct in this case. Mr. Adams and his friends allege that Mr. Propert not only aided and abetted Mrs. Russell in her proceedings against Mr. Adams—which of course he had a right to do, if he believed her story—but that when he first took up the case, he refused to Mr. Adams the commonest courtesy and justice. He denied to him—a Professional brother, and once a friend—the opportunity which English justice and fair play accord to the meanest and most notorious offenders. He condemned him unheard, and refused to listen to a word of explanation, and referred him to a jury. Of course Mr. Propert has his party, and hence any one who has the slightest grudge against Mr. Adams, may say that there must have been "something" in the charges brought against him, else they never could have been entertained by so benevolent a man as Mr. Propert.

We think it a misfortune for the Profession that such a source of ill-feeling should exist; and we heartily wish that some means could be devised—some third impartial party be appealed to—who could investigate the matter at issue, and show the world either that Mr. Adams is guilty, or that Mr. Propert was under a delusion when he wrote those implacable letters to Mr. Adams. Mr. Propert has been challenged to speak out, if he have aught to say, in defence of his letters of December, 1861. He would find it easy, without the slightest risk, to justify himself and to crush Mr. Adams, or, on the other hand, to acknowledge his having been misled, and withdraw from the affair handsomely. But he is silent.

It is, indeed, said that he proposes to explain his policy at the approaching dinner of the Royal Medical Benevolent College on the 29th. This, we hope, is a mistake. The College has nothing to do with Mr. Adams, nor with the private proceedings of Mr. Propert. If Adams has done wrong, the College cannot be a bit the better; and if Propert has done wrong, it is a pity that it should be any the worse. Yet the worse it must be if Mr. Propert persevere in his intention. People will object to a charitable meeting which is likely to be an arena for angry discussion, and they will not choose to identify the Propert who founded a College for the destitute and widow and orphan, with him who spurned poor Adams when he made that almost abject appeal to be allowed to justify himself. If Mr. Propert is surrounded with a kind of halo, and must not be rudely dealt with because of his age and benevolence, and his services in founding the College, it must be noted that he should not have put all this *prestige* into the scale against an innocent man. The College must not be used as a sledge hammer to crush Adams, nor yet as a shield to screen Mr. Propert. We must say that his refusal to explain himself, except at the dinner of his own College, reminds us of a man who had a squabble at his club, and then would not walk down St. James's-street unless his wife was on his arm.

## THE WEEK.

## SYMPATHY FOR MR. ADAMS.

WE are informed that a powerful committee is in process of organisation for the double purpose of giving a kind of moral support to Mr. Adams, and making a public profession of disbelief in the charges brought against him, and likewise of raising a subscription to assist in defraying his legal expenses. These expenses have amounted to nearly £1000, and although Mr. Adams expressed his willingness to bear the whole burden, his friends thought that it was unfair to allow him to do so. Such actions, as we have been taught of late, may be brought against any one of us; and they who read the reports with interest, and watch the proceedings with a sense of security and delicious kind of *suave mari magno* feeling, may express their sympathy with the victims, and

give some trifle as a thank offering that they are exempt from similar persecutions. We shall be glad to hear that Dr. Waters' friends intend to give him a similar substantial testimonial.

THE EPIDEMIOLOGICAL SOCIETY.

OUR readers will be glad to learn that this Society is receiving the support which it so thoroughly deserves from men of influence both in and out of the Profession. In a list of recently elected officers of the Society, which we publish elsewhere, occur the following new names:—The Earl of Carlisle, the Earl of Shaftesbury, Right Hon. Wm. Cowper, Dr. Acland, Dr. Copland, Dr. Farr, Dr. Jenner, and Sir J. Ranald Martin.

THE PRINCESS LOUIS OF HESSE.

WE congratulate the country on the rapid and uninterrupted progress made in the health of the Princess Alice. To her Medical attendants also are due our congratulations. The following is their final bulletin:—

“Windsor Castle, April 13.

“Her Royal Highness the Princess Louis of Hesse has had a most favourable recovery.

“The infant Princess continues well.

“CHARLES LOCOCK, M.D.

“ARTHUR FARRE, M.D.

“No further bulletins will be published.”

PARLIAMENTARY.

THE House of Commons, by adjourning on Wednesday, paid the last tribute of respect to the memory of Sir George Cornwall Lewis. His sudden death has been felt by men of all shades of opinion as a national rather than a party calamity. A political and a literary career so varied and so successful have already furnished themes for many pens, and it would be not only superfluous but out of place in this Journal to enlarge on them. But we may notice with eulogy the tone and bearing which the deceased minister invariably assumed when brought into contact with subjects relating to Medical science, or with its Practitioners. As Secretary of State for the Home Department he had not unfrequently referred to him matters which trench, in a greater or less degree, on the domain of medicine. Those of our Profession who had on such occasions to meet Sir George Lewis have always expressed with high encomium their impression, not merely of his courtesy, intelligence, and penetration, but of that freedom from prejudice, and willingness to be informed, which were eminently his characteristics. On questions of pure science he did not trust his own opinion. It will be long remembered to his honour that, by referring the question to Sir Benjamin Brodie, he cut the gordian knot in Smethurst's case, and, in thus seeking counsel from the highest Medical authority of the day, satisfied alike the Professional and public mind.

By the time this Journal is in our readers' hands, Mr. Gladstone's budget will have satisfied the curiosity of the country. We suppose that it is vain to hope for a more equitable adjustment of the income-tax, but we trust that the reduction which has been prophesied will turn out to be true. For the clumsy and ineffective *ad valorem* duties on sugar we are promised, by those endowed with political prescience, a more just and equable mode of taxation. The valid objections to the present mode of levying the duty have already been noticed in these columns. Our Profession will be glad to find that the minister has introduced any measure which has for its object the improvement of the quality of this important food-product in the English market.

DROGHEDA QUARTER SESSIONS.—ELLIS v. MILLS.

THIS case belonged to a class which have hitherto received but scant justice at the hands of judges, juries, and taxing-masters. A Medical Practitioner is subpoenaed on a trial by

an attorney; he obeys the mandate, and sacrifices time and business for a varying number of days. When the case is over, he is informed that he can only receive the miserable pittance which the law allows him. From this there is no appeal, unless a special contract for proper remuneration can be proved. Fortunately for Dr. Ellis, in this case the jury held that a special contract had been entered into, although the fact was roundly denied by the defendant. We cannot, however, recognise the justice of their pecuniary award to Dr. Ellis; admitting the contract, the motive of diminishing his claim from £22 1s. to £13 3s. seems incomprehensible. The evidence in chief of the plaintiff, will acquaint our readers with the chief facts of the case. The cross-examination was a specimen of the licence which barristers allow themselves, and of the kind of treatment which a Professional man must be prepared to face if he go into a witness-box to obtain what is justly his due. The defendant, Mr. Mills, is an attorney, and the case on which he subpoenaed Dr. Ellis was a “speculative” action for seduction, the plaintiff having been a poor woman in receipt of a few shillings a week. Dr. Ellis attended in Dublin, at Mr. Mills's request, during six days, but was not called as a witness, as the case was settled out of court by the defendant paying Mr. Mills £200 to cover costs and damages.

“Dr. Ellis sworn and examined by Mr. Hamill: I am a Medical Practitioner in Drogheda; I know Mr. Henry Mills, solicitor; I know a person named Bridget Gibson; I was subpoenaed to attend as a witness in a case brought by her against a person named Flynn; I got 10s. with the subpoena; I went to Dublin in pursuance of that; I recollect meeting Mr. Mills; the trial was to take place in the Court of Exchequer, and I met him in the Round Hall; I had a conversation with him there, and called his attention to the long list; this case was No. 11 on the list; I told him I could not afford to lose all my time; that I would expect three guineas a day and incidental expenses; I then recommended him to get counsel to apply for a certain day to try the case; when I mentioned that I should get three guineas a day and 10s 6d. for expenses, he assented to it; in consequence of what took place, I came back on Tuesday; on Sunday I received a message from his clerk, and I went on Monday in accordance with that; I saw him on Monday; had a conversation with him, and told him he had no business to bring me up on that day; he told me the trial might come on at any moment; I attended every day; he desired me to do so; I went home that night and returned next day; he told me there was no chance of the trial going on; I attended six days at his instance.

“Court: Did you go backward and forward every day?—Plaintiff: Yes.

“Examination resumed: During those days I had conversations with him about loss of time and expenses in attending from day to day, and he said he would guarantee the payment; I learned from Mr. Mills that the case had been compromised; he told me the terms, and said he would satisfy me according to arrangement, and that the defendant would pay Dr. Horgan's expenses; he said £200 was given in the case; I furnished him afterwards with a bill (bill produced); after I furnished that account, I did not see or hear from him until I wrote. I recollect afterwards going to his office where Mr. Murray lives; he offered to give me £5 on account, and asked me for a receipt; I said I would take nothing of the kind; I called after in a few days; Mr. Murray was there; Mr. Mills began to say the charge was too much, and Murray said he should give another pound; I then walked away; on the first occasion he offered me £5 on account he made no objection to the charge, and it was on the second occasion that he objected to the amount.

“Cross-examined by Mr. O'Driscoll: You thought three guineas a-day was what you should get?—Witness: That was what I always got in Dublin.

“Mr. O'Driscoll: Upon your oath, how many times did you get three guineas a-day?—Witness: I got it for the only principal case I attended in Dublin; it was a case in which a railway company was engaged.

“Mr. O'Driscoll: How many cases did you get three guineas a-day for besides the ‘only principal case?’—Witness: I got four guineas for a day in Drogheda the last sessions.

"Court: Was that in a crown case?—Witness: Yes, your worship.

"Mr. O'Driscoll: Now, how often did you get two guineas a day in a civil court? Now, tax your memory.—Witness: I got two guineas in Drogheda always.

"Mr. O'Driscoll: Then you never got two guineas in your life. Now, I have again to ask you how many times in your life did you get three guineas a day in a civil case?—Witness: I answered before that I never was engaged to my knowledge except in a railway case; I was the plaintiff myself.

"Mr. O'Driscoll: And you summoned yourself?

"Cross-examination continued: The case was heard; I got a verdict, and I presume the costs were taxed; I cannot swear that they were; I am perfectly correct in what I stated regarding the conversation I had with Mr. Mills; his words were, 'I'll pay you;' I might have said that he said 'I'll pay you, or have you paid;' he told me plainly twenty times that he would pay me; upon my oath he did not say he would have me paid such expenses as I was entitled to; I used the word 'guarantee' to him, and I said I would expect three guineas a day, and 10s. 6d.; I told Mr. Mills that it was neither more or less than a speculative suit; I am fully aware that at the time there was a decree in this court against the defendant in the case of *Gibson v. Flynn*; I did not know there was an action pending for breach of promise of marriage; I might have heard it.

"Court: I mean to tell the jury, Mr. O'Driscoll, that whether it was a speculative action or not, they have nothing to say to that.

"Cross-examination continued: I know that this wasn't a special jury case at all; I attended all those six days at the special request of Mr. Mills; Mr. Murray's son did not say to me three minutes before the train started on one day, that I was not required in Dublin; nor did I say that I would go up, or that I had been very badly treated by Mr. Mills.

"Mr. O'Driscoll: Do you earn three guineas a day?—Witness: I can; five sometimes.

"Mr. O'Driscoll: Every day in the year?—Witness: No, nor you either (laughter).

"Mr. O'Driscoll: I ask you again, do you on an average earn three guineas a day?—Witness (to the Court): I think, your worship, that is a question I am not entitled to answer.

"Mr. O'Driscoll: Well, Doctor, I will ask you no more. You are not angry with me?

"The jury, after a short absence from court, found 'that there was a contract to pay for loss of time and travelling expenses,' and a decree was given for £13 3s. An appeal against the decision was immediately lodged."

#### THE MOA.

THE Moa seems likely to take the place of the sea-serpent in furnishing aliment for the marvel-loving appetite of the British public. Even scientific men are inclined to suspect that there may be some basis of truth in the reports which have reached this country from New Zealand. Professor Owen has long asserted the possibility of some of the smaller species of *Dinornis* being found living in the Middle Island. About two years ago, a story appeared in a Nelson paper, that some explorers of a remote district in that island had, in the early morning, noticed the fresh footprints of a large struthious bird in a situation where nothing of the kind had been observed on the previous evening. There is also good evidence that, at no remote period, the *Dinornis elephantopus* furnished food to the natives. The existing species of *Apterix* and the *Notornis*, discovered living by Mantell, were contemporaries of the Moa. Still it seems incredible that the larger species, one of which was at least ten feet high, should be in existence and no evidence have been obtained of the fact from the Maori. The Melbourne correspondent of the *Times* now states that some explorers, who have lately penetrated to the west coast, have found recent bones of the Moa on the surface, and also footprints of a large bird. He proceeds:—

"I see no reason to believe that the moa does not exist, and I think the probability is that it does. The Middle Island was never very thickly peopled, and it is nearly thirty years since it was almost depopulated by Te Ranperaha's tribe. The natives were confined to the eastern side of the

island, and never penetrated to the mountains on the east coast. Their superstitions militated against it. They believed that a race of wild men inhabited the mountains, which were also infested by the dreaded taniwa, a great lizard which ate men. They also had a tradition that the moa still lived in the ranges. Since the Europeans have inhabited New Zealand no lizards have been seen larger than about eighteen inches, and certainly no wild men have been met with by the explorers, so that the superstition of the natives only proves their ignorance. The bones discovered during the last twenty years prove that the moa lived at no very distant day. Why should he be extinct? We know of no enemy likely to exterminate him, and if the untrodden wastes of the Middle Island furnished him with food at a period not distant enough to fossilize his bones, we know of no change which has altered the condition of the islands on that score up to the present day. There are birds which could not so easily preserve their existence, and which have not as yet become extinct. The kiwi-kiwi (*apterix*) we instance, and the kaka-po (night parrot), which is also wingless. Both these birds are small, and have numerous enemies, especially native dogs, which would be powerless against the moa. It is therefore by no means impossible—I even think it probable—that Professor Owen may yet be gratified by a recent specimen of this gigantic bird."

The tale, which has been reproduced in the *Times* from an Otago paper, of two miners being disturbed at their camp fire by the apparition of an enormous bird, which, without reckoning the head and neck, seemed seven feet high, is in all probability a fabrication. A correspondent of the same paper, Mr. H. J. Webber, has stated his conviction that the extinction of the Moa has been due to the fires which are constantly occurring in the dense bush of New Zealand, and that all the bones of the bird which he has examined there exhibited traces of the action of fire. Yet there seems nothing unreasonable in the expectation that some specimens of the smaller species of *Dinornis* (the smallest of which was three feet high), may before long take their place by the side of the struthious birds of the old world in European galleries—relics of a phase of animal life as wonderful as any foreshadowed by fable, or whose history is preserved in the crust of our globe.

#### MEETING OF THE MEDICAL PROFESSION IN CHESTER ON DR. WATERS' CASE.

ON Monday an important and highly influential meeting of members of the Medical Profession of Chester and surrounding districts was held at the Infirmary, to express sympathy with Dr. Waters on the recent action brought against him and decided in his favour. The following gentlemen were present:—Dr. Davies; Dr. Williams, Mold; Mr. Morris, Marford; Mr. Moreton, Tarvin; Dr. Braid, Neston; Mr. Churton; Dr. Biggs, Kelsall; Dr. Fyfe, House-Surgeon, Chester; Dr. Stolterfoth; Mr. Jones, sen., Ruthin; Mr. Bage; Mr. Dickson; Mr. Brittain; Mr. Weaver, sen.; Mr. Brierly, Tattenhall; Mr. Thelwall, Farndon; Dr. Bury; Dr. Jephcott; Dr. Williams, Wrexham; and Dr. Powell.

The CHAIRMAN, in opening the proceedings, said they all knew that a gentleman, an ornament to his profession, and one who had gained the credit and goodwill of a large number of persons, had unfortunately been made the victim of a person whose character no doubt had been such as to deceive her intimate friends. She had brought herself into discredit, and evidently wanted to shield herself at the expense of her Medical friend. They all knew the satisfactory way in which that charge had been met, and how very handsomely Dr. Waters had been treated by all parties in the case, the judge himself expressing his full conviction that the charge was not borne out by the evidence. However, the matter would not be allowed to rest there; they had a duty which they owed to themselves and to the Profession. Their Profession was one peculiarly liable to such charges, and whenever a brother fell under an imputation of the kind it behoved them all to rally round him, and endeavour by every possible means to defend him from these imputations. A somewhat analogous case had lately occurred

in London, in which Mr. Adams was made the victim; but that gentleman got triumphantly through a very painful lawsuit, and met with the sympathy of almost every Medical man in the Profession. He (the Chairman) only hoped the same warm sympathy would be manifested on this occasion. Although Dr. Waters was placed in a trying position, he (the Chairman) hoped that the difficulties under which he had been labouring would only serve to bring more fully into view the many good qualities he possessed, and prove him more worthy and deserving even than ever the regard and esteem of his Medical brethren. (Applause.)

The SECRETARY then read letters from a large number of Medical gentlemen expressive of the great interest they felt in the case, and regretting their inability to attend the meeting. The Secretary referred particularly to a letter received from Dr. Bennett, of Edinburgh, who suggested a general subscription might be entered into that might suffice not only to express their sense of his merit, but for their desire by means of union to put down the odious calumnies and injuries to which they were all exposed. He thought, however, that the movement should originate amongst the Medical Profession in Chester, who might jointly form themselves into a committee for this purpose. The writer continued that he would be glad to take charge of the Edinburgh subscriptions, to which he would gladly contribute, and recommended that the testimonial should be presented to Dr. Waters at a banquet to be held in Chester, say early in August. The Secretary said he thought this letter of Dr. Bennett's very important indeed, and, although that meeting had been nominally called for the purpose of congratulating Dr. Waters on the issue of the recent trial, the letter was valuable as showing the feeling amongst the Profession in distant places on the subject. (Hear, hear.)

Mr. H. CHURTON then moved the following resolution:—"That a subscription be entered into by the Medical Profession generally for the purpose of assisting to defray Dr. Waters' expenses of the late trial, and for presenting him with such a testimonial as will be agreed upon by the subscribers."

Mr. FFOULKES seconded the resolution, which was carried unanimously.

Mr. GRIFFITH, Wrexham, said all the Wrexham Practitioners were ready to co-operate with a committee in any manner to testify to Dr. Waters the deep sympathy which they felt for him under the painful circumstances under which he was placed, and their admiration of the bold, English way in which he confronted the charge. (Hear, hear.) He thought they ought not to separate without some remark—it might be a delicate matter to do so—but he did think the time was come when some remark should be made respecting those Professional gentlemen who had come down from London in the case, darkening the character and blasting the reputation of a fellow-member of their Profession. (Hear, and loud applause.) On looking at the trial, he could not conceive that either Dr. Lee or Dr. Ramsbotham—for he made no delicacy about names—could form an *ex post facto* opinion, and venture to say the treatment adopted by Dr. Waters was wrong. (Hear, hear.) Not one of them—and although they did not bear the high names of the two gentlemen he mentioned, still they possessed common sense, they possessed a knowledge of their Profession, and most of them had a good deal of experience—would venture to say in such a case that the treatment was improper. It might have been all very well if it had been the case of an ignorant person, who might have adopted wrong treatment, and then in the interests of the Profession and the public he should be held responsible; but there was no such evidence here. What was known of the necessities of the case at the time it came under Dr. Waters' care? (Hear.) Something was due to the reputation, and experience, and skill of Dr. Waters in his diagnosis of the case, and applying proper treatment to it. He (Mr. Griffith) believed that Drs. Lee and Ramsbotham had no adequate foundation for condemning the treatment of Dr. Waters in this case, and guided their statements on preconceived ideas as to a certain point of practice in the treatment of these diseases. As to the speculum, they all knew that Dr. Lee had for a long time been waging a crusade against its use, and he thought that was a point on which the meeting were bound to express their opinion, to discourage men from being made the tools of any party or to fill up gaps in evidence; to sacrifice their reputation and those feelings of delicacy and honour which should exist between one man and another in the Profession, and the time

had come when they should generally express their disapprobation of such a course of proceeding. (Applause.)

In answer to an inquiry made by a gentleman present, the CHAIRMAN said the subscription to be entered into would be strictly confined to the Medical Profession, inasmuch as there would be a meeting the same evening of a more public character, at which it was intended to have another subscription. In referring to Dr. Bennett's letter, he said his (Dr. Bennett's) suggestion was what the meeting intended itself to have proposed.

Mr. HARRISON (Nicholas-street) said there had been a preliminary meeting at which he had been asked to take upon himself the duty of drawing up an address to Dr. Waters. This address at first contained some remarks respecting the course taken by the two Medical gentlemen who had come down from London, but on reconsideration it was thought better to omit these portions. Mr. Harrison then read the address proposed to be adopted, as follows:—

"To Edward Waters, Esq., M.D., F.R.C.P. Ed., etc., etc.

"Dear Sir,—We, undersigned Medical Practitioners in the city and county of Chester and the adjacent counties, assembled at the Chester Infirmary, April 13, 1863, beg to tender you our hearty and most cordial congratulations on the issue of the recent trial which has just occurred in this city. The rumours circulated during the past winter in connexion with your name caused us great pain, and it was with an anxiety scarcely inferior to that which you yourself must have felt that we awaited the time when an opportunity should be afforded you of vindicating your character from the aspersions that had been cast upon it. The result, however, has amply proved the exactness of our anticipations, and we now sincerely rejoice that a member of the Profession whose name has been hitherto held in the highest esteem among us has passed unscathed through the painful ordeal to which you have been exposed. Having carefully watched the progress of the trial, we beg to express to you our great satisfaction at the verdict, and to offer you the united testimony of our unabated confidence in your Professional judgment and skill, as well as in your honour and integrity as a man; and we should be glad if we could believe that this slight tribute on our part could afford any consolation to you for the great suffering which you and the other members of your family must have endured for so long a period, and while passing through the painful and appalling trial to which you have been subjected. We beg to subscribe ourselves, dear sir,

"Your faithful friends."

The address was signed by all the Medical gentlemen present.

Mr. CHURTON said it would be well to form a committee to devise the best mode of proceeding in the matter. He thought the bare presentation of a testimonial—say a piece of plate—would not be sufficient; Dr. Waters had been at a great outlay in getting up his defence, and he ought to have something in money. (Hear.)

Mr. BRITAIN asked would the subscription amongst themselves interfere with that to be entered into in the evening.

The CHAIRMAN replied that it would not.

Mr. BRITAIN: Because if the other subscription goes to pay the law expenses, ours might be appropriated to the testimonial.

Mr. J. HARRISON then moved the adoption of the address to be presented at a proper time to Dr. Waters.

Mr. MORETON (Tarvin) cordially seconded the proposition, and observed that they would be justified in expressing their opinion to Dr. Waters on the conduct of Drs. Lee and Ramsbotham.

The SECRETARY: Don't you think it would be better to leave that to the Medical press? Otherwise I think it would be taking it out of good hands.

Mr. BRITAIN: I believe there are several Medical gentlemen in Manchester and Liverpool who have expressed a wish to join us in the subscription.

The SECRETARY said that he thought it would be better to have separate meetings in those large towns, as it would have much more effect than having one common meeting in Chester.

A committee was then appointed to carry out the various arrangements, after which the proceedings concluded.

DR. LANKESTER has held an inquest on an illegitimate child, nine months old, who had been taking two of Morison's Pills daily.

## REVIEWS.

*On Effusions of Blood in the Neighbourhood of the Uterus, or the so-called Periuterine Hæmatocele.* A Thesis for the M.D. Degree. By HENRY M. TUCKWELL, M.A., M.B. Oxon, late Radcliffe Travelling Fellow. Pp. 41. Oxford: Parkers. 1863.

THAT a Doctor of Medicine of Oxford should write a thesis on an obstetric subject is a good sign for that branch of the Profession, which thus shows its attraction for men of the highest education and pretensions. We hope, too, that the barbarism, "periuterine," will be the last of its class. Dr. Tuckwell gives us a clear *resumé* of what has been written and ascertained on the subject matter in very small compass, and adds a copious table of cases and references.

*Jahresberichte der Gesellschaft für Natur und Heilkunde, in Dresden, 1861-62.*

*Yearly Report of the Society of Medicine and Natural Philosophy, Dresden,*

CONTAINS abstracts of the papers read at the meetings of the Society, and of the consequent discussions, and three or four entire essays on subjects in Medicine and Physics; that they are worth reading is sufficiently guaranteed by such names as Erdmann, Keiler, Zenken, Seiler, and Küchenmeister.

In a communication on the "Propagation of Syphilis by Vaccination," Dr. V. Bulmerineq, noticing the doctrine of Viennois and Stricker, that pure lymph, though taken from a syphilitic patient, will produce only a pure pock, but that lymph mixed with blood will communicate syphilis, makes the pertinent objection that it is impossible, however careful the operator may be, to get lymph entirely free from blood-corpules.

Dr. Seiler's clinical observations on the "Use of Quinine in Typhus," would possess a higher value if he had given the diagnosis of the fever he treats; he calls it "typhus," but he describes no rash, and he speaks of "diarrhœa" as a symptom; he only advocates the use of "moderate doses" of quinine, and does not go beyond believing them to be a valuable aid to *treatment*, especially of cases in which nervous complications predominate; he does not even hint at *curing* typhus by means of quinine.

## GENERAL CORRESPONDENCE.

BROMWICH v. WATERS.

LETTER FROM DR. RAMSBOTHAM.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the last number of your Journal you pass a censure, in no measured terms, on Dr. Lee and myself for having attended to give evidence in the late case at Chester. You say "you heartily regret the evidence given by us, and you would fain that we can represent ourselves as misled or drawn in against our will."

As far as being misled, the result has proved that we were grossly misled by the chief witness, who made her statement to us with a degree of simplicity and absence of exaggeration not often united to falsehood, and who never wavered in the minutest particular in the account she first gave, although she underwent many very severe examinations and cross-examinations as well by medical men—myself being one—as by acute counsel and solicitors. She has turned out to be the most artful and thorough impostor, as well as the most arrant hypocrite, that it has ever been my lot to hear of.

For myself, I had been consulted in the case some time before I had an idea that it was to be brought into a court of justice; and, as soon as I ascertained that, I strongly advised, more than once, as did Dr. Lee also, that the case should be abandoned. I told both the counsel and the solicitors that they would certainly lose their cause (whatever might be their feelings on the subject of the girl's truthfulness), supported as it was chiefly, if not entirely, on her testimony, and that my evidence would be of no use to them. I assure you it was with great pain to myself that I became implicated in the case; but, having given an opinion that there was no mark remaining of an ulcer ever having existed in the os uteri, I was obliged to appear to speak to that fact.

With regard to the evidence given by Dr. Lee and myself, which you "heartily regret." You say "Dr. Lee is reported to have deposed that no ulceration ever existed at all; Dr. Ramsbotham, that if there had been an ulcer there would be a cicatrix." I shall leave Dr. Lee to answer for himself, as you well know he is quite capable of doing; but, for myself, I must say you have not put what I said fairly in this passage; and a reference to your own report will show you that. I made a distinction between a deep-seated and superficial ulceration of the os uteri; and I told the court that if the first kind of ulcer had existed, there would have been a cicatrix when I examined; but if the latter kind, there would be no indication of the disease left at that distance of time. But to put the question in an intelligible light, I will transcribe, as far as I can recollect, the substance of the whole of my evidence. I said it must have been an obstinate case of ulceration to require the use of the caustic every week or fortnight continuously for so many months as the girl swore to, six or seven applications being sufficient in ordinary cases. Dr. Waters, after my evidence had been given, contradicted her, and swore he did not apply it more than six or eight times, not ten at the farthest. I said that I never had used the speculum to a chaste, unmarried female, unless it had been had recourse to by some other Practitioner previously. This I said, believing the girl to have been a virgin when she first consulted Dr. Waters. He swore that on his first examination *per vaginam* he discovered she was not a virgin. I said I thought the speculum and caustic should be discontinued, if their use produced such aggravated fits of hysteria as we heard had supervened in this case during the treatment. This was really the only point of practice in which I differed from Dr. Waters. It must be borne in mind that I had not the advantage of hearing his version of the story before I gave my evidence, as Drs. Simpson, Keiller, Fyfe, and Mr. Brittain had; if that had been so, very little difference indeed would have been discovered between his treatment and my own. My evidence was entirely given in reference to what she had sworn to. I said, also, that when I examined the girl I found the uterus perfectly healthy, with no appearance of there ever having existed an ulcer at the mouth. I said that if any considerable portion of the substance of the organ had been destroyed by ulceration a cicatrix would have been left, but if a part of the membrane covering it only had been destroyed, that membrane, in common with other mucous membranes, possesses such a restorative power within itself, that all traces of its having been diseased would soon disappear. I stated that to require the application of caustic every week, or every other week, for more than a year, would generally imply that the substance was affected; but that superficial ulceration, or abrasion of the membrane, had such a tendency to recur, that a return to the former treatment might be necessary more than once during that interval. I said, also, that it did not accord with my experience that hysteric females were invariably given to falsehood, because I knew many hysterical women who were quite truthful; and that marriage was often beneficial in hysterical cases, but that women who had ulcers in their womb were generally separated from their husbands while under treatment.

This I believe to be the sum of my evidence, and I do not think it will be controverted by many of my Medical brethren.

I heartily congratulate Dr. Waters that he has been enabled to clear himself from such a heavy and grievous charge, not only for his own sake, but also for that of the Profession to which we both belong.

It would give me indeed great pain did I feel that I deserved the censure you have passed on me; because throughout my whole life my chief desire and object has been to uphold the honour, dignity, usefulness, and respectability of the Medical Profession.

I am, &c.

FRANCIS H. RAMSBOTHAM.

ACTION AGAINST A CRITIC.—M. Constantine James, the well-known French writer upon mineral waters, has just brought an action against the editor of the *Gazette des Eaux*, on account of an anonymous letter which appeared in its columns, insinuating that he puffed up the newly-discovered mineral waters at Martigny for pecuniary considerations. One portion of the charge is the term "Hydrologist" being contemptuously applied to the author. The editor was condemned to pay a fine of 100 francs and the expenses.

## REPORTS OF SOCIETIES.

## OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MARCH 4, 1863.

Dr. OLDHAM, President, in the Chair.

THE following gentlemen were elected as Honorary Fellows of the Society:—Prof. Martin, of Berlin; Dr. Beatty, of Dublin; Dr. Pagan, of Glasgow; Prof. Braun, of Vienna; Prof. Depaul, of Paris; and Prof. Faye, of Christiana.

The following gentlemen were elected as ordinary Fellows of the Society:—J. H. Galton, M.B., Brixton; H. V. Garman, Esq., Bow-road; W. Hanna, Esq., Belfast; R. W. Jenkins, Esq., Philpot-lane; J. W. J. Oswald, Esq., Kensington; Josiah T. Powell, M.D., City-road; John Rowland, M.D., Strata Florida, Lampeter, Cardiganshire; Joseph Rushforth, Oxford-terrace; J. H. Tutin, Esq., Ripon.

The President announced that the volume of Transactions for the past year would be in the hands of the Fellows in a few days.

## READY-MADE PLASTERS.

Dr. TILT drew attention to the fact that when a hundred or a hundred and fifty grains of common starch are boiled in an ounce of glycerine, the result is a very stiff glutinous compound, which has no smell, and does not become rancid; and although sticking firmly to the skin, it can be removed and reapplied. Instead of ordering belladonna plaster, Dr. Tilt prescribes three grains of sulphate of atropia to be rubbed down with a few drops of glycerine, then incorporated with an ounce of hard glycerine ointment, and thickly spread by the patient on gutta-percha cloth, or impermeable wash cloth. This can be removed for the morning ablutions, and reapplied after spreading a little more ointment on the same plaster. Morphia and other alkaloids are prescribed in the same way. The samples exhibited by Dr. Tilt were made by Mr. Bullock, of Hanover-street.

Dr. MEADOWS exhibited a specimen of

## UTERINE POLYPUS WHICH HAD COMPLICATED LABOUR.

The tumour, which had completely filled the vagina, was about twice the size of the foetal head. During the labour it was entirely protruded by the descent of the child, but was returned on its expulsion. It again, however, descended, and was removed by ligature two days after delivery. The growth was attached by a long pedicle to the cervix uteri, and weighed when removed nearly four pounds. The patient did well.

A paper by Dr. W. H. BROADBENT was read

## ON DISPLACEMENT, ETC., OF THE BLADDER AS A CAUSE OF TEDIUS LABOUR.

The purport of this communication was to show that, besides the mechanical obstruction which may be presented by the prolapsed and distended bladder to the descent of the head of the child, prolapsus of the bladder, complete or partial, frequently renders the first stage of labour long and painful. The uterine contractions, causing pain in the displaced bladder, it was said, were replaced by spasmodic contractions of the abdominal muscles, which forced down the uterus, but had no effect in dilating its mouth. These were attended with much suffering, of a character very different from the natural labour pains at this stage, which with tactile examination would lead to a recognition of the cause. The measures recommended for the relief of the pain and for expediting the progress of the labour were the supine position, prevention of accumulation of urine by the use of the catheter, and, in severe cases, chloroform. Cases were given in support of these conclusions.

A paper by Dr. CHARLES CLAY was read on

## OBSERVATIONS ON OVIOTOMY, ETC., STATISTICAL AND PRACTICAL; ALSO, A SUCCESSFUL CASE OF EXTIRPATION OF BOTH UTERUS AND OVARIES.

Dr. Clay gave a brief and interesting outline of his experience on this very important branch of surgery. Of 109 peritoneal sections, of which 104 were for ovarian extirpation, 3 for cutting down upon the tumour to establish ulceration where its removal was known to be impracticable, 1 for the Cæsarean operation, and one for the removal of both uterus and ovaries. Of the 104 ovarian cases, 72 recovered, 32

died; all the 3 ulcerative cases recovered; the Cæsarean section lived to the fifteenth day; and, lastly, the case of entire removal of both uterus and ovaries recovered. Of the 32 deaths, 10 died from the immediate consequences of the operation, 10 from inflammation, 10 from prostration, and 2 from hæmorrhage. The great majority of the first and second series were young females, as well as a portion of the third division. Those from prostration were chiefly elderly females. Some other statistical facts were elicited, as well as the following remarks from the author:—Dr. Clay still defends the raised temperature of the room for operation, and attributes much of his success to its influence; is not certain if chloroform has added anything to the successful results, although he values it highly as an agent which it would now be difficult to lay aside, although the first fourteen of his cases were performed before it was discovered, and of which nine recovered; and he still thinks, if a woman could face the difficulty without it, it would be in her favour. The large incision is still practised by him, and deemed far preferable to the smaller opening. Of course, the author wished to be understood that the incision was to be commensurate with the tumour to be extirpated. Dr. Clay gave many reasons for this preference. The distressing vomiting he conceives to be in a great measure owing to the use of chloroform, as he saw but little of it in the first fourteen cases where it was not used. For this troublesome symptom he advises patience until the blood has got rid of its load of carbon, the simplest of drinks, and as little food as possible. Some very well-ascertained facts of critical days were adduced, which would require too much space to dwell upon; suffice it to say, the third, sixth, and ninth were the principal, and the causes of each were pointed out. No particular age seems to be prominent in respect to the success of these cases. Dr. Clay himself stated them to be about equally successful at all ages from sixteen to fifty-seven. Purgatives are not admissible; and he relies on enemas, with ox-gall, etc. This part of the paper was concluded by some interesting remarks on ovariectomy for the last twenty years, and the difficulties the author had to encounter, not the least of which was misrepresentation. The author next gave in detail a new and interesting operation, which he believed to be the first of its kind, successful at least, in this country—namely, the entire extirpation of the uterus and its ovaries through the abdominal walls, which has ended most fortunately, the lady returning to her friends on the thirty-fifth day after the operation, and still continuing well, thus establishing another great fact in reference to abdominal Surgery. The case was that of a fibroid uterus of eleven pounds weight, with the ovaries in an unhealthy condition; and the tumour by its growth had latterly so entirely filled up the cavity of the pelvis as to render the passage of the fæces and urine extremely difficult. The particulars of the case throughout its progress were given. Dr. Clay does not suppose that many uterine cases could be advisedly extirpated, but thinks some of those densely-hard fibroid masses, where the constitution has not been greatly prostrated, might afford a fair prospect of cure under the knife.

Mr. BAKER BROWN prefaced his remarks by warmly thanking Dr. Clay for the very practical and admirable paper just read. Mr. Brown considered it one of the most valuable he had ever heard, and wished it had been brought forward a few weeks earlier, as it was calculated to strengthen the hands of other ovariectomists, and enable them to contend against those who doubted the value of the operation. With regard to the temperature of the room, Mr. Brown stated that he believed that Mr. Lane, than whom no one had been more successful in ovariectomy, disregarded this subject, as did also another gentleman present at the meeting, who had also had great success. For himself, Mr. Brown believed that where the operation was likely to be long, and the viscera long exposed, it was of great importance; but that where the operation was quick, and the viscera were kept back by hot flannels, the question of temperature would not affect the success. As to the long incisions, he believed Mr. Walne followed Dr. Clay; whereas Dr. F. Bird and Mr. Lane had contended for the short incision, and with good results. Mr. Brown always made a small incision first. If it appeared that on tapping the cyst the tumour could be withdrawn, he did not enlarge it; but if there appeared strong adhesions, or the tumour was very multilocular, he found it easy to make the incision larger, and agreed with Dr. Clay that it was advisable to see clearly where the adhesions and difficulties in removing the tumour were situated. At the same time, with the very large

success of Dr. Clay, it was folly to say that short incisions were preferable to the long. Dr. Clay still preferred the ligature of Indian hemp. Mr. Brown had used it till the invention of the carpenter's callipers as a clamp, which he found more convenient and comfortable. He could not, however, agree with Dr. Clay as to the inadvisability of bleeding. In two or three cases where peritonitis had come on quickly after the operation, he had found venesection most valuable, and attended with success. He always advised hot linseed-meal poultices to be applied over the whole abdomen when there was a chance of peritonitis, believing that they kept hot longer than ordinary fomentations. Mr. Brown's experience as to the frequency of the ovary attacked was contrary to Dr. Clay's. He had examined many hundreds, he might say thousands of cases, but thought that one could not decide which ovary was diseased till an incision was made. His experience, from cases submitted to operation, was that the left ovary was most frequently affected. He agreed with Dr. Clay that age does not make much difference. He was glad to hear that Dr. Clay had come to the conclusion that the question of success did not depend on the operation itself, but on the after-treatment. Mr. Brown believed that in his earlier operations he lost more patients because the after-treatment was not so well understood as now. He had learned from Dr. Clay the valuable practice of never giving the patient anything but the most simple food till asked for. He preferred giving beef-tea and wine, if required, by the rectum for three or four days after the operation. Mr. Brown considered Dr. Clay's testimony valuable as to the great advantage of small over general hospitals for these operations, not on account of the operation itself, but because the nursing, ventilation, and atmosphere were so much better in small special institutions. Mr. Brown had twice removed both ovaries with success. He thought that the question of exploratory incisions had been unfairly treated by the profession. They were made with an honest endeavour to ascertain the truth before risking the patient's life. Mr. Brown had never seen a fatal result follow them, and thought they should be commended and encouraged, not condemned. He was glad to hear Dr. Clay say that in his last operation he had made it a stipulation that it should be left to him to decide whether he should proceed after making an incision. As to opium, Mr. Brown had at one time been as great an advocate for it as Dr. Clay; but believed that it increased the sickness, and he now never gave it unless imperatively called for.

Mr. SPENCER WELLS said that he must not be supposed to undervalue the very useful paper of Dr. Clay, or to be ungrateful for the lessons which he had taught us all by his able advocacy of ovariectomy, if he (Mr. Wells) ventured to discuss two very important steps of the operation in which his own practice, and the practice in London generally, differed from that of Dr. Clay. Dr. Clay still advocated the long incision; and he still left the tied end of the peduncle and the ligature within the peritoneal cavity. He could boast of a success attending this practice of 70 per cent. of recoveries to operations, and as success was the best criterion in Surgery, it might seem presumptuous to question the wisdom of any operative proceeding practised so successfully. But his (Mr. Wells') own experience had led him so decidedly to prefer the short to the long incision, and to keep the tied end of the pedicle outside rather than to leave it in, that he could not help suspecting that Dr. Clay's great experience in the operation had led him to success in spite of a method which more recent experience had modified or corrected, and which men of less experience could not follow without great danger of failure. After long incisions there was so much more exposure or escape of intestine during the operation, so many more serious symptoms after it, and so comparatively protracted a recovery, even in successful cases, that his (Mr. Wells') own experience had taught him to avoid any greater length of incision than was necessary for the exposure and removal of the cyst or tumour. Every inch in the length of incision appeared to add something to the chances against the patient, and in cases where he had the choice either of making a long incision and removing a tumour entire, or of breaking up a tumour and removing it through a small opening,—even though ovarian fluid might unavoidably escape into the peritoneal cavity and require careful sponging for its removal,—he would prefer this alternative rather than make a very long incision. So, in his experience, those patients in whom it had been necessary to leave the pedicle and ligature within the peritoneal cavity had suffered so much more after the

operation, and their recovery had been so much more protracted than others where the peduncle had been kept outside, that he would always prefer to keep it out if he could, and so avoid the danger of absorption of the putrid matter of the strangulated stump, or the peritonitis connected with the effusion of fibrine thrown out to circumscribe the stump and ligature. It seemed probable that the frequent occurrence of peritonitis in Dr. Clay's practice was in some measure due to his manner of treating the pedicle; for in his (Mr. Wells') own practice, peritonitis was a rare accident. Of eighteen fatal cases, it had only had any important share in the fatal result in two; in all the others, shock or exhaustion after the operation, or blood-poisoning, having been the cause of death; while in successful cases he hardly remembered peritonitis in any patient where the pedicle had been kept out. As to the temperature of the room, in his earlier cases he had followed Dr. Clay's practice; but latterly he had found it better simply to have the room kept comfortably—not excessively—warm, and after the patient was in bed to keep a good fire burning and a window open night and day. In the use of opium also he had learnt to avoid all excess. If there was pain or restlessness, it was given in moderate doses, and repeated if necessary; but some patients had recovered without taking a single dose, and others with not more than two or three doses. Sometimes it was given to secure a good night, even if there was no pain. With regard to the removal of uterine tumours by abdominal incision, it was only under the most exceptional circumstances—where the life of the patient was in great danger from hæmorrhage or the effects of pressure—that such an operation as that so successfully performed by Dr. Clay could be justifiable. Pedunculated peritoneal out-growths from the uterus might be removed with moderate risk, and so might in-growths towards the uterine cavity or vagina; but any attempt to enucleate interstitial fibrous tumours of the uterus, either by incision through the abdominal wall, or by incising the cervix *per vaginam*, was attended by such very great risk that nothing but the most urgent necessity would justify the practice. He (Mr. Wells) said this rather as the result of his own observation, than as any conclusion suggested by Dr. Clay's successful case.

Dr. CLAY, in reply, expressed his great gratification at the manner in which the paper had been received by the Society. With respect to the details of the operation, he adhered to the principles laid down in the paper. It was remarkable that many of the best recoveries after ovariectomy had taken place in his practice after making the long incision, and where the tumour was large he preferred it. The use of Indian hemp for ligatures he still preferred. With respect to the remarkable case of extirpation of the uterus, he would observe that on his way to town to attend the meeting he had accidentally met the patient who had been the subject of the operation at a railway station, and in perfect health.

---

## EPIDEMIOLOGICAL SOCIETY.

MONDAY, MARCH 2, 1863.

Dr. BRYSON, F.R.S., in the Chair.

THE SECRETARY read a paper, by Deputy-Inspector Dr. Smart, R.N., on

### THE EPIDEMICS OF YELLOW FEVER IN BERMUDA.

It was illustrated with numerous statistical tables, and accompanied with an accurate map of the groups of islands. Without going further back than the close of last century, it appears that the dates of the successive outbreaks of fever there have been 1796, 1812, 1818 and 1819, 1837, 1843, 1853, and 1856. The following are the principal conclusions drawn by Dr. Smart from his extended researches:—1. That in the best recorded yellow fever epidemics of Bermuda there has been generally a coincidence of the same disease on the American coasts. 2. That on such occasions there has been an epidemic constitution, manifested by the prevalence of catarrhal affections in the spring, and of gastric affections in the early summer—these yielding to fever, which, at its climax in the autumn, assumed the type of yellow fever with black vomit in a greater or less proportion of the attacks. 3. That during these epidemic seasons comparative immunity has usually favoured the native population, and those of the European residents dwelling under good sanitary conditions.

4. That the most intense manifestations of the disease have arisen in crowded barracks and convict hulks, etc., especially when the healthy and sick have been kept together. 5. That inasmuch as in the worst instances recorded it has been found that removal from infected localities has been always followed by an almost complete exemption of those not already infected, by amelioration of the state of the attacked, and lastly by an early extinction of the epidemic character of the fever, it is therefore just to consider the essential causes of the disease to operate, under ordinary circumstances, by material local agencies rather than by those of person. 6. That sanitary measures are the means to be relied on upon the approach of the epidemic constitution (a) in any locality. 7. That, in the event of an epidemic outbreak, the same measures are highly valuable, but the only measure of certain value then is removal from the locality, and, in the case of crowded communities, as in barracks, ships, etc., immediate dispersion into wider space of all persons within the range of the noxious local agencies. 8. That, although the direct proof of personal contagion be still wanting, there are ample reasons for concluding that the highest degree of local infection has been generated in the Hospitals, naval, military, and convict, so that the malady has been propagated among the attendants as well as among the sick. 9. That with regard to Hospital arrangements for the treatment of yellow fever, owing to the peculiar predisposition arising from the debility of ill health, yellow fever Hospitals should be distinct and special, and under sanitary cordon; and that, considering the disadvantages of the climate of Bermuda, the minimum of space, even when perfect ventilation can be maintained, should not be less than 1500 cubic feet per man in fever wards. After alluding to the terrible mortality from this fever in several ships of the West India squadron in 1861, during the passage to Halifax, and after their arrival there, Dr. Smart remarks: "I must confess that such results, placed side by side with those of immediate removal of men from infected localities as exhibited in Bermuda experience, have raised a doubt in my mind whether equal losses of life would have been incurred by the immediate removal of the crews from their ships into some suitable quarantine establishment in the West Indies."

Drs. Bryson, Camps, Stratton R.N., and Milroy, and Mr. Marson took part in the discussion of this very elaborate and valuable paper, which had been communicated to the Society by the courtesy of Sir John Liddell, Director-General of the Medical Department of the Navy.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen passed the First Part of the Professional Examination for the Licence of the College on April 8 and 9, 1863:—

John Henry Ashton, St. Bartholomew's Hospital; Edward Brown, St. Bartholomew's Hospital; George Edgelow, St. George's Hospital; Thomas Edgelow, St. George's Hospital; Robert Henry Kinsey, St. Bartholomew's Hospital; Jordan Roche Lynch, St. Mary's Hospital; Charles Durrant Pearlless, St. Bartholomew's Hospital; Llewellyn Powell, St. Bartholomew's Hospital; Chauncy Puzey, Guy's Hospital; Thomas Francis Raven, St. Bartholomew's Hospital; Frederick William Richards, St. Bartholomew's Hospital; James Walbridge Snook, St. Bartholomew's Hospital; James Byers Thomas, St. Bartholomew's Hospital; Arthur Cromack Turner, Sheffield; Alexander Waugh, St. Bartholomew's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a Meeting of the Court of Examiners on the 14th and 15th insts., and, when eligible, will be admitted to the Pass Examination:—

G. T. Hankins, Charles Smith, C. G. Bott, H. T. Broughton, H. G. Howse, G. H. Savage, Edward Shorland, F. T. Tayler, George Paddon, F. W. Humphreys, Thomas Collier, James Milward, J. A. Ball, J. A. Ensor, Joseph Johnson, and T. P. Warren, students of Guy's Hospital; C. D. Pearlless, A. S. May, C. T. Dalley, W. G. V. Lush, S. H. Simpson, W. A. Harvey, G. A. A. Coates, A. C. Reade, T. A. Compton, G. H. Shaw, J. T. Evans, and F. J. Cropp, of St. Bartholomew's Hospital; Thomas Howells, Franklin Gould, A. E. Adamson, S. F. Bagnall, E. L. Fenn, Frederick Noyes, C. B. Greenfield, E. F. Boulton, S. M. W. Wilson, F. J. Burge, and

(a) This vague and obscure, although classical, phrase is used by Dr. Smart simply to denote a sickly condition of the general health of a community, as indicated by the unusual prevalence and severity of catarrhs, alvine fluxes, etc., for some time prior to the development of malignant fever in the latter part of the summer or beginning of the autumn—the season when all the epidemics of yellow fever have appeared in Bermuda.—Sec. of Epid. Soc.

Pares Bradshawe, of King's College; Walter Smith, G. W. Rigden, T. H. Green, H. G. Walker, R. C. Beck, and William Akerman, of University College; C. E. Saunders, Daniel Iles, and S. S. Stephens, of St. Thomas's Hospital; J. W. Warburton, T. D. Leigh, and J. H. Gornall, of Liverpool; John Carlisle, George Clements, and H. W. Freeman, of the Middlesex Hospital; Gifford Ransford and H. R. Archer, of St. George's Hospital; G. W. Malin and W. N. Hiron, of Birmingham; E. S. Grattan and James Cooke, of Belfast; R. E. Thredgale, C. F. Knight, and F. C. F. Milburn, of Charing-cross Hospital; D. W. Tomlinson and Richard Cresswell, of St. Mary's Hospital; J. B. Ward, Leeds; and H. G. Samuels, Dublin.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, April 9, 1863:—

Edward Harley, King's College; Thomas Carter, Guy's Hospital; Frederick Kelly, London; Thomas Martyn Cann, Virginstown, Devon; William Row, Clapham-road; William Henry Cecil Tessier, London.

The following gentlemen also on the same day passed their First Examination:—

Samuel Duckering, Sheffield; Richard Wheeler Haines, King's College; John Burges Welch, King's College; Francis Henry Burdett, Birmingham.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Names of candidates who passed the Major Examination as Pharmaceutical Chemists on April 15:—

Victor Guesdon, London; John Fletcher, Camberwell; Geo. S. Taylor, Harrogate; Parnell Bond, Bristol; William Curtis, Barnstaple; Richard Wadsworth, Preston.

APPOINTMENTS.

\* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BENNETT, ROBERT, M.D., of Buxton, has been appointed Coroner for the Hundred of High Peak, in the county of Derby.

HACON, EDWARD D., F.R.C.S. Eng., has been appointed Surgeon to the Stamford-hill Dispensary.

HINTON, JAMES, M.R.C.S. Eng., has been elected Surgeon Aurist to Guy's Hospital.

KNIGHT, J. SLADEN, M.D., M.R.C.P. Lond., has been elected Consulting Physician to St. Bartholomew's Hospital at Chatham.

LANGSTON, J., M.R.C.S. Eng., has been elected Consulting Surgeon to St. Bartholomew's Hospital at Chatham.

ROBERTS, EDWARD STOKES, M.R.C.S. Eng., has been appointed one of the Honorary Surgeons to the Hull and Sculcoates Dispensary.

SMITH, W. ABBOTTS, M.D., M.R.C.P., has been appointed Physician to the Finsbury Dispensary.

DEATHS.

FOWLER, RICHARD, M.D. Edin., at Milford, near Salisbury, on April 13, aged 98.

JONES, MICHAEL T., at Shardlow, near Derby, on March 30, aged 69. In practice prior to 1815.

SURRAGE, THOMAS L., M.R.C.S. Eng., at Clifton, Bristol, on March 31, aged 83.

THOMSON, JOHN, M.D. Edin., at Lewisham, Kent, on April 1, aged 73, Surgeon R.N.

SPECIALTIES IN TEACHING.—Signor Larghi, well known for his works upon sub-periosteal operations, and on the treatment of disease of bone, has just been appointed Lecturer on Diseases of the Bones in the Turin University.

NATIONAL GALLERY.—Amongst the recent additions to the national collection of pictures is Haydon's "Punch, or May-day," bequeathed to the nation by the late Dr. Darling. The friends of the venerable Physician will well recollect the picture which used to hang in his dining-room.

FIRST LIST OF THE COMMITTEE OF THE ADAMS TESTIMONIAL.—The following, with many other gentlemen, have formed themselves into a committee:—Wm. Bowman, Esq., Lawson Cape, Esq., W. Coulson, Esq., W. H. Covey, Esq., J. E. Erichsen, Esq., Wm. Fergusson, Esq., Joseph Henry Green, Esq., F.R.S., etc., W. W. Gull, M.D., E. Lankester, M.D., Jos. Paget, Esq., Richd. Quain, M.D., W. B. Richardson, M.D., Brown-Séguard, M.D., Spencer Wells, Esq., John B. Walker, Esq., 17, Clifton-gardens, Maida-hill, Hon. Sec.

ST. THOMAS'S HOSPITAL.—There is a vacancy in the Surgical Staff of this institution, occasioned by the resignation on Saturday last of Mr. John Flint South, after a connexion of half a century as pupil and Surgeon at the Hospital, of which charity he is about to be made a life governor, in

recognition of his long and valuable services. Mr. South is still a member of the Court of Examiners of the Royal College of Surgeons, where he has twice filled the President's chair.

**THE ROYAL SOCIETY.**—There are no less than forty-five candidates for the Fellowship of this learned Society, including as many as fourteen members of the Medical Profession, viz., Henry Foster Baxter, M.R.C.S.; William Brinton, M.D., of St. Thomas's Hospital; John Charles Bucknill, M.D.; Thomas Spencer Cobbold, M.D., of the Middlesex Hospital; William Charles Hood, M.D.; William Jenner, M.D., of University College, Physician to the Queen; Edmund Charles Johnson, M.D.; Henry Letheby, M.D., Officer of Health to the City of London; Sir Charles Locock, M.D., Accoucheur to the Queen; Robert McDonnell, M.D.; Frederick William Pavy, M.D.; John George Perry, F.R.C.S.; Charles Bland Radcliffe, M.D.; and Samuel James Augustus Salter, M.B.

**DR. PRIESTLEY.**—The Profession will be glad to hear that this accomplished Physician has recovered from his late severe and dangerous illness. During his attack, Drs. Jenner and West were unremitting in their attention to him, and we need scarcely state that on all sides the progress of his illness has been watched with the greatest solicitude by his Professional brethren.

**AN EARLY PREGNANCY.**—Dr. Curtis has thoroughly examined into the evidence in this case, and comes to the conclusion that the girl, Elizabeth Drayton, became pregnant twenty-four days before she was ten years old, and was delivered of a fine full-grown male child, weighing fully eight pounds, when she was ten years, eight months, and seven days old. The reputed father of the child is said to be about fifteen years of age. The mother menstruated once or twice before conception, was tolerably healthy during gestation, and had rather a lingering but quite natural labour.—*Boston Medical Journal*, February 19.

**DISCOVERY OF FOSSIL HUMAN REMAINS.**—The French journal *L'Abbevillois* contains an account of the discovery, by the well-known French writer, M. Boucher de Perthes, of some fossil remains of a human being. He found in a deposit, known as the "Moulin-Quignon-lèz-Abbeville," a flint implement, accompanied by a human jaw and tooth, all three of the same colour, and, as he believes, undoubtedly fossil. The objects were deposited 4 metres and 52 centimetres from the surface, and close to the chalk. Drawings have been made of them by an able young archæologist, M. Oswald Dimpre.

**ACCIDENT TO MR. NEWTON, OF NEWCASTLE.**—A deplorable accident has befallen Mr. Wm. Newton, Surgeon, of Newcastle-on-Tyne, and an active member of the Town Council. On Friday afternoon, between four and five o'clock, Mr. Newton had been riding out upon the Town Moor in company with a Mr. James Scott, when the horse upon which the latter was riding took fright, and Mr. Newton's mare sprang after it, and the jerk threw her rider. Mr. Newton fell with his back upon a stone. Assistance was speedily rendered him, and he was removed to the Herd's cottage, where he was attended by Sir John Fife, Dr. Heath, Dr. Hawthorn, and other of his Medical brethren. His condition was so precarious that he was not removed home until ten o'clock at night, when he had to be carried on a stretcher to his residence in Hood-street. Upon an examination it was found that his spine was injured. On Saturday, Mr. Newton was in a very dangerous condition, and it is feared that, if he ever recover, his extremities will be paralysed.

**THE MURDERER BURTON.**—This man, convicted of murdering a boy at Chatham, was hanged at Maidstone on Saturday last. The *Observer* states that for a long time he exhibited a great deal of bravado, but latterly his spirits gave way, and he expressed sorrow for his crime. He stated that in consequence of having been turned out of the public-house at Chatham he made up his mind to kill the landlady of the house, but he thought he would kill some one else first, and then try to murder the woman afterwards. He then met by accident the deceased lad, but his dying shrieks so frightened him that he gave up his further criminal intention, and wandered about till he could bear it no longer, and then gave himself up to justice. Up to the last moment he continued to express his penitence for the crime which he had committed.

**MONMOUTH DISPENSARY.**—At a special general meeting of the subscribers, held on Thursday, the 2nd inst., the Rev. E. F. Arney in the chair, it was proposed by the Rev. J. D. Watherston, seconded by Mr. J. Endell Powles, and unanimously resolved, that Mr. Thomas Prosser should be elected one of the Surgeons of the Institution, in the place of the late Mr. Mayou. The Secretary to the Committee was requested, on the motion of Dr. Willis, seconded by the Rev. J. L. Dighton, to write to Mrs. Mayou, expressing how warmly the subscribers sympathise with her in the loss she has sustained in the death of her lamented husband, who had been professionally connected with the Dispensary for upwards of twenty years.

**ST. THOMAS'S HOSPITAL.**—The *City Press* urges the establishment of convalescent branches to all large Hospitals. Convalescent establishments would receive discharged patients for a definite term; they would provide them with suitable diet, recreation, and employment, and save many a family from final wreck, and many a constitution impaired by a long period of suffering, and the frequently exhaustive effects of remedial treatment from sinking at the very moment when the claim upon the Hospital ceases and the frame is yet unequal to the activities of life. All the great endowed Hospitals have increasing incomes, while of many it may be said with truth, that there is no likelihood of any great increase in the demands upon their ordinary resources. These augmenting revenues might doubtless be well applied in attaching to these institutions homes for convalescents, where charity might render her last aid to the afflicted poor, and make the Hospitals themselves tenfold more beneficial.

**ODONTOLOGICAL SOCIETY, APRIL 6, 1863.**—A paper, by Mr. Spence Bate, was read on the "Treatment of Inflamed Dental Pulp," in which he advocated that for all practical purposes the conversion of the internal pulp into bone was very doubtful after once an inflammatory action had been set up, and, as a curative treatment, most unsatisfactory. The treatment that he advocated was therefore extirpation of the pulp by instrumental manipulation if possible. If not, then by the means of an escharotic. In order to do this he differed from that which Practitioners advocated, being the minute but important alteration of exchanging a minimum for a maximum dose of arsenious acid, which he introduced into the cavity on a pledget of cotton wool that had been previously dipped into creosote, and hermetically sealed it in with a temporary stopping of gutta-percha. Mr. Bate stated that if this were properly effected the operation was changed from a painful into an almost painless one, and that his experience for the last nine months has been that the fear of alveolar abscess, so much complained of, was *nil*. The paper excited considerable discussion, in which Mr. Coleman, Mr. Tomes, Mr. Keene, and others took part.

**THE ETHNOLOGICAL SOCIETY.**—A crowded meeting of this Society took place on Tuesday, the attraction being a paper "On the Antiquity of Man," by Mr. J. Crawfurd, the President. The author objected to the recent work of Sir Charles Lyell, in respect to certain branches of the subject on which he had bestowed special attention. He stated at once his own conviction that the presence of man on the earth had an antiquity far beyond the usual estimate, and that there was no question as to his having been the contemporary of the fossil elephants, lions, and rhinoceroses. He opposed Sir C. Lyell on the points of the unity of the human race and the Aryan theory of language, and the origin by transmutation of man from the apes. On the first point Mr. Crawfurd concludes that there is no shadow of evidence for the unity of the human races, and none for any having undergone any appreciable change of form. If 1000, or 4000, or 10,000, or 100,000 years, supposing the last to be the age of the skeletons of the Belgian race contemporary with the Mammoth, have yielded no differences from the present European type, it is, he believes, reasonable to consider that multiplying any of these sums by a million of years would yield nothing but the same cipher. On the second point, he said that Sir Charles's object, following the philosophers of Germany, would seem to be to reduce all languages to a small number of primordial ones, in the same manner as the authors of the theory of transmutation of species would reduce all the species to a few monads. If there were any truth in the Aryan theory thus advocated, it would, Mr. Crawfurd says, of necessity follow that there would be no language at all in Western Asia or Europe, ancient or modern, and that Sanskrit, Greek,

Latin, with all the modern languages, would be reduced to the rank of mere dialects, or subdivisions of one primordial tongue—the airy and fabulous Aryan, the mere creature of Teutonic imagination. On the third point, Mr. Crawford confessedly took only a popular view. He considered that man was marked by a superiority of intellect, by having the power of speech and the capability of framing languages, and that although monkeys have an outward and even a structural resemblance to man beyond all other animals, it was nothing more than a mere resemblance, and that why nature had bestowed upon them this similarity was a mystery beyond our understanding. In the animated discussion which followed, Sir Charles Lyell, Sir Roderick Murchison, Professor Busk, Mr. James Wyatt, of Bedford, Dr. Collier, Professor Macdonald, and Mr. Mackie took part. It was stated by Sir Charles Lyell that, by a letter he had received this day, he had heard that M. B. de Perthes had found a human jaw in the flint-bearing beds of Abbeville; but, on the other hand, it was said that Mr. Prestwich had seen the specimen, and was not convinced of its genuineness. Nothing certain seemed to be known about this relic.

EPIDEMIOLOGICAL SOCIETY.—At the annual meeting of this Society, held on the 6th inst., the following office-bearers were elected for the ensuing year:—*President*—Benjn. Guy Babington, M.D., F.R.S. *Vice-Presidents*—His Excellency the Earl of Carlisle, K.G.; Earl of Shaftesbury, K.G.; the Right Hon. W. Cowper, M.P.; H. W. Acland, M.D., F.R.S., Regius Professor of Medicine in Univ. Oxford; Alex. Bryson, M.D., F.R.S., R.N., Inspector-General of Fleets and Hospitals; Edwin Chadwick, Esq., C.B.; James Copland, M.D., F.R.S.; William Farr, M.D., F.R.S.; J. Brown Gibson, M.D., C.B., Director-General Army Medical Department; R. D. Grainger, Esq., F.R.S.; Sir Charles Hastings, M.D., D.C.L.; William Jenner, M.D., Physician to the Queen, etc.; Sir John Liddell, M.D., F.R.S., C.B., Director-General Navy Medical Department; Sir J. Ranald Martin, C.B., Physician to the Council of India; Alex. Nisbett, M.D., R.N., Inspector-General of Fleets and Hospitals; John Simon, Esq., F.R.S., Medical Officer of the Privy Council; Sir Andrew Smith, M.D., K.C.B.; Thomas Watson, M.D., F.R.S., President of the Royal College of Physicians. *Treasurer*—Dr. Camps. *Secretaries*—Gavin Milroy, M.D.; J. N. Radcliffe, Esq. *Foreign and Colonial Secretaries*—Belgium and France, Dr. Walter Lewis; Germany and Russia, Dr. Herman Weber and Dr. Swaine; Sweden, Norway, and Denmark, Dr. Gordon Latham, F.R.S.; Portugal and the Brazils, Dr. Bryson, R.N.; Egypt and Syria, Dr. Camps; East Indies, Dr. James Bird; West Indies and North America, Dr. Milroy. *Other Members of Council*—Dr. Aldis; F. G. Burger, Esq.; Dr. Chowne; Dr. Dickson, R.N.; Dr. Greenhow; Colonel Hough; Ernest Hart, Esq.; C. F. J. Lord, Esq.; J. F. Marson, Esq.; Dr. Morehead; Dr. Murchison; Dr. Odling; Dr. Richardson; Dr. Sanderson; Dr. Seaton; Dr. Haward.

WESTMINSTER. — PREVALENCE OF SMALL-POX AT PIMLICO. — REFUSAL OF A MOTHER TO HAVE HER CHILD BURIED.—Dr. Aldis, who is the Officer of Health appointed for St. George's, Hanover-square, applied to the police magistrate at Westminster, with respect to the interment of a child three years of age, who had died of small-pox, and was lying at 12, Spring-gardens, Pimlico, in a small back room, occupied by its father and mother and three other children. He stated that there are not only twenty-six souls in this six-roomed house, but it is situated in a very crowded locality, in which the small-pox is very prevalent among the humbler classes. Under these circumstances it was essential that this child should be buried at once. Efforts had been made to effect this, but in vain. Mr. Badderly, overseer of the parish, informed him that although the father of the child was anxious that the child should be removed and buried, the mother positively refused to allow it. Mr. Badderly sent Osborn, who had charge of the funerals of the parish, to take away the child. He placed it in a coffin for that purpose, when the mother took it out again, and restored it to its cradle or cot, and several Irish persons of the neighbourhood having collected, intimidated him by their threats, and he felt compelled to retire. Dr. Aldis subsequently went with Mr. Grant, and tried to persuade the mother to let the child be removed, but she refused, although her husband pressed the removal. He added that it was of great importance that the child should be immediately interred. Mr. Selfe was of opinion that the father had the

power to order the removal of the child, which was, as Dr. Aldis had said, highly necessary, and he thought that there could be no impropriety in the police accompanying the parish officer to see that there was no breach of the peace upon the removal of the child. [If Dr. Aldis had but carried out the provisions of the Nuisances Removal Act for England, 1855, Section 12, and taken out a summons against the owner for having his premises in such a state as to be a nuisance and injurious to health, the difficulty might have been got over more quickly.]

NUMEROUS TAPPINGS.—Dr. Paolo relates a case in which during the period of ten years and eight months paracentesis abdominis was repeated 255 times, the amount of fluid discharged being calculated at 3,111 litres, or about 685 gallons. He cites numerous cases to prove that this is the most remarkable of its kind on record.—*Omodeis Annali*, vol. clxxxix, p. 275.

A COMMON CAUSE OF BALDNESS.—A writer in the *Boston Medical Journal* suggests that the compression, by means of the hat, of the veins which return the blood from the scalp is a common cause of baldness. He refers, in proof of this, to the much greater proportionate number of persons exhibiting baldness among the class who wear hats, compared with the lower orders who do so more rarely. Again, if we compress the frontal vein of a bald-headed person moderately with the finger, the scalp becomes speedily swollen and turgid; and, on inquiry, we shall find that he experiences an uncomfortable sense of fulness and constriction about the head whenever he wears a hat, especially in hot weather. It is true the hat does not induce baldness in all its wearers, those most liable to it being men of soft and pliable tissues, with large, superficial, and easily compressed veins. A large proportion of them have a long occipito-frontal compared with the bi-temporal diameter of the head—favouring the compression of the frontal and occipital veins.

### BOOKS RECEIVED.

The Dublin Quarterly Journal of Medical Science, No. LXIX., February, 1863. Dublin: Faunin and Co.

\* \* \* Contains a note of Professor Haughton's papers on Diabetes Mellitus.

The British and Foreign Medico-Chirurgical Review, No. LXII., April, 1863. London: Churchill and Sons.

\* \* \* A good number, but with less than there should be of the foreign element.

A Clinical Report on Cancer of the Female Sexual Organs. By Thomas Hawkes Tanner, M.D., F.L.S. London: Renshaw. 1863. Pp. 60. (Reprinted from the London Medical Review.)

\* \* \* A highly creditable monograph, and well worthy of being read and "bound" by any one who is collecting facts or statistics of cancer. A case is mentioned incidentally, in which a patient with chronic mammary tumour was operated on for cancer by that horribly cruel American method which was brought into vogue by Dr. Fell.

A Case in which a Disease like Measles arose from an unusual cause, with some Brief Remarks. By Henry Kennedy, A.B., M.B., etc. From the Dublin Quar. Journ. Med. Sc., February, 1863.

\* \* \* A short paper, but very suggestive. The cause was the inhalation of musty linseed powder; and Dr. Kennedy collects together a variety of information showing the power of minute fungi to produce diseases analogous to measles.

A Report upon some of the Colonial Medicinal Contributions to the International Exhibition, 1863. By Charles Hunter, late House-Surgeon to St. George's Hospital. London: Churchill and Sons. Pp. 43.

\* \* \* A short account of an investigation into the properties of foreign drugs, undertaken at the instance of Miss Burdett Coutts. The *Contarea Speciosa*, from Trinidad, seems to promise febrifuge virtues worthy of further research.

On the Convulsive Diseases of Infants. By Thomas Ballard, M.D. London: Churchill and Sons. 1863. Pp. 34.

\* \* \* Dr. T. Ballard adheres as vigorously as ever to his own special opinion that "fruitless sucking" is the true source of convulsions, idiocy, etc. What would happen to anyone who tried to suck the logic out of Dr. Ballard's book?

The Australian Medical Journal, No. 29, January, 1863. Melbourne: Wilson and Co.

\* \* \* One writer traces much of the diarrhoea of the colony to intemperance in the use of effervescing drinks for quenching thirst.

Mentou: Essai Climatologique sur ses Différentes Régions. Par le Dr. Jacques-François Farina, Docteur en Médecine, etc. Paris: Ballière. 1863. Pamphlet. Pp. 72.

\* \* \* A readable essay on the climate and topography of Menton, for the benefit of phthisical persons who are in search of a winter residence.

A Dictionary of Chemistry and the Allied Branches of other Sciences, founded on that of the late Dr. Ure. By Henry Watts, B.A., F.C.S., assisted by eminent contributors. Part I. Abichite—Ammoniacal Salts. Part II. Ammonium—Arsenic. To be completed in 16 parts at 5s. each. London: Longmans. 1863. Pp. 193-384.

\* \* \* Some of the best chemists in the world are engaged on this Dic-

tionary, which is indispensable to the Professional chemist. The article on Arsenic is remarkably clear and good.

Observations on some of the Causes of Infanticide. By George Greaves, M.R.C.S., Consulting Surgeon Chorlton Union Hospital, Lecturer on Midwifery, etc. Read before the Members of the Manchester Statistical Society. Manchester: Caue and Lever. 1863. Pamphlet. Pp. 26.

\*.\* The real cause of infanticide is illicit connexion and vice generally. Whoever will control these, will save the lives of infants. As for legal enactments, or "institutions specially devoted to the reception of that class of women," etc., etc., you may as well make laws for the winds. Mr. Greaves, we are sorry to see, spoils his well-meant pamphlet by joining in the foolish hubbub against wet-nursing, and thinks that "no man has the right to diminish, by ever so little, the chances of life of another infant in order to add to those of his own." An argument which may be carried further than Mr. Greaves seems to see.

Montpellier Médical: Journal Mensuel de Médecine, Rédigé par MM. Bérard, Lordat, etc. 6me année. February, 1863. Tome X., No. 2. Montpellier: Boehm; Paris: Asselin.

\*.\* Contains a rare combination of thoughtful, scholarly, and practical articles. The article on Pyrétologie, Dr. Girbal, deserves perusal.

The War Office List and Civil Directory for the British Army, January, 1863. First publication. Compiled from official and other documents, under permission of the Secretary of State for War, by Denham Robinson, of the War Office. Price 6s. London: Harrison. 1863.

\*.\* A remarkably useful and well-arranged book; much to be commended for its fulness of information and facility of reference. It contains a full list of Medical Officers of the Army according to the date of their appointments; an analysis of public accounts connected with the Army, and reference to dates of all Minutes, Warrants, and Debates in Parliament concerning the War Office, the Medical, and Ordnance and Educational Departments.

Essai sur la Nature et le Traitement du Cholera. Par Adolphe Rodrigues-Barrat, D.M. Edin. Maurice. 1863.

\*.\* An interesting and well written essay. The writer is a thorough believer in the portability of cholera; he denies premonitory diarrhoea, and trusts to large doses of belladonna in the treatment.

The Englishwoman's Journal, March, 1863. London: Published at the Office of the Englishwoman's Journal Company, 19, Langham-place, Regent-street, and by W. Kent and Co., Paternoster-row.

\*.\* This number contains an article on Fever in its Social Aspects, from which its gentle readers may extract a good deal of useful information as to the prevention and management of fevers.

Twelfth Annual Report of the Wilts County Asylum, Devizes, for the Year 1862.

\*.\* This Asylum is under the able management of Dr. Thurnam, the well known ethnologist. A case mentioned in his Report shows the extreme difficulty of diagnosing criminal insanity. A man was admitted from the Salisbury gaol under a warrant of the Secretary of State, having been "found insane before trial" on a charge of "burglary." Dr. Thurnam had a strong suspicion that he was feigning, and soon after the alleged lunatic managed to effect his escape, exhibiting in accomplishing his object great cunning and ingenuity.

Richmond District Lunatic Asylum, Dublin. Report of the Resident Medical Superintendent for the Year 1862. Dublin: Joseph Dollard. 1863.

\*.\* Dr. Lalor, the Resident Medical Superintendent, has tried the Turkish bath in thirteen cases of melancholia or dementia. Some slight improvement followed in four of the patients. He concludes that the bath proved harmless, but not curative.

The Seventh Annual Report of the state of the United Lunatic Asylum for the County and Borough of Nottingham, and the Fifty-second of the Original Institution, formerly the General Lunatic Asylum. 1862. Nottingham: Shaw and Sons. 1863.

\*.\* Dr. Stiff, the Superintendent, in his Report notes that the number of admissions has not been raised by the poverty resulting from the depression in the cotton manufactures. The distress which existed in Coventry and its neighbourhood in 1860 and 1861 was not accompanied by any corresponding increase in mental disorders.

The Forty-seventh Annual Report of the Manchester Eye Hospital. Manchester. 1863.

\*.\* Mr. J. Windsor, F.L.S., after forty-three years' service in the Hospital, has retired, accepting the honorary post of Consulting Surgeon.

The Fifteenth Annual Report of the Manchester Medico-Ethical Association. Manchester: W. Hutchinson. 1863.

\*.\* The Report states that this Association was the first attempt to organise a society which should bend itself to the practical illustration of the principles and theories contained in Dr. Percival's "Medical Ethics." During the past year the Association have appointed a sub-committee to watch the operations of the Medical Act, and have petitioned Parliament on the inefficiency of its provisions for suppressing illegal practice.

Registration of Births and Deaths in Ireland. From the British and Foreign Medico-Chirurgical Review, April, 1863.

\*.\* An able criticism on the provisions and antecedents of Sir R. Peel's Bill. We thoroughly agree with the following:—

"A provision for the payment of a small fee for every Medical certificate, properly filled up, of the proximate cause or manner of death—adding, if possible, the causes or antecedents of the fatal illness—would have been a greater boon to the whole Profession than the registration shillings to be appropriated by the dispensary Surgeons only; and, what is of greater moment, it would have immensely increased the scientific value of the mortuary returns. The local boards might then have been left at liberty to appoint a humbler class of persons, like the majority of English registrars—e.g., schoolmasters or good scribes; and the measure would have been perfected by a scientific machinery for local supervision."

The Fourth Annual Report of the Sussex County Lunatic Asylum, Haywards Heath. 1862.

\*.\* Dr. C. L. Robertson, the superintendent of this asylum, has lately published in the Journal of Mental Science a paper entitled "English

Patients in Foreign Asylums." The cheapness of the French and Belgian Maison de Santé is an inducement which has led to the exportation of many lunatics. Although Dr. Robertson's paper seems to have been suggested by incidents in "Lady Audley's Secret" and "Buried Alive," it is highly probable that evils exist in the system of foreign lunacy treatment which might be lessened by a system of visitation of English patients, to be arranged by negotiation through the Foreign Office. Dr. Robertson, however, states no facts.

Annual Report of the Dorset County Lunatic Asylum.

\*.\* The Medical Superintendent, Mr. J. G. Symes, in his report advocates the establishment of "Middle Class Asylums" where patients could be received at from 15s. to 21s. a week. Were these more common, it would check the practice of consigning English lunatics to the tender mercies of Belgian and French proprietors.

Heroes, Philosophers, and Courtiers of the time of Louis XVI. In Two Volumes. Hurst and Blackett. 1863.

\*.\* We are told that these volumes are written by the author of the "Secret History of the Court of France," a work whose title-page bore the name of Dr. Challice; but, although they treat on one of the most momentous passages in history, the light sketchy and somewhat desultory style, the fertility of illustrative anecdotes, and the exuberance of details of persons and manners give countenance to the suspicion that the sagacious Physician of Southwark must be indebted to Mrs. Challice for the greater part of the composition. The subject of the work is the influence exerted by the chief actors in the American Revolution, and the Liberal party generally—Voltaire, Rousseau, Lafayette, and Franklin—in accelerating the French Revolution. The author describes "how superstition and charlatanism arose in proportion as religion and loyalty declined in France;" and shows how the same persons who disbelieved the Christian faith could trust in Cagliostro, Mesmer, and other professors of sham science.

"To the excited view of France, in 1778, natural science beyond her ken was miraculous. The wonders of electricity paved the way equally for Dr. Mesmer and for Dr. Franklin, and the abuses of the Schools of Medicine in France had paved the way for any pretension by which the ills that flesh is heir to might be mitigated.

"Men of science, and charlatans who aped them, flocked now to France, there to try their experiments and their fortunes. As chief of these celebrities, we must here give place to Dr. Anthony Mesmer. Mesmer was forty-four years old when he appeared in Paris; he was of a noble and imposing presence and demcanour. He was welcomed in Paris, just as the Royal Faculty of Medicine there was experimentalising on electricity. Mesmer professed to be possessed of a secret which should lay bare all the mechanism, and reveal all the mysteries, of nature; which should operate upon bodies animate and inanimate; which should prolong life, if not annihilate death altogether; and which should subdue the will of another to your own. He declared that this great secret was a principle unique, and, at the same time, simple and sublime; also, that it was a universal principle.

"Vienna had cast out Mesmer, because the people of that city had declared that without they saw they would not believe, and what they did see did not convince them. Paris, tottering in its ancient faith to Cross and Crown, was prepared to cling to anything; but Mesmer had grown wary by his Austrian experience. Although the people of Paris were ready to hail him as a prophet, especially when the death of Voltaire made them eager for a fresh draught of excitement, Mesmer fortified himself by gaining over one of the Faculty of Paris, Dr. Deslon by name, whom he initiated into the mysteries of Animal Magnetism, just as the Faculty was straining every nerve to change probabilities into facts. Facts came thick and fast—at all events, to the excited view of the multitude. The sick were cured; old men dreamed dreams, and young men and maidens saw visions. Dr. Mesmer looked and spoke like one inspired. Enthusiasm is contagious, and Mesmerism spread like an epidemic through all classes and conditions of men in France, just as sympathy for American liberty was spreading. The old Duc de Richelieu had, years before, placed himself under the treatment of the Count de St. Germain, by whose magic it had been said that the gallant duke had been restored to fresh strength, youth, and beauty. The Count de St. Germain had applied raw veal to the duke's body, thereby drawing from it the poisonous effects of time. But raw veal was superseded now. Even the golden elixir of life, which the Count de St. Germain was said to possess, was thrown into the shade by the marvels of Mesmerism. Count de Maurepas, the King's first minister, who, as Madame du Deffand said, 'laughed at everything,' seriously considered Mesmerism. De Maurepas was a sceptic generally, but his hope of living beyond the allotted term of man's life was the parent of his belief in the power of Mesmer to enable him to do so.

"Confident of his power over de Maurepas, Mesmer presented that cabinet minister with a memorial, written by his own hand, in which he prayed the King not only to have the truth of animal magnetism tested, and placed by proofs beyond all doubt, but to endow him with a certain chateau and estate, which he designated, as a reward for his discovery; threatening, moreover, that in case of the King's refusal of his demands, he would forthwith leave France and her sick to take care of themselves.

"The Cabinet of Versailles condescended to answer Mesmer's memorial by sending the Baron de Breteuil to him to offer, as a substitute for his demand, an income of 20,000 livres, and an annual douceur of 10,000 francs, that he might establish a clinical magnetism, and for training in his system three persons chosen by Government—with a further promise of increased royal favour should his discovery prove permanently beneficial. Upon receiving these proposals, Mesmer took offence, or pretended to do so, and withdrew from Paris to Spa. The people of Paris were in despair, and the will of the people of Paris had begun to rule the throne of France.

"Deslon, Mesmer's initiated disciple, continued to practise animal magnetism in Paris. Mesmer hearing of this, and jealous of Deslon his pupil, declared from Spa that Deslon was an impostor. Many of Mesmer's patients had flocked after him to Spa. One of these, a M. Bergasse, proposed that a subscription should be raised for Mesmer ('de cent actions à cent louis chacune') which subscription soon accumulated such wealth to Mesmer, that in defiance, as it seemed, of Versailles, he returned in fresh glory to Paris, and opened a hall of treatment there, to which hall multitudes flocked, looking upon the prophet now in something also of the light of a martyr to royal tyranny.

"Courtiers, unable to resist the tide of excitement which seemed to have gathered fresh strength from the momentary check, also showed themselves there. Scandal proclaimed that the Hall of Treatment was

not a school of virtue. Owing to this rumour, it was decreed by his Majesty that Dr. Franklin, one of the most scientific moralists in the kingdom, should, with other learned commissioners, examine and inquire into the truths of Mesmerism. Experiments were made at Passy, at the house of Dr. Franklin there. The commissioners (the learned Bailly was one of them), submitted to be experimented upon by Dr. Mesmer—with more or less success. Franklin, looking on, determined to oppose the power of his will to that of Mesmer. Franklin's theory was, that Mesmerism was mainly due to the imagination of the person acted upon. The failure of the experiment upon himself confirmed his theory.

"Dr. Mesmer was powerless against Dr. Franklin; and the latter quietly crushed the occult pretensions of the former, coolly declaring animal magnetism to be 'mainly due to the effect of the patient's excited imagination; to imitation in numerous assemblies; and to the singular facility with which nervous affections propagate themselves, as in the common contagion of tears or laughter.' Of course Mesmer had still his warm defenders. His cause was advocated by some amongst learned men, and the people still continued to crowd after him; but, after Franklin's decree, being no longer in hope that his former claims would be acceded to by the Court at Versailles, he soon afterwards took himself and some of his disciples off to Germany, not forgetting to carry with him the money which had been subscribed for him in France" (a).

It would be difficult to give a more just description of the patrons of Mesmerism and its allied folly, Homœopathy, than is given here by Dr. Challice—the old debauchees, the ignorant seekers after the miraculous, and the enemies of Rational Faith.

A Clinical Memoir on Certain Diseases of the Eye and Ear consequent on Inherited Syphilis. By Jonathan Hutchinson, F.R.C.S. London: John Churchill and Sons. 1863.

Introductory Address on the Study of Anthropology, delivered before the Anthropological Society of London, February 24, 1863, by James Hunt, Ph.D., F.S.A., F.R.S.L., President. London: Trübner. 1863.

Annual Report of the Bourton-on-the-Water and Cotswold Village Hospital, January, 1863.

Clinical Memoirs on Diseases of Women. By Alfred H. McClintock, M.D., F.R.C.S. Dublin: Fannin and Co.

The Fifteenth Annual Report of the Somerset County Pauper Lunatic Asylum. 1862.

Remarks on all the Human Entozoa. By T. Spencer Cobbold, M.D., F.L.S.

English Patients in Foreign Asylums. By C. L. Robertson, M.B. Cantab. The Seventh Annual Report of the United Lunatic Asylum, Nottingham. 1863.

The Forty-seventh Annual Report of the Manchester Eye Hospital. Manchester. 1863.

Transactions of the Obstetrical Society of London, Vol. IV. London: Longman and Co.

## NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

In the common intercourse of society, when a man complains of the conduct of attorneys, barristers, clergymen, or any other class, he is by no means considered to condemn every individual, but solely those who are guilty of the practices referred to. Mr. Orridge need not therefore take umbrage at observations intended solely for obscure individuals, guilty of specific bad practices.

We advise such of our readers as desire to make themselves acquainted with the full particulars of the case of *Bromwich v. Waters*, and to form their own judgment on any points in question, whether as regards the plaintiff, the defendant, or the witnesses, to order the *Chester Record* of April 11 and 18. We particularly refer to the evidence of Dr. Waters himself. Nothing can be more satisfactory to the Medical Profession than the tone maintained by the able conductors of the *Chester Chronicle*, and *Chester Courant*, and *Record*. The whole community is benefited when the public press is in firm, conscientious, and intelligent hands.

*The Life of a Statesman*.—To compensate for a queer temper, Nature gave to Sir James Graham a splendid faculty of working. In this power of work he and Sir Robert Peel were the admiration of each other, and of all who knew them. When Sir Philip Crampton, on one occasion, found Sir Robert Peel not looking over well, he ventured to suggest that the Premier did not allow himself sufficient time for rest and relaxation. "Do you think so?" was Peel's reply; "why, what I do in the way of work is nothing to what Graham does." Graham not only overworked himself, but, in order to preserve his mental vigour, underfed himself. His breakfast consisted of a cup of tea and a biscuit; he took no luncheon, and he did not dine till eight o'clock. All the day and much of the night he spent in the Home Office or in the House of Commons. He went little into society; when he did go, he returned home early, that he might give two or three hours to his papers before retiring to rest. He read everything relating to his department—every report in print or manuscript, together with the evidence on which it was founded. All new books and pamphlets he likewise attacked which had to do with his duties; and they might be found on his table with the margins well marked.—*Times*.

(a) *L'Encyclopédie*, tome iv., p. 95.

Dr. T. B. Peacock and Dr. Meadows write to complain that they have been treated with discourtesy because we did not publish *in extenso* their reports on the charge of plagiarism brought by Dr. Mayne against Dr. Fowler. We have no doubt that Drs. Peacock and Meadows did a public service to the Profession in investigating so injurious a charge, and that their report was most laboriously accurate, impartial, and satisfactory. Nevertheless, in the discharge of our duties, we decided that the substance of the report would not possess the slightest interest to our readers, and that it was of no use to revive the history of charges which ought never to have been made, and had better be forgotten. We believe that the whole Profession are satisfied with their decision, and want to hear no more of the matter.

### EXPULSION OF A FOUNDATION SCHOLAR FROM THE ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

We have received from Dr. Charles Taylor, of 4, Bethel-place, Camberwell, a letter stating a case of what he considers great injustice towards one of the Foundation Scholars of the Royal Medical Benevolent College, Epsom. Dr. Taylor states that—

"About two weeks before last Christmas holidays, one of the masters, the Rev. Mr. Hackman, who had been backward with his class, desired the boys to prepare what they considered an undue amount of Euclid. To this they demurred, and among them was H. W. Collicott." A *fracas* followed, which our correspondent thus describes: "The master lost his temper, and resented this, striking the boy several times, and pulling his hair (by the custom of the school none except the head master are allowed to use personal chastisement); the boy, in self-defence, raised his arms, which was construed by the master into a show of fighting. This passed off, the boy being permitted to join in the school Christmas amusements, and to continue his daily tasks, nothing more being said to him, nor was any notice sent to his mother of the alleged offence.

"On the morning of December 16, he was ordered to be ready to accompany the masters to London; and on the same day a letter was forwarded by post from the Secretary, requesting his mother to meet them in Soh-square at four p.m. At this time the boy's mother was from home on her daily task of teaching music, having a family of six children still depending upon her exertions. After the receipt of the letter, the Secretary called, and very blandly inquired if they had a bed for the boy, thus showing the case was prejudiced. In the absence of the mother, the boy's elder brother was sent for from the City. He attended, having no knowledge of the charge against his brother, and therefore unprepared to meet it.

"During the investigation, the master admitted he was so out of temper that he could not say what he did; the boy's statement was that he, with others, remonstrated, and only defended himself against the master's violent attack. When questioned by one of the Educational Committee as to the attitude he assumed, he raised his arms in one of self-defence, which the gentleman wrongly considered an attitude of fighting. The boy's brother was now requested to withdraw him, or be would be dismissed; having no authority from his mother, he declined doing so, but, upon being pressed, was ultimately compelled. The mother and friends of the boy, considering that the case was prejudiced, and that if due notice had been given it would have been fairly met, objected to this termination. One member of the Educational Committee stated the boy had been at the school long enough; but as during his scholarship he had been an invalid for upwards of one year, and on one occasion was at home for some months, his friends considered it to his interest that he should remain the time allowed by the rules of the school.

"The boy's brother-in-law, Major Edmund Campbell, called with the boy on Mr. Propert, who remarked on the want of gratitude displayed; and asked was this a return for all the trouble and expense he had incurred? the boy had been there long enough; and that if the boy had not been at the school so long, it would have been different. Subsequently, a meeting of the council was held, and also an adjourned meeting, and mutual explanations were given, Major Campbell, who appeared for the boy, not being able to refer to all the subjects in dispute, as no official account of the offence had been forwarded. The head master's statement was a recapitulation of petty schoolboy offences; he admitted the assault by Mr. Hackman, and also that he had chastised other boys on various occasions, although contrary to the established rule of the school, the junior masters not having authority to chastise the boys; that he (Dr. Thornton) had never admonished the boy on the occasion, or required him to apologise; stated vaguely that the boy had been guilty of various acts of insubordination, and that he had written separately to his mother on the subject, but that he had no private document referring to such acts of insubordination. The boy's mother denies ever having received such letter, or any other than the usual terminal reports. An extract from a recent note of Dr. Thornton's says, 'It is just possible I might be mistaken in making allusion to H. W. Collicott's discourteous manner and want of obedience.'

"I enclose these reports for nearly the last two years, which, signed by the head master, Mr. Hackman, and others, are unusually good, and certainly disprove any repeated acts of insubordination. Besides the school reports, I enclose two letters bearing testimony to the boy's character for five years,—1st. From the Rev. Mr. Richmond, under whom the boy was for three years; 2ndly. From the Rev. Mr. Pentreath, under whose care the boy was after Mr. Richmond, and has been conjointly with the Rev. Mr. Hackman for the last two years.

"The Council finally supported the decision of the Educational Committee at the expense of justice, and dismissed the boy. The boy's friends leave you and the Profession generally to judge of the justice of the case. They feel assured if the President and the Visitor of the College caused an impartial inquiry to be made and judged by impartial persons, the result would be the withdrawal of such a grave charge, and its consequent punishment against the boy, the establishment of his character, and the condemnation of the Head Master and the Rev. Mr. Hackman for, to say the least, great want of judgment in this matter.

"I am, &c.

"CHARLES TAYLOR, M.D., etc.

"4, Bethel-place, Camberwell, April 13."

We would be the last to countenance insubordination or rebellion in a public school, but we must confess that the case which has thus been brought before our notice appears to have been most harshly dealt with. We have received and returned to our correspondent Collicott's reports

for the years 1861 and 1862, signed by the master of his form, and by the head master. We extract their written judgment of the boy's progress and conduct during the Easter term of 1862, as a specimen of the opinion they entertained of the lad, on whom for a single act of insubordination, the authorities of the school have inflicted the most serious punishment of expulsion, a punishment the effects of which may probably tell on the lad's whole future career:—"Divinity, very good; Classics, he has worked *hard* throughout the term, and has given me much satisfaction; History and English, particularly good; French, better; German, good; Arithmetic and Mathematics, slow; Drawing, fair; Writing, good; Diligence and Progress highly commendable; Conduct, highly satisfactory."—Signed, Frederick R. Pentreath, M.A., Master of the Form. Countersigned, R. Thornton, D.D., Head Master. This is a fair specimen of these reports. The lad's conduct is certified as being "very good;" "excellent;" "good;" "very good," and "highly satisfactory" during five successive terms. It is to be remembered that Collicott was a Foundation Scholar and fatherless; to such a boy the Committee should be more than ordinarily lenient. Deprived of a father's discipline at home, such a lad is apt to acquire unruly habits; he is sent to school for the very purpose of being disciplined, not only in mind but in temper; in obtaining his election as a Foundation Scholar the subscribers who supported him doubtless held that purpose. In our great public schools expulsion is never resorted to, except as a punishment of moral delinquency. Who ever heard of a boy being expelled from Eton or Westminster for an act of boyish insubordination, which under such circumstances would be probably almost involuntary? It is impossible that any school can succeed if such is the notion the authorities have formed of government and responsibility.

#### THE APOTHECARIES' HALL OF IRELAND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In noticing a letter which appears in the last week's number of the *Medical Times and Gazette*, with the signature "Anti-Humbbug," I have to state that the legal opinion therein quoted, having been given under erroneous representation, is of no value whatever.

I am, &c.

C. H. LEET, M.D.

The Apothecaries' Hall of Ireland, Dublin, April 14.

#### MEDICAL AGENTS—CASE OF WEISS v. MACKENZIE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your anxiety to protect the Medical Profession from attempts at extortion, led you to make some remarks in your last week's number, which render it desirable for me to address you. I think it only due to Mr. Orridge and Mr. Pearce (the manager of the Bowmer agency) to state that, from the commencement, they offered me every assistance, and did all they could to vindicate the honour of their order. Both these gentlemen, not without considerable inconvenience to themselves, attended at Kingston to give evidence as regards custom, though, as the case turned out, my counsel did not think it necessary to call them.

I am, &c.

MORELL MACKENZIE, M.D. Loud.

George-street, Hanover-square, April 14.

#### CONSULTATION IN FORCEPS CASES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your last Number, a writer attributes to me the dictum that "the forceps should never be used except in consultation." This is opposed to my teaching and practice. The opinion expressed by me on the trial alluded to by the writer, bore simply upon a special case, that case being that a gentleman on being engaged to attend a patient who had previously undergone instrumental labours, undertook to call in the aid of one of two Practitioners, who were specified by name, in the event of instruments being required. Whether or no such a contract were actually made is not important. That was the hypothesis upon which my answer was founded; and I believe the tenor of your editorial comments on the case was to the same effect as my answer.

I am, &c.

ROBERT BARNES, M.D.

12, Finsbury-square, April 14.

#### LATEST NEWS OF GARIBALDI'S WOUND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As considerable doubt and uncertainty have again arisen, with much talk in professional circles and amongst the public as to Garibaldi's wound, it might be useful to state that what was explained by the "undersigned," as the protocols say, in a previous letter in your well-informed Journal, was substantially correct: that Mr. Partridge was not permitted to examine the wound—hence the imperfectness of any opinion founded on mere opinions of others. The wound is not yet healed; fragments of dead bone or other foreign body it is supposed still keep up irritation. Letters from Caprera in a morning paper say that Mr. Ferguson is expected, as he has offered to go out to Italy. The wound is not yet healed; but Mr. Partridge tells me that a very full account of the case is now about to be published. Let us remember the advice of the other "weeklies" was that amputation above the knee was the "perfect cure" for Garibaldi! and thank the old moral of the fable of the "hare and the tortoise," viz., slow and sure wins the race.

I am, &c.

April 10.

P.S. A Yankee Surgeon, after much observation of the London Hospitals, says:—"If a Brodie should advise excision of joints for acute synovitis, or a Fergusson propose division of the peroneus longus as a means of facilitating union in staphylophary," it would be noticed with great gravity in the *Lancet* and other journals. But Garibaldi's case has had no attention directed to it, nor was amputation above the knee the perfect cure it was supposed.

#### ACCOUNT OF AN EPIDEMIC RESEMBLING CHOLERA AT DONAGHADEE, COUNTY DOWN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—During the past three months several of the inhabitants of this town have been attacked with an epidemic resembling Asiatic cholera, more especially those who have lately come to reside here. The cause or causes of this curious complaint appearing at this time of the year do not seem to be very clear, but it is probable that it is owing to the very severe

gales of wind (principally from a north-easterly direction) which have been prevalent for the last two or three months, and to which this town is exposed, as also to the sudden changes of weather from wet to dry. The patients that have been attacked by this disease complained of nothing in particular save a slight indisposition a day or so before the bowels became affected. The nature of the discharge might at first have led one astray, as it appeared to arise more from a disordered state of the stomach, with a general bilious system, than a warning that a more serious disease had seized the patient, and in a few days a slightly mucous discharge showed clearly the nature of the malady. The pulse 100 to 120 in the minute. Tongue brown; fauces parched; appetite bad; and teuesmus present. The treatment which was found to succeed best was a combination of stimulating tonics with sedatives. Such as the following gave decided benefit:— $\mathcal{R}$  Acetatis plumbi, gr. iii.; camphoræ, gr. xii.; pulveris opii, gr. vi.; pulveris capsici, gr. iii.; ext. gentian, qu. s. Divide in pilulas vi. Sumat unam ter in die, with a tablespoonful of brandy in new milk thrice daily. In one severe case the patient was so much exhausted that enemata of chicken broth, etc., had to be given. After the most urgent symptoms subsided, quinine mixture, with wine and out-door exercise, were found to be of benefit.

I am, &c.

H. S. PURDON.

#### ELECTRICITY IN DIPHThERIAL NERVE AFFECTIONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your Number of April 4, you give a short account of Dr. Greenhow's paper on "Diphtherial Nerve Affections," read before the Royal Medical and Chirurgical Society. In treating of such serious lesions, I felt surprised that neither Dr. Greenhow nor any gentleman taking part in the discussion mentioned electricity among the remedies suitable for such cases, having in my own practice found it of all remedial measures the most powerful and certain in severe forms of paralysis consequent upon diphtheria. I trust you will give me a nook in your pages to supply what I consider a grave omission, as regards that part of your report bearing upon the treatment of diphtherial paralysis, whether of the nerves of sensation or motion.

I am satisfied that much time is lost in treating such cases with tonics, generous diet, quinine, steel, strychnia; these are all very well, and ought to be employed, but do not let us exclude the most direct and powerful nerve tonic we possess—the galvanic battery; moreover, its employment will not interfere with any system of treatment that may be had recourse to. I have used it now in several apparently hopeless cases, which had resisted all kinds of treatment, and which, in my opinion, must have terminated fatally but for its successful employment.

I am, &c.

A. S. MYRTLE, M.D.

Harrogate, April 14.

#### RENNET WINE.—"COAGULATION OF MILK" TEST.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As the above remedy was, through the medium of your Journal, in last July brought extensively to the notice of the Profession, and now appears to be coming into pretty general use, I wish, through the same medium, to remind those who prescribe it of the simple but satisfactory method of testing its quality which I then proposed. Any one can apply the test thus:—Place a small cup containing milk in a vessel of hot water until the milk becomes bloodwarm. Then add a teaspoonful of the rennet wine, and, if the preparation be genuine, the milk will in two or three minutes become as solid as blancmange. I have seen lately some spurious compounds sold under the name of rennet wine, having no coagulating property, and therefore worthless. I wish also to remind those who prepare the remedy that the best strong-bodied sherry should be used. If made with a weak, inferior wine, it will not keep sound very long in the approaching warm weather. I find, also, that a fortnight's digestion is quite sufficient. The wine, then, after being tested, may be strained off, and bottled for use, and fresh wine added as long as it will bear the test. Allow me to add that I have no pecuniary interest whatever in the matter, and should be glad to hear of any improvement on my method, merely premising that any good solution of the gastric juice of the calf will solidify milk, while acids will only change it into curds and whey. I consider this distinctive property of great value.

I am, &c.

Leeson-street, Dublin, April 13.

GEORGE ELLIS.

#### INTRA-CAPSULAR FRACTURE OF CERVIX FEMORIS, WITH SUPPOSED OSSIFIC UNION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A case in many respects similar to that of Mr. Mason's, will not, I trust, be unacceptable, differing in treatment, however, and in the much longer period of rest required.

The patient was a poor woman, 84 years old, active, and, with the exception of rheumatism, very healthy. The approach to her bedroom was by means of a ladder, I can hardly call it a staircase; it was polished and slippery from long use; she lost her footing one day in descending, falling on the hip, and lay on the floor insensible until her friends discovered her. When I saw her, she was in bed, lying on her back, the injured limb drawn up, and the foot everted, returning to this position after extension, which produced much pain; being fat, there was some difficulty in moving her. I caused the attendant to rotate and extend the thigh, when there was unmistakable crepitus felt by the hand placed over the trochanter, and the application of the ear was corroborative of the same. Thus satisfied, and bearing in mind the good previous health of the woman, I determined to give her the chance of rest, and hoped, notwithstanding her years, that she might again get up. She resided at a very long distance from my house, so, taking the readiest materials at hand, I encased the limb in a stiff starch splint, covering the prominences with tow; she was confined to her bed fourteen weeks; had no bed sores (although they might have been expected from the incontinence of urine), and made a good recovery, going about with the aid of a stick for a twelvemonth or more, when she sank under an attack of acute pempthigus, with subsequent bronchitis. She bore the starch imprisonment well for four weeks, when she complained of severe and constant pains in the thigh, partly, as I judged, rheumatic, and partly muscular; she got up at first with the aid of a crutch, and the help of somebody's support; the crutch was made out of a discarded sweeping brush, and the weight of the limb was gradually taken off by a stout sling, extending from the nape of the neck to the foot. The shortening did not exceed one inch and a-half.

I recommend the starch splints, well surrounded with bandages brought round the trunk and opposite thigh, as a simple contrivance, and worthy the trial in such cases—more especially of my former colleagues, the ill-

paid and overworked Union Medical officers. The result in both Mr. Mason's case and mine is encouraging. I am, &c.

HENRY USSHER, M.B., Surgeon.

Wandsworth Provident Dispensary, April 13.

ON THE PREVENTION OF LACERATION IN FORCEPS CASES.  
TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the discussion upon Mr. I. Baker Brown's paper on Vesico-vaginal Fistula, read at the meeting of the Obstetrical Society of London on February 4, and reported in the Number of your Journal for April 4, Dr. Oldham expressed his opinion "that the more frequent employment of instruments would result in the laceration of the structures at the floor of the pelvis, particularly the laceration through the sphincter of the rectum," etc. This opinion, which is shared by a large number of Practitioners, causes a great tendency to delay in the use of the forceps, and even to their entire avoidance in cases where they are indicated.

The means which I have been in the habit of adopting in all forceps cases, for a long series of years, obviate, I think, all danger of lacerating the perineum, except to a very slight extent in primiparæ. When the forceps have been applied, and the head of the child has been brought down sufficiently low on the perineum that the forefinger of the Accoucheur introduced into the rectum can reach, for instance, in occipito-anterior presentations, beyond the frontal eminence, the instrument should be withdrawn, or, if that be not convenient, all traction should be discontinued, and the finger, still retained in the rectum, should be used after the manner of the vectis, pressure being made with it, first on the space between the frontal eminences and the root of the nose, and afterwards on the upper jaw, and perhaps, if necessary, on the chin, as these parts successively come within reach. By this means the head is made to rotate in the axis of the outlet, and, being directed forwards under the pubes, its pressure on the perineum is greatly relieved.

I have adopted the above plan not only in a large number of forceps cases, but also in hundreds of instances of ordinary labour, with the effect of greatly expediting delivery during the last and most painful stage, and of protecting the perineum to an extent which the usual method of supporting it cannot accomplish. In no case have I found any inconvenience or injury to arise from the pressure of the finger upon the recto-vaginal septum. I am, &c.

Birkenhead, April 11.

CHARLES RICKETTS, M.D.

REMUNERATION OF MEDICAL MEN BY INSURANCE OFFICES.  
TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The question of Life Insurance Office fees is one that demands, in my opinion, particular attention on the part of the Profession. The remuneration is becoming gradually cut down to an absurdly low figure. One office offers the munificent sum of half-a-crown for an examination and report. Generally it may be said that a principle of graduation is adopted, the fees being proportioned to the sums insured. But it is to be observed that this principle is only made use of for the purpose of lowering the fees for the advantage of the office. It seems but equitable, if the referees consent to accept these low fees on the small insurances, that the scale should be extended to the larger sums insured in a corresponding increasing ratio. I for one should be sorry to hamper those small insurances which the thrifty labouring classes are likely to effect, by exacting higher fees than can be well afforded in such cases; but I think that, if Medical men, acting in a liberal spirit, acquiesce in these diminished fees, the offices ought to meet them in a like liberal spirit. With these views I have lately drawn up a letter addressed to the Secretary of the United Kingdom Provident Institution, an office which has at least two agents in this town, and has appointed most, if not all, of the resident Practitioners as its referees. The scale of fees of this office is as follows:—Under £200, 5s.; £200, and under £500, 10s.; £500 and upwards, £1. Here the scale stops, and, however much the sum insured, the fee of the Medical examiner is never more than one pound. The letter in question represented the insufficiency of this remuneration, and conveyed a refusal to act any longer on the same terms. It also contained the following conditions, representing the terms on which the signers are willing to act, not only for the United Kingdom Provident Institution, but for all other insurance offices:—

"Conditions.

- "1. The minimum fee for which we will make reports to those offices which adopt fixed fees, is £1 for each case.
- "2. In the case of those offices which adopt a fluctuating scale of fees, commencing below £1, the minimum rate of remuneration for which we will make reports is, for each case, 5s. per cent. on the sum proposed to be insured, and we will not examine or report for any such offices unless the scale is adapted and made applicable to all insurances, whether large or small, at the same rate per cent. for the higher as for the lower amounts.
- "3. We will not under any circumstances whatever make a report for a smaller fee than 5s.
- "4. We require to be furnished by any society for which we may be called on to act with a plain written or printed statement of the mode and amount of remuneration usually given to its Medical referees.
- "5. We will not furnish reports to offices which require the candidates for insurance to pay the fees of the Medical examiners.
- "6. We will not on any consideration furnish reports to offices which do not remunerate the Medical examiners in compliance with the foregoing conditions."

The letter was signed, with one exception, by all the Medical Practitioners in this town, who pledged themselves therein to abide by the above conditions in their future dealings with all Life Insurance Societies. At the same time each one was left at liberty to demand higher terms for his services if he should choose to do so.

I cannot but think if other towns and districts would band together in the same way, that a stop would soon be put to the shameful cheapening of the services of Medical men at present practised by the insurance offices. It is by no means necessary that we should be unanimous in order to effect this object. If the highminded and honourable will combine to resist the extortion, the office of insurance referee will soon be delegated to the wolves and jackals of the Profession—those who are willing and ready at every turn to undersell their brethren. It is clear that in this case the offices would be far from having the best and most reliable advice to depend on. In short, it can hardly be doubted that they would have as their Medical advisers the winnowed chaff—the very scum and dregs of the Profession. It will, then, be for them to decide whether they have what they want. It is for us to say now whether they shall have sterling goods at the prices of a "cheap Jack" in a fair.

I am, &c.

# TOWLE'S CHLORODYNE.

**CAUTION.**—For the convenience and safety of prescribing Chlorodyne, in combination with other ingredients, so as to avoid decomposition (a result known to have taken place) through the use of SECRET COMPOUNDS, Mr. TOWLE begs to call the attention of the Profession to the following component parts in his Preparation:—

CHLOROFORMYL.  
ETHER.

OL. MENTH. PIP.  
ACID. PERCHLOR.

TINCT. CANNABIS INDICÆ.  
ACID. HYDROCYAN.

TINCT. CAPSICI.  
MORPHIA & THERIACA.

The proportion of Morphia— $\frac{3}{4}$  gr. inf. ʒj. Dose—Five to Twenty Drops.  
Letter from ALFRED ASPLAND, Esq., F.R.C.S. Eng., J.P. Chester and Lancaster, Surgeon 4th Cheshire Batt. V.R., Surgeon to the Ashton Infirmary.—“After an extensive trial of your Chlorodyne in Hospital, Infirmary, and Private Practice, I am able to state that it is a valuable medicine. I have found its action peculiarly serviceable in Bronchial, Spasmodic, and Neuralgic Affections. I have never found it produce headache or feverish disturbance, results which not unfrequently occur from other forms of Chlorodyne. As a sedative to allay excitement arising from the abuse of intoxicating drinks, so commonly witnessed in our Barrack Hospital, I have been perfectly satisfied with it. Its known composition will doubtless prove an additional recommendation to the Profession.”

Sold by Wholesale Houses in bottles, 1 oz., 1s. 6d.; 2 oz., 2s. 6d.; and 4 oz. to 20 oz., 1s. per fluid oz.

Sole Manufacturer—A. P. TOWLE, CHEMIST, &c., 99, STOCKPORT-ROAD, MANCHESTER.

## *Pulvis Jacobi ver, Newbery*

“INVENTED AND DISCOVERED, IN 1844, BY RICHARD FREEMAN.”

(Extract from Affidavit made before S. C. WARD, Esq., Chancery Record Office, Chancery-lane, London, June 16th, 1862.)

The Inventor begs to thank the Medical Profession for the liberal support he receives from them, and to assure those who have not yet tried his Chlorodyne that it is superior to any other maker's, being more certain and more lasting in its effects; and the low price which he charges for it allows the poorest sufferer to enjoy its extraordinary beneficial influence. The immense demand for it by the Profession is a convincing proof that they find it a most valuable therapeutic agent. The following are a few out of many voluntary Medical Testimonials:—

From W. VESALIUS PETTIGREW, M.D., Hon. F.R.C.S. Eng., formerly Lecturer upon Anatomy and Physiology at the St. George's School of Medicine.

“I have had the opportunity of trying the effects of Mr. Freeman's Chlorodyne, and find it an excellent Anodyne and Antispasmodic medicine.”

From H. J. O'DONNELL, M.R.C.S.E. and L.M., &c., &c., Albert-terrace, London-road, S.

“I can with much confidence bear testimony to the efficacy of Mr. Freeman's Chlorodyne as a Sedative and Antispasmodic, having used it for some years in Colic, Neuralgia, Phthisis, and Asthma. I daily administer it in after-pains, and in all cases find it infallible. It is the most valuable medicine we have in Labour cases. I find, since I have used it, the pains

seldom or ever exceed the third day, while with the former remedies my patients suffered eight or nine days. In fact, I cannot speak too highly of it.”

From F. W. HOOPER, M.D., M.R.C.S. Eng., &c., &c., Medical Officer, Christ Church District, Camberwell.

“I have much pleasure in stating that, after a sufficient trial of Mr. Freeman's Chlorodyne, I am fully persuaded that it is superior to any preparation of the kind, and, from its moderate price, is a great boon to the suffering poor, who daily acknowledge its salutary benefit.”

From W. G. KING, M.D., M.R.C.S. Eng., Hackney.

“I have used your Chlorodyne for some time, and can bear testimony to its efficacy and value in all cases in which a Sedative has been indicated.”

Manufactured by RICHARD FREEMAN, Pharmacist, Kennington-road, London, S.; And Sold by all Wholesale Houses, in bottles, 1 oz., 1s. 6d.; 4 oz., 5s.; and 8 oz., 10s. each.

TRADE MARK

# CHLORODYNE

WAS DISCOVERED AND INVENTED IN THE YEAR 1848 BY  
DR. J. COLLIS BROWNE, M.R.C.S.L. EX-ARMY-MED. STAFF  
AND IN 1856 HE CONFIDED  
THE ORIGINAL AND ONLY FORMULA  
FOR ITS MANUFACTURE  
SOLELY TO J. T. DAVENPORT, PHARMACEUTIST,  
33, GREAT RUSSELL ST. BLOOMSBURY SQUARE, LONDON.  
REGISTERED, 1856.

## NOTIFICATION.

THE attention of Medical Men is directed to the Piratical application, by some parties in the Trade, of the term “Chlorodyne” to various mixtures compounded of Chloric Ether Opium, Indian Hemp, and Peppermint, in Imitation of the ONLY Genuine preparation of this name.

The dangerous expedient of encouraging or advocating the assumption of a name specifically indicating a particular property or remedy—such as *Chlorodyne* is to spurious imitations and substitutions—ON THE GROUND OF CHEAPNESS, is a subject of surprise and grave reproach, supremely so, when the adulteration, sophistication, and tampering with Drugs, becomes so serious and important a consideration in the successful practice of Medicine.

The fact of these Piracies must fully convince the Profession of the extraordinary efficacy of the Genuine Chlorodyne; whereas the sad results and disappointment arising from the use of spurious compounds cannot be expressed.

Each Genuine Bottle bears a Red Stamp, with the words, “Dr. J. COLLIS BROWNE'S CHLORODYNE,” in White Letters.

To be obtained from all Wholesale Druggists in 1oz., 2oz., 4oz., and 8oz. Bottles.

**NOTICE. — REDUCTION OF PRICE TO THE PROFESSION.**

In Bottles, 1oz., 3s.; 2oz., 5s.; 4oz., 8s.; 10oz., 15s. To Hospitals and Charities in large quantity, a Liberal Discount.

PROFESSOR HUXLEY'S LECTURES  
AT THE  
ROYAL COLLEGE OF SURGEONS.

LECTURE V.

(Being the Fourth of Six Lectures on Classification, and on the Characters of the Principal Groups of the Animal Kingdom.)

IN the rapid survey of the animal kingdom with which we have been hitherto occupied, I have, for reasons which will be obvious by-and-by, taken group by group, and considered each separately upon its own merits, without attempting to say anything at all of the characteristics of the larger divisions into which these classes may be arranged. That is a point to which I shall return on a future occasion.

But with those animals which are called "vertebrated" such a course as that which has been pursued hitherto would involve a great and unprofitable expenditure of time and much repetition, because the five classes of animals which pass under this name, the classes *Pisces*, *Amphibia*, *Reptilia*, *Aves*, and *Mammalia*, are obviously united and bound together by many common characteristics, and are well known to be so bound together. I shall commence the present lecture, therefore, by enumerating the most important of those structural peculiarities which these five groups exhibit in common.

In the animals to which our attention has hitherto been confined, the external or integumentary and parietal portion of the blastoderm never becomes developed into more than a single saccular or tubular investment, which incloses all the viscera. So that if we make a transverse section of any one of these animals endowed with a sufficiently high organisation to possess a nervous system and a heart, that section may be represented diagrammatically as in Fig. 1 (I), where

FIG. 1.

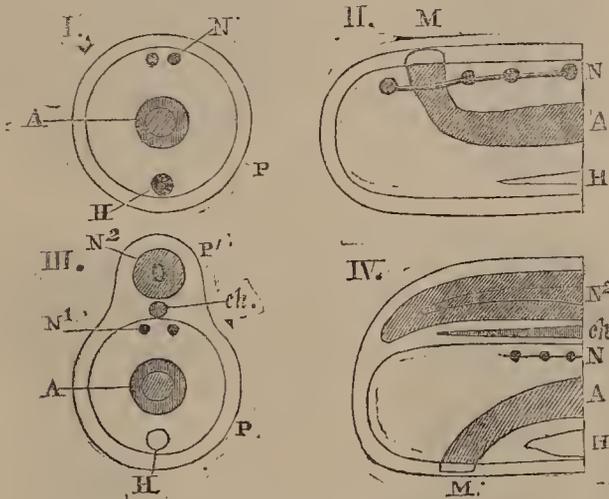

FIG. 1.—Diagrams representing generalised sections of one of the higher Invertebrates (I, II), and of a Vertebrate (III, IV.); I, III, transverse, II, IV, longitudinal section. A, alimentary canal; H, heart; P, parietes of the body; P', parietes of the neural canal; N, nervous centres of Invertebrate; N<sup>1</sup>, sympathetic, and N<sup>2</sup>, cerebro-spinal centres of Vertebrate; ch, notochord; M, mouth.

P represents the parietes or wall of the body, A the alimentary canal, H the heart, and N the nervous centres. It will be observed that the alimentary canal is in the middle, the principal centres of the nervous system upon one side of it, and the heart upon the other. In none of these animals, again, would you discover in the embryonic state any partition formed by the original external parietes of the body between the nervous centres and the alimentary canal.

But in the five vertebrate classes, the parietal portion of the blastoderm always becomes raised up upon each side of the middle line into a ridge, so that a long groove is formed between the parallel ridges; and the margins of these, eventually uniting with one another, constitute a second tube parallel with the first, by a modification of the inner walls of which the vertebrate cerebro-spinal nervous centres are developed; so that after any vertebrated animal has passed through the very

earliest stages of its development, it is not a single, but a double tube, and the two tubes are separated by a partition which was primitively a part of the external parietes of the body, and which lies between the cerebro-spinal nervous centres and the alimentary canal. Hence, a transverse section of any vertebrated animal may be represented diagrammatically by Fig. 1 (III), where for the most part the letters have the same signification as in the foregoing case, but where (P') denotes the second, or cerebro-spinal tube. The visceral tube (P) contains, as in the case of the invertebrate animal, the alimentary canal, the heart, and certain nervous centres, belonging to the so-called sympathetic system, and the two latter are situated upon opposite sides of the former; so that the cerebro-spinal tube appears to be a super-addition,—a something not represented in the invertebrate series. The formation of the cerebro-spinal tube of vertebrates, in the manner which I have described to you, is a well-established fact; nor do I entertain any doubt that the cerebro-spinal centres, viz., the brain and the spinal cord of vertebrates are the result of a modification of that serous layer of the germ which is continuous elsewhere with the epidermis. Two years ago, I took some pains to verify the remarkable discoveries of Remak in relation to this point, and, so far as the chick is concerned, at any rate, his statements appeared to me to be fully borne out. But, as Von Baer long ago suggested, it is a necessary result of these facts that there can be no comparison between the cerebro-spinal nervous centres of the *Vertebrata* and the ganglionated nervous centres of the *Invertebrata*, and the homologues of the latter must be sought elsewhere, probably in the sympathetic.

Doubtless in close connection with this profound difference between the chief nervous centres of the vertebrate and the invertebrate is another remarkable structural contrast. In all the higher invertebrates, with a well-developed nervous system, the latter is perforated by the gullet, so that the mouth is situated upon the same side of the body as the principal masses of the nervous system, and that some of the ganglia of the latter lie in front of, and others behind the oesophagus. A longitudinal vertical section of such an animal therefore may be represented by Fig. 1 (II).

A similar section of a vertebrated animal shows, on the contrary, the chief centre of the nervous system imperforate by the oesophagus; the latter turning away from it and opening upon the opposite side of the body (Fig. 1, IV).

Another structure sharply distinctive of the vertebrate classes is the "chorda dorsalis" or "notochord," an organ of which no trace has yet been discovered in any of the invertebrates, though it invariably exists, in early embryonic life, at least, in every vertebrate. Before the cerebro-spinal canal is complete, in fact, the substance of the centre of its floor, beneath the primitive median line of the embryo, becomes differentiated into a rod-like cellular structure which tapers to both its extremities, and in a histological sense remains comparatively stationary while the adjacent embryonic tissues are undergoing the most rapid and varied metamorphoses.

To these great differences in their early condition between vertebrates and invertebrates many others might be added. In all *Vertebrata* that part of the wall of the body which lies at the sides of, and immediately behind the mouth, exhibits a series of thickenings parallel with one another and transverse to the axis of the body, which may be five, or more, in number, and are termed the visceral arches. The interspaces between these arches becoming thinner and thinner, are at length perforated by corresponding clefts, which place the cavity of the pharynx in free communication with the exterior. Nothing corresponding with these arches and clefts is known in the invertebrata.

A vertebrated animal may be devoid of articulated limbs, and it never possesses more than two pair. These limbs always have an internal skeleton, to which the muscles moving the limbs are attached. Whenever an invertebrate animal possesses articulated limbs, the skeleton to which the muscles are attached is external, and is connected with an external body skeleton.

When an invertebrated animal possesses organs of mastication, these are either hard productions of the alimentary mucous membrane, or are modified limbs. In the latter case there may be many pairs of them—numerous *Crustacea*, for example, have eight pairs of limbs devoted to this function. In no vertebrated animal, on the other hand, are limbs so modified and functionally applied, the jaws being always parts of the cephalic parietes specially metamorphosed, and totally

distinct from the limbs. All vertebrated animals, finally, possess a distinct vascular system, containing blood with suspended corpuscles of one kind, or of two, or even three, distinct kinds. In all, save one, there is a single valvular heart—the vessels of the exception, *Amphioxus*, possessing numerous contractile dilatations. All vertebrates possess a hepatic portal system, the blood of the alimentary canal never being all returned directly to the heart by the ordinary veins, but being more or less largely collected into a trunk which ramifies through and supplies the liver.

These are the most important characters by which the vertebrate classes are distinguished, as a whole, from the other classes of the animal kingdom; and you will observe that their number and importance go a long way to justify the step taken by Lamarck when he divided the animal kingdom into the two primary subdivisions of *Vertebrata* and *Invertebrata*.

If we seek now to construct definitions of the first two classes of the vertebrata, *Pisces* and *Amphibia*, we shall meet with some difficulties, arising partly from the wide variations observable in the structure of fishes, and partly from the close affinity which exists between these and *Amphibia*.

No fish exhibits any trace of that temporary appendage of the embryo of the higher vertebrates which is termed an amnion, nor can any fish be said to possess an allantois, though the urinary bladder of fishes may possibly be a rudiment of that structure. The posterior visceral clefts and arches (a) of fishes persist throughout life, and are usually more numerous than in other vertebrates, and upon, or in connexion with, them are developed villi, or lamellæ, which subserve the respiratory function.

Median fins, formed by prolongations of the integument, supported by one or other kind of skeleton, are very characteristic of fishes, and it is questionable if any fish exists altogether devoid of the system of median fin-rays and their supports, which have been termed inter-spinous bones and cartilages. On the other hand, no vertebrate animal, other than a fish, is known to possess them.

When the limbs, or pectoral and ventral fins, are developed in fish they always exhibit a more or less complete fringe of fin-rays. No amphibian is known to possess such rays in its lateral appendages, but there is some reason to believe that the extinct *Ichthyosauria* may have been provided with them.

In most fishes the nasal sacs do not communicate directly with the cavity of the mouth, but the *Myxinoidea* and *Lepidosiren* are exceptions to this rule.

The blood-corpuscles of fishes are always nucleated, and are commonly red, but by a singular exception those of *Amphioxus* (the Lancelet, which is an exception to most rules of piscine organisation,) are colourless.

Almost all fishes have the heart divided into two auricles and one ventricle; but *Amphioxus*, as I have previously stated, is devoid of any special heart, being provided instead with a number of contractile, vascular dilatations; while *Lepidosiren* possesses two auricles, and at the same time is provided with lungs.

It is useless therefore to appeal to the olfactory organ, the blood, the heart, or the respiratory organs, for characters at once universally applicable to, and diagnostic of, fishes.

The *Amphibia* (or Batrachians, Salamandroids, *Cæcilia*, and Labyrinthodents) resemble fishes, and differ from all other vertebrates in the entire absence of the amnion, and the questionable character of the supposed rudiment of the allantois. They resemble fishes yet again, and differ from all other vertebrates in possessing branchiæ developed from the visceral arches during a longer or shorter period.

None are known to be provided with median fins supported by fin-rays, and their limbs are never fringed with fin-rays.

Furthermore, in all *Amphibia* which possess limbs, the skeleton of these limbs is divisible into parts which obviously correspond with those found in the higher vertebrates. That is to say, in the fore limbs there are cartilages or bones answering in their essential character and arrangement to the humerus, radius and ulna, carpus, metacarpus, and phalanges; and in the hind limb to the femur, tibia and fibula, tarsus, metatarsus, and phalanges of the higher vertebrates. This is the case in no fish; for, whether fishes possess parts corresponding with, e.g., the humerus, radius and ulna, etc., or not, certain it is that the elements of their limb skeletons are

(a) The relation of the perforated pharynx of *Amphioxus* to the visceral arches and clefts is not known.

very differently disposed from the arrangement in *Amphibia* and in higher vertebrates.

In all *Amphibia* the skull articulates with the spinal column by two condyles, and the basi-occipital remains unossified. Furthermore, the cranial peduncle or suspensorium, to which the lower jaw is articulated, gives attachment to the hyoidean apparatus.

These last are characters by which the *Amphibia* are sharply distinguished from the higher vertebrates.

There is a striking contrast between the close affinity of the fish and the amphibian and the wide separation of the *Amphibia* from the succeeding classes, all of which possess, in the embryonic state, a well-developed amnion and allantois, the latter almost always taking on, directly or indirectly, a respiratory function.

The amnion is a sac filled with fluid which envelopes and shelters the embryo during its slow assumption of the condition in which it is competent to breathe and receive food from without. The mode of its formation is shown in the accompanying figures of the early stages of development of the common fowl. Fig. 2, A, represents the first step in the differentiation of the embryo from the central portion of the blastoderm—that thin membranous cellular expansion which lies on the surface of the yolk where we see the cicatricula, or "tread:" a well-defined, though shallow, straight

FIG. 2.

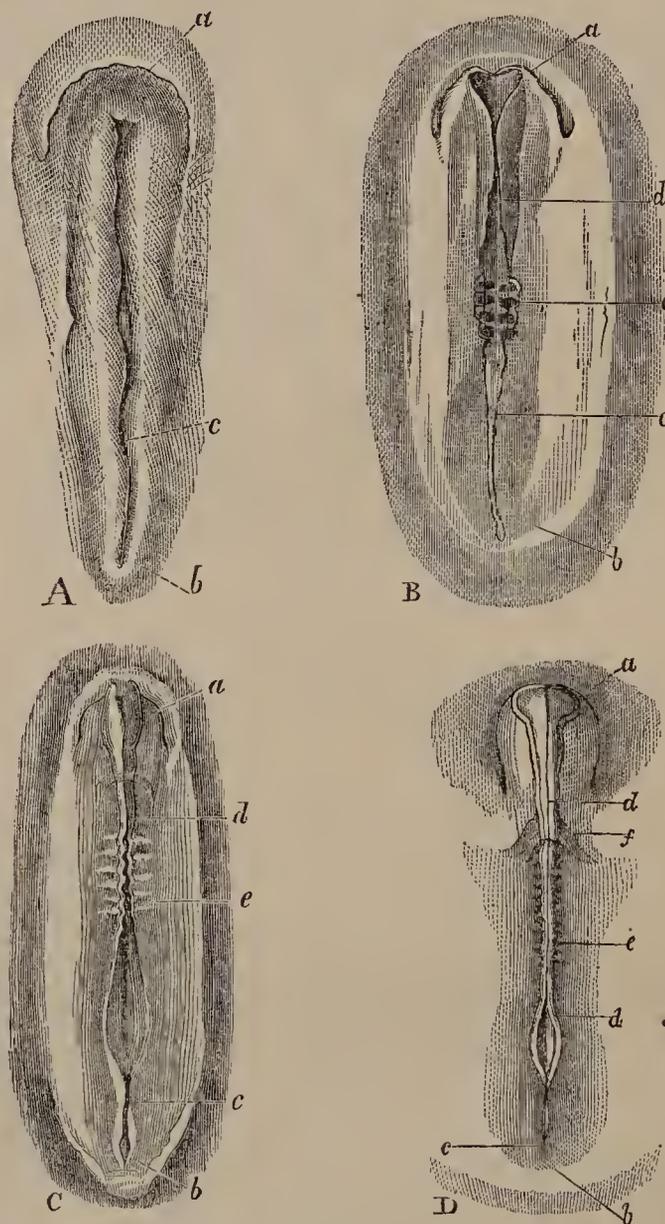

FIG. 2.—Development of the Chick.

- A. First rudiment of the embryo; a, its cephalic; b, its caudal end; c, primitive groove.  
 B. The embryo further advanced; a, b, c, as before; d, the dorsal laminae developed in the cephalic region only, and nearly uniting in the middle line; e, the proto-vertebrae.  
 C. Letters as before. The dorsal laminae have united throughout the greater part of the cephalic region, and are beginning to unite in the anterior spinal region.  
 D. Embryo further advanced (second day), the dorsal laminae having united throughout nearly their whole length. The proto-vertebrae have increased in number, and the omphalo-mesenteric veins, f, are visible

FIG. 2.

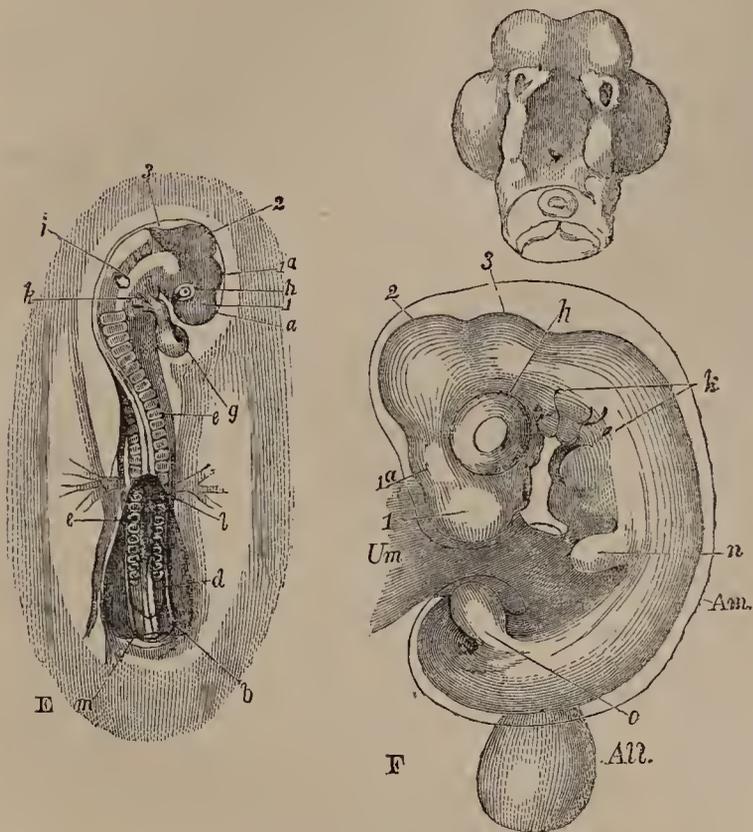

FIG. 2.—Development of the Chick.

E. Embryo at the third day; *g*, heart; *h*, eye; *i*, ear; *k*, visceral arches and clefts; *l*, *m*, anterior and posterior folds of the amnion, which have not yet united over the body; 1, 2, 3, first, second, and third cerebral vesicles; 1*a*, vesicle of the third ventricle.

F. Chick at the fifth day; *n*, *o*, rudiments of the anterior and posterior extremities; *Am*, amnion; *All*, allantois; *Um*, umbilical vesicle.

groove, the "primitive groove," bounded at the sides by a slight elevation of the blastoderm, indicating the position of the future longitudinal axis of the body of the chick. Soon, the lateral boundaries of this groove, in what will become the anterior region of the body, grow up into plates—the dorsal laminae—(Fig. 2, B.); and these dorsal laminae at length uniting inclose the future cerebro-spinal cavity. (Fig. 2, C, D) The blastoderm beyond the region at which the dorsal laminae are developed grows downwards to form the ventral laminae, and where the margins of these pass into the general blastoderm, the outer serous or epidermic layer rises up into a fold, which encircles the whole embryo, and the anterior and posterior parts of this fold growing more rapidly than the lateral portion, form a kind of hood for the cephalic and caudal ends of the body respectively. (Fig. 2, E.) The margins of the hoods and of their lateral continuations at length meet over the middle line of the body, and there coalesce, so that the body is covered for a while by a double sac, the inner layer of which is formed by that wall of the fold of the serous layer which is inferior, or nearest to the body of the embryo; while the outer layer is formed by that wall which is superior, or furthest from the body of the embryo. The outer layer eventually disappears as a distinct structure, while the inner remains as the amnion. From the mode of formation which has been described, it results that the amnion is a shut sac enveloping the body of the embryo, and continuous on the ventral side of the body with the integument of a region which eventually becomes the umbilicus.

The allantois is developed much later than the amnion, neither from the serous nor from the mucous (or epidermic and epithelial) layers of the germ, but from that intermediate stratum whence the bones, muscles, and vessels are evolved. It arises, as a solid mass, from the under part of the body of the embryo, behind the primitive intestinal cavity and enlarging, becomes a vesicle, which rapidly increases in size, envelopes the whole embryo, and, being abundantly supplied with arterial vessels from the aorta, serves as the great instrument of respiration during foetal life; the porosity of the egg-shell allowing the allantoic blood to exchange its excess of carbonic acid for oxygen by osmosis.

The amnion and the external part of the allantois are thrown off at birth.

That which has just been stated respecting the development and characters of the amnion and allantois of the chick is true not only of all birds, but of all reptilia.

ORIGINAL COMMUNICATIONS.

NOTES ON LABOURS.

By CHARLES DAVID DOIG, Surgeon.

LARGE statistics on Surgical practice supply information that is not to be got from the investigation of a few cases. The data thus obtained owe their value to the care and accuracy with which the observations have been taken, as well as to numerical quantity.

Labours form a topic of Obstetric Pathology which has been in no small degree elucidated by numerical inquiry. The annual Medical report of Guy's Hospital [J. C. Steele, M.D.,] contains a special account of labours, of which the following is a summary, during the years 1854, 1856, 1861:—

"The patients are attended by the pupils of the Hospital, under the immediate superintendence of the two Obstetricians. Two of the senior pupils are in constant residence for two months at a time to keep the records and to attend to cases of urgency when the others are engaged, as well as to direct the junior pupils in cases of doubt or difficulty. The records of this department of the Hospital have always been carefully kept, and the small rate of mortality attending its operations is a sufficient criterion of its administrative success. The charity is entirely confined to the south side of the river, and embraces a densely-populated neighbourhood of considerable extent. Taking the Hospital as a centre, its radius extends two miles in every direction—from Lambeth-walk on the west to Rotherhithe on the east, while the High-street, Borough, forms the central line, and subdivides the area into two nearly equal parts."

The total number of labours that occurred during the three years was 5254, of which there were—During the year 1854, 1738; during 1856, 2011; during 1861, 1505.

		Single.	Twin.	Triplet.
Of 1755 births during 1854,	there were	1721	17	
„ 2028	„ 1856	1994	17	
„ 1527	„ 1861	1485	18	2
		5310	5200	52 2

It is shown that single births are largely preponderant, that twins happen once in about 101 deliveries, while triplets occur only so often as one in 2627 deliveries.

Births.	Alive.	M.	F.	Still-born.	M.	F.	Abortions.	Monsters
Of the 1755	1680	869	811	66	36	30	8	1
„ 2028	1932	1019	913	96	57	39	..	..

	5310	2641	2447	213	120	93	8	1

It thus appears that while a larger number of males are born than females, the number of still-births among the males is greater than among the females, being, in the former, 1 in nearly 23; in the latter, 1 in 27; the total still-births, excluding abortions and monsters, being nearly 1 in 25.

Presentations in 5310 Births.

### MARRIAGES OF CONSANGUINITY. (a)

By GILBERT W. CHILD, M.D. Oxon., M.R.C.P.,  
Physician to the Radcliffe Infirmary, Oxford.

Two very opposite views have been maintained recently by different physiologists as to the effect of what is called close-breeding amongst domestic animals, or consanguineous marriage among the human race. One party, and the more popular of the two, has maintained that such unions are unnatural, contrary, that is, to some unknown law of nature; and that they entail degeneracy upon their offspring by way of natural consequence, and independently of the ordinary laws of inheritance. Amongst the supporters of this view may be enumerated Dr. Bemiss, of Louisville, Dr. Devay, of Lyons, and M. Boudin; and, if I may judge by the conclusion of his recent work on the "Fertilisation of Orchids," Mr. Darwin, among English physiologists, inclines to the same view. Others, again, believe that no such law of nature exists, and that, on the other hand, where ill effects are observed to follow upon the unions in question, they do so by ordinary inheritance only. This is, if I mistake not, the view of Von Baer, of Dr. Elliotson, of Dr. Davy, and several recent French writers to whom I shall presently have to refer.

My object in the present paper will be to examine shortly the facts and arguments which form the evidence for each view, to adduce some few fresh observations which I have been able to collect, and finally endeavour to show to which side the balance of evidence inclines. The case will, I hope, prove to be somewhat clearer than it is supposed to be.

In April, 1861, I published a paper in the *Medico-Chirurgical Review*, the conclusions of which were strongly in favour of the latter of these two opinions. Very shortly after this there appeared (in the *Comptes-Rendus* for June 16) a summary of some investigations of M. Boudin, which has been since very widely circulated in this country, wherein he shows (a) that the number of deaf-mutes born of marriages between blood relations in France is four times what it ought to be, as compared with the proportion which such marriages bear to the total number of marriages, and (b) further states that the phenomenon cannot be one of ordinary inheritance, inasmuch as deaf and dumb parents, unless related in blood, are not found to have deaf and dumb children. Since the appearance of this memoir a great deal of interest has been manifested in the subject both here and in France.

This question has been investigated to a considerable extent by both the methods which are applicable to it, viz., that of observation and statistical report in the case of the human race, and that of direct and most extensive experiment in the case of the lower animals. I expect to be able to show (1) that of these two methods the former is that upon which the first of the two views I have mentioned is almost exclusively based, but that it is liable to several sources of error, and that even the evidence which it has afforded is conflicting. (2) That the latter method alone is capable of affording results either scientific or satisfactory, and that these results are entirely inconsistent with the view to which I refer.

To begin with the former.

1. The principal charges brought against the marriages of blood-relations are that they are apt to produce sterility, idiocy, insanity, deaf-mutism, deformity, and scrofula. There is to my mind an *a priori* difficulty in believing that one and the same cause can produce results so diverse that several of them seem to have no relation to one another; but of this I will not speak further at present. It will be unnecessary to compare the various sets of statistics which I have met with at any great length, and to do so would prolong this commu-

nication to an inconvenient extent, but I will refer such of my readers as are interested in the subject, and wish to check my statements, to sets of statistics by Dr. Bemiss and Dr. Howe in the *Journal of Psychological Medicine* for April, 1857, by Dr. Devay, in his work on "Hygiène des Familles," second edition, and to M. Boudin's memoir above referred to. They will find, as I have done, that in each of the four some one form of disease or defect greatly predominates, and in each case a totally different form, but all—as we are asked to believe—the result of the same cause. Thus, to compare them as nearly as I can in four particulars: Dr. Bemiss gives amongst the offspring of 34 marriages, 23 cases of scrofula, 4 idiots, 2 deformed, and none deaf and dumb. Dr. Howe, in the offspring of 17 marriages, 12 scrofulous, 1 deaf, none deformed, and 44 idiots. Dr. Devay, among the produce of 121 marriages, finds 1 deaf-mute, no idiots, and 27 deformed persons, he says nothing of scrofula, but supports from other sources exactly the view on the subject of deaf-mutism subsequently confirmed by M. Boudin. Again, sterility is a marked feature of the marriages enumerated by Dr. Devay, while those collected by Drs. Bemiss and Howe considerably exceed the average in fertility. The impression produced on my mind by statistical results such as these, is that by a similar process it would be equally easy to support the proposition that the intermarriages of persons having blue eyes or black hair was contrary to the laws of nature, and accordingly I was not surprised at meeting with a paper in the *Lancet* for July 5, 1862, by Mr. Anderson Smith, wherein he shows that results considerably worse than those above given have followed in forty cases of intermarriage between natives of different European countries, the statistics of which cases he has collected.

The application of the statistical method to matters of this kind is, in fact, attended with very great difficulties. There are, no doubt, a vast number of points connected with pathology and Medicine, as with most other subjects, to the elucidation of which statistics have already contributed enormously, and will contribute still more. No better instance of this fact could be given than is to be found in such investigations as those of Louis into the frequency of the deposit of tubercle in one lung rather than the other, or in one portion of the lung in preference to other parts; or again in the lung as compared with other organs of the body. In such matters, provided only a sufficient number of cases be examined, and reasonable care be exercised in the examination, statistics are no doubt a most valuable source of knowledge. Even in some cases where human agency is concerned, the same may be true, as in Mr. Buckle's celebrated instance of the regularity existing in the number of letters put into the post every year without addresses; but I cannot believe that the rule holds good where human interests and prejudices are largely concerned, unless it can be shown that these are equally involved on both sides of the account. Thus, to take the instance before us, M. Boudin states expressly that in very few cases were the parents of the deaf-mutes themselves deaf and dumb. Now, if his inquiries extended no further than the parents, he is certainly not justified in the conclusion which he draws that therefore the phenomenon is not hereditary. In so arguing he entirely leaves out of the account the phenomena of atavism, as it is called, and other well-known but apparently irregular vagaries of admittedly hereditary diseases. If, on the other hand, M. Boudin did carry his investigations beyond the immediate parents, I have no hesitation in saying from my own experience, corroborated, as I doubt not it will be by that of any one who has ever tried to extract a family history from a patient, that it must have been simply impossible, in the great majority of the cases, to obtain anything like reliable information. Poor persons are, as a rule, too ignorant, or unintelligent, or suspicious. Well-to-do persons commonly guard a family secret with the most irritable jealousy, and are, moreover, themselves not seldom kept in ignorance by their parents.

The details of M. Boudin's statistics have not yet been published, or at least had not been a few weeks ago, and therefore are not open to criticism; but even if they are exposed to no other source of fallacy, the two which I have now mentioned would go far to invalidate his conclusions. It is worthy of remark, moreover, that, taking M. Boudin's report as it stands, in only one case of deaf-mutism out of every four was consanguinity on the part of the parents found to have existed. He is therefore, I think, hardly justified in assigning one out of a large and complicated group of antecedents

(a) Read before the British Association for the Advancement of Science at Cambridge, October, 1862.

as the cause of a phenomenon which is itself absent in the great majority of cases in which the phenomenon in question occurs.

While upon this part of the subject, I may further point out that the supporters of the opinion which I am now combating do not seem to have allowed their fair weight to some other of the known facts of ordinary inheritance, such as the comparative rapidity and certainty with which a particular point of external conformation is perpetuated by close-breeding, as in several well-known breeds of sheep; and the curious fact that even acquired defects are found to be inherited. Perhaps the most familiar instances of this are the well-known cases in which a mare with curbs, and a stallion with blindness acquired late in life, have been found to produce offspring presenting the same defects almost, if not quite, congenitally. The following short paragraph, which I quote from Mr. Youatt's well-known work on the horse, is almost conclusive on these points. As regards that animal he says, p. 317:—"There is scarcely a disease by which either of the parents is affected that the foal does not often inherit, or at least occasionally show a predisposition to it. Even the consequences of ill-usage or hard-work will descend to the progeny. There has been proof upon proof that blindness, roaring, thick wind, broken wind, spavins, curbs, ringbones, and founder have been bequeathed to their offspring both by the sire and the dam. It should likewise be recollected that although these blemishes may not appear in the immediate progeny, they frequently do in the next, or even (some) more distant generation."

If these remarks can at all be extended to the human race, they will at once show how much more is to be attributed to ordinary inheritance than we are apt to suppose, and at the same time demonstrate the utter impossibility of getting at such truths by collecting family histories.

It is to be remembered, too, that the diseases laid to the account of consanguinity in the parents are for the most part such as are not thoroughly understood—that is to say, we are not acquainted with all their antecedents; and it appears to me not impossible that just as chorea and rheumatism have been found to occur so often in different members of the same family that it is impossible to regard their relation as one of mere coincidence, and yet it has been but recently remarked so; upon further investigation a similar relation may be found to exist between deaf-mutism in the child and some totally dissimilar malady in the parent. If all these considerations be allowed their fair value, I think they will go far to explain the authentic cases in which ill effects have been found to follow from the marriage of blood-relations, without driving us to the extreme measure of extemporising a new law of nature which such unions infringe.

II. I pass on to consider the evidence derived from experiments upon the breeding of animals, and here again I will not occupy the time of the section by entering into detail which may be found in abundance elsewhere, but will simply say that the records of the Herd-book and the Stud-book prove incontestably that many of the very finest horses and horned cattle to be found in England during the last hundred years have been bred with a degree of closeness incomparably greater than is possible in the human race. In proof of this, I need only refer to the facts mentioned in a memoir by M. Sanson, to be found in the *Comptes-Rendus* of July 21, to those given in my paper already referred to, and to another very valuable memoir, by M. Beaudouin, in the *Comptes-Rendus* of August 5. In this paper, M. Beaudouin gives an account of a flock of Merino sheep which he has himself bred in-and-in for two-and-twenty years with perfectly satisfactory results, neither the health nor the fertility of the animals having suffered in the slightest degree. To give one more instance, in one of the cases which I have quoted from the Herd-book the same animal is shown to have served as the sire of four successive generations.

In point of fact, the evidence derived from the breeding of animals against the hypothesis that mere consanguinity in the parents has an injurious effect upon their offspring, is so unambiguous and so much more conclusive than is that obtained from observations upon mankind in its favour, that unless we are prepared to believe that the physiology of reproduction in the human race proceeds upon laws altogether different from those by which that function is governed throughout the entire animal and vegetable kingdoms, it might be fairly supposed to settle the question against that hypothesis. At the same time, certain objections have been alleged against the admissibility of such evidence which it is necessary to meet before any case can be rested upon it. Thus:—

(1.) The following suggestion has recently been made with special reference to M. Boudin's investigations, viz., that there is a kind of special provision of Providence to prevent close breeding in the human race, and hence deaf-mutism is its appropriate punishment, inasmuch as man is the speaking animal. I shall presently have to relate a case affecting one kind of domestic animal, viz., a cat, which will bear upon this point. Meanwhile, two answers may be made, viz., (a) that deaf-dumbness means, as a rule, congenital deafness, and such a defect is almost as serious where it exists in the lower animals as in man. (b) That, as I have shown elsewhere, the Mosaic law gave strong, though indirect inducements to the marriage of blood relations, and that such marriages did prevail of old among the Jews is easily proved by passages in their history. The whole story of the book of Tobit turns upon a case of the kind.

(2.) It has been contended both by Dr. Devay, and more recently by M. Gourdon (*Comptes-Rendus*, August 11) that our carefully bred domestic animals are artificially modified for particular purposes by man, and are therefore physiologically monstrosities, and not to be set up as standards of perfection in their several races. This objection places the matter upon an entirely false issue. To be valid it should show, not that the form of the animal's body is modified, which everyone knew before, but that the healthy discharge of its animal functions is injuriously interfered with. This, as far as I know, has not yet been proved, and even if it were, it would remain a question whether the degeneracy so shown to exist was the result of close breeding itself, or of an artificial mode of existence continued through several generations. On the other hand, in the case of horses at any rate, we have direct proof that the reverse is the case; for it is notorious that no horse bears fatigue so well or recovers from its effects so soon as a thoroughbred one; yet I may state, on the authority of the well-known writer on sporting subjects—Stonehenge—that almost all our blood horses are bred in-and-in.—("The Horse in the Stable and Field," p. 139.)

(3.) A third objection is of a different kind, and is adduced by M. Beaudouin in the paper previously referred to. It is this, viz., that the same kind of careful selection, which is always employed by successful breeders of animals, is not, and cannot be so used in the case of human beings; and hence, as he believes, the difference in the results which follow in the two cases. There is, no doubt, much weight in this objection, but it is obvious that it proceeds upon the hypothesis that the ordinary laws of inheritance govern close-bred animals equally with others,—the precise view which I am supporting, and which Dr. Devay and M. Boudin expressly repudiate. Moreover, it is obvious to remark that selection is just as much and just as little applicable to consanguineous marriages among mankind as to any marriages at all.

I will now proceed to illustrate the foregoing remarks by relating a few observations most kindly sent me by Dr. Davy, and made by himself, which tell strongly in favour of the view I have been supporting, and also the case of a breed of cats which has come under my own notice, and is somewhat remarkable in itself; and will then shortly state the conclusions to which my examination of this question has led me.

"There are some facts," says Dr. Davy, "which lead me to think, that if animals coming together to breed are quite healthy, free from any taint of disease, that their offspring will be healthy.

"In small isolated societies there must be much breeding in-and-in, unless special precautions be taken to prevent it. I shall mention a few instances in which, I believe, no precautions of the kind have been attended to.

Some forty years ago I visited the secluded little dale, Glenfinlass, in the highlands of Perthshire, and I there learned that, with one exception, there was no instance in the memory of man of a Stuart marrying out of the glen. The few families, I believe, were healthy. At the house we were entertained, our hostess was remarkable for beauty, and was above the average size of women. They lead a pastoral life, milk forming a good part of their diet. In the Scottish islands and islets, in many of which the inhabitants are few in number, and having little intercourse with the mainland, there the same kind of marriage must often occur. Yet the people are supposed to be, and I believe are, nowise degenerate. We are told on good authority that pulmonary consumption is comparatively rare amongst them. In Cornwall there are small fishing villages so situated, so in a manner isolated, that marrying of blood relations must be common, such villages

as Mousehole and Newlyn, in the Mount's Bay; yet these people bear no marks of degeneracy, but the contrary; they are remarkable for their good looks, and I believe good health, to which the active habits of both sexes, and their fish diet, may greatly conduce, and their living so much in the open air.

"In the Mediterranean there are many similar examples of small isolated societies, amongst whom there appears to be the enjoyment of more than ordinary health and freedom from hereditary disease. They occur in the Lipari Islands, in the islands or rather islets belonging to the Ionian Islands, such as Fanno, Marquisi, Vido, Cerigo. As well as I could judge when I visited these spots, their inhabitants were peculiarly favoured as to health and as to good constitutions.

"The population of Stromboli, one of the largest of the Lipari, amounted when I was there some thirty-five years ago to about 1500. There was not a Medical man or a lawyer in the island. Agriculture was the main occupation of the inhabitants—the culture of the vine. No man there was idle, and all seemed in easy circumstances favourable to health. One of the most considerable of them told me that the only precaution he took to keep himself in health was to change his shirt after working in his vineyard.

"In the island of Fanno, towards the entrance of the Adriatic, the inhabitants lead much the same kind of life, and are I believe equally healthy and as personable in their appearance. As to size, theirs is not less than the average; they are singularly contrasted with their cattle, a small breed, smaller by far than that of the neighbouring Corfu, or of Italy, or the Calabrian coast, yet of delicate make and very active. This peculiarity as to size may be owing—such was my conjecture on the spot—to a scanty pasturage and purity of blood, and, in relation to health and form, goodness of climate, and wholesomeness of food, though scanty. I have given an account, in the *Proceedings of the Zoological Society*, of a goat that belonged to me while in the West Indies that had four fine kids, the genitor of which was the offspring of the mother, and about four months old. As soon as the mother required the male, the kid was ready for the generative act. She had before given birth to two kids, one of which was the male in question.

"It is, as we all know, related in Genesis that the offspring of Lot's daughters—boys—became the progenitors of important tribes. The principle, if I may use the expression, that seems to me most in accordance with facts is that, if there be vigour and health, and no taint of blood, the offspring of parents, however nearly allied, need not be degenerate."

The observations upon the cats to which I have alluded above are shortly as follows:—A white cat in my possession had a litter of kittens in 1860, the sire of which I had every reason to believe was a large black cat, a frequent visitor to my garden. One of the kittens which I kept upon growing up turned out to have two odd eyes—one of which was blue—and to be stone-deaf. This fact attracted my attention, because it occurred just at the time that I had been reading Mr. Darwin's work on the "Origin of Species," wherein he mentions, as a curious instance of correlation of growth, the invariable coincidence in cats of blue eyes and deafness. I set myself, therefore, to investigate the history of this cat which I had received as a kitten from a college stable. I found, on inquiry, that her immediate parent was also white, and had been brought from another part of the town, nearly half a-mile distant. The gentleman from whose house this ancestress of my white kitten was procured being an acquaintance, I went to him, and found that he had possessed for some years this family of white cats, and that he had noticed every now and then an individual with one blue eye, but never any with both blue. None of these had been known to be deaf with the exception of one which he had given as a kitten to a relation at a distance. The lady to whom this belonged supposed it to have become deaf by accident, but this I think hardly likely. The gentleman to whom I refer has at this time a white cat with one blue eye, which is certainly not deaf. There are two points in this case which are worthy of remark as bearing on my present subject; viz.—1. The reappearance of a marked peculiarity after two generations, and almost certainly two distinct crosses. 2. That that peculiarity should be one so intimately connected with congenital deafness, by which also it was accompanied in the case which came under my own observation.

Finally, the following conclusions seem to me to be warranted

by the facts and arguments which I have now laid before the Association:—

1. That statistical evidence from observation on mankind is especially inapplicable to questions of this kind.

2. That the evidence in favour of the theory that close-breeding is contrary to a law of nature is in the highest degree unsatisfactory.

3. That there is positive evidence from the results of recorded observations upon animals that no such law affects them, *i.e.*, that where other causes of degeneracy are absent any degree of close-breeding may exist without producing ill effects, and therefore

4. Unless we are prepared to believe in two distinct physiologies, the same must be true of the human race.

5. It will remain an interesting question how far similar reasoning will be found to affect the views put forward by Darwin in his recent work on the "Fertilisation of Orchids," and in reference to this I will venture to call the attention of all who are interested in the subject to the recent experiments of Mr. Hallet upon the cultivation of wheat.

## REPORTS OF HOSPITAL PRACTICE

IN

### MEDICINE AND SURGERY.

#### GUY'S HOSPITAL.

##### SUCCESSFUL CASE OF OVARIOTOMY.

(Under the care of Dr. OLDHAM and Mr. THOMAS BRYANT.)

[From notes by Mr. G. P. WILKS, M.A., Clinical Clerk.]

ANN G., aged 25, a single woman, came up from Swansea, and was admitted into Guy's Hospital in February, 1863, with an ovarian tumour apparently growing from the left side. She menstruated for the first time at the age of 19, but the catamenia were always irregular. Fifteen months previous to her admission, they stopped altogether, and did not reappear for one year; since that date they have been scanty and irregular.

The tumour was first observed four years ago; it then appeared in her left side, and caused her some pain; it gradually grew till November last, when she was admitted into the Swansea Infirmary, and was there tapped, ten quarts of fluid being drawn off. She was much relieved for a time, but the cyst gradually refilled, and when admitted into Guy's, scarcely two months after the operation, the tumour was as large as it was before.

When admitted, she was apparently in good health. She was of a fresh colour, and had all the external appearances of a healthy woman. It appeared, however, that she had been the subject of several bronchitic attacks, one or two having been of a severe nature. The abdomen was large and flaccid, measuring thirty-six inches in circumference. Fluctuation was very distinct, and the tumour apparently was composed of only one cyst. The vagina and uterus appeared healthy, and were quite free from abnormal pelvic attachments, and the case promised well for an operation.

On March 20, Mr. Bryant performed ovariectomy in the presence of Drs. Oldham and Hicks, and Mr. Cooper Foster, who kindly assisted. The operation was undertaken in a private room, and only such students were admitted as were required to assist, or who were acting as dressers and clerks to the case. The operation was a very simple one. An incision about five inches long having been made and the cyst tapped, the tumour readily passed from the abdominal cavity; a piece of omentum, which was firmly adherent, was ligatured in two places and divided, the clamp fixing the narrow pedicle. The edges of the wound were then brought together with wire sutures, and water dressing applied to the wound.

Some slight vomiting followed the operation, which was attributed to the chloroform, and in the evening she began to cough. Tea and milk were ordered for her, with a little effervescent mixture.

March 21, 9 a.m.—Had passed a quiet night, although she had not slept much. The abdomen was flaccid, and quite free from pain; tongue and skin moist; pulse 100; cough still troublesome, evidently bronchitic. Small doses of morphia were given every six hours.

23rd.—Abdomen as comfortable as it could be. Cough still very bad, and expectoration profuse; respiration

wheezing, and pulse quick—120; skin moist. Has passed a little flatus without difficulty. Urine quite clear. Beef-tea ordered and brandy.

24th.—Cough improved, and expectoration less; pulse stronger, 105; tongue moist; perspiration profuse; abdomen quite comfortable, and to all appearances the wound has healed. Wine  $\zeta$ vj. ordered, and plenty of nourishment. Continue medicine.

25th.—Going on well; removed the superficial sutures, wound having evidently healed.

27th.—Deep sutures removed.

28th.—Cough improving, but still troublesome.

29th.—A careful examination of the chest was made, when old bronchial mischief was detected.

From this time there is nothing of importance to relate, the bronchitic mischief alone causing anxiety, and although she is not quite well, she is gradually improving; but as far as the operation is concerned, she may be looked upon as convalescent.

There is one point of interest in this case which demands notice, and that was shown by the interesting fact that the rapid repair in the abdominal wound was not for one moment interrupted although a bronchitic attack of a severe nature was present from the first; indeed, the wound may be said to have healed by primary union.

## UNIVERSITY COLLEGE HOSPITAL.

### MALIGNANT TUMOUR IN THE NECK—STRICTURE OF ŒSOPHAGUS—APHONIA—PERFORATION OF THE ŒSOPHAGEAL (?) ARTERY—AND DEATH FROM HÆMORRHAGE.

(Under the care of Dr. HARLEY.)

*History.*—David B., aged 40, a lamp-maker, came under Dr. Harley's care at University College Hospital in the middle of February. He stated that, notwithstanding having lived a very irregular life, he had enjoyed good health until the last five months, when he began to suffer from difficulty in swallowing, loss of voice, cough, and pain in the lower part of the neck, extending down the right arm. Latterly, all these symptoms had become aggravated, and in addition they had, during the last month, been associated with spitting of blood.

On examining the patient's neck, there was nothing remarkable to be observed externally. The thyroid was well developed, but not abnormally so. The larynx was mobile, and no hardness or unusual swelling was anywhere apparent. On pressing the thyroid backwards a slight fulness was perceptible, and the patient complained of pain in the region of the brachial plexus, the pain extending up the neck and down the arm. On examining the chest by means of percussion, no dulness was found except over a small space in the right sterno-clavicular region. At this point a peculiar tracheal murmur, like what one could imagine would arise from a constriction of the trachea, or from air passing suddenly from a smaller into a larger space, was also distinguishable. The respirations were 19 in the minute. Over the dull area, the heart sounds, as well as the vocal resonance, were very distinct. In the cardiac region, on the other hand, the heart sounds were more than usually feeble, though otherwise normal. Pulse 84, and equal at both wrists. The pupils of both eyes were of similar diameter, thereby showing there was no marked pressure on the cervical sympathetic, although it was evident from the loss of voice that the recurrent laryngeal nerves were affected. As the man complained of great difficulty in swallowing, a bougie of half an inch in diameter was passed down the œsophagus; it met with an insurmountable obstruction, however, at a distance of six inches from the teeth; whereas a bougie of a-quarter of an inch in diameter was readily passed into the stomach. There was no enlargement or tenderness of any of the cervical or axillary glands. The symptoms above described gradually got worse, especially the spitting of blood, which soon became almost constant. Sometimes pure blood was brought up, on which occasions it was generally fluid, and of a florid colour. The usual thing, however, was for the blood to be mixed with the sputa. The patient stated that he occasionally brought up, without any exertion, portions of coagulated blood, especially after lying on the left side. He slept more easily on the right side.

Although it was perfectly evident that the stricture of the

œsophagus, pressure on the trachea, on the brachial plexus, and on the recurrent laryngeal nerves, were all due to the same cause, namely, the presence of a tumour, the true nature of the growth remained a mystery. The first idea was that it might be cancerous, but against that supposition was the absence of any cancerous cachexia, enlargement of lymphatic glands, and emaciation, together with the patient's statement that all his symptoms supervened suddenly. The next idea was that it might be aneurismal, but here again the signs were almost all negative, so the question remained unanswered till the post-mortem solved the difficulty.

The patient was one night suddenly seized with a fit of coughing, and almost immediately expired. After death it was ascertained from his friends that the history he gave of his illness was not perfectly correct, for instead of his having become suddenly ill about five months previous to his coming to the Hospital, it appeared that he had been ailing for upwards of a year, and that his symptoms had supervened gradually. This information of course strengthened the former and weakened the latter theory regarding the nature of the case.

On examining the neck, a tumour, the size of a duck's egg, was found lying to the right, and partially between the trachea and œsophagus, immediately behind, and a little to the right of the upper margin of the sternum. The section of the tumour was of a pale, somewhat dirty white colour, and with the microscope it was found to be composed in greater part of encephaloid cancer in an early stage of development. Some portions of the tumour were of a scirrhous hardness, and contained numerous caudate scirrhous cells. There was an ulcerated opening into the œsophagus, and perforation of one of the œsophageal (?) arteries had taken place, from which there had been great and fatal hæmorrhage. The stomach was found half full of coagulated blood. The tumour seemed to have originated in one of the lower cervical glands.

## ST. BARTHOLOMEW'S HOSPITAL.

### ENDOCARDITIS—HEMIPLEGIA—GANGRENE OF THE TOES—AMPUTATION—RECURRENCE OF ULCERATION IN THE STUMP—A SECOND AND THIRD OPERATION.

(Under the care of Mr. LAWRENCE.)

ABOUT two months ago, Mr. Lawrence amputated below the leg on account of intractable ulceration of an old stump. Some years ago, the patient, who was of robust build, was admitted under the care of Dr. Hue for pericarditis and endocarditis. Mortification of the toes of the right foot setting in, he was transferred to the care of Mr. Lawrence. He was then apparently not far from death, his pulse was not perceptible, and it appeared, Mr. Lawrence said, as if the supply of blood to the whole body was being cut off. It seemed, he said, as if the patient had been sent to his ward to die. Indeed, his Colleague a few days after called at the ward to inquire on what day he died, but found him not only alive, but better. Being a man of good constitution, he gradually recovered, but he lost the toes of the right foot, and the surface granulated so tediously, and was so unhealthy, that Mr. Coote, having charge of the case in the summer session, removed the anterior part of the foot. The man got well, but, on using the foot, the ulceration recurred in the sole, so that Mr. Coote amputated above the ankle. So long as the man kept quiet, the stump remained healthy, but on trying to use it, it again ulcerated. The patient was most anxious that another operation should be done. Mr. Lawrence therefore amputated below the knee.

The following note of this case was made at the time when the patient was under Dr. Hue's care; unfortunately it is very imperfect:—

A man, aged 22, was admitted under the care of Dr. Hue March 10, 1853. He was hemiplegic on the left side, and there was a blowing, systolic murmur to be heard over the base of the heart. He said that six months ago he had had "inflammation of the lungs," and that this affection lasted six weeks. A few days before admission he became hemiplegic. The attack was attended by loss of consciousness for a moment only.

In a few weeks he regained power in the leg, but did not recover it in the arm.

Three months later, gangrene of the great toe came on, which soon extended to the other toes.

The patient had no doubt after endocarditis, embolism of one of the cerebral arteries, probably, as is usually the case, of the middle cerebral. As this artery supplies the anterior and middle lobes of the brain and the corpus striatum, the sudden cutting off of the supply of blood to these parts produces paralysis on the opposite side of the body. The principle is the same when hemiplegia follows surgical ligation of the carotid. In the same way the gangrene of the toes, and the subsequent intractable ulcerations of the stump after removal of the foot, were due, no doubt, to similar occlusion of some large artery of the left leg. Ulceration will occur in paralysed limbs where there is no occlusion of their arteries, as for instance in infantile paralysis; but it does not often occur in the ordinary motor paralysis of hemiplegia in adults. This patient then had ulceration of the leg, not because it was paralysed, but because its supply of blood was cut off by obstruction of the arteries of the limb. In fact, the gangrene came on three months after the patient had recovered the use of the leg.

SATURDAY, APRIL 25.

### VACCINATION, AND SOMETHING MORE.

THERE is a story told of a Dutch colony, planted in days gone by on the other side of the Atlantic, which suffered grievously from the attacks of mosquitoes. The colonists were at their wits' end for means of defence. Some plastered themselves with salves, some used veils and other kind of armour, whilst, as it was observed that those who were much bitten became after a time exempt from the attacks of the little pests, some persons gravely advised newcomers to get bitten as much as possible, so as to purchase future exemption at the risk of a little immediate suffering. At last, however, a new governor came, and drained the swamps, filled up ditches, and cultivated the ground properly, and the mosquitoes were seen no more. This story may illustrate the double set of measures necessary for getting rid of small-pox.

In the first place, there is the protective virtue of vaccination. Is this used to the fullest extent, and in the best manner available? Certainly not. Laws for enforcing it are systematically evaded. The machinery of registration devised for ascertaining the amount of protection enjoyed by the population is utterly neglected. The functionaries employed are miserably paid by the public. Private patients are equally stingy and improvident. The Practitioner, instead of taking the lymph direct from a healthy arm, and transferring it at once to the patient, saves a little trouble and expense by charging "points," or "tubes," or "glasses," and so runs the risk of absolute failure, or of decomposition of the lymph, and irritable vesicles. All the thousand "charges" of lymph which certain institutions boast of sending out every year are but so many evidences of bad organisation, parsimonious patients, ill-paid Practitioners, and slovenly vaccination. Vaccination, then, has not had fair play.

But even in cases in which it has been skilfully performed and carefully repeated, vaccination is not an absolute protective. In a vast majority of instances it saves the sufferer from loss of life and loss of eyesight, as well as from serious disfigurement. Yet it does not actually protect from the possibility of small-pox in a slight degree. We have no right to complain of this, because *absolute* protection, like all other things absolute, has no place in this terrestrial creation. So we must accept the fact, as we do all the other facts of nature, and get the best lesson we can from it.

The nature of small-pox, and of the other diseases of its class, can as yet be only guessed at. It is certain that the material cause of the disease, whatever it be, has periods in which it is dormant, followed by others of sudden and intense activity. In this it follows the example, not of inorganic, but of organised existences. There are seasons in which there are no partridges, no flies, mackerel, cucumbers, mushrooms, and the like; and other seasons in which they are exuberantly abundant. Hence the theory that small-pox, with its allied diseases, is excited by some minute organised body. How this theory is confirmed by the known facts of diphtheria and charbon, and by the singular cases collected by Dr. Kennedy in his late paper on a disease resembling measles, is obvious. Dr. Kennedy shows that a *musty* substance, *i.e.*, one impregnated with minute fungi, will produce a quasi-zymotic disease. The French, like ourselves, are driven by the facts of these diseases to seek for them a source extrinsic to the human body. At a meeting of the *Société Médicale des Hôpitaux de Paris*, most of the speakers concurred in the opinion that the sudden and simultaneous origin of measles and scarlatina in different and distant parts of a country prove some other mode of origin and propagation than mere infection from the sick to the healthy. Nothing is more probable than that minute organisms, lurking in some of the numerous hiding and breeding places so abundantly provided for them, acquire from time to time, with favourable conditions of heat and dampness, power of propagating themselves in great abundance, and so producing an epidemic fit of the appropriate disease.

We were once talking with an eminent Hospital Surgeon in the country, who was showing us over a gaol of which he had the Medical charge. We inquired about the health of the inmates. "Healthy," he said, "of course they are healthy. They have air, food, and exercise calculated to keep them well, and there is nothing here to breed illness. *There is no waste organic matter here.* The walls are of brick, often limewashed; the floors of stone; the corridors of iron; not a flea can harbour itself about the well-washed bodies or clothes of the prisoners, so where is a source of disease to lurk? *We have no flies here.* Sometimes a stray one enters at one of our open windows; but he always goes out again directly, and, as he buzzes away, seems plainly to say 'There is nothing for me here!'"

Can this be said of most houses? Are there no nooks in which minute organisms can lurk and propagate? Think even of the common house fly. Every one of them was once a maggot, and must have had some organic matter to feed on; then it was a crystal, and must have had a safe dormitory till it could burst forth in its last and busiest stage as a fly. But where these could lie hid, there myriads of fever-breeding fungi could do so likewise.

Be it observed that an indefinite, though very intelligible relation has been constantly observed between insects and pestilence. The Hebrew poet says, "He spake the word, and there came all manner of flies and lice in all their quarters;" and this was just before the destruction of the first-born. The late Dr. Knox and other observers spoke of the appearance of strange insects in cholera times. Mosquitoes, marshes, and agues always go together. In fact, wherever the conditions which are known to breed or foster zymotic disease exist, there minute animal and vegetable organisms are known to flourish likewise.

Again, think of what is involved in *dampness*. "This room has a very damp smell," is often said; but what is it that smells? Not wet merely; that has no smell; but the simultaneous existence of organic matter which is rotting, and of fungous growths which are feeding upon it. Hence the smell. But these damp smells, which we know will produce coryza, may accompany fungous growths of any sort.

If, then, we wish to do our best to exterminate small-pox, we must not confine our efforts to merely rendering our population invulnerable,—a thing in which we are sure to be defeated by the order of nature and by human negligence, which we suppose is part of the order of nature. We must concurrently attack and exterminate the seeds of the disease in their hiding-places. Have we no old, well-worn clothes put by in closets; old, dirty carpets, curtains, bedding; old, dirty wall-papers; old rotten floors; interstices between floors and ceilings filled with the dust and vermin of generations; old cellars with old hampers, boxes, and forgotten rubbish; basements, vaults, and musty, neglected corners, out of the way of sun and wind, where pestilence germs can flourish undisturbed? If we have, let us get them all swept out and purified, before we sit down and groan over the inefficacy of vaccination, or bewail that inexorable law of Providence which rouses us up and goads us into activity and cleanliness by visitations of pestilence.

### THE WEEK.

#### GOOD NEWS FOR FEMALE PHYSICIANS.

AT the Sorbonne, on Saturday last, a young lady (Mademoiselle Emma Chenu) passed a brilliant examination, and was admitted to the degree of Bachelor of Sciences. This is the first instance of a woman being allowed to take honours in the University of Paris. The example was set at Lyons a short time ago. Mademoiselle Chenu was warmly congratulated by M. Milne Edwards, who was in the chair at her examination, and loudly cheered by the crowd of students.

#### THE CASE OF RUSSELL v. ADAMS.

WE print in another column a correspondence between Mr. Adams and Mr. Propert, which will tell its own tale. We are glad to say that the committee, which we spoke of last week, is increasing in numbers and importance. Its first effect will be to give Mr. Adams an efficient moral support. It is fortunate for our Profession that men of independence and character will neither combine to protect and whitewash a "black sheep," nor yet allow an innocent man to be made the victim of an open attack or of underhand insinuations. As to the substantial operations of the committee, there is time for consideration as to the best form they should take. Mr. Adams' friends think that in consequence of his courage in resisting an attempt at extortion, he ought to be reimbursed in the amount paid for legal expenses. We make no doubt that the subscription will be general and ample. Members of our Profession as they contribute may reflect that it may be their turn next, and may look upon their subscription as a kind of payment for mutual insurance.

#### GENERAL RE-VACCINATION.

THE Medical Officers of Health are moving the authorities of the various London parishes to cause a general re-vaccination of the population, and to erect or provide temporary Hospitals for the reception of persons affected with small-pox. Of the expediency of the latter measure there can be no doubt. Every small-pox patient who is allowed to remain in the crowded habitations of the working-classes becomes a source of infection to all around him. The re-vaccination, too, is highly to be commended, provided it be effected by fresh lymph, taken from a healthy arm, and not by the "points" or "charges," which are the means of so much disappointment

and deception. But, in order that re-vaccination should be something more than a mockery, every adult and child before the operation should be compelled to take a warm bath, and to have his clothes well purified. Most poor people carry about with them on their skins and wearing apparel enough organic matter to be the germs of a dozen diseases.

#### HOW TO SPEND A GUINEA USEFULLY.

THERE are many benevolent persons who think nothing of an "annual guinea," and are ready to present that sum to almost any institution on behalf of which they may be canvassed. If we were asked in what way such a sum, or ten times the amount could be most usefully spent, with the greatest amount of good, the smallest amount of abuse, we should say, Go to the nearest "Public Bath," buy a guinea's worth of tickets for second-class warm baths or swimming baths, and give them away to the children of the nearest school. One guinea will purchase 140 such tickets, and will give 140 children the unwonted luxury of a clean skin; it may even lay the foundation of habits of cleanliness which may last through life.

#### PARLIAMENTARY.

MR. GLADSTONE'S financial scheme has put every one in a good humour. The twopence in the pound off the income-tax and the reduction on tea are so undeniably pleasant, that the public seem generally content to wait and hope that from his next budget the financial enchanter may produce a relief of precarious incomes and a readjustment of the sugar duties. The subject of the utilisation of sewage was brought before the House of Commons by Dr. Brady on Friday night.

"He called attention to the reports of the Royal Commission appointed to inquire into the best mode of utilising the sewage of towns and applying it to beneficial and profitable uses, and to the inexpediency of granting any further public money for the use of the Commission. In an argument of considerable length he maintained that large sums were wasted by the neglect of town sewage; that the fertilising properties of this sewage, applied to the land, largely increased its productive qualities, and consequently its value; and that the opposition to its use was traceable to the interested motives of those who were connected with the supply of artificial manures. He joined issue, he said, with the report of the Royal Commissioners, the result of whose inquiries was unfavourable to the employment of town sewage for general farming purposes. He contended that the conclusions of the Commissioners were incorrect, and that it was inexpedient to prolong a Commission which had so ill fulfilled the objects of its appointment.

"Mr. K. Seymer, as one of the Royal Commissioners, in reply to Dr. Brady, observed that the Commission had been originally appointed to inquire into the best mode of getting rid of the sewage, and that there existed a great fallacy as to the quality of town sewage in this country, which was largely diluted with water, the residuum being proved to be of little value. He referred to the evidence taken by the Commissioners, from which he drew conclusions materially varying from Dr. Brady's. If the House, he said, thought a stop should be put to the proceedings of the Commission, let it be so; but the sum now in hand would be sufficient to complete its experiments.

"Mr. Cowper observed that, as there were differences of opinion upon this subject, this was a reason, not for putting an end to the Commission, but for further inquiry.

"After some remarks by Mr. Paget, Mr. Ayrton, and Sir J. Shelley, the subject was allowed to drop."

It may be remarked that Mr. Seymer's argument derived from the dilution of the sewage only affords a reason for that separation of the sewage proper from the rainfall which has been lately advocated in this Journal.

"On Tuesday, Mr. Roebuck gave notice that when the Chancellor of the Exchequer brought forward his proposal relating to the income-tax, he would move a resolution declaring that in the opinion of the House the tax imposed on precarious incomes should be lower than that imposed on permanent incomes."

In reference to the importation of cattle diseases,

“Mr. Griffith asked the Vice-President of the Privy Council whether he had any objection to lay upon the table of the House the report of the commissioner sent by Government in the course of last autumn to the Continent to inquire into the existence of sheep and cattle contagious or infectious diseases in foreign countries, and into the liability of their introduction into this country.

“Mr. Bruce, in the absence of his right hon. friend, said that the report, which was a very long one, was now under the consideration of the department, and if it were found suitable for official publication it would be printed in the appendix of the usual annual report of the Medical officer.

“Mr Griffith asked when that document was likely to appear.  
 “Mr. Bruce.—Very shortly; at any rate in a few weeks.”

THE HEALTH OF THE UNITED STATES ARMY.

TYPHUS and typhoid fever are very prevalent in the United States army, and in the civil and military hospitals. The *American Medical Times* states that in many instances the fever seems to be purely typhus, and very contagious. Two of the Medical officers, of the resident staff of Bellevue Hospital, fell victims to it in one week. Hospital gangrene, also, is said to prevail. Its ravages at the General Hospital, Annapolis, have led the Surgeon-General of the United States Army to appoint a Commission of Investigation. The reports, for the year ending June, 1862, however, of the Actuary to the Sanitary Commission and of Assistant-Surgeon Woodward, show that, although the mortality had up to that period been high, it had been less than that of the British army in time of war. At least this is the conclusion arrived at in the journal above quoted. It may be observed that the data for calculation cannot be very accurately ascertained, inasmuch as the actuary, Mr. Elliott, states the general mortality of the army at 53.2 per 1000, whilst Assistant-Surgeon Woodward places it at 65 per 1000. According to Mr. Elliott, 44.6 deaths were from disease, and 8.6 from wounds received in action. The English loss during the Peninsular war is said to have been 165 per 1000, of which 113 were from disease and accident, and 52 from wounds in action. In the Crimean war the death-rate of our army was 232 per 1000. In the Mexican war the mortality of the American army was 118 per 1000. The writer of the article we are quoting observes:—“It is apparent that the general mortality of the United States Army forces is comparatively very small. The ratio of mortality from diseases and wounds is, as usual, markedly in favour of the former. The mortality from diseases was five-sixths for the men, and two-thirds for the officers. In the Crimean war seven-eighths of the mortality of the British troops were from diseases. The differences of the causes of deaths among officers and privates is noticeable. The liability of the private to die of disease is double that of the officer, while his liability to die of wounds is only one-third as great.” We confess, however, to grave doubts on the subject of American statistics.

POST-GLACIAL OR PRE-GLACIAL MAN?

THE advocates of man's extreme antiquity are just now in a perilous position. The state of the contending parties is closely similar to that of the French revolutionists in 1795. The “Reign of Terror” has passed away; the anarchists have recently suffered a severe check; and the “Committee of Public Safety” which sound geologists have established, once more reasserts its power to check the hypotheses of the special pleader, or refute the attacks which may be made upon the groundwork of inductive geological science. Our excitement consequent upon the publication of Sir Charles Lyell's work has been subordinated to the dictates of our sober judgment; and we are once more at liberty to accept or to reject any fact which may be satisfactorily brought before us.

Some attention has recently been paid in the public daily journals to the fen deposits of the eastern and midland

counties of England. We regret this procedure exceedingly, as we consider that it may mislead the public to an extent much to be deprecated. Our knowledge of the fen deposits is even more full and complete than our cognizance of any other stratum in England, and we shall not allude to the question further here than to declare our conviction that no examination of the fen deposits will ever throw any light on the origin and antiquity of man, for the satisfactory and sufficient reason that we have evidence of man's existence in beds long anterior in date to the fen deposits. The annexed diagram will perhaps exhibit the true state of the question to our readers, it being distinctly understood that examples of the more characteristic beds only are shown:—

RECENT.	Peat. Fen deposits. River beds. Pileworks of Switzerland. Shell-mounds (Kjökkenmöddings) of Denmark, with possibly coeval tumuli containing human bones. Nile and Mississippi deltas. Ohio mounds. Elevated strata of the centre of Scotland.	Man, evidences of his bones and works. Λ O

OLDER PLIOCENE.	NORWICH CRAG.			
	RED CRAG.			
	CORALLINE CRAG.			

As we are fully aware of the fact that no new light on the question will be thrown by an examination of the fen deposits, we regret exceedingly that so little attention has been paid in the recent controversy to the evidences of human remains and human works of art from river-beds, of undoubted historical antiquity. Such remains have been derived from the beds of the rivers Blackwater and Nore, in Ireland; from Muskham, Battersea, and Eastham in England. They are frequently associated with stone implements (with the surfaces ground), appertaining to the “stone,” in contradistinction to the “Drift” period. They are probably not nearly so ancient as the shell-mounds of Denmark; some of them may, however, be equivalent to the Swiss *Pfahlbauten* (of which so many inaccurate descriptions have recently been promulgated).

While, however, these comparatively recent beds afford to English geologists some interest, our attention has been sud-

denly called to the far more ancient Somme valley deposits, from whence the veteran Boucher de Perthes has recently derived a human jaw, respecting which some zoologists have ventured to express very decided opinions. It has been alleged that this jaw differs in its anatomical conformation from that in the existing races of Western Europe, and Dr. Carpenter goes so far as to say that no one "who carefully examines the undisturbed condition of that bed can entertain a doubt that the bone in question is a true fossil, dating back to the time of its original deposition." Geologists, however, of that cautious stamp to which Mr. Prestwich and Mr. Alfred Tylor belong, have expressed a contrary opinion. The latter high authority regrets that the patriarch of primæval archæology, Boucher de Perthes, should have been so grossly deceived by the workmen in the quarry at Moulin-Quignon. While the mineral character of the jaw in question is so totally dissimilar from that of the other bones from the Somme valley gravel, and the most able tertiary geologists express the strongest doubts as to its genuineness, associated as it was with forged flint implements, we are perfectly willing to consign it to what has been called "the limbo of all hasty blunders." We are aware that one of England's greatest palæontologists, himself an illustrious member of the Medical Profession, has pronounced the jaw to indicate an individual of the Papuan race; but we are also aware of the inaccuracy of the drawing which is now going the round of scientific coteries. A similar case of error of observation amused the Ethnological Society a fortnight ago, when a gentleman laid on the table a human jaw from the coprolitic (?) deposits of Suffolk, alleged to be contemporary with the *ichthyosauri*, which he stated were abundant in that formation, and exhibiting marked anatomical peculiarities. On comparing this abnormal jaw with the homologous organ in the whole human race in general, and an individual named Jenkins, who was executed by the Californian Vigilance Committee, in particular, the discoverer of this unique anthropolite was led to consider it to be an irrefragable evidence of that which he termed an "anterior man." Professor Busk, on the other hand, thought the bone to be that of an old woman who had lost her front teeth, and did not assign to it any great antiquity. We are cordially disposed to concur in this opinion, and are willing to relegate both Dr. Carpenter's and Dr. Collier's jaws to the same niche in the temple of science. Impressed with the conviction that the premature deductions which have been recently made do not deserve our serious consideration, we must not, on the other hand, forget that the "cuckoo cry," which has been so often repeated, that human bones have never been found in veritable drift deposits, is scarcely warranted by the facts. The president of the Geological Society, in 1861, told us of the cavern near Arcy, in the Department de l'Aube, in which are three distinct beds of drift, the lowest of which M. Vibraye considers to be an undisturbed mass of materials washed into the cavern by the same force which spread the pleistocene drift characterised by the remains of the mammoth, tichorhine rhinoceros, the cave bear, and cave hyena. In this lowest bed M. de Vibraye found a human jaw containing two of its teeth. This formation Sir Chas. Lyell compares with the "diluvium gris" of Paris. The conditions of deposit in the Arcy cave are wholly different from those of such cave deposits as Engis or Brixham, and the objections of the convulsionist, applied to the ordinary cave deposits, are here totally inapplicable. Some attention of late has been paid to the "forest bed" of Norfolk, which immediately overlies the Norwich crag, and underlies the drift deposits in the same locality. Why this stratum especially should be selected for popular attention we are not aware, as our knowledge on the subject is actually the same as it was thirty years ago. Although it may be deemed, to use Burton's expression, "a subject popular, and therefore to be avoided," we are free to admit that the bed contains many objects of interest. This is the bed, be it remembered, in

which Professor Heer discovered among the cones of the fossil spruce-trees of the Norfolk forest a few which had only the axis remaining, the peripheral portion having, according to his interpretation, been gnawed off by the squirrels of the newer pliocene. We are not aware whether our British botanists have universally corroborated this opinion of Prof. Heer, and we should be very glad to elicit some authoritative opinion on this question, and once more bring it within the limits of accurate scientific discussion. These forest and lignite beds, on the testimony of Dr. Falconer, besides containing the remains of the mammoth (*E. primigenius*) also contain more frequent evidences of the *Elephas meridionalis* and the *Elephas antiquus*, *Rhinoceros etruscus*, and *Hippopotamus major*. No evidence of the *Elephas primigenius* has, however, been derived from the Norwich or from the Suffolk crag. Speculators on the extreme antiquity of man have hinted that we may yet find bones of man in the forest-bed, contemporary with *Elephas meridionalis*. This evidence of "preglacial" man, however, has not yet been discovered; and, until we have some material evidence, speculation must be silent. Should, peradventure, man be found in such a deposit, we fully coincide with Sir Charles Lyell, that the discovery "would carry back the antiquity of man to a distance of time probably more than twice as great as that which separates our era from that of the most ancient of the tool-bearing gravels yet discovered in Picardy, or elsewhere." Discovery of man's remains in such a stratum would give the stamp of inductive truth to the bold speculation propounded by Prof. Waitz, of Marburg, that the period of man's existence on this earth cannot be less than 35,000 years in duration, and that possibly he may have appeared as long ago as 9,000,000 of years. We hope our readers will not underestimate the period of probable duration of time which has elapsed since the age when the *Elephas meridionalis* and *Rhinoceros etruscus* wedged their way through the thick forests of spruce pines and Scotch firs that spread their foliage in Norfolk in the pliocene period. Without, however, wishing to hypothetically assume the future discovery of man in the forest bed, we must remember that we have already obtained his remains from the drift, and that the period which has elapsed since the deposition of that stratum has been computed by Sir C. Lyell at 188,000 years, and by a writer in the *Natural History Review* of this month at 224,000 years. Allowing the lower estimate to be correct, we should be led to infer, in the words of the last-named writer, that "the antiquity of man is 188,000 years + *x*, the unknown element being in all probability the greater of the two."

#### CATTLE DISEASE IN RELATION TO PUBLIC HEALTH.

ON Saturday last, at the meeting of the Metropolitan Association of the Officers of Health, Mr. Gamgee, of Edinburgh, read a paper on a subject of very great importance, "Disease of Animals in Relation to Public Health and Prosperity." Mr. Gamgee considered the sale of diseased meat as it affected the health of stock, the health of the people, and the wealth of the dealer. It was, he argued, to be put down on all these grounds. In speaking on the first, there was, he said, practically little difficulty with indigenous diseases, as the amount of stock destroyed by them was limited, and besides they were greatly under control by proper hygienic measures. But with imported disease it was different. "A cargo of Dutch or German beasts arrives from Rotterdam or Hamburg. The whole stock is only fit for slaughter, and it enters our ports with signs of the foot and mouth disease. These animals are exposed with British stock in our markets, grazed in our fields, and soon show signs of pleuro-pneumonia. We kill them out, but our stock has been seized; the diseased continue to be slaughtered, but are also permitted to travel on roads, in railway-trucks, in steamers, and to be handled by butchers in the public markets amongst animals for store purposes, and dairy cows that

are to supply our children with milk. These animals in their turn become affected, and the number increases in geometrical proportion." He considered that the energetic measures adopted in the epidemic of small-pox in sheep in Wiltshire had prevented that disease from spreading "throughout the length and breadth of the land." But with cattle it was very difficult to persuade the farmer to make an early sacrifice in order to get rid of a contagious disease. It seemed to him a reckless extravagance to bury or turn to manure the carcass of a diseased animal which it was possible to sell at an auction of live stock or at market. Thus: "The farmer's practice now is to generate disease and sell diseased stock." Again: "Rather than spend £5 in professional advice, he would lose £500 by disease." Mr. Gamgee did not think that Veterinary Surgeons could do much when the disease was raging; but a vigorous and talented body of men ought "to prevent damage, to smother flames, and attend to the property in the neighbourhood." To prevent contagion, and not to drug individual cases of the disease, should be the Surgeon's object. He insisted very strongly on the contagious nature of the foot and mouth disease, and of pleuro-pneumonia. In support of this view he had recently obtained a large mass of evidence in replies to a circular he had sent out to 300 Veterinary Surgeons. The fact that these diseases rarely appear in breeding districts, but affected the neighbourhoods of markets and lines of traffic, showed that this opinion was correct. In speaking of the effect of the sale of diseased meat on the health of the community, Mr. Gamgee first alluded to the diseases of the pig. It was well known, he said, "that it is not only the irritating tapeworm that we derive from the pig, it is the prostrating and destructive trichina, which penetrates our muscles and kills. Probably there are many more cases of trichina disease than of tapeworm, and the day is not far distant when the number of well-recorded cases of death due to trichina in man will convince every one that the meat-shops, slaughter-houses, and bacon-factories must be looked after to stop the sale of dangerous bacon just as much as we require to analyse for the adulteration of groceries."

"I am, however, quite convinced that the tens of thousands of carcasses of diseased animals sold in all large towns are stealing life from human beings when and where we least expect it. It is asserted by many at home and abroad that the flesh of cattle affected with pleuro-pneumonia is wholesome. I hope the day will soon arrive when we need scarcely discuss such a question in England, and, if Government wishes, this can be attained; but, as the disease is here, I must say that last year my opinion became confirmed that the flesh of cattle affected with pleuro-pneumonia when eaten by man induces boils and carbuncles to an incredible extent. My observations have been made in three establishments. One where 1500 men are known to be supplied, fraudulently of course, with little else than diseased meat; another where several hundred soldiers are in the same position; and a third where about seventy individuals fed, too often to my knowledge, on the flesh of cattle affected with pleuro-pneumonia, have been seized occasionally with vomiting, diarrhoea, abdominal pains, etc., and have traced such accidents to the meat, to such an extent, that many refused to eat it."

He spoke also, and adduced examples, of the injury produced by eating the flesh of animals which had died of "splenic apoplexy," "parturition fever," and "foot and mouth" disease. Mr. Gamgee next referred to the loss to the town dairyman, to the breeder of cattle, and to the community. Dealers, he said, have looked on him as their worst enemy, whereas they would, he had little doubt, find in time that he was their best friend, as he was sure that free trade in live stock, without due regard to the prevention of contagious diseases, "had been the curse of this stock-producing country since 1842." It was a great mistake to suppose, as some argued, that the poor gained anything even in the amount of food. It was much higher in price since the importation of foreign stock, and, at the same time, of foreign contagious diseases.

"Beef, in 1841, sold at from 3s. 8d. to 5s. the stone. It now sells at from 5s. 4d. to 8s. 10d.; and when you consider that the amount consumed in the United Kingdom is estimated at 80,000,000 stones, if we take the increase in price during the last twenty-two years, in round numbers, at 2s. 6d. a stone, the meat-consuming public is paying £10,000,000 more now for the same amount of meat than it did in 1841."

He considered that this injury to the public health and waste of the national resources might be put a stop to with certainty, not by the action of individuals, but by sound legislation on the subject of the importation of diseased cattle. The present systems of inspecting imported cattle and of inspecting markets were extremely inefficient. The paper advocated the appointment of a Government Inspector, who, while making rules for the control of the trade in foreign stock, and for the stricter supervision of markets, might become the centre towards which information should converge, and from whose experience advice for the whole country might proceed. The paper excited very great interest. In the discussion which followed, Mr. Edward Holland, M.P., pointed out the defects in the present laws relating to disease in cattle, and showed that this was an opportune time for an amendment in the law, as the present Act of Parliament on the subject expires in August next. Mr. Field thought that imported cattle should be inspected before they were landed. Mr. Chadwick adverted to the origin of the disease abroad. The cattle, he said, were kept in ill-ventilated, over-crowded sheds, and in the unhealthiest conditions on board ship. These conditions had great influence on the spread of the disease. And again, with regard to small-pox in the human subject, Mr. Chadwick called attention to the fact that this disease prevailed in just the same localities that generate typhus and other contagious diseases. Dr. Sanderson thought that the severity of the eruptive diseases might be increased by filth, but he protested against its being assigned as their cause. He asked for information as to the pathology of pleuro-pneumonia. Dr. Gibbon said that in London the inspector might go to the slaughter-houses and see the viscera of the animals killed, but in other districts they could only inspect the meat when exposed for sale. Dr. Aldis spoke of the practice of inoculation in pleuro-pneumonia. It was, he considered, a barbarous practice. Mr. Gamgee then made some observations in reply. He did not think that either the foot and mouth disease, or the pleuro-pneumonia was generated from bad sanitary conditions. Animals died from pleuro-pneumonia just as much in pastures as in town dairies. It spread from contagion alone. He considered that all cattle from infected districts should be slaughtered, as it was impossible at first to tell which animals were diseased and which were not. In reply to Dr. Sanderson's query, he said that pleuro-pneumonia was a specific fever of the ox tribe, with exudation in the lungs. A Veterinary Surgeon could, by the stethoscope, recognise the disease a fortnight before the dairyman could. Epizootic apthæ (foot and mouth disease) was more like diphtheria, and he believed the statement made by Dr. Starke, of Edinburgh, was correct, that the so-called diphtheria in children is really epizootic apthæ, caught from the milk of cows affected with that disease. He did not think that quarantine was of any use, as in pleuro-pneumonia the stage of incubation was about forty days, nor did he recommend inoculation, as it was cheaper to keep the disease from our doors. Still inoculation was to a very great extent preventive, and, until the disease was excluded from England, it might be practised with advantage.

#### THE CULTURE OF FISH.

At the Royal Institution on Friday, the 17th instant, Mr. Frank Buckland gave an admirable lecture, "On the Artificial Incubation of Fish." The Duke of Northumberland presided.

The speaker, who made no pretence to eloquence, did not fail to instruct and amuse a crowded audience by his clear, often humorous descriptions, enthusiastic manner, and plain, easy, unaffected diction. On the table in front of Mr. Buckland were shown a variety of boxes of different kinds, but all of the simplest forms, in which on a bed of clean gravel, and beneath a shallow stream of water, the eggs of trout, salmon, perch, etc., in various stages of development, were being hatched. He began by considering the eggs. Fish are the most productive of all living creatures. A good fowl will lay 120 eggs in a year; but he had found by experiment that a salmon or trout produces 1000 eggs to every pound of its weight. It follows that a salmon of from 15 to 30 lbs. would contain from 15,000 to 30,000 eggs; a trout of 1 lb., 1003 eggs. A turbot of 8 lbs. has been found to contain 385,200 eggs; a roach of  $\frac{3}{4}$  lb., 48,000; a mackerel of 1 lb., 86,220; a brill of 4 lbs., 239,755; a sole of 1 lb., 134,466; a perch of  $\frac{1}{2}$  lb., 20,592; a herring, 19,840; a Jack of  $4\frac{1}{2}$  lbs., 42,840; and a cod of 15 lbs., the enormous number of 4,872,000 eggs. And yet we have to pay from half a guinea to a guinea for a turbot. Any one would think that with this fecundity we have only to let them alone, and fish would cultivate themselves; but this is not the case. We find that only one in every thousand of trout becomes a fish. A fish at the time of spawning seeks out a convenient place in which to deposit her eggs, and covers them over with earth or gravel. Will these 15,000 or 30,000 eggs then become fish? If so, why should salmon be from 1s. 6d. to 2s. per lb.? The salmon seeks shallow water because nature teaches her that shallow waters are the best for the hatching her eggs. The salmon-leaps are one kind of difficulty she meets. These we help her over by means of ladders, or an arrangement of alternate stages. The fish soon find out the water staircase, and flock to the spot, in preference to attempting the passage elsewhere. Again, we have to provide against accidents at the time of spawning, perhaps a flood on the one hand, which would wash the eggs away, or a drought on the other, which would be equally destructive. Again, the fish will eat their own eggs. Trout and salmon do so. Five hundred eggs have been found in the maw of a trout, and afterwards hatched. Among insects, we may count as enemies water-shrimps, the larva of the dragon fly and of the May fly. Some birds, the water-ousel and the dabchick, had been accused of robbery of the spawn, but the lecturer had proved them innocent. They came to feed on the insects, and, so far from being destroyed, should therefore rather be preserved. A bird that did a vast deal of mischief in the way of devouring spawn was the swan. He was a great poacher. The common house rat, too, would get at the spawn and eat it. And then there were the human poachers, who would catch the parent fish, and send the "old soldiers," *i.e.*, the spent, scabby, diseased fish to France, where they found a ready market. When a salmon had gone through all these perils, to the age of fourteen months, it went to sea, and there on the margin of the salt water it met with a fresh host of voracious enemies, of whom the most destructive was the angler fish. He feared there was no safeguard against these depredations. But we might materially increase the number of those that left the river by guarding against the former causes of loss, by hatching the spawn themselves, by the removal of nets and other obstructions which hindered the ascent of the fish, and by seeing that the water was not unnecessarily poisoned by the refuse from manufactories. For the first purpose the only plan was to make an artificial nest either out of doors or indoors. All that was required was a common box for outdoor hatching, or for indoors an earthenware basin fitted with a series of glass tubes, or a series of zinc boxes, a slight layer of gravel that had been boiled to free it from the insects that might otherwise hurt the spawn, a shallow stream, and a continuous current. The temperature of the water should be from 40° to 45°; and when the spawn was in it must be let alone. There was a great art in letting things alone;

and if the spawn was not let alone it was sure to die. Thirty to thirty-five days were sufficient to develop the eggs, and the fish broke through the eggs with very large eyes to enable them to see their enemies and keep out of their way, with no mouths when they first emerged, but with a large umbilical sack or bag attached to their bodies, which contained the albumen of the egg, and which was gradually absorbed into the body of the fish, until it grew big enough to have a mouth to feed itself. This would be in eight or ten days. They had all heard of Mr. Youle's efforts to introduce salmon into Australia, and in the course of the experiments on the best way of preserving fish spawn they had kept the eggs on a block of ice for ninety days, and the eggs were still alive. Another batch had been thus kept for fifty-nine days, and were still as good and as much alive as on the day the fish laid them in the water. It was a most important discovery in what he might justly call the science of artificial incubation, for it showed that by taking such precautions the salmon spawn might be transmitted to Australia safely, and they meant to do it. For comparatively shorter distances—as in the case of some spawn of grayling and some trout he had received that very evening from France and Switzerland—it was only necessary to put the fresh spawn in bottles, and carefully pack the bottles in boxes of damp moss. For the rest, to hatch them, all that was wanted was a box of cleaned gravel, an equal temperature, and a stream of running water from an inch to an inch and a-half deep. As to the mode of treatment of the newly-hatched fish, they might be first kept in a pond and fed with liver. The French people fed them with frogs. They will eat almost anything. In France the system of hatching fish-spawn had been carried on most extensively by the Government, and with enormously beneficial results. They had there hatched no less than 6,000,000 eggs, and re-stocked thousands of acres of their rivers. The Thames Angling Preservation Society wished to stock the Thames, and had placed boxes at Hampton, and Mr. Ponder, who had been one of the first to lead the way in this admirable scheme, had this year turned out into the Thames many thousands of salmon. Some people said that they would never get these fish back. That might be true or not, and he hoped not, but at all events it was worth trying; and it, at least, was certain that they would never get them back if they did not first put them in. They could put the young fish into the river at the rate of four for a penny, and Mr. Ponder would altogether turn nearly 70,000 fish of different kinds into the Thames this year. Looking at it only with a view to money profit, the system of artificial hatching would prove largely remunerative to lake and river owners. The annual value of the salmon imported from Ireland was no less than £330,000, and from Scotland as much as £500,000. All England only produced salmon to the value of £30,000 a-year, and Yorkshire was so poor in this noble fish that he was told all the rivers in that large county only furnished to the value of £128 per annum. It was therefore no mere scientific plaything that was proposed to the owners of these fisheries, but a source of money value to them, which he was sure they would be only too glad to avail themselves of when the immense advantages of the system were pointed out to them. During the course of the lecture, the progress of the fish in its various stages of development in the egg up to an age of four or five days was most fully illustrated by means of a microscope and the electric light, which threw the image of the objects magnified on a white canvas screen suspended for the purpose. Some of these illustrations were exceedingly interesting, every movement in the ova being distinctly visible; and, in the case of the young fish, its rapid breathing, and even circulation of the blood over the umbilical sac and downwards towards the tail, could be detected. The activity of these formidable young monsters—for so they appeared when magnified—on their approaching or touching each other, created a great deal of amusement, and added not a little to the difficulty of keeping them in the field of view at all.

## THE CASE OF DR. EDWARD WATERS, OF CHESTER.

### MEETING OF MEMBERS OF THE LIVERPOOL MEDICAL INSTITUTION.

A SPECIAL general meeting of the members of this Institution was held on Monday evening, April 20th, "To take into consideration the best mode of expressing sympathy with Dr. Edward Waters, of Chester, in reference to a late trial which has taken place in that city."

Dr. Vose presided, and the following gentlemen were present:—Dr. Chalmers, Dr. Grinsdale, Dr. Skinner, Dr. Imlach, Dr. H. Taylor, Dr. Petrie, Dr. M'Naught, Dr. Gee, Dr. A. T. H. Waters, Dr. Thompson, Dr. Graham, Dr. M'Intyre, Dr. Shearer, Dr. Dickinson, Dr. Stopford, Mr. Desmond, Mr. Denton, Mr. Irvine, Mr. Steele, Mr. Marsh, Mr. Hakes, Mr. Bickersteth, Mr. Lowndes, Mr. C. B. Wilson, Mr. M'Cheene, Mr. Martin, Mr. Parkes, Mr. Pennington, Mr. Swift, Mr. Stubbs, Mr. Halton, Mr. Manifold, Mr. Dawson, Mr. Oxley, Mr. Danson.

The Hon. SECRETARY (Dr. A. Stookes), then read letters of apology from several gentlemen who were unable to attend the meeting.

The CHAIRMAN read some observations which he had prepared relative to the case of Dr. Waters.

Dr. M'NAUGHT moved the first resolution:—"That this meeting desires to express their hearty congratulations to Dr. Edward Waters, of Chester, on the result of a recent trial in that city, which leaves his character unsullied after sustaining attacks which have seldom been equalled for persevering malignity." I have great pleasure, Dr. M'Naught said, in bringing before you the resolution placed in my hands by the Council. It is a resolution, I am convinced, which will meet with perfect unanimity here, and be approved of abroad by every right-minded man; whether in or out of the profession. It is to offer our congratulations to Dr. Edward Waters, upon the happy issue of his late trial at Chester. (Applause.) Most of you, I dare say all of you, have read the evidence, the pleadings of counsel on both sides, the judge's charge, and it is scarcely necessary for me to express an opinion as to the malignancy of that prosecution, or rather I should say persecution. (Applause.) That any one, and especially a man of Dr. Waters' high social and professional position, should be exposed to such base calumny in the exercise of pure Samaritan-like benevolence, and upon such wicked and worthless testimony, is really and truly deplorable. It makes one shrink with indignation to think that a virtuous, kind-hearted man should be brought before the public to defend himself against so virulent, clumsy, and vile a conspiracy—(applause)—against his honour and reputation. But, gentlemen, what was Dr. Waters' case yesterday, may be yours to-morrow, and some of us, perhaps, might not possess either the moral courage or pecuniary resources necessary for the establishment of an insulted character, as he fought for and effected. I say, therefore, he richly deserves the congratulations of the whole Profession for his energetic and manly conduct in resisting all attempts at a compromise. In fighting his own battle, gentlemen, he has also been fighting ours—(applause)—and after such an *exposé*, and such a triumphant verdict, it is to be hoped that credulous elderly vestals will not be so ready to place implicit faith in the cunningly-devised tales of hysterical, lascivious girls. We all know what hysteria is, and if lawyers were as well acquainted with the deception practised, and the ingenuity often exhibited on points of immorality in some cases of that protean malady, they would be less disposed to undertake such cases as that of Bromwich versus Waters. (Applause.) I shall only touch upon the sympathy generally felt for the distressing ordeal Dr. Waters has undergone. Supported even by the conscientious feeling of innocence, it is a terrible thing for a pure mind to be dragged before the public upon so gross and wicked a charge. With these few remarks, I beg to submit the resolution. (Loud applause.)

Mr. BICKERSTETH: It affords me much pleasure to second the resolution, and I do so with peculiar satisfaction, because I think that Dr. Waters is entitled to the unqualified gratitude of the profession for the manly and courageous way in which he has boldly met the vile charges with which he has been assailed. It is well known that long before the trial took place offers of compromise were made to Dr. Waters, and not

only made but urgently pressed upon him. Few men could have resisted the desire to avoid such a trial; but Dr. Waters, conscious of his moral rectitude, declined to submit to any compromise after the aspersions that had been made upon his character, and determined to have the whole truth brought to the light of day. When I think of the nature of the charge against Dr. Waters, and of the absurd evidence upon which it was attempted to substantiate that charge, I ask myself, and I ask you, which of us might not any day find ourselves in a similar position, if unfortunately we should happen to have been consulted by some designing woman? (Hear, hear.) In private practice we are frequently called upon to make secret and private examinations when entirely alone with our patient. The presence of a third party on such occasions is often offensive to the feelings of a woman. It may be politic to propose that a friend should attend; yet I confess that I think it is generally unnecessary. It would often not only be cruel to the patient, but derogatory to our position, as confidential advisers, to insist upon the presence of a third party. Our position is indeed a dangerous one, but it is rendered doubly dangerous when, as in the late trial, we find members of our own Profession (one of whom does not hesitate to state that he felt convinced the case against the Doctor must fail as there was no evidence to support the charge) who do not hesitate to undertake a journey to Chester to propound opinions peculiarly their own, and upon the correctness of which alone it was possible to convict Dr. Waters. (Applause.)

The resolution was then put, and carried unanimously.

Mr. STEELE moved the second resolution, as follows:—"That this meeting feel called upon in the interest of the Profession to record a solemn and energetic protest against Medical witnesses, to the great injury of their brethren, assuming the functions of advocates, and volunteering opinions when they are only required to testify to facts,—a practice deplorably frequent, and which has reached its culminating point of impropriety at the hands of Drs. Lee and Ramsbotham in the case of Bromwich v. Waters." Mr. Steele said that however painful and disagreeable it might be to pass censure and condemnation upon the conduct of Medical men of eminence and reputation, it was their imperative duty to come forward on this occasion in support of the resolution which he had read—a resolution which he hoped would obtain the cordial and unanimous approbation of the meeting. The resolution was not directed so much against the gentlemen named personally as against the objectionable practice of which their recent conduct had formed so graphic an illustration, namely, the practice of Medical witnesses assuming the functions of advocates, and volunteering evidence when they were only required to testify to facts. He need not detain the meeting by showing that this course had been adopted by the Medical witnesses for the prosecution in the case of Bromwich v. Waters. That the practice was deplorably frequent must be pretty evident to most of those who were acquainted with the numerous cases which had lately occurred in the law courts, where charges had been brought against members of the Medical Profession which had proved to be unfounded, but in which there appeared to be no difficulty in inducing Medical men to come forward on the part of the prosecution, and give evidence in such a way as to produce a prejudiced and unjust impression upon the judge and the jury, who could not be supposed to understand all the intricacies and delicacies of Medical questions. Whoever had read the verbatim report of the recent trial at Chester must have arrived at the conclusion that Dr. Waters had not only escaped from an atrocious and abominable charge attempted to be made against him—a charge described by the judge as nothing less than one of rape—but that he had also shown by his conduct, which had also undergone the most searching investigation before a legal tribunal, that he had acted throughout as a Physician of the purest possible motives, and with the kindest consideration for his patient. Notwithstanding, however, the triumphant result of the trial, there was a time during the ordeal when his case was placed in the most imminent peril. And how, from, and by whom? By the Medical evidence that was offered on the part of the prosecution. The learned judge told the jury that if they believed the evidence of Drs. Lee and Ramsbotham that the treatment was improper, it would "enormously corroborate" the case against Dr. Waters. Now, when they considered the consequences which would have resulted from an adverse verdict, they could not but think that had not Dr. Simpson been able

to contradict the evidence of these Medical witnesses, Drs. Lee and Ramsbotham would not have had so fortunate an escape from a result which would have filled the rest of their lives with self-accusation and remorse, from the consciousness of their having been the main instruments in consigning an innocent and an honourable man to infamy and ruin. In order to illustrate more clearly the character of the evidence of Drs. Lee and Ramsbotham, Mr. Steele pointed out that, under all circumstances, when the propriety or impropriety of Medical treatment was canvassed by Medical men, it had been hitherto deemed contrary to Medical etiquette, and injurious to the interest both of Medical men and patients, to give an opinion upon a case which had been under the care of another Medical man, without the presence of that Medical man himself. Even if they differed from the treatment which had been adopted, and thought it wrong, they would hesitate to condemn it until, at all events, they had held an interview with him, and had heard his own description and explanation of the case at the time he attended it, and also the reasons for employing his treatment. This was the straightforward line of conduct which, from time immemorial, had guided all right-minded men in their dealings with their patients. If, therefore, this was their incumbent duty on a matter which merely involved a question of Medical etiquette, what should they say when the consequences ensuing upon the violation of this rule were absolute social death to the party implicated? (Hear, hear.) Then, with regard to the way in which this Medical evidence was brought forward. It was by the merest accident in the world that Dr. Waters became aware that Medical experts were to be called to give evidence against him. Shortly before the trial, it appeared that the prosecution desired to have a commission to go to the continent to take the evidence of a Medical man there who had had Mary Whalley under his treatment at Malvern; and in consequence of this the solicitor for Dr. Waters obtained information that it was probable that other Medical men would be called. When the evidence taken by commission was shown to Dr. Waters by his solicitor, he said, and very properly,—“Why, this is the most arrant nonsense ever put upon paper.” His solicitor replied,—“Never mind, it is the opinion of a Medical man—an opinion which is thought of great value by some persons, and therefore it must be answered.” Then it was that Dr. Waters considered it necessary to submit this evidence to Professor Simpson, of Edinburgh, who gave him a hint that some eminent Medical men in London would be called against him, though Dr. Waters was very hard to convince that it would be so. It was at this time that the guess was made that Dr. Lee was likely to be called, because it appeared that he was in the habit of meeting in consultation with Dr. Gully, of Malvern. They all knew, however, that these gentlemen came down, and they also knew the extraordinary grounds upon which they based their opinions. He (Mr. Steele) need not dwell upon these opinions to show the animosity to Dr. Waters, but he could not refrain from saying that he had heard, upon very excellent authority, that Dr. Ramsbotham himself did not hesitate to aid the counsel in cross-examination, and that Dr. Lee was handing a speculum round the court, evidently with the intention of prejudicing the case against Dr. Waters. Surely, after this it was not too much to say that improprieties of the kind mentioned in the resolution had “culminated at the hands of Drs. Lee and Ramsbotham. (Hear, hear, and applause.) Dr. Ramsbotham had made some sort of explanation and apology in the public journals, and had told them that if he had heard Dr. Waters' version of the story before he gave his evidence, there would have been very little difference of opinion between them. Well, now, did not this show how completely Dr. Ramsbotham had forgotten that excellent rule, to which he (Mr. Steele) had alluded; for had he adopted that rule he would never have placed himself in that highly reprehensible light in which he now stood, and which had called upon them to enter their protest against the practice which he and Dr. Lee, by their presence at the trial, had sanctioned and approved. In conclusion, Mr. Steele pointed out the importance of adopting a resolution which, while asserting the entire innocence of Dr. Waters, would at the same time afford protection to younger members of the Profession, in the event of their being assailed in a similar manner.

Dr. DICKENSON seconded the resolution, observing that Drs. Lee and Ramsbotham had shown great want of judgment and proper Professional feeling, and with regard to Dr.

Taylor, though his name had not yet been mentioned, it would be unfair to pass him by. He was not called upon to give evidence in a question of this kind, and he had no business to come down to give evidence upon a subject which was a matter of doubt.

Mr. PARKER, while concurring in the observations which had been made by previous speakers, was anxious to make a suggestion which this trial had brought to his mind, and which was also warranted by the frequency of similar trials, viz., that the time had arrived when the Medical Profession might very seriously take into consideration the propriety of forming a “Medical Defence Association,” in order that the expenses of such proceedings might be met without harass and ruin to individuals.

Mr. STEELE was afraid that the establishment of such an association would give the public the idea that the Profession feared and expected these actions, and that it would also have the effect of inducing juries, if the verdict happened to be against the Medical man, to give heavy damages, because payment would fall upon the society, and not upon the individual. He would rather take his stand upon the dignity and honour of the Profession, and fight the battle single-handed as Dr. Waters had done, throwing himself upon the sympathy and consideration of the Profession, if necessary. (Applause.)

The resolution was then put, and carried unanimously.

Mr. FLETCHER moved the third resolution:—“That this meeting recommend that a subscription be opened with a view of indemnifying Dr. Waters for any pecuniary loss he may have incurred in conducting his defence, and for the further purpose of presenting him with some lasting memorial of the high approbation with which they have regarded the dignified fortitude of his bearing under the prolonged persecution to which he has been subjected.” Mr. Fletcher proposed this resolution with peculiar pleasure, seeing that he had known Dr. Waters for thirteen or fourteen years. He knew him in Paris and Vienna, and he knew then, and had known since, no man in whose character he had greater confidence, who was more thoroughly a gentleman and a Christian, and whose mind was more thoroughly accomplished and delicate. As far as he (Mr. Fletcher) had had an opportunity of judging, Dr. Waters was about the last man of all his acquaintance against whom he should ever have imagined such a foul accusation would have been launched. Coming to the £ s. d. part of the resolution, Mr. Fletcher said he believed that they should do a great deal of good by subscribing to pay whatever expenses Dr. Waters might have incurred. He would not accept anything more than the amount he was out of pocket by the proceedings, but it would be gratifying to his own feelings and the feelings of his friends to have something as a memorial, not only that they considered him innocent, but that he had acted in a way which they regarded as meritorious, and had resisted temptations under which many men would have fallen. Dr. Waters had throughout strongly resisted, first the offer of private investigation, then reiterated offers of compromise, and had stood entirely upon his right; and from the very first step he took in his course to its triumphant termination he had been guided by a firm consciousness that he was in the right, and that “God would defend the right.” (Renewed applause.) With regard to the costs incurred, he (Mr. Fletcher) knew that £500 had been paid by Dr. Waters before he went into court, but he did not know how much of this sum would go under the head of “taxed costs.” From all he had heard, however, on the subject, he believed that the taxed costs paid to the victor in a case such as this bore but a small proportion to the real costs, or actual amount which a person was out of pocket even where he came off victorious. With regard to the subscription itself, Mr. Fletcher would rather see a large number of small subscriptions than a few large ones, for the great value of the money was this, that the public would look upon it as a real, honest manifestation of their belief, not only that Dr. Waters was innocent, but that his conduct throughout the whole matter had been marked by very high merit. (Hear, hear.) Then there was another point. They must remember the awful suspense in which Dr. Waters was kept between six o'clock, when the jury retired, and somewhat after midnight when they returned with their verdict. Upon that jury they knew that eleven were wise, and that one was “otherwise;” and so it was in general society. Some people were stupid enough, and others base enough, to believe any accusation, however absurd; and it was therefore no mere sentimentalism, but was a point of real

and practical value that they should come forward not only with their resolutions, but also with what money might be wanted to make up Dr. Waters' pecuniary loss, and to present him with something which he would leave to his children as a practical proof that not only his Professional brethren in Chester and elsewhere, but those who knew his character and standing believed him to be thoroughly innocent of the charges brought against him. Whatever they did, they could never undo the ill which had been done, never give him back anything which would make up for the agony through which he had passed; but they could do something to replace a sense of wrong by the expression of their cordial sympathy. (Hear, hear, and applause.) To say that the injury to Dr. Waters was due to a few gossiping old women, or tittle-tattling dowagers of Chester, was not true. The real venom had come from their own Profession. A weak and dirty weapon had been chosen; but a very little poison placed upon it by Drs. Lee and Ramsbotham might have made it effective for the work of destruction. What would Mary Whalley have been without Drs. Lee, Taylor, and Ramsbotham? Who gave the instructions to Serjeant Shee? They must have been given by a Medical man. (Hear, hear.) The *animus* of the instructions as to the charge relative to the speculum could have come only from Dr. Lee, aided by Dr. Ramsbotham, and the suggestion as to the drugging must have been known to Dr. Taylor. It must be remembered that these gentlemen had been for months in consultation with the lawyers; and that, whatever they might have *said*, actions spoke louder than words. (Hear, hear.) Though Dr. Ramsbotham might have advised in so many *words* that they should not bring the action, he advised in *deed* that they should. He (Mr. Fletcher) was certain that all they could do would be done on behalf of the right cause; and although they could not undo the evil which had been done, they could cordially and thoroughly avow their belief in the complete innocence of Dr. Waters, in order that in future years no doubt might remain upon the case. It was most important, in regard to the future, that Dr. Waters should not only be clearly exonerated by the verdict of the jury, but that his Professional brethren should declare that this foul accusation had been thoroughly rebutted, and that there was no man who more completely carried with him the sympathy and best wishes of his friends in the Profession. (Loud applause.)

Dr. A. T. H. WATERS, who seconded the resolution, expressed his most cordial concurrence with the preceding resolutions. It was, he thought, very desirable, considering the mental anguish and trying circumstances through which Dr. Waters must have passed, that they should express their sympathy with him, and their congratulations at the successful issue of the trial. It was also desirable to express their reprobation of the conduct of those members of the Profession who on this and similar occasions had been willing to lend themselves to those who were attempting to injure the character or ruin the reputation of a Professional brother. (Applause.) Though not in any way related to his namesake of Chester, he (the speaker) had known Dr. Waters for several years, chiefly in connection with the meetings of the British Medical Association. He had known him as president of the Lancashire and Cheshire branch of that Society, and as the reader of the address at the annual meeting of the Association in 1859. He mentioned these circumstances because they might not be known to every one present, and because they would show the high estimation in which Dr. Edward Waters was held by his Professional brethren in the counties of Lancashire and Cheshire. (Hear, hear.) It was very desirable (the speaker thought) to raise a subscription in the terms of this resolution for the purpose of indemnifying Dr. Waters from pecuniary loss incurred in conducting his defence; but they should not be satisfied with doing this merely, but subscribe to present him (as the resolution expressed it) with some lasting memorial of the high approbation with which they regarded the dignified fortitude of his bearing under the painful circumstances in which he had been placed. (Applause.) When they looked at the report of the trial, and read the searching cross-examination to which Dr. Waters was subjected, they must feel not only how ably he had withstood the attacks of the learned serjeant, but that only a feeling of strict moral and professional rectitude could have carried him unscathed through such an ordeal. (Renewed applause.) They ought not, under circumstances like these, merely to express their feelings in words, but to

make also a substantial contribution, in order to show the public that on such occasions as this when a Professional brother was unjustly and scandalously attacked, they were prepared to carry him safely through the cost of it. (Hear, hear, and cheers.) The speaker then alluded to the mode in which the Medical Profession, and the public at Chester had come forward, including the highest dignitary of the Church and almost every member of the Profession, in order practically to show their sympathy with Dr. Waters, and their high estimation of his character. (Applause.)

The CHAIRMAN mentioned that the sum which the solicitor of Dr. Waters had already disbursed was considerably beyond that incidentally mentioned by Mr. Fletcher; and further, that the actual amount of the expenses incurred could not be known until Dr. Waters' bill had been taxed, a form which could not be gone through until next term.

The resolution was then put, and carried unanimously.

After some further discussion, the details as to subscriptions were referred to a sub-committee.

Mr. DESMOND moved that the proceedings of the meeting be forwarded to the London Medical Journals for publication.

Dr. CALLON seconded the motion.

On the motion of Mr. HAKES, seconded by Dr. M'NAUGHT, a vote of thanks was passed to the chair, and the proceedings closed.

## REVIEWS.

*The Pharmacopœias of Thirteen of the London Hospitals, arranged in Groups for Easy Reference and Comparison.* By PETER SQUIRE, F.L.S., etc. 18 mo. Pp. 153. London: Churchill and Sons. 1863.

THE President of the Pharmaceutical Society has done us some service by the compilation of this little work, which must have cost a good deal of time and pains. As he tells us in the Preface, some of the formulæ are valuable to the Practitioner; and others convenient to Pharmaceutical Chemists, who are often called upon to make up prescriptions according to the formulæ of various Hospitals. But more than this, Mr. Squire not only gives us useful matter, but he points out to the Hospital authorities the expediency of harmonising their formulæ with each other, and of bringing them into accordance, in all cases where it shall be possible, with those of the new Pharmacopœia. We must say, that an intelligent pharmacist must wince in his inmost soul at the provoking discrepancies between formulæ which ought to be alike, at the shabby contrivances, and the wonderful diversity of doses which these formulæ exhibit.

*On Diseases of the Skin.* By ERASMUS WILSON, F.R.S. Fifth Edition. London: Churchill and Sons. 1863.

THE fifth edition of the English text-book on cutaneous diseases needs at our hands no commendation. Its place in Professional estimation is secure. The success of Mr. Wilson's work is due to its clear arrangement, its natural system of classification, and its pre-eminently practical character. The nosological classification introduced by Mr. Wilson is based on the structures affected and the causes from which the diseases arise. The whole family of skin affections are referred by him to two great groups,—the first, of diseases affecting the general structure of the skin, the second, of those affecting the special structures. The first group are divided into diseases arising from general causes, *e.g.*, erythema, lichen, eczema, impetigo; diseases arising from special external causes, *e.g.*, scabies, gelatio; diseases arising from special internal causes, *e.g.*, lepra, lupus, elephantiasis; diseases arising from the syphilitic poison; and, lastly, diseases arising from animal poisons, giving rise to the eruptive fevers. The second group contains diseases of the vascular, nervous, papillary, and pigmentary structures, the sudoriparous and sebiparous organs, the hair follicles, and hair and nail follicles and nails. This classification is, as we have said, a natural one, and, contrasted with the old artificial classifications of Plenck and Willan, and their various modifications, is an undoubted advance and boon to the student, substituting pathological ideas for mere names.

The chapter on the general pathology of the skin is conceived in the same spirit. Mr. Wilson teaches that erythema, lichen, eczema, and impetigo, representatives of the exanthemata, papulæ, vesiculæ, and pustulæ of Willan, are really

all phenomena of inflammation of the superficies, and that they are mutually convertible. Erythema is simple vascular congestion; lichen is congestion of the pores and superficial portion of the follicles, producing a tumid state of those parts, and constituting *pimples*; eczema is a vascular congestion accompanied by effusion, and giving rise to vesicles; impetigo, a similar pathological condition, resulting in the production of pus and pustules. The same in essential nature, they are simply modifications arising from accidental conditions. This teaching we believe to be philosophical as well as practical.

In warmly recommending this edition to the Profession, we would observe that it has received numerous additions and emendations as well as some new illustrations. The contained matter is at least double in quantity that of the earlier editions.

*On Human Entozoa: comprising the Description of the Different Species of Worms Found in the Intestines and other parts of the Human Body, and the Pathology and Treatment of the Various Affections Produced by their Presence.* To which is added a Glossary of the principal terms employed. By WM. ABBOTTS SMITH, M.D., M.R.C.P. Lond., Senior Assistant-Physician to the Metropolitan Free Hospital, etc. Pp. 251. London: H. K. Lewis. 1863.

CONSIDERING the rapid advances which the study of human and other parasites has made within the last few years, and considering, also, the peculiar interest which naturally attaches itself to the history and production of the *Entozoa*, we are quite in the humour to welcome from the hands of the English student of parasites any work which shall bring our knowledge of this subject up to the present hour; and we should also be still further gratified if we found any English author producing a work which not only did this, but even extended our knowledge of the genesis, migrations, and economy of this singular class of beings.

On looking into the work bearing such an imposing title as that here given, we confess to have felt considerable disappointment, for not only is it deficient in the very kind of information which we so much require, but, we are pained to add, that it does not appear to be, in any legitimate sense, an original treatise. The greater part of it is, in point of fact, neither more nor less than a translation from Mons. Davaine's well-known *Traité des Entozoaires, et des Maladies Verminestres de l'Homme et des Animaux Domestiques*.

If Dr. William Abbotts Smith had candidly announced on the title-page that his book was for the most part a translation of those portions of Mons. Davaine's treatise relating to the human entozoa, then we should have no fault to find; but, unfortunately, whilst recording in the preface "his deep sense of obligation to Dr. Davaine," and also "to Messrs. Baillièrè and Son, the proprietors of the copyright," he allows his name to appear on the title-page as if he were the author of an original work. Dr. Smith says the *nature* of the work is "sufficiently indicated on the title-page," and therefore it is unnecessary for him "to occupy the reader's attention with any lengthened prefatory remarks;" but he carefully screens the important fact that the matter of its pages is principally mere translation.

To make good our words, we turn to the First Part, and compare the two authors:—

"DR. SMITH, P. 1.

"PART I.

"*Synopsis of the Entozoa which are found in Man.*

"Entozoa are parasitic animals which live in the organs of other animals, and which possess neither a distinct respiratory apparatus, nor articulated appendages specially adapted to locomotion.

"The entozoa found in man may be arranged into five separate classes, namely, the Protozoa, the Cestoidea, the Trematoda, the Nematodea, and the Acanthotheca."

"MONS. DAVAINÈ, P. 1.

"*Synopsis des Entozoaires de l'Homme et des Animaux Domestiques.*

Les entozoaires sont des animaux qui vi vivent dans les organes des autres animaux, et qui n'ont point d'organes respiratoires distincts ou déterminés, ni d'appendices articulés propres à la locomotion.

"Les entozoaires sont organisés d'après six types distincts; ce sont, les Protozoaires, les Cestoïdes, les Trématodes, les Acanthocephales, les Nématodes, les Acanthothèques."

In this style, sometimes more literally, seldom less, omit-

ting foot-notes, Dr. Smith goes on and on, until, out of Mons. Davaine's synopsis of 92 pages, he has modestly contented himself with extracting 52 pages, which he calls Part I.

As Mons. Davaine gave Dr. Smith "permission to make use of any portions of his work," he has copied a considerable number of the woodcuts; but we do not find any statement in the descriptions of these cuts as to the source whence they are derived. Neither is Dr. Smith to be congratulated on the selection which he has made, for Fig. 7 is a remarkably poor illustration of the common fluke (*Distomum hepaticum*); whilst Fig. 9 would, in our opinion, do the pictorial honour for the sea-serpent quite as well as for the common lumbricus (*Ascaris lumbricoides*), which it is intended to represent. The latter figure may be an original one, but certainly all the others are copies.

In no instance has Dr. Smith thought fit to employ inverted commas or brackets, although page by page is usually translated in the most careful, and, we must in justice add, most able manner. In short, with the talents our translator possesses, we think it a great pity that he should not have frankly called it a translation.

Messrs. Baillièrè only very recently issued an English edition of Moquin-Tandon's "*Éléments de Zoologie Médicale*," (translated by Mr. Hulme)—a little work which contains an admirable and succinct account of the human entozoa. We repeat, Moquin-Tandon's *resumé* on this subject is the best account of the human entozoa which we at present possess to recommend to the student, whilst Dr. Lancaster's translation of Kuchenmeister will long retain its position as a standard work of reference. Mons. Davaine's treatise is really a valuable book; but in the mutilated form in which Dr. Smith has here presented part of it to the English public, it will neither bring credit to himself, nor advance the science of which it treats.

There is another point on which we must comment before concluding, for it will hardly be credited that Dr. Smith not only omits to do justice to M. Davaine, but even translates passages which Davaine himself reproduces from other writers with careful acknowledgment. Thus, for example, at p. 63, Dr. Smith commences a sentence thus:—

*The colour of the face is changed, sometimes flushed, sometimes pale, and sometimes of a leaden hue; a bluish semicircle appears*

and so on for twenty-nine lines, copying the original sentence, which consists of nineteen closely printed lines, and which commences thus, with inverted commas:—

*"Couleur du visage altérée, tantôt rouge, tantôt pâle, tantôt plombée; demicercle azuré*

the French sentence being continued, and finally closed with another pair of commas and a foot-note reference. This reference indicates that the passage is a quotation from M. Pinel's *Nosographie Philosophique*, but Dr. Smith never once mentions Pinel's name, neither is there the slightest indication by which the English reader might know that the passage is simply a quotation translated.

Finally, we may remark that we have compared scores of pages and hundreds of passages in Dr. Smith's work—or rather, in the work the title of which bears his name as if he were the author—with scores of pages and hundreds of passages in Mons. Davaine's work, and we find by far the greater number of the said pages and passages in the two books to correspond with each other. Here and there a number of sentences, and sometimes a number of pages are skipped by the translator, and occasionally a sentence appears to be made up in such a way that one might almost suppose it to be original. Some of the foot-notes are original, but, like celestial visitants, they come few and far between. Certainly, in all our experience of books, we never witnessed such a plagiarism (by permission?) as Dr. Smith's book exhibits.

PROFESSOR CHARLES HOOKER, M.D., died in Newhaven, Conn., on March 19. He was a native of Berlin, Conn., and a descendant of the leader of the first settlers at Hartford, the Rev. Thomas Hooker. He graduated in Yale College, in 1822, and then began practice at Newhaven. In 1828 he was appointed to the chair of Anatomy and Physiology, which he retained until his death. He was the author of several valuable papers. In his death the Profession in America has lost one of its most esteemed members.—*American Medical Times.*

## PROGRESS OF MEDICAL SCIENCE.

## Selections from Foreign Journals.

## THE SPONTANEOUS ORIGIN OF ERUPTIVE FEVERS.

M. ROGER communicated to the Paris Hospital Society the fact that a somewhat severe epidemic of scarlatina and measles had prevailed for some time past at the Children's Hospital. In a case of scarlatina, proving fatal on the third day, two series of lesions, both remarkable for their intensity, were observed. The first of these was a considerable *psorenteritis*, in which the follicles of the small intestine presented a development such as is rarely seen in typhoid fever, but unaccompanied by ulceration. The other lesion was a most intense, violaceous congestion of all the viscera, brain, spleen, kidneys, etc.—the testicles themselves and the tunica albuginea presenting a turgescence lividity. But the highest degree of congestion was found in the lungs, which were gorged with blood, of a violet red, and of a soft consistence. The pulmonary vessels were filled with black, semi-coagulated blood. At the inferior lobe of the right lung there was a vast apoplectic extravasation. In this case, the condition of the lung would prove a cause of rapid death independently of the scarlatina poison.

M. Chauffard was of opinion that, with respect to the eruptive fevers, there is too great a disposition to refer them to contagion or infection. The rapid appearance and vast extension of these epidemics would seem rather to point to a kind of spontaneous production, the causes of which are at present not understood. M. Roger was much disposed to agree in this opinion; for in private practice, in which the progress of these cases can be better followed, it is not always possible to refer them to a contagious origin; and, in the midst of epidemics, unable to follow the traces of a contagion, we are often obliged to at least admit the appearance of a spontaneous eclosion. Quite lately M. Roger has met with two cases of measles followed by pertussis; this secondary affection being only explicable by its importation during the short visit of the Medical attendant, or by its spontaneous origin, for the children had been most carefully isolated. M. Behier, in corroboration, observed that towards the spring and autumn he has every year observed epidemics of eruptive fevers break out in the different schools in Paris, situated at such remote distances from each other as to exclude all idea of contagion. He took this opportunity of mentioning a remarkable case. He had attended three children of a family for the measles, and was called five or six years later to see one of these children who had a well-marked second attack of measles. The parents were congratulating themselves at the absence of the other two, at boarding-school, when at the very time of the visit one of these latter was sent home, also suffering from measles. How rapidly contagion is sometimes communicated he illustrated by another case. A mother, entering the Tuileries with her child, on hearing an infant near her suffering under a paroxysm of pertussis, at once withdrew. Nevertheless, at the end of some days her child was seized with pertussis. M. Empis considered the admission of the spontaneous development of the eruptive fevers to be a mere gratuitous hypothesis, which may have a mischievous effect by diminishing circumspection in regard to preservative measures. The true mode of propagation of these affections is by infection, to which in populous localities there is constant exposure. M. Roger explained that no one would think of contesting the contagion of the eruptive fevers. All that is now advanced is that we may admit a kind of spontaneous development when contagion has not been in operation. M. Chauffard observed that, while it cannot be doubted that certain diseases were originally imported from distant regions, yet, once brought here, may they not become in some sort naturalised, and be liable to spontaneous eclosions? In 1855 there had been numerous cases of cholera in Paris, without any such appearing in the provinces, when, on June 7, the same day on which the first case was observed at Avignon, the disease appeared at several distant points. Here spontaneous eclosion is a more natural explanation than infection; and do we not see the same thing occurring daily with respect to variola, rubeola, and scarlatina. M. Simonet replied that a geographical progress has always been attributed to cholera. Its propagation may thus be traced, and

its spontaneous origin here cannot be admitted. As to the eruptive fevers, children are constantly taken to the promenades, and how are we to ascertain when and how they have contracted the contagion. M. Guérard remarked that we have constantly the opportunity of observing that the most infectious diseases may affect isolated individuals, without any epidemic or endemic extension. These are sporadic cases, which in some manner preserve the germ of the disease, special influences, the nature of which we are ignorant, being requisite to give to this germ the generalisation of an epidemic. These great epidemic manifestations, such as the variola of 1825, are generally somewhat sudden in their origin, rapid in their progress, and, in this sense, of spontaneous origin.—*L'Union Médicale*, No. 48.

## FOREIGN CORRESPONDENCE.

## FRANCE.

PARIS, March 20.

THE Winter Session of the Medical School of Paris has drawn to its conclusion, and for a short time the lecture-rooms are closed, the Summer Session commencing in April. The academic season has been marked by little novelty, except, perhaps, the display of the exuberant admiration of the students for freedom of thought and of action. The time has passed away when the School of Paris was the most distinguished source of Medical education, and when the Practitioner could hardly be supposed to have received a finished education unless he had studied within its walls. The European reputation of Majendie and Orfila, with the facilities of acquiring anatomical information, combined to give a reputation to the University which it has feebly maintained. The English student finds in the schools and Hospitals of London all that is necessary to perfect his education, and now it is somewhat rare to find young men from Britain attending the lectures, whilst a few years since they were amongst the most numerous of the youthful foreigners who were devoting themselves to the acquirement of the science which they were afterwards to practise. There are still, however, some most distinguished professors of the different faculties, and many skilful operators in the Hospitals, who are fully capable of affording the most valuable instruction, and whose lecture-rooms are crowded with men anxious to gain information. Velpeau, Andral, Trousseau, Nélaton, and Rayer are names known wherever the sciences are cultivated, and to have attended their lectures is a recommendation of which any student may be proud.

Velpeau may be looked upon as one of the most distinguished men of the age. The son of a country blacksmith, he commenced his career as an humble student of the veterinary art, and, acquiring some knowledge, he ventured on practising upon the peasant what he had learnt from the horse. This led to his giving to an unfortunate patient a dose of hellebore, to remedy whose effects a more experienced Practitioner was called in, who, when scolding the young Velpeau for his unskilful administration of the drug, was so struck with his replies, that he undertook to assist in procuring an education for him. He made a rapid progress in all the branches of Medical science, and on his arrival at Paris he passed his degree of Doctor with great *éclat*. He became Surgeon at the Charité. His promptitude in diagnosis, his skill in operation, his lectures, have placed him in the highest rank of professors, and his lecture-room is always crowded with admiring pupils.

Andral, the son of a Physician, has from his earliest youth been an ardent lover of science. Pathological anatomy has been his principal study. To compare the observations during disease with the effects produced, has always been his object; he may be considered the first Physician who showed the necessity of autopsy. His auscultation is supposed to be perfect, and from him the best lessons upon this important diagnostic have been obtained.

Trousseau distinguished himself as Professor of Therapeutics and *Materia Medica*. He is one of the most agreeable lecturers of the day; his language always is correct, and he has a facility of expressing himself that renders his lectures peculiarly agreeable.

Nélaton is an admirable operator. When he is about to extract a calculus there is an immense throng of spectators eager to watch his skilful manipulation.

Tardieu's works upon pathology have of late acquired considerable reputation, and this season he has been lecturing on Medical Jurisprudence, for which he has every kind of knowledge, but he dwells too much on some subjects that are not likely to be brought before the Medical man during a long life, at any rate in England, where the vices upon which he expatiates are little known, and upon which he is scarcely ever called upon in a court of justice to give evidence. The subject, too, is one little adapted for the study or even the comprehension of young men. M. Tardieu is a man of great intelligence, and commands the attention of his audience as much by his manner as by the subject he discusses. There will be a pause of a month between the two sessions. Clinical Surgery and Medicine will then be resumed at La Charité and at the Hôtel Dieu. Medical natural history and botany will be commenced, and for two months ample occupation will be found for the student.

The increase of mental alienation from demonosophy is attracting great attention at all the Asylums at Charenton; several cases have been admitted, but no less than forty unfortunate individuals have to attribute their disease to spirit-rapping, and to the new-fangled doctrines of the spiritualists.

At the Hôpital Lariboisière, the method proposed by Dr. Chassaignac, of amputating limbs without the aid of the knife, has been successfully tried by the application of a caustic bracelet to the diseased limb; the soft parts are separated, and as soon as the bone is visible, it is cut through by the chain saw. Where patients are so feeble as to render the ordinary operation dangerous, this new plan is found eminently successful. Dr. Chassaignac has written an essay upon the subject, which gives the minute steps of his proposed addition to Surgical science.

Dr. Guyon has read before the Academy of Science a very interesting memoir upon the parasitic insect of hot countries, the Chique, *Dermatophilus penetrans*, in which he enters largely upon the parasitic insects which find their way into the skin of living beings, or inhabit any portion of the tissue. He describes the common flea very minutely, as the type of a large series of small insects, which have the power of inflicting considerable punishment upon animated beings. The mouth, he shows, is armed with three portions, included in two sheaths, which represent a conico-cylindrical beak, which case is capable of folding itself together by peculiar articulations. The body is covered by a hard envelope, almost horny, formed of several pieces articulated together. These pieces cover the thorax, and give origin to three pair of feet, admirably adapted for taking leaps. These insects undergo several changes during their existence, from an oval and white egg they come out under the shape of small worms or larvæ; they roll rapidly round upon themselves. After living for twelve days without any nourishment, they become red, and form a cocoon of fine silk, in which they become a chrysalis; and then, leaving this abode, they are formed into a perfect insect, and are fitted to become tormentors of the human race. The insect product of the itch is of this class; it penetrates under the epidermis, making an oblique path for itself, in which it deposits a little vesicle full of limpid liquid; it is difficult to discover, because it does not remain in the centre of the elevation that it produces, but moves rapidly to another point.

GENERAL CORRESPONDENCE.

THE CASE OF RUSSELL v. ADAMS.

LETTER FROM MR. WM. ADAMS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to forward to you a correspondence which has recently taken place between myself and Mr. Propert, and upon which it is unnecessary for me to make any comment.

I am, &c. WM. ADAMS.

5, Henrietta-street, Cavendish-square, April 22.

(1.)

"5, Henrietta-street, Cavendish-square, W., April 15, 1863.

"Sir,—The following quotation is from a letter received from a gentleman occupying a high position in our Profession:—

"The sting of the matter is, that spite of the late trial, and notwithstanding the evidence since afforded by Dr. Cottam, Mr. Maitland, Dr. Webb, Mr. Toynbee, and others, as to the antecedents of the prosecutrix, there are some persons who still adhere to Mr. Propert, and who justify him in his apparently harsh treatment of you at the beginning of the affair, when he condemned you unheard, and refused to listen to the explanations you offered him, and who not merely condemn you by implication, but affirm positively as follows—viz., that were Mr. Propert's

version of his proceedings made public he would be seen to be entirely justified, and that he is displaying great forbearance towards you in not noticing the attacks made upon him, and that his holding his tongue is safety to you. These latter expressions I have heard this week from the mouth of a personal friend of mine, a man of sense, and one whose opinion I value. He is a friend of Mr. Propert's, and as such believes that Mr. P.'s statement would crush you."

"I wish to know whether the statement made in the above quotation be true or false.

"Is it, or is it not true that you are dealing out any such insinuations, or any insinuation whatever against my character?"

"I must demand a plain and simple answer to this question, and without delay.

"Jno. Propert, Esq."

(2.)

"6, New Cavendish-street, W., April 17, 1863.

"Sir,—In reply to your letter of the 15th inst., I beg to state that I never heard of the statements alleged to have been made by friends of mine, with reference to yourself, in your letter referred to, neither do I consider myself in any way responsible for the opinions which they may entertain respecting you. I have, however, always felt much regret that a gentleman of your position in our Profession should not have availed himself of the proposal by Mr. Johnson, the attorney acting for Miss Russell, in the action brought by that person against you, contained in a letter addressed to your attorney, dated March 22, 1862, namely, 'that both the plaintiff and defendant should be examined as witnesses on the trial of the action,' and that such proposal should have been declined by your attorneys in their letter to Mr. Johnson in reply, of April 11, 1862.

"I remain, sir, yours, &c.

"WM. ADAMS.

(3.)

"5, Henrietta-street, Cavendish-square, April 18, 1863.

"Sir,—In my letter of the 15th inst., I asked you a plain question to this effect: 'Is it, or is it not, true (1) that you have said you were forbearing towards me by not replying to explanations which have been demanded from you for your conduct towards me; (2) that holding your tongue is safety to me; (3) have you implied that you are aware of allegations injurious to my character, which you withhold out of forbearance to me?'

"In your reply of April 17, you do not answer this question. I must therefore repeat my demand for an answer.

"You have introduced in your letter a subject totally irrelevant to my question, but I will remind you that, however desirous I was to be examined as a witness, and it would undoubtedly have been much to my advantage, the laws of evidence did not permit of it. You might learn this from any solicitor, and if you will refer to the published charge of the Chief Baron, of which I send you a copy, at page 30 you may see that the judge said, 'Miss Russell cannot be examined, nor can Mr. Adams.'

"Mr. Lush, in his opening address, explained this peculiarity in the law of evidence, and Mr. Serjeant Shee did not suggest that any other course could have been adopted. This, however, is a mere matter of legal procedure that has nothing whatever to do with the question to which, as a member of the same Profession, I require a plain and truthful answer.

"I am, sir, yours, &c.

"WM. ADAMS.

"Jno. Propert, Esq."

(4.)

"6, New Cavendish-street, W., April 22, 1863.

"Sir,—Having, in my letter of the 17th inst., answered the questions contained in your letter to me of the 15th inst., I have no reply to make to your letter of the 18th, and I must decline any further correspondence on the subject of your letters.

"I beg to remain, sir, your obedient servant,

"W. Adams, Esq."

"JOHN PROPERT.

OBITUARY.

THE DEATH OF MOQUIN-TANDON.

THE distinguished Professor of Medical Natural History in the Paris Faculty of Medicine died suddenly, apparently of an affection of the heart, on the 15th inst., in the 59th year of his age. The day before he seemed in vigorous health, and took part in the proceedings of the Academy of Medicine, presenting a memoir on Fevers, by Dr. Girbal, of Montpellier. He afterwards went into the library, and placed in the hands of Dr. Ruzf, the Director of the Jardin d'Acclimatation, an address which he intended to give the next day, on the occasion of distributing the prize medals. He passed the evening at the house of a friend, and returned home without expressing any feeling of illness. Soon after retiring to rest, he was awakened by a vague feeling of pain in the region of the heart, and died almost immediately. As a botanist and zoologist, Moquin-Tandon stood in the first rank. He is best known in this country by his work on "Medical Zoology," the only book on the subject. He was the intimate friend and literary executor of Geoffroy St. Hilaire, and succeeded him as Vice-President of the Imperial Society of Acclimatation. On the day after his death the address which he should have delivered at the Jardin d'Acclimatation was read by Albert Geoffroy St. Hilaire. He was borne to his last home by representatives of the various societies of which he was a member. M. Costa attended from the Institute, Larrey on the part of the Academy of Medicine, Rayer for the Faculty of Medicine, and Passy for the Botanical and Acclimatation Societies. In accordance

with a wish expressed during life, the usual official eulogium was omitted at the grave. It appears that Moquin-Tandon was himself aware that he was labouring under serious heart disease, but, with curious pertinacity, refused to be examined with the stethoscope, and would not even allow his pulse to be felt. He had just prepared, at the desire of the Emperor, and at the instigation of our Society for the Prevention of Cruelty to Animals, the "Report of the Academy of Medicine on the Practice of Vivisection."

## MEDICAL NEWS.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—At a general meeting of the Fellows, held on Monday, April 20, 1863, the following gentleman, having undergone the necessary Examination, was duly admitted a Member of the College:—

Peter Daniel Anthonisz, M.D. St. Andrew's, Ceylon.

At the same meeting, Edward Nölloth, previously an Extra-Licentiate of the College, was also admitted a Member. Also, at this meeting, the following gentlemen, having undergone the necessary Examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—

Thomas Rutherford Adams, Kilmoganny, County Kilkenny, Ireland; Henry Earber, M.D. St. Andrew's, Ulverstone, Lancashire; Jas. Bisshopp, 1, Lawn-place, South Lambeth; Thomas Blunt, Wigston Magna, Leicester; Alfred Brocard Boulland, Merthyr Tydfil, South Wales; Hugh Campbell, St. Paul's-grove, Canonbury; Thomas Carter, Richmond, Yorkshire; John Ellerton, M.D. St. Andrew's, Wakefield, Yorkshire; Francis Hyde Forshall, Woburn-place, Russell-square; Edward Harley, King's College; Edward Hott, Bromley, Kent; Thomas Lyle, Stratton, Cornwall; Hugh Richard Duncan Mackintosh, The College, St. Bartholomew's Hospital; William Peter Rawlins, M.D. St. Andrew's, 2, Francis-terrace, Kentish-town; John Reynolds, Truro, Cornwall; John Roberts, Kidwelly, Carmarthenshire; Joseph Septimus Steward, Eusemere-hill, Cumberland; Alfred Wiltshire, M.D. St. Andrew's, Malvern, Worcestershire.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 21st inst., viz.:—

Messrs. Denis Collins, Liverpool; Charles Etheidge, Stoke Ferry, Norfolk; Herbert Everitt, Norwich; Arthur Evershed, Arundel; William Carter, Newbury, Berkshire; Herbert Morris Spencer, Ackworth, Yorkshire; George King, Leekford, Hants; John Spencer Ferris, Bradford-on-Avon, Wilts; Frederick John Tucker, Milton-street, Dorset-square; Harry Gage Moore, Lymington, Hants; Charles Stephen Abbott Atkinson, Norwich; John Reynolds, L.R.C.P., L.S.A., Truro, Cornwall; Samuel Hall, Belper, Derbyshire; Anthony John Newman, L.S.A., Newport, Monmouthshire; Samuel George Freeman, Stoney Stratford; Albert Weaving, Oxford; David Howell Thomas, Swansea; Christopher Jeafferson, Leamington; John Henry Simpson, Marksbury, Somerset; John Barrett, Bath; Thomas Carter Wigg, East Dereham, Norfolk; Henry Addison Hobbs, L.S.A., Croydon; Thomas Evans, Llandyssil, Cardiganshire; and William Quarrell, Weston-super-Mare.

At the same meeting of the Court, Messrs. Robert Edwardes and Henry Hadlow, of the Royal Marine Infirmary, Woolwich, passed their Examinations for Naval Surgeons. These gentlemen had previously been admitted Members of the College, their Diplomas bearing date respectively May 4, 1857, and June 24, 1859.

Admitted Members on the 22nd inst.:—

Messrs. John Baily Grewcock, Folkingham, Lincolnshire; William Gill, Truro, Cornwall; Basil Ringoose, Potter's Bar, Middlesex; John Hurd Wood, Notting-hill; Frederick Thomas Faggs, Hythe, Kent; Arthur Benjamin Jackson Eddowes, Loughborough; John David Frankish, Christchurch, New Zealand; Thomas Edward Mason, M.D. St. And., Deal, Kent; Edward Whitfield Thurston, Ashford, Kent; John Walker Martindale, Windermere; Thomas Carter, L.R.C.P., and L.S.A., Richmond, Yorkshire; Walter Llewellyn Nash, Cheltenham; Aaron George Medwin, M.D. St. And., and L.S.A., Blackheath-road; Hugh Richard Duncan Mackintosh, L.R.C.P., Cheltenham; John New Moore, Moreton-in-the-Marsh; Walter Rumbold, L.S.A., Ramsbury, Wilts; Samuel Woodman, Finchley-road; Sidney Rossell Henson, Hull; James Forman Milner, Hull; Robert Bowie, Hull; John Whitehead, M.D. St. And., and L.S.A., Preston, Lancashire; Joseph Good, Watford, Herts; and Charles Beviss, M.D. St. And., Sydling, Dorset.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, April 16, 1863:—

Charles Augustus Greaves, Wardwick, Derby; Thomas Hepple, New-castle-on-Tyne; Edward Mahony, Richmond-road, Dalston; David Lewis Bronayron, Llangatho, Wales; Stephen Winter Fisher, Cotham-park, Bristol; Charles Beviss, Sydling, Dorset.

The following gentlemen also on the same day passed their First Examination:—

Joseph Wilkinson Warburton, Royal Infirmary, Liverpool; James Walbridge Snook, St. Bartholomew's Hospital; Henry Rayner, St. Thomas's Hospital.

## APPOINTMENTS.

\* \* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

DAVIS, J. HALL, M.D., has been appointed Physician-Accoucheur to the Middlesex Hospital.

FOWLER, JAMES, M.R.C.S. Eng., has been appointed House-Surgeon to the Clayton Hospital and Wakefield Dispensary.

KENDALL, THOMAS MASTERS, F.R.C.S. Eng., has been honoured with the appointment of Medical Attendant on their Royal Highnesses the Prince and Princess of Wales when residing at Sandringham Hall.

MITCHINSON, GEORGE, L.K.Q.C.P.I., has been appointed third Physician to the Lincoln Lunatic Hospital.

## DEATHS.

BAINBRIDGE, JOHN NATHAN, M.D. St. And., at 86, St. Martin's-lane, W.C., on April 16, aged 63.

BIRTWHISTLE, JOHN, F.R.C.S. Eng., at Primrose-cottage, Rosebank-road Old Ford, Bow, on April 11, aged 63.

BROOKES, WILLIAM C. F., M.R.C.S. Eng., at Warrington, Lancashire, on March 23, aged 41.

BULLOCK, JOSEPH, F.R.C.S. Eng., at Congleton, Cheshire, on March 26, aged 66.

GARLAND, HENRY, M.R.C.S. Eng., at Yoxford, Suffolk, on April 2, late of Belitha-villas, Barnsbury-park.

GUY, HY., M.R.C.S. Eng., at 1, Dorset-square, N.W., on April 14, aged 52.

LINDSAY, Dr., of Liverpool, on March 18, aged 47.

STEDMAN, SILAS, M.R.C.S. Eng., at Durrington, near Worthing, on April 11, aged 66, formerly of Guildford-street, Russell-square.

WELLS, RICHARD FORESTER, F.R.C.S. Eng., at the Isle of Portland, Dorset, on April 9, aged 47, late of Artillery-place, London.

MR. HEATHER BIGG has been appointed Anatomical Mechanician to H.R.H. the Prince of Wales.

MR. JOHN BURTON, Walsall, passed his first Professional examination at the University of Aberdeen on the 6th and 10th of April.

HALL, the too celebrated plaintiff in the case of "Hall v. Semple," has applied to Sir Creswell Creswell for a divorce from his wife, on the plea of cruelty.

WILLIAM TURNER, M.B. LOND., F.R.S.E., F.R.C.S.E. & L.—On the 9th inst., Mr. Turner, of Edinburgh, was presented with a handsome claret jug and two silver salvers with the following inscription:—"Presented to William Turner, M.B. Lond., F.R.S.E., F.R.C.S.E. and L., on the occasion of his marriage, by his old and present pupils, as a mark of their esteem for him as their teacher and friend." An address was also presented at the same time, with a list of the subscribers, in number 160.

**FACULTY OF MEDICINE OF THE UNIVERSITY OF MADRID.**—There have been inscribed for the present scholastic year the names of 670 students, 366 Practitioners, and 3 Midwives. There are in Spain also ten other Medical schools besides that of Madrid.

**PRIZE QUESTIONS OF THE MADRID ROYAL ACADEMY OF MEDICINE.**—1. Exhibit the fundamental positions of a system of general pathology. 2. Pass under critical examination the methods hitherto employed for the extraction of morphia from opium, and expose the chief modifications these are susceptible of. The prize of 3000 reals (810 francs), a bronze medal, and the title of Corresponding Member, will be adjudged to the authors of the successful essays. The memoirs, written in Spanish, Italian, Portuguese, Latin, or French, must be forwarded to the Secretary of the Academy by October 1, 1863.

**PRIZE QUESTION ON INSANITY.**—So many cases in which the plea of insanity has been raised with very little success having of late occurred, it may interest our readers to learn that M. André has placed a prize of 1000 francs at the disposal of the Paris Medico-Psychological Society for the best essay on Moral Insanity (*Manie raisonnée*). The essays must be forwarded to Dr. Brochin, Secretary of the Society, 7, Boulevard Sébastopol, before December 31, 1863.

**ST. THOMAS'S AND BETHLEHEM HOSPITALS.**—At a General Court of the Governors of St. Thomas's Hospital, held on Tuesday, the 21st inst., at the Terminus Hotel,

London-bridge, it was resolved:—"That the Grand Committee be empowered to continue the negotiation with the Governors of Bethlehem Hospital for obtaining the site of that hospital, and to submit proposals to that body either to build for them a new hospital in conformity with the plans and estimates prepared by Mr. Currey, the surveyor of this hospital, at a cost not exceeding 150,000*l.*, including the site, or to pay for the site and buildings of Bethlehem the sum of 150,000*l.*, subject to the approval of the Court of Chancery, and the sanction of Parliament and of this Court."

**TRAINING INSTITUTION FOR NURSES AT BRISTOL.**—A Nurses' Home, similar in character to the training institutions of London and Liverpool, has been lately opened at Bristol. Its objects are to provide trained nurses for the public, on the usual terms, and to supply gratuitous nursing to the sick poor. A home is provided for the pupils, under the direction of a resident lady superintendent; but, as thorough training can only be obtained in an hospital, the committees of the Bristol Royal Infirmary and the Bristol General Hospital have consented to admit the pupils of the Home to those institutions, and have arranged a complete course of instruction for them. Dr. Martyn, physician to the Bristol General Hospital, is treasurer to the new Institution.

**THE Wiltshire papers contain long notices of the death of Dr. Richard Fowler, in the neighbourhood of Salisbury, in his ninety-eighth year. The deceased was the oldest member of his Profession, and of the Royal Society, of which body he was a Fellow, and was also one of the originators of the British Association, the meetings of which he invariably attended until within the last year or two. Only five or six years ago he made a journey to Glasgow, where an able paper which he had just written, "On the State of the Mind during Sleep," attracted much notice. Dr. Fowler received his Medical education at Edinburgh and Paris, and was well acquainted with Mirabeau and others who took a leading part in the affairs of France at that time.—The Guardian, April 22.**

**DEATHS BY FIRE.**—In the fourteen years 1848-61, 39,927 persons—about eight a-day—were burnt alive in England, or were scalded to death; 1344 were infants under one year of age; 4500 were children of one and under two years of age; 9777 were between two and four years of age—and in these two years the child, not having learnt to dread the fire, incurs the greatest danger. The boys being, in nursery language, "most mischievous," are up to four years of age burnt in greater numbers than girls; but afterwards the clothes of boys are less combustible than the clothes of girls, and fewer of them are burnt to death. Between the ages of five and fifteen 6255 girls, but only 3750 boys, were burnt to death in the fourteen years. Subsequently men are exposed to fires and explosions in mines and works, and die by fire in much greater numbers than women up to about fifty years of age, after which the men grow more cautious or are partially withdrawn from danger, and the combustible dresses of women again turn the scale against them. 2122 old women (above sixty-five) in their feebleness were burnt to death in the fourteen years.—*Dr. Farr, Registrar-General's Report.*

**ANTHROPOLOGICAL SOCIETY OF LONDON.**—April 21.—Dr. Hunt, President in the Chair.—A paper was read by Alfred Tylor, Esq., F.G.S., F.L.S., "On the Discovery of Supposed Human Remains in the Tool-bearing Drift of Moulin-Quignon." The author quoted the accounts of this alleged discovery which appeared in the Abbevillois newspapers of April 9-18, and stated that on April 13 Messrs. Prestwich, Evans, and himself visited M. Boucher de Perthes, and observed circumstances which led them to suspect a deception had been practised by the quarrymen. The axes appeared to be artificially stained with the iron deposit of the gravel. On being put into water for a time they looked so much changed that it seemed likely that a good brushing would have brought the whole of the colour away. Moreover, the presence of certain flints lying in a heap in the quarry, which flints had evidently been practised upon, did not escape the experienced eye of Mr. Evans. Mr. Prestwich suspended his opinion on their authenticity. Mr. Tylor considered that further examination may possibly prove whether the bone (a lower jaw) and the axes were genuine or not. At present the discovery cannot be accepted as proven, as there are strong grounds for suspecting that the reward offered by M. de Perthes has induced the quarrymen to in-

troduce bones and flint instruments into the gravel so skilfully as to deceive even the patriarch of primeval archaeology himself. Dr. Hunt entertained no doubt that the flint implement exhibited by Mr. Tylor was a forgery. Mr. Charlesworth, F.G.S., was also inclined to doubt its authenticity, and said that the reward offered by M. Boucher de Perthes would act as a strong stimulus to the perpetration of similar frauds. Mr. Carter Blake said that the appearance of the flint implement on the table was very different to that of the remains which had been derived from gravels in England. After some observations from Mr. Bendyshe, Mr. Davies, and Mr. Mackie, the Secretary read a paper, by Dr. Julius Schwarcz, F.G.S., of Stuhlweissenburg, "On the Permanence of Type," in which the author demonstrated that the pre-Alexandrian Greeks uniformly recognised the doctrine of distinct foci of creation, and condemned the theory of the unity of origin of mankind. A discussion arose, in which Mr. Collingwood, Dr. De Meschin, Mr. Higgins, Mr. Blake, and the President took part. A paper was also read by C. S. Wake, Esq., F.A.S.L., "On the Relations of Man to the Lower Animals." The meeting adjourned to May 12.

**ROYAL VICTORIA HOSPITAL AT NETLEY.**—The sixth session of the Army Medical School was opened on the 15th by an address from Professor Longmore, Deputy Inspector-General. The lecturer commenced by a reference to the removal of the school and invalid establishment from Fort Pitt to Netley, and to a lecture he gave in October, 1860, and published in the *Army Medical Report*, in which was an account of the formation of the School, and of the purposes it was intended to accomplish. The main design of the School being to teach the means of diminishing the mortality in the army, and of reducing the number of incompetent and disabled soldiers, it was necessary as far as possible to show the Surgeons entering the army what were the effects of service on the soldiers, and in no place could this be done so effectually as in the Great Invaliding Establishment, to which sick men from all parts of the world are sent. The School was therefore established in the first instance at Fort Pitt, and now necessarily accompanied the Invalid Establishment to its new locality. The arrangements for the School at Netley were noticed, and very favourably spoken of. It was stated that since the formation of the School in 1860, three Surgeons, forty-four Assistant-Surgeons, and eighty-nine candidates for commissions had passed through the courses of the School, forming no less than one-eighth of the entire number of Army Medical Officers. Reference was then made to the deaths of Drs. Schmitz and Hope, the only two gentlemen who have been at the School who have died. The former died of fever brought on or rendered fatal by his exertions during an outbreak of cholera, and the latter died of cholera. Both these young officers were most favourably spoken of, and their early deaths were deeply regretted. Allusions were then made to the best mode of study, and to the necessity of cultivating the habit of correct writing and expression, a want of which was considered to be one of the most general defects in Medical education at the present day, and the lecturer concluded a very admirable lecture by describing the arrangements for the current session. The lecture was attended by the Commandant, Colonel Wilbraham, C.B., Dr. Anderson, Principal Medical Officer, Major Ravenhill, Commanding Engineer, Major Rawlings, and other officers connected with the Hospital, and a few of their private friends. At the close of the address, Colonel Wilbraham observed that he hoped the opening of this great establishment at Netley would be productive of a twofold benefit; that it would give the old soldier worn out with the fatigues of foreign service a comfortable home and resting-place until his final discharge from the service, while for the Medical Staff, he hoped that the Royal Victoria Hospital would be what Woolwich was to the artillery—a head-quarters which all would think of with pride and affection. He concluded with a high compliment to Dr. Anderson and the other Medical officers for the zealous and kind co-operation they had given him, and for the accommodating spirit in which they had met all the difficulties of the first organisation of so large an establishment.

**THE NEW TEST FOR SUGAR IN DIABETIC URINE.**—The great interest excited by the announcement that the urine of diabetic patients rapidly renders the tincture of iodine colourless, has induced M. Trousseau to furnish some details which would otherwise have been left for a future memoir. In the first place, his field of observation, though

of short duration, has been of considerable extent. The urines of all the patients occupying the sixty-eight beds of the Clinique of the Hôtel Dieu, were tested every day for a fortnight in the presence of pupils and practitioners, as also urine supplied from the other wards by the students or employés. Then, there were ten nursing-women, whose urine exhibited very various characters. The fact seems decisively proved that glucosic urine has alone the property of decolourising in a few seconds a determinate and relatively considerable quantity of the tincture of iodine. The procedure is as follows:—Into a test-glass containing six cubic centimètres of urine, four drops of the tincture are dropped, sometimes five or six drops being required to produce a sufficiently deep colour of the urine. In other cases, two or three drops are amply sufficient for this purpose. The physiological or pathological circumstances rendering these different quantities necessary are not yet determined, it seeming, however, that the acute or chronic state of the malady is not the determining cause of such difference. The important clinical fact is that all morning urine, freshly collected, and acting on litmus-paper, whether derived from a healthy or sick person, will become highly coloured by from four to eight drops of tincture of iodine, and that during a variable period; while glucosic urine will very rapidly render colourless from four to even thirty-two drops of the tincture. Without impeaching the above statement, it has been objected that all urine will effect such decolouration; but the reply is furnished by comparing the effects on urine derived from any source, providing only that it is acid with glucosic urine after dropping in the iodine. It has been said that it is the uric acid which effects the decolouration, and not the glucose; but while the chemical action of the acid in effecting such change is unknown, it is very singular that the urines taken from a hundred patients should contain so little acid that they did not decolour four drops of the tincture, while glucosic urine, which generally does not contain much uric acid, alone possessed the property of rapidly decolourising from eight to thirty-two drops. M. Trousseau, and his colleague, M. Dumontpallier, have not asserted that glucose decoloured the tincture, but that this was done by glucosic urine. In fact, their own experiments have shown them that the glucose of commerce, whether added to water or to the urine of healthy or diseased subjects, will not decolour the iodine, although it reduced the blue fluid of Barreswill, and gave a reddish brown with potass. Moreover, they have found that cane-sugar, dissolved in water or urine, exerts no decolourising power; and again, some diabetic sugar, extracted with the greatest care, mixed with water or urine did not decolour the iodine. The experimenters were, then, well justified in limiting this power to natural glucosic urine, this operating in proportions which astonished all those who witnessed the decolourising action for the first time. Another curious fact is, that glucosic urine neutralises the action of iodine on starch. Thus, if into a mixture of starch and glucosic urine some drops of tincture of iodine be poured, the ordinary violet blue is not produced, the action of the iodine being neutralised by the presence of the glucosic urine. But if the number of drops of the tincture be increased, the urine assumes a beautiful blue colour, again to disappear on an excess of glucosic urine being added.

### BOOKS RECEIVED.

The Consumptive Poor of South London. By Theodore E. Ladd, M.D. London: A. M. Pigott. 1863. Pamphlet. Pp. 31.

\*\* Dr. Ladd descants on the prevalence and fatality of consumption, and quotes the dicta of great Physicians to the purport that it is curable. He briefly alludes to the causes, or alleged causes, especially in women; and foremost amongst these he places "crinoline." He gives, in not very clear statistics, the proportion which consumption and other diseases of the chest bear to the total mortality, viz, 28 per cent. He then proposes to reduce the mortality amongst the poor "by giving him access in his hour of need to the same skill that aids the rich man in his weakness." Then he shows that the north side of the river boasts of four special institutions for chest disease, whilst the south has not one. "We want, undeniably, in south London a Hospital for consumption, asthma, and diseases of the chest." We have no objection to such an Hospital, nor yet to Dr. Ladd as chief Physician thereof, but we cannot help remarking that he makes use of some bye arguments, or admissions strangely destructive of his main purpose. His experience has taught him, that unless consumptive patients gain speedy admission to a "special" institution, positive harm results from the existence of such institution. The mental anxiety consequent on the effort to get admission; the toil of going backwards and forwards as out-patients; the journeys in omnibuses and steamers in bad weather; the cost of such journeys; foul air of the waiting-room; the time consumed in waiting to see the Physician, and

then to get the medicine,—all these things do more harm to the patients than they get of good from the drugs and advice. But since it is impossible to provide Hospital accommodation for a disease which kills at least one-fourteenth of those who die, therefore, on Dr. Ladd's own showing, one additional institution may do more harm than good. Cheap railway fares and steamboats, cricket fields, athletic exercises, healthy dwellings, and something like obedience to the laws of Life,—if we could but inculcate these, we should be doing more good than by adding to the number of Hospitals.

On Ringworm, Scall-head, Baldness, and other Parasitical Diseases of the Head and Face. With an Appendix on the Constitutional Relations of Diseases of the Skin and Principles of Treatment. By George Ross, M.D., etc. London: Henry Renshaw. 1862.

\*\* Dr. Ross's little book is plain, easy reading. It does not contain much that is new, but it gives some information as to pathology and some general hints in treatment. In accordance with the views of Dr. Hughes Bennett and others, Dr. Ross asserts the vegetable character of the cell-growths both in ringworm and favus. The scraps of dialogue between the Doctor and his patients, which interlard the few "illustrative cases" given at the end, are undoubtedly the most original features in the book. Colloquies have been much used to enliven books of popular theology, whence we suppose Dr. Ross has taken the idea, deeming it (and few of his readers will disagree with him) necessary to do something to enliven his popular Medicine. Here is a specimen.

Subject, Lupus.  
Dramatis Personæ,  
Dr. R.  
Patient, J. H.  
Mother.

"Dr. R.: This is a serious business.—Mother: Yes, indeed, she has been ill two years; we were told at first that it was cancer (looking anxiously for an answer). Dr. R.: How did it originally appear?—Mother: Like a hard pimple inside the nose; we did not think much of it at first, but as it did not go away, we consulted Mr. —, who prescribed some ointment and lotions, and a variety of things, but it did not get a bit better. Dr. R.: Well?—Mother: We then saw Mr. —, and she seemed to improve while with him; but the skin broke at last. Dr. R.: She had better take a course of arsenic—a medicine that will require careful watching. J. H.: I have taken arsenic, and it did not benefit me. Dr. R.: How long?—J. H.: A month or two. Dr. R.: Then you must begin again." *Of course the patient is cured.*

Medical Record of Australia.

\*\* We are strongly inclined to criticise the treatment of dysmenorrhœa propounded by Mr. Beane. We think that "hysterotomy and dilatation" would lead to fearfully abused results, if Mr. Beane's practice were imitated by less skilful and cautious Practitioners. We deny that an os uteri which is "patulous, and admits the apex of the finger in the intervals of menstruation," even though it may be closed by spasm during accession of pain, is fitly treated by hysterotomy.

The Present Aspect of the Doctrine of Cellular Pathology. By William Turner, M.B. Lond. Edinburgh: Oliver and Boyd.

Catalogue of the Pathological Preparations in the Museum of Guy's Hospital. Vols. I. and II. By Samuel Wilks, M.D. Lond. London: W. Mackenzie. 1863.

The Pharmacopœias of Thirteen of the London Hospitals. By Peter Squire, F.L.S. London: John Churchill and Sons. 1863.

The Photographic Journal for April, 1863. London: Taylor and Francis.

The Medical Record of Australia. January and February, 1863. Melbourne-Bulletin de l'Académie Royale de Médecine de Belgique for 1862. Tome V., No. 11. Bruxelles. 1862.

### NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Dr. Cotton.—The paper shall appear as soon as possible.

A review of *Dr. Savage's* excellent Anatomical Plates shall appear next week.

Assistant will be very much obliged to the editor of the *Medical Times and Gazette* for information as to the following question:—"Assistant" attends an inquest on his master's patient. He receives the fee of £1 1s. To whom does it belong? Please reply in the forthcoming number of your Journal.—April 20. [To the master.—Ed.]

The Report of Mr. Hy. Thompson's Paper, read at the last meeting of the Medico-Chirurgical Society, on the "Successful Treatment of Severe Stricture of the Urethra by gradual Distension at One Sitting," will appear next week.

A. B.—It is not desirable to repeat club scandal and gossip. It is absurd to say that a man dies because he is bled. If a man is dying because the blood cannot pass through his lungs, the Practitioner may be justified in bleeding, to relieve the suffering organ. The fact that blood was drawn shows that the illness was a severe and hazardous one.

The following cases are in type, and will appear shortly:—Cases of Throat Dysæsthesia, with Clinical Remarks by Dr. Handfield Jones, St. Mary's Hospital; Vesical Calculus in the Female, and Excision of the Knee-joint, by Mr. Terry, Bradford Infirmary; Excision of the Hip-joint, by Mr. Hulke, Middlesex; Case of Entropium, by Mr. Spencer Watson, Royal London Ophthalmic; Amaurosis from Disease of the Cerebellum, Central London Ophthalmic; Case of Chorea in Congenital Syphilis, by Dr. Brinton, St. Thomas's Hospital; Cases of Diseases of the Spine and Spinal Cord, under the care of Dr. Brown-Séguard, Hospital for the Epileptic and Paralysed.

*The Silkworm in France.*—M. Guérin-Méneville at a late sitting of the Société d'Acclimatation gave an account of the results obtained in various parts of France from the endeavours to overcome the baneful effects of the disease of the silkworm. It appears from this account that all the attempts to find a specific against this disease have signally failed; but that most practical men are now of opinion that the disorder is owing to the blight which has attacked the mulberry-tree in various districts. It is now certain that breeds brought from places where the disease of the silkworm does not exist yield a good crop the first year in the infected districts, but cannot be propagated, their eggs being tainted like those of the diseased worms. Hence breeders are obliged every year to import eggs from foreign countries, when they can find healthy ones, which becomes daily more difficult. Nevertheless, from the experiment, made with great care, it would seem that eggs obtained from diseased silkworms will produce a breed exempt from the disease in a country where the latter has not yet broken out. In order the better to compare the results obtained in different departments, M. Guérin-Méneville has established a "central laboratory of comparative sericulture" at the school of Ailanthiculture, which he has founded at the Emperor's farm near Vincennes, where all the experiments made by the various agricultural societies of France are repeated, compared, and centralised. The acclimatisation of the silkworm which feeds on the Ailanthus, or Japan varnish tree, is progressing favourably both in France and in other parts of Europe. The Palma Christi silkworm has succeeded admirably at La Plate. That which feeds on the oak has failed in France for the present, but it is likely to succeed this year in Holland, eggs having been brought over from Japan by M. Pompe Van Meert der Woort. This silkworm is called "Ya-ma-mi" by the Japanese; it lives in a wild state in an island called Fatsy-sio, which is a place of exile. The silk it yields is made into very strong stuff, which never changes its colour, but which, on the other hand, takes no dye. This silk is a monopoly of the Japanese Government, and is not allowed to be an article of trade.

THE ARMY MEDICAL DEPARTMENT.

The *Madras Times* of February 16, in an able article on the treatment the Army Medical Department has received at the hands of Government, draws a common sense inference as to the probability of similar injustice being enacted towards the other branches of the Indian Army. The tardy restitution made in the last Warrant has had no effect in weakening the valid conclusion to be drawn from the whole history of the Department since the promulgation of the Warrant of 1858.

"There is little doubt that the battle of the Medical Service must be fought either by men not actually in the ranks, or by those who are not long enlisted, and capable, with advantage to themselves, of throwing up a service whose realities differ so widely from the promises by which they were deceitfully allured. This is not a pleasant way of getting justice. It is fatal to that zeal and love for his service, to that *esprit de corps* and high sense of reciprocal obligation, which the well-treated servant naturally feels towards a just and benevolent master. The painful grinder may be removed, we are relieved of his constant and aggravating annoyance, but we do not forget the wretch, the unpleasant operation which at length emancipated us, and we look with suspicion, for the future, on grinders in general. But the present treatment of the Medical Service in this country is calculated to make all officers doubtful of their future. If a warrant for one particular branch can be ruthlessly set aside, ignored, trampled upon by those to whom power has been entrusted, by executives whose acts are meant to represent those of the Sovereign, what other warrant is safe? Who shall say where the next coward blow may be struck? If acts contrary to the law of the land (for a warrant under the Queen's hand and zeal is undoubtedly law, and good law) can be repudiated with impunity, nay with triumph, we do not see what security there is for other branches of the military service. Another feature, which in the eyes of Englishmen renders these late proceedings in regard to the Medical Warrant more open to reprobation, is that they have been adopted towards a service which has, so to speak, no interest. Any similar attempt directed against the Army Department would immediately fall to the ground—the rank, position, and powerful political interest of the Army in general, render any tampering with their rights a hopeless affair; but with the Medical Department, and, we may add also, with the Indian Army, it is different. The laborious character of the Medical officer's duties, the comparatively few opportunities for distinction, the slowness of advancement, and the absence of the purchase system, to say nothing of the long preliminary education and the unfashionable nature of the study, have always kept men of wealth and titled rank from entering that profession. It is not "*distingué*," and the remuneration bears far too low a proportion to the labour. It has therefore few friends, and becomes thus proverbially amenable to all the hard hits which inconsiderate power may choose to administer. To a certain extent the Indian army suffers in the same category. It is an army for work—it is doomed to dwell in tropical jungles, and is therefore not fashionable. Its toes may be trodden on, and it may get an occasional kick without any great dread of the consequences. All this being contrary to John Bull's idea of fair play, we may yet have hope for the Indian services. If honest John only becomes thoroughly acquainted with the real state of affairs, he will soon take the proper steps to set matters right. He is slow to move, and glad to escape the trouble of thinking, if others will think for him, but when once thoroughly roused, as we have seen—at the miseries in the Crimea, in the Indian famine, in the Lancashire distress, the Slidell and Mason affair, etc.—his acts are very much to the point, and their issue far from doubtful. We believe, then, 'publicity' to be the best friend of the Indian services. They must get their case thoroughly made known to the home public. In this lies their hope; and, if Parliament will only honestly take up the question, their present and future rights are secure."

MEDICAL ADVOCATES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Dr. Robert Barnes explains his evidence against Dr. Halford, in the action for malpraxis with the midwifery forceps, by stating that his evidence was founded upon the hypothesis of a contract to call in certain other Practitioners in case instruments should be required. On referring

to the report in *The Times* of June 21 and 22, and the *Medical Times and Gazette* of June 29, 1861, I find that "Dr. Barnes and others were called to show that the use of instruments in a case of the present kind, without assistance, was wrong; and that the injuries were caused by the pressure of the forceps upon the sciatic nerve; and that such injuries could not have resulted from natural causes; and that the defendant did not administer the chloroform in a proper manner."

Now, what connection can exist between a question of contract and this "expert" evidence I am simply unable to comprehend.

*Gattie v. Halford* is a case of much greater importance than that of *Bromwich v. Waters*; the latter is one where expert evidence can seldom be used to strain a case against a particular person; but if so-called "experts" are to be found, who, for the sake of a fee, or for mere notoriety, will propound such opinions as those of Dr. Barnes, no man can practise medicine without being in constant jeopardy of some frivolous, but ruinous, action, and it behoves the Profession to at once check such proceedings by refusing to meet the performers. I am, &c.

35, Finsbury-circus.

JAMES EDMUNDS, M.D.

PUFFIN ISLAND.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following account of a sad shipwreck on the Cheshire coast may possibly interest many of your readers:—

From the best information I can gather it appears that two wretchedly rigged boats, despite of Admiral Fitzroy's cones, set out from London for a trial trip to the Welsh *Waters*, the one, as far as I could see through a strange instrument called a speculum (which is highly thought of here), looked like a Quaker boat, the other like a Ram's Bottom, or Monitor. A violent storm arose, which due precaution might have prevented the luckless craft encountering. The Quaker boat was driven almost to pieces on a *Lee* shore, whilst the Ram's Bottom sank more peacefully, from the thickness of its bulkhead, etc. The utmost efforts to save any valuables from the Quaker were made by an intrepid *Waters-guardsman*, Welsby, who dived in the bell. The boat he strangely found *faced* with brass, but it had no name, *nor age*, and contained nothing but an old log-book, *ten years old*, which, however, was utterly at variance with the ill-fated boat's present course, and was scrawled over with relics of Russian and Scotch.

The angry *Waters* are now peaceful; they have closed upon the wrecks. They saw them—are still—and satisfied. I am, &c.

CYSURO.

THE CONSOLIDATED LIFE ASSURANCE COMPANY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg to enclose you a form of application sent to me by the "Consolidated Life Assurance Company":—

"Sir,—A proposal having been made to this Company to effect an assurance on the life of Mr. ———, and he having made reference to you for information as to the general and present state of his health, I have to request that you will (*for his benefit*), at your earliest convenience, write answers to the annexed queries, and transmit the same according to the address on the back hereof.

"Whatever information you may be pleased to communicate will be considered 'strictly confidential.'

"I am, Sir,

"Your most obedient servant,

"D. MACGILLIVRAY, Actuary and Secretary.

"45, Cheapside, London, April 9."

To this application I decidedly declined to accede, unless I were paid the usual fee of one guinea. Four days have elapsed, and I have received no answer; I therefore hand the office over to your valuable Journal for a little beneficial ventilation, which I hope will have the effect of teaching it that Medical men are not to be mulcted of their just demands by any body of directors who may choose to make such unjust regulations.

I am, &c.

S. DAY GOSS, M.D., L.R.C.P.

24, Newington-place, Kennington-park, April 16.

COMPULSORY BURIAL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In a report of the proceedings taken at the Westminster police-court, in reference to the refusal of a mother to have her child buried, and published in your Journal of the 18th inst., you remark—"If Dr. Aldis had but carried out the provision of the Nuisances Removal Act for England, 1855, Section 12, and taken out a summons against the owner for having his premises in such a state as to be a nuisance, and injurious to health, the difficulty might have been got over more quickly."

Permit me to explain some of the circumstances of the case more fully, when I think it will appear that I could not have acted more promptly. I reported the house, No. 12, Spring-gardens, Pimlico, to be infected with small-pox on April 8, upon which the inspector visited the premises, and served a notice on April 11 for their being cleansed forthwith. The assistant overseer informed me on the 10th, that the father of the child had applied at the workhouse the evening before for the child to be buried by the parish, but when the man who has charge of the funerals was sent, the mother refused, and behaved in the manner already described. The inspector hearing of this, went to the house to persuade her to have the child buried, when she consented, which caused a little more delay. But when the man went a second time to remove the body, she again refused. I also went afterwards, hoping to persuade the mother to allow the child to be buried, but she declined. The overseer complained to me again on the 11th, when I told him that I had no power under any Act to cause the dead body to be removed, and advised an application to a magistrate, which I made to Mr. Selge on the morning of the 12th with a satisfactory result. I may add that it is always usual to issue a notice before serving a summons, and as the owner was willing to cleanse the house, the latter process became unnecessary.

I am, &c.

C. J. B. ALDIS, M.D.,

Medical Officer of Health for St. George's, Hanover-square.

1, Chester-terrace, Chester-Square, S.W., April 20.

CHINESE GELATINE, OR "YAN YAN."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I enclose a specimen of the above very valuable gelatinising substance, which I have no doubt will come into general use when better known.

"Yan Yan" is procured by boiling a sort of moss that grows on the house-tops in various parts of China, and squeezing the product through a cullender into cold water; it is then taken out and dried in sand. It is used commonly by the Chinese to thicken soups, etc., and the simplest

way of, preparing it is to soak two drachms (3ij) in a little cold water for two or three hours till it swells, then boil it over a slow fire in a porcelain saucepan with a quart of water until dissolved, and flavour with wine, sugar, etc., to taste. On cooling it forms a stiff jelly, which sets in any weather.

The cost of this preparation in China is about two shillings and sixpence per pound, and, as it has ten times the gelatinising power of either isinglass or gelatine, and is particularly light and bulky, it will be found most economical; two ounces and a quarter being required of isinglass to make a quart of jelly, while 3ij of the Chinese gelatine is amply sufficient to make the same quantity. This gelatine has one great advantage over Irish moss, being quite devoid of taste or smell, and can therefore be flavoured to any taste, as many persons (especially children) object to both the taste and smell of the Carrageen. I am informed by intelligent Chinese that the jelly if made strong will keep good for three or four months.

Trusting you will bring this matter before the Profession by giving space in your journal for the above, and allow the specimen to be inspected by any persons who may feel interested in the subject.

I am, &c.

A. W. THORNTON.

Muswell Brook, New South Wales, Feb. 2.

P.S.—I have written the Chinese name of the article on the wrapper.

#### BROMWICH v. WATERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The late trial of Bromwich v. Waters brings forcibly to my mind advice given me some years ago by a distinguished obstetric Physician "never to examine female patients with the speculum without the presence of a third person." It furnishes ample proof of the soundness of the advice, and it is to be desired that this painful case should at least have the good effect of making Medical men in future take care to have a third party present whenever uterine disease requires the use of the speculum. This simple precaution would be a guarantee both for Doctor and patient. Accusations of improper conduct on the part of Medical men in such cases only receive a colour of probability from the privacy of the consultation, and the presence of a third person must be the best means of rendering it impossible for artful and unprincipled women to bring charges of misconduct against respectable Professional men. There is one point in the evidence of the above case which appears to be of importance, from its bearing on the physical proof of female chastity. Dr. Waters is reported to have said in his evidence on the trial "he was sure from the first examination he made of Mary Whalley that she was not a virgin." I confess I have not hitherto been aware that examination per vaginam could furnish physical proof that a woman was not a virgin. It is, however, never too late to learn, and I should be glad if some of your numerous readers would tell me how they would prove from examination of the vagina in the case of an unmarried woman who had not had a child the fact that she was not a virgin. The absence of the hymen is no proof, nor does the smaller or larger capacity of the vagina prove anything. Burns in his work on "Midwifery" quotes a case in which a woman, aged 51, who had been a prostitute from the age of 15, had a vagina small as that of a virgin, and the same remark has been made of other prostitutes on the contrary side. I have myself had a case of a young unmarried woman of good reputation, who consulted me for prolapsus uteri brought on from working hard; she had a large pelvis and capacious vagina. This was evidently a case of natural formation, but I have no doubt the size of the vagina is sometimes increased by vicious habits, independently of sexual intercourse. A Medical man may from examination per vaginam think it highly probable that his patient is not a virgin, but he must not confound the evidence of probability with that of demonstrative proof. That the extent of our knowledge on the subject should be clearly ascertained is certainly desirable, not only from scientific, but from moral considerations, lest, setting too much value on the want of supposed proofs of virginity, we should unwittingly blast the fair fame of innocent and modest women.

I am, &c.

M. D.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your Number of April 11, in commenting upon this case, you remark:—"Yet there is a singularity in the circumstance that a middle-aged lady, living in a country town, whose counsel remarked that she was of no great means, and that the expenses of a lawsuit must be seriously inconvenient to her—to say nothing of the worry and turmoil—should think of going to the enormous expense of such an action as this. It would interest us all very much if all the motives and advice, legal and otherwise, which prompted a step so momentous, could be fully known and analysed."

No doubt all this appears very singular to you, sitting in your editorial chair some two hundred miles from the seat of war; but here all is known and fully appreciated within and without the Profession.

The plaintiffs were governesses in a highly respectable family, living on small means with a brother now deceased, whose little property they came into at his death. Happy in the acquirement of some additional means, they were happier still in the obtaining and keeping the fast friendship of a wealthy banker's daughter, who, contrary to the advice and even the remonstrances of her kith and kin, persisted in bringing the malefactor to justice, confident in the success of her scheme, backed as it was by the Malvern Jupiter, at once her friend and adviser, and the ill-concealed foe of the Doctor. That Miss Bromwich really retained Mr. Serjeant Shee; that she employed detectives in various parts of the country to sift, and, if possible, find a flaw in the Doctor's character, no one here believes. Indeed, Miss Bromwich herself stated to several ladies, at an early stage of the business, that "a kind friend" was paying the expenses of Whalley's being put under Dr. Gully's treatment, as they (Miss Bromwich and her sister) could not afford to do so. If they, then, could not conveniently pay the homeopathic fees, can it be supposed that they could meet such an allopathic dose as would necessarily be administered to them by Mr. Serjeant Shee, and a perfect army of other legal gentlemen (one specially retained) and by Medical and other witnesses? The very idea is absurd.

Leaving, however, the ladies to the sweet reflections that a conscientious discharge of duty ever leaves behind it, and to the sober realities that will present themselves to them in due course on the appearing of the Little Bill to be provided for the inexorable lawyers, I will pass to the more pleasing subject of calling your attention to a couple of resolutions which were unanimously passed at a large and influential meeting of Dr. Waters' friends, held in Chester on Monday week:—

Proposed by the Rev. F. Ford, seconded by the Rev. J. Montgomery,—

"That we, the undersigned, hereby concurring in the justice of the verdict pronounced by a jury of his country, desire to express our warmest sympathy with Dr. Waters, and our undiminished confidence in his high moral and Professional character."

Moved by General Hervey, seconded by Thomas Helps, Esq., "That this meeting, deeply sympathising with Dr. Waters in the painful ordeal through which he has passed, and aware of the heavy legal expenses necessarily incurred by him, deem it proper and fitting that a subscription be entered into to assist him in defraying the same."

These have not ended (as the Malvern cure frequently does) in cold comfort, but already between £200 and £300 of subscriptions are announced, including amongst the contributors the bishop, the dean, clergymen, the Faculty, and others of every shade of opinion, religious and political.

Perhaps your readers may be now tired of this business; if you think they are not, I may, perchance, address you on a future occasion.

I am, &c.

A COUNTRY PRACTITIONER NOT TEN MILES FROM CHESTER.

#### BEER v. COFFEE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Nothing in my opinion would do more to elevate the working classes of this country than the greater use of coffee as a stimulant. I say as a *stimulant*, because people in general have no correct idea of using it in that form simply. They mix it with various ingredients of a heavy, cloying character, such as chicory, brown sugar, and hot milk, which make it more or less nutritious, but heavy and unwholesome to the full stomach, and which mask its pure and beneficial action on the brain.

If coffee is to be used to satisfy hunger, or as part of a meal at which hunger may legitimately be appeased, of course it should be treated in an appropriate way. For this purpose it may, if the drinker likes, be mixed with chicory, dandelion, brown sugar, burnt sugar, "finings," and the other adulterating articles, and, above all, it should be mixed with abundance of hot milk. This constitutes part of a refreshing and substantial meal—a proceeding intended to appease natural bodily hunger; and along with the coffee and milk, bread, butter, meat, bacon, eggs, and similar articles of nourishment are most appropriate.

But people want refreshment at times which shall not be of this solid, filling description. There is what the poet calls, in the old song, "Drink to me only with thine eyes,"

"The thirst that from the soul doth spring."

Man is a social animal, and requires not merely food which shall enable his bodily machine to go through its daily amount of toil, but a kind of sustenance which shall cheer the mind, promote the flow of talk, make him fit for good fellowship, dissipate care and its attendant selfishness (for a man who is brooding over his own troubles is, *ipso facto*, selfish), and excite feelings of benevolence. In fact he wants *stimulants*.

It is of no use to argue, as some persons do, that man "ought not to want stimulants," just as they say, too, that he ought not to want music, fine clothes, and the like. To the man of sense the two facts suffice, that man is led by instinct to seek them, and that Providence in its bounty has furnished them. We may as well preach to the wind as say that stimulants ought not to exist, or shall not be used.

Then the question comes, What stimulant? And at present the working man has only three to choose from—spirits, beer, and tobacco. These he can get in abundance anywhere, and often of good quality; they serve the purpose desired, but, unhappily, are attended with the most terrible dangers in the temptation to abuse.

Tea is accompanied also with disadvantages if used as a pure stimulant. But this I will not enter upon now. But to coffee there is no objection. It is aromatic, warming, exhilarating, sets the brain at work, inspires social and vivacious ideas, and fulfils all the conditions requisite for a *stimulant* for men who have had food enough, and want to enjoy themselves as rational and social beings.

But how should it be taken as a stimulant? Why, certainly hot, strong, clear, with a little pure white sugar. In this state it stimulates stomach and brain, and adds not a feather's weight to the labour of digestion. With coffee like this, working men would find their supper digest, and their talk genial and fluent, and would be disposed to enjoy their book, music, or any other rational amusement.

On the other hand, unfortunately, most people know coffee only as a weak, lukewarm, opaque, heavy mess, cloying to the stomach, and damping the nervous energy.

You may see people, even after good dinners at good houses, *horribile dictu*, after soup, fish, salad, entrées, roti, fowl, jellies, sweets, cheese, ices, dessert, and half-a-dozen kinds of wine, commit a last outrage upon their unfortunate stomachs by gulping down a mess of lukewarm coffee with sugar and milk. What such people are thinking of at the time, or what their dreams at night, or why those stomachs do not burst, it were vain to inquire. What is wanted after a good luxurious dinner is the little cup of coffee, hot, strong, and clear, as a filip,—not the nutritious mess that would do for a schoolboy's breakfast. But in this, as in most other things, fashion, or supposed fashion (for it is not real; real taste demands the *café noir*, with its *chasse* or *gloria*,) overrides common sense.

Still more is the mistake made of supposing that working men can find in the thick, unstimulating mess presented to them as *coffee* at common coffee-houses, railway refreshment-rooms, and the like, anything to counterbalance their love of, or need for, beer, spirits, and tobacco. A man, whose stomach is full already, does not need hot stuff like soup, but the clear, bright, aromatic, nerve-compelling stimulant.

Some time ago, I entered a coffee-room, which is an appurtenance, and a most rational one, to a "mission house," established for the purpose of improving the morals and manners of the labouring class in this parish. There was a comfortable room, newspapers, some religious placards, rather too glaringly displayed on the walls, and everything well meant. I sat down, and ordered a penny cup of coffee after some interesting talk with the superintendent on the means of promoting the welfare of the working classes, and weaning them from the public-house. But when the coffee came, all my spirits fled at the sight of it. Not poor Mr. Pallett, in "Peggy Pickle," could have felt greater horror at the sight of the *sillykickaby* which was offered him at the "feast after the manner of the ancients." I tasted a little drop, opaque, treddy, and vapid. To swallow it would have been *felo de se*; how to get rid of it without offence to the worthy superintendent who was talking to me I could not tell. At last, when his back was turned, I offered it to a groom who sat on the same bench. He shook his head emphatically in refusal. I, as a last resource, left the table, seized my hat, and fled.

As I walked away, I could not help asking myself if it were reasonable to expect working men to leave the cool pewter pot, with its frothy, tonic, appetising potation, for such a sickly and hypocritical decoction of brown paper and treacle?

It would be perfectly easy to give a good cup of coffee for a penny. The superintendent of a coffee-shop might roast and grind the berry, and give half an ounce of coffee to a third of a pint of boiling water, and two lumps of white sugar. This would be worth drinking. This might compete with the half-pint of beer which a penny will purchase, and which, in my judgment, is a good investment for any poor man's penny.

It is much to be hoped that the promoters of working men's clubs and dining-rooms will not taboo good table-beer, not, at least, until Pall-Mall can show a teetotal club for the aristocracy. But whilst we do not forbid table-beer at meals, we should endeavour to show that, for purposes of stimulation, for the purpose which wine answers at the rich man's table—that is, to promote jollity, good feeling, and social talk—good coffee is better, cheaper, and more agreeable, as well as safer than gin-and-water and tobacco. And to this end the working people must have something in the shape of coffee that shall be worthy of the name.

As your ably-conducted Journal seems to take an interest in all social questions, I venture to ask you to insert the above.

I am, &c.

R. DRUITT,

Medical Officer of Health to St. George, Hanover-square.

THE SILVESTER METHOD IN CHLOROFORM ACCIDENTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As we have nearly worked out the problem of the cause and the best mode of prevention of fatal accidents from chloroform, perhaps you would bear with me for a few more remarks on the note of the 11th inst. of Dr. Silvester, and the four last deaths in London from that agent.

I have individually studied with some care over ten thousand administrations of chloroform. I have never had any sort of chloroform accident in my own practice: my views are set forward in the three last volumes of the *Transactions* of the British Association, as the Medical Journals, except yours, steadily refuse to state, or misrepresent, what is doing about anaesthetics. Dr. Silvester suggests the elasticity of the ribs as useful to get the chloroform out of the air in the lungs in impending or actual death from chloroform, but he forgets the chloroform is not in the air, but is in the blood of such a patient, and there is probably little or no air at all in the lungs, as the respiration will probably have ceased for five, or seven, or ten minutes, at the exact time when the "Faradisation" current is so useful in producing full inspiration and breathing. Of course everyone tries the Silvester method in such accidents. It was tried in the recent case, the subject of his remarks, but it is not sufficient. I believe if continued for any time, too, it pushes mechanically a large quantity of blood out of the liver and portal vessels into the cava and right auricle. The very thing we do not want, as the death is in reality in asphyxia (apnoea)—cases attended by, if not directly caused by this enormous mechanical congestion of the right cavities. The "blood stands still," as my friend Mr. Paget once said to me, and we can only give it a fresh start through the pulmonary artery by immediate full action or dilatation of the lungs and respiratory muscles. This, in hundreds of experiments on the lower animals, is observed to be best effected by the Faradisation current (with intermittent broken circuit) through the phrenic nerve and diaphragm.

M. Florens has just pointed out this marked congestion of the veins of the cerebral membranes as diagnostic of chloroform coma as distinguished from the coma of apoplexy. The cause, in fact, is the same—the *remora*, or back tide of blood in the veins (partly from the mechanical efforts at resuscitation, by rubbing the limbs, etc.), the right side of the heart engorged and not receiving the blood from the jugulars, where it stagnates. The left or systemic side of the heart, on the contrary, continuing active to the last, even after the pulse is gone. (a) I must confess I do not like the violent Silvester pressure on the ribs of patients under chloroform; they groan as if in great agony from it; they describe it as a hideous nightmare pressure worse than all the agonies of the operation without chloroform at all. I think I now begin to see that in Hospitals and by Dentists' assistants chloroform is given too often as a matter of routine, and one set of nightmare agonies are thoughtlessly substituted for the old sharp cut of the Surgeon's bistoury, not half so bad without chloroform. I believe the "Faradisation" current differs from all other varieties of galvanism, as vaccination is milder and differs from small-pox, and it makes chloroform now quite safe; but the Silvester method is imperfect.

A few words will prove useful as to the latest deaths from chloroform in London. One is noted last week. A young woman, aged 29, Selina L., Edgware-road, who died in an instant, apparently of syncope, as she was about to have a small tumour of the gum (epulis?) removed. No one to blame, it being one of those singular and miserable cases of idiosyncrasy that can scarcely be anticipated. Dr. Lankester made some excellent remarks, as is his wont, at the inquest. Would that all our coroners were like him. A second case of death was at Guy's Hospital. A man put under chloroform for a dislocation to be reduced; he bore the anaesthetic one day very well, but the reduction was not effected, and he was desired to come again, I think, next day, but he was only half way under chloroform when his death, as a flash of lightning, suddenly occurred. The third case was removal of a small tumour, I believe an asphyxia case. This and the fourth, somewhat doubtful, are described in the *Social Science Review*. They all bear out the chief points I have urged of the operations being usually of a slight or trivial kind, or connected with tendinous tissues about joints. I see an erroneous case (typical!) in a book of Casper's, translated by the Sydenham Society. An old man, in uttermost exhaustion, pulse above 110, has his scapula cut out or removed by a tremendous surgical operation, and dies of shock and exhaustion seventeen hours after! This is not at all a death from chloroform, though it is certain to be copied as such into our manuals of toxicology. The deaths from chloroform, in a word, are all sudden; they are twice as numerous in male adults as females; they all occur in trivial operations; they are nearly unknown in children. Syncope from injury of tendinous tissues (as long ago referred to by John Hunter), syncope from touching the urethra with sounds, latent delirium tremens, etc., are the most frequent sources of the syncope seizures which form, perhaps, 40 per cent. of all the cases. This

(a) A coroner's jury, the other day, and the coroner, held that the pulse came from the right! ventricle, that there could be no engorgement as there was a pulse, and were within an inch of bringing in a verdict of malpraxis against an innocent Surgeon, and three Medical Journals supported this dictum!

at least is what thousands of operations on the lower animals and careful deductive cataloguing of 200 deaths in the human subject point to.

I am, &c.

APPOINTMENTS FOR THE WEEK.

April 25. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m.; Charing-cross, 1 p.m.

ROYAL INSTITUTION, 3 p.m. Professor Max Müller, "On Language."

27. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.

MEDICAL SOCIETY OF LONDON. Special General Meeting, 8 p.m. Clinical Discussion, 8½ p.m.

28. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Dr. A. T. H. Waters, of Liverpool, "On a Remarkable Case of Injury of the Head." Dr. T. K. Chambers, "On the Therapeutics of Continued Fever." Dr. H. Weber, "On the Pathology of Crura Cerebri."

29. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.

30. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopaedic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.

May 1. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m. Meeting of Council.

WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON, 8 p.m. Annual Meeting.

EXPECTED OPERATIONS.

King's College Hospital.—The following Operations will be performed on Saturday (to-day) at 2 p.m. :—

By Mr. Fergusson—Lithotripsy; For Caries of the Sternum.

## PICHOT & MALAPERT'S CARBONIFEROUS PREPARATIONS.

*Extensively used in all the French Military and Civil Hospitals.—(See Notice in MED. TIMES AND GAZ., March 7, 1863, p. 248.)*

CARBONIFEROUS CHARPIE, in 1 lb. and  $\frac{1}{2}$  lb. boxes, 7s. 6d. per lb.; Bags of ditto, ditto, each box containing 10, 4s. per box.

CARBONIFEROUS PAPER FOR COMPRESSES (containing 100 Dressings), 2s. 3d. per packet;

Ditto, ditto, large size (containing 25 Dressings), 1s. 4d. per packet; Ditto, ditto, Tissue, 9d. per sheet.

*May be had of all Respectable Chemists.*

WHOLESALE AGENTS—S. MAW & SON, 11, ALDERSGATE-STREET, LONDON, E.C.,  
Of whom Pamphlets on its uses and mode of application may be had, post free, on application, gratis.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

The Best House for Second-hand Instruments,  
Where there is the Largest Stock in London, is Mr. WILLIAM LAWLEY'S, 78, FARRINGDON-STREET, CITY.  
Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each.

## *Pulvis Jacobi ver, Newbery*

is the ORIGINAL & GENUINE, was ESTABLISHED A.D. 1746,

And is Prescribed, with the greatest success, "by the highest authorities," for  
Fevers, Ague, Cerebral Congestion, Rheumatism, Chills, Influenza, &c. &c.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.;  $\frac{1}{4}$  oz., 3s. 4d.

## NEPENTHE, OR ANODYNE TINCTURE.

OBTAINED EXCLUSIVELY FROM OPIUM.

Prepared only by FERRIS, TOWNSEND, LAMOTTE, & BOORNE, Manufacturing Chemists  
and Wholesale Druggists, Bristol.

MESSRS. FERRIS AND COMPANY take leave to direct the attention of the Medical Profession to a selection from various reports upon the use of this most valuable form of Opium. NEPENTHE may be used with perfect safety in every case where an opiate is indicated; and, from the peculiar process by which it is prepared, it is deprived of all constituents which render the Tinctura Opii, and most other forms of opium, in numerous instances, wholly inadmissible. NEPENTHE is always of uniform strength, and, in this respect, possesses high advantages. It may be procured direct from the Manufacturers, Messrs. FERRIS and COMPANY, Bristol, or through the leading Wholesale Druggists in London, and from most respectable Dispensing Chemists in Great Britain and Ireland. Every bottle has a fac-simile of Messrs. FERRIS and COMPANY'S Signature pasted over the Cork, to imitate which is forgery.

The price of NEPENTHE to the Profession is 8s. per lb., and the dose the same as the Tinctura Opii.

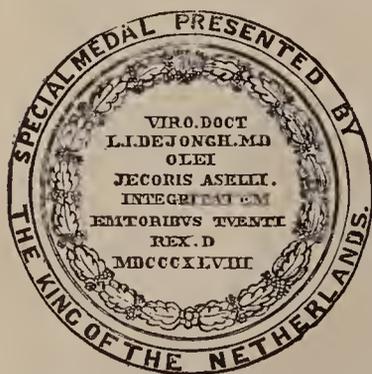

*Report from F. PORTER SMITH, Esq.*

I have pleasure in bearing testimony to the decided advantages possessed by Messrs. Ferris and Company's preparation of Opium called "Nepenthe" over other preparations of that important drug. I have used it for several years in Cancer of the Uterus, continuing it, with scarcely abated advantage, as a sedative, in one such case, for the long period of eighteen months, in doses of, at the utmost, half a drachm, which served the purpose to the end. I have used it in "Subcutaneous Injection" for Neuralgia, without producing any local irritation, such as abscess, &c. In the cases of unusually

severe "after-pains" in connexion with labour, I can strongly recommend and endorse its successful and satisfactory employment. I have never met with any unpleasant symptoms, such as sometimes occur in some constitutions after the administration of morphia, &c., during an extensive use of this valuable addition to that "Practical Pharmacopœia" which waits for no "imprimatur" from College or Council.

F. PORTER SMITH, M.B. Lond.,  
Everceech, March, 1862. Associate of King's College, London, &c.

\*\* Fresh Reports will be published in the Medical Journals from time to time.—Bristol, 1862.

DR. DE JONGH'S  
(Knight of the Order of Leopold of Belgium)

## LIGHT-BROWN COD-LIVER OIL.

SELECT MEDICAL OPINIONS.

Sir HENRY MARSH, Bart., M.D., Physician in Ordinary to the Queen in Ireland:—"I consider Dr. de Jongh's Cod-liver Oil to be a very pure Oil, not likely to create disgust, and a therapeutic agent of great value."

Dr. BARLOW, Senior Physician to Guy's Hospital:—"I have been well satisfied with the effects of Dr de Jongh's Cod-liver Oil, and believe it to be a very pure Oil, well fitted for those cases in which the use of that substance is indicated."

Dr. LANKESTER, F.R.S., late Lecturer on the Practice of Medicine, St. George's School of Medicine:—"I consider that the purity and genuineness of

this Oil are secured in its preparation by the personal attention of so good a Chemist and intelligent a Physician as Dr. de Jongh, who has also written the best Medical Treatise on the Oil with which I am acquainted. Hence I deem the Cod-liver Oil sold under his guarantee to be preferable any other kind as regards genuineness and medicinal efficacy."

SOLE CONSIGNEES AND AGENTS,

ANSAR, HARFORD, & CO., 77, Strand, London, W.C.

## Diabetes.—Blatchley's Bran Biscuits,

prepared according to Dr. CAMPLIN'S prescription, (see "Camplin on Diabetes.") The Bran used by E. Blatchley is carefully prepared, rendered free from starch, and finely ground by steam machinery.

THE PREPARED BRAN for making the above may be had in any quantity of E. BLATCHLEY, Confectioner, 362, Oxford-street, three doors from the Pantheon. Established 23 years.

Full particulars for making the diet will be found in Dr. Camplin's work.

TO THE MEDICAL PROFESSION.

## Charcoal Biscuits, Manufactured from

the purest Vegetable Carbon, affording speedy relief to persons suffering from Bile, Indigestion, Flatulency, &c. Sold only in tins, at 1s., 2s., 4s., and 8s. each, by J. L. BRAGG, Sole Manufacturer, 2, Wigmore-street, Cavendish-square, London. Wholesale Agents, Messrs. MAW and SON, Aldersgate-street, E.C. Chemists and others allowed a liberal discount. Post-office Orders made payable at the Vere-street Branch.

ORIGINAL LECTURES.

PROFESSOR HUXLEY'S LECTURES

AT THE

ROYAL COLLEGE OF SURGEONS.

LECTURE V.

(Being the Fourth of Six Lectures on Classification, and on the Characters of the Principal Groups of the Animal Kingdom.)

(Continued from page 419.)

ALL embryonic *Reptilia* are provided with an amnion and an allantois, like those just described in the foetal fowl. In the embryonic state also they possess visceral arches and clefts, but no respiratory tufts are ever developed in the arches, nor are reptiles endowed with an apparatus for breathing the air dissolved in water at any period of their existence. The skull of all *Reptilia* is articulated with the vertebral column by a single condyle, into which the ossified basi-occipital enters largely (Fig. 3). Each ramus of the lower jaw is composed of a

FIG. 3.

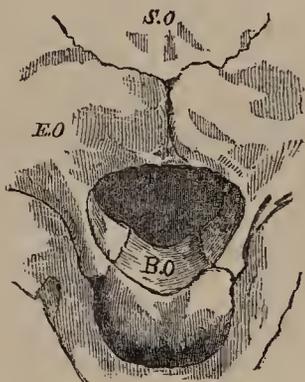

FIG. 3.—The occipital condyle of a Crocodile's skull viewed from behind. B.O., Basi-occipital; E.O., Ex-occipital; S.O., Supra-occipital.

number of pieces, and articulates with the skull, not directly, but by the intervention of a bone—the os quadratum—with which the hyoidean apparatus is not immediately connected. (Fig. 4.)

FIG. 4.

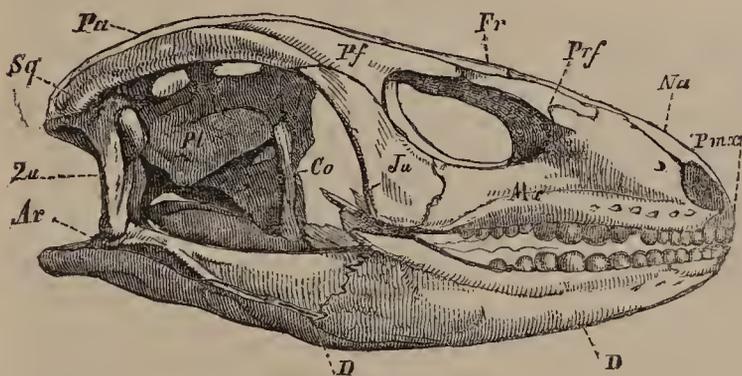

FIG. 4.—The skull of a Lizard (*Cyclodius*). D D, Dentary piece of the lower jaw; Qu, Os quadratum; Sq, Squamosal.

The fore-limb of Reptiles never takes the form of a wing, such as is seen in Birds, the "wing" of the remarkable extinct flying reptiles, the *Pterodactyles*, being constructed on a totally different principle from that of a bird. In no known reptile, again, are the metatarsal and tarsal bones ankylosed into one bone.

In all *Reptilia* the greater and lesser circulations are directly connected together, within, or in the neighbourhood of, the heart, so that the aorta, which is formed by the union of two arches, contains a mixture of venous and arterial blood. The blood is cold, and the majority of the blood-corpuscles are red, oval, and nucleated.

The bronchial tubes are not connected at the surface of the lungs with terminal saccular dilatations or air vesicles.

When the epidermis of *Reptiles* is converted into horn, the corneous matter takes the form of broad plates, or of overlapping scales, neither plates nor scales being developed within pouches of the integument.

VOL. I. 1863. No. 670.

The class of *Aves* consists of animals so essentially similar to reptiles in all the most essential features of their organisation, that Birds might fairly be said to be merely an extremely modified and aberrant Reptilian type.

As I have already stated, they possess an amnion and a respiratory allantois, and the visceral arches never develop branchial appendages. The skull is articulated with the vertebral column by a single condyle, into which the ossified basi-occipital enters largely. Each ramus of the lower jaw, composed, as in Reptiles, of a number of pieces, is connected with the skull by an os quadratum, to which the hyoidean apparatus is not suspended.

In no existing bird does the terminal division of the fore-limb possess more than one digit terminated by a claw, and the metacarpal bones are commonly ankylosed together, so that the "manus" is of little use, save as a support for feathers.

In the hind limb of all birds the tarsal and metatarsal bones become more or less completely ankylosed, so as to form a single osseous mass, the "tarso-metatarsus."

The greater and lesser circulations of birds are completely separate, and there is only one aortic arch, the right. The right ventricle has a muscular valve. The blood is hot, hotter on the average than that of any other vertebrates, and the majority of the blood-corpuscles are oval, red, and nucleated. The bronchial tubes open upon the surface of the lungs into air-sacs, which differ in number and in development in different birds. Lastly, the integument of birds is always provided with horny appendages, which result from the conversion into horn of the cells of the outer layer of the epidermis. But the majority of these appendages, which are termed "feathers," do not take the form of mere plates developed upon the surface of the skin, but are evolved within sacs from the surfaces of conical papillæ of the dermis. The external surface of the dermal papilla, whence a feather is to be developed, is provided with a median groove, which becomes shallower towards the apex of the papilla. From this median groove lateral furrows proceed at an open angle, and passing round upon the under surface of the papilla become shallower, until in the middle line, opposite the median groove, they become obsolete. Minor grooves run at right angles to the lateral furrows. Hence the surface of the papilla has the character of a kind of mould, and if it were repeatedly dipped in such a substance as a solution of gelatine, and withdrawn to cool until its whole surface was covered with an even coat of that substance, it is clear that the gelatinous coat would be thickest at the basal or anterior end of the median groove, at the median ends of the lateral furrows, and at those ends of the minor grooves which open into them; while it would be very thin at the apices of the median and lateral grooves, and between the ends of the minor grooves. If, therefore, the hollow cone of gelatine, removed from its mould, were stretched from within, or if its thinnest parts became weak by drying, it would tend to give way along the internal median line opposite the rod-like cast of the median groove and between the ends of the casts of the lateral furrows, as well as between each of the minor grooves, and the hollow cone would expand into a flat feather-like structure with a median shaft, as a "vane" formed of "barbs" and "barbules." In point of fact, in the development of a feather such a cast of the animal papilla is formed, though not in gelatine, but in the horny epidermic layer developed upon the mould, and, as this is thrust outwards, it opens out in the manner just described. After a certain period of growth the papilla of the feather ceases to be grooved, and a continuous horny layer is formed, which constitutes the quill.

Between *Aves* and *Mammalia* there is a hiatus, not perhaps quite so wide as that between *Amphibia* and *Reptilia*, but still very considerable.

All *Mammals* possess an amnion of an essentially similar character to that of Birds and Reptiles, and all have an allantois. But the latter either ceases to exist after a very early period of foetal life, or else it is "placentiferous," and serves as the means of intercommunication between the parent and the offspring. Of the nature and characters of the "placenta" developed in the majority of the mammalia I shall speak more particularly by-and-by. For the present, I pass it over as a structure not universally characteristic of the class.

The visceral arches are, throughout life, as completely devoid of branchial appendages in *Mammals* as in *Birds* and

Reptiles. In the skull, the basi-occipital is well ossified; but though it may enter into the formation of the cranio-spinal articulation, the latter is not single, as in Reptiles and Birds, but double, and the atlas has corresponding articular facets.

FIG. 5.

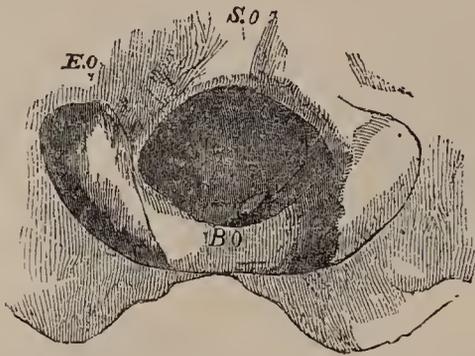

FIG. 5.—The occipital condyle of a Dog's skull viewed from behind. Signification of the letters as in Fig. 3.

Each ramus of the lower jaw is composed of only a single piece, and this articulates directly with the squamosal bone of the skull, and not with the representative of the quadrate bone.

FIG. 6.

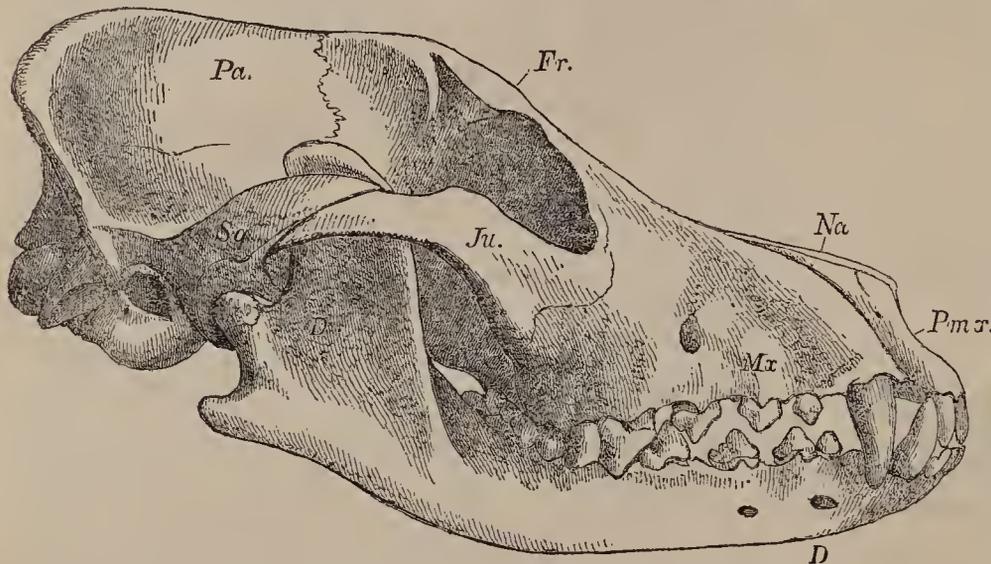

FIG. 6.—The skull of a Dog. Signification of the letters as in Fig. 4.

The greater and lesser circulations of Mammals are as completely distinct as in Birds, and there is but a single aortic arch, the left. The majority of the blood-corpuscles are red, free nuclei, and these are always discoidal, and usually circular in form. The blood is hot. There is a complete diaphragm, and none of the bronchi end in air-sacs.

Some part or other of the integument of all Mammals exhibits "hairs"—horny modifications of the epidermis—which so far resemble feathers, that they are developed upon papillæ inclosed within sacs; but, on the other hand, differ from the horny appendages of birds, in not splitting up as they are protruded, in the fashion so characteristic of feathers.

Finally, all Mammals are provided with organs for the secretion of a fluid which subserves the nourishment of the young after birth. The fluid is milk; the organs are the so-called "mammary" glands, which may probably be regarded as an extreme modification of the cutaneous sebaceous glands. These glands are aggregated into two or more masses disposed upon each side of the median line of the ventral surface of the body, and in almost all Mammals the aggregated ducts of each mass open upon an elevation of the skin common to all—the nipple or teat. To this the mouth of the newly-born mammal is applied, and from it, either by suction on the part of the young, or by the compressive action of a special muscle on the part of the parent, the nutritive fluid makes its way into the stomach of the former.

ROYAL INFIRMARY, EDINBURGH.—We understand that Dr. John Struthers has just resigned his appointment as one of the Surgeons to the Edinburgh Royal Infirmary, on account of the occupation of his time with his anatomical duties. In England, Anatomical Demonstrators resign their lectures so soon as they are engaged with Surgical duties.

A CLINICAL LECTURE  
ON  
MENORRHAGIA DEPENDING ON MORBID  
CHANGES IN THE OVARIES.

DELIVERED AT  
The Middlesex Hospital,  
BY  
W. O. PRIESTLEY, M.D.

(Continued from page 395.)

THE connecting link between the form of menorrhagia I have attempted to illustrate, and the recently-described disease known as "pelvic hæmatocele" is most interesting, and the study of the two subjects conjointly mutually elucidates both. In pelvic hæmatocele, blood is extravasated from some portion of the generative apparatus of the female either into the peritoneal sac behind the uterus or into the pelvic cellular tissue; and, provided the blood is not in too large quantity, it there becomes encysted. It is preceded and attended by definite symptoms, the observation of which enables the physician to determine the true nature of the case. Thus it has been remarked that the subjects of pelvic hæmatocele habitually menstruate profusely; and,

again, that in a large proportion of examples menorrhagia precedes the extravasation of blood, and the development of the attendant symptoms. Corresponding to these two facts, and bearing directly on the subject of the present lecture, we find in the statistics on hæmatocele, which have been collected by M. Voisin, in France, that the extravasation of blood was occasioned by rupture of the ovary or some of the vessels leading to it, in two-thirds of the patients affected, and that in a considerable proportion of the cases the ovary had undergone some antecedent softening or degeneration, the progress of which had probably provoked the previous sympathetic menorrhagia. The two subjects are no doubt intimately associated together, and in some cases of menorrhagia, dependent on morbid excitement of the ovary, I have had reason to believe that blood has escaped into the peritoneal cavity from over-distension and rupture of the ovarian vessels, provoking acute symptoms, but being insufficient in quantity to form such a tumour as is understood by the term hæmatocele.

M. Puech, of Montpellier, in an interesting thesis on hæmatocele, has shown that apoplexy or morbid extravasation of blood into the textures of the ovary is not an uncommon occurrence when the vessels of the organ are unduly congested, and that, if the distension of the ovary be excessive, rupture of its coats may take place, and blood make its escape either into the cavity of the peritoneum, or into the pelvic cellular tissue. Death either by syncope or peritonitis speedily ensues if a large quantity of blood is poured into the peritoneal cavity, but in moderate quantity it may, without terminating life, become surrounded by inflammatory adhesions, and thus form an encysted hæmatocele; or, if the effused blood be still smaller in quantity, it may provoke a limited peritonitis in the pelvis, which subsides under appropriate treatment. In the slighter cases, which terminate in recovery, we cannot have the aid of dissections to confirm diagnosis during life, but the following case, which I watched carefully, seemed to me an instance in which menorrhagia was followed by slight extravasation into the pelvis.

Case 3.—A married lady, 32 years of age, who had borne one child eight years before, but had not since been pregnant, was seized during the night with severe pain in the hypogastric region. The menstrual period had passed off a few days previous in the usual manner, and the day before she was in ordinary health, but had experienced fatigue in searching for a house, and in the evening had become extremely chilled by going out on foot with too light a dress for a cold evening. During the night the patient awoke with uneasiness in the abdomen, which gradually increased to severe pain, and induced her to send for Medical aid early in the morning. On arriving, I found her with a quick pulse, flushed and restless countenance, and suffering acute pain, but able to

move about without any great increase of distress. There was some tenderness over the region of the uterus, and slight distension of the abdomen. Examination by the vagina only enabled me to ascertain that the point of greatest tenderness was the region of the left ovary, but there was no tumour, and the uterus was apparently healthy. An opiate with a mustard-plaster and fomentations gave but partial relief, and half-a-dozen leeches were consequently applied round the anus. A marked alleviation followed, and, although the pain returned in severe paroxysms occasionally, it was kept in abeyance by the use of morphia suppositories. The next day I could feel the left ovary distinctly by the vagina. It was swollen, very tender to the touch, and had apparently by its increased weight sunk within reach of the finger. On the third day after the commencement of the attack I was informed that the period had come on profusely, and that since the discharge began there was a diminution of pain, but still much uneasiness in the left groin. Two days later there was a sudden accession of severe pain, attended by slight rigor, and such an increase of the sanguineous discharge as to amount almost to flooding. The pain was described as somewhat like labour-pain, and there was a sensation of weight and bearing-down in the rectum. The patient's face was again flushed, and the pulse rose to 120 from 95. There was considerable pain on pressure over the hypogastrium, and some abdominal distension. On making a vaginal examination, I found a boggy swelling, about the size of a walnut, behind the vagina and uterus, situated, I judged, in the retro-uterine cul-de-sac of peritoneum, and apparently separate from the enlarged ovary. It was slightly tender to pressure, irregular, and undefined at its upper part, and somewhat harder about its circumference than in its centre. The antecedent and attendant symptoms, together with the sudden formation and character of the swelling, led me to infer that blood had been extravasated into the retro-uterine cul-de-sac, probably as the result of excessive congestion of the ovary and rupture of some of its tissues. There was subsequently no further enlargement of the swelling, and the acute symptoms gradually abated. A somewhat profuse catamenial period occurred a fortnight later, but it was unattended by severe pain. After it was passed the retro uterine swelling was found contracted and much lessened. At the end of six weeks from the formation of the tumour there was no trace of its presence except a slight thickening in the situation where it had been detected, and the patient's health was re-established.

There is a point of considerable interest in reference to ovarian menorrhagia which deserves remark. It would seem that it is only those morbid conditions of the ovary which simulate, but in an exaggerated degree, the physiological changes connected with healthy menstruation, and in which the ovary is not extensively diseased, that have any influence in the production of uterine hæmorrhage. If you turn to Dr. West's chapter on Ovarian Dropsy, you will find evidence of the fact, that when cystic disease of the ovary is so far advanced as to have caused disorganisation of the ordinary structure of the ovary, the occurrence of menorrhagia is an exceptional symptom, and in a considerable proportion of cases, indeed, menstruation is altogether suppressed.

The causes of ovarian menorrhagia may be briefly stated to be those producing morbid congestion of the ovaries. Imperfect recovery after delivery, the patient being too much in the upright position before the uterus and its appendages have undergone the necessary involution, as was probably the case with the first patient whose history was detailed; the occurrence of abortion in the early months, when the ovary is yet large from the presence of a *corpus luteum*, and readily becomes morbidly congested at a subsequent menstrual period; a sudden chill, either during the menstrual period or interval, may take the initiative,—the ovary becoming congested in preference to some other organ of the body. Whatever suddenly checks the menstrual flow may lead to the same result. M. Puech has described the case of a woman whose menstruation was suddenly arrested with severe pain, and who after this accident menstruated profusely and too frequently, until she at length died of extravasation of blood from the ovary into the peritoneal cavity. The early events of married life, before pregnancy occurs, may be concerned in its production, and undue sexual excitement at any time is a recognised cause both of ovarian and uterine congestion. It is no uncommon occurrence to find prostitutes suffering from menorrhagia without appreciable disease of the uterus, and which may be referred to ovarian irritation. I

have noticed this affection among the sequelæ, in some cases where gonorrhœa was supposed to have passed along the Fallopian tubes, producing peritonitis, and probably, also, inflammation of the ovary. I have, however, seen it in private practice most frequently, I think, in married women who are sterile. It is highly probable that sexual excitement which is not followed by the occurrence of pregnancy, leads in many cases to permanent congestion of the ovaries, and this may readily be lighted up into more active disease.

The treatment to be adopted in such cases as I have described may be conveniently spoken of as divided into two parts, viz., the treatment of the attack, and the management of the patient during the interval, or when no menorrhagia is present.

During the attack, if the hæmorrhage be at all profuse, above all other things it is needful to enjoin absolute rest in the horizontal posture. But besides this it will be desirable to prescribe some astringent, as the compound infusion of roses; tannin, or gallic acid in six or eight-grain doses every three or four hours; or the acetate of lead with opium may be given instead of these, if there be any reason for preferring it. The dull aching pain, or more acute paroxysms of suffering so commonly present, generally demand the administration of some opiate or other sedative, and these may be given by the mouth, with the astringent, or in the form of enema or suppository by the rectum. When given by the rectum, twenty-five minims of laudanum, with a cup of prepared starch, is a common form of injection for the purpose; but five grains of the pil. saponis c. opio, or a third of a grain of morphia made into a suppository with butter of cocoa, is even more convenient. Considerable care must be exercised in the use of opiates internally, for in the subjects of these attacks sickness of a very distressing character is sometimes provoked by them, and, indeed, the stomach is often so irritable, that for a time it needs no additional incentive to reject all nourishment. When experience warns against the employment of opium or morphia, a third of a grain of extract of belladonna with two or three grains of camphor every three hours may prove useful, and the extracts of henbane, conium, and Indian hemp are other remedies deserving a trial when other means are inadmissible or fail to relieve pain. The topical application of belladonna with chloroform and oil has seemed to me a serviceable adjuvant, and we may have recourse to this the more readily, as some other topical applications are less admissible. Thus, I should hesitate to apply cold for the hæmorrhage if much deep-seated pain were present, and hot fomentations are, as a rule, to be avoided after hæmorrhage has come on; for not only are they likely to encourage bleeding from the uterus, but they may possibly determine extravasation of blood, already impending, from the distended ovary into the peritoneum. Dry cupping-glasses may be applied either above the groin or over the sacrum, and are not open to the same objections. Constipation of the bowels must be avoided. The diet should be simple and taken cool, stimulants being taken sparingly, except in cases where the loss of blood is extreme. The clothing should be light, but sufficient to prevent chilliness of the surface, and consequent congestion of internal organs.

When the menorrhagia is past, the efforts of the Medical attendant must be directed to lessen the congested and irritable condition of the ovary, and perhaps also of the secondary and permanent uterine congestion. Or if the pathological changes have advanced beyond these, and inflammatory deposits have been thrown out either on the surface of the peritoneum or into the pelvic cellular tissue, attempts must be made to promote the absorption of them. Some patients require little more than rest in the recumbent position, avoidance of sexual excitement, with careful regulation of the bowels, and liberal diet to re-establish health. But whenever one or both ovaries are left painful and tender, and prolapsed much below their natural position by increase of weight, and if combined with this there be enlargement of the uterus, besides rest, counter-irritation of some form ought to be employed. This may be by dry cupping-glasses frequently applied, or by friction with a croton liniment over the sacrum, or by the repeated application of sinapisms or tincture of iodine over the hypogastric and iliac regions. And problematical as it may seem to bleed a patient who has already lost too much blood, the application of three or four leeches to the cervix uteri or anus is, perhaps, of all others, the means which affords the most marked relief to pain, and, by lessening the congestion in the interval, it diminishes the

severity of the symptoms at the next menstrual period. After various other measures have failed, I have repeatedly seen this local abstraction of blood midway between two periods begin the first improvement of the patient, which has at length terminated in the restoration of health. Great care must also be taken to regulate the bowels and to guard against the accumulation of fecal masses which might press injuriously on the parts affected. Inaction of the liver should also, as far as possible, be counteracted, so that no further congestion of the pelvic organs be favoured. Attention must at the same time be directed to improve the strength of the patient, and to make up, as far as prudence will permit, for the previous loss of blood. The Hospital patient, whose case I first described, took the "Haustus ferri sulphatis," for which I have given the formula. I know of no better tonic aperient than this common prescription for such cases, either in Hospital or private practice, and its proportions may be varied according to circumstances.

If, however, the case is so far chronic that it does not readily yield to treatment, and particularly if the oft-repeated attacks have resulted in permanent enlargement of the ovaries and uterus, or in the production of that immobility of the pelvic organs, and hardness of the cellular tissue surrounding them, which is characteristic of the exudation of plastic lymph, I should be disposed to give drachm doses of the liquor hydrarg. bichlorid. twice or thrice a day, for the purpose of promoting absorption, and when this had been continued sufficiently long, five-grain doses of bromide of potassium.

In conclusion, you must not lose sight of those general indications which are applicable to all patients whose strength has been impaired by any illness. I allude more particularly to matters of hygiene, and especially to change of air when it may be expedient, to generous diet, and such stimulation as prudence dictates in each individual case.

## ORIGINAL COMMUNICATIONS.

### "WHAT IS DIABETES?"

By ROBERT VENABLES, M.A., M.B. Oxon.,  
Physician to the Royal Kent Dispensary.

"WHAT is diabetes? Urine saccharine; specific gravity, 1025-1030; if not diabetes, what is it?" Such are the semi-Socratics occasionally pressed upon me, and they involve a problem not quite so easy of solution as at first sight may appear. The question has often proved not a little embarrassing. I hit upon an answer, however, which, though not quite satisfactory, has mostly answered its purpose. My reply now usually is: "It is much more easy to say positively what a thing is not than always strictly to define what it really is; I therefore affirm that this (disease) is not diabetes, never has been diabetes, and the probability is never will become diabetes."

Until the time of Prout, at least two species of diabetes were admitted by nosologists,—the mellitic and insipid; and this division is recognised by some even in the present day. Under this division, every form and variety of diuresis was referred to the *genus* Diabetes, the only distinction being the saccharine or the insipid state of the urine. This view naturally led to great confusion, for diuresis of every kind—no matter what the cause, or however transient the diuresis itself—was pronounced diabetes. We know, however, that diuresis (a) often proves a mere temporary affection—in hysteria, for example—and soon disappears.

There is a form of diuresis characterised by the large amount of urea in the urine. So abundant at times is this principle, that the urine gelatinises, as it were, into a solid crystalline mass on the addition of strong nitric acid. (b) In many such the specific gravity, upon which much reliance has been placed as indicative of the presence of sugar, is very high, often rising to 1030 or 1035. I have seen it as high as 1038, and in one instance 1042. These are extreme cases, and probably of very rare occurrence.

In excess of urea (azoturia) the urine voided at each micturition cannot always be considered excessive. Indeed it is

(a) Voidance of large quantities of urine.

(b) The acid must not be too concentrated, and should be reduced by the addition of one or two parts of water; neither should it contain any nitrous acid. In either case, if too concentrated, or intermixed with nitrous acid, the urea will be decomposed, and error may result.

often below the natural quantity; but the constant desire to pass water, and the frequent micturitions in consequence, render the whole amount of urine voided in a given time much above the normal standard.

We meet with other cases of diuresis (c) in which the urea is far below the normal amount (anazoturia). (d) Such are sometimes attended with the voiding of very large quantities of urine, and, as may be readily imagined, of very low specific gravity, 1.010, or even lower. There is a marked contrast between the two urines just described. The first abounds absolutely in urinary principles, the latter is deficient in these.

Reagents show that the former is—at least comparatively—rich in the urinary pigments; whereas, in the latter, these are greatly diminished, and in some instances afford scarcely a trace. Uric acid, too, is often spontaneously deposited in cases of diuresis with excess of urea, (e) indicating a true acidity of the urine, and a phlogistic diathesis. In anazoturia, on the contrary, the urine is often alkaliescent, loaded with carbonate of ammonia, and prone to spontaneous fermentation, whence in all probability the carbonate of ammonia. Prout mentions instances in which enormous quantities of urine have been voided—in such instances, sixteen, even twenty pints in the twenty-four hours. Excessive quantities of urine have been passed by young children in similar circumstances.

Many of such cases have been looked upon as diabetes, and detailed as such, and Prout makes a similar remark. Hence the necessity of establishing a distinction between true diabetes and these spurious forms. I recommended that the term be restricted to those affections in which the urine is saccharine. Hence, I define diabetes to be a disease in which a saccharine state of the urine is the characteristic symptom." (f)

This was a step in the right direction. There is good reason for believing that another error frequently prevails. Though the term diabetes be restricted to those urines only of which sugar is a constituent, as a counterpoise, it is sometimes, if not often, held that all saccharine urines are necessarily diabetic,—a source of nearly as much error (and far more serious in its effects) as that which Prout (to be hoped not unprofitably) struggled to correct. Prout's dictum, if it may be so named, is not unfrequently misunderstood. He did not intend that all saccharine urine should be regarded as unquestionably diabetic, nor that saccharine urine and diabetes were reciprocal terms, and therefore universally predicable of each other. I had Dr. Prout's co-operation in several cases of saccharine urine, but neither of us for a moment entertained the notion of any alliance with diabetes.

Diabetes may be defined a disease in which a saccharine state of the urine is an *essential characteristic*; without this saccharine state it is quite right to question, indeed to deny the claim to the diabetic character, and I believe this is now admitted by the most experienced in this affection. What, then, the inference? That many of the instances of successful treatment are to be explained upon these principles that they were *not* cases of diabetes, nor even allied in any way to this affection, except in the one circumstance of saccharine urine.

Of simple saccharine urine I see numerous instances; many of these merely transient, which pass off without any treatment whatever; others more permanent and more obstinate. Some of these require treatment, not only Medical, but by strict, sometimes severe regimen. Some recover, and get rid of the sugar altogether after protracted intervals; with others the saccharine diathesis—if it may be so named—is more obstinate, and may continue without the least inconvenience, or even the patient's consciousness of his position. I know the case of a gentleman, now far advanced in years, whose urine, to my own personal knowledge, has been saccharine for the last eight or ten years. He suffers no inconvenience whatever; the urine varies in specific gravity, and the quantity of sugar increases or diminishes apparently guided and regulated by changes in the habits of the patient for the time being.

(c) By the term diuresis is to be understood an inordinate or excessive flow of urine. I use the term *uresis* in contradistinction, meaning merely urine voided in the ordinary quantity, or not in remarkably permanent excess.

(d) "There is a great advantage in expressing disease concisely, explicitly, and, when possible, in single terms. Dr. Willis in adopting a nomenclature of this sort, has set a good example—hydruria, anazoturia, and azoturia, are all single terms, derivatives from the Greek, and express watery urine, urine with deficiency of urea, urine with excess of urea—this being the type of the anazotizing process of the kidneys."—Author's Lectures, &c., *Med. Gazette*, March 2, 1839.

(e) Prout acknowledges two kinds of azoturia; one without, and the other with diuresis.

(f) "On Stomach and Renal Diseases," p. 24.

Dr. Pavy tells us "that a diabetic patient may, by a purely animal diet, keep down and limit the amount of urinary sugar voided to 1000 grains per day, and thus the patient not in any way know of the existence of his complaint, otherwise than by the necessity of restricting himself to the regimen essential to this object."

Prout himself tells us that a saccharine condition of the urine is not necessarily diabetic. Thus he says:—"Indeed, a saccharine condition of the urine exists in dyspeptic and gouty individuals much oftener than is supposed, and hundreds pass many years of their lives with this symptom more or less constantly present, who are quite unaware of it till the quantity becomes increased." (g)

What, then, are we to infer from these facts? That many of the cases treated successfully as diabetes were really explicable upon these principles; that they were cases of ordinary uresis; some of the saccharine forms, others the insipid, but neither in any way allied to true diabetes. What, then, is diabetes, and how is the real to be distinguished from the spurious disease?

The first question to be answered is whether the urine be saccharine or not, because, if there be no sugar there can be no diabetes, and there is an end of the matter. Then how are we to determine the presence of sugar? A variety of means affords us a choice, and we can readily satisfy ourselves upon this point. It is, however, no part of the object of this paper to detail at any length the different plans; still I think one or two hints may save the analyst a great waste of time, and no little amount of unnecessary trouble.

First, the taste, if it gives the sensation of sweetness, settles the question at once; but it must be recollected that urine may hold a considerable quantity of sugar in solution, and yet not taste sweet; but, on the contrary, saline and bitter. This I have found often the case, and when the taste gave no sensible evidence whatever of sugar, chemical tests gave very satisfactory indications of this principle in tolerably large quantity. What, then, is to be done? When the specific gravity (h) or any other condition of the urine renders the presence of sugar questionable or doubtful. The more expeditious, or at least the readiest plan, which I always adopt, and which I recommend to the busy Practitioner, whose object must always be to economise time, is the fermentation test. I introduce into a small phial, of from half-an-ounce to an ounce capacity, sufficient of the urine to nearly, but not completely, fill it. Next introduce a small fragment of the German yeast, shake so as to diffuse the ferment, and put into a tumbler of water heated to about 90° or 100° Fahr. It will very soon acquire the temperature of 70° or 75°. The bottle may now be corked and transferred to the waistcoat or trousers pocket. Fermentation, if sugar be present, will soon begin, in times varying from one to two, three, or four hours. If this does not happen, the phial with its contents may be kept at the fermenting temperature for from twelve to twenty-four hours; it is unnecessary to point out the means of doing this, as it may be accomplished in various ways. The fermentation takes place with more or less rapidity, and more or less activity—violence—in a ratio no doubt proportioned, *cat. par.* to the quantity of sugar held in solution. If, after a reasonable time, there be no evidence of fermentation, I look upon the question of diabetes as completely settled. Sugar cannot exist in solution, exposed to the influence of a ferment at the temperature mentioned, without undergoing the vinous fermentation, with the evolution of carbonic acid gas and the generation of alcohol.

We shall now suppose the alternative fermentation to have taken place, is sugar necessarily present? By no means. Urine may ferment, more especially under the influence of a fermentative, even though there be not a particle of sugar present. Therefore the object of the above is only to decide whether additional inquiry be necessary.

Several methods have been recommended, and Trommer's (i) seems to be the best, and perhaps as manageable as any. If fermentation and the copper test confirm each other, the cautious Practitioner will avail himself of several others, if not at his first examination, at some of his subsequent ones. This general confirmation will not leave room for a possibility

(g) "On Stomach, &c., Complaints," p. 32. Possibly he might have added which may never occur, or any of the phenomena of diabetes.

(h) To save time and space this quality will in future be symbolised by the initials "sp."—"gr."

(i) Tichling and various others have tried to simplify, but the reader is referred for information to G. Bird, Bence Jones, Thudichum, and my own essay on Urinary Analysis.

of doubt. It not unfrequently happens in complicated conditions of the urine that the colouring pigments and the cloudiness not removable even by filtration will so embarrass and so vitiate the results, that doubt, even serious error, may ensue. The removing of all these causes of obstruction may therefore in certain cases be found advisable, sometimes absolutely necessary. There are means, no way difficult, of effecting this object. In my lectures on the Chemical History, etc., of Urinary Diseases (*Medical Gazette*, 38, 39), I suggested acetate of lead for clarifying, etc., the urine, and precipitating by hydro-sulphuric acid gas. (k) This seemed to many a troublesome and otherwise inconvenient process, and I then proposed to remove all embarrassing agents by acetate of lead in slight excess, and removing this last by phosphate of soda in the equivalent proportions, or rather in slight excess. By these means a perfectly clear, transparent, and, in most instances, colourless urine will be obtained, and the tests for sugar will act with unfettered energy and give satisfactory results.

The above plan removes albumen, and all other urinary constituents that can offer any obstacles, and will be found far more expeditious and much more effective than evaporation to dryness, boiling the residue in distilled water, filtering, etc., not unfrequently recommended.

So far, we have only determined the presence of sugar; but is the disease diabetes? It is clear the answer must be determined by collateral circumstances. Sugar, as already observed, is but one,—though an absolutely essential one,—of the elements in the diagnosis.

The collaterals laid down by Prout are perfect transparency; pale straw colour, with a greenish tint, and a faint, peculiar smell. The odour that of newly mown hay; sometimes of sour milk. Taste in a greater or less degree sweet; specific gravity from 1020 to 1050 (l), but there is no precise limit to the possible height of the gravity, the elevation above the normal of course depending upon the amount of sugar in solution. It may be assumed, however, that really diabetic urine should, *cat. par.*, always have a standard not under 1.030. This may appear a singular proposal, when I refer to a case in which the gravity of diabetic urine was under 1009. But in this instance the patient was at death's door—more appropriately, death was at the patient's door. As the fatal issue approaches, I have often observed that the gravity falls very low; the daily urine diminishes in quantity; urea decreases; uric acid nearly disappears; and even the quantity of sugar becomes greatly reduced. These may be considered as portending the fatal issue close at hand.

To recapitulate concisely the symptoms on the first appearance, or in its incipient stage, of diabetes:—*saccharine diuresis*; an absolute essential; inordinate appetite, ultimately becoming voracious; urgent thirst, at last insatiable; arid, rough, unperspirable state of skin; emaciation; lassitude, listlessness, and disinclination to any kind whatever of exercise or other exertion, bodily or mental. These symptoms, from being at first slight, as the disease advances become aggravated, ultimately terminating in organic disease of some of the viscera—not unfrequently terminating in

(k) The urine should be boiled for a few minutes with the required quantity of crystallised acetate of lead in about the proportions of four grains of crystallised acetate of lead to every sixty grains of urine. Boil the mixture, and immediately a copious precipitate, of a dirty white colour, somewhat resembling cream, is formed. Filter, and treat the filtered portion with sulphate of soda in excess—*i.e.*, for every four grains of acetate of lead add eight grains of crystallised sulphate of soda. The mixture being again heated, sulphate of lead is deposited. Then filter; a clear, transparent liquid passes, which contains the sugar and some unimportant salts. The liquid thus obtained is neither acted on by the cupropotass reagent, nor by the caustic potass, unless sugar be present. These reagents in this way become perfectly reliable, very accurate, but afford no results when sugar is not present. The acetate of lead separates albumen and other organic matters, which now can give no trouble. I cannot at present recollect the authority for this process; probably I took no note, because it is identical with my own process, which I have repeatedly exhibited to my pupils upon every apposite occasion, the only difference being that I used the phosphate instead of sulphate of soda for precipitating any excess of lead. I generally clarify and purify from a half to one ounce of the urine, and take a determinate proportion for each experiment. If the analyst wishes to avoid the weighing out upon each occasion the salts, acetate, and sulphate or phosphate, the tests may be dissolved in their relative proportions in merely the necessary quantities of distilled water, so as to have as little excess of the solvent as possible. The operation can be thus always readily performed, and almost instantaneously, as the solutions can be kept adjusted ready for use. It is advisable to add a few drops of acetic acid to the lead test to prevent its precipitation, which is apt to occur from the carbonic acid in the atmosphere.

(l) Prout has seen it as low as 1010. In No. 436 of this Journal, November 6, 1858, I mentioned a case in which the specific gravity was only 1013, and one subsequent examination gave a specific gravity 1008.71. I questioned the diabetic character, but I found it admitted of no doubt.

disorganization.(m) The tongue is coated with a whitish mucus, from which it cannot be freed; a frothy, glutinous saliva exudes from the angles of the mouth, encrusting them, and giving a peculiar thickness to the voice, so that the patient articulates as if he had marbles, or some other foreign substance in the mouth. There is another, a local symptom, which, though not an invariable attendant, yet is present sufficiently often to deserve notice,—I mean an affection of the penis in men; of the orifice of the urethra in women. It often appears in the former as phymosis, and, not unfrequently, as a sort of erythematous blush, attended with a thin, curdy secretion, of a viscid character, not from the urethra, but from the external coating of the glans itself and the internal lining of the prepuce. This was the condition of an officer, a captain in my own old corps, the Royal Artillery. The moment I saw the condition, I believed it to be a commencing gonorrhœa, for which I know this condition has been mistaken; but I was saved from committing any blunder by his stating he was suffering from diabetes. Anaphrodisia is by no means an uncommon concomitant of diabetes.

But the object is not a detailed or complete history of diabetes, but to show the necessity of limiting the application of the term, and confining it to its legitimate boundary.

My own inference is, and from no very narrow experience, that diabetes is an incurable disease, at least so far as our present knowledge and means extend.

With respect to the natural constituents of the urine, they are said to be in the normal proportion of health, while in relation to the quantity of fluid they appear in a ratio very much diminished. My own observations warrant the notion that sugar is both a foreign and an exclusive principle, at least in so far as diabetes is concerned. The quantity of urea is generally reduced when sugar is copious, and they seem to alternate with each other;—as the amount of sugar increases, the urea diminishes, and *vice versa*; upon which Prout observed, this alternation of a principle containing nearly half its weight of nitrogen with one containing no nitrogen at all, exhibits one of the most singular of the phenomena in physiology.

Lithic acid is often present, in very large quantity, in simply saccharine urine, and such is highly acid, the crystals depositing spontaneously in extraordinary profusion. The case to which I have so frequently referred—No. 436—was of this character. The amount of deposit very large; the urine saccharine acid, and of specific gravity 1045. The disease was reported "Diabetes," and particulars in accordance with this view were then given. But I have very good grounds for believing that this was a mistake, and altogether an inadvertent misrepresentation. Although both urea and uric acid may exist in diabetic urine, they exist—especially the latter—in very diminished quantity. The amount of lithic acid in comparison with that of the watery portion of the urine is so small that a minute quantity of urine affords but very slight evidence of its existence, and hardly any of the amount. How much less than in diabetes, where the fluid portion so greatly predominates!

When we consider that lithic acid—and we may also add urea—begins to reappear in the urine in either its amorphous or crystalline form, it affords a much more favourable view of the nature of the case. Were it not that this doctrine is supported by the authority of Prout, I should feel disposed to question whether such cases are really diabetic, but rather instances of simply saccharine diuresis in its most aggravated forms. As urea often abounds, and lithic acid spontaneously deposits in either its crystalline or amorphous form, it seems no outrageous stretch of the imagination that such urines may be explained, not unfrequently at least, upon the principles above stated.

If diabetes is to be admitted as one of the *genera morborum*, it must contain species, two at least, under it. We have ignored altogether the division into the insipid, a saccharine condition of urine being essential.

I think it much more practical, and I presume it will be found much more consistent with the phenomena of diabetes to admit an acute and a chronic form of this disease. I have, however, seen cases which have exhibited but little more than the ordinary phenomena, yet without any obvious cause become suddenly aggravated, and carry off the patient with scarcely any warning. As an instance, I may refer to the case,

already mentioned, to illustrate the extension of the redness, heat, and irritation of the tongue and mucous membrane to the urinary organs—the glans and orifice of the urethra presenting all the appearances of gonorrhœa.

This gentleman had spent some years in Ceylon, China, and other low latitudes; had been subject to nocturnal emissions. On returning to England, to use his own expression, "he was struck with the cold of this climate." His health became seriously affected, and Medical opinion pronounced him suffering from congestion of the liver, of the kidney, and of others of the viscera. I saw him first on March 3, 1860; he was then clearly suffering from diabetes, so pronounced by Bouchardat and others of the most experienced urinologists in this country. When I saw him there was no evidence whatever of any organic visceral disease. I saw him in all two or three times; very shortly after, I heard he had gone to Margate, and about a fortnight or three weeks after I heard of his death, but whether this occurred in London or Margate I could not learn.

With respect to the essential nature of this disease, it seems universally admitted that we really know little or nothing. It is well known that starch and other vegetable matters may be easily converted into sugar.

Nor is this a morbid product, generated by diseased or perverted action. It appears only as the result of imperfect assimilation, or of arrested metamorphosis. The starch transformed into sugar in diabetes passes through the system in health daily; but with this difference, that, having become sugar, this is further transformed into carbonic and the vegetable acids already named. Where these various transformations take place, how effected, we still remain ignorant, and are left to mere conjecture; nor are we any better informed how these transformed matters escape from the organism. We are like the mariner at sea without his compass: he knows not where he is, what the course he is pursuing, or that which he ought to steer. So we are with respect to sugar in the blood. Where, or to what organ, are we to take it for disintegration, and the rearrangement of its constituent elements? Can this take place in the lungs? In No. 436 of this Journal, I mentioned the case of a Medical gentleman in consumption, whose urine was distinctly saccharine. Could this state be owing to any imperfection or any impediment to the pulmonary function? Was it through any defect here that the sugar in the venous blood did not undergo the fatty transformation and deposit itself in its appropriate tissue?

I have since examined the urine of many consumptive patients, and in a great proportion I have found sugar in the urine. If the sugar which passes through the system undergoes the fatty metamorphosis in the lungs, or is there fitted for its ready transformation in some other of the organs, the appearance of sugar in the urine in phthisis would be no longer a mystery. It would greatly assist this inquiry if we could examine the arterial and venous blood of phthisical patients. If both were found saccharine, the question would be settled.

*Curability.*—With respect to the curability of this disease, I can only say for myself I have no notion at present of any such happy possibility. Most of the plans proposed seem based upon the principle of reducing the amount of sugar and diminishing the quantity of urine; but neither of these—sugar or superabundance of urine—constitute the radical of the disease. They are merely the effects, the symbols, of a condition of which we really know nothing. Who has, or even pretends to have, explained the "ratio symptomatum" of this disease? In a discussion on diabetes at which I was present, it was asserted that the large quantities of urine voided arose from the large quantities of drink taken by the diabetic patient. I maintained, on the contrary, that he drank because he was thirsty, and he urinated because he drank. Which of these is the true explanation? Thirst is a most irksome and intolerable sensation; it exists, and must be appeased, which can be effected only by drink. Grant this, and the rest is clear. Excessive potations overload the blood with fluid; the kidneys, as depurators, set to work to free the blood from a principle which renders it watery and poor, and unfits it for circulation. This, to some extent at least, explains the excessive diuresis which prevails in diabetes. But these are not the essential agents; we can consider them only as the results of certain morbid conditions, the nature of which have hitherto baffled all our efforts to drag them to light and expose them to our view. We may suppress, we may stifle these effects, but the root of the evil remains intact; it is only the

(m) I do not understand organic disease in the usual acceptation of this term. I look upon all perceptible changes in the organism, organic for instance, inflammation, congestion, tumefaction, destruction of tissue, would be more correctly named disorganisation.

branches that are lopped, to revive under more congenial circumstances.

In the instance of the officer of artillery, the urine at one time exceeded two gallons, and at times much beyond this. When I last saw him it was reduced to between three and four pints, and the quantity of sugar was also greatly diminished; still the disease was not subdued. There was no evidence of any visceral disease, nor of any particular derangement (besides the diabetic) of the health, yet the patient died, as already stated, very unexpectedly. Considering everything, I can come to no other conclusion than that, however the milder cases may be kept in check, the cure of confirmed diabetes in the present state of our knowledge is beyond the reach of our art.

These observations may perhaps be looked upon by some and condemned as discouraging all further attempts to investigate the nature and phenomena of diabetes. Nothing can be farther from the object of this paper. On the contrary, it is rather calculated, or at least intended, to show that the field for inquiry is still open to new energy, and ready for further cultivation. Therefore let the reader not despond, but put his shoulder with more vigour to the wheel. My endeavour has been, if possible, to free the matter from some of its difficulties. How far I have succeeded is not for me to judge. The zealous and energetic pathologist I would encourage in the words of Seneca—"Multum egerunt qui ante nos fuerunt, sed non peregerunt, multum restat operis, multumque restabit, nec ulli post mille annos nato præcludetur occasio aliquid adjiciendi."

P.S.—In No. 90 of this Journal, January 25, 1851 will be found a paper by the author "On the Adjustment of Urinary Sediments for Microscopical Examination;" and 436, November, 1858, "On the Crystalline Modifications of Uric Acid," in which a plan for the examination of urinary deposits with greater ease, and calculated to save trouble and time.

## REPORT OF A FATAL CASE OF SNAKE-BITE.

By L. EMANUEL, B.A. and M.D.,  
Assistant-Surgeon to the Bengal Army.

CASES of snake-bite in European subjects being rare, perhaps the particulars of the following case, which rapidly ended fatally, may be worthy of your insertion:—

On the night of September 3, 1862, the 104th Regiment being encamped near Meerut, a soldier lying on his cot suddenly complained that he had been bitten. By the advice of a comrade, he applied some vinegar to the wound, and was brought into Hospital about a quarter of an hour later. There was then a dark-red spot, size of a sixpence, just below the right nipple; the limits of the discoloured areola were distinctly defined, and around it was a little swelling. The pulse was good, regular, full, and somewhat accelerated. The skin generally was bathed in clammy perspiration. The respiration was at this time natural and easy. There was extreme restlessness and anxiety. The wound was scarified, and nitric acid applied, and stimulants given internally; they were, however, immediately vomited.

A few minutes after admission he complained that he was unable to open his eyes, ptosis of both eyelids having taken place. The pupils were at this time natural, but sluggish. It now became extremely difficult to induce him to swallow anything. Small quantities of brandy and ammonia were given, but had a tendency to pass into the air-passages, or were instantly spit up. He showed great unwillingness to take anything. From time to time his lips were convulsed. He remained much in this state, the pulse keeping good, the skin becoming colder and more clammy for about three-quarters of an hour. At the end of this time he was still conscious, for when asked to put out his tongue he slightly protruded it.

The respiration now began to be difficult, infrequent, and shallow. The lips had become livid, and the skin bathed in copious clammy sweats. A few minutes later he had become quite unconscious. The pulse was still tolerably full, but weaker than it had been. The power of swallowing was completely lost. He lived about half an hour longer. The pulse only began to fail about ten minutes before death. There was no stertor at any time.

It is remarkable that in this case the eyelids became paralysed early, and later the muscles employed in deglutition.

When he could no longer answer questions, he gave signs of understanding them, and it was never necessary to shake him or repeat the question.

The brain was examined after death. The sinuses of the dura mater and the veins on the surface of the brain were gorged with blood; there was very little fluid in the ventricles.

## REPORTS OF HOSPITAL PRACTICE

IN

### MEDICINE AND SURGERY.

#### ST. MARY'S HOSPITAL.

#### THROAT DYSÆSTHESIA—CASES AND CLINICAL REMARKS.

(Under the care of Dr. HANDFIELD JONES.)

*Case 1.—Simple Throat Neuralgia—Benefit from Iron and Quinine.*—Jane B., aged 35, admitted October 1. Had suffered a year with her throat. There was no soreness in swallowing, nor any evidence of inflammation, but it was the seat of distressing constant aching pain, which came on first after a tooth had been removed. The pain was not constant; would come and go; and was increased by fatigue and causes of depression. She was exceedingly nervous, but showed no fussiness or hyperæsthesia, and seemed to have a calm, well-ordered mind. She was of large, rather lax make. She lived not far from a canal. She had occasionally not full power over her jaws. Often lost her voice, and said her throat felt weak. She had had the tonsils amputated without any benefit. November 16.—Has taken citrate of iron and quinine with benefit. The throat has been much relieved, but becomes again raw and tender when she takes any fresh cold.

*Case 2.—Throat Dysæsthesia—Laryngeal and Pharyngeal Constrictive Spasms—Cure by Iodide of Potassium and Iron and Quinine.*—M. B., aged 67, admitted December 14, 1857. She had been ill six months. She complained of feeling as if she should be choked; the phlegm "kept rising." At times she had dysphagia, and was always hawking. She had not much cough. She referred her pain to the region of the os hyoides. There was nothing morbid to be felt externally, and internally the top of the epiglottis could be reached with the finger; it seemed normal; there was nothing wrong to be found in the throat. She had a sallow aspect. Tongue clean. Appetite very good. Bowels regular. Often suffered from frontal headache, which "took her sight away." An œsophagus bougie passed readily without pain. Had nausea and retching of a morning. ℞ Potassi. iodidi, gr. iij.; sodæ carb., gr. v.; infusi. gent. co., ℥j. ter. die. ℞ Pil. hydr., gr. ss.; ext. rhei, gr. ij. in pil. omni nocte. A blister to the front of the throat. 21st.—Much better; she can swallow better, and has not the heat and burning round the throat and mouth which she had. ℞ Potassi. iodidi, gr. v.; tinct. cinchon., ℥j.; infusi. gent. co., ℥j. ter. die. 31st.—Has been much better, but is now for the last two days suffering in the same way. She complained of irritation about the throat, referred to the thyroid cartilage, with a sense of dryness. Bowels open; urine normal. She now took for a week small doses of carbonate and sulphate of magnesia, with vinum colchici and tincture of opium, but with little or no advantage. The dysæsthesia was absent occasionally. She was now ordered, on January 7: ℞ Ferri et quinæ citratis, gr. v.; potassi. iodidi, gr. j.; tinct. nucis vomicæ, ℥x.; aquæ, ℥j. ter. die; pil. hydr. col., gr. v., alt. noct. 14th.—Throat and mouth much easier, though dry at times. 28th.—Has now scarce any of the old affection. She was now to take the iron and quinine without the iodide of potassium. On February 11 she was discharged well.

*Case 3.—Laryngeal and Pharyngeal Spasm cured by Hydrochlorate of Ammonia and Bark.*—Hannah C., aged 20, was admitted October 18. She had been ill one week. She stated that she had been taken in the night with choking sensations in her throat; "her breath seemed to be leaving her." At the same time she had palpitation, lasting a quarter of an hour. Her tongue was much coated, and her appetite was bad. Bowels open. Some menorrhagia. Pil. hydr. coloc., gr. v., alt. nocte. ℞ Spt. ammon. fœtid., ℥i.; infus. valerian., ℥v., ter. die. 29th.—Food seems "to stick in her throat" as before. ℞ Ammon. muriat., ℥j.; mist. camph., ℥i., ter. die;

(pil. rhei co., gr. v., p. r. n). November 5.—Throat much better. ℞ Tinct. cinchonæ, ʒss.; infus. gent. co., ʒi., ter. die. 12th.—Much better. 19th.—Better. Discharged.

Case 4.—*Cranial Rheumatism, Throat Dysæsthesia, Laryngeal Spasm cured by Iodide of Potassium and Iron.*—Charlotte H., aged 37, admitted September 13. She had been ill eighteen months with great pain in the top and sides of the head, with feelings of fright, and a tendency at night to jump out of the window, and to scream. She was rather feverish at night. Urine very clear. Bowels always relaxed. Loss of appetite. Pulse of fair force. Skin warm. She had lost four children: they all died in the birth. No eruption was observed on them. She was ordered at first mistura ammoniæ acetatis, ʒi., 4tis hōris, and an alum gargle. On the 18th this was changed—℞ Potassii iodidi, gr. v.; infusi. gentianæ co., ʒi., ter. die.; and pil. saponis co., gr. v., omni nocte. October 9.—She reported that her head was very much better, but she had choking sensations in her throat, so that at times she had to fight for her breath. This was mostly at night when she awoke. She felt as if she had something to bring up from the throat, which was a little inflamed. Urine very clear. Pulse steady. Pt. c. mist., ter. die. ℞ Ferri carb. saccharati, ʒj.; ft. pulv., ter. die. 30th.—Throat quite well. Head a little queer at times. Pil. c. mist. et pulv. At the next visit, November 6, she was well.

Case 5.—*Throat Dysæsthesia—Debility—Cure by Iodide of Potassium, Iron, and Quinine.*—Eliza W., aged 36, admitted October 23. She had been ill one month. She has a dreadful "worried feeling" in her throat, which she said prevented her sleeping, and affected her eyesight; when the feeling was bad it made her "violent," and caused her to scream. She could take no tea, coffee, or beer. Tea "made her throat bad directly." Pulse of fair force. ℞ Potassii iodidi, gr. iv.; ammoniæ sesquicarb., gr. iv.; infusi. gentianæ co., ʒj. ter. die. ℞ Ferri carb. saccharati, ʒj., Ft. pulv. ter. die. November 3.—Was much better; sleeps well at night. 10th.—Going on well. Rep. pulv. ℞ Quinæ. disulph., gr. iij.; tinct. zingib., ʒx.; aquæ, ʒj. ter. die. December 8.—The "worried" feeling in her throat is entirely gone; she was able to sleep at night; speech was affected at times if she took tea or coffee. 29.—She has had a severe shock from the death of her youngest child four days ago; had not been able to sleep since. ℞ Ferri et quinæ citratis, gr. x.; tinct. nucis vomicæ, ʒx.; aquæ, ʒj., ter. die. Under this treatment she continued to hold her ground fairly well up to the present time, January 29, in spite of nursing a sick child.

Remarks by Dr. Jones.—The above cases are examples of an affection which, as far as I know, is not noticed in standard works, and, though not a life-perilling disorder, is one which causes no little distress, and for the cure of which patients are very grateful. I confess to a predilection for the study of these minor and more manageable diseases rather than for those grave affections where there is room for diagnosis,—and little more. It seems a poor thing to know all about a disease except the most desirable knowledge, viz., how to cure it. It is very possible to confound these affections with the so-called hysterical, from which, however, I consider that they are positively differentiated by the results of treatment. The term hysteria or hysterical should be applied, I think, to no case where there is really an honest desire on the part of the patient to get well, and where there is no morbid tendency to exaggerate the sufferings. A genuine specimen of hysteria will lead the unfortunate doctor a pretty dance of attendance on one symptom after another, and will be infinitely more benefited by moral discipline than by all the drugs that were ever invented. The patient is sick because she wills to be so, and sick she will be as long as it suits her, and no longer. There are doubtless examples common enough of a mixed kind, where, along with some real bodily disorder, there is more or less hysterical mental perversion. But there can be no question that the cases recorded above were not of this kind. Plainly and clearly the patients got well on a drug treatment that would have done small good to an hysteric.

As to the nature of the disorder, it seems plain that it was a pure neuralgic affection, as evidenced by the absence of visible disease, the remissions, the general state, and the juvenia. Now, the great rule to bear in mind in dealing with all neuralgia, which does not depend on some actual cause of irritation (as a decayed tooth), or on gouty or syphilitic poison, or the like, is, that in 99 cases out of 100 it is either rheumatic or simple. The former it probably is if the urine is thick with lithates, the strength pretty good,

and the patient has suffered previously from rheumatism; the latter if the urine is pale, clear, of low sp. gr., if the patient is feeble, and gives no history of rheumatism. However, it is very common, as these cases exemplify, that the two affections run into each other in the same patient, and that the dysæsthesia at its outset is rheumatic, and afterwards becomes simple. In the rheumatic condition iodide of potassium and hydrochlorate of ammonia are the two remedies, the latter if muscular tissue seems to be specially involved. Alkalis should be given with the iodide as long as lithates are deposited. In the simple, neuralgia, quinine, iron, and opium may be relied on, with rest, good diet, and pure air. It is often in doubtful cases good practice to begin with the treatment directed against rheumatism, replacing it if it fails, or proves inadequate to effect a complete cure, by the direct tonics. Not only in throat dysæsthesia, but in a multitude of disorders like in nature, only varying in situation, the above plain directions will lead to satisfactory results.

Dr. Türck (*Wien. Allg. Med. Zeitung*, vii., 9, 1862) has described an affection which seems to be similar to, if not identical with, the one I am considering. He calls it neuralgia and hyperæsthesia of the entrance of the throat, and describes particularly its exact seat. His therapy consists in resection of a piece of the gustatory nerve, and application of lunar caustic. This, he says, has been successful; but in my cases I am sure that the branches of the glosso-pharyngeal and sympathetic were much more involved than the gustatory nerve. In lingual neuralgia, on the other hand, which is a far more obstinate affection, division of the gustatory might, I think, be advisable.

## MIDDLESEX HOSPITAL.

### CASE OF ACUTE PHTHISIS — INFILTRATED TUBERCLE OF THE RIGHT LUNG — PHLEBITIS — DEATH — REMARKS.

(Under the care of Dr. GOODFELLOW.)

[Communicated by W. DUNNETT SPANTON, late Resident Obstetric Assistant.]

Charles R., aged 27, single, admitted on November 1, 1861. The patient was always strong until three months ago, when he caught cold, and from that dates the commencement of his illness. For some years he had been a clerk in a warehouse. No history of phthisis can be traced in any member of his family.

On admission, he had all the symptoms of acute phthisis; on the left side of the chest only a little moist friction was heard, on the right side the signs of tubercle in all its stages were well marked throughout the lung. He had frequent hæmoptysis. Respiration 52; pulse 120; urine abundant, free from albumen or sugar. Ordered to have milk diet and beef-tea, and to take a draught containing iodide of potassium and cinchona three times a day; the chest to be rubbed with an ointment of mercury and opium where painful.

November 3.—Urine specific gravity 1040, free from albumen. Ordered to have the right infraclavicular region painted with tincture of iodine.

6th.—Seems rather better; the chest is free from pain. Pulse, in recumbent posture, 99; sitting, 120; respiration 32. On the left side the friction sound remains, on right side chest signs are much the same. To have meat diet and beef-tea. Urine specific gravity 1030, free from albumen.

16th.—To take two teaspoonfuls of cod liver oil three times a day.

18th.—As he complained of much pain in the right infra-mammary region, a small blister was applied. Although his general health continues much the same, emaciation steadily progresses.

30th.—Since last night the right leg has become œdematous. There is no tenderness on pressure. The patient thinks that the limb became uncovered when he was perspiring freely in the night. Skin dry and hot; appetite failing; tongue dry, and coated with yellow fur; pulse 120, sharp; respiration 30, short; no rigors.

December 2.—Restless in the night; had one rigor. Countenance dusky, with hectic flush. The œdema of the right leg is somewhat less. Along the inner side of the ankle is a dusky red line, disappearing rapidly and entirely under pressure, not painful. The femoral and other large veins of the leg are cord-like and hard, and tender on pressure. The right femoral glands are enlarged and tender. Pulsation is good in both femoral arteries. Pulse 120 to 126,

small and sharp; respiration 30, short. The sputa under the microscope were found to consist of tubercular matter and some yellow elastic tissue. The limb was ordered to be covered with cotton wool, and over this thin gutta-percha. He was also ordered to take a draught of chlorate of potash and hydrochloric acid thrice daily, and a pill containing quinine and Dover's powder twice a-day, and to have six ounces of wine and eggs.

3rd.—Right leg rather more swollen about the groin, not elsewhere. Pulse 130, extremely weak.

4th.—Right leg less swollen, free from pain. The patient can bear to have it gently rubbed. Pulse 138; respiration 34; thirst great. Urine specific gravity 1035, free from albumen.

6th.—Some delirium during the night. He is now exceedingly weak. Leg remains in same condition. Pulse 130; respiration 34, abdominal. Urine specific gravity 1035, free from albumen. To take instead of the quinine, a draught containing chlorate of potash, carbonate of potash, and nitric ether in peppermint-water every four hours, and linctus often.

8th.—No delirium. Right leg much the same. There is slight œdema of the left leg, and tenderness on pressure over the course of the principal veins. Pulse 140; respiration 34.

9th.—A line of redness has appeared on the inner side of the left ankle, as was the case before in the right foot. The œdema is much the same. Pulse 144; respiration 36. Sputa have a gangrenous fœtor. Over the whole of the right side metallic respiration, voice, and cough are heard.

He became gradually weaker, and died on December 12.

*Post-Mortem Examination made Thirteen Hours after Death.*—Extreme emaciation; great œdema of lower extremities, but more of right than of left; none elsewhere. *Head.*—Sinuses filled with dark blood. Brain and membranes normal. *Chest.*—Seven ounces of clear straw-coloured serum in pericardium. Surface of heart smooth. Right cavities full of dark soft coagulum; small dark coagulum in left cavities. Aortic valves competent, and valves generally healthy, with the exception of an abnormal deficiency at each extremity of the aortic valves, the free margin of the valve being at this part formed by a narrow tendinous cord. Weight of heart 9 ozs. Right lung much collapsed in front, and inseparably adherent at apex. About 3 ozs. of turbid serum in right pleura. Surface of lower lobe, and back part of upper lobe, covered with membranous shreds of semi-organized lymph, detached without difficulty. Whole of lower lobe, from base to apex, infiltrated with soft yellow tubercle, breaking down into cavities from the size of a pea to that of an orange. One large one at apex, the size of the latter. Several of the cavities in the lower lobe had their walls formed by disintegrating pulmonary tissue, and contained a dirty greenish fluid, of a decidedly gangrenous odour. Weight of right lung 58 ozs. Left pleura contained about 10 ozs. of turbid serum. Lower lobe covered with a thick, semi-organized, detachable, false membrane, with some recent lymph. Weight of left lung 21½ ozs. It was quite free from tubercle, but the greater part of the lower lobe was condensed and carnified, sinking in water, smooth on section, and very tenacious. Near the anterior inferior angle of the lower lobe was a patch of lobular pneumonia, the size of a cherry, coated on the pleural surface with thick yellow lymph. On section, this indurated mass was found to be partially detached at its circumference, and to exhale a gangrenous odour. Immediately behind this was another patch of lobular pneumonia, as large as a walnut, in an earlier stage. *Abdomen.*—About 8 ozs. of clear straw-coloured serum in the peritoneal cavity. Liver 59½ ozs., not adherent; surface smooth. Parenchyma pale yellow, flabby and soft. Hepatic cells contained an unusual amount of oil. Spleen 6 ozs., normal. Right kidney 5¼ ozs., left 5¾ ozs.; surfaces smooth. Capsules non-adherent; parenchyma normal; stomach, intestines, pancreas, and supra-renal capsules normal. The lower four inches of the vena cava, the right common, and external iliac, femoral, popliteal, and posterior tibial veins, with all their tributaries, were distended so as to resemble firm, rounded, blue cords; the right external iliac being as large as the fore-finger. The left common iliac vein was almost empty, but the left external iliac and femoral was distended like those of the right side, though to a less extent. On slitting up the vessels, a firm, decolourized, fibrinous coagulum was found occupying the lower four inches of the vena cava and the right common iliac. This was firmly adherent to the venous coat, except at its upper inch and a half. The venous coats were thickened and matted externally to the surrounding tissues. Below

this the vein was found filled with firm dark coagulum, at some places adherent, at others not. At the adherent parts, as for instance in the right femoral, the venous coats were found considerably thickened, and of a dark red colour on the inner surface.

*Remarks.*—This case is related as an example of phlebitis coming on during the course of phthisis. Dr. Goodfellow had in the Hospital another phthisical patient at the same time, in whom very similar symptoms manifested themselves, and after death the condition of the veins was almost identical with that in the case of C. R. Phlebitis does not seem to be of rare occurrence in cases of phthisis, though many writers on the subject have not alluded to it. Louis, in his work on Phthisis (Syd. Soc. Ed., p. 19), records a case in which the affection extended into the iliac veins as far as the vena cava. The lungs in this case were healthy, except at the right apex, where there was a cavity. Hasse also relates a similar case, and refers to one other. Dr. Cursham has related four cases of a similar kind, in one of which the lower part of the vena cava was obstructed. In the case of C. R. it is remarkable to find the obstruction extending as high as four inches along the inferior vena cava. The phlebitis most probably arose from the absorption of pus from the diseased lung into the blood Dr. Goodfellow thinks; but why, under these circumstances, the inferior veins of the body only should be affected does not seem clear. There was an entire absence of any intestinal lesion in the case related; and in the cases of the authors alluded to, as well as those of Dr. Basham, there appears to have been very rarely any. The patches of pneumonia in the otherwise healthy lung seem easily accounted for in the same manner as the phlebitis. A very interesting point revealed by the post-mortem examination was the large size of the tuberculous lung, and the entire freedom from tubercle of the left lung. The occurrence of the pneumonia has been alluded to. The presence of tubercle does not seem necessary to account for it. Two other points of considerable value in the post-mortem may be mentioned. Where the "cracked-pot" sound had been very distinctly heard during life there was found a large cavity, with the lung adherent to the chest wall; and at the part where œgophony had been very distinct there were found adherent shreds of lymph, with but a small amount of fluid in the pleura.

#### CASE OF EXCISION OF THE HIP-JOINT—DEATH FOUR MONTHS AFTERWARDS.

(Under the care of Mr. HULKE.)

A FAIR, delicate girl, aged 4 years, was admitted into Regent Ward, under Mr. Hulke's care, on May 31, 1862, with disease of the left hip-joint, which had begun four years previously. It was attributed by the mother to a blow, after which she limped, and complained of pain in the knee and hip during several months; then the hip became swollen, and abscesses burst in the upper part of the thigh and buttock. These remained open about three months and then closed. Fibrous ankylosis took place, and the joint remained quiet till Christmas, 1861, when fresh abscesses formed. At the date of her admission, the left lower extremity was apparently three inches shorter than the right, but the actual shortening was only one-eighth of an inch, the remainder being due to obliquity of the pelvis. The thigh was flexed on the trunk, rotated inwards, and adducted, the inner side of the knee resting on the front of the other thigh. The femur was very slightly movable on the pelvis; the slightest motion caused great pain, which was felt more in the knee than hip. There were several sinuses communicating with the joint. No disease of the thoracic or abdominal viscera could be detected. The pulse averaged 120. She was thin, slept but little, and was worn with suffering.

During the first three weeks of her stay in the Hospital, much relief was derived from extension, with a weight hanging from a cord attached to the leg by a stirrup of plaster; but towards the end of June, fresh abscesses formed in the hip, and the discharge from the existing sinuses became more profuse. At this time, in spite of every care, a bed sore formed over the sacrum, the child's appetite failed, and her strength was declining.

July 8.—A careful examination under chloroform having established the presence of caries, the head of the femur, with the trochanters and part of the brim of the acetabulum were removed. The rest of the acetabular surface, though denuded of cartilage, was clothed with granulations. The

bleeding was trifling. The limb was fixed in a line with the body, by a long splint interrupted at the hip. The child slept several hours during the night. On the following morning her pulse was 136; at night it had risen to 144; the skin was hot and the hip red, but not painful unless she moved. A caoutchouc bag of ice was ordered to be kept constantly applied to the hip.

11th.—Slept well; is now easy and cheerful; she says she has been much more comfortable since the use of the ice; relishes her food. Pulse 132.

From this date she steadily improved, till the middle of August, when an obstinate diarrhœa set in, coincidently with which the suppuration, which had much diminished, became profuse. Soon afterwards, whilst Mr. Hulke was absent from town, the splint was left off, in consequence of a sore having formed on the outer ankle from pressure, and the thigh became slightly flexed, and soon after œdematous. In October the diarrhœa returned, was not amenable to treatment, and the child died in November, soon after her mother had taken her from the Hospital, and about four months from the time of the operation. An examination of the body could not be procured.

### BRADFORD INFIRMARY.

#### CASE OF EXCISION OF THE KNEE-JOINT—RECOVERY—CONDITION OF THE LIMB EIGHTEEN MONTHS AFTER THE OPERATION.

(Under the care of Mr. TERRY.)

ARTHUR M., aged 9 years, was admitted into the Bradford Infirmary, under the care of Mr. Terry, on July 30, 1861, with disease of the knee-joint. About two years before he was kicked by another little boy; this was immediately followed by considerable pain and swelling. He immediately applied at the Infirmary, and, after leeching and fomentation with rest in bed, he appeared relieved, a slight stiffness and halt remaining.

On admission he was pale and unhealthy-looking. The leg was considerably shortened, from the partial displacement of the tibia backwards and outwards. There was great pain in the joint, with considerable effusion, more especially on the outer side of the ligamentum patellæ. The starting of the limb was always worse in the night, so that he got no sleep, and his general health began to give way.

On August 23, chloroform having been administered, excision of the knee-joint was performed by making the H incision as strongly recommended by Professor Fergusson. The upper surface of the tibia and a portion of the condyles of the femur and the patella were removed. The osseous structure was very vascular and healthy. The joint contained a large quantity of thick, curdy matter, with a large quantity of pulpy synovial membrane. The wound was then drawn together by wire sutures, the limb was secured in Lawson and Parkinson's splint, resting on Salter's swing apparatus, which is highly recommended by Professor Fergusson in his work, at page 458. In the evening of the same day he was very restless, and complained of great pain in the knee, which was relieved by an opiate.

24th.—The wound looked well, and was quite easy.

25th.—Continuing to do well; wound still looking well. Ordered beef-tea.

26th.—Wound looking well, and beginning to suppurate. In the evening, he complained of much pain in the wound, and had severe shivering, and there was diminished suppuration. The wound looked a little reddened and tense; this was relieved by removing several sutures.

27th.—He still continued very poorly. Pulse quick; tongue brown and dry, with rigors and sickness. The wound presented an erysipelatous blush for some distance above and below. Ordered the tincture of iron to be applied over the blush, and to take a mixture containing steel and quinine.

28th.—Much better than yesterday, the wound looking healthier, with increased suppuration. The remainder of the sutures were removed; he then continued to do well, and the splint was re-adjusted on September 24.

On December 24 he was allowed to get up, and the metal splint was exchanged for a gutta percha one.

This boy was seen by Mr. Terry in February last, eighteen months after the operation, and he was looking very well, and walked several miles daily to school. He had no pain, no swelling or thickening, and there was some slight motion.

#### VESICAL CALCULI IN A FEMALE—PECULIAR NUCLEI—OPERATION—RECOVERY WITHOUT INCONTINENCE OF URINE.

(Under the care of Mr. TERRY.)

HANNAH W., a very hysterical, pseudo-modest kind of girl, aged 24, unmarried, sent by a resident Practitioner for operation, was admitted into the Infirmary on February 3, 1863. She stated that symptoms of stone came on about a month ago, with violent pain in the bladder and along the urethra, with constant desire to pass urine. On passing a sound it immediately struck against a large and apparently soft stone. The bladder at the time was very much contracted.

February 13.—The operation had been delayed to give time for the cessation of the menses. Chloroform being administered, and the bladder injected with warm water, a small lithotrite was introduced into the bladder with the intention of crushing the stone. But the substance of the stone appeared so soft and elastic that the lithotrite had no power over it. Mr. Terry then proceeded to dilate the urethra with the finger, which was done readily, and then seized the stone with a small pair of lithotomy forceps. On passing the finger again into the bladder, he discovered a second stone, and this was removed in the same way as the former one. He then washed out the bladder freely with warm water, after satisfying himself that there was no more.

On examining the calculi, they were found to be exactly similar in appearance, size, and form; but that they were two distinct calculi was quite clear from the absence of any indication of connection. The shape was exactly like a Brazil nut, the length of each would be about two inches and a-half, and about an inch in breadth, and one edge was thicker than the other. On making a section, it was clear that it was some vegetable matter covered over by a great deposit of phosphates, forming an entire coating, which was readily separated by the finger. On examining the nucleus more carefully, it was found to consist of a cellular vegetable growth. The girl denied having introduced anything into the urethra.

14th.—Passed a good night; she was quite easy, and had no incontinence. Passed water about every hour, which was rather bloody and purulent. Ordered half a drachm of tincture of hyoscyanus every three hours.

16th.—Retains the urine for two hours. Pus diminishing, and no irritation.

17th.—Retains her urine four hours, and it is less purulent; no pain. On putting the question to her this morning as to what she had used, she confessed that she had used two pieces of a Swede turnip, and pushed them into the urethra about five weeks since. The symptoms followed immediately. At first she denied having introduced anything into the bladder:

20th.—Discharged cured, and without incontinence.

## Medical Times and Gazette.

SATURDAY, MAY 2.

#### SMALL-POX BEHIND THE SCENES.

We are glad to receive at the present time Dr. Thomas Herbert Barker's book on Malaria and Miasmata. (a) He is well known to have collected an immense body of facts relating to

(a) "On Malaria and Miasmata, and their Influence in the Production of Typhus and Typhoid Fevers, Cholera, and the Exanthemata." Founded on the Fothergillian Prize Essay for 1859. By Thomas Herbert Barker, M.D., F.R.S. Ed. London. 1863.

these much disputed subjects, and to have performed a laborious and well-devised series of experiments. His opinion on the propagation and habitat of zymotic diseases is precisely that which we gave expression to in our leading article last week, viz., that they are caused by organic poisons, capable of increase and propagation in the human body, which they infest and distemper, but also having lurking-places or breeding-places without, amidst filth and rubbish: that at times they lie dormant, and at times—like all other low organisms—propagate themselves with marvellous fecundity. This theory, it will be seen, reconciles the contagionists and the anti-contagionists. Zymotic diseases may be propagated by infection from the sick; again, they may be developed out of germs which lurk amidst decaying organic matter; and whatever "epidemic" states of heat and moisture favour "contagion," will also favour a seemingly *ab initio* development of these diseases.

In the case of small-pox, we are mercifully provided with a process which protects us against the disease, and, by lessening the disease, limits the source of infection. The small-pox germs, scattered amongst a well-vaccinated population, would resemble seeds sown in a soil which had been exhausted of certain elements necessary for those seeds' growth. Here and there a stunted plant might spring up, but no more.

But, unfortunately, it is found that we are practically not able to use vaccination to an exhaustive degree, and all the notions about the "extermination" of small-pox in which our progenitors indulged are but idle dreams. We are met by the following stern and unmistakable facts. There is the fact that some persons soon wear out the protective power of vaccination, as they do that of small-pox, and are liable to either disease again and again. Secondly, human ignorance, carelessness, and prejudice are very formidable forces, and are sure to cause a residuum of unvaccinated persons, to say nothing of some who are ill-vaccinated, through the lazy and detestable practice of using "charges" of lymph on "points," "bottles," "tubes," etc. Thirdly, there is the fact that the state of health of a large number of children is such as to be an excuse—good or bad—for indefinite delays of vaccination, and is a possible cause of degeneration of the virus, or of its contamination by syphilitic or other poison. In the face of these facts, it is absurd to harp constantly on the old string. Vaccination will do much, but it cannot do all. There remain the extrinsic sources of small-pox, whence it bursts out from time to time, and these must be attacked with greater vigour. We must look upon an epidemic of small-pox as evidence, not merely of neglected vaccination, but of the existence of a destitute, filthy, ignorant, vagrant, brutalised portion of the population, amongst whom disease breaks out by a natural law, and from whom it spreads to the better classes, to remind them of their duties to their benighted brethren.

Desirous of knowing the facts from real life, we set out last Saturday afternoon to call on the Medical Officer of Health of a well-known London parish. "Do let us see the inside of things," we said. "Why this raging small-pox? Is vaccination neglected? if so, why is not the law put in force? Who is to blame?"—for in this, as in other calamities, we experience the true English feeling that it is somebody's fault. "You have come in the nick of time," was the reply, "for I have just received from the Registrar Vaccinator a list of four children who have been vaccinated, but whose parents have neglected to bring them on the eighth day for inspection, as the Act directs. Here is also a list of children who have been registered, but not vaccinated; and these lists are sent to me that I may coax or threaten, or go to law if I please, so as I get the thing done. Come with me, and you can make your own observations."

So off we set, and about ten minutes' walk brought us to a decent street, leading into one of the largest thoroughfares in London. We call at No. 69, and ask for Mrs. Thomson, the

first name on the list. "No such person here," was the reply; "there was such a person, who left six months ago, and who keeps a stall in the street close by." Undaunted by this rather discouraging reception, our friend determined to go on, and find out the guilty person. So we came out into the great thoroughfare, the pavement of which was fringed for about half a mile with costermongers and other persons selling fish, periwinkles, vegetables, penny toys, fruit, ballads, crockery, cheap prints, and similar goods at stalls and barrows. Here our unabashed friend began to inquire of these stall-keepers if they knew Mrs. Thomson? "What Thomson?" "Why, she keeps a stall, and has a baby." The reiteration of this question soon produced a good deal of uninvited sympathy from the bystanders, mingled with occasional sarcasm; but at last he succeeded in finding a man named Thomson, who kept a fish stall. Our friend, first of all, adroitly found out where he lived, and then inquired about his wife and the baby. The fishman, in reply, swore that his wife had no baby; that if she had, it had not been vaccinated; that she was not right in her head; and that he knew nothing about the matter. Leaving him, we went off to the house where he said he lived. There we found his wife, a butcherly-looking woman, with a miserable baby in her arms, covered with patches of ecthyma. She vowed that the child had never been taken to be vaccinated, and that we must be in search of a different person. There was nothing more to be said or done here. Then we looked up case the second,—a woman with twins; out at work all day long; not to be seen. Case the third,—a young woman who had taken her child into the country. Case the fourth,—no house in the street of the number described.

"Now," said our friend, "how, in the name of common sense, are we to take civil proceedings against costermongers, vagrants, and persons with no fixed address? As for case the second, those twins whose mother is out at work all day must die soon, and then what will it matter? What Act of Parliament will induce such a poor wretch to lose the half day's work, which she must lose if she is to take her twins to be inspected?"

These perquisitions took up a good deal of time, so we went home to dinner, promising to return early on Monday morning, in order that we might see some of the persons whose children had not been vaccinated.

On Monday morning, accordingly, we went, and set out as before. On our way our friend said he would first of all call at a house to which the clergyman had directed his attention, because there was not a sufficient supply of water for the inmates, especially on Sundays.

The house, as we found, was a very large one, pretty clean, but most densely peopled—a family in each room—and not fewer than forty souls in it. Our friend first asked for the owner, a small tradesman, who occupied the shop. We were received by his wife. On stating the complaint, "Serve them right," she cried; "of course they've got no water. So soon as it comes in on Saturdays, they all go to the cistern and fill their buckets and tubs with it, and keep it in their own rooms. So some have more than they want, and waste it; others go without; and the end of it is, that we never have any from the middle of the day, Sunday, 'till it comes in on Monday afternoon, because the water is not turned on on Sundays." Our friend then proposed to see the cistern, to which the woman consented, and taking us into a back place, showed us, over a water-closet, a slate cistern, which, roughly measured with a walking-stick, seemed to be 4 feet long, 2 high, and 2 ft. 8 in. wide. Hence it would contain about  $21\frac{1}{2}$  cubic feet, which is equal to about 133 gallons of water, which was the allowance for forty human beings for forty-eight hours for washing and cooking, as well as for the use of the water-closet. But oh! the closeness, the horrid shut up smell, the nauseous bedroom and drain air that filled that house!

This was an episode. So on we marched to find the people

whose babies had not been vaccinated. First case—people out at work. Second case—people cannot be found; the house inhabited by many families, each in single rooms; indescribably nauseous from accumulated bedroom smells and want of open windows. Case third—mother did not believe in vaccination. Eldest daughter had had small-pox when a child, though she had been vaccinated. *Ergo*, etc., etc. Besides, the baby was not well enough. It was an ill-developed, white-brown child of a year old, with big wrists, hot skin, and very few teeth. The woman was threatened with legal proceedings.

We had now seen enough, and came home. We put these details before our readers, some of whom may think them trivial, vulgar, undignified, not fit for a Medical journal, etc., etc. We say that in this class of facts lies the real cause why we have epidemic visitations of small-pox. When the Lords of the Queen's Most Honourable Privy Council can give the low Irish the habits of even the low English, when by a stroke of the pen they can demolish foul old houses, thin out their inhabitants, give them plenty of water, and grace to use it, and teach them to be cleanly as well as godly, then their mandate for universal vaccination will be of some service.

### "SPIRITUALISM."

"And all the courses of my life do show,  
I am not in the roll of common men."

"I can call spirits from the vasty deep."

So long as the art of "spirit rapping" only supplied amusing recreation for the busy, and harmless excitement for the idle, it was no more a subject for our notice than are the performances of Houdin or of the Wizard of the North; but when showmen and professors insist that the phenomena which they exhibit under the name of "spirit rapping," or under the more pretentious title of "spiritualism," are in reality communications from the world of spirits, they appeal to some of the most universal and deeply-seated feelings of the human mind;—the thirst after the unknown and the unseen, the ardent desire to peep behind the veil that divides the material from the immaterial world, and the longing after *proofs* of our own immortality. Such apparent success has attended the bold promise of the "spiritualists" to satisfy these perennial yearnings of the soul, that "spiritualism" has become a most injurious and dangerous form of excitement; confounding and blurring the boundaries between truth and falsehood, confusing and unsettling the weak, rendering men incapable of separating the domain of reason from the cloud-land of the imagination, and finally landing its unhappy votaries in our lunatic asylums. Forced thus by the most melancholy proofs to recognise in "spiritualism" a possible cause of terrible disease, we can no longer pass it by with only a smile and a shrug of the shoulders; we must face it, and examine it, as we would any other of the enemies we especially have to do battle with. We must inquire into its real nature and powers, learn its pretensions, and test the foundations, if any, on which they rest. In this spirit of inquiry we have read the latest, and we suppose we may call it the greatest publication of the "spiritualists," Mr. Home's "Incidents in my Life." Its object is to show that Mr. Home, like Glendower, "is not in the roll of common men;" that he, too, can call spirits "from the vasty deep," or "from their golden day," and that they "come when he does call for them," and not only then, but that whether he calls them or not, whether he is willing or unwilling, they come; and in this respect poor Mr. Home is less happy than was Glendower; he does not command the spirits, but is their servant and slave; by day and by night, in season, and out of season, they insist upon holding communion with him; very rarely indeed, if ever, so far as we can learn, for any useful or instructive purpose, but apparently for their own entertainment or amusement; because they are in "high spirits," and disposed for fun; or because in their disembodied state they suffer from *ennui*, and they return to
