## ORIGINAL LECTURES.

LECTURES ON THE  
BLOOD OF VERTEBRATA.

DELIVERED AT THE

Royal College of Surgeons of England,

DURING THE SESSION 1861-62.

By GEORGE GULLIVER, F.R.S.

Professor of Comparative Anatomy and Physiology to the College.

LECTURE VIII.—*Colour of the Blood—Discordant Observations on the Colour of Arterial and Venous Blood reconciled by Effects of Temperature—Causes of the Bright and Dark Colour of Blood—Uses of the Red Corpuscles.*

*Colour of the Blood.*—We now proceed to consider the effects of the red corpuscles on the colour of the blood, as introductory to the interesting inquiry as to their agency in vivifying it and the parts through which they circulate, as well as their use in connexion with respiration and the production of animal heat. When the corpuscles are seen singly as transparent objects under the microscope, they are of a pale straw colour, of a redder hue when a few of them are so aggregated as to allow of less light passing through them, and of a darker colour when still more clumped together. Newton observed that blood is one of those fluids which is yellow when viewed in very thin slices. To the naked eye the colour is so well known, that "as red as blood" is a popular phrase; and no physiologist can be ignorant that this colour is owing, in vertebrates, to the red corpuscles, and is of a bright scarlet in arterial blood, and of a dark-red or Modena hue in venous blood. But the precise causes of this difference of colour, and the circumstances under which it increases, diminishes, or even ceases in the healthy animal, are by no means so well known.

*Discordant Observations on the Colour of Arterial and Venous Blood reconciled by Effects of Temperature.*—In the first place, as to the effect of temperature. The difference of colour is most marked in very cold weather, and least so in very hot weather; but having been always taught the striking floridness of arterial blood, and the darkness of venous blood, and having commonly witnessed this difference of colour in our own temperate climate, we seldom or never think of the possibility of any doubt or question as to this subject. Yet there have been very discordant observations, and by some of our best physiologists, as to the difference of colour between arterial and venous blood; and as the question is an important one, and even connected with the practice of our Profession, a few historical notices will be well calculated to fix this interesting point on our attention. Harvey believed that the colour of the two kinds of blood is essentially the same, though he admitted that there might be an accidental difference in the colour of the blood as it flows from the artery or vein of a living animal. But the question was a subject of controversy fifty years afterwards. Lower specially proved the difference of colour, and correctly inferred, from experimental inquiry, that the change of colour is produced in the lungs; and further supported this inference by observing that air produces just the same florid hue on the surface of the blood-clot out of the body—an observation which had also been made, two or three years before, by Fracassati, in a paper published in the *Philosophical Transactions*. Mayow fully admitted Lower's conclusions, and attributed the change of colour in the blood, during its course through the lungs, to its abstracting from the atmosphere a "nitro-aërial spirit," many of the properties of which, as he describes them, belong to oxygen. Dr. William Hunter, in his Lectures, as early as 1759, taught the true difference of colour between arterial and venous blood. Yet we find Haller, in 1756 and 1780, opposing the correct conclusions of Lower, and even asserting, that a hundred observations in dogs had convinced him that there is no difference of colour between the blood of the pulmonary artery and the blood of the pulmonary vein. But Priestly, who discovered his dephlogisticated air—our oxygen—in August, 1774, ascertained the correctness of Lower's results, and that air will act on the blood through a moist membrane; and he also proved that the brightened colour of the blood is produced only by the oxygen, and that

carbonic acid, hydrogen, and azote have a contrary effect. Mr. Hunter removed the sternum from a dog, kept up the breathing of the animal by a bellows, and saw the blood acquire the scarlet colour in passing through the lungs. Then, at last, we have Dr. Davy making observations on sheep, at Malta, in the summer of 1829, when he carefully compared the blood of the jugular vein and of the carotid artery, and could see no difference whatever in their colour; in each it was less florid than the arterial blood of the same animal in an English winter, and less dark than the venous blood, being of a hue between the two. And this observation was so carefully conducted, that there could have been no mistake. In explanation, he supposes, that the higher the atmospheric temperature, and, consequently, the less need for the production of heat within the animal, the less difference there will be between arterial and venous blood, and the less power the venous blood will have of combining with oxygen, and of forming or evolving carbonic acid. Now, it is remarkable that Dr. Crawford's experiments, upwards of fifty years before, lead to the same opinion. He put a dog for more than half-an-hour into warm water, and then found it difficult to distinguish the arterial from venous blood.

Here, then, is a series of facts not without value either in a physiological or in a practical point of view. The former has just been mentioned; and as to the latter, we must be very cautious in judging from the colour alone during hot weather, when the temperature of the atmosphere is upwards of 80°, of whether blood flowing from a wound be arterial or venous. Very likely Harvey's experiments were made at the hot season in Italy, and that Haller's took place during a warm summer at Lausanne.

*Causes of the Bright and Dark Colour of Blood.*—And now, having discussed the effect of temperature on the colour of the blood in the living body, we come to consider by what agent and how this effect is produced in the blood both in and out of the body. It is well known that blood is darkened even by a very brief stagnation both in living arteries and veins; and I have often been amused at the trick by which scheming farriers show "the blood as black as pitch," in order to prove their sagacity in having let out "that bad blood." No doubt, the general opinion, that the florid colour of arterial blood is due to the action of oxygen, according to the old views of Mayow, confirmed a hundred years afterwards by Priestly, is the correct one; but, in 1835, this was controverted very ingeniously by Dr. Stephens. It had been long known that earthy and alkaline neutral salts will render dark venous blood florid; and he was led to the conclusion, that the florid colour of arterial blood is caused by the agency of the salts of the serum on the hematozine, and that oxygen changes the colour of blood from venous to arterial merely by removing the carbonic acid, which, we have already remarked, Dr. Priestly had long before proved to darken the colour of the blood, and Dr. Stephens considers as the cause of this dark hue in venous blood. These views were adopted by Dr. Turner in his work on Chemistry, and Mr. Hoffman was also favourable to them. Dr. Christison agitated atmospheric air with a mixture of serum and red corpuscles of blood, and always found that oxygen disappeared, while carbonic acid was produced, but, owing to the strong solvent power of serum on this acid, he believed that more of it was formed than appeared in the residual air. In all these experiments venous blood acquired a bright vermilion hue, and the florid colour of arterial blood was heightened. Dr. Davy obtained the same results as to the absorption of oxygen by the blood, and the consequent brightening of its colour; but in the residual air he could detect only a trace of carbonic acid, and none at all when, instead of atmospheric air, pure oxygen was agitated with the blood. He further observed that venous blood, when subjected to the air-pump, did not acquire the arterial hue, even when carbonic acid was extracted; and yet that the florid colour was imparted to venous blood by agitating it with a mixture of oxygen and carbonic acid gases, although the blood certainly absorbed a much larger portion of the carbonic acid than of the oxygen.

These results are quite irreconcilable with the doctrine of Dr. Stephens, but agree well with the older views which he disputes. Dr. C. J. B. Williams gave some experiments to prove that the florid effect produced by oxygen and the salts is by their causing more light to be reflected through the colouring matter. Dr. Davy concludes that neutral salts brighten the blood by so separating the corpuscles that they reflect more light; that water, acids, and other agents

darken the blood by altering the form of the corpuscles, and partially dissolving the colouring matter; and that hematozine is black only in mass, and red when powdered, or when viewed in a small portion by transmitted light. My own observations are to the same effect generally. I found, after Nasse, Scherer, and Mulder, that agents, as pure water and carbonic acid, which darken the blood, make the corpuscles tumid or globular, and that florid arterial blood soon became dark coloured when kept in a jar, and remarkably so when putrefaction began; and the form of the red corpuscles was more or less altered, when the true bright vermilion hue of arterial blood could no longer be restored in it either by oxygen or neutral salts. The effect, too, of these salts in fresh blood is always to separate the corpuscles, and render them slightly thinner, smaller, or more compact, which oxygen produces also in a less degree; nor could I find that either neutral salts, sugar, or oxygen, would strike a scarlet colour with pure and nearly black hematozine.

But the valuable observations of Dr. Wells, published in the *Philosophical Transactions* of 1797, and strangely neglected, notwithstanding Dr. Davy's notice of them in 1838, are so conclusive on this subject, that much discussion might have been spared had Wells' paper not been forgotten. He obtained the same results, as those just mentioned, as to the action of air and neutral salts not brightening the colour of pure hematozine—that nitre does not change the colour of a solution of hematozine, and proved by an ingenious experiment that the opacity of blood, and the reflection of light from it, are increased by neutral salts; and observed that these salts and air—of course the oxygen—affect the blood, just as bright vermilion is produced from dark cinnabar by subjecting it to minute mechanical division. Thus, then, the result is, that it is not simply to chemical agency, but either to changes in the form of the corpuscles, or to their more or less state of aggregation, so as to dispose them either to reflect or to absorb more or less light, that the effect of many substances on the colour of the blood is owing; and we have already specially stated how neutral salts and oxygen act in this respect. Nor can we dismiss the observations of this eminent man, made upwards of sixty years since, without remarking the grievous injustice to him and to English science, by our translators and commentators adopting the sorry claim of very recent German genius to “the discovery that everything relating to the colour of the blood does not pertain to chemistry!”

If you look again at the diagrams you will see that the red corpuscles, when highly magnified and viewed by transmitted light, appear of a pale straw colour, and that they are of a deep red hue only when seen in mass, and are, consequently, more or less opaque. The extension or diffusion of their surface, and of the light through them, under the microscope, are just what might be expected from a consideration of chromatic laws. Hematozine only appears black in mass; in small transparent portions and in powder it is red. Now, it is well known that the more concentrated the colouring matter the darker it is, and the more diffused or diluted, *ceteris paribus* the lighter it becomes. The more, also, the colour is mixed with white or reflected light, and the purer the white ground on which the colour is spread, so much the brighter is the effect. Indeed, the great masters of colouring of the Venetian school practised their consummate art on these beautifully simple principles. The colours they used were transparent, not black; and darkness or blackness were produced rather by a concentration of colour than by a direct use of any black pigment.

*Uses of the Red Corpuscles.*—And now, having shown the difference of colour, and the cause of modifications or even cessation of that difference, between arterial and venous blood—to what agent the effect is owing, and how it is produced, we are prepared to enter on a further consideration of the functions of the red corpuscles. In a former lecture it was mentioned, incidentally, that the red corpuscles vivify the blood, and through it the animal frame; and this mainly by means of their function as carriers of oxygen. We now propose to adduce such evidence as may be sufficient to support this proposition, which will lead us, among other interesting questions, to a consideration of that of the source of animal heat; into which difficult subject, however, it is only intended at present to enter as far as may concern the immediate agency of the red corpuscles in this important process, and by way of illustrating their use in the animal economy, reserving some details for the next lecture.

In the course of this inquiry we cannot fail to be impressed

with a strong sense of the vast importance of these corpuscles, small and insignificant as they might appear to the uninquiring mind; and that, so far from being only microscopic curiosities, as they were too often regarded about the time when my researches concerning them were commenced, they are, in the vertebrate sub-kingdom, endowed with special functions, absolutely essential to the existence of the animal, from man downwards, throughout the whole classes, orders, and species, to one or more of the lowest fishes, as *Amphioxus*, where the necessity for the red corpuscles would appear to cease among Vertebrata. So that, without the red corpuscles we could neither live nor breathe, nor move, nor have our being; and even a slight change in their texture, or an alteration in their proportion relatively to the other proximate constituents of the blood, may be the cause of disease or death. And this consideration might suggest an inquiry as to what variation in this proportion may be consistent with health in the two sexes of the human species, and in the inferior animals; but our present purpose is not to treat of pathology.

The red corpuscles would appear to be connected with nutrition, and with the maintenance of the action or excitability of parts. The muscles lose their power of motion when the current of arterial blood is cut off from them, as was long since observed by Stenson, and confirmed by subsequent experimenters. After tying the aorta or the iliac artery in dogs, I have frequently seen, as no doubt Sir Astley Cooper and others had done before, more or less paralysis of the hind limbs, which diminished as the collateral circulation became established; and this in cases where there was no sufficient injury of the nerves to account for the diminished power of motion. But until recently we had no demonstration of the manner in which the influence of the arterial blood is exerted. That the red corpuscles vivify the blood and the parts to which they are carried by virtue of the oxygen which they convey, has often been supposed, believed, or stated; but the proof, and that proof so legitimately carried out as to command the merit of discovery, is due to the researches of Dr. Brown-Séguard. Now, suppose either man or brute animal, dead and stiff, cold, the post-mortem rigidity so fully established that the muscles are no longer capable of being affected by any kind of stimulus previously known to affect them until they had become stiffened after death, such as mechanical, chemical, or galvanic action; in short, having lost all remains of vital endowment and returned to mere dead matter. Suppose, then, the discovery of an agent capable of so far reanimating this dead and stiff body—this stark cadaver—as to revive the muscles, restoring their flexibility and their susceptibility to stimuli, and it might seem that we were asking for the supposition of a modern miracle! Yet the red corpuscles, charged with oxygen, really constitute this marvellous agent; and we well know how in the living body they are incessantly supplied with oxygen from the atmospheric air during their circulation through the lungs, and how intimately this process is connected with the breathing function. Here is one of the experiments, to which these remarks are the prelude:—A mixture of red corpuscles and serum, charged with oxygen, was injected into the radial artery of a man, after cadaveric rigidity, when the injected blood, which, of course, had been made scarlet by the oxygen, returned blackened through the veins, while the irritability and flexibility of the muscles were restored! And that this wonderful effect was produced by the red corpuscles is fairly inferred from the facts, that no fibrin was injected, and that trials with serum alone produced only negative results. Nay, it was further found that the integrity of the red corpuscles is necessary to the success of the experiment, since corpuscles altered by incipient putrefaction or otherwise, will not carry the oxygen like the regular fresh corpuscles, as already described when treating of the colour of the blood.

And I may add, that the oxygen was carried alone by the red corpuscles may be as surely concluded from Dr. Davy's experiments, published many years since, from which it results that healthy serum, though capable of absorbing more than its own bulk of carbonic acid gas, is nearly, or quite, incapable of absorbing oxygen gas; and that venous blood will absorb more oxygen than arterial blood, as might be expected from the corpuscles of the arterial blood already containing oxygen, to be given out or enter into combinations according to the wants of the economy, before the conversion of the florid arterial blood into the dark venous blood. In his experiments, Dr. Davy used the same kind of apparatus as had before been employed by Dr.

Christison, the eminent chemist of Edinburgh, in a similar inquiry. Dr. Davy experimented on blood deprived of its fibrin, and he always found that, when the remaining mixture of red corpuscles and serum was agitated, either with atmospheric air or with pure oxygen gas, there was a marked diminution of the volume of air, most in venous, and least in arterial blood. The air which disappeared from absorption by the blood was oxygen only; and that this is absorbed simply by the red corpuscles is to be inferred from the very curious and important fact already mentioned, that serum is scarcely capable of absorbing this gas. When ten cubic inches of the venous blood of the sheep were agitated with common air, there was an absorption of one cubic inch of the air; and arterial blood, similarly treated, absorbed from  $\cdot 3$  to  $\cdot 4$  of a cubic inch. The venous blood, agitated with pure oxygen, absorbed 1.25 cubic inch. It is remarkable that there was no evolution of carbonic acid; but it might have been formed and held by the serum. We shall have to recur to these experiments in connexion with respiration. For the present they are merely cited as proofs that the red corpuscles, and not the serum or liquor sanguinous, are the absorbers and carriers of oxygen. It is no part of our purpose now to enter at length into an inquiry as to the potent agency of this element. We have simply to represent the great importance of the red corpuscles as the distributors of it throughout the animal frame, confining our attention to some of the most obvious effects of the oxygen thus dealt out wherever the red corpuscles of the arterial blood may penetrate. Nor can we, even thus limited, avoid being reminded of the mistake of our illustrious Hunter, in attaching such comparatively little importance to the red corpuscles. He seems, indeed, almost to have taken a dislike to them, a feeling in which he was followed by some other eminent physiologists.

Now, while the experiments already alluded to lead to the conclusion, that certain secretions are increased under the influence of blood charged with carbonic acid, and that the superoxygenation of the blood may diminish or suspend the secretions, the inference results that there can be no nutrition in vertebrates without a sufficiency of oxygen. It appears, also, that the properties which the blood possesses of nourishing or maintaining the vital properties of the tissues, of the nervous and contractile organs, and the special action of the brain, depend on the oxygen which the blood contains, in accordance with the old observations of Bichat. We have already seen that the red corpuscles are the agents by which this oxygen is taken up and distributed throughout the frame in vertebrate animals, and may well be lost in admiration of the immense import of these beautiful little organisms even in this point of view; while we can now understand the great value and interest of all well-directed research as to everything connected with their nature, and that these inquiries are, indeed, the reverse of mere curiosities. Why, to revert to the results of the experiments just cited, it would appear that the contractile tissues, the nervous tissues, and the brain, after having completely lost their vital properties or functions, recover them under the influence of the red corpuscles charged with oxygen. And, finally, that carbonic acid, so far from being all a mere useless or excrementitious substance, has a favourable influence on the formation of certain secretions; with the further conclusion, that certain contractile tissues of Vertebrata may be stimulated or excited by blood charged with this acid.

## ORIGINAL COMMUNICATIONS.

### A CASE OF CANCER OF THE THROAT,

INVOLVING BOTH WIND-PIPE AND OESOPHAGUS—TRACHEOTOMY  
—DEATH AFTER FIVE MONTHS.

By CHRISTOPHER HEATH, F.R.C.S.,

Assistant-Surgeon to, and Lecturer on Anatomy at, the Westminster Hospital.

THE following case is, I think, worthy of record as an example of complicated disease, in which the patient was rescued from immediately impending death by the operation of tracheotomy accomplished under great difficulties, and survived the operation in comparative comfort for five months:—

In December, 1861, Mrs. S., aged 60, the widow of a

Medical man, came under the care of Dr. George Johnson and myself, suffering from what appeared to be chronic laryngitis, with occasional attacks of dyspnoea. Some enlargement of the thyroid gland had existed for some months, and it was exceedingly hard, but did not seem large enough to induce pressure on the wind-pipe. The patient was a thin, delicate woman, suffering much from indigestion and occasional slight attacks of jaundice, the result of long residence in India.

On December 10, 1861, I was summoned, as the dyspnoea had become urgent, and met Mr. Musgrave, of the Finchley-road, who had been called in. I found her breathing ten per minute with great difficulty, with feeble pulse, and cold skin. We agreed that an operation would be necessary in all probability, but determined to try the effect of administering stimulants for an hour. No improvement taking place, and Dr. Johnson concurring, I proceeded, at nine p.m., to perform laryngotomy, so as to avoid interference with the enlarged thyroid. Having made an incision over the crico-thyroid space, I found a portion of the enlarged thyroid overlying the larynx, and just at the spot was a portion with several large veins distinctly visible, and I was, therefore, obliged to resort to tracheotomy. I prolonged the incision to the sternum, and found an immense dense mass of tissue, apparently altered gland (*gy. scirrhus*), overlying the trachea. Having dissected through this, I thought I felt the rings of the trachea (in which Dr. Johnson agreed), and cut into it, but found it still to be the same dense tissue. I then cut deeper with the same deceptive sensation, but without discovering the wind-pipe. Having cut to the depth of nearly two inches without any sign of trachea, and, under the peculiar circumstances of the patient being particularly anxious as to the result, I suggested that Mr. Ferguson should be consulted before proceeding further. The hæmorrhage was only slight, and was arrested by pressure. Mr. Ferguson arrived in an hour; and, upon putting his finger into the wound, thought, as I had done, that he felt the trachea, and attempted to introduce a tube, but failed. He then cut very freely for some time without result, but, at last, some air escaped, showing that the trachea was reached. Mr. Ferguson had great difficulty in again finding this orifice, but, at last, got the handle of the scalpel into it, and enlarged the orifice downwards with a bistoury, and was then able to introduce a very long tracheotomy tube, which he had fortunately brought with him. The incision was about three inches deep. The patient could not bear the introduction of the inner tube, but breathed pretty comfortably through the divided external one. She coughed up a quantity of viscid, bloody sputum, but got some sleep after the operation. The patient was pretty comfortable next morning. She was only able to take small quantities of food at a time, owing, apparently, to the presence of the tracheotomy tube.

12th.—Much better altogether. I changed the tube, introducing one of a different angle, which permitted the introduction of the inner tube, and did not prevent her swallowing. The wound is beginning to suppurate.

14th.—The patient is able to take solid food. No medicine given, but wine at short intervals. There is but little expectoration, and that quite clear. Dr. Johnson examined the chest, and found the lungs quite clear.

From this time to March 16, 1862, Mrs. S.'s condition was very satisfactory. The enlargement in the neck diminished slightly, but continued to be of stony hardness, and the glands under the sterno-mastoid became enlarged and very hard. Some difficulty was caused by the contraction of the wound, and, on one occasion, I enlarged the internal orifice slightly with a curved bistoury. To obviate the difficulty caused by the granulations finding their way into the outer tube, I had an old-fashioned double tube made with no split in the external portion, and this proved quite satisfactory. The patient's general health was pretty good, and she was up every day, and went out once for a drive. A slight difficulty of swallowing had occurred on two or three occasions; and she found, during February, that she was obliged to be careful, in swallowing, to take as much fluid as possible, and to take plenty of time. No air whatever passes through the larynx.

From March 10 to 16 there was a good deal of difficulty of respiration, due apparently to some pressure against the tube, for by tilting the lower end slightly backwards it was immediately relieved. This difficulty I attempted to remedy by altering the curve of the tube, without much effect; and the attendant found that most relief was given by passing a piece

of whalebone down the tube, so as to alter slightly its direction.

On March 16 it was noticed that some of the breakfast passed through the tracheotomy tube, giving rise to severe cough, which was also excited by swallowing the saliva. I was out of town, but saw the patient the next morning, and tried to pass a tube down the œsophagus, but failed. I succeeded, however, with a No. 10 elastic catheter, through which she was fed by means of an India-rubber bottle. She was ordered to spit out the saliva, as it invariably gave rise to cough when swallowed. The attendant to feed with the tube four times a-day.

March 23.—Mrs. S. has decidedly lost ground during the week, and has lost heart too. The nurse manages the feeding with the catheter very well.

April 1.—A decided improvement in the general appearance. Was able to drive out for an hour yesterday. Feeding continued as before.

12th.—The difficulty in passing the tube down the œsophagus has increased, and a larger quantity comes through the tracheotomy tube at each feeding. Each feeding produces a violent paroxysm of coughing, which distresses her much. I ordered a tube to be made of the size of No. 10 catheter, but as long as the stomach tube in ordinary use, in hope that, by passing the fluid further on, it might not be vomited again.

17th.—I had a note to say that the patient was suffering so much at each time of feeding, that on the previous day Mr. Musgrave recommended that it should be abandoned, and that food should be administered *per rectum*. I went to see her, taking with me a small rectum tube, as the long catheter was not ready. I passed the rectum tube for a short distance down the œsophagus without difficulty, but then found an obstruction, through which the tube passed with difficulty, giving rise immediately to violent coughing, air being drawn freely in and out of the tube. I ventured to push the tube a little further on, in hopes that, if it were in the œsophagus, it might go beyond the opening in the trachea, but was obliged to withdraw it, as it nearly suffocated the patient, having, I believe, passed into the trachea. I believe, therefore, that the œsophagus is nearly or entirely obstructed by the cancerous growth, and that a large opening exists between it and the trachea, through which the food has for the last few days either found its way directly, or perhaps a very small quantity having passed into the stomach, has afterwards been vomited, and has thus got into the trachea.

19th.—Having procured the long catheter I made another attempt with precisely the same results, and, therefore, gave them up for the future. Mrs. S. has nourishment administered *per rectum* every four hours, and is relieved at not having to undergo the painful operation of feeding.

26th.—Has decidedly lost ground since the last report. Is troubled with occasional efforts at vomiting, though, of course, nothing comes up. Within the last two days the left arm has become somewhat swollen and œdematous, and, I find, that there are a few large glands in the left axilla.

May 3.—Condition much the same; but the patient is weaker, and has constant sickness, and brings up bile through the tracheotomy tube. Face slightly puffed.

12th.—Lying in an unconscious condition.

13th.—Mrs. S. died quietly at 6 a.m.

*Post-mortem Examination.*—I removed the tongue, larynx, œsophagus, and enlarged glands in the neck, *en masse*. On laying open the œsophagus from behind I found that it was completely obstructed by the thick edges of an ulcer, of malignant appearance, in the centre of which was a large aperture, opening directly into the trachea, opposite the wound made in the operation. Several rings of the trachea were gone at this point; and, in fact, there was one large *cloaca* at this spot. In the larynx on the left side was a growth of soft cancer, completely blocking the passage, and, no doubt, this was the original cause of the dyspnoea. The cricoid and thyroid cartilages were necrosed, a large portion of the former being wanting, and the latter being broken in half. The thickened tissue in front of the trachea seemed to have almost entirely disappeared; but there was a mass of cancer on the left side of the neck, through which the vessels and nerves ran, and with which the muscles were inseparably involved, but this did not seem to have exercised pressure in the trachea. The thyroid gland was a little enlarged on the right side, but could not be defined on the left.

There can be no question, I think, that the primary disease

and cause of the dyspnoea was the growth in the larynx; and had the laryngoscope been as much in vogue then as it is now, it is probable that this might have been discovered. Even then, however, I do not see that any other treatment than that adopted could have been pursued, since it would have been impossible to have interfered with the growth from the mouth. The difficulties encountered in the operation of tracheotomy were such as will be seldom met with, for even Mr. Fergusson, with his immense experience, had never met with a parallel case. It may be questioned whether the opening into the œsophagus was not the result of the irritation and pressure of the tracheotomy tube, since several cases have been recorded of this nature; but I am inclined to believe that in this case the disease commenced in the œsophagus and cut through into the trachea, on account of the difficulty of swallowing, noticed prior to the formation of the opening, and also on account of the disease found in that viscus. What the tissue was which caused the extreme difficulty in the operation of tracheotomy must remain undecided, as the growth had almost entirely disappeared (no doubt partly by suppuration) at the time of death, five months after the operation, at the date of which it presented every appearance of scirrhus. Mr. Bryant, of Guy's Hospital, has recorded a case (Clinical Surgery, Part II.) in which a tumour in a similar position, and necessitating tracheotomy, entirely disappeared after the operation.

31, Sackville-street, W.

## CLINICAL MIDWIFERY.

By FRANCIS H. RAMSBOTHAM, M.D.

Physician-Accoucheur to the London Hospital, etc.

(Continued from page 598.)

THE following seven cases of transverse presentation occurred in my practice during the years 1843 and 1844:—

### *Left Shoulder Presentation.*

*Case 166.*—On February 24, 1843, at 2:30 p.m. I was sent for by one of the midwives of the Royal Maternity Charity, to Mrs. J., Spitalfields, in labour of her fourth child. With her first child the head presented; the second and third had been transverse cases. I found that the membranes broke at 12 noon, and that just before I was sent for the hand appeared externally. The left shoulder was occupying the pelvic brim, the arm down, the palm of the hand was looking forwards, and the head was resting on the left ilium. There had been scarcely any uterine action since the liquor amnii was discharged. I introduced my left hand without difficulty into the uterus, hooked my finger in the left ham, turned, and extracted the child easily. It was living. The placenta was expelled speedily, and she recovered well.

### *Transverse Presentation.*

*Case 167.*—On September 2, 1843, at 9:30 a.m., I was sent for by a Medical friend to Mrs. T., Limehouse, in labour of her second child; the first was born nine years ago. The membranes broke at 7 o'clock the evening before, previously to which my friend "could not feel any presentation." After that the uterus remained passive for three or four hours, and then began to act vigorously, when the right hand came down into the pelvis. Being foiled in his attempts to turn, he sent for a neighbouring Practitioner, who also failed; and then a third was summoned, who was as unsuccessful as the other two. Throughout the night I understood that many abortive efforts at delivery were made. When I arrived, the patient, her husband, and two sisters all declared that nothing more should be done, but that she should be allowed to die in peace; however, after reasoning a little with them, I was permitted to make an examination. I found the right hand external, much swollen, and livid, the palm looking forwards, the head resting above the right ilium, and the edge of the right scapula presenting very high at the pelvic brim. The left hand and forearm were also in the pelvis at the posterior part; and the left foot, with the noose of a tape around it, and the ankle joint severed, was at the brim towards the left ilium. The uterus was very strongly contracted round the child's body, and the vagina and external parts were acutely tender. The conjugate diameter of the pelvis at the brim measured but little over three inches. I was told the first labour had been easy; but it is quite

probable, that during the intervening nine years the pelvis might have deteriorated in size. As passing the hand into the uterus to turn the child was out of the question, I proposed to exviscerate the chest and abdomen. I, therefore, made an aperture with Smellie's scissors below the axilla; but the part lay so high that I could not get away any of the viscera. I then, with some difficulty, passed the tape which was round the ankle up above the knee, and thus got a firm purchase downwards; then, by pulling at the tape, and at the same time pressing against the upper part of the child's trunk, I made the body revolve, and brought the breech into the cavity. The shoulders cleared the brim comparatively easily; but I was compelled to perforate the skull behind the ear, and evacuate a considerable portion of the brain before the head would pass. The uterus acted well during extraction; but some hæmorrhage coming on induced me to introduce my hand for the purpose of removing the placenta; it was firmly adherent throughout about half of its extent, and that part was much firmer and more solid than natural, with a quantity of coagulable lymph thrown out into its structure, as well as on its maternal surface, so as to give it a leathery feel, and white appearance. The woman did well.

The fortieth case, which I have reported in the Number of this Journal for February 15 of this year, will be found to be a case of transverse presentation, complicated with unavoidable hæmorrhage.

*Transverse Presentation at Seven Months—Exvisceration.*

Case 168.—On January 25, 1844, at ten p.m., I was requested by a Professional friend to see Mrs. J., behind the London Hospital, between seven and eight months advanced in her first pregnancy. Pains came on early in the morning of the previous day, the 24th, but no presentation could be discovered by her Medical attendant. The membranes broke at noon, still the child lay too high for any part of its person to be felt by the finger. Directly the membranes had ruptured, the uterus ceased to act, and did not resume its contractions till seven o'clock on the evening of the 25th. Her Medical friend was summoned at 8; he then found an arm doubled in the vagina, and, having made an unsuccessful attempt to "turn," he sent for me. The left hand was then external, with the palm looking forwards, the head above the left ilium, and the brim of the pelvis completely filled by the child's chest, which was wedged into it strongly; the cuticle was peeling, and a fold of the funis quite flaccid prolapsed. The uterus was acting very forcibly. As "turning," if practicable, would have been both difficult and dangerous, I at once perforated the chest, by means of Smellie's scissors, took away the viscera of the chest and abdomen, so that the trunk doubled upon itself; and by fixing a crotchet on the fetal pelvis within its body I brought the breech down, caused it to sweep along the sacrum and perineum, and thus extracted the trunk, breech foremost. During this time the perineum was placed greatly on the stretch, but it sustained no injury. The operation did not occupy half an hour. The placenta passed quickly, and the patient recovered exceedingly well.

*Transverse Presentation.*

Case 169.—On March 27, 1844, at 7.30 a.m., I was requested by one of the Surgeons to the Royal Maternity Charity to visit Mrs. R., Waterloo-town, in labour of her third child. The membranes broke twenty-four hours before; but, as is usual in these cases, the midwife had not discovered the presentation, and the uterus ceased to act after the water was discharged. It resumed its contractions at 5 a.m. The midwife was summoned at six; she found a hand external, and sent for the District Surgeon, who, having tried ineffectually to turn, dispatched a messenger for me. I found the right hand external, the palm looking forwards, and the head resting above the right ilium. The funis was also prolapsed, not pulsating. With some difficulty I passed my hand into the uterus, but could not introduce it high enough to reach a foot. I therefore hooked my finger in the right ham, and turned comparatively easily. The placenta followed soon, and I left her comfortable. She went on very well for nine days, and then began to complain of pain in the right hypochondrium. This was relieved by leeches; it was not, indeed, severe. But on April 7, after eating an orange, she was attacked with violent vomiting, which continued all night most distressing. She said she was convinced something had given way within her. She gradually sank, and died at eight o'clock the next morning. On a post-mortem examination we found a fleshy tubercle, the size of an ordinary

apple, on the right side of the uterus externally, in a state of suppuration and gangrene.

*Transverse Presentation.*

Case 170.—On May 14, 1844, at 11 p.m., a Medical friend sent for me to Mrs. H., Mile-end-road, in labour of her third child. The first was a natural labour; the second a transverse presentation. The membranes had broken one hour; the right shoulder was at the pelvic brim, the head on the left ilium, the face looking towards the mother's spine. The uterus was acting very feebly. I passed my left hand without difficulty into the uterine cavity, and turned the child easily, having seized both feet. In consequence, however, of the pelvis being narrow at the brim, the head gave me some trouble. Nevertheless, the child was born alive; the placenta passed soon, and the woman did well.

*Right Shoulder Presentation—Spontaneous Evolution.*

Case 171.—On November 21, 1844, at 9.30 p.m., I was summoned by a Medical friend to Mrs. S., Ratcliffe, in labour of her sixth child, at full time. The membranes broke at 4 p.m., and the right arm came down; the palm was looking backward, and the head was above the right ilium. At 8, the pains became very forcing, and the side of the child was wedged in the pelvic cavity. The whole of the shoulder was expelled, the sternal end of the clavicle thrust forcibly under the symphysis pubis; the breech was squeezed into the pelvis along the left ilium, was then propelled along the sacrum, and expelled, distending the perineum to an enormous extent; while the body of the child turned on the under surface of the symphysis pubis as on an axle, the angle formed by the neck and the clavicle being the point on which it revolved. The left arm and the head immediately followed. I arrived in time to observe the latter part of this process. The child was, of course, dead; it was larger than the average size, and the right arm, shoulder, and right side of the chest and back, almost as far down as the pelvis, were much swollen and quite livid, indicating the strong pressure to which its body had been exposed. My friend said that at 6 o'clock he felt the shoulder and the neck, and at 8 o'clock the ribs, distinctly. The placenta was speedily expelled, and the woman recovered very well. She must have had a much larger pelvis than usual to admit of the child passing in this doubled state.

N. B.—Douglas and Denman thought the shoulder receded into the uterus, as the breech was expelled downwards, and they, therefore, called it a "spontaneous evolution;" but I am quite convinced, from this, and three or four other cases of the same kind that I have watched, that the shoulder does not recede, but, on the contrary, with the chest, is thrust further and further external in proportion as the breech descends into the pelvis.

## CASE OF POISONING BY VERATRUM VIRIDE.

By G. N. EDWARDS, M.D. Cantab.,  
Assistant-Physician to St. Bartholomew's Hospital.

ON Thursday evening, December 18, I was summoned to see a gentleman, a scientific chemist, who had taken, experimentally, one drachm of tincture of green hellebore (equal to about twelve grains of the powder). On my arrival, I found him sitting in the water-closet vomiting into the pan. His features were sunken; skin cold, and covered with a profuse, clammy sweat; his pulse quite imperceptible. He complained of intense pain about the epigastrium. The vomited matter appeared to consist at first of the food and contents of the stomach, afterwards of glairy mucus. I gave him immediately about an ounce and a-half of pure brandy, which at once checked the vomiting. At this time I was joined by Mr. Buxton Shillitoe, the patient's usual Medical attendant. As he had slightly rallied, we had him moved into a room a few yards from the water-closet, and laid on the couch in front of the fire. The surface of the body was still very cold, especially the extremities. The clammy sweat continued, but the pulse could be felt indistinctly, beating, very feebly and irregularly, forty-four in the minute. A dose, containing Sp. æther. sulph. co. ʒss., and sp. ammon. arom. ʒj., was given, but immediately rejected by the stomach; but some brandy, given directly afterwards, was retained. A large mustard poultice was applied to the epigastrium, and a hot-water

bottle to the feet. Two or three efforts at retching afterwards took place, and he once or twice vomited food, mucus, and a small quantity of blood. Warmth gradually returned to the surface, and the pulse became somewhat better in volume and power. Brandy was given at short intervals, and after about an hour a second dose of æther and ammonia, which was retained. The patient then fell asleep, slept for about a quarter of an hour, and awoke with the expression, "I am all right now," and appeared comparatively well. There was no diarrhoea throughout. He had two or three times a slight return of the symptoms; did not sleep during the night, but was quite easy; and the next morning only felt the discomfort arising from the mustard poultice and the soreness of the muscles caused by the retching. He then gave us the following account of his feelings during the attack:—

"Before taking the dose of the tincture, I had consulted Pereira, and, finding Dr. Mead's dose of the Tinct. helleb. nig. to be two teaspoonfuls twice a-day, and knowing the green hellebore to be of the same tribe, I considered, in taking one teaspoonful, I was rather under than overdoing it. The drachm of the tincture was taken about half-past four or a quarter to five o'clock p.m., and my stomach soon afterwards whispered that I had admitted a troublesome guest. I went upstairs and sat down, thinking a cup of tea would set all right; but the uneasy constriction of the stomach continuing, with a tendency to sickness, made me retire to the water-closet. The sickness, once commencing, soon became alarmingly violent, with the most excruciating pain in the lower part of the stomach, the pain extending to about the size of my hand; the feeling of the seat of the pain was, that all the warm tea, water, etc., that I took to provoke the vomiting, went under the pain, making the constriction more and more violent. Finding the case getting desperate, I sent off for Medical aid; the pain continued to increase, and the ejection from the stomach was now glairy mucus with blood, with running from the nose and eyes. The most painful and profuse cold sweating now came on, and the difficulty of breathing became more and more laboured. I could not help wondering at the presence of anything like heat or constriction of the throat; my mind was perfectly calm; and, although I thought it more than probable that I should die, I did not feel alarmed. Hearing and recognising the voice of one of my Medical friends is all I recollected for some time afterwards. Immense circles of green colour appeared round the candle, which, as vertigo came on, and I closed my eyes, turned to red. The pain continued excruciatingly at the pit of the stomach, and a slight tendency to cramp existed when my legs were touched. It was some hour or more afterwards when I awoke, and found myself comparatively well. The sting of the mustard I can well recollect, and the horror of being forced to swallow brandy is even now with me. My bowels were not at all acted on. The next morning I took a dose of eitate of magnesia, and, in the evening, a blue pill, with colocynth, which relieved my bowels this morning."

Veratrum viride does not appear to have been much used in this country; but, in America, a pamphlet has been published, on its employment, by Dr. Ephraim Cutter, of Woburn, Mass.; and several articles have appeared in the Medical journals respecting it. It is also described in the last edition of "Percira's Materia Medica," where the symptoms from an overdose are stated to be precisely those observed in our patient. No authenticated case of poisoning by it has been recorded. The full dose of the tincture is eight minims.

**WHALE STEAKS.**—In passing along the street we saw strips of whale-flesh, black and reddish-coloured, hanging outside the gable of almost every house to dry, just as we have seen herrings in fishing-villages on our own coasts. When a shoal of whales is driven ashore by the boatmen, there are great rejoicings among the islanders, whose faces, we were told, actually shine for weeks after this, their season of feasting. What cannot be eaten at the time is dried for future use. Boiled or roasted it is nutritious, and not very unpalatable. The dried flesh which I tasted resembled tough beef, with a flavour of venison. Being "blood-meat," I would not have known it to be from the sea; and have been told that, when fresh and properly cooked, tender steaks from a young whale can scarcely be distinguished from beef-steak. —*Pen and Pencil Sketches of Laroe and Iceland.* By A. J. Symington. Longmans, 1862.

## REPORTS OF HOSPITAL PRACTICE

IN

### MEDICINE AND SURGERY.

CONDUCTED BY

JONATHAN HUTCHINSON,

Assistant-Surgeon to the London Hospital, and Surgeon to the Metropolitan Free Hospital,

AND BY

J. HUGHLINGS JACKSON, M.D.,

Physician to the Metropolitan Free Hospital.

### ST. BARTHOLOMEW'S HOSPITAL.

#### CLINICAL REMARKS ON A CASE IN WHICH PART OF THE SCAPULA WAS REMOVED FOR MALIGNANT DISEASE.

(Case under the care of Mr. PAGET.)

In this journal for November 15 we gave a brief note of Mr. Paget's operation for removal of a malignant tumour of the scapula, and also a report of the remarks he then made. In his next clinical lecture, Mr. Paget spoke more at length on the case. The following is a brief report of the lecture:

He began by saying that, in a case like this, the whole interest before the operation lay in the diagnosis as to the nature and position of the tumour. In this case the situation of the tumour would help also to show its nature.

First, as regards the situation. It was clear that it covered nearly the whole of the infra-spinous region of the scapula. The first point to decide was, as to whether it affected the under surface of the bone as well as the upper. As the scapula was not projected from the chest wall, it seemed that the under surface was free. In cancer of bone, both sides are generally affected, and hence the fact, that in this case one side only was affected, was evidence against malignancy. It was not very important, but still it was some evidence, and might help to lead astray in diagnosis. Having thus decided that the tumour was on the upper side, the next question was, does the tumour grow from the bone? On this point there were differences of opinion. The scapula is naturally so movable that it is difficult to tell when a tumour is fixed to it or not. Mr. Paget believed that it grew from the bone. Another question was, as to the position of the tumour as regards the muscles. There was a means (Mr. Paget said) of ascertaining generally whether tumours were above or under muscles. It was this: to fix the parts which the muscles in question act on, and then direct the patient to endeavour to perform the resisted movement. The muscular action, if the muscles were under the tumour, would elevate it; on the contrary, if above, they would depress it. A peculiar sensation also was given to the hand, which was to be learned in practice, and was difficult to explain. This was only felt when the muscle was superficial, not when under the tumour. The same method would guide us in diagnosing the position, in reference to muscles, of fluid as well as solid tumours.

In this case, then, Mr. Paget came to the conclusion that the tumour was seated under the muscles, that it was fixed to the scapula, and that it did not affect both sides of the bone.

As to the nature of the tumour, it might be either fibrous, recurrent fibroid, cartilaginous, myeloid, or medullary. It might also be a deep-seated abscess, or hydatid. First, was it fluid or solid? The feeling of indistinct fluctuation was no sign at all that it was fluid. In the case of a small abscess the fluctuation might be indistinct, but in one so large as this, if fluid were present, the fluctuation would be distinct.

Another kind of fluid swelling was often taken for a solid one, viz., hydatid. We ought always to be on the alert for this, especially in tumours of bone. Hydatids may distend bone, so that their covering becomes so thin that the feeling may be quite that of a medullary tumour. Indeed, in such cases, it is wise to proceed in the operation on the supposition that it may be hydatid. As to the list of solid tumours, Mr. Paget said that he did not know from touch any characters by which medullary tumours could be certainly distinguished from the others, as even the cartilaginous tumours were sometimes soft.

The chief points in diagnosis of its nature are—1st, the position. A considerable proportion of tumours of the scapula are medullary. 2nd, the age of the patient. A majority of large tumours in persons so young are medullary.

3rd, the rapid growth—in twelve months. This is not decided evidence, but adds greatly to the probability. It was, therefore, most probable, but yet not actually certain, that the tumour was medullary. We ought to act on probabilities, and proceed cautiously. The puncture of the tumour, at the time of the operation, would not always decide the question as to its nature. The matter in the trocar, in this instance, might have been taken for myeloid.

Mr. Paget next spoke on the grounds on which we ought to operate in such cases. He said that it was impossible to be actually certain that the disease was cancer, until the operation was half over. Also, he would not say, that it was not justifiable to remove cancer of bone, as, although the disease is sure to recur, there is generally a period of immunity from it. In many cases, we must operate almost against hope, with a very small probability of recovery. This is so when we are certain that the disease will ultimately recur. When uncertain, the grounds for operation are all the stronger. He had two cases in mind which showed clearly that life was lost from not giving the patient the chance of operation in what was supposed to have been malignant disease. In one, a tumour grew rapidly in the upper part of the thigh. It was thought to be malignant, and was, therefore, left alone. The patient died a miserable death. Then it was found that the tumour was simply cartilaginous. This patient might have lived to old age if his leg had been amputated. Mr. Paget related another case somewhat similar. In this instance, the tumour, also of the thigh, was cystic. It is very rare (he said) that we can arrive at such absolute certainty as to decline to operate. Another question as regards operation in case of cancer of bone is,—Is it sufficient to remove the part affected, or should we take away the whole bone? The answer is,—That if the removal of the whole bone does not increase the risk to life, do it; but otherwise remove only the part affected. As regards disease of the scapula, the question is not often raised; a disease of this bone is rare. But in cancer of the lower end of the femur, we ought not to remove the whole femur, as amputation at the hip-joint is an operation involving great risk to life. If, however, we have cancer of the middle of the tibia, we ought to amputate above the knee.

### THE LONDON HOSPITAL.

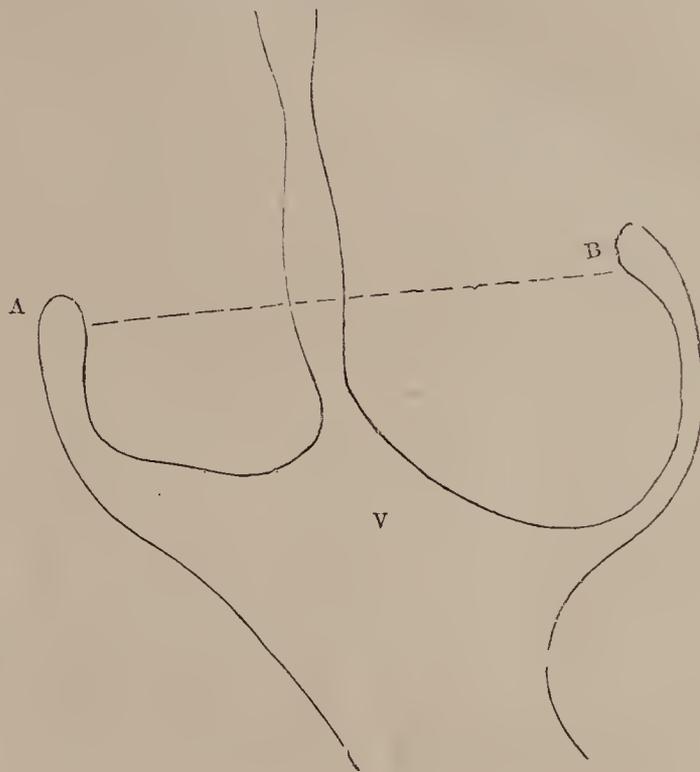

#### HYPERTROPHIC ELONGATION OF THE CERVIX UTERI—FAILURE OF CAUTERISATION—AMPUTATION BY MARION SIMS' METHOD—SUCCESSFUL RESULT.

(Under the care of Dr. BARNES.)

G., a woman aged 35, was admitted an out-patient on February 12, 1862. She has had five children and one abortion. The last labour was two years ago; it was a cross-birth. Since then she has suffered much from metrorrhagia, dysuria, painful defecation, leucorrhœa, pelvic and dorsal pains, loss of strength and flesh, and bearing down. The os uteri was near the vulva, but there was no marked descent of the body of the uterus; the uterine sound penetrated more than three inches; the apparent prolapsus was due to the greatly hypertrophied and elongated condition of the cervix. The anterior lip was especially affected; it expanded into a hard tumour, which fretted the vagina by constant pressure and friction. The potassa cum calce was applied to the anterior lip, so as to produce a large eschar, and it was thought that some diminution of bulk followed the healing of the sore. The cauterisation was repeated several times in the course of the ensuing four months. The ultimate advantage was very doubtful. She then wore a stem pessary for some time, but this only doubled up the elongated cervix, without producing any diminution of bulk, or bringing the patient material relief. Dr. Barnes, therefore, determined upon amputation as the only means of restoring the patient's health.

On September 5, she was admitted as an in-patient. Under the influence of prolapsus and friction, the enormously enlarged cervical portion, acting as a polypus or foreign body would, had caused considerable inflammation of the vaginal mucous membrane, as well as of that covering the cervix. Dr. Barnes kept her in bed some days, to allow this condition to be relieved under rest. This being accomplished, and a menstrual period having passed by, Dr. Barnes proceeded, on September 27, to amputate the vaginal portion of the cervix on the method practised by Dr. Marion Sims. The patient

being placed under chloroform, the uterus was pressed downwards by firm pressure over the abdomen, whilst the cervix was seized and drawn forwards by Museux's vulsellum, the vagina being opened by a duck-bill speculum on either side. The anterior and posterior lips of the hypertrophied cervix were then successively cut off by bent scissors. An even incised surface was secured by paring off the mucous membrane at the angles of union of the lips. Very little bleeding occurred. A small roll of lint, soaked in solution of perchloridè of iron, was placed in the canal of the cervix. The stump was then covered by bringing together the edges of the mucous membrane by iron wire carried by the curved tubular needle. In this manner a very neat and perfectly covered stump was made.

The dotted line A B represents the line of amputation. V. Vagina expanded above by the hypertrophied cervix uteri.

No examination of the patient was made for ten days. At the end of that time, the greater part of the stump was found to have healed. The sutures were removed at the end of fourteen days. There was a little healthy suppuration from the central part, but the cure was essentially complete. The patient suffered very little; she passed a menstrual period without discomfort, was free from vaginal distress, and was made an out-patient on October 21. In November, having returned to laborious avocations, she experienced some degree of prolapsus, which might be anticipated from the long-maintained relaxation of the pelvic structures. In general health she was quite restored. What little local distress remained was effectually relieved by the use of the stem-pessary generally adopted by Dr. Barnes in this Hospital. There is now no excess of cervix in the vagina, and the os uteri may be considered normal.

### KING'S COLLEGE HOSPITAL.

#### CLINICAL REMARKS ON RE-EXCISION OF THE KNEE-JOINT FOR DEFORMITY.

(Case under the care of Mr. FERGUSSON.)

MR. FERGUSSON made the following remarks in reference to a case in which he operated to restore deformity, which had followed after excision of the knee:—

The operation was a re-excision of the joint, or rather the cutting out of a wedge-shaped piece of bone. The patient, a girl about fifteen years of age, was first operated on by him about a year ago. She had chronic disease of the joint and a distorted limb. The limb was arrested in its development by the disease; it was bent and useless. He, therefore, performed an operation to take out the remainder of the joint, and a wedge of bone, in order that he might put the limb straight. In cases of deformity from disease of joints, it was right (he said) to try ordinary mechanical means. In some cases they

were efficient, but a case like this was not a fit one for extension treatment. He, therefore, took out a piece of bone; the result was, that the limb was at once placed in a perfectly straight position. Soon after the operation, however, the girl had severe fever—very like pyæmia. She had abscesses in various parts of the thigh, none of them directly communicating with the wound of the operation; it was, therefore, impossible to retain the limb in the position in which it had been placed after the operation. No splint could be applied, so that during the time of her illness the limb got out of place. After all, however, she recovered well, the wound healed, and ankylosis took place, but, as stated, the limb was in a wrong position, the leg being much flexed on the thigh. There was, however, nothing left but deformity; there was no actual disease. At one time (Mr. Fergusson said) it was thought that, if a diseased joint could be removed safely, the result was very good, and the case would then have been thought a very satisfactory one.

Sir Philip Crampton once removed a knee-joint, and thus got rid of all the disease. The patient recovered, but the leg was bent at a right angle. It was useless, and would have been better off. The patient, however, was delighted with the result—so well satisfied that she bequeathed her leg to Sir Philip. The leg is now in the College of Surgeons' Museum. Such a result, however, would not satisfy him (Mr. Fergusson). His object was to give the patient an useful limb, as well as to get rid of the disease. This latter seemed to be the only result aimed at by some of the curers of diseased joints. Surgeons might do a great deal, but to say that disease of a joint was cured, when the result was that the limb was useless, was a perversion of language. It was better to amputate than to leave the patient with a leg which was simply cumbersome. As he had said, there were cases in which mechanical means would straighten bent limbs; but, as this was a case of ankylosis, it was better to cut out a piece of bone. This was, therefore, a second excision. In one instance he had excised portions of bone no less than three times, and with a most satisfactory result. Of course, in case of excision of a joint the limb could never be quite as good as its fellow. This could not be expected any more than that a limb, after the so-called cure of disease of a joint, should be perfect. Some writers seem to him (Mr. Fergusson) to expect that the leg, after excision of the knee-joint, should be as good as it had ever been. If compared, however, with a wooden-leg, or the best possible mechanical contrivance, it was much superior.

The worst feature in case of excision, and one much dwelt on, was, that the leg was shorter than the other; granting that, the result was still better than many cases of cures, or than amputation. Another thing against the operation often spoken of was, that the muscle of the calf wasted. This was contrary to fact. In his cases the muscles had regained their fullness and vigour after the operation.

In the case he had just operated on there was less risk than in amputation. In fact, no one could compare the risk of taking a wedge of bone out of an ankylosed limb, and amputation of the thigh.

### ST. THOMAS'S HOSPITAL.

#### CASE OF TYPHUS RESEMBLING TYPHOID, AND PROVING FATAL AT AN UNUSUALLY LATE PERIOD OF THE DISEASE—WITH REMARKS.

(Under the care of Dr. PEACOCK.)

A NIGHT nurse, 27 years of age, was admitted into Elizabeth's ward, St. Thomas's Hospital, on November 25, under the care of Dr. Peacock. She had been ailing for nine days, but so severely ill as to be confined to bed for three or four days. When admitted, she complained of pains in all parts of the body, and especially in the head and back, and of sore throat; and, on examination, the fauces were found red and swollen; the pulse was quick, the skin hot, and perspiring profusely. On examining the body, spots, bearing a complete resemblance to those of typhoid, were found on the abdomen and thorax. They were insulated, elevated, of a rose colour, and faded completely on pressure, and were only few in number. Two days after, she had become prostrated and torpid, and the spots had much altered their appearance; they were still elevated, but no longer of a rose colour, and had become livid, and did not entirely fade on pressure. An obscure purple mottling was also visible in the interjacent skin. At a still

later period of two days, the original spots were no longer to be distinguished, but their situations were indicated by small purple patches, not elevated, and not affected by pressure; and the obscure mottling of the interjacent skin had become a full livid rash, which was perfectly characteristic of typhus. With the progress of the disease also, the symptoms had become more decided: her intelligence was greatly impaired, so that she could not be got to take sustenance, or to protrude the tongue; the tongue was dry and black; sordes formed on the lips and teeth: the face was excessively flushed; the pupils contracted; the conjunctivæ injected; and there was tremor of the extremities, great distension of the abdomen, and the involuntary discharge of fæces. The urine was partly retained, partly passed unconsciously. The bowels also were, from time to time, much relaxed. By the employment of blisters to the back of the neck, scalp, etc., and the exhibition of stimulants and support, by the mouth when possible, and by the rectum, she was partially rallied, but the coma recurred; there were slight convulsive movements of the head and neck, and extreme prostration, and she died on December 9, or the seventeenth or eighteenth day of serious illness, and the twenty-third of indisposition.

On examination after death, there was found scarcely any fluid beneath the arachnoid or in the ventricles at the base; the brain retained its natural consistence, but the red dots were unusually numerous. The posterior and inferior parts of the lungs were congested, and in places collapsed. The bronchial tubes, generally of the left lung, and the smaller tubes of the right, contained an unusual amount of secretion, and the mucous membrane of the former was congested. The heart was flaccid, and contained blood in all its cavities, but no coagula. The mucous membrane of the alimentary canal was free from any appearance of disease, except some passive congestion of the cæcum and colon. At the lower part of the ileum the plates were barely visible; not distinctly defined; depressed below the level of the adjacent surface, and marked by the dark spots or lines usually seen after death from acute affections not connected with the bowels. The mucous membrane was not injected, and retained its natural tenacity, allowing of being drawn off in stripes of the usual length. The serous coat was free from any appearance of redness, and the mesenteric and mesocolic glands were not enlarged. Some solid fæcal matter was contained in the colon. The spleen was large, and somewhat soft. The liver, supra-renal capsules, and kidneys were congested.

This case was made the subject of some observations by Dr. Peacock, in one of his lectures. He remarked—

1st. That it showed how closely a case of typhus may sometimes simulate typhoid. The mode in which the case commenced was not that which is usual in typhus. The patient had been ailing for several days before the severe symptoms commenced; and, when admitted, she had rather the appearance of a patient suffering from a feverish cold than from specific fever. She had been acting as night nurse in the ward since the opening of the temporary Hospital in September, and had, during all that time, been exposed to the contagion of typhus from patients under treatment. She had, however, been sleeping in a room on the ground floor, in which there was no proper system of under-drainage, and where, consequently, she might have contracted typhoid. The eruption also, when first seen, bore an exact resemblance to the usual appearance of typhoid spots, and it was only by watching the case that the true character of the rash was made apparent. Dr. Peacock had referred to cases of the same kind in his lectures on the "Discrimination of the Varieties of Continued Fever" (a); but he said that the present was the most striking instance of the kind which he had seen.

2nd. Though the cerebral symptoms were, during the greater part of the attack, very marked, and the patient became comatose, and was slightly convulsed before death, the brain did not present any signs of disease; and even the congestion which was detected was probably only the result of the obstruction to the pulmonary circulation in the last periods of life.

3rd. The congestion and collapse of the dependant portions of the lungs, were very marked; but these also may be ascribed to the failure of power in the heart and of respiratory movements, from the influence of the fever poison.

4th. The patient died at a later period than usual in cases

(a) *Medical Times and Gazette*, 1856.

of typhus—certainly not before the seventeenth or eighteenth day, probably as late as the twenty-third; and during the latter part of her illness had diarrhœa, at intervals very profuse, and great abdominal distension. If, then, these symptoms had been indicative of any active disease in the intestines, there was ample time for such to have manifested itself. The examination after death showed, however, that the intestinal tissues were entirely healthy, except that some passive congestion existed in the large intestine, corresponding with that of the chylopoietic viscera, and of the body generally. These conditions, therefore, like the involuntary discharge of fœces and the retention of urine, are all to be ascribed to the excessive prostration of strength and of nervous power.

That these various changes may be traced to the direct influence of the febrile poison on the system is in accordance with the deduction, from widely-extended experience, that the various symptoms which accompany fever are to be combated chiefly by means directed to the support of the patient's strength, in the hope that life may be sustained for a sufficient length of time for the poison to be decomposed or eliminated from the system, and for its effects to cease.

### ST. GEORGE'S HOSPITAL.

#### ANEURISM OF THE ARCH OF THE AORTA PRESENTING BENEATH THE LEFT CLAVICLE.

(Case under the care of Dr. FULLER.)

J. A., a stableman, aged 35, was admitted into the York ward of St. George's Hospital on April 2, 1862. He had been an out-patient for nine months, suffering from cough, pain in the chest, and between the shoulders, shooting down the left arm, and frequent giddiness and headache. When first attacked, he brought up about half-a-pint of dark-coloured blood, and six weeks afterwards had a slight recurrence of hæmoptysis, since which time the sputa have been streaked with blood occasionally. Three weeks before admission, he for the first time perceived a small circumscribed swelling, attended with pulsation on the sternum towards its left side, and on a level with the second rib. Twelve years previously he had a kick on the chest from a horse, but recollects little about it, except that such an occurrence took place.

On admission, his aspect was natural; tongue white; bowels reported regular; urine clear; his pulse was 72, soft and regular; the right radial pulse was scarcely perceptible. There was dyspnœa and some degree of orthopnœa, and frequent cough, with expectoration of thick yellow mucus. A circumscribed pulsating tumour, about the diameter of a hen's egg, existed to the left of the mesian line of the sternum, on a level with the second rib. He reported that this swelling increased in size after coughing, and on two occasions, after long freedom from cough, had entirely disappeared. The heart's impulse was natural, and its sounds were clear both at the base and apex. The pulsation of the tumour was synchronous with the systole of the heart. Both sounds of the heart were heard over the tumour, and there was no perceptible murmur. Both pupils were moderately and equally dilated.

He was ordered—Tr. hyoscyami, ʒj.; haustus nitri., ʒxj., ter. die.; haustus morphiæ, ʒj.; olei ricini, ʒjv., p.m., (ordinary diet); emplastrum belladonnæ, regioni cordis.

He went on without much variation until the 7th, when the tumour had increased considerably in size; the integuments around it were somewhat œdematous; he suffered much pain in the region of the tumour, was extremely restless, and was unable to obtain ease in any position. Slight ptosis of the right eyelid was also observed, and extreme contraction of the right pupil. The left pupil was moderately dilated, and both acted under the stimulus of light.

On the 8th, paroxysmal attacks of urgent dyspnœa occurred; he complained of frequent giddiness, the pulse was 72, irregular, and the pulse at the right wrist was imperceptible.

From this time the tumour rapidly increased in size, and the symptoms became more urgent and distressing. Considerable pain was felt around the tumour; the dyspnœa became constant; frequent attacks of fainting occurred; and he was usually bathed in a clammy perspiration.

On the 12th the ptosis of the right eyelid was observed to have decreased, but the contraction of the pupil continued as before.

On the 15th, whilst eating his dinner, a paroxysm of dyspnœa suddenly came on, and, after half an hour's struggle, he died.

The post-mortem examination was performed twenty-four hours after death. A soft livid prominence, nearly circular, of about three inches in diameter, covered the upper part of the sternum, and reached as high as the notch. This was most prominent a little to the left of the mesian line. A deep hemispherical cup was hollowed in the upper part of the sternum. This might have held half a tennis-ball. Between the articulations of the two first ribs on the left side the sternum was absorbed and worn through, and the sternal extremity of the first rib was also destroyed. The heart was natural. In front and to the left of the ascending aorta was an aneurismal pouch, which formed two-thirds of a sphere, and was about an inch in diameter. This was connected with the aorta by a smooth round opening, about an inch above the semilunar valves. At the superior part of the arch was another smooth circular opening, of rather more than an inch in diameter. This was placed slightly towards the anterior aspect of the vessel, and led to a large globular sac, thickly lined with coagula. The innominate artery opened into this sac near to its orifice, and, from its position, it was obvious that the artery must have been compressed by the tumour which laid against its anterior wall and its orifice, obstructed by the coagula which lined the sac. The carotid opened into the sac in a similar manner, just within the orifice of the sac and to its extreme left; the subclavian sprung from the aorta just beyond the boundary of the sac. These vessels appeared to be healthy; but the lining membrane of the aorta was raised in many places by soft atheromatous deposits. The right lung was œdematous; it contained a few crude tubercles, and a small vomica at the apex. The left contained several small vomicæ at the apex, crude tubercles scattered throughout, and an old tubercular cicatrix near its inferior edge. Both lungs were adherent to the diaphragm. The kidneys and other abdominal organs were congested, but structurally sound. The arachnoid was somewhat thickened over the superior and lateral portions of the brain, and was studded with minute opaque spots. At the base of the brain it was quite natural in appearance. The substance of the brain was watery; and seven drachms of fluid were collected. The blood throughout the body was very fluid.

### HOSPITAL FOR THE EPILEPTIC AND PARALYSED.

#### EPILEPSY—AURA FROM THE TIP OF THE RIGHT INDEX FINGER—CONVULSIONS AND CRAMPS ON THE SAME SIDE OF THE BODY—RECOVERY.

(Case under the care of Dr. BROWN-SEQUARD.)

HENRY E., aged 17, was admitted an in-patient on May 7, 1862. As the interest lies chiefly in the peculiarity of the aura, and on the treatment of the case, many things noted according to a certain scheme at the Hospital are here omitted.

There was no history of any of the class of diseases supposed to be hereditary, except that his mother had a fit of some kind about a year before her death, which was at the age of 37. He had had, he thought, some kind of convulsive seizure in infancy, but could not be certain of it. He had never had worms, except ascarides five years before the first fit of the present series.

The first attack occurred in sleep. He was in it, he was told, for three hours, but he knew nothing of it next day; except that he was a little sickly, he felt quite well again. On the day after the fit, he had, what he then thought little or nothing of, a cramp in the right side of his body, the face, arm, and leg. He, however, kept well for six months, and then had another fit. Altogether, he has had twelve. He has no tremor, nor giddiness, nor *petit-mal*, and rarely headache, and his memory is good. His sight and hearing are good, and he has no loss of sensation or of motion anywhere, and, except a little temporary loss of power on one side, after an attack of cramp, he is quite well, except when he has the fits. In other words, his condition between the paroxysms appears good. His urine is free from albumen and sugar.

He always knows when the fit is coming on by a twitching and sensation of "pins and needles" in the tip of the right index finger, and this point is at all times tender to the touch.

Next, the feeling of "pins and needles" goes up the arm to the shoulder, and then down the side to the foot, so that after a while he has the sensation on the whole of the right side, except the face and head. Very soon after this warning he becomes insensible, but he has no twitching of the arm and leg before this. No accurate description of the fits was to be obtained, as he only had one after he came to the Hospital, and in this he was not affected quite in the same way as he had previously been. He had no warning. He was convulsed, however, on one side, that on which the aura was felt. He had several attacks of cramps in this side, and probably these were abortive fits, not going on to complete insensibility. In these attacks the face was drawn to the right side, and the arm and leg of the same side were drawn up. Once, after a rather more severe attack than usual, he lost power on this side of the body, the arm, and leg. When he flexed the last joint of the finger it caused pain, which "ran up the arm as high as the shoulder; it was like a cramp." He had the attacks of cramp about two or three times a-week. Sometimes, also, the hand would simply "crumple" up.

Iodide of potassium was given, and the cramps were kept off by blisters round the finger, below the point from which the aura started. This kept off the cramp for long periods. Next, an ointment of aconite was applied to the finger. He had but one real fit after admission, and after August 18 he had no attack of any kind. Up to this date, December 5, he is well.

## Medical Times and Gazette.

SATURDAY, JANUARY 3.

1863.

THE intelligence of Dr. Knox's death last week cut short the article in which we had proposed to ourselves to review the current events of 1862. That year was ushered in by a cloud that overshadowed every grade of society. The death of one so revered for qualities of heart and head as was the Prince Consort—a man who, by the sole force of moral and mental worth, and by unobtrusive, though unremitting toil for the good of people and Sovereign, had won the esteem, nay, the affection of a nation notoriously slow in surrendering national prejudices, and insular in feeling as in geographical position—sat like an incubus on all. Bitter the regrets, and all the more poignant, because the worth which death has indelibly stamped, in life too often escaped recognition. With the Sovereign the nation sympathised, as only a people can whose home-ties and domestic affections are the ruling powers of their national life. But time has softened, although it has not repaired the loss, and the year wanes amid brighter hues, and under a more joyous sky. True, a dark shadow still hangs over a large portion of the national industry. But it has called into play, on the one hand, the noblest qualities of the sufferers; on the other, the most generous efforts on the part of those who are removed from its immediate influence. The pulse of the nation beats healthily, and its aspect is

hopeful. The marriage of the heir to the throne, accompanied by every circumstance of political and personal fitness, will throw a brightness over the coming year, which must penetrate at once the humblest cottage and the proudest hall. Our Profession will cordially join in the general hope that, in the new ties which are thus to be founded, our beloved Sovereign may find alleviation under her burden of life-long sorrow.

We, too, sustained heavy losses by death. The mind reverts to the familiar names of Brodie, Stanley, McWilliam, Farre, Waller, Fyfe, Traill, O'Beirne, Crozier, and many others of minor note. Abroad, Medicine has lost one of its brightest ornaments by the death of Professor Schroeder Van der Kolk. No word of ours is required to embalm their memories or extend their fame. To us their example and their works remain,—a memorial and a heritage.

To turn to lighter topics. 1862 was productive of many events which directly affect the position of our calling. On the brighter side of the picture we find certain efforts that were made, on the part of the General Medical Council, and of most of the examining bodies, to extend and improve Professional education; the growing appreciation, on the part of the public, of the pre-eminent fitness of the Physician to investigate judicially the cause of death in doubtful cases, and the extension or adoption of sanitary improvements in many towns and districts. The election of Dr. Lankester to the coronership of Central Middlesex, uninfluenced as it was by political motives, may be taken as an exponent of the general reception of a truth which has been only gradually winning its way. Then, again, the meeting of the British Medical Association in London—the gathering together in our metropolis the representatives of foreign Medical science, attracted by the great Exhibition in Hyde-park, and the consequent traffic in intellectual wealth, and establishment of reciprocal friendships, are all circumstances which tend to enhance the position of the Profession scientifically and socially. Medical science, too, has itself advanced. New means of examination and diagnosis are being discovered, or old ones improved, every day. We need only point to the use of the laryngoscope and of the ophthalmoscope in the investigation of obscure disease of the vocal organs, the eye, and the brain. Curative measures are now daily adopted, which, a few years ago, were scouted as impracticable or worse. The operation of ovariectomy is saving many lives, which, not long since, were hopelessly condemned. The conditions of safety and cure are being reduced to something like mathematical certainty, and the Profession are daily proving their claim to be regarded the benefactors of mankind.

Amongst the most notable recent advancements in science is the discovery of dialysis by Mr. Graham—a process which, by taking advantage of the different rates of diffusibility of liquid substances, effects the analysis of composite fluids by a very simple process, manageable by those who have no great knowledge of analytical chemistry, and applicable, among other things, to Medico-legal inquiries, therapeutical preparations, and inquiries in physiology and organic chemistry. A full notice of the process and its applications will be found at page 111, vol. ii. of our journal for 1862.

If we now turn to the future, the point to which the attention of the Medical press is likely to be emphatically directed in 1863, is the action of the General Medical Council. Long denied to that passionate importunity which accompanies hope deferred, Medical Reform came at last. A Council was elected, representing institutions rather than the Profession directly, but certainly consisting of an unexceptionable selection of the best names in the Profession. Assured of peace at last, and of the existence of an authority whose word should be final, our members submitted quietly to what was virtual disfranchisement, and consented to pay a somewhat heavy fee for admission to the new register. Ere long, it was found that the Council afforded no protection to the Practitioner; they refused to

prosecute offenders. Their delay in issuing the new British Pharmacopœia has been unlucky, though unavoidable. They responded promptly and efficiently to the voice of the Profession in repudiating the new grain weight. But the delay in issuing the Pharmacopœia, coupled with the activity of the leading pharmacists in devising new forms of medicine, seem to show that the functions of a Pharmacopœia will henceforth be very limited. There must be standard strengths for solutions and compounds of the more energetic and poisonous medicines, and for the preparation of some of the more commonly-used compounds, such as the colocynth pill. But for the future, the list of the "Materia Medica" will depend on the repute of medicines for usefulness; the preparation of the chemical compounds will be directed by the considerations of cost and convenience to the manufacturer, whilst, as for *prescriptions*, properly so-called, they must and will vary at the pleasure of prescribers. Some new belladonna liniment may any day be discovered which will supersede that which has already acquired an undesirable notoriety.

But it is in respect to the functions of the Medical Council, as a Council of *Education*, that the greatest disappointment has arisen. It is now matter of history, that the Council propounded a certain scheme of education; that the College of Surgeons set them at defiance, and proposed another scheme, diametrically opposite to that which constituted its main feature; and that the Council, after discussion, quietly submitted to the revolt of the College of Surgeons. Thus, ancient chaos would seem to resume her sway, were it not that the growing appreciation of sound and prolonged Medical education by the public, and the good sense of students, will impel them to pursue the higher and better course marked out by the Medical Council, and to give that body a moral support against the defection of one of the most powerful corporations.

The peculiar function of a weekly journal is to lay before its readers the most advanced researches,—things that are not yet to be found in books. The substance of most of the best books appears in our columns, in the form of vigorous first sketches, a year or more before it is collected into those masses which, out of deference to ancient civilization, we still call "volumes." Another is to furnish an easy vehicle for bringing forward those results of long experience which are enumerated in the private notes and case books of the ablest Practitioners. The lectures and papers of Laycock, of Gulliver, Arthur Mitchell, Rolleston, William Adams, Professors Owen, Williams, Beale, and Radcliffe, Spencer Wells, Ramskill, and Soelberg Wells, well illustrate one department; and those by Conolly, Ramsbotham, John Adams, W. R. Wilde, and Whitehead, the other; whilst the crowd of original observations by such men as Paget, Le Gros Clark, Wilks, Risdon Bennett, Bulley, Peacock, Kirkes, George Johnson, Basham, Richardson, Cock, Prescott Hewitt, Barnard Holt, Gull, Aitken, Fincham, Hillier, Lawson, Cotton, Leared, Price, De Morgan, Fayrer, Alison, Ogilvie, Haynes Walton, Hutchinson, Hughlings Jackson, well show the advancing position which our Profession is taking up in its warfare against the multiform causes of mortality.

So far as the future is concerned, we can assure our readers that we have at our command a mass of original and spontaneous communications which gives us the occasional embarrassment of selection, but that, with due foresight, we take care to secure contributions on those points in which there is something to be learned which has not yet found its way into books. For instance, we propose, in some of the following numbers of the *Medical Times and Gazette*, to give an account of the details and results of the series of experiments on the urine of healthy men, recently undertaken by the Rev. Professor Haughton, M.D., with the object of founding a theory of work applied to man considered as a machine, mechanical and mental. His establishment of a

definite relation between the daily work, bodily and mental, and the daily food of man; his demonstration of the greater amount of food required by brain-workers than by mere mechanics; and his estimation of the relative nutritive values of Hospital diets, will be interesting to all of our readers. Equally so, no doubt, will prove an account of his researches upon the antagonism of strychnia and nicotine, of his investigations into the phenomena of saccharine and insipid diabetes, and of his experiments on the mode of action of the muscles by the determination of the pitch and note of the muscular *susurrus*. For this purpose we have secured the assistance of Mr. A. W. Foot, M.B., who is familiar with the views of Professor Haughton on these subjects, having been fortunate enough to have assisted in many of his experiments.

Professor Simpson will favour us with lectures on Fibroid Tumours of the Womb; Professor Quain, F.R.C.S., with clinical Surgical observations; the experiences of Conolly and Ramsbotham will be continued. We are promised some more of the clinical records so carefully kept up by Dr. Robert Lee, whose great authority in Midwifery makes us regret his opposition to some new curative procedures. We shall, with the aid of a numerous and able staff, direct the attention of our readers to the subjects of Chemistry, Philosophical Anatomy, the Microscope, and Blood-letting. But, instead of more promises, we will ask any one of our readers to estimate the enormous mass of fresh and varied Professional information contained in our volumes for 1862, and accept them as evidence of what we shall give them in 1863.

---

---

### THE WEEK.

#### DR. RADCLIFFE'S LECTURES AT THE ROYAL COLLEGE OF PHYSICIANS IN LONDON.

In his eighth and last lecture, Dr. Radcliffe spoke of pain and paralysis, prefacing what he had to say with some remarks on the "state of irritation." It is impossible, in the few lines at our disposal, to give even the barest outline of the argument used when speaking of the "state of irritation"; and it must suffice to say, that a physical explanation was offered which was in accordance with the physiological view of muscular action and sensation propounded in the first four lectures, and that the "state of irritation," thus explained, is seen to have nothing to do with an inflammatory or congestive condition, except that it may, in some instances, give rise to such a condition secondarily. Speaking of pain, and sensation analogous to pain, Dr. Radcliffe adduced evidence to show that their physiological and pathological conditions were, in every particular, analogous to the physiological and pathological conditions of the various forms of convulsion, spasm, or tremor. The physiological evidence adduced was very curious, the facts themselves being at once novel and striking. The pathological evidence amounted to this—that pain, and the sensation analogous to pain, were, as a rule, associated with a state of wanting vigour in the circulation, respiration, and innervation, and not with the contrary state. It was argued, for example, that pain, as a rule, is the precursor of inflammation, and not the attendant; that pain gives place to tenderness when inflammation is developed, except in those cases in which the inflammation is in a place where the due amount of swelling cannot take place, and where, consequently, this resisted swelling becomes a very intelligible cause of pain. The treatment suggested by these considerations is analogous to that recommended in the different forms of tremor, convulsion, and spasm; and, with respect to this matter, the lecturer said, that his own experience left him no room to doubt that this mode of treatment led to more satisfactory results than that which is dictated by the notion, that pain and the sensation analogous to pain are the signs of exalted vital activity in nerve tissue. With respect to paralysis, the lecturer had much to say upon the current views which look upon cramps and other disorders of muscular motion,

and pain and the analogous disorders of sensation, as conclusive evidence that the paralyzing lesion is of an inflammatory or congestive character. Dr. Radcliffe holds that the very opposite view is much nearer the truth, and he supports his opinions with no small amount of evidence. For the rest, something was said upon the use of strychnia and belladonna in the treatment of paralysis; and the conclusion come to is, that the two classes of cases in which these drugs are likely to be useful or harmful are not those in which they are, on high authority, spoken of as being useful or harmful, but rather the reverse. In a word, the lecturer maintained that symptoms of irritation are in no sense a reason for the adoption of remedies which will diminish a hyperæmic condition of some part of some nervous centre, and in that way lower functional activity, but rather the reverse; and he asserted broadly that he had good reason for believing that this view would bear the test of actual practice.

#### FEMALE PHYSICIANS.

WE have received the fourteenth "Annual Catalogue and Report of the New England Female Medical College," published at Boston, U.S., 1862. As we have said before, it is a College constituted by public authority, and partly supported by endowments. It has produced forty-two graduates in nine years. We only, at present, quote the following emphatic passage:—

"The objection urged in England against the education of male and female Medical students together, on the score of propriety, appears to us an entirely valid one, and it is likely to be avoided there, as it is here, by the establishment of Medical Colleges for women."

#### THE IMPUTED PLAGIARISM.

THE imputation of plagiarism, to which we referred in a note last week, has again been brought under our notice by a letter from Dr. Murchison, which we publish in another part of our columns. Dr. Murchison's "Researches on Fever" have given him a lasting claim on the consideration of the Medical Profession. Few men have sought or obtained larger opportunities of studying the continued fevers of our own and warmer climates, and, we are bound to say, that few men have made better use of their opportunities. He has observed fever in Bengal, in Burmah, Dublin, Paris, Edinburgh, and London; and has twice experienced, in his own person, the dire, but fortunately, in his case, not fatal, effects of the disease of his special adoption. We may further say, that the results which he has obtained are so important, that any work on "Fever" in which they were overlooked would be simply behind the present position of science. It was, therefore, with no surprise that we read the following passage in the preface to his comprehensive work just published:—"Many of the tables contained in the essay referred to (read before the Medical and Chirurgical Society in 1858), together with my remarks upon them, have been adopted by Dr. Tweedie, in his 'Lumleian Lectures,' published in the *Lancet* for 1860. Dr. Tweedie being about to republish his lectures, I feel it due to myself further to state, that most of his facts and reasonings, bearing on the question of the 'Change of Type of Continued Fevers,' will be found in a paper published by me in the *Edinburgh Medical Journal* for August, 1858." He, however, goes on to say—"As Dr. Tweedie omits to mention my paper, I think it necessary to allude to the circumstance, lest it might appear that I had now borrowed some of my remarks from his lectures without acknowledgment." The information we received last week led us to suppose that the tables drawn up by Dr. Murchison were compiled at the request of Dr. Tweedie from the records of the Fever Hospital, in order to be used in his lectures before the College of Physicians, and that, therefore, the tables, and the deductions from them, were fairly common property, or, at

least, might be ceded by a junior to a senior Physician without the slightest imputation. Dr. Murchison's letter gives a different complexion to the affair. We confess we are unable to understand how the results at which Dr. Murchison had arrived from a study of the statistics of the Irish Hospitals could be claimed by Dr. Tweedie, and the same remark applies to the facts and reasonings on the "Change of Type of Continued Fever," published in the *Edinburgh Medical Journal*. If Dr. Tweedie (than whom, as an energetic and accomplished worker in the same field as Dr. Murchison, no man deserves more Professional respect) will throw some further light on the subject, we shall gladly receive it. In the meanwhile, we trust that a misunderstanding, which is detrimental to the interests of Medical science and Professional honour, will not be allowed to continue. Plagiarism is a harsh term. We have said that Dr. Tweedie could not, in justice to his hearers and readers, do otherwise than quote Dr. Murchison; and he has more than once referred to Dr. Murchison by name in connection with the passages in question. It would have been better had he more carefully and clearly ascribed to their source the paragraphs which he quoted; but the character and position of the author of the Lumleian Lectures, and his connection with Dr. Murchison as a colleague, forbid us to suppose this anything worse than an inadvertent omission. The very nature of scientific observations forbid their being clothed in a variety of diction; and it is a thousand times better to quote *verbatim* an original writer on matters of science than to obscure or weaken his meaning by translation. In fact, even out of pure science, by far the larger amount of literary labour consists in pouring, either knowingly or unknowingly, from one vessel into another. We regret that this matter was not allowed to remain where Dr. Murchison left it in his preface. He there had fully and sufficiently vindicated his claim to his own property. But it will be observed that he there does not accuse Dr. Tweedie of plagiarism; and we have undoubted authority for asserting that Dr. Murchison has had nothing whatever to do with any review of his book that has appeared since its publication. What would be the effect on the library of the College of Surgeons if all the Medical, scientific, and philosophical works in it were, by some benevolent fairy, reduced to the dimensions of the original observations, facts, and reasonings of their respective authors? Eight-tenths would vanish at once, and the transformation of the remainder would be as startling as the Miltonic miracle—

"They, but now who seem'd  
In bigness to surpass earth's giant sons,  
Now, less than smallest dwarfs, in narrow room  
Throng numberless."

#### THE ALLEGED NEGLECT OF DUTY BY A MEDICAL OFFICER AT LIVERPOOL.

AN investigation before a Poor-law Commissioner has lately taken place at Liverpool, which furnishes another instance in support of the moral we have been lately inculcating. As Medical men we are literally the servants of the public, and if we value our good name and peace of mind we must unreservedly accept our position. Our services must always be rendered when required, at whatever sacrifice of ease, comfort, or even physical strength, unless absolute illness prevent, or we can procure a substitute. "Ready, aye ready," is the only motto, but it is a cognizance we may well be proud to bear. We know that our aid is often not appreciated; that it is very often unnecessarily sought, and repaid with the worst ingratitude; that no consideration is shown for the ease or convenience of the Doctor. Still, give it we must, and that promptly, if we would be true to ourselves, to our own reputation and interests, and to the honour of Medicine. The case which has again obliged us to touch on this subject is, doubtless, one of a kind of considerable hardship to the Poor-law Medical Officer. Late in the evening, after the long day's work is over, an order is put into his hands requesting him to see a pauper

patient. He learns, on inquiry, that the person has been ill for days, and he naturally enough says, "I can't come to-night—I will call in the morning." He does call the next day, and finds that the patient has died in the interim without Medical attendance. Stripped of all the minor points of evidence, many of which are most contradictory, this is the history of the unfortunate business in which Dr. Lodge has become involved. In his case, there are many extenuating circumstances. The order he received was not marked "urgent" by the relieving officer, as it should have been, according to the regulations of the Poor-law Board. This functionary had also neglected to visit the man before signing the order for Medical relief. It is true that he alleged that there was an understanding between himself and Dr. Lodge, that orders should not be marked "urgent," except in special cases. This, however, was denied by Dr. Lodge, who proved that he had received an order so marked in the case of another patient but a short time before. The greatest mistake which, in our judgment, Dr. Lodge committed, was that of giving a certificate as to the cause of death, although he had never seen the patient during life. It is to be feared that this is too often done by some Practitioners; but we hold that it can never be justified. In another part of our columns is a notice of a remarkable case of death from puncture of the pericardium, in which the same error was committed. We know well that Physicians and Surgeons to Hospitals and Dispensaries are frequently compelled to give certificates of death to the friends of out-patients, under circumstances which are far from being entirely satisfactory to the certifiers; but in all such cases the Practitioner has seen and prescribed for the individual, and they are, therefore, in a different category. We assert, that under no circumstances can a certificate be given, with propriety, unless the patient has been attended during life, or a post-mortem examination has fully revealed the cause of death. In the latter case, the whole circumstances of the case should be set down in a certificate especially drawn up for the purpose. The ordinary form should not be used. A woman, a Mrs. Jardine, who carried the order to Dr. Lodge, asserted that she informed him as to the urgency and danger of the case. He, however, did not allow that this was the fact. In his evidence he said:—

"He remembered Mrs. Jardine bringing the order to his house for him to attend William Saxan. He received it about seven o'clock, and he did not remember her saying that it was an urgent or dangerous case. The order stated that Saxan was suffering from dysentery, and the woman said he had been suffering from it nine or ten weeks. She asked him to go and see Saxan that same night, but she did not say it was a dangerous case, nor did she ask for any medicine to soothe the man, or he should have given it. He heard the woman state in her evidence that she applied for medicine, and he did not cross-examine her upon that point, because he thought he could elicit nothing more than she had stated. The woman said she wanted to get the man into the workhouse that night, as her husband would not allow him to remain in the house; but when he found it was a case of chronic dysentery he declined to go that night, as the order was not marked 'urgent,' and the woman gave him no reason that it was a dangerous case. He thought she wished him to see the man, not because the case was urgent, but because she wished to get him into the house that night; that was his impression. He did not tell her that all persons requiring parish relief must have their notes signed by nine o'clock in the morning. She had said so, and he did not cross-examine her, because he had no witnesses to contradict her.—The Commissioner: Is it usual for a Medical man to give a certificate of the cause of death when he has not seen the deceased alive? Witness: It was not usual, but it was sometimes done when the Medical man was satisfied that death had resulted from natural causes.—The Commissioner: How do you reconcile this? You certify that you attended William Saxan, aged 54. Witness: I think I cannot defend the giving of the certificate in that form. Had I written it upon a plain piece of paper it would have been different, and I ought to have passed the pen through

the words—'I hereby certify that I have attended.' I had never attended upon the man or prescribed for him in my life. The coroner's clerk (Mr. Blake) told me that I was fully justified in the course I had taken in giving this certificate, although I had never seen the man."

In the course of the investigation a large number of Dr. Lodge's pauper patients came forward to testify to his constant kindness and attention. The case remains for the decision of the Poor-law Board. We trust that they will carefully weigh the points urged by Dr. Lodge in his defence, viz., the imperfect character of the order he received, and the fact that he supposed the application had only been made to him in order that the man might be received into the poor-house the same night. These are certainly exculpatory points, which, if they do not entirely justify, at least place Dr. Lodge's refusal in a different light.

PROPOSED ESTABLISHMENT OF DEODORISING WORKS AT FULHAM—POLLUTION OF THE THAMES.

THE District Board of Works of Fulham, and that inscrutable corporation known as the Metropolitan Board of Works, are at cross purposes, and the subject of their difference is one of no minor importance, for it involves a question of principle in which we are all concerned, both as Medical men, as sanitarians, and as dwellers in London. The Fulham Board very properly stands upon its rights, and, fortifying itself with the professional opinion of its accomplished Medical Officer of Health, Mr. Burge, refuses to be silent. We will endeavour to explain to our readers the ground of dispute. But for this purpose we must go back a few years—to the passing of the original Act for the better local management of the metropolis in 1855. By that Act the main sewers in the metropolis were vested in the Metropolitan Board, which was required to carry out such "works as they might think necessary for preventing all or any part of the sewage within the metropolis from flowing or passing into the river Thames, in or near the metropolis." They were also empowered to dispose of the refuse from the sewers as they might see fit, "but so as not to create a nuisance." Public protection against the adoption of any inefficient plan of interception was provided for, or attempted to be provided for, by the necessity they were laid under of obtaining the approval for their plan by her Majesty's Commissioners of Public Works. We pass over, as unnecessary to dwell upon here, the difficulties which this arrangement introduced into the settlement of a plan. Suffice it to say that a plan was at last agreed upon, and an amended Act was obtained to sanction an extension of the time within which the works were to be completed. This amended Act was passed in 1858, and it commences with these words: "Whereas it is necessary, with a view to the health of the metropolis, that works should be speedily undertaken and completed for the purification of the Thames, and for the improvement of the drainage of the metropolis," etc. It passes on to say that the Metropolitan Board shall cause all works to be executed under this Act, to be constructed and kept so as not to be a nuisance, and shall, in deodorising any sewage, and in disposing of any sewage or refuse from sewers, act in such a manner as not to create a nuisance; and the occurrence of any such dead lock in future as was threatened under the scheme which demanded the sanction of the Commissioners of Public Works, was got rid of with the necessity of obtaining any such sanction. In place of it, the Board were left to follow its own devices uncontrolled; and a power was given to the Secretary of State to direct a prosecution in the event of any nuisance being actually created. We have been thus full in referring to the Acts of Parliament in order that the state of affairs, which we are about to detail, may be fully understood. The Metropolitan Board, in dealing with the sewerage of the extreme west of London, propose carrying out a plan which the Fulham District Board believes cannot be carried out without infringing the very principle on which

the whole main drainage scheme hinges, and without nullifying the very objects for which it was projected, namely, the purification of the Thames and the amendment of public health. True, the Fulham Board need not protest; they may wait, and perhaps, like good subjects, ought to wait, until they and their constituents are arrived at that bourne whence they will not care to urge the Secretary of State to institute a prosecution. But as they prefer, very naturally, to complain while above ground, instead of giving directions to their statuary to inscribe upon their tombstones—"Poisoned by order of the Metropolitan Board of Works," they have compromised their loyalty by two memorials to the Board, in which they humbly plead that they would rather live a little longer.

The plan of the Metropolitan Board of Works is this—to construct works for the deodorising of the sewage of the western district at Sand's End, Fulham, close to the Cremorne Gardens, the amount to be daily operated on being estimated at 9,500,000 gallons, and then to cast the deodorised sewage immediately into the Thames. The tank for the reception of this amount of sewage will occupy two acres in extent, with a depth of eleven feet. The material to be used is the perchloride of iron. Whether the clear liquid only is to be thrown into the Thames, or the whole sewage, solid and liquid together, does not, from the report of Mr. Bazalgette, the engineer of the Board, appear quite evident. The latter, however, seems to be what is really intended. To either arrangement, however, the Fulham Board and their Medical Officer of Health take exception, and the grounds on which they do so are stated at length, both in the memorial of the Board and in the excellent report upon the subject drawn up by Mr. Burge. Even on the financial part of the question, the Fulham Board joins issue with the Metropolitan Board; but, with a rare appreciation of their responsibility as guardians of the public health, they regard this "as being not even of secondary importance in the matter, when they consider, that the great object of the Legislature, in the constitution of the Metropolitan Board of Works, was the purification of the river Thames from those evils occasioned by the sewage of the vast metropolitan area flowing into it; and, being convinced that such evils can be perfectly prevented, they say again, that the western district should not be made an exception in the scheme of interception." Their first memorial was forwarded in August; their second, on December 3; and it is to the latter that the lucid statement of Mr. Burge is appended, which will now occupy our consideration. First, Mr. Burge applies himself to the question of deodorising at Fulham, upon the notion that the whole deodorised material will be thrown bodily into the Thames. Here he objects, that not only is the perchloride of iron an inefficient agent in preventing putrefaction, but that a further result of its use would be the contamination of the river with arsenic. Drs. Odling, Letheby, Hofmann, and Frankland all agree in this, that the perchloride of iron has, in respect of deodorising, a very limited operation; that it is able, for the space of a few days, to retard or delay the putrefaction of sewage, which, in warm weather especially, soon proceeds as actively as if no perchloride had been used; that it is probable that the water of the Thames would be blackened by the use of this material; and that the bulky precipitate would, from its high specific gravity, soon subside upon the banks of the river, where its disgusting appearance would be certain to excite alarm, and where putrefactive changes, which it must undergo, would assuredly render it no less offensive than the present mud. And, as respects the arsenical contamination, Mr. Burge quotes from a report of Dr. Letheby, in which he shows that Dale's perchloride contains no less than 296 grains of chloride of arsenic in the gallon of solution. Even on Dr. Hofmann's showing, it contains 126 grains. The latter chemist asserts, that the arsenic will find its antidote in the peroxide of iron formed in the decompo-

sition of the perchloride; but Mr. Burge argues, that, "even if thus precipitated, it assuredly would, by contact with chlorides and other chemical agents in solution in the water, become again converted into a soluble state, and carry poison in its course." Even allowing to the full the antidotal power of the peroxide of iron (which, on the authority of Orfila, he disputes), Dr. Letheby, taking a medico-legal view of the matter, objects to this addition, as throwing a probable obstacle in the way of modern criminal jurisprudence. He writes:—

"Over and over again, the presence of this poison, not in the proportion of 1 part in 3000 (which would be the proportion it would hold in the sediment from sewage), but of less than 1 part in 140,000 of the soil of a graveyard, has embarrassed the labours of the chemist, and obstructed the progress of justice. Many a criminal, accused of having murdered with arsenic, has found a successful defence in the fact, that the soil in which the dead body has laid may have been charged with arsenic, and may have furnished the poison found in the corpse. Who, therefore, would rashly complicate such an inquiry by adding arsenic to the soil in which a poisoned body may be found? Or why, as in the present instance, should you resort to a disinfectant which is not only useless and expensive in its application, but so dangerous in its results; for where, let me ask, would be the chance of a conviction if, after the saturation of the soil of the Thames with arsenic, a cunning poisoner were to get his victim stranded upon the shore of the river?"

But what if the deposit be not thrown into the river, but only the clear, deodorised liquid? To this, also, Mr. Burge objects. Of course, this plan would involve a process of filtration which necessarily would occupy more or less time, and this process, Drs. Hofmann and Frankland agree, is involved in considerable difficulty: "The putrefactive tendency of the deposit separated by filtration or subsidence, renders its rapid removal from the reservoirs or filters a matter of the utmost importance, especially during summer, for the process of putrefaction, when once commenced, can be arrested only by quantities of disinfectants practically impossible." They add: "The actual process of deodorisation will probably present less difficulty than the mechanical separation of the deposit by filtration or subsidence. This separation will involve the temporary storage of immense quantities of sewage, the rapid removal of large quantities of deposit, and a number of operations which can be successfully carried out only with considerable system and under strict inspection. Operations of this kind should be, as far as possible, conducted at a distance from densely-populated districts." So much for the deposit which is to be dealt with; but what harm can arise from the deodorised clear liquid? Listen to Dr. Letheby:—

"When chloride of iron is added to sewage, the utmost effect of it will be but to fix a small portion, about one-third, of the ammonia contained in sewage, and to precipitate the sulphuretted hydrogen as a black and filthy-looking compound. This precipitate will be rapidly cast down, and will carry with it the suspended matters of the sewage, leaving a clear liquor, in which the organic miasms are untouched; and here it is that chemistry, when unassisted by pathology, physiology, and hygiene, is liable to the most serious errors, and may give rise to a dangerous confidence in her abstract speculations. Doubtless, the removal of a filthy odour like that of sulphuretted hydrogen may, in some degree, be an advantage; but there is not the remotest proof that these are the only or even the principal agents which excite disease, and there is no scientific reason whatever for believing that their removal is sufficient to interfere with the origin and spread of epidemic disease."

We have preferred using the very words of these eminent chemists, behind whose authority Mr. Burge entrenches himself, because we could not state the argument more concisely in our own language.

On Tuesday evening, the Metropolitan Association of Medical Officers of Health met to hear a paper from Mr. Burge, and to receive a report from a committee which had undertaken the consideration of the subject. This report bore the signature of Dr. R. D. Thomson, one of the most eminent chemists in London. After pointing out that the proposed plan was mainly adopted upon economical grounds, it stated that "the use of perchloride of iron as a disinfectant was originally recommended by Mr. Ellerman in 1847, and reported on by a committee of the vestry of Marylebone, in December of that year, as being somewhat superior to chloride of lime, chloride of zinc, and nitrate of lead, in destroying the odour of night soil and other similar substances. But the committee," so the report goes on, "are not aware that there is a single ascertained fact to warrant the conclusion, that the perchloride of iron absolutely removes any deleterious ingredient from sewage, or that sewage thus merely mingled with solution of perchloride of iron, and discharged into the saline water of the Thames in summer, does not undergo the usual putrefactive decomposition to which the river has been subjected in a greater or less degree for several years. Such deodorisers appear only to act on sewage in its concentrated form. The truth of this position was demonstrated some years ago, when an attempt to deodorise the contents of the main trunk sewers by means of lime ended in failure, because, as soon as the sewage was diluted with the impure river water, the influence of the deodoriser terminated, and a putrefactive action was set up in the body of the stream, which was as energetic as if no disinfecting agent had been employed. The committee are, therefore, under the necessity of coming to the conclusion, that the simple mixture of the perchloride of iron with the sewage will only operate during the brief detention of the sewage in the reservoir, and that its use will be found expensive and fruitless, so far as the removal of the smell from the river is concerned." This report received a full discussion, in which several of the most distinguished of the Health Officers present took part. Mr. Burge asserted, as the result of his own experiments, that the clear liquid of sewage, after addition of the perchloride, ran into putrescence at a temperature of 65° or 70° in the course of a few days. Mr. Liddle, Dr. Aldis, and Mr. Chadwick, quoting from the several reports of Mr. Bazalgette in 1856, 1861, and recently, dwelt much upon the breach of faith which they exhibit in the matter of interception, since, from the first of these reports to the Metropolitan Board, Mr. Bazalgette appeared to drop the deodorising scheme for the western division in consideration of "objections which had been raised to the establishment of deodorising works in the locality mentioned;" and no hint has subsequently been given that he and the Metropolitan Board of Works in any way contemplated returning to this idea. The result of the meeting was the passing of the following resolution:—

"That the attention of the Association having been called to the plan proposed for the deodorisation of the sewage of the western district of the metropolis, and its subsequent discharge into the Thames, the Association wish to record their opinion that it will be ineffectual in its operation, pernicious in its influence on the river, and entirely subversive of the principles on which the intercepting scheme was originally based."

They passed further resolutions, to the effect that this expression of opinion should be forwarded to all the vestries and district boards of the metropolis, and that a deputation from the Association should wait upon the Metropolitan Board of Works, in the hope that they may be induced to reconsider their determination. Mr. Burge, the Fulham District Board, and the Health Officers of London, have thus done their duty manfully. It remains to be seen what effect these protests will have upon the central authority, which has the power to do a large benefit to the metropolis, or an incalculable damage.

## REVIEWS.

*Statistical, Sanitary, and Medical Reports for 1860: Army Medical Department.* ("Ophthalmic Surgery." By Assistant-Surgeon Dr. P. FRANK.)

*Ophthalmia.* By Assistant-Surgeon Dr. MARSTON, Royal Artillery. (Reprints of Contributions from "Beale's Archives of Medicine.")

WE have, from time to time, kept our readers *au courant* with the latest observations of continental writers upon Ophthalmia, in its epidemic or endemic forms. It is not a little remarkable that English authors should have hitherto maintained a perfect silence with regard to the very important pathological changes and appearances in the palpebral conjunctiva, which the eyelids of soldiers and others, living gregariously, so frequently exhibit. To the Danish, Belgian, and German observers, we have been indebted for all we know upon the subject.

Perhaps no disease is of more importance than Ophthalmia; whether we have regard to the organ attacked, the frequency of its occurrence, the rapidity with which the disease often attains a widely-spread sphere of prevalence in regiments, schools, etc., its contagious properties, and the enormous cost which ophthalmia annually entails upon our Government. In the two works at the head of this article, we have such a large mass of information and observation, that English observers can no longer be said to be left behind in the progress of this part of our science; nor can the facts described be any longer ignored, as if they either did not exist, or had failed to be regarded.

For the present, we refrain from entering any further into the materials of this Medical blue book than into the part bearing upon this subject.

In Dr. Frank's most able Report upon "Ophthalmic Surgery," we have a very full and highly interesting account of all the cases of ocular disease admitted into the Surgical Division of Fort Pitt. The paper is too long for analysis here, but we would particularly direct attention to those cases illustrated by capital views of the ophthalmoscopic appearances, and to his observations upon internal lesions of the eye. To say that this Report could only have been written by an exceedingly well read and accomplished Surgeon in this branch of his art, is a small meed of praise; for it contains the result of so much personal experience and original observation, that the best informed will find matters for suggestion and thought, as well as matters of a practical interest in it (a).

Dr. Marston's pamphlet is a reprint of papers originally published in Beale's "Archives"; and it must prove a source of much pleasure to him to find his observations upon conjunctival disease so fully corroborated by Dr. Frank's Report.

We shall confine ourselves, for the present, to the subject of that ophthalmia, or conjunctival disease, of which both writers treat.

The specific feature of this affection—and one which contradistinguishes it from ordinary conjunctivitis—is the presence of small deposits in that membrane, as the sole characteristic of its primary stage. Dr. Frank says:—

"The first signs of abnormal nutrition consist in the appearance of small, round, opalescent, sago-grain-like bodies, either isolated, or disposed in clusters or rows, more or less densely crowded over the conjunctival surface, and generally making their first appearance on the lower lid. These so-called vesicular granulations may form and exist for an indefinite period, without the occurrence of any inflammatory symptoms calculated to direct attention to the affected lids."

The histological origin and exact seat of these bodies have been strongly-contested points, as Dr. Frank's references sufficiently indicate. Our limits will not allow us to follow our authors into these; suffice it to say, that the original statement by Van Roosbroëck and Bendz, relative to the presence of closed, solitary follicles in the palpebral conjunctiva, must be conceded as correct. Dr. Marston says:—

"It is in the highest degree probable that the vesicular

(a) The great merits of this Report remind us that the Army Medical Department can no longer number its writer among its members. The retirement of a man like Assistant-Surgeon Dr. Frank can only be regarded as a great loss to the service. The influence exerted by the presence of an enthusiastic, able, and ingenious man in the junior ranks, upon his fellows, is always great and useful. We should be glad indeed—for the sake of the soldier and the credit of the authorities—to see such men animated by a stronger attachment to the public service, instead of, as now, so frequently quitting its ranks.

looking bodies, sparsely shed in the palpebral conjunctiva, are these follicular organs altered by disease. When, however, the disease has continued for any time, or advanced to any extent, it will be found that these bodies exist in such disproportionately large numbers, and often in such superimposed strata, as it were, as to lead to the conclusion that they cannot *all* have had their origin in pre-existing follicles. The appearance of follicles is exactly mimicked by the morbid products in the connective tissue; and in diseased lids it is extremely difficult to determine the one from the other."

He adds, therefore, that these bodies may also have their origin in the delicate sub-epithelial stroma; and that, then, there will be a little nest of cell-growth bounded by fibrillated-looking tissue, in the meshes or interstices of which the new products are seated. So defined, these bodies exactly assimilate to follicles filled with granular and cell contents, nearly identical in appearance and constitution with that vesicular-looking condition which the mucous follicles of the colon assume in incipient dysenteric disease.

Dr. Frank has some very interesting remarks upon the same subject which are very nearly allied to those quoted. What our authors strive to prove—and, to our minds, have succeeded in proving—amounts to this:—These little bodies are among the commonest appearances of diseased conjunctiva in bodies of human beings living as in regiments; and they are very powerful predisposing causes to ophthalmia in general, particularly to that form which results in the "granular" lid, although their presence, *per se*, may give rise to scarcely any symptoms, and their detection may require careful scrutiny of the eyelids. Thus we read:—

"In order to study the typical character of vesicular granulations, they must be sought for in the conjunctivæ of apparently healthy eyes; and this has led to their existence being overlooked and denied by many who are not in the habit of examining the conjunctiva prior to the invasion of inflammatory symptoms. Innocent as these primary lesions may appear, they gain in importance by the predisposition they engender to inflammatory attacks, and by the contagious nature of the secretion, which, under such circumstances, is furnished by the affected conjunctiva."

Dr. Marston says:—

"The vesicular bodies appear as the primary lesion, and are the very first products generated by the morbid agency. That these are not the sequelæ of an inflammatory process, but rather the powerful predisposing causes to, and modifying agents of, any inflammatory phenomena that may ensue, appears certain."

In his paper, he attempts to trace the relation of these bodies to the prevalence of ophthalmia, in an epidemic or endemic form, among the military at Malta and Gibraltar, and at the convict establishment at the latter station. Those scourges of the army—"purulent ophthalmia" and "granular lids"—must, in future, always be viewed with reference to the existence or not of a pre-existing stage of vesicular granulation.

The reason these bodies are not found is, that they are not looked for until inflammatory changes have ensued, by which their presence is masked. Dr. Frank says, in a note:—

"The influence of a hyperæmic condition in masking vesicular granulations can be easily appreciated by their disappearing, as it were, before the very eyes of the observer, when a lid has been kept everted for a short time, and reappearing again when the congestion has been allowed to subside."

Both writers enter into the causes of this singular affection—Dr. Marston, by recording the actual results of his own experience and observation; Dr. Frank, by epitomising the views of the latest and best writers upon the subject. They may be referred to two heads:—1. Contagion. 2. An unhygienic mode of life, by which miasmata are generated. The last appears highly probable as a cause of such generation, irrespective of the former, from the observations made, not only upon man, but the lower animals. Of the first, as a cause, there is so little doubt, that many writers consider this as the only means by which the specific agent, or virus, is propagated. Dr. Marston writes:—

"So certain do I feel that the prevalence of vesicular disease of the lids is in direct ratio to the amount and degree of defective sanitary arrangements, that I conceive the palpebral conjunctiva offers a delicate test and evidence as to the hygienic condition of a regiment."

Much has been lately said as to the propagation of ophthalmia through the agency of pus cells, floating in the atmosphere of ophthalmic wards. The statement was originally made by Eiselt, and his observations have been corroborated by some recent experiments at Lariboisière Hospital. Professor Parkes, in his interesting "Review of the Progress of Hygiene during the Year 1861," in the present blue book, remarks, that Dr. Frank (by means of an *aëroscope*, used in the wards of Fort Pitt), had detected, in several instances, unequivocal epithelium cells. Dr. Marston, by means of the same instrument, does not appear to have satisfied himself of the presence of pus globules, in a current of air driven over a vessel containing moist pus, although he could easily determine their presence in air passing over desiccated pieces of lint which had been previously steeped in fluid pus.

The subject should be carefully followed up by investigations in places where cases of purulent ophthalmia are located.

Dr. Frank points out how this apparently trifling and incipient stage may lead to atrophy of the tissues, incurvation of the lids, and disordered vision. If these statements bear even an approach to accuracy, how important are they! To state the presence of "sago-grain-granule" in the eyelids of men of a regiment, for instance, is tantamount to saying that ocular disease, or a predisposition to the gravest kind of ophthalmia, is endemic in that regiment. Difficult as these cases are of treatment in their advanced stages, they are easily treated during the earlier. What is far more important, however, is the knowledge that we possess a power over the spread of the disease to healthy individuals.

Dr. Marston's very able paper contains tables, by which the proportion of vesicular to healthy lids, and the proportion of each of these to the more advanced stages of the disease, can be traced. It has many illustrations also, one of which is colored; and, in an appendix, he describes the form and epidemic progress of the ophthalmia lately affecting the children of the Central London District Schools. In this he embodies also important observations from Mr. Bowman's reports to the Board of Guardians of the school in question.

We cannot do better than conclude, first, by strongly recommending those of our readers likely to be interested in these subjects to read these articles; and secondly, by quoting from Dr. Frank's paper:

"The interest of the affected individuals, and of the community to which they belong, demands most careful attention to these primary conjunctival changes; and it may be presumed that, in regiments to which ophthalmia clings, an explanation of its endemicity may be found in the presence of men affected with this insidious lesion.

"We might regard the presence of foci of this, as well as of all other infectious agencies, with indifference, if we could place implicit reliance on the infallibility of our sanitary arrangements, and their strict and universal observance. In the meantime, measures of isolation should not be despised, and a careful treatment of the disease in its embryotic stage should be thought worthy of attention by military Surgeons as a prophylactic measure of signal importance.

"A due appreciation of the fact, that the conjunctival deposits can exist for an indefinite period without giving rise to any inflammatory symptoms, is, therefore, not only necessary for the efficient prevention and treatment of the disease, but also to enable justice to be done to the claims of the soldier who is disabled by the results of ophthalmia.

"In the abstract of a private, invalided from the 41st Regiment, it was stated that the disease was contracted in St. Lucia, where ophthalmia was *not prevalent* at the time; the disease was, however, prevalent at head-quarters of the regiment; and not only were the anatomical changes in the conjunctiva the same as are only observed in genuine miasmatic ophthalmia in this and other cases from the 41st Regiment, but the most exquisite vesicular granulations were discovered in the conjunctiva of two other men with eyes apparently healthy, invalided for other causes from the same corps. It was, therefore, justifiable to assume, that the first patient had contracted vesicular granulations before his company was detached from head-quarters, but that the infected lids had remained quiescent till an exciting cause of sufficient intensity to bring on an acute inflammatory attack had acted upon them."

## FOREIGN CORRESPONDENCE.

## AUSTRIA.

CARLSBAD, December 9.

## THE CONGRESS OF GERMAN NATURALISTS AND PHYSICIANS.

SEVERAL important communications were made to the section for Surgery and Ophthalmology of the above Congress, which have not been mentioned in my previous letters. Professor Von Hübbenet, of St. Petersburg, spoke on "Pyæmia," as observed after amputation and disarticulation. His experience in the Hospitals of Sebastopol was decidedly in favour of the latter operation. During the siege of that fortress, he had performed altogether 3345 major operations (amputations, resections, and disarticulations), but had, from want of time and other circumstances, been unable to observe more than 636 cases in their entire course. Amongst these there were 338 operations on the right, and 298 operations on the left side: of the former, 63 were successful; of the latter, 74; that is, altogether, 137 (21 per cent.) The most unfavourable cases were those of amputation of the thigh, as out of 264 only 24 (9 per cent.) recovered. The unfavourable results observed in Sebastopol were chiefly due to the crowded state of the Hospitals, and the destructive action of the modern projectiles, but not to any want of proper care, which was, on the contrary, more anxious than it had ever been in times of peace. Another circumstance which had to be taken into consideration, was the low and depressed spirit of the vanquished army, which was especially perceptible in those who had not taken part in the pitched battles, but had always been in the fortress. No importance, however, was to be ascribed to the less considerable force of vitality in the Slavish nations, upon which Dr. Paul had laid so much stress; for of 33 operations performed upon French prisoners, only three proved successful. In the majority of cases, the amputations were done early and without scrupulous regard to the indications laid down in treatises on Surgery; the excuse for this being, that hygiene and the consideration for other patients required had contused wounds to be changed into clean incised wounds. Simple dry dressing was used throughout, and the diet and medicines prescribed were made to suit the requirements of each individual case. In the discussion which followed, Dr. Paul mentioned that, in 12,000 cases of amputation and disarticulation he had collected, the rate of mortality was 1 in 4 of the former, and 1 in 5 cases of the latter operation.

Dr. Von Trölsch, of Würzburg, spoke on the "Diagnosis of the Diseases of the Ear," and condemned, in rather severe terms, the way in which this was generally made. He entered fully into the objective and subjective means of examination, and said that the former, such as speculum, funnel, catheter, rhinoscopic mirror, etc., might serve to lead us to conclusions concerning morbid conditions of the external meatus, the membrana tympani, and the Eustachian tube, but did not help us to distinguish diseases of the cavity of the tympanum and the labyrinth. These latter could only be recognised by subjective signs. The majority of cases of deafness were due to morbid processes about the two fenestræ. Diseases of the labyrinth were rare, and could only be diagnosed after excluding all others. The cavity of the tympanum was chiefly affected by catarrh. There were many peculiar symptoms observed in persons suffering from deafness: some were able to hear the ticking of a watch at a certain distance, but did not hear spoken words; others heard, with one ear, only sounds, and with the other, words; others heard only certain notes of the scale, etc.; but, contrary to the opinion of other aurists, Dr. Von Trölsch contended, that at present we knew nothing certain with regard to the significance of these peculiar symptoms, nor did we know by what morbid changes they were produced. Dr. Voltolini, of Breslau, quite agreed with the speaker in this particular, but contended, that diseases of the labyrinth were more frequent than Dr. Von Trölsch was inclined to assume; it was such diseases, and also morbid processes in the acoustic nerve itself, which caused absolute deafness.

Dr. Wuth, of Hanover, exhibited a hypertrophied lachrymal gland which he had removed from a patient who, after the operation, merely complained of impaired motion of the eyelid, dryness of the conjunctiva, and a sensation of burning in the

eye. Professor Arlt, of Vienna, said that he had never observed a case of hypertrophy of the lachrymal gland; this organ could, from its seat and surroundings, only be hypertrophied in a backward direction, and would necessarily cause exophthalmos; it was impossible to excise it without removing, at the same time, a portion of the conjunctiva; and he was inclined to consider the specimen exhibited to be a tumour. Dr. Niemetschek, of Prague, however, remarked, that he had seen a specimen of hypertrophied lachrymal gland in the collection of Professor Adelman, and which had been microscopically examined by Virchow, who had found that it was true hypertrophy. Professor Patruban then spoke on "Neurectomy for Tic Douloureux;" and Dr. Van der Loe, of Venlo, described a modification of the plaster of Paris splint, which had the advantage that, after the gypsum had become quite hard, it could be easily removed and again put on. Dr. Förster, of Breslau, then read a paper on the "Limits of the Field of Vision," and described a series of experiments he had undertaken on this intricate subject. Professor Von Hübbenet spoke on "Hemeralopia," and said that he had observed annual epidemics of this affection in Russia, during Passion time, and which disappeared spontaneously after that period. There was, in these cases, peripheral limitation of the field of vision, dryness of the conjunctiva and cornea, and fatty degeneration of the epithelial cells. Dr. Förster said that hemeralopia was rare in Silesia, but that he had seen a few epidemics of it. Professor Arlt contended that there were two different forms of this affection: one of them was related to retinitis pigmentosa, was, probably, a hereditary disease, and always accompanied by limitation of the field; the other form was much the same as snow-blindness, which was observed in the Alps, was caused by dazzling, and was, in recent cases, curable by shutting the patients up in a dark room. In this form there was only hyperæmia of the retina, but no other pathological alteration, and no limitation of the field. After Dr. Niemetschek, of Prague, had made some remarks on a "Case of Villous Tumour of the Cornea and Conjunctiva," Dr. Ellinger, of Mergentheim, spoke on the "Treatment of Erectile Tumours by Liquor Ferri Chlorati," which was attended with favourable results. Dr. Streubel declared himself averse to this operation; while Drs. Eulenburg and Paul asserted that it was well worthy of a trial. The statement, that the blood coagulated after the injection, that the tumour became harder and smaller, and could, therefore, more easily be excised, was, no doubt, correct; but the solution used by Dr. Ellinger (viz., one drop of liquor ferri to thirty drops of water) was too weak.

In the section for Gynæcology, Dr. Freund, of Breslau, spoke on "Retroflexio Uteri," and its consequences, such as chronic infarctus, diseases of the bladder, indigestion, etc. In this affection the connective tissue was considerably altered at those points where the flexion had taken place; there were adhesions between the fundus and the rectum, owing to peritonitis, and which were frequently incurable. The posterior wall of the flexed womb was filled with masses of connective tissue, the seat and extent of which determined the ease or difficulty of reposition. Hydronephrosis was a frequent concomitant affection, and was caused, either by real stenosis of one or both ureters, or by flexion, owing to dislocation of the womb. After perimetritis the ureter frequently adhered to the lateral wall of the uterus; and this explained the symptoms of hydronephrosis during life, viz., violent lumbar pains, shooting downwards along the ureters, neuralgia in the lower extremities, headache, difficulties of the bladder, and dyspepsia, all of which were formerly incorrectly attributed to hysteria. The condition of the urine resembled that observed in catarrh of the bladder. Pyelitis might often be the consequence. Regarding the treatment, Dr. Freund recommended reposition by mechanical means, more especially by Valleix's sound and medicated enemata.

Professor Hecker, of Munich, spoke on "Congenital Rickets," a subject which he had, together with Professor Buhl, closely studied. He also exhibited some extraordinary specimens of this disease. Dr. Hegar, of Darmstadt, then read a paper on "Abortion in the First Few Months of Pregnancy." This was a very frequent occurrence, as for eight or nine regular births there was one abortion.

In the section for Zoology and Comparative Anatomy, Dr. Von Frauenfeld, of Vienna, gave an account of the scientific collections made by the naturalists of the Austrian ship *Novara*, during her voyage round the world. A *catalogue raisonné* of these collections, which will soon be exhibited in

the Viennese Museum, is just being written by the most eminent zoologists of the Austrian capital. The largest number of new species brought by the *Novara* is of the class of insects. The spiders seem to have been particularly well preserved: the following was the method pursued:—They were first placed in weak spirit, and afterwards in strong alcohol; they were then put in small bottles, each one being separated from its neighbour by a piece of cotton-wool. Fishes were wrapped in cotton-wool, and packed up in boxes of sheet-iron; when such a box was full, it was soldered up, so that only a small opening remained; the box was then filled with alcohol, and the last opening also closed. Professor Stein, of Prague, then described several new species of Infusoria he had discovered in the Baltic, during a sojourn at Vismar; and afterwards spoke on the "Paramæcium Coli," an infusorium which had been discovered by M. Malmsten, of Stockholm, in the lower bowel of two men who had fallen ill with choleraic symptoms. Leuckart had already found that this "paramæcium coli" was no paramæcium at all, but was identical with an infusorium very frequently met with in the rectum of the pig, and which he described as a species of *Holophrya*. Professor Stein has, however, by close observation, been led to the conclusion, that, from the peculiar position of the cilia, the animal appears to be a species of *Balantidium*. Up to the present time, only one species of this animal was known, viz., the *Balantidium entozoon*, which is often found in the rectum of the frog: Professor Stein, however, has discovered two new species of it, one of which (*B. elongatum*) lives in the rectum of the *Salamander aquaticus*, and the other (*B. duodeni*) in the upper part of the small intestines of *Rana esculenta*. Several other communications on newly-discovered animals were made; but as they were only of interest to zoologists, and of no importance to Medicine, I shall not enter into the subject of these papers. The papers read in the section for Physics, Mathematics, and Astronomy were likewise of no general or Medical interest.

In the section for Chemistry and Pharmacy, Professor Böttger, of Frankfort, described the metal "Thallium" which had been discovered by Mr. Crookes, and was distinguished by a peculiar spectral line. It was chiefly met with in the refuse of sulphuric acid manufactories. He showed the thallium line in the spectral apparatus; and Dr. Scheibler, of Prague, showed the lithium lines by burning tobacco leaves. Dr. Jeiseler, of Königsberg, made a linguistic communication on the "Spelling of Sulphur," which, according to him, should be "sulfur," as that was the spelling of the Sanskrit root. Professor Böttger then spoke on the "Most Powerful Means of Oxidation," which, according to him, consists of a mixture of two parts of permanganate of potash and three parts of sulphuric acid. Dr. Ilisch, of St. Petersburg, attacked Liebig's theory of fermentation, and contended that fermentation was impossible without sporules, that albuminous bodies in a state of incipient decomposition were likewise necessary for it, and that compounds of ammonia promoted fermentation. Dr. Scheibler described the effects produced by light upon solutions of sugar, and declared Gerhard's parathionie acid to be a myth. M. Patera showed some compounds of the new spectral metals "Cæsium and Rubidium," which had been obtained from the Carlsbad sprudel. Professor Strecker spoke on the "Effects of Hydrogen in the Nascent State upon Nitro-benzoic Acid," and described two new bases which were homologous to creatine and creatinine, viz., glycoeyamine, obtained by combination of cyanamide and glycocholl, and glyeo-cyanamidine, obtained by heating glycoeyamine with hydrochloric acid to 300°.

DR. A. DAVIDSON, the Medical missionary sent out by the London Missionary Society, writes from Madagascar thus:—"I reached the capital (Antananarivo) after twelve days' jolting in a palanquin. I opened a dispensary the first week I arrived. My patients at present are at the rate of 5000 or 6000 per annum." After describing some of his surgical operations, of which there are many, he says:—"I have a part of my dispensary set apart for such cases, that they may continue beside me during treatment. The dispensary has been presented by the Prime Minister, who had gout, but is now better. He has suffered nine years, sometimes a month ill at a time. I have been chosen Court Physician, and have received from the King the medal of the Order of Radama for my successful treatment of his son."

## GENERAL CORRESPONDENCE.

## DR. TWEEDIE'S LECTURES ON FEVER.

LETTER FROM DR. MURCHISON.

[To the Editor of the Medical Times and Gazette.]

SIR,—I trust to your justice, to allow me to reply to a paragraph in the last Number of your journal. You have either been greatly misled, or your information has been derived from one entirely ignorant of the facts. The materials, to which you allude, were not analysed by me for the purpose of illustrating Dr. Tweedie's lectures, but were prepared expressly for the paper published by me in the *Med. Chir. Transactions* (vol. xli.) I had the permission of the Fever Hospital Committee, and the sanction of both the Physicians, Dr. Southwood Smith and Dr. Tweedie, for making this use of them. My investigations were commenced long before I knew that Dr. Tweedie was going to give any lectures on "Fever"; the paper was presented to the Society on March 30, 1858; and it was finished and submitted to the perusal of Professional friends several weeks before Dr. Tweedie gave his first lecture on March 12, 1858, as I can prove by the testimony of a distinguished Fellow of the College of Physicians who attended Dr. Tweedie's lectures. It is not the case that my investigations were made under Dr. Tweedie's directions, or that he suggested any plan whatever for conducting them. The fact is, that a portion of the tables drawn up by me with great labour, together with a few brief memoranda explaining their object, were lent by me to Dr. Tweedie, for the illustration of his lectures, but it was on the distinct understanding that they had been prepared for my memoir above referred to. A comparison of our respective works is sufficient to show that I was not a mere mechanical drudge in the hands of Dr. Tweedie.

You err, however, in thinking that Dr. Tweedie has been accused of appropriating, without acknowledgment, the statistics of the Fever Hospital tabulated by me; for, in truth, at page 198 of his Lectures, he acknowledges that he is indebted for the tables in question to my paper in the *Med. Chir. Transactions*. He observes:—"I am bound to acknowledge that for the statistical facts I am indebted to the recently-published paper of my colleague, Dr. Murchison, who, availing himself of the ample opportunities the Fever Hospital afforded, has produced a most valuable monograph on the mortality of the different forms of fever, and on the causes which apparently influence their prevalence.—*Med. Chir. Transactions*, vol. xli." (Dr. Tweedie's Lectures, p. 198).

The complaint is, that Dr. Tweedie has appropriated the conclusions to which I was led by my researches, and, in fact, the *ipsissima verba* of my published essays, in such a manner that, if I had not noticed the circumstance, I would have rendered myself liable to the imputation, that, in my recently-published work, I had borrowed some of my remarks from his lectures, without acknowledgment. Several of the passages in question had no reference to the statistics of the Fever Hospital. The paragraph in my Preface, objected to by Dr. Tweedie, was referred by him nearly four weeks ago to a distinguished Fellow of the College of Physicians, who, after the closest inquiry, and hearing all that both parties had to say, informed Dr. Tweedie, by letter, that he considered my remarks justified, and that silence on my part would have laid me open to serious misconstruction.

That my remarks were called for you must admit, on perusing the paragraphs here appended in parallel columns. They illustrate the use which has been made of my writings; they prove that Dr. Tweedie has been credited with having written a paragraph contained in my previously-published essay; and they show that the very way in which he has introduced my name is calculated to disconnect me from the authorship of the passage. Moreover, the numerical results here given, extending over forty years, and having no reference to the London Fever Hospital, were worked out by me specifically for the memoir referred to.

I shall not trouble you with further details, which will be found in a letter addressed by me to the *British Medical Journal*.

I am, &amp;c.

CHARLES MURCHISON.

79, Wimpole-street, W., December 27.

## DR. MURCHISON.

(*Medical and Chirurgical Transactions*, vol. xli., 290; communicated March 30, 1858.)

"To all of these results the Irish Hospitals present a marked antithesis. Out of 150,939 cases of fever admitted into the Dublin Fever Hospital since the year 1817, only 10,632, or less than 1 in 14, have died; and during the last eighteen years it will be seen from the table that the mortality has only been 1 in 13 $\frac{2}{5}$ . Again, in the Cork Fever Hospital, the mortality has been even much less. Since the year 1817, out of 82,293 patients only 3222, or 1 in 25 $\frac{1}{2}$ , have died; and during the eighteen years contained in the table the mortality has only been 4 $\frac{1}{3}$  per cent., or 1 in 23 $\frac{1}{4}$ . Moreover, the rate of mortality has varied much less in different years than it does in England and Scotland. Thus, in Dublin, in no year during the last forty has it reached 10 per cent.; and in the Cork Hospital in only one year of the last forty has it slightly exceeded 6 per cent. In the year 1838, Dr. Cowan, of Glasgow, drew attention to the striking discrepancy in the mortality from fever between the British and Irish Hospitals; and I find, on referring to Barker and Cheyne's Report of the Irish Epidemic of 1817-19, that out of 100,737 patients in the Hospitals of all Ireland, 4349 died, making a mortality of 4.3 per cent., or of only 1 in 23 $\frac{1}{6}$ . No doubt the circumstance, to which I have just called attention, is partly accounted for by the greater facilities afforded to mild cases for entering the Hospitals in Ireland; but whether this be the case or not, it plainly shows that there is a form of fever constantly present in Ireland, which is much milder, and the mortality from which is much less, than is the case with the fever we more generally meet with in this country."

## DR. TWEEDIE.

(*Lancet*, May 19, 1860, p. 486; and "Lectures on Fevers," 1862, p. 202.)

"To these results the Irish Hospitals present a marked antithesis. Out of 150,939 cases of fever admitted into the Dublin Fever Hospital since the year 1817, only 10,632, or less than 1 in 14, died; and during the last eighteen years the mortality has been only 1 in 13 $\frac{2}{5}$ . Again, in the Cork Fever Hospital the mortality has been much less. Since the year 1817, out of 82,293 patients only 3222, or 1 in 25 $\frac{1}{2}$ , have died; and during the eighteen years contained in the table the mortality has only been 4 $\frac{1}{3}$  per cent., or 1 in 23 $\frac{1}{4}$ . Moreover, the rate of mortality has varied much less in different years than in England and Scotland. Thus, in Dublin, in no year during the last forty has it reached 10 per cent.; and in the Cork Hospital, in only one year of the last forty has it slightly exceeded 6 per cent. In Barker and Cheyne's Report of the Irish Epidemic, 1817-19, it is stated that out of 100,737 patients in the Hospitals of all Ireland, 4349 died, making the mortality 4.3 per cent., or only 1 in 23 $\frac{1}{6}$ . No doubt, as Dr. Murchison says, this small mortality is partly accounted for by the greater facilities afforded to mild cases for entering the Hospitals in Ireland; but whether this be the case or not, it plainly shows that there is a form of fever constantly prevailing in Ireland which is much milder, and in which the mortality is consequently much less, as compared with the fevers that prevail in this country."

## DR. PICKELLS.

(*Cork Fever Hospital Report for 1860*, read February 21, 1861.)

"To these results, the Irish Hospitals," Dr. Tweedie remarks, "present a marked antithesis. Out of 150,939 cases of fever admitted into the Dublin Fever Hospital since the year 1817, only 10,632, or less than 1 in 14, died; and during the last eighteen years the mortality has been only 1 in 13. Again, in the Cork Fever Hospital the mortality has been much less. Since the year 1817, out of 82,293 patients only 3222, or 1 in 25 $\frac{1}{2}$ , have died; and during the eighteen years contained in the table the mortality has been only 4 $\frac{1}{3}$  per cent., or 1 in 23 $\frac{1}{4}$ . Moreover, the rate of mortality has varied much less in different years than in England and Scotland. Thus, in Dublin, in no year during the last forty has it reached 10 per cent.; and in the Cork Hospital in only one year of the last forty has it slightly exceeded 6 per cent."

## REPORTS OF SOCIETIES.

## WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, DECEMBER 5.

Mr. JAMES R. LANE, Vice-President, in the Chair.

A PAPER, by Dr. CAHILL, was read on  
PLUGGING THE NOSE.

In cases of excessive epistaxis, the author had found that the ordinary mode of plugging the nose effectually, both in front and behind, was attended with considerable distress to the patient, and with some inconvenience to the operator, although it might not be attended with much difficulty. The method he had adopted consisted of passing a piece of dry and compressed sponge, about two inches long, and of sufficient size to pass easily, along the floor of the nares. This was secured in the middle by a piece of tape or twine doubled. When the sponge was fairly pushed by a probe, or, what was better, a female catheter, through the posterior nares, the tape was drawn upon; the sponge then took a direction transverse to the nasal cavity, doubling upon itself, and so blocked up, when swelled by the absorption of blood, the posterior nares. The two ends of the tape now passing out of the nostril, being then separated, the anterior cavity was filled with cotton-wool, and the tape then tied across the whole in front of the nose. Removing it was easily managed by pushing the sponge into the pharynx, and so brought out through the mouth. The simplicity of this operation was shown by the author upon the skeleton.

A paper, by Dr. WAX, was read on

STRICTURE OF THE OESOPHAGUS.

The disease had occurred in a woman aged 52, which had commenced ten months previously to her death with the usual symptoms, viz., difficulty of swallowing, vomiting imme-

diately after taking food, accompanied with pain. Towards the termination of the disease, shreds of mucous membrane were vomited, with some relief to the symptoms. These shreds of membrane, upon examination, were found to be perfectly healthy. The post-mortem examination showed the upper part of the oesophagus to be dilated, and the stricture to be confined to the lower fourth. The mucous membrane of this part had been removed, exposing the sub-mucous tissue, which was found infiltrated with colloid cancerous disease. There were also some small glands affected in the same manner. The liver was elongated, but no trace of cancer could be discovered. The post-tracheal glands were cancerous. Life had been prolonged by nutrient enemata. The diseased portion of the oesophagus was exhibited.

A paper, by Dr. MARTYN, was read on

INDUCTION OF PREMATURE LABOUR.

This proceeding had been recommended, and performed by him in the case of a woman aged 45, who had previously had four children, and whose labours had been more tedious and difficult at each succeeding delivery. Still-born children had been the result of the long-continued pressure and the violent contractions of the uterus. Contraction in the antero-posterior diameter of the pelvis had been made out to be the sufficient cause of the obstruction. At the end of the eighth month, the author, to induce premature labour, injected, by means of a catheter, four ounces of warm water a few inches within the os uteri. Three hours afterwards slight pains came on, but without any further result. The following day, six ounces of water were injected six inches within the uterine cavity. Labour pains set in four hours afterwards. Prolapse of the funis took place, when the liquor amnii was discharged, but the author managed to hook the funis over one of the arms of the child while still *in utero*, and, leaving the rest to the natural efforts, the child was born eight hours from the commencement of the labour pains. Both mother and child did well.

## OBITUARY.

## MR. EVANS, OF BELPER.

THE death of Mr. Evans, of Belper, which took place on November 20 last, is an event which requires more than a passing notice.

For the last eight or ten years, owing to the infirmities of advanced age, he had retired from the active duties of his Profession, but for many years previous to that time he was known far and wide as one of the most eminent Surgeons of his day. As an operative Surgeon and oculist, he was surpassed by few, his operations in many cases being marked by great ingenuity and boldness—a boldness almost always justified by success.

He tied the carotid artery three times—twice successfully. As a lithotomist and operator for hernia and cataract, he was particularly successful.

One striking excellence in Mr. Evans' professional character was the tenacious perseverance he displayed in applying the resources which great natural ability and careful observation constantly suggested; and he was thus, under Providence, the means of saving life under circumstances often considered hopeless, as illustrated by the following cases:—

A case of poisoning by laudanum—the patient having taken an ounce and a-half of laudanum and half-a-pint of gin—in which he successfully emptied the stomach on December 6, 1817, by means of a large syringe attached to an œsophageal tube, on the principle of the stomach-pump, two years before that instrument was invented. The case was published in the *Transactions of the Associated Apothecaries and Surgeon-Apothecaries of England and Wales for the year 1823.*

But the operation which caused a great sensation at that time, and extended his reputation to foreign countries, was a case of aneurism of the arteria innominata, treated successfully by ligature of the common carotid on the distal side of the tumour, and recorded in the *Lancet* of November, 1828, and in Wardrop's work on "Aneurism." It may be interesting to the Profession to know that the patient on whom this operation was performed, is still living at Belper, in the enjoyment of good health, after a lapse of thirty-four years.

About the year 1833 he extirpated a cancerous uterus in the case of Mrs. H., who survived the operation thirteen months. The uterus is at present in the museum of Queen's College, Birmingham.

The unwearied attention and kindness which Mr. Evans exercised in the discharge of his Professional duties, his readiness at all times to lend his aid, and the confidence he inspired in those who sought it, will be testified to by all who knew him, in every station of life.

Of his general character it is more difficult to speak. Unobtrusive and retiring, and possessing an almost child-like simplicity, he was distinguished in an eminent degree by that charity which "thinketh no evil;" while, at the same time, he was ever active in suggesting and promoting every good work. He is gone, full of years, to his rest, having entered his 83rd year; but his memory will be long cherished, not only by his numerous family, but by the many friends far and near who have long appreciated his worth.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise on Wednesday, December 24, 1862:—

Peter Swales, Helmsley, Yorkshire; Francis Young, 114, Carlton-road; William Leonard Cass, Goole, Yorkshire; Adam Rae Martin, Rochester, Kent; Albert Louis Peacock, Huntingdon; James Murray Lindsay, Queen's-road, Grove-lane, Camberwell.

## APPOINTMENTS.

**ALDRIDGE, RUSSELL, M.D., L.R.C.S. Edin., L.S.A.,** Yeovil, to be Certifying Surgeon under the Factory Inspectors' Act, *vice* Sporland.  
**BROWN, ALFRED, M.R.C.S.,** has been appointed Consulting Medical Officer to the Dispensary, Wandsworth.  
**HEATH, CHRISTOPHER, F.R.C.S.,** has been appointed Lecturer on Anatomy at Westminster Hospital.  
**HOLTHOUSE, CARSTEN, F.R.C.S.,** has been appointed Lecturer on Surgery at Westminster Hospital.  
**WYER, OTHO, M.R.C.S. Eng., L.S.A.,** Nuneaton, to be Certifying Surgeon under the Factory Inspectors' Act, *vice* Herbert.

## DEATHS.

**BARNES, JOHN,** Surgeon, Maghull, on December 21.

**BOSSEY, PETER, F.R.C.S. Eng.,** at Worthing, on December 22, aged 56.

**MACKENZIE, JOHN, L.R.C.P. Edin.,** at Ullapool, N.B., on December 17, aged 27.

**MIALLARDET, JOHN WILLIAM,** at Crail, Fifeshire, on December 19, late Deputy Inspector-General of Hospitals of H.M. Madras Army, aged 57.

**ODY, JOHN, M.B. Lond., M.R.C.S. Eng.,** at Market Harborough, on December 24.

**SAWYERS, JOSEPH, M.D. Aberd.,** 86th Regt., at Waterford, on December 26, aged 35.

**UNIVERSITY OF DUBLIN.**—At the winter commencement held in the Examination-hall of Trinity College, on Wednesday, December 17, 1862, the following Medical and Surgical degrees were given:—*Doctors in Medicine*—Rev. Samuel Haughton (*stip. cond.*); Thomas Waugh Belcher. *Masters in Surgery*—John Blair Elmes; Philip P. Lyons; John Fred. Boyes. *Bachelors in Medicine*—John E. Barker; Francis Johnson; Thomas White; Philip Patterson Lyons; Dionysius F. Keegan; John Fred. Boyes; Rev. Samuel Haughton (*stip. cond.*); William H. J. Humphreys; Arthur Wynne Foot.

**UNIVERSITY COLLEGE STUDENTS' CHRISTIAN ASSOCIATION.**—On Friday evening, December 19, a special meeting of the above Association was held in the lecture-room behind Regent's-park Chapel, to commemorate the founding of the Society, exactly twelve months previously. The chair having been taken at eight o'clock by Professor Malden, A.M., the Rev. Dr. Hoppus offered prayer. The Secretary, Mr. Coxeter, then read the past minutes of the Society, after which short addresses were delivered by the President, Mr. C. Reed, Professor Hoppus, Dr. Hare, Dr. Edward Ellis, Mr. W. Scannell Lean, Mr. Bompas, M.A., and others. About forty students were present on the occasion. In concluding, the chairman expressed the very great pleasure he had felt in being present at such a meeting, and sincerely hoped that the Society would be increasingly prosperous. This Association, now numbering nearly fifty members, composed of students from both the faculties of Medicine and Arts, and which is entirely unsectarian in its character, has for its objects the conversational study of the Scriptures and prayer; and it also affords to new students, especially those who are strangers in London, an opportunity of forming good and useful friendships.

THE Rector of Wanstead writes to the *Times* that—"Thomas Lucas died at Wanstead on Saturday, December 20, 1862, at the reputed age of 105, and was certainly 104. He was born at Bygrave, in Hertfordshire, and was baptized in 1762. According to what his mother told him, he was either four or five years old when baptized, and he remembered walking to church on that occasion, when a younger brother was baptized with him. The old man's memory was so good that there seems no reason for doubting the accuracy of his statement. His family consider him to have been 105. He was formerly farm-bailiff to Mr. Long Wellesley, at Wanstead-house, had been married, and had several children, of whom some at advanced ages are still living. He had a remarkably healthy aspect and clear grey eye, was of courteous manners, and of a very cheerful temper, and retained excellent health and the complete use of all his faculties (including his memory, hearing, and eyesight) till almost the end. Until within a few months of his death, he chopped his own firewood, was conversational and agreeable to visitors, and was generally in the full enjoyment of life. As he died on December 20 (the day before his birthday, which was on December 21), he had, in point of law, completed 105 years. He suffered considerably during the last six weeks, but his end was tranquil and happy."

**AN UNQUALIFIED PRACTITIONER.**—On Tuesday, the adjourned inquest on the body of Mrs. Sarah Bowler, who, it was alleged at the former inquiry, had met her death through the unskilfulness of her Medical man, a non-qualified Medical Practitioner, was resumed at the "Wheatsheaf," St. Leonard's Avenue, Bromley, before H. R. Walthew, Esq., the deputy-coroner. Mr. Marsh appeared for Mr. Talbot, and a large number of the Medical Profession were present. From the evidence adduced at the former inquiry, it appeared that the deceased was delivered of a male child on Monday, December 8, by Mr. Talbot, of Grundy-street, at ten o'clock in the morning, hæmorrhage occurring immediately after. At one o'clock, Dr. Kennedy was seen passing by, and Mr.

Talbot tapped at the window, and called him in. Dr. Kennedy immediately removed the placenta, but deceased died half-an-hour afterwards. He was of opinion that the placenta should have been removed within from half-an-hour to three-quarters after the hæmorrhage occurred. The coroner now observed that, since the former inquiry, he had referred to "Denham's Practice," and he believed it was a general opinion that the placenta should be removed as soon as possible after the child was born, providing the patient was not in a fainting condition. There was no doubt that three hours was a very long time to elapse before taking those steps; and, with respect to the law, if it was proved that the deceased was able to undergo the operation, but that it was unnecessarily delayed, then the case would amount to that of manslaughter. Dr. Kennedy had stated that, when he was called in, the deceased was not in a fainting state; on the other hand, Mr. Talbot stated, that she was in a fainting condition the whole of the time. He (the coroner) was surprised that a gentleman like Mr. Talbot should practise without being properly qualified under the Act. Mr. Talbot had stated that he attended lectures for three or four years at Guy's Hospital, but the attending of lectures, and holding certificates to that effect, did not qualify a man for practice, but merely showed that the holder of them had been present on such occasions. The jury having consulted, returned a verdict, that deceased died from hæmorrhage produced by natural causes.

**DEATH BY FIRE.**—At the inquest held by Mr. Bedford on the bodies of six children named Spencer, who perished by fire, in Soho, Dr. Buzzard said:—"Certain characteristics were common to all of them. There was little or no decomposition. In all the eyelids were firmly closed. In all the extremities were contracted, and the fingers firmly clenched. With one exception the burns were not at all deep, but they were very extensive. As a rule, fully three-quarters of the whole surface of the body were injured. In all the hands were the parts most affected. In the three eldest children, both arms were drawn up across the chest, the hands being doubled up, the fingers clenched, with the nails close to the chest, as though they were trying to open the chest with the fingers. All the children were in precisely the same position. He opened Edward, his being the body which was least injured by the fire. In cutting through the integuments covering the chest he found them deeply injected with a brilliant red colour. He found that the lungs were very much congested with an unusually bright red fluid. All the cavities of the heart were empty. The brain was found somewhat congested with bright red blood. Generally, none of the blood he met with in the course of his examination presented the ordinary character of venous blood. There was no black blood; it was all red. In the case of Edward he believed the cause of death to have been the shock from sudden and extensive burns, and not from suffocation. Judging from that one examination, and the characteristics common to all, he should pronounce the cause of death to have been the same in all the cases."—A Juror: Do you think the children were burnt while alive?—Dr. Buzzard: I cannot give an opinion on that point. I believe the burns were inflicted during vital action, but I could not tell whether consciousness existed. There cannot be any possible evidence whether the children were asleep or not at the time the fire reached them.—The Foreman: The children were burnt to death—not suffocated?—Dr. Buzzard: Burnt to death, undoubtedly. There is no evidence of suffocation.

**FEVER**, which has been rife in Liverpool, has filled the fever wards of the Workhouse Hospital. At a late meeting of the Workhouse Committee, certain reports which had found their way into the local papers concerning the sanitary condition of the house, were thus disposed of by the chairman:—"Few—none, comparatively speaking—of the fever cases treated in the Hospital were generated in the Workhouse. They were brought from the courts and alleys of the town. Stop this source of supply, and the Hospital might be closed in a month. It was certain that no defects in the management or arrangement could be responsible for the present state of the Hospital, either in respect to the number of cases or the intensity of the disease. The Medical Officers who attended to the poorest classes of the inhabitants did not, in fact, as a rule, treat typhus fever in their district. The worst, and indeed all practicable, cases were removed to the Hospital, although, from the unwillingness of many

poor people to enter a workhouse, the removal was in many cases delayed until, except for the sake of those untouched by the disease, removal was useless. At the present moment there were in the Hospital four members of one family from one house in Rose-place. The District Medical Officers made weekly reports to the Committee, and they had instructions to call attention to defective sanitary arrangements in their several districts. Copies of such reports as they made were regularly forwarded to the Medical Officer of Health under the Health Committee. In regard to the Fever Hospital of the Workhouse itself, it should be stated that it contained ample accommodation for 64 fever patients, with separate wards for the reception of patients suffering from other malignant disorders, such as small-pox, etc. These wards contain beds for 32 patients in addition to the number of fever cases. The ground floor of the Hospital was not included in the foregoing, and there was there accommodation for 24 beds. On an average of the last five years there had been 37 patients in the Hospital—the average of the year 1860 being only 20, while the average for the last two months was 78. In consequence of the great increase it had become necessary to make increased provision for the reception of cases, not, as appeared to have been supposed, by crowding more beds into the several rooms, but by appropriating more rooms to fever cases. Thus, the small-pox cases had been removed to the Hospital for Infectious Diseases in Everton, and the ground-floor of the Fever Hospital had been appropriated to fever cases, thereby adding 56 beds to the accommodation, and providing for the reception of 120 cases. It thus appeared that, while the Hospital, under the ordinary management, was calculated to accommodate 96 patients, there had rarely been more than 37 in it. During the last five years there had passed through the Hospital 4243 patients, of whom 662 had died. When it was considered that many of the cases were brought to the Hospital in an almost dying state, the proportion of deaths did not appear to be excessive. With regard to the alleged mortality amongst the Roman Catholic priests of the town, it might be observed that, although, unfortunately, two who had been in the habit of visiting the Hospital had fallen victims to this disease within the last six months, these had been the only deaths under similar circumstances during the last fifteen years. In the case of Dr. Roskell, whatever might have been the general state of his health, he was certainly not a man of robust constitution. There could be no doubt that the duties which these gentlemen performed were more than usually hazardous. Being, from the nature of their duties, brought into immediate contact with the sick, without, it was to be feared, taking any special precaution against contagion, and remaining in the ward, as had been done, for four or five hours a-day, it was certainly not to be wondered at that deaths should, under such circumstances, sometimes occur. In conclusion, he (the chairman) asked to be allowed to say that the article they had to complain of was calculated to do great injury, by working upon the prejudices of the sick. It was also to some extent a reflection upon the Medical staff of the workhouse, for these gentlemen had never expressed themselves dissatisfied with the accommodation the Hospital afforded. The senior Medical attendant of the Hospital, Dr. Gee, was a gentleman of high position in his Profession, and had probably had as much, if not more, experience in the treatment of typhus than any Medical man in the country; and his recommendations had always been acted upon by the select vestry. (Hear, hear.) That was what he (the chairman) had to say in regard to the observations contained in the article to which he had alluded."

**SINGULAR DEATH OF A CHILD IN LEEDS.**—**THE PRACTICE OF MEDICAL MEN.**—At the Town Hall, yesterday, Mr. Blackburn, coroner, held an inquest on the body of Emily, the daughter of Henry Tate, bookkeeper, Sheepscar-fields. The deceased was two years and eight months old, and had enjoyed good health up to the time of her death, which occurred soon after midnight on Friday last. On the evening of that day the child was sitting near the table playing with a needle, and, as it is supposed, broke the needle by pressing it against the edge of the table. She complained of having been pricked, and a red spot, about the size of a pin's head, was found on her chest, just over the heart. The child did not scream or cry, and it was not supposed that anything very serious had occurred. A poultice was applied to the child's chest, and the family retired to rest about ten o'clock. At that time only half the needle could be found. In about twenty minutes the child began to retch and vomit seriously,

and the parents, unable to account for the sudden illness, gave the child some brandy and water. She became no better, however, and in about two hours and a-half the father went for Mr. Turner, Surgeon, Camp-road, but before he arrived the child was dead. On the day after, Mr. Turner gave the following certificate:—"I was called up to visit the child of Mr. Tate in the night, death having taken place a few minutes before I reached there. It is my opinion that the child's death was caused from shock to the nervous system and collapse, the result of excessive attempts at vomiting." This certificate was taken by the father of the child to the registrar, and that officer was not satisfied with it. On Sunday, Mr. James Braithwaite, Surgeon, and Mr. Turner, called together to see the child, and they gave a joint certificate to the same effect as the above. Still the registrar was not satisfied, and he applied to the coroner. After hearing all the circumstances, the coroner ordered that an inquest should be held, and a post-mortem examination of the body made, and the result of this proceeding was the discovery of the missing half of the needle, firmly embedded in the cartilage of the chest, the point of the needle piercing the bag of the heart. The interior of the bag was full of blood, and that led to the death of the child. The evidence given at the inquest was of a rather contradictory character. Mr. Tate stated that when he arrived at home his wife's sister told him that the child had been playing with a needle, that she had broken it, and that only one half of it could be found; but, on being called, the lady denied having made any such statement to him, or having seen the child playing with a needle at all. The Medical men admitted having been informed about the breaking of the needle and the missing of half of it; and the coroner expressed his surprise that, in the face of the almost irresistible conclusion that the missing half of the needle was in the body of the child, the Surgeons should have given the certificates they had. He then called the attention of the jury to the improper practice of Surgeons who had never seen persons during life, giving certificates of the probable cause of death, with the view of trying to prevent the holding of inquests. He (the coroner) was anxious to avoid holding unnecessary inquests, but in practice he found that many of the certificates of Medical men were not to be relied upon. There were grades in the Medical, as well as in the legal and other Professions, and the certificates of some men he could with confidence believe; but he knew that in many cases the Medical man constituted himself coroner, and himself decided whether there should be an inquest or not. It was a very improper proceeding, and was done by Medical men who had good patients, to avoid the holding of inquests. Mr. Braithwaite admitted that the practice complained of was adopted. The jury expressed their disapproval of the practice, and also expressed surprise that in the case of the above child a Medical man was not sent for earlier. A verdict of "Accidental death" was returned.—*Leeds Mercury*, Dec. 24, 1862.

**A NICE RESIDENCE.**—Mr. Richard Burton, in a letter to the *Times*, advocates the formation of a new convict settlement in Africa. "The Cameroons Mountain, rising in the depths of the Bight of Biafra, and within 4.25 degrees, or about 300 miles, of the Equator, is not, as has been supposed, an isolated mass breaking the continuity of the level and mangrove growing coast. I believe it to be the abutment of a great *sierra*, which, connected by the 'Rumbi' and 'Qua' hills, extends in a north-easterly direction to Mount Alantika. The Cameroons buttress may contain 500 square miles of successive bush and jungle, wood and forest, grass and barren ground. If connected, however, with Alantika, the number might be multiplied by 50. The first work to be expected from convicts located at Amboise Bay, at the foot of the Cameroons, would be a sanitarium. This poisonous coast calls aloud for some such establishment. During the last year, her Majesty's ship *Prometheus*, Captain Bedingfield, stationed at Lagos, lost, by death and invaliding, 84 out of 100 whites. In the Bonny River, it is calculated that, of 280, some 134 died in seventy-eight days. One ship, the *Osprey*, lost all her crew of 17 men except the master. The disease was yellow fever, which still continues in the New Calabar River, while in the Bonny it has been succeeded by a no less deadly typhus. At Fernando Po, 76 men died in two months, out of a total of 231 whites. I, therefore, conclude that we do want a sanitarium. It is vain to assert that a change to England is sufficient. Returning by the African steamship *Athenian*, Captain Lowry, I remarked that, despite the care

of our excellent Doctor, every passenger from the coast fell ill; one officer, who never had had fever in Africa, suffered from it on board. The first establishment at Amboise Bay would be on Mondori Island, an oval rock some 200 feet high at the entrance of the bay, and catching the pure Atlantic breezes, which at Clarence Town, Fernando Po, must pass over a long tract of jungly swamp backing the settlement. The second station—it is unwise to transport fever patients suddenly from low ground to high altitudes—would be on Mount Henry, an eminence about 150 miles from the mission station on the beach, and upwards of 1500 feet above sea level. The third would be a ledge of ground, grass-grown, but not wholly out of the wooded region, 7000 feet high, and sheltered from the north-east wind by a formation which my companions and I called the "Black Crater." A stream of degraded lava leads to this, the highest point where European invalids might be settled, and cutting and zigzagging would easily render it practicable for four-footed animals. Above the Black Crater all is grass and clover, lava and clinker. In places the land is level enough for pleasant riding; snow could be stored for the whole year, and those who enjoy cold can pass a night or two at "Saker's Camp," where at dawn the mercury stands below zero, the blankets are stiff, and the noble peak is hoar with frost. Being unprepared to assert in England that felony would justify divorce, and not unacquainted with the horrors of Norfolk Island, I agree with Mr. Laird in thinking it no small advantage that the convicts who prove themselves orderly and industrious should be able to intermarry with the women of the country. With respect to the chances of escape, a bottle of rum given to the natives would bring in any fugitive; and as the lowlands are deadly, as the highlands are healthy, as all the craft upon this coast is so frail that even the half-amphibious negroes often lose their lives—and, finally, as the mountain, though thinly populated, and wholly desert above an altitude of 3000 feet, is almost surrounded by populous regions, full of well-armed men, commanded by "General Tazo," *alias* swamp fever—it is not to be expected that a convict station in Western Africa will ever breed a race of bushrangers.

**SAN FRANCISCO AS A HEALTH RESORT FOR THE PHTHISICAL.**—Dr. Blake, of San Francisco, says:—"As regards temperature, our Coast Range, during the summer months, affords one of the most desirable localities for the treatment of phthysical patients. The temperature for July is, perhaps, that which is the most agreeable for living out in the open air—the thermometer never below 57°, and never higher than 82°, and with a variation, during the twenty-four hours, never greater than 20°. But it is not only in the advantages as regards temperature that the Coast Range affords a most suitable climate for phthysical patients, as in this respect it might be equalled, and perhaps surpassed, by many other localities, as, for instance, the Sandwich Islands, Madeira, and other sea climates; but in this State, and probably in this State alone, are to be found combined all those climatic influences which are even of greater importance than mere temperature in the treatment of the disease. Together with this agreeable temperature, the atmosphere is dry and bracing—almost always calm, and the sky is unclouded for months together. The last summer, there was no rain from the beginning of May until the end of November, so that my patients were not driven in by the weather until November. Towards the middle of September, they left their summer camp for a lower point on the mountains, gradually descending as the season advanced. The climate of the lower ranges is analogous to that at greater elevations, and affords one of the most desirable localities for our patients during the early summer and late autumn months. Another important advantage that the Coast Range of mountains possesses is in the abundance of game; so that a good hunter can always keep the camp supplied. With the return of winter, however, our patients necessarily have to seek other quarters, and, being obliged to change the free mountain breezes for the badly ventilated, sunless rooms of our habitations, a great deal of the good that has been done during the summer is apt to be lost. Should the case be not very far advanced, our patients can hold their ground, during an average winter, in our coast valleys, or on the lower hills of the Sierra. But they can, by going a few hundred miles down the coast, again enjoy all the advantages afforded by their summer residence in the mountains. In the northern parts of Mexico, the rainy season, which corresponds to our winter, sets in in June and July, and is over by the

end of October or the beginning of November; after which time, no rain falls until May or June. There are many points on the coast where the mountain range of the Sierra commences at a slight distance from the sea, and, although the low land is unhealthy, being subject to malarious diseases, yet, as soon as a moderate elevation is attained, the climate becomes dry and bracing, and very analogous to that of our own Coast Range during the summer. Fortunately, these localities are now easily reached, as the communication between San Francisco and Mazatlan is taking place, either by steamer or sailing vessels, three or four times a month. The country is well settled; and as large mining operations, conducted by our countrymen, are being carried on there, all sorts of supplies can be procured. About eighty miles back from the coast, the mountains already have an elevation of some thousand feet; and, although I have no accurate meteorological observations of the climate, yet, from the description of it by those who have passed the winter there, I am confident that it must be very analogous to that of our Coast Range. Our patients may thus enjoy a perpetual summer, or, at least, a climate in which they can pass the whole of the year in the open air. I believe, in no other part of the civilised world can such favourable conditions be found for treating phthisis as on this coast. That the disease cannot be cured by drugs is a fact becoming generally admitted by the Profession. That it can be cured by out-door life in the mountain air, is a fact of which I have seen abundant proofs, and which others, who have crossed the plains, have had opportunities of verifying. My own opinion is, that a large proportion of the cases of phthisis will be found to yield to one or two years' open-air treatment; and where the circumstances of the patient enable him fully to carry out such a plan, this coast offers, I think, by far the most favourable locality of any yet resorted to by phthisical patients."—*Pacific Medical and Surgical Journal*.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon*.

THE first lecture of Professor Simpson on "Fibroid Diseases of the Uterus," is in type, but the proof had not been received from the author at the time of publication of our present Number.

THE Profession will learn with pleasure that a subscription has been set on foot to indemnify Dr. Semple and his family in the legal expenses of the late action of *Hall v. Semple*. On inquiry, it has been found that the sum required to obtain a new trial was far beyond the means at Dr. Semple's disposal, and the project has been, therefore, reluctantly abandoned, although it had received high legal approval. Dr. Waller Lewis, of the Medical Department of the Post-office, and Dr. Forbes Winslow, 23, Cavendish-square, have consented to act as the Honorary Treasurers of the fund which is now being raised. We are sure it is only necessary that it should be publicly known that such a subscription has been set a-foot, for it to receive a generous response on the part of the Profession. Cheques or Post-office orders may be sent to either of the Honorary Treasurers. The former should be crossed to Messrs. Coutts and Co.

*Derensis*.—Mr. Fumaux Jordan's cases of "Fibro-cellular Annulus of the Leg" were published in the *Medical Times and Gazette* for March 1, 1862, p. 208.

We regret that our arrangements do not permit us to insert births and marriages, neither the deaths of any other than members of the Medical Profession.

That indefatigable philanthropist, Mrs. Baines, of Brighton, has written to us on the subject of the prevention of accidents by fire. The following is the formula she proposes for rendering ladies' dresses non-inflammable:—

"Tungstate of soda, prepared expressly for rendering fabrics non-inflammable, can be obtained, by order of any chemist, about 1s. per lb. Directions for use:—To three parts of good (dry) starch, add one part of tungstate of soda, and use the starch in the ordinary way. If the material does not require starching, mix in the proportion of one pound of tungstate of soda to two gallons of water; well saturate the fabric with this solution, and dry it. The heat of the iron in no way affects the non-inflammability of the fabric."

Dr. Leigh, of St. Helier, Jersey, sends us the following hint on the treatment of incontinence of urine:—

"In a corner of an India-rubber sponge bag, fasten a tube with a yard of India-rubber tubing, which will conduct the urine into a vessel on the floor. The same apparatus can be used for the irrigation of stumps, or for refrigeration, etc.

"St. Helier, Jersey, December 20."

*Parhydor, or Impermeable Silk for Surgical Purposes.* (Prepared by the Patent Waterproofing Company.)—It is claimed for this impermeable silk, by the inventors, that—

"It is free from smell; it is not rendered adhesive by tropical heat, warm rooms, etc.; it may be boiled in water without injury; it is not irritating to the skin, or otherwise injurious when in use; and that it may be packed for exportation in large quantities, as it is not liable to spontaneous combustion."

It certainly appears to us to be the pleasantest specimen of its sort that we ever examined; light and not sticky; and we do not hesitate to recommend it to our readers.

*Buckle's Pure Bottled Beef-Tea.* (Prepared by C. F. Buckle, Culinary and Pharmaceutical Chemist, 3, North-place, Gray's-inn-lane, London, W.C.)—Good beef-tea often makes the difference between a quick and a slow recovery, if not absolutely between life and death. There are many families in which, from want of skill in the servants, or from want of servants, good beef-tea cannot be had. Under such circumstances, Mr. Buckle's bottled beef-tea well deserves trial. We have submitted it, not only to our own experienced palate, but have caused it to be tasted by persons of all ages, including one invalid, whose comfort greatly depends on a supply of good beef-tea. All pronounce it remarkably nice, with a rich *meaty* flavour. It is not in the least gelatinous or sticky; neither is it *clear*; but it contains fibrinous and other elements, which are extracted by cold water and curdled by heat.

THE LAST PASS-LIST OF THE COLLEGE OF PHYSICIANS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—You will oblige by changing the address of Morris Tonge to 5, Bolton-row, in the list of names admitted Members of the College.

I am, &c.

W. COPNEY.

LEGALITY OF MIDWIFERY PRACTICE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—If your correspondent, "L., M.D.," will refer to the Medical Act, he will discover that he is mistaken in supposing a midwifery licence to be unrecognised by, and incapable of, being registered under that Act. The fact is, the Medical Act distinctly states that the licence in midwifery of the College of Surgeons entitles the holder to be registered as such.

December 27.

M. D.

SCARLATINA CO-EXISTENT WITH MEASLES?

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Dr. Richardson having named, in your journal of November 29, that he had seen scarlatina existing with rheumatism, I shall feel obliged if any of your correspondents will inform me whether they have ever seen it existing with measles; and whether the following case can have been scarlatina?

C. R., aged 5, after being in company with a little girl who broke out with measles on the following day, had the usual symptoms and eruption ten days after. On the third day, the eruption disappeared, and, on the third day after that, an eruption, resembling scarlatina, made its appearance, with fever and slight sore throat. This terminated on the fifth day, with desquamation of cuticle. Three of her brothers and sisters were kept away from her on the first appearance of the measles, but in the same house, and none of them took either of the diseases. I am, &c.

December.

R. C. B.

## QUESTIONS OF QUALIFICATION AND PRECEDENCE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—(1.) I wish to know if the licence of the Royal College of Physicians of London qualifies you to practise Surgery with the degree of M.D.? (2.) Will the licence with the M.D. enable its possessor to hold a Union practice in England? (3.) Would an M.R.C.S. Eng. and L.A.C. have precedence to the above qualifications? I am, &c.

RUD., M.D.

1.) An open question. (2.) We believe not. (3.) Precedence would depend on age, character, and social position. Whilst M.D.'s keep chemists' shops, L.A.C.'s may drive a pair of horses and dine with a duke.—ED.

## SMELLIE'S WORKS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The New Sydenham Society, some time since, promised a new edition. Little has hitherto been known of this celebrated man, who, in his day, rendered such important service to Obstetric Practice. It is to be hoped, therefore, that the learned editor of the new edition will enrich his work with a more ample biography of his author than has yet appeared in print. There is one very interesting point with respect to Smellie it would be desirable to hear something more about, namely, "He confesses that he submitted his various publications to the revision and correction of a friend, who is known to have been the celebrated Dr. Smollett."

I am, &amp;c.

A FELLOW OF THE OBSTETRICAL SOCIETY OF LONDON.

[ Warwick.

## SCARLATINA AND RHEUMATISM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you allow me to ask a question as to the cases of scarlet fever complicated with acute rheumatism and heart disease, reported in the *Medical Times and Gazette* of November 29? I have been taught, as a recognised fact, that scarlatina is not unfrequently accompanied by inflammation of the joints, sometimes going on to suppuration, and by pericarditis, or pleurisy, also by peritonitis, as seen in a case lately under Dr. Gull's care, but have never heard that true rheumatism has been observed in such cases before. What was there in the cases reported, in the perspiration, urine, tongue, pulse, or other symptoms, to lead to the supposition of two poisons co-existing in the blood? There was a case lately under Dr. Barlow, in which a mild case of scarlet fever was accompanied by pain in several of the joints, and the presence for a time of a systolic murmur, heard over the base of the heart; but these symptoms were not regarded as at all anomalous, and were certainly not accompanied by any others observed in rheumatism.

Hoping some one of your correspondents may explain the matter to me, I am, &c.

Guy's Hospital.

A MEDICAL STUDENT.

## DIGITALIS IN DELIRIUM TREMENS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The effect of large doses of digitalis in a case of "delirium tremens," which occurred in my practice a short time since, tends powerfully to corroborate the theory of its action, as held by Dr. Haudfield Jones in his communication in your last Number. The case was briefly this:—

E. F., 28, a prostitute and confirmed drunkard, first seen in her own house at 7 p.m. She has taken no food, except a little milk, for three days; has been drinking beer and spirits; fancies herself dead; surface of body is cold; pulse 90, soft and small; secretions, as well as can be ascertained, normal. To take ʒss. tinct. digitalis immediately; the same to be repeated in four hours; and subsequently ʒij. until the desired effect be induced.

9 a.m.—Has slept six hours and taken two quarts of milk; pulse 84, full and natural; surface warm; is thirsty; quite sensible, and willing to take beef-tea and continue the milk; has had three doses of the digitalis; excretions natural.

On the following day, there was some little nausea and slight delirium, but these yielded readily to ordinary remedies and slight stimulation. There was no relapse, and the case ended most favourably.

There can, I think, be no doubt that digitalis acted here the part of a "cardiac tonic" in a case of decidedly "asthenic" delirium, etc.

I am, &amp;c.

Ivy-house, Woodford, December 16.

ROBERT DUCHESNE, M.D.

## EPILEPSY—RENAL HÆMORRHAGE—IRREGULAR MENSTRUATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you kindly insert the following, as I am anxious to avail myself of the experience of others who may have met with a similar case?—

Sarah L., aged 30, single, of fair complexion, florid, and of full habit, had good health until 17 years of age, when she first experienced an epileptic seizure, which have since recurred, at intervals of a few months, till the last two years. These fits were unaccompanied by aura, nor did they appear materially to injure her general health, although she has been unable to pursue any active employment in consequence of occipital headaches, which sometimes were very severe, and which were alone relieved by setons and cupping at the back of the neck: menstruation has always been irregular, but never suppressed for any lengthened period. Nearly two years since she commenced, without assignable cause, to pass bright blood intimately mixed with the urine, which at first contained numerous small clots, apparently moulded by small ducts in the kidneys, and accompanied by slight lumbar pain; the clots soon disappeared, but for some months, with one or two short intermissions, the hæmorrhagic symptoms continued until the spring of the present year, when the kidneys resumed their usual healthy functions.

At first the case was considered as one of vicarious menstruation, partly from the almost inappreciable amount of constitutional disturbance, and partly from the absence of the normal menstrual flux. This view was, however, soon dispelled by the return of the courses, which continued with tolerable regularity for several months, and more than once took place whilst the urine was mixed with much blood. In spring last, from a bright florid colour, it gradually became of a dark hue, and then perfectly clear and free from albuminous traces. Since these symptoms commenced, the epileptic seizures have given place to fainting fits, whilst the head symptoms have been much relieved; but strange to say, during the

absence of hæmorrhage for four months this summer, the catamenial flow, which had occurred with tolerable regularity, was entirely suppressed.

In September last the old symptoms recurred, with suppression and much lumbar pain; no sickness; tongue clean, and pulse soft and regular. On several occasions nothing has been passed from the bladder for seven or eight days, and then little else than pure blood, and ever this has only followed the application to the loins of the cupping-glasses. The practical value of this remedy as a powerful therapeutical agent is here most strikingly demonstrated. At first a few ounces were taken weekly, giving slight relief; but for the last ten weeks, at intervals of a few days, the cupping-glasses have been applied (dry), and allowed to remain on about twenty minutes. This plan has, without exception, resulted in the passage of blood mixed with two or three ounces of urine within an hour of the removal of the glasses. In about twenty-four hours its beneficial effect appears to subside, and no further relief ensues until the re-employment of this remedy.

I am, &amp;c.

Walton, near Ipswich, December 23.

## APPOINTMENTS FOR THE WEEK.

January 3, Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.

5. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.

ODONTOLOGICAL SOCIETY OF LONDON, 8 p.m. Anniversary Meeting.  
MEDICAL SOCIETY OF LONDON, 8½ p.m. Mr. Hancock, "On the Superiority of Chopart's Operation and Excision of the Ankle over any other Method in all Cases admitting their Performance."

6. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

7. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.  
OBSTETRICAL SOCIETY OF LONDON, 8 p.m. Anniversary Meeting. Address by the President, Dr. Tyler Smith. Paper by Dr. Aveling, of Sheffield.

8. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.

9. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

## ORIGINAL LECTURES.

## CLINICAL TEACHING AND CLINICAL STUDY.

A LECTURE ADDRESSED TO THE STUDENTS OF THE WESTMINSTER HOSPITAL.

By GEORGE T. FINCHAM, M.D.  
Physician to the Hospital.

GENTLEMEN,—Before bringing before your notice any of the cases we have now the opportunity of studying in the wards, I wish to say a few words, especially to those who are attending clinical lectures for the first time, as to the scope and object of such lectures generally. The great end of clinical teaching is to bring before the student's mind the appearances and treatment of disease in connexion with the individual—as it actually occurs in the living patient. And in this consists the great difference between clinical lectures and those on the principles and practice of Medicine and Surgery, as given systematically by your teachers on those subjects.

In the latter you have disease, as it were, in the abstract brought before you; all peculiarities are eliminated; the symptoms most commonly present in any given malady are carefully grouped together, so as to produce a complete picture—a perfect typical image. Now this sort of description stands pretty much in the same relation to disease as it exists in the living patient, as an anatomical diagram stands to an actual dissection of the subject. Both are very clear, very intelligible, the colours bright, the outlines sharp; but then, on the other hand, they are too distinct, too neatly drawn; so that, if taken alone as a guide, they are apt to mislead, by making the student expect that the reality will be as well defined as the representation. Do not, however, imagine that these highly-coloured descriptions of disease, any more than anatomical diagrams, are without their use. Up to a certain point they are of the greatest service. They tend to fix in your minds the main outlines of the subjects you are engaged upon. They tell you what to look for. But, then, you must not stop there. In both cases the study of the actual object must come in, if you would know with anything like accuracy how things really are. Most of you have realised this in the case of anatomy. You are well aware how impossible it is for the man who does no more than pore over books and plates to be anything like a good anatomist. You know how poor a figure he makes when a scalpel is put into his hands, and he is told to cut down upon this vessel, or separate that fascia. And so you will find it to be the case with medicine, when you come into actual practice for yourselves. You will find yourselves terribly at a loss if you have contented yourselves with dwelling exclusively on the typical portraits of diseases, as drawn in systematic works and lectures. These will give you, comparatively, but scanty help, unless you have studied on the living subject. And why is this? Because you will not always find the well-marked picture of any disease with which you have familiarised yourselves, reproduced in all its exactness in every individual case of the disease which you come across. The result will be that you will be puzzled and confused; then, it may be, disheartened and discouraged. But this is not all: instead of beginning practice, knowing what you profess, you will have to learn your experience; in other words, to experiment upon the first patients who are unfortunate enough to fall into your hands.

Now, it is to save you from this state of things, so humiliating to yourselves, and so injurious to the public, that clinical lectures are given, and an attendance upon them so properly insisted upon by the licensing bodies; their object being to introduce you to actual practice—to help you to recognise disease as it occurs in the individual patient. I say *help* advisedly, because, unless you yourselves take a full part in the matter, lectures are of but scanty use. It follows, therefore, that, unless you yourselves come regularly into the wards of the Hospital, and watch the cases on which comments are made in the lectures, these will avail you but little. In other words, clinical *study* must accompany clinical teaching.

And now, what is clinical study? Surely, it is something more than making an occasional visit to the wards, lounging in a listless fashion from bed to bed, coming one day, staying away the next, utterly indifferent to all that is going on

around you. This is not clinical study; yet I am afraid it is what passes for such with not a few. I am sure I do not exaggerate when I say that scores of pupils pass through their period of study without ever having watched carefully one case of disease from its beginning to its end: they may have skimmed the living book open before them; as for reading and marking its contents, this they have never dreamed of doing. Clinical study, then, is something more than this. It is the watching and noting disease as it occurs in the individual; it is the acquainting yourselves with it as modified by age, sex, and habits—by the complication of previous or intercurrent disorders—by, in short, the numberless circumstances which make, or ought to make, each separate case a special object of study. This, then, is clinical study, and its first great use is to help you in diagnosis, in ascertaining what disease you actually have to treat. And this help is very needful, for the modifications I have alluded to constantly throw a sort of haze over the case, dulling its sharp outline, and necessitating trained eyes to separate off the essential disease from its accidental complications, and so to recognise its real character. But if clinical study be all important to help you to form a correct diagnosis, still more is it necessary in order that you may treat your patients properly. The more you see of practice, the more you will learn to know that there is no such thing as typical treatment of disease—that disease in the abstract cannot be laid hold of—that there can be no plan which holds good independently of the individual. No; each case has its own special indications of treatment; and it is the power of ascertaining what these are that constitutes the skilful practitioner. It is the ignorance of this truth that makes people so fond of asking, “What is good for this or that disease?” “What is good for a pleurisy,—what for a fever?” Such questions cannot be met in the way people expect. The proper answer is, “Show me the person suffering from this or that disease or symptom, and then I may be able to tell you what may do them good; otherwise, I may rather harm them.” And here it is that homœopaths, and their followers, catch the ear of the ignorant, and seem to triumph over us. They profess to have a specific remedy not only for each disease, but for every symptom. They will tell you what “is good” for every thing—from an itching of the skin to an inflammation, it may be, of the brain. No malady is so small, none so great, but that some drug will hit and extinguish it completely; and all this is laid down in books with such pretended accuracy, that old women of both sexes practise domestic homœopathy with the greatest confidence, and, of course, with the most complete success. The practitioner of rational medicine, however, does not talk quite so big; he does not profess to have found an exact remedy which, under all circumstances, is, as it were, to kill the disease. We profess to have few so-called specifics. With the exception of quina, for ague and its allied affections; mercury, in some forms of syphilis; iron for anæmia; fresh vegetables for scurvy; and, possibly, the alkalies for rheumatic fever, we have scarcely any remedy capable either of neutralising, in an antidotal fashion, a morbid element, or of directly adding to the system something absolutely wanting. We do not, then, profess to cure disease, in the vulgar sense of the term, by meeting it in direct antagonism. We trust, in the main, to nature to repair her own work. We believe that the same processes by which the functions of the body are carried on in health, have a direct tendency to restore them when diseased; and we hold, that the true office of the Physician is to put the patient as much as possible in such a condition as will most favour the free working of these processes. But, to do this properly, he must well observe disease, not only in the abstract, but as it occurs in the individual patient, and so learn to discriminate the special need of each; for, although it may be quite true that a certain plan of treatment has been found advantageous in five cases of the same malady, there may be something in the sixth which necessitates a very different plan, in order that the patient may be brought into a state in which nature will best employ her restoring power. Thus, for example, in typhoid fever, you may have several cases in which exposure to fresh air, and a full supply of easily digested food, given at short intervals, with little or no wine, are sufficient to sustain the patient until the balance between the supply and waste of tissue is restored. But, in the next case, you may find far more required. You see your patient with wandering intellect, dry and tremulous tongue, twitching muscles, and a streara-like pulse—here the waste

has been so great, that both nerve and muscle are failing. You give alcohol with unstinting hand, because you know that this agent will alike retard further waste, and stimulate and sustain the flagging heart. To take another acute disease, pneumonia. Here, in a large majority of cases, the application of turpentine stupes to the chest, after previous local blood-letting, should there have been much pain, diaphoretics, and a nutritious diet, will be the remedies best adapted to restore your patient to health. On the other hand, wine and brandy, with ammonia—in short, a stimulating plan of treatment is absolutely necessary, when the flagging pulse, and cold, wet skin show that the circulation is failing. You must then, gentlemen, if you would know anything of the healing art, study both disease and its treatment in the wards, in the persons of individual patients; and, to this end, I should like to see you, with your note-books in your hands, really busying yourselves with the phenomena of disease, and accurately recording them. Do not, however, take too lengthy notes; do not burden your pages with a number of unimportant trifles which very likely you will never read again; but take only the main points of each case, and, of course, the treatment adopted. Moreover, when you return home in the evening, re-write these notes in a book, to be kept for future use, and, at the same time, read up in your text books the account of the malady of which you are studying the particular example. I am addressing myself now to those students who have completed at least one year of study at a Medical School, and who are not quite unfamiliar with the appearances of the more common diseases. I do not recommend the same plan to be adopted at once by those who find themselves in the wards for the first time. These I should not advise at first to take notes, but rather to acquaint themselves generally with the more palpable and prominent features of disease, before they proceed to study it more deeply. They should learn to recognise its physiognomy, so to speak, and much information may be gained in this way. Thus, the profuse sour sweat, the bright complexion, and the clear intelligence of a patient point at once to rheumatic fever; whilst from the dusky flush, dulled perceptions, and supine posture of the sufferer from typhus, you learn at a glance with what malady you probably have to deal. So, too, with more chronic diseases. Who that has once realised the salient phenomena of Bright's disease—the soft, silky skin, the puffy face, and swollen limbs, the very

"Aquosus albo  
Corpore languor"

of the Latin poet—could fail to recognise it again? It is, then, to the study of these palpable objective phenomena that I strongly advise those of you who are beginning clinical medicine, at first to confine yourselves. Pass two or three months in this way, and then begin to take notes in the manner I have suggested; and I should further recommend you, if you have the opportunity, to take, at the same time, notes of several cases of the same disease. You will thus be able to compare them together, and to ascertain how far they fall short of, or come up to, the typical picture of the malady as drawn in books.

As to the exact mode in which to take your notes, I strongly advise you to adopt the plan, which has been drawn up for your use, in the little work entitled "Hints for Clinical Clerks in Medical Cases." This you can have on application; it will not, therefore, be necessary for me to speak to you more fully on this subject. By taking notes in this way, even of a comparatively few cases, systematically and regularly, besides forming habits of attention and observation, you will acquire a knowledge of disease and its treatment which you will never forget, and which will be of incalculable use to you in after life.

## ORIGINAL COMMUNICATIONS.

### ON VESICO-UTERINE FISTULA (a).

By JAMES R. LANE, F.R.C.S.,  
Surgeon to St. Mary's Hospital.

A VESICO-UTERINE fistula is an abnormal communication between the bladder and uterus, which communication, in the cases hitherto observed, has always been situated between

(a) Read at the Western Medical Society, November 21, 1862.

the base of the bladder and some part of the canal of the cervix uteri. Such a condition, of course, implies a complete incontinence of urine, just as in the more common case of a vesico-vaginal communication, since the urine, after passing through the fistulous channel into the uterus, immediately flows away, through the os uteri, into the vagina.

Vesico-uterine fistulæ are of very rare occurrence. Very few cases have been recorded or noticed by British writers; and abroad I know of only one Surgeon, M. Jobert de Lamballe, who has paid much attention to the subject. To this gentleman's researches, and to other recorded cases, I shall presently recur; but I prefer to commence by describing an example of this accident, which I have recently treated, and which is the only one in which, in this country, as far as I am aware, any remedial measures of an operative character have been resorted to.

C. R., a spare Irishwoman, aged 45, was admitted into St. Mary's Hospital, on May 9, 1862, under the care of Dr. Tyler Smith, who afterwards requested me to take charge of her. The following is the history she gave of herself:—She had been married four years. Four months after marriage she miscarried. Two years afterwards she was confined of a child at the full period. The labour was protracted, and she suffered severely, being finally delivered with instruments, but no bad results followed on this occasion. In January of the present year, four months previous to her admission into the Hospital, she was again delivered of a child at the full period. On this occasion she was in labour twenty-four hours, and again suffered greatly; but she was not aware whether or not instruments were again used. The child did not live. Immediately afterwards she found herself unable to retain her urine, and the whole of it had since escaped involuntarily, so that her clothing by day, and her bedding at night, had been constantly saturated with it. The labia and inside of the thighs were much excoriated by the continual irritation.

On examination with the speculum, there appeared to be nothing the matter with the vagina or urethra; the vesico-vaginal septum was perfectly sound throughout; but when the os uteri came into view, a small quantity of fluid was observed to flow from it into the cavity of the speculum. By digital examination, the os uteri was found to be somewhat larger than natural; it would just admit the tip of the finger, with which, about half an inch above the os, and in the canal of the cervix uteri, an opening could be felt on the anterior surface, leading towards the bladder. A sound introduced into the bladder by the urethra could, with a little manipulation, be brought into contact with the finger in the cervix uteri. The opening appeared to be rounded, and to be about the size of a pea, as if a small piece of the uterus had been punched out.

The accompanying diagram will show clearly the exact position of the aperture of communication, and will also serve to illustrate the normal anatomical relations of the implicated parts, of which, especially as regards the arrangement of the peritoneum between the bladder and the uterus, it may not be waste of time to say a few words. Supposing, then, the

average length of an unimpregnated uterus to be three inches, the upper two inches, or rather less, may be allotted to the fundus and body, and rather more than the lower inch to the cervix. The line of reflection of the peritoneum anteriorly, from the uterus to the bladder, takes place as nearly as possible

opposite the junction of the cervix with the body, and is, therefore, at least an inch above the lower end of the organ. The neck of the uterus has been divided, anatomically, into the vaginal and supra-vaginal portions, the former being that small part which may be seen from the vagina; the latter, the larger portion situated above the insertion of the vagina, and between that point and the junction of the neck with the body. The whole of this latter part of the cervix is in immediate relation, anteriorly, with the base of the bladder, without the intervention of peritoneum; and it is here that vesico-uterine fistulæ have, in every instance, been found.

The reflection of the peritoneum posteriorly is widely different, the whole posterior surface of the uterine neck, and also the upper three-quarters of an inch of the vagina, being covered by that membrane.

From this brief anatomical digression I will return to the case in question, the nature of which I had accurately ascertained in the manner above described. It remained to determine if any, and what remedial measures should be attempted.

Two plans of operation, essentially different in their nature, had been suggested by Jobert, the only authority I know of who has paid special attention to the subject. The first plan which he suggests consists in making free lateral incisions through the os uteri and through the upper end of the vagina, so as to convert the lower part of the cervix uteri into two flaps, anterior and posterior, by separating which, the fistulous aperture might be brought into view, so as to admit of its edges being pared and sutures being applied. He suggests that these incisions should pass completely through the lower end of the uterus, and be continued into the upper end of the vagina, until they penetrate into the loose areolar tissue of the broad ligament. These incisions, he says, render it easy to get at the aperture of communication, and enable the Surgeon to perform his manipulations with facility, and without any obstacle whatever.

This plan of procedure I must say I felt considerable hesitation in adopting. Free incisions into the uterine tissue are not, perhaps, attended with much risk—as modern practice has pretty abundantly demonstrated—but to penetrate into the loose cellular tissue of the broad ligament, seemed to me to be a rather serious matter. No one would, I think, be much surprised to find such incisions followed by peritoneal inflammation, or by diffuse suppuration in the pelvic and sub-peritoneal cellular tissue. Neither could I, from my experience in plastic operations high up in the vagina, accept without some reservation M. Jobert's statement as to the extreme facility of a similar proceeding in the interior of the uterus. He, however, records a case in which he operated in this way in the year 1849, and in which he ultimately succeeded in curing his patient, though a rather serious train of symptoms followed the operation, and the treatment was protracted over a period of several months. Three months after the operation an escape of urine took place through a small opening in the track of one of the sutures which had not been removed, but this was closed under the application of the nitrate of silver. Though the progress of this patient was, in many respects, tedious and unsatisfactory, and her life appears to have been in considerable danger, still, to have succeeded at all in so difficult a case, especially before metallic sutures had been introduced, was, undoubtedly, a great triumph in Surgery.

I, however, thought it better, for the reasons above stated, to reject this mode of operation; and the idea which suggested itself to me to reach the fistula was to enlarge the opening, in the downward direction, by dividing that portion of the uterus which was situated below the fistula, and by continuing this incision into the upper end of the vagina in the longitudinal direction. I should thus have obtained a large longitudinal opening, the upper angle of which would have corresponded to, and have been formed by, the fistula itself. I believe that this would have enabled me to get at its upper end, where the fistula was placed, and which was the only difficult part to deal with, so as to apply the necessary sutures. If, however, I did not find sufficient room, I could have obtained more by making lateral incisions in the cervix uteri, in the direction indicated by Jobert, but of less extent. This plan would, doubtless, have been attended with considerable difficulty, still, I believe, it was not impracticable—the danger would not have been great; and, if I could have succeeded in closing the uterine portion of the wound in a first operation, there would have been comparatively little difficulty in dealing with the vaginal portion on a subsequent

occasion. But there was the alternative of the second operation, suggested by Jobert in his treatise, but which I did not then know that he had ever put in practice. It consisted in closing the os uteri by suture, thus shutting off the communication between the uterus and the vagina, but leaving the fistula itself uninterfered with. When this was done, the urine would still, of course, get into the uterus, but it could not pass further; and the remedy, so far as the escape of urine externally was concerned, would be practically as perfect as if the fistula itself had been closed. Future pregnancy would, of course, be impossible, and menstruation must be performed through the bladder, by means of the fistulous opening; but these disabilities appeared, to my mind, to be more than compensated for (especially taking into consideration that the patient was 45 years of age) by the avoidance of all risk from the operation itself, by the greater certainty of success, and also by the fact, that should it not succeed, or should any difficulty in the matter of menstruation be subsequently met with, a slight incision through the new line of union would at once restore the parts to the same condition as before the operation, and either of the other procedures to which I have before alluded would have been as applicable to the case as ever; whereas, if I had commenced with either of the other plans, their failure would not have left the parts in nearly so favourable a condition for this more simple method.

Accordingly, I decided in favour of this operation, and on May 14 proceeded to put it in practice. The patient being placed in the lithotomy position, Bozeman's speculum was introduced, and held so as to depress the posterior wall of the vagina, and bring the anterior wall and the os uteri into view. The anterior wall of the vagina, just below the os uteri, was then seized with one vulsellum, and the posterior lip of the os uteri with another. By these means, with a little traction, the parts were drawn down within convenient reach, and were held in the required position by assistants. I then, with a narrow knife, freely denuded the edges of the os uteri, and brought the raw surfaces together with four silver-wire sutures, passed by means of the tubular needle. I brought the ends of the wires through the holes in a thin leaden plate, and fastened them with perforated shot, after Bozeman's method. I greatly prefer, in this and all similar cases, the use of the leaden plate to the fastening the wires by simply twisting their ends. The slight pressure which the plate exercises is of great service in keeping the part steady and motionless; and it also acts most advantageously in keeping the sutures throughout at a proper distance from each other, thus preventing that gaping apart of the wound in the intervals between the sutures which is so likely to take place if they become unduly approximated to each other. After the operation, a double curved silver catheter was retained in the bladder, and was connected by a piece of elastic tube to an India-rubber bag to receive the urine.

For three days after the operation, she suffered no pain whatever; her pulse was natural, and there was no sign of constitutional disturbance. No escape of urine took place, except through the catheter.

On the fourth day, she complained of pain in the back and lower part of the abdomen, her pulse was quickened, and there was slight thirst and feverishness. This was followed during the night by an escape of blood with the urine through the catheter, and the next day the feverish symptoms had disappeared. The discharge of blood with the urine continued for three days, and gradually ceased on the fourth. It was evidently the re-establishment of menstruation, which had not occurred since her confinement in January, four months previously. No discharge of blood took place per vaginam, nor was there any escape of urine, except through the catheter.

On May 21, seven days after the operation, I removed the plate. The os uteri seemed firmly closed. There was no escape of urine. The catheter was retained for two days longer, when it was discontinued by degrees, at first for a short time only, afterwards for a longer period. At the end of a fortnight after the operation, she was able to dispense with it altogether, and had perfect control over her urine.

On June 4, three weeks from the operation, she left the Hospital perfectly well. I saw her occasionally for three months after she left the Hospital; she remained quite well, menstruating regularly through the bladder at intervals of about three weeks. The passage of the menstrual secretion through the bladder was attended with no pain or difficulty whatever; on the contrary, she seems to consider it a very convenient arrangement.

On looking into the literature of this subject, the first recorded instance of a vesico-uterine fistula appears to be one given by Madame Lachapelle in her "*Pratique de l'Art des Accouchemens*," published in 1825. This patient was delivered after a natural labour, but not till three days after the loss of the liquor amnii. Eight days after delivery incontinence of urine set in, and she was ultimately discovered to have a fistula four lines in diameter in the neck of the uterus. She was considered incurable. Another case which occurred in 1828 is given by Professor Stoltz, of Strasbourg. This patient died forty-one days after delivery, and a vesico-uterine fistula was found about the middle of the cervix; but there was also a communication posteriorly between the neck of the uterus and the peritoneal cavity, directly opposite the vesico-uterine communication. This patient appears to have died from peritonitis, caused by the escape of urine through this last-mentioned opening. A third case is that given by M. Jobert, to which I have already alluded, and which I believe is the first in which any operation was performed. It occurred in 1849, and will be found in his "*Traité des Fistules Vésico-Uterines*," &c., published in 1852.

A very singular case is given by Dr. Simpson, of Edinburgh, in which an abscess formed between the bladder and the neck of the uterus, and opened a communication between the two cavities. Dr. Simpson dilated the os uteri, and applied nitrate of silver to the opening, under which treatment it gradually contracted and closed. (See Simpson's "*Obstetric Memoirs*," vol. i. p. 232.)

Dr. Leishman, Physician to the Lying-in Hospital, Glasgow, published an account of a case of vesico-uterine fistula in October, 1861, in the *Glasgow Medical Journal*. This patient had a lingering labour, and the liquor amnii was evacuated two days before the delivery was completed. Incontinence of urine did not commence till some days after delivery. In this case the incontinence gradually diminished. A year afterwards she was able to hold her water for four or five hours; and when the urethra was compressed, and she was directed to make an expulsive effort, no urine escaped through the uterus. The os uteri was healthy in appearance, and "firmly closed." It was remarkable that this patient, as the incontinence disappeared, had ceased to menstruate in the ordinary way, but had regularly, at monthly periods, passed blood with her urine. From this circumstance, together with the apparent closure of the os uteri, I should infer that the incontinence ceased, not because the fistula itself had closed, but because some spontaneous obliteration of the cervical canal had taken place below the abnormal communication; that nature had, in fact, performed the very operation which I practised myself in the case which forms the basis of this paper.

These were all the facts relating to this subject that I could at first meet with, and they were all that Dr. Leishman also, in his paper published in 1861, was able to collect. I, however, wrote to M. Jobert, asking him whether he himself had performed any other operations in similar cases, besides the one recorded in his book; and I was somewhat surprised to hear from him, in reply, that he had operated in thirteen cases, of which eleven were cured. They are all recorded, he informed me, in the *Lancette Médicale* and the *Union Médicale*. I have not been able to meet with any journal going by the first of these two titles, but I have searched the *Gazette* (or *Lancette*) *des Hôpitaux* and the *Union Médicale*, and in them I have found very circumstantial and elaborate accounts of seven cases, besides the one to which I have already alluded. (See *Gazette des Hôpitaux* for July 19 and August 20, 1853; also *L'Union Médicale*, November 22, 1856, January 6, 1859, three cases, and October 18, 1860.) After his first case, M. Jobert appears to have given up the attempt to get at the fistula itself by making extensive lateral incisions in the uterus and vagina; and to have resorted, as I did, to the easier and safer, though physiologically less perfect, operation of closure of the os uteri.

One of his patients died from peritonitis. In this case the os uteri had been much injured, and its lips were puckered and irregular. Free lateral incisions were made in this case to relieve cicatricial tension, and to these incisions most probably the fatal peritonitis owed its origin. All his other cases appear to have terminated satisfactorily, and the patients obtained perfect control over their urine, while menstruation took place regularly and without difficulty through the bladder.

It is very remarkable, that in the majority of these men-

struation took place, precisely as it did in my case, within a few days of the performance of the operation, whereas, from the time of the formation of the fistula to the time of the operation nothing of the kind had been noticed. It appears as if the continual stream of urine passing through the cervix uteri in some way or other interfered with the re-establishment of that function, but that the mere entrance of a small quantity of that fluid into the uterine cavity did not produce the same effect.

In one particular, the case observed by me differed from all the others, if the history given by the patient is to be relied on. She passed her urine involuntarily immediately after delivery; whereas, in all the others, the incontinence was not established till some days afterwards, and in several was preceded by the separation and discharge of a slough. The immediate escape would seem to indicate a laceration of the uterine tissue, rather than a sloughing from protracted pressure, which is the most common and most probable cause of vesico-uterine, as well as of vesico-vaginal, fistulæ. It might be, however, that, in this case, the incontinence for the first few days was of a temporary nature, and depended upon debility and loss of power in the sphincter of the bladder following the labour, which power might not have been regained till after the separation of a slough, and the establishment of a permanent incontinence as the result of the fistula.

In conclusion, I have only a few words further to add. There may, possibly, be some who think it an almost unwarrantable proceeding, even though it may not be a dangerous one, to produce occlusion of the os uteri; and, by so doing, not only to divert the menstrual secretion, but to produce an absolute barrier to future child-bearing. No doubt, it is a thing which should not be undertaken lightly, or on insufficient grounds; but I hold that there was ample justification for it in such a case as that which I have related. The condition of the patient, while unrelieved, was such as to render her existence loathsome to herself and to all around her, and utterly to preclude her from gaining her living by any employment which would bring her in contact with strangers. Furthermore, even if child-bearing were held to be the principal end and aim of female existence, it is next to impossible that impregnation should take place with a continual stream of urine flowing through the os uteri, mixing with and intercepting the seminal secretion. It should also be remembered, that those in whom such a lesion has occurred have almost always passed through the ordeal of parturition, once at least, at imminent risk of their lives, and that they will gladly consent to any operation, which will not only relieve them from their present misery, but will have the further merit (as they will most probably consider it) of preserving them in the future from dangers such as they have already gone through.

#### HISTORY OF A CASE IN WHICH

### INTESTINAL MATTER WAS VOIDED FOR MANY YEARS BY THE URETHRA.

WITH REMARKS.

By A. M. McWHINNIE, F.R.C.S.

Mr. E. C., an old attached Medical friend, a country Practitioner of a healthy family, himself of good constitution, informed me, as far back as the summer of 1840 (he being then about 35 years of age), whilst driving with him in his neighbourhood, that air passed through the urethra during and after micturition. Feeling himself otherwise quite well, this occurrence gave him no great concern; he regarded it as singularly strange, but did not attach the importance to the case which evidently belonged to it. This passage of flatus had suddenly attracted his attention a short time previously; no pain or inconvenience had preceded it, nor was there any other accompanying feature observable.

Without giving Mr. C. more ground for serious apprehension of his case, than was necessary to secure a careful management of himself, I recommended him to abstain from over exertion, to take simple food, and to keep the large intestine habitually free, either by gentle aperients, or, if necessary, to prevent its distension by enemata—an advice which he afterwards constantly followed, and to which his comparatively comfortable condition for many years was, in

all probability, mainly due. From my notes I find that I enjoined especially that the injections should be used in the evening, so that the lower bowel might be empty and tranquil during the night, taking care that the ivory or elastic tube should be introduced gently, and be directed towards the hollow of the sacrum, and that it should not be passed in with violence, or far beyond the sphincter. On causing him to empty the bladder under water, it was evident that the bubbles of air were produced by intestinal gas. I could discover nothing wrong by examination of the abdomen, nor did the patient feel any pain or inconvenience. The urine was voided freely, and was uniformly clear.

For several years after that time I visited him occasionally with my colleague and friend, the late Dr. Roupell; the same symptoms continued, but no new feature had presented itself. His professional duties were not interfered with. Sometimes I accompanied him in a drive, or for a day's shooting, without any allusion being made to the infirmity, of which none others were aware, except some members of his family.

In the winter of the year 1849, however, one of his brothers, now a Surgeon in London, came to inform me that my patient's case had assumed now a more serious aspect,—a partridge bone had passed through the urethra, and, besides air, there was occasionally faecal matter, which then caused some little impediment to the flow of urine. In this condition he came to London, on November 21, 1849, and I met Sir B. Brodie, Mr. Stanley, and Dr. Roupell in consultation; our patient suffering both in mind and body, much pulled down and depressed, as I had been informed by his family, but was buoyed up by the hope—and in which he was encouraged by the gentleman to whose house he came, formerly in the Profession—that some operative proceeding might be suggested for his relief; and, indeed, it was his own impression that the seat of the disease was not remote from the prostate.

A circumstance had always struck him as well as myself, that, whilst intestinal matter had found its way freely, and often, through the urethra, no urine was ever discovered to flow into the rectum. The urine voided was, on this occasion, wholly mixed with faecal matter, dispersed through it. A most careful examination by the rectum revealed nothing abnormal at or near the prostate. No unnatural condition of parts could be detected by the finger passed beyond the gland; nor was there anything wrong discoverable by external manipulation of the abdomen. The exact seat of the mischief remained a matter of conjecture. From the circumstance of no urine flowing into the bowel, we concluded that the fistulous track of communication with the bladder must be in a more elevated part of this viscus. Sir B. Brodie even hinted that it might be between the fundus of the organ and the transverse arch of the colon,—adhesions having previously been formed between the two.

The urine, when voided, was usually clear at first, but afterwards became mixed, more or less, with feculant matter; still, none of the urine escaped by the rectum,—a circumstance, Sir B. Brodie remarked, that he had also observed in all similar cases that had come under his notice. No positive light was, therefore, thrown upon the exact nature of the case by our examination. All that we could advise was, to follow up the simple rules of treatment that common sense would dictate. We recommended simple diet; to continue to keep the lower part of the bowel free by mild aperients, or by enemata, if necessary, in the evening; and to sleep as much as possible on the back (upon this point I had written to him); to avoid exertion and abstain from night work, as I had always strongly enjoined.

The prognosis of my friend's case was, of course, very unfavourable, and gave us much uneasiness. Sir B. Brodie, who had always seen a fatal termination to these cases, considered that he could not long bear the irritation and inflammation of the bladder, arising from the introduction, constantly repeated, of foreign matter into it, and believed that he would not long survive.

Mr. C., however, returned home, and, with care, was enabled to resume most of his duties. In the January following, his brother informed me that he could go through all excepting his night work. Dr. Roupell shortly afterwards received a summons to visit him, on account of distension of the abdomen, accompanied with hiccup. Aperients were given, and leeches applied to the iliac fossæ. Under this treatment relief was afforded.

From this period we had reason to congratulate ourselves that a favourable turn in the history of the case was dated; and it is remarkable that the aperture of communication between the two viscera, wherever it may have been situated, seemed to have become so far diminished or closed, that intestinal matter had ceased to make its way into the bladder; and he now continued in comparative comfort for many years, troubled, however, at intervals, by attacks of bowel obstruction, due, we imagined, to the existence of some constriction near the seat of the original mischief.

I select a note of Mr. C.'s condition when I visited him in June, 1854. He has lately been much disturbed by flatus collecting, as he imagined, in a large pouch connected with the sigmoid flexure of the colon, and situated, he thought, below some constricted point of the canal. It formed a temporary swelling in the left lumbar region. This swelling disappeared when the air had ascended through the constricted part, and which it would do with a very audible noise. Of this occurrence he complained as being very annoying and troublesome. Of late much less air has entered the bladder. He looks well, but is occasionally very irritable. He still fancied that when air did pass into the bladder it was near to the neck of the viscus. From the symptoms I always considered that the aperture was above the ureters; and, as he would unreservedly discuss the point with me, I made a sketch of where I supposed was the seat of the mischief, and which, I daresay, would be found amongst his papers.

Mr. C. wrote to me occasionally to say that he had attacks of obstruction—relying chiefly on the enemata and mild purgatives for relief. An obstruction of this kind would confine him to his bed, and might be followed by twenty or thirty evacuations. In this way life was prolonged several years, his professional duties, however, being interrupted by these attacks—sometimes very alarming, occurring at intervals of a few weeks, but yielding to simple means; the seat of such obstruction being, we thought, in all probability, at or near the part of the bowel which had communicated more or less directly with the bladder. In other respects there seemed a permanent change for the better; and, with the exception of occasional irritability of temper, and a rather anxious expression of countenance, he looked like one in rude health,—his physiognomy contrasting, as was often remarked at the spring meetings of our club, with the less healthy complexions of the metropolitan members; and about three months before his death last year, when he came to introduce to me his two sons, who had entered our Profession, I complimented him on his healthy appearance.

On Friday, August 23, he drove over to visit one of his brothers in practice in the same county, and seemed to be in his usual state of improved health. On his return home at night, however, he felt unwell, and complained still more the next day. On Sunday his brother was sent for, and found him very unwell, but left the next morning, after employing the usual remedies, believing that he would be "all right again," the distension being, apparently, not greater, or so great, as in many former attacks. His condition did not improve, and on Tuesday afternoon (August 27) the family were alarmed, and sent for his brother again. He prescribed and left him, still not apprehending any immediate danger. "At night," as his son writes, "one of the younger children, who always slept in the same room with the sufferer, came and awoke us all up in a great fright, saying he was dying. We found him quite black in the face, gasping for breath. We gave him brandy, under which he rallied. We immediately sent for a neighbouring Medical friend, who did everything possible, but to no effect. At 7 a.m., our poor father, whilst in the act of turning round, became quite black in the face, and gasped for breath, until life became extinct an hour afterwards. It was an awful sight." He adds,—"We have often seen him quite as ill as he at first appeared in this attack. It was from his old complaint—the bowels. Very little passed from the bowels, and he became swollen to the size of a barrel. No doubt the cause of his death was the wind pressing upwards on the lungs."

The sad and appalling termination of this protracted case in a very hot season of the year, did not permit the thought of a post-mortem examination until it seemed too late for it to be undertaken, when I proposed it to the family, knowing, as one of the relatives remarked, that the poor fellow himself would have wished it.

Interesting as would have been such an examination, we

should doubtless, however, have found, as in the records of similar instances, that this case would have been quite out of the reach of operative Surgery. On forwarding to Sir B. Brodie the result of this case, in which I knew he was particularly interested, I was favoured with the following reply:—

“Broome Park, Betchworth, Surrey,  
September 3, 1862.

“My dear Sir,—I thank you very much for your kindness in communicating to me the result of poor Mr. C.’s case. Such cases are not of very common occurrence, but every now and then they have come under my observation, but in no case that I have seen did nature do so much towards the accomplishment of a cure as in the present instance. I conclude with you that the immediate cause of death was a constriction of the bowel. It seems to me very desirable that the case should be put on record, and I am glad to find that you contemplate a publication of it.

“I remain, dear Sir, yours truly,

“B. C. BRODIE.”

The extraordinary amount of distension of the abdomen induces me to think, with others, that it may have been partly produced by the giving way of some of the surrounding adhesions, and the consequent effusion into the cavity of the peritoneum. I had postponed the publication of these interesting particulars, until I had an opportunity of seeing the friend who was called in at the time of the fatal termination, to learn if any more light had been thrown upon the case. He considered that the immediate cause of death was the asphyxia arising from the pressure upwards of the diaphragm.

This gentleman found some impediment to the introduction of the elastic tube, which he in vain employed per anum for his relief, but was not clear as to its nature. I never heard my patient complain of any difficulty in introducing the ordinary tube; and we know, as I observed to this gentleman, that an obstacle to the introduction of a long elastic tube for the purpose of relieving the large intestine of its contents, may arise from the varying course of the bowel above the rectum, and which may give rise to the supposition of the existence of stricture. Of this there is an illustration in the museum of St. Bartholomew’s Hospital, which I have been in the habit of exhibiting, in which the sigmoid flexure was so long, tortuous, and loose, that it might have been protruded through the inguinal canal of the right side.

Preparations will be found in our collections which not only exhibit the different points at which the intestinal canal may communicate more or less directly with the urinary bladder, but also explain the original causes of such communication.

My attention was directed by Mr. Stanley, during our attendance on our late friend, to illustrative specimens of this kind preserved in the pathological museum of Fort Pitt, Chatham.

Dr. Longmore has obligingly refreshed my memory by sending me the catalogue descriptions of these specimens, and from which I select the two following instructive ones:—

“Preparation 1766.—A large sac, situate at the posterior and superior fundus of the bladder, external to its walls, containing a small irregular shaped piece of bone, with sharp points and edges, and of a greenish-black colour. The sac communicated with the bladder by two openings, situate a little to the inner side of the entrance of the right ureter; one of a size to admit a common quill, and the other, capable of receiving a probe. The sigmoid flexure of the colon adhered to the sac, and communicated with it by an ulcerated opening about the size of a crown-piece, with ragged, irregular edges; the piece of bone had probably been swallowed, become entangled in the folds of the intestine, and produced ulceration.

“Preparation 1767.—Sac of a large abscess, situate to the left side, between the bladder and rectum, communicating with the former by an opening capable of admitting a common quill above and between the entrance to the ureters; the surface of the rectum is very irregular—much ulcerated, and communicates with the sac by five large openings, the consequence of dysentery of four months’ standing.”

It is stated that in the present instance no urine was ever observed to enter the rectum. This circumstance may afford some clue as to the part of the bladder implicated, the aperture being probably higher up in its posterior wall than in the specimen preserved in the museum of St. George’s Hospital, where urine had passed freely into the bowel. Here the communication, situate at the lower part of the posterior

wall, of the diameter of a goose-quill, communicates with the sigmoid flexure of the colon.

The case is described by Mr. Charles Hawkins, in vols. xli. and xlii. of the *Med. Chir. Transactions*, and derives additional interest from the fact of fecal matter having formed the nucleus of a large stone, which was removed by lithotripsy by that gentleman. Hence, the importance sometimes of washing out the bladder, and which the patient may be instructed to do. In my case this treatment did not seem necessary from the easy exit of the foreign matter. The patient whose case was complicated by stone, which Mr. Hawkins successfully crushed, continued afterwards to pass fecal matter with his urine, and, until within a few weeks of his death, he daily washed out his bladder with warm water by means of a syringe and catheter.

We cannot for a moment entertain the idea that Surgical interference could be of any avail in cases of this description, nor do we derive encouragement from recorded dissections, or from the examination of preserved specimens in our museums. What, then, are we to say to a patient thus afflicted? We must say that the fistulous passage, it is true, is beyond our reach, but we may hope to accomplish much towards his comfort by assisting the restorative powers of nature, aiding her in her instinctive tendency to heal, knowing from such a case as the foregoing that, if there be no serious complication existing, a patient so circumstanced may have his life prolonged for a very considerable period; that, in fact, so far as the aperture of communication between the two viscera is concerned, nature may effect its closure. The Surgeon acquainted with the facts of a history like this would, instead of at once giving the sufferer up to despair, be enabled to impart to him great comfort and consolation. These observations may, perhaps, be not unworthy of attention, as illustrative of the treatment of so grave an affliction, for life was here, in all probability, prolonged by attention to the rules prescribed.

5, Crescent, New Bridge-street.

#### A CASE OF RUPTURE OF THE AORTA, IN A YOUNG WOMAN OF TWENTY.

Communicated by GEORGE HILL, M.D., L.R.C.S.E.

A. D., aged 20, housemaid at — Hotel, was suddenly seized with violent pain in the left side, followed by syncope, on the evening of November 20. Shortly after having recovered consciousness, she became sick, and vomited several times. These symptoms she ascribed to “biliousness,” from which, she said, she suffered occasionally. On the 21st, the patient stated that she had passed a rather restless night. Sickness continued, and the stomach rejected all ingesta. Pain, however, was not so severe, and, towards evening, the violence of the symptoms abated. On the morning of the 22nd she felt so much better that she expressed to her fellow-servant her intention [of rising and resuming her work; but when the latter returned to the patient’s bed-room, she found her motionless, and supposed that she was again in a state of syncope. Medical assistance being procured, it was found that life was extinct.

The patient had resided in — Hotel for three years, and during that time enjoyed good health. The only symptom of which she complained was, throbbing in the left side of the neck; and pulsation in the left carotid was quite visible, becoming more manifest when she was nervous or excited. For some weeks previous to her death she was rather depressed in spirits.

The above imperfect history of this case was derived from the evidence, at the inquest, of the patient’s fellow-servant, who had resided with her for eighteen months, and attended her during the two days of her illness. During her three years’ residence at — Hotel, she had no Medical attendant. My partner, Mr. Lingard, saw her for the first time on the morning of the 22nd, immediately after she expired.

At the post-mortem examination, on the 25th, we found nearly a quart of coagulated blood in the sac of the pericardium. The escape of blood, we discovered, was due to a laceration of the aorta, of nearly an inch in length, immediately above the origin of the artery. The coats of the vessel were preternaturally soft near the lesion, and of a whitish

colour, but there was neither dilatation nor thickening. The semilunar valves were normal. Indeed, we could not discover any other abnormality.

*Remarks.*—The remarkable feature in this case was the absence of dilatation, or thickening of the arterial coats; the only apparent deviation from healthy structure being softening, with lacerability, evidently the result of morbid deposit. The question at once suggests itself—Was this preceded by an inflammatory condition of the artery? It is improbable that it was; for, although the history of the case is imperfect, yet the patient had never complained of the symptoms usually attendant on such a disease. Rokitansky and many other eminent pathologists assert, that inflammation is an essential constituent of these morbid deposits. There are many cases on record, however, which do not accord with this theory; but, on the contrary, seem to prove that these deposits are frequently adventitious, and that individuals of a certain diathesis are peculiarly liable to their occurrence. The throbbing in the carotid artery, in this case, may be explained by the loss of elasticity in the aorta, and the consequent irregular propulsion of the blood through the other arteries.

Hooton, Cheshire.

## REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

### CASES OF INJURY OF THE SPINE AND OF DISEASES OF THE SPINAL CORD.

(Continued from page 465, vol. ii., 1862.)

WE continue this week the series of cases commenced in this Journal November 1, 1862. It is next to impossible to arrange them in any definite order, as few will admit of any but an arbitrary classification. Indeed, the three cases about to be related are remarkable for their differences, and seem to agree only in what we may call their geography, that is, they all affected the spine or the contents of the spinal canal. One is a case of apoplexy of the cord, in a patient fifty years of age; the next, disease of the spinal cord, probably one lateral half, following rheumatism in a child; the third, necrosis of the spine, with disease of the supra-renal capsules, there being, apparently, no disease of the cord itself, and, consequently, no paralysis. We hope, in future series, to be able to furnish clinical illustration of most of the important diseases and injuries of the spine and spinal cord.

#### HOSPITAL FOR THE EPILEPTIC AND PARALYSED.

#### APOPLEXY OF THE SPINAL CORD—LOSS OF SENSATION AND MOTION IN ALL PARTS BELOW THE NECK—PARTIAL RECOVERY.

(Under the care of Dr. BROWN-SEQUARD.)

This case (Dr. Brown-Séquard said) is one of great rarity, as apoplexy of the spinal cord is much more rare than apoplexy of the brain. The suddenness of the paralysis renders it quite certain that it was due to effusion of blood. As to its precise seat, the complete loss of sensation renders it pretty certain that the grey matter was extensively affected.

To rough observation, this patient was, soon after the attack, in the same condition as a patient who had had apoplexy of the pons Varolii. (See the case related in the Hospital Reports of this Journal, April 26, 1862.) But, on closer examination, there are important differences. In both, the arms, legs, and trunk were suddenly deprived of sensation and power of motion. In the case of apoplexy of the pons Varolii, however, the disease, being much higher, the face also was paralysed, both as to sensation and motion, and the external recti muscles of the eye were also paralysed. In the case we are relating there was no paralysis of the face.

A case, related by Dr. J. W. Ogle, of "anæsthesia of almost the entire surface of the body, as well as of partial motor power," has a superficial resemblance to the cases we have just mentioned; but the cause of the extensive anæsthesia in Dr. Ogle's case was quite different. It was due to the effusion of lymph on the roots of the spinal nerves, chiefly the posterior sensory roots.

Joseph H., aged 50, was admitted July 29, 1861. This patient

had suffered from paralysis for fifteen years. One day, fifteen years ago, he fell down in the street in a state of insensibility. He was picked up and taken home, and in a little time (how long is not remembered) recovered his sensibility. He then found that he had lost all feeling in his neck and in every part of the body below. He said that he had not "the least feeling in the world." He had not the slightest power of movement either in the arms or legs. His face was not affected, he says, in any way; there was no distortion, no numbness, and no alteration of temperature; and his sight was not at all affected. He could move his head and face in all directions. Hot water once fell on his thighs by accident, but he did not feel it. Directly after the accident he had retention of urine, and catheters were passed. He passed his motions involuntarily. He was about three months in this condition, and it was twelve months before he could stand alone. He recovered feeling first in the feet. When admitted, he had recovered feeling to a considerable extent; but he could not feel pinching in the neck, except very severe pinching with the nails. He could not close his hands so as to grasp the hand, but could grasp firmly anything large enough—*e.g.*, both hands. Although his grasp was so much impaired, it was, as the above shows, only so far as complete grasping is concerned. He could not extend his fingers completely. At his second visit to the Hospital he lifted a weight of 112 lbs. He could easily walk about, but was not steady on his legs, and he was obliged to look to his feet. However, with great caution he could walk in the dark. His sight, except a little presbyopia, was very good. No alteration of pupils. He has had two children since the attack. Dr. Brown-Séquard ordered iodide of potassium with ammonia.

September 29, 1862.—The following note was made to-day:—

The pupils are rather small, but not abnormally so, and act by light. His sight is pretty good; but now and then, even with spectacles, it is dim. There is, however, no marked defect. With spectacles he can read No. 1 (Jager) with the right eye, and No. 2 with the left. The optic discs looked healthy. There was a large crescentic patch on one side, but he was not short-sighted. He says that his hands are in winter very cold. He does not feel that they are so, but others tell him that they are like ice. He walks badly in the dark, and cannot walk safely with his eyes shut. In cold weather he has great difficulty in getting along, until after he has got warm by a little exertion. He has improved, however, considerably, both in the power of using the arms and in walking. There is still considerable anæsthesia.

The following case seems to be somewhat like that related at page 465 of last volume, but in this instance the cord has been more extensively affected. There was loss of sensation in the left side and of motion on the other, symptoms indicating that the right half of the cord was extensively injured. In a series of cases of diseases of the spinal cord, p. 463, vol. ii., 1862, we remarked on the symptoms produced by such an injury. We shall return to this subject in a future Number, when we shall give the particulars of an interesting case of the kind, which occurred in the practice of Dr. Brown-Séquard.

#### BIRMINGHAM GENERAL HOSPITAL. DISEASE OF THE CERVICAL SPINE, FOLLOWING RHEUMATISM—LOSS OF MOTION OF THE RIGHT ARM AND LEG, AND SENSATION OF THE LEFT.

(Communicated by Dr. RUSSELL, Physician to the Birmingham  
General Hospital.)

I first visited the following case at the request of my friend, Dr. Keyworth, and, by his permission, paid an occasional call subsequently.

March 29.—M. C., aged 12 years. The family history is as follows:—No evidence of inherited rheumatism, save in the instance of the father's mother. No symptom of struma, excepting that one sister has had a diseased knee, now stiff, which had "discharged matter;" nor was there any testimony in favour of congenital syphilis, the parents' history being clear, so far as inquiry without the direct question went. The patient's front teeth are well formed; the sister with the diseased knee is just cutting hers, but they appear normal. Two children lost—one at birth, the other mainly by hæmorrhage from leech bites.

On November 5 last, patient was attacked with rheumatism, and remained ill with it for two or three months, the symptoms shifting and varying in intensity. Careful inquiry seems to

establish the rheumatic character of this illness. During the rheumatic attack she suffered from pain in the neck and in the back, and, as the pain in the neck did not yield, as did the other symptoms, she walked to Dr. Keyworth's surgery, two months ago, to complain of it. A blister was then applied. For six weeks this pain has been worse, and had moved from the median line behind to the region of the sterno-mastoid muscles. The pain was chiefly present when she first rose from the recumbent posture. Of late she has been accustomed to support her head with her hands.

Three weeks ago her mother discovered by accident that the power of the right arm was impaired. The failure of power increased, and in about a week the right leg participated. Within the last week both limbs have become perfectly powerless. Yesterday morning, as the patient was being dressed, she complained of much pain in her neck, and suddenly cried out that the left arm and leg had gone to sleep. This sensation still continues. Urination and defecation have not been affected further than that the former is very unfrequent.

The child has always been healthy. Two years ago she had diphtheria. The present is the first attack of rheumatism from which she has suffered. She is well nourished, has dark hair and eyes, and is very intelligent.

I found her lying on her back, afraid of the least movement of the head or neck, and hardly venturing to use her limbs. She indicated the right sterno-mastoid as the seat of pain. The right upper and lower extremities were perfectly powerless, and no reflex movement was excited by tickling the sole; but sensation seemed little, if at all, affected. On the other hand, the left lower extremity was moved as freely as her awkward position and fear of any change of posture permitted, and so was the forearm; but the shoulder muscles seemed feeble. Sensation was almost abolished in the left lower extremity, but in the upper extremity was little affected. (The state of the trunk is not noted). Ribs moved to a limited extent only in breathing; I could not discover any difference between each side; but, from her twisted position, this portion of the examination was inexact. There was, obviously, fluid secretion collected in the bronchial tubes; she had been observed to cough for three days; sounds of the heart were peculiarly ringing; a remarkable tendency to perspiration had been observed the past few days. I need not add that it was impossible to ascertain the condition of the vertebral column, excepting that, when the finger was passed to the posterior region, decided induration could be felt towards the median line.

On April 1, her state had undergone little change; she had not stirred from her posture at my last visit; sensibility of left arm dull—I thought also of the right; had not had a fecal evacuation since I last saw her.

8th.—She was able to move the toes of the right foot, and had entirely recovered sensation in the left limbs; any movement to smooth her bed caused exquisite pain in the neck, continuing for two hours afterwards. On passing my hand to the back of the neck I could only discover rigidity of the vertebral muscles, with great tenderness in the region of the upper spinous processes.

26th.—She had recovered power to flex the right lower extremity, though, when flexed, she was unable to extend it again; the calf of the leg was between a quarter and a half an inch less in girth than that of the left leg; the left shoulder also possessed normal power in its muscle. By a great omission this is the first day on which any note is made of the pupils, which then were equally and widely dilated; she preserved her health, though she scarcely performed any movement from day to day.

May 21.—Her mother had been accustomed to raise her every Saturday for the purpose of cleaning her; the operation had always caused much pain, and the patient had not been so well for two or three days afterwards. Up to the last occasion the patient had been progressing favourably, though her arm had remained powerless. After the cleaning on the 17th she complained of unusually severe pain; this continued in frequent paroxysms ever since, producing loud cries. Today the paroxysms have been less severe; the pain here spoken of was confined to the back of the head, in the right occipital region, and with space between the posterior cervical muscles; it did not affect the face or the limbs; she had also constant vomiting on the 18th, as she had also after the previous cleaning; she has wasted considerably; movement is effected about as at the last report; her pupils have become

quite natural; she would not even allow me to lay my hand on her pillow; perfect absence of all movement was now strictly enjoined.

July 16.—She is able to move her head a little, just raising it from the bed, and rotating it slightly; respiratory movements are ample and complete; but motor power in the right side has not increased; her face is plump, but her limbs are emaciating very considerably.

On the 8th of this month (December) I found her greatly improved. For the preceding three weeks she had been able to rear herself up in bed, and to assume a half sitting posture; she could also flex and rotate her neck, though, of course, I did not venture on ascertaining to what extent. Had perfectly regained motor power in her right limbs, and could write and sew with her right hand; the nutrition of the hitherto paralysed limbs has recovered itself. Her general health continues good. My examination of the neck was still incomplete, but I could discover evident bony deposit in the region of the laminae, I think of the second and third vertebrae, and chiefly on the left side; the spinous processes, too, are much enlarged.

I called the other day to learn the result of an experiment to adapt a splint to the head, neck, and shoulders, but found that she could not yet bear its weight.

In the former of two cases of spinal hemiplegia, detailed by Dr. Todd, in his Clinical Lectures (Case ccxiv.), the disease lay in the odontoid process: the second case, which recovered, seems more nearly to resemble the one I have just detailed. I much regret that I made no examination of the urine, especially with reference to the presence or absence of sugar.

#### MIDDLESEX HOSPITAL.

#### A CASE OF CARIES AND NECROSIS OF THE LUMBAR REGION OF THE SPINE COMPLICATED WITH DISEASE OF THE SUPRA-RENAL CAPSULES—NO BRONZING OF THE SKIN.

(Under the care of Mr. HULKE.)

Mr. Hulke remarked that, in a recent article in the Guy's Hospital Reports, by Dr. Wilks, it is stated that disease of the supra-renal capsules had been found by Dr. Addison in three cases of spinal caries, and that this complication had been since observed on two or three other occasions. From the fact, that in every instance the lowest dorsal or upper lumbar vertebra, in the neighbourhood of which the capsules lie, were those affected, Dr. Wilks thinks it not improbable that the morbid process extends from the spine to the capsules. Mr. Hulke thought that this view was supported by the present case, where, from the morbid appearances noted in the examination of the parts, it is probable that the spinal preceded the capsular disease in order of time, and where that capsule which was contiguous to the older spinal abscess was most disorganised. He thought that the probably short duration of the capsular disease, inferable from the generally firm, lardaceous character of the organs, and the presence of vestiges of their proper tissues, might account for the absence of bronzing.

A mechanic, aged 30, was admitted into the Middlesex Hospital, in September last, with pain and tenderness in the lumbar region of the spine, and a deep fluctuating swelling in the left lumbar and inguinal regions, which communicated beneath Poupert's ligament with a large indolent abscess lying across the top of the thigh, between the common femoral vessels and the anterior superior spine of the ilium. These local signs were accompanied with emaciation, a degree of feebleness quite out of proportion to the loss of flesh, a very irritable stomach, and obstinate constipation. It was plainly a case of spinal caries with psoas abscess. A horizontal posture was enjoined, and small doses of strychnine were ordered. Under this treatment the stomach became less irritable, he was able to take more nourishment, and his general condition slightly improved. The abscess during this time remained nearly stationary. November 6, at 9 a.m., on rising from his bed to go to the neighbouring water-closet, he became faint, grew weaker during the day, and expired at 8 a.m. on the following morning. During this last attack his pulse was very weak and irregular, his breathing quiet, air entered the chest freely, but his lips became blue and his complexion dusky.

At the post-mortem examination, made thirty hours after death, an abscess, holding nearly a pint and a-half of pus, was found in the course of the left psoas magnus. Its source was a small cavity hollowed out in the bodies of the third and fourth lumbar vertebrae, which contained a small seques-

trum, surrounded with thick, curdy pus. The corresponding portion of the intervertebral disc had disappeared; the walls of the cavity were uneven and friable, and the bony tissue for some distance around was solidified by a lardaceous deposit in the cancelli. The sac of the psoas abscess was very thick, particularly at its lower end, where it communicated with the portion below the groin by a small circular opening beneath the outer extremity of Poupert's ligament. The mass of the psoas had disappeared; only a small quantity of pale, muscular tissue in connexion with the twelfth dorsal and second upper lumbar vertebræ remained, and this contained several small, scattered, circumscribed abscesses. On the opposite side of the spine there was a second and smaller psoas abscess, reaching as high as the twelfth dorsal, and below, crossing beneath the anterior common ligament at the third lumbar vertebra, to communicate with the cavity in the spine and the larger psoas abscess already described. The sides of the bodies of the first and second lumbar vertebræ were denuded of periosteum, and bathed in pus; the bony surface was rough, and its vascular foramina large, but neither carious nor necrosed. The abdominal viscera were healthy, with the single exception of the supra-renal capsules, which weighed 5ij. gr. xx. and 5ij. gr. xxxv. They were hard and knobby. A section presented a homogeneous appearance, mottled with a few small, yellowish, friable specks. In several microscopical preparations traces of the proper structure were discernible. The enlargement appeared due to infiltration of the organs with a material which, in a fresh state, is nearly translucent and structureless. The apices of both lungs contained a few scattered deposits of tubercle. The right pleural cavity was obliterated in nearly its entire extent by old adhesions. The left side of the heart was almost empty, whilst the right auricle was distended with a black, spongy, friable clot; and the right ventricle contained a tough mass of fibrin wrapped around the musculi papillares and chordæ tendinæ, and prolonged through the trunk and primary branches into the small divisions of the pulmonary artery.

PRISON EXPENDITURE.—A correspondent of the *Times*, Mr. C. P. Measor, writes:—"I find that, in the estimates laid before Parliament and passed for the year 1851-52, each convict at Portland Prison was to be clothed, fed, and safely kept for £23 15s. 3d., and the Report of the Convict Directors for 1851 shows, moreover, that this estimate was not exceeded. The discipline of that, the model Public Works Prison, was acknowledged to be as nearly as possible perfect, and, as regards industry, the Directors reported that the work executed amounted 'to £25 per man on the total daily average of 821 confined in the prison, or more than the entire cost of the establishment.' The profit is elsewhere stated to be £3800, thus ostensibly realising the aim of Mr. Charles Pearson, the lamented solicitor to the City of London,—a self-supporting penal establishment, a genuine labour prison. From this happy and successful era in prison management there seems to have been a gradual and sure decline. In that year the estimate covered the actual cost, but each year's subsequent expenditure has been in excess of the Parliamentary estimate, and the estimates again annually enlarged to meet the necessary expenditure, until at the end of ten years we have this result, that the estimate per man for 1861-62 is £35 4s., and the actual cost, by the table of expenditure annexed to the annual report, is £37 16s. 1d. at this same prison of Portland. At Chatham Prison the actual cost was £40 13s. 1d. per convict; and the entire difference between estimate and expenditure for the whole home convict prisons was this—that Parliament voted for the year 1861-62 £272,243 to maintain 8136, but that it took £275,985 6s. 1d. to maintain a daily average of 7291, being at the rate of £37 17s. per head for male and female convicts, instead of £33 9s. 2d., as voted. This immense increase of cost from £23 15s. 3d. at Portland in 1851-52 to £37 16s. 1d. in 1861-62 is to be accounted for in various ways. The cost of supervision has increased in that time from £9 17s. 4d. to £14 9s. 2d. per convict, there being a larger proportionate staff of officers now required, and, where one to eight prisoners sufficed ten years ago, there being now about one to six. Beyond this the entire increase goes in some way or other to the augmentation of the convict's personal comforts. His gratuities for 'willing industry' have been largely increased, his clothes, which then cost at Portland £2 18s. 6d., cost last year £4 2s. 1d., and his victualling, then averaging £8 5s., has advanced to £12 6s. 7d."

SATURDAY, JANUARY 10.

VERTEBRAL PATTERNS.

BEFORE we proceed to adduce examples in detail of the relations which exist between the different parts of vertebræ, and of any ideal pattern to which they may be referable, it will be interesting to give a brief sketch of the mode by which the first idea and consequent inductive demonstration of the vertebral theory of the skull was originally conceived. Oken himself describes the mental process by which he arrived at this happy idea. Except Newton, the discoverer of the law of gravitation, few great discoverers have revealed the means by which the conception of a general law became developed to their minds. In August, 1806, whilst Oken was travelling in the Hartz Mountains, he saw the whitened skull of a deer lying on the ground. He picked up the partially dislocated bones, examined them most attentively, when suddenly the truth flashed across his mind, and he exclaimed, "It is a vertebral column!" This idea, however, was not like the sudden inspiration, or premature deduction of an uneducated man, who fancies an analogy in objects intrinsically dissimilar; none could have arrived at so philosophical a thought but a comparative anatomist who had spent his life in the practical manipulation of vertebræ and skulls. The idea, however, having once occurred to Oken, he pondered deeply thereon, testing his conclusion by comparison with the skulls of a cetacean, a chelonian, and a codfish at Bremen; and when he returned to Jéna his generalisation was published in a lecture on the "Signification of the Cranial Bones." In this work (1807), the theory was first propounded that the skull was composed of three vertebræ. A few of his antagonists, unable to demonstrate that the vertebral theory was a philosophical untruth, attempted to exhibit it as an idea which had been previously arrived at. Meanwhile, Autenrieth, Jean-Pierre Frank, Ulrich, and Kielmeyer propounded various vertebral theories, all more or less identical with those of Oken, though differing from his doctrine in many unimportant points. The idea was, however, now fairly started, and it was only necessary for some clear-headed mind to disembarass the subject from all confusion.

Oken's generalisation was too good a discovery to escape the appropriating spirit of the poet Göthe, in whom, as Owen has remarked, "the moral element was the least developed." In the year 1820, when the vertebral theory had been generally canvassed, the ingenious poet quietly published a pamphlet to the effect, that the vertebral nature of the bones of the skull had been discovered by him in 1790. He, however, divided the skull into six vertebræ. Göthe's most philosophical biographer has defended his conduct, and regarded it as a mere accidental coincidence that the same idea should have occurred to both Oken and Göthe. It is, however, very significant

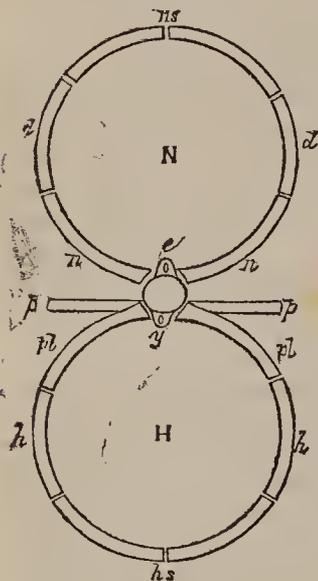

that Göthe suppressed all mention of his discovery until the year 1820, when the vertebral theory, having received from the labour of others the imprint and stamp of authority, was received into "the treasury of accepted truths."

When the theory was canvassed in France, Geoffroy St. Hilaire supported it; Cuvier, whose reticent mind towards the close of his career led him to reject any new theory, opposed it. In 1830, a dispute arose in the Paris Academy between these two master-minds, when the supporters of either theory ranged themselves under the banners of the rival anatomists. The victory was undecided; and the death of Cuvier shortly afterwards terminated the conflict.

In this manner the great philosophical dogma was promulgated, which the illustrious anatomist, Robert Knox, who has passed away within the last month, used to term "the transcendental theory of organic bodies, the greatest discovery which has ever been made, not even excepting the law of gravitation." The inductive demonstration of the relations which each vertebra bears to an ideal pattern was subsequently given by Owen in the year 1848, and belongs to a later period of history.

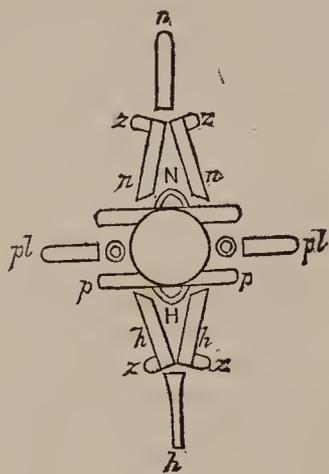

We must premise that in no known vertebrate animal are the whole of the contained structures developed to the same extent as in the ideal archetypal pattern, which we now insert :

FIG. 1.

ns. neural spine.  
n. neurapophyses.  
d. diapophyses.  
c. centrum.  
p. parapophyses.  
pl. pleurapophyses.

FIG. 2.

h. hæmapophyses.  
hs. hæmal spine.  
z. zygapophyses.  
e. epapophyses.  
y. hypapophyses.

This has been defined to be "a diagram, embodying all the organs or parts which are found in the group, in such a relative position as they would have, if none had attained an excessive development." The metaphysical fallacy involved in this definition has been already pointed out, no standard being given by which the author's estimate of what he may or may not deem excessive can be accurately gauged; and a more precise definition shall not be offered in this place. In the fish, however, the type pattern approaches nearest to the archetype; and if our readers have the opportunity, such fishes as the sturgeon or the lamprey, which are not unfrequently in our markets, should be especially selected as objects for comparison. It is necessary to remark that each segment of the skeleton consists of a round central body, on which two arches, the one above and the other below, are built. The upper one, termed "neural arch," because it contains the spinal cord and nervous system throughout *Vertebrata*, is composed of two lateral processes, termed "neurapophyses," which, joining at their upper ends, form a bone sometimes bifid, termed "neural spine." The lower arch, which envelops the circulatory, digestive, and respiratory systems, is termed "hæmal," and is also composed of two

lateral processes, or hæmapophyses, uniting together to form a hæmal spine. Across the lower part of the neural arch run right and left two lateral buttresses, the diapophyses; beneath them, attached to the centrum, two more or less lengthened lateral buttresses, the parapophyses. When these two processes are confluent, the arbitrary term "transverse process" is often applied to them. At the end of the transverse process is often attached a bone, the pleurapophysis; backwards from the neural arch run the anapophyses; outwards and peripherally, the metapophyses. Above the centrum a small arch, internal to the neural, and formed by the epapophyses, is sometimes developed, and beneath the centrum an analogous one, formed by the hypapophyses within the hæmal arch. From the neural- and diapophyses often diverge backwards prominences termed "zygapophyses." The anterior and posterior extremities are considered, morphologically, as diverging appendages, the fore limb, *e.g.*, being the diverging appendix to that hæmal arch, of which the shoulder-blade is the pleurapophysis. These diverging appendages are in the ideal archetypal skeleton, and in the fish, the reptile, and the bird, developed transversely, and stand outwards and backwards from the thoracic ribs (pleurapophyses) along their series. In the mammal, and in man, they are, however, suppressed, excepting in parts of the skull and the fore and hinder limbs. As may be expected, the anterior limb is of the same essential nature as the posterior. The pelvis forms the pleurapophyses and hæmapophyses, whilst the leg bones in all *Vertebrata* are diverging appendages. The demonstration of such relations forms what has been called "serial homology." This is so obvious that we apply the term "vertebra" to the homologous structure which is found in the neck (cervical), in the back (dorsal), in the loins (lumbar), or in the tail (sacro-caudal) parts of the body. The bone is seen in each of these cases to be composed of similar or homologous parts.

Special homology is a theory which almost every one will instantly appreciate. We see plainly that the wing of a bird is framed upon a structure, the whole of which is parallel in its nature to that of the forelimb of a dog; *i.e.*, that the humerus in both articulates with the scapula, and joins at the elbow with the ulna and radius, which support carpals, metacarpals, and phalanges. We also see that the bones in the paw of the cat or the monkey answer, in their nature, to the bones of the human hand, and we, by the aid of a little reflection and practical science, can recognise in the hoof of the horse the special homologue of the middle finger in man. The jawbone, which supports the teeth in all vertebrate animals, has certain common characters. Many of these are so self-evident, that the homologies of the monkey's limbs are recognised to be those which regulate the form of the feet and hands of man, which, though homologically composed of the same bones, are adapted to a different purpose than that which subserves the erect position of man. Special homology has, consequently, been readily accepted by all biologists, as well as by the general public, since the days of Vicq d'Azyr and Barclay.

General homology is the relation which each bone bears to an ideal pattern or typical vertebra. If any one will take the skull of a bird, and hold it before him, looking at the back of the skull, he will perceive half the occipital vertebra. The large foramen magnum is the neural arch; the small, round, basi-occipital bone beneath it is the centrum of the vertebra. The hæmal arch of this segment is not apparent, it being displaced to form the anterior extremity. But, if we drop the lower jaw of the bird to a line at right angles with the upper jaw, we see the hæmal arch of the frontal segment. This corresponds to its own proper neural arch, intercalated amongst, and confluent with, the other cranial bones.

Each organ may be, to another organ, either an analogue or a homologue. Thus, the pectoral member or wing of a bird is homologous in its nature with the forepaw of a lion, or the forefoot of an ox; it is also, in a certain sense, homo-

logous with the pectoral fin of a flying fish, as being developed from the fore-member of the body; but it is merely analogous with the wing of a butterfly. An analogue is, in short, a part or organ in one animal which has the same function as another part or organ in a different animal; a homologue is the same organ in different animals under every variety of form and function.

The neurapophysis is the first vertebral element which demands our attention. We see it nearly in its typical form in the dorsal vertebra of any mammal. We see it proportionally maximised in the alisphenoid of the human skull; minimised in the little ridges perceptible on the caudal vertebræ of many vertebrates; suppressed in the last caudal. The usual form of two bony plates, united at the upper extremity by a neural spine, is rarely departed from. The neural spine, or metaneurapophysis, we see maximised in the parietal bone of man, where its enormously expanded plate serves to enclose the greater portion of the brain case; usually, however, its form can be best recognised in the "spinous process" of any vertebra. In the thoracic and abdominal vertebræ of tortoises, it forms a flattened and depressed plate; while we see in the rectangular bony buttress of the cervicals of the marsupial another example of its maximisation. In the cervicals of the mole, on the other hand, it is suppressed. To give an example of the segmental constitution of any vertebra is most easy; and we shall take the occipital vertebra of man, contrasting the same with the homologous structure in the *Lepidosiren*, or mud-fish (*Protopterus*).

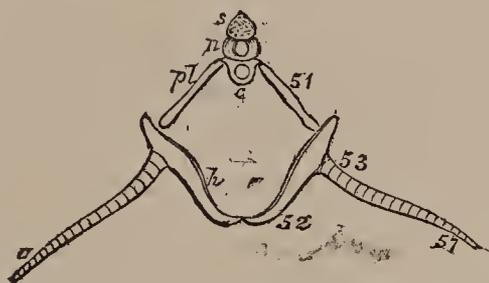

DIAGRAM OF THE OCCIPITAL SEGMENT OF MUD-FISH (*Protopterus*).

- |                                     |                                   |
|-------------------------------------|-----------------------------------|
| c. centrum, or basioccipital.       | 52. hæmapophyses, or coracoid.    |

| 51. pleurapophyses, or scapulæ.     |                                   |

The basilar piece of anthropotomy is the centrum. On its inferior face is seen, in the human skull, a tubercle for the attachment of the constrictor muscle of the pharynx; this, in man, is merely a tubercle; in some *Rodentia* and *Cetacea*, its place is occupied by a remarkable depression. In the crocodile and the ostrich, there is, on the contrary, a voluminous projection. This is the hypapophysis. The neurapophyses are formed by the exoccipitals, which form the lateral walls of the neural arch, or foramen magnum. Partly from the exoccipitals, and partly from the basioccipital, are developed the condyles, which are homologically zygapophyses. In the *Mammalia*, as in man, there are two condyles; in the bird, but one; in the crocodile, and in most *Reptilia*, but one; in *Batrachia*, and in the extinct labyrinthodonts, there are two condyles; in fishes, instead of a condyle projecting into the atlantal cup, there is a conical depression, filled with a gelatinous capsule, in the centre of the basioccipital bone. Above the exoccipital is the "squamous body," or supraoccipital. We see it in man enormously expanded; it is also largely exposed in the walrus, seal, mole, elephant, and monkey. As Bertrand has pointed out, sometimes it merely serves to form a portion of the flattened hinder wall of the cranium; sometimes, as in many edentates, ruminants, the horse, and some pachyderms, it is composed of two plates, united at a right angle, the upper plate belonging to the cranial chamber, the lower plate to the posterior wall of the skull. The composition of the supraoccipital, as regards the number of its ossific centres, has been much obscured, owing to the diversity of opinion between various authors on the subject.

Holden, we think, correctly assigns to it but one centre of ossification. Other authors have regarded that part of the bone originating above the semicircular line as possessing a distinct centre; while some have assigned to the supraoccipital three, four, or even five centres. These opinions are partially corroborated by the very frequent presence in Peruvian and other crania of a so-called "interparietal" bone, the *os épactal* of Blasius, which is still often alleged to represent in man the interparietals of the inferior *Mammalia*. More accurate information has dispelled this illusion. In a skull of the Limbu tribe, from Nepâl, Owen has pointed out an instance in which the so-called interparietal has been divided into three distinct *quasi*-symmetrical bones above the semicircular line. The edges of the exoccipital, near the jugular eminence, or point of insertion of the *rectus capitis lateralis*, a process, the paroccipital, is very often developed, which has now been observed in nearly every race of mankind, and more commonly in the "dark races." This process is sometimes as long as the true mastoid. It is the lower transverse process, or parapophysis, of the occipital vertebra. Between it and the mastoid, Professor Hyrtl has described another process, termed by him the "pneumatic process," but of which the connexion with the occipital segment is as yet undemonstrated. We are at present wholly in ignorance as to the homological relation of this singular development.

The hæmal arch of the occipital segment is displaced from its normal position, articulated to the transverse process, and will be found in man beneath and behind the cervical series. The scapula is the pleurapophysis; its coracoid process, the hæmapophysis; the humerus, ulna, radius, carpals, metacarpals, and phalanges, are segmental divisions of the diverging appendix. We shall not, however, at the present stage, enter into the question of the nature of limbs. The occipital segment, in its simplest state, can be seen in any fish, where the anterior extremity, or pectoral fin, is articulated to, and a component part of, the skull. In the cod, one branch of the suprascapula articulates with the paroccipital; another lower branch is connected with the exoccipital; and thus, the forelimb, homologous with the arm of man, is seen to be an essential part of the skull. Such a structure can scarcely be perceived by those who have made anthropotomy a special study, to the exclusion of the more catholic branches of biology; but it must again be iterated, that the study of the more simple forms of *Vertebrata* affords us a certain clue whereby to interpret the complicated forms of life, through which successive dynasties of being, existing through the vast ages of geological time, have passed. We rather prefer to believe that the archetypal vertebrate skeleton, whatever exact form it might have possessed, was once manifested in the flesh, as an objective entity, than conceive it merely as a process of the Creator's thought. Idealists may sneer at our "mystical and exceedingly delusive anatomy;" ultra-nominalists may tell us that we "seek to introduce an obsolete and scholastic realism into biology;" "practical men" will make use of the little that they do understand to depreciate the larger range of thought which they do not understand; but inductive students, seeking in the vast field of osteological science a *vera causa* for the relations which animals admittedly bear to some common type, from the assemblage of corroborative facts before them, will accept the corollary of the existence of an original supreme archetypal pattern of life, whence all forms have been derived, either by successive creation, through the fiat of an Almighty Life-giver, or by descent, with modification operating through laws analogous to those which govern the reproduction and succession of individuals.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—For the recent Preliminary Examination for the Membership of this College, 105 candidates offered themselves, of which number 95 were successful; want of space precludes us publishing the list.

## THE WEEK.

## THE ARMY MEDICAL DEPARTMENT.

IN another part of our impression we publish some extracts from a letter by an Assistant-Surgeon of the Indian army, giving publicity to a strong feeling of discontent at the present position and prospects of that branch of the service. We are sorry to have again to call our readers' attention to the fact, that a similar feeling prevails in the Army Medical Department at home. It becomes every day more manifest that the Royal Warrant of October, 1858, is practically no longer in force. Not only is the obnoxious additional Warrant of March, 1861, which deprived the Army Surgeon of the rank granted him by the Queen, by placing him junior to the same rank of combatant officer—that of major—unrepealed, but complaints are daily reaching us that other provisions of the original Warrant are constantly being infringed. For instance, Surgeons of cavalry regiments are not allowed forage for the same number of horses as regimental officers of the same rank; and, on committees and mixed boards, junior combatant officers are allowed to take precedence of the Surgeon, in direct contravention of the provision of the Warrant. Again, the whole department has recently been aggrieved by the appointment of a German Physician, Dr. Emil Becher, whose age is considerably in advance of the specified time, to an Assistant-Surgeoncy, his commission being antedated February 13, 1855, and he being thus promoted over the heads of more than four hundred and fifty Assistant Surgeons. Dr. Becher, at the date of his commission, was not only, as a German graduate, unqualified by the rules of the service, but was not a naturalised British subject. True, his acquirements and talents as a pathologist are undoubted. We believe that he rendered valuable assistance to the late Dr. Tice in the Hospitals at Scutari, and that since the Crimean war he has acted as pathologist in China and at Fort Pitt. But, during all that time, he has received liberal payment for his services. We do not, however, for one moment, grudge Dr. Becher any reward the Government may think fit to give him; but we do complain of the injustice done to every Assistant-Surgeon who has been thus placed below him. Promotion is now excessively slow. We believe that scarcely an Assistant-Surgeon has been promoted in the last four months. It is, therefore, no slight injury that has been inflicted on these gentlemen. As might be expected, this treatment of the Medical branch of the service is beginning to tell outside. Candidates do not come forward in sufficient numbers to fill the vacancies. This was the case at the last examination, and will certainly be the case again, if the authorities do not keep better faith with those who have already been induced to enter the service by the baits held out in the Warrant of 1858.

## THE ANNUAL ELECTION OF OFFICERS AT THE PATHOLOGICAL SOCIETY.

AT the last meeting of the Pathological Society, held on Tuesday, there was a larger attendance than we have seen for several years. Mr. Erichsen, in proposing a vote of thanks to the retiring President, alluded, we suppose sarcastically, to this attendance, as evidence of the great prosperity of the Society. It was well known that the election of Mr. Prescott Hewett to the Presidency, the candidate proposed by the Council, would be opposed, and it was this election spirit, rather than love of pathology, which crowded the rooms of the Society. Whilst the ballot was open there was a long discussion as to a supposed informality in the manner of voting. It appeared that some of the members had received two voting papers quite alike as regards the list of names, but with little differences of printing, showing that they were not both issued by the Society. After a great deal of talk on both sides of the question, the President ruled that any list might be received provided it contained the proper number of names. The two scrutineers appointed by the President were Dr. Broadbent

and Mr. William Adams. The result of the voting was that the gentlemen proposed by the Council were elected. Of course we do not know the relative number of votes recorded for Mr. Prescott Hewett, but it was reported in the room that he received eighty votes, whilst another gentleman, Mr. Coulson, is said to have received half that number. We say again, that we give this merely as a report. If it were correct, there must have been 120 members present, as voting by proxy is not allowed. It would indeed speak well for the Society if so many were brought together on account of zeal for pathology.

## FEES TO MEDICAL WITNESSES IN POLICE-COURTS.

MR. GREENWOOD, of Islington, has brought the injustice to which Medical Practitioners are subjected, who are called to give evidence in police-courts, again into public notice. He was called up on boxing-night to attend a woman who had received a severe scalp wound at the hands of a bricklayer's labourer. He gave the patient a long attendance, for which he was not paid, and was then summoned to give his evidence at the police-court, where he had to appear on two separate occasions. The case terminated in the committal of the woman's assailant for three months. Mr. Greenwood then applied for his costs of attendance. The magistrate, Mr. D'Eyncourt, said he could not allow any expenses, as he had no fund at his disposal for that purpose. Mr. Greenwood said that he thought "it was very hard that Medical men should be called up at all hours of the night to attend to cases for which they got no fee, and then be compelled to attend the police-court, and not be paid for their loss of time. If Medical men refused to get up and attend to such cases, they would be thought very hard-hearted, and public indignation would be raised against them." Mr. D'Eyncourt said that Mr. Greenwood had better write to the Home-office; he would certify that the case was one in which costs ought to be allowed. Mr. Greenwood said he would act on the magistrate's suggestion. We hope that Mr. Greenwood will in this case get his costs; but, if he do, we believe it will be an exception to the general rule. Before a higher tribunal remuneration is allowed for the attendance of the Medical witness. Certainly, the fact that a case is disposed of by a magistrate cannot lessen the claim of a Medical Practitioner to be remunerated by the public, for what involves frequently a greater expenditure of time and far more trouble and annoyance than attendance in a superior court.

## THE SUSPECTED POISONINGS AT MAREHAM-LE-FEN, LINCOLNSHIRE.

AN investigation has just taken place before Dr. Clegg, the coroner for Boston, which has terminated in the committal of a grocer named John Garner, of Moorhouse, in the parish of Mareham-le-Fen, near Horncastle, and his wife, on a charge of having poisoned the mother of the male prisoner, Jemima Garner, by the administration of arsenic. The deceased died in December, 1861. In consequence of various reports which had reached the coroner, he ordered the exhumation of the body in November last. The post-mortem examination was made by Dr. Boulton, of Horncastle, and Mr. George, Surgeon, of Revesby, the latter of whom had attended deceased during her life. According to the evidence of Mr. George, she had suffered from the symptoms of irritant poisoning—vomiting and purging: he had treated her accordingly, and had certified that her death took place "after six days' diarrhoea." The examination of the body showed that the external parts were much decomposed, that the coats of the stomach and muscles of the abdomen were covered with yellow stains, and that the tissues in the neighbourhood of the spine were deeply tinged and saturated with a bright yellow colouring-matter. The organs of the chest and

abdomen were sent for analysis to Professor Taylor. The following is Dr. Taylor's evidence :—

“On Saturday, November 29, I received, at the chemical laboratory, Guy's Hospital, from Sergeant Lampton, three jars well secured and sealed. These were kept locked up until the analysis was made. I have embodied the results in the following report :—

“*Small Jar.*—Seven ounces of bloody liquid in a putrescent state. It was tested for mineral poison, but none could be found in it. *Large Jar* (containing viscera of deceased).—On opening this jar there were found in it the liver, heart, lungs, spleen, kidneys, stomach, and intestines, with a portion of the bones of the spinal column (lumbar vertebræ). These organs were in a good state of preservation, so that all the structures would be easily recognised. The heart and intestines were so preserved that they appeared as if they had been taken from a person recently dead. The liver was shrunk, small, and of a dark slate colour. It weighed about 1 lb. Its structure appeared healthy. The heart was of the usual size, scarcely altered by putrefaction. Its cavities were examined as well as the valves. There was no appearance of disease in any part. The lungs were more decomposed than the other organs. They presented no unusual appearance. The stomach and intestines presented, on the external coat or membrane, patches of a deep yellow colour. The most extensive patches were on the stomach, and chiefly on its under or posterior surface (that part which is nearest the spinal column); one of these, covering about five square inches, was found in the fat of the mesentery, surrounding the intestines. The stomach was more decomposed than the intestines. The stained portion was firm, but other portions had given way in one or two places. The interior was then laid open. There were no fluid contents in it, but the inner coat or lining membrane was covered with a thin dark substance, in which were numerous small particles of a bright yellow colour. This substance, when placed in water, gave to the liquid a reddish-brown colour resembling that of decomposed blood. It was examined by the microscope, but presented no other appearance calling for remark. The coats of the stomach were thinner than natural. This is the usual condition when bodies have been buried for many months. The coats of the intestines were thinner than natural (a result of changes in the dead body). In addition to the yellow stains, they presented a well-marked redness in the upper portion, such as would be caused by inflammation, &c., taking place during life. They were quite empty, and entirely decomposed at the lower part, but at the upper part they were fresh and firm. The portion of the spinal column in the jar presented a remarkable appearance. There were, in the soft parts which covered the bones in front, several patches of a deep yellow colour, resembling those found in the stomach and intestines. These stains were firmly incorporated with the membrane and ligaments covering the bones of the spine, and some were found dyeing the flesh still attached to the vertebræ. This flesh was red and firm, and had undergone but very little change from putrefaction.

“*Analysis.*—The first was to determine the chemical nature of the yellow stains or patches of colour on the stomach, intestines, and spine. Portions of the colouring matter were removed from these different structures, and separately examined. They did not contain any bile or biliary matter, but consisted of orpiment or yellow sulphide of arsenic, mixed with arsenic in a soluble form. This is a mineral poison. All the stains examined were due to this substance, which had penetrated into and had become incorporated with the soft structures of the body. A small portion of the yellow colouring matter was removed from the front of the spine and reserved. An unstained portion of the coats of the stomach was submitted to chemical analysis, and was found to contain arsenic in a form in which it was soluble in water—that is, white arsenic. All parts of the stomach examined contained arsenic. Portions of the intestines were examined, and were found to contain arsenic. The quantity of orpiment found in or upon the stomach, intestines, and spine was estimated at from six to eight grains, corresponding to five or six grains of white arsenic of the shops. Two analyses were made of portions of the liver, and arsenic was found in each case. It was present in corresponding large proportions. The conclusions, the results of the analyses, are :—1. That arsenic was present in the stomach, intestines, liver, and heart of the

deceased, in all the parts of these organs submitted for examination. 2. That the arsenic was contained in the stomach, intestines, and in the flesh and ligaments of the spine, partly in a soluble and partly in an insoluble form—that is, as orpiment or yellow arsenic. 3. That the orpiment or yellow arsenic which causes the patches of colour in the stomach, bowels, and in the spine, has probably been produced by a chemical change in the white arsenic contained in the stomach and bowels at time of death. 4. That the yellow stains found on the spine were produced by arsenic escaping through the coats of the stomach after death, and the yellow stains on the mesentery were caused by arsenic escaping through the coats of the intestines. 5. That the quantity of yellow arsenic altogether was probably not less than six to eight grains, equivalent to from five to six grains of white arsenic. 6. That the discovery of arsenic in the substance of the liver and heart renders it probable that the deceased had taken the poison some time—that is, one or two days before death. 7. That the quantity found in the body would be fatal to a human being, and, in the absence of any other apparent cause, would be quite sufficient to account for death. The third jar contained earth from the grave, and in this a small quantity of arsenic was found; but the arsenic here was in a form perfectly insoluble in water, and it could not in any way account for the arsenic found in the body of deceased. It was not in the state of orpiment or yellow arsenic. The symptoms described by Mr. George would be those of poisoning by arsenic. I should say that deceased must have had arsenic in several doses for two days or more prior to death.”

Evidence was also given to prove that the accused persons, who at the time were not married, had both frequently ill-used the deceased, and that they had together mixed the arrowroot which was administered to her in her last illness. The female prisoner, who, before the marriage, had acted as servant to Garner, had been heard to say that she would be “out of the old woman.” Garner, after he had been arrested, gave a curious diagnosis of poisoning to the superintendent of police.—“Professor Taylor may say what he likes; I do not believe granny was poisoned. Poison makes things struggle when they die—the same as my three horses did last year—but she died like a lamb.” A considerable quantity of arsenic was found on the prisoner's premises. The motive appears to have been simply that the old woman was dependant on her son, and a burden. Suspicion has also arisen that Garner's former wife was disposed of in the same way. The body has been exhumed by order of the Secretary of State. Drs. Boulton, of Horncastle, and Clegg, of Boston, conducted the examination, and the viscera have been forwarded to Dr. Taylor. It is asserted that a considerable quantity of arsenic was found in the stomach, although not so much as in the body of Jemima Garner. Arsenic was also detected by Dr. Boulton.

#### PRISON LIFE.

THE history of prison discipline in this country has yet to be written. We know of few subjects which, in skilful hands, would make a better theme for a Medico-historical essay. Even if the comparatively short period be taken which commences with the appearance of Howard's great work, and ends with the Earl of Carnarvon's address at Winchester, on Monday last, we should find abundance of matter to fill a volume of surpassing interest. The sentiments and measures of men collectively, and often, too, of men individually, seem to obey a property analogous to elasticity. The further a force or impulse carries them in one direction, the greater will be the rebound in the other. We all remember Lord Macaulay's celebrated apothegm, in which he sums up the history of the saintly régime of the Commonwealth, and the licence of the succeeding period. Amongst individuals, many a good Tory, like Southey, begins life with a devout faith in liberty, equality, and fraternity; and, on the other hand, a Robespierre first courts public favour as the author of a treatise advocating the abolition of capital punishment. The history of Medicine is full of

parallel antagonisms, which have succeeded each other as though necessitated by law. As remarkable a revulsion of opinion and action has taken place in this country on the subject of the treatment of criminals. Sixty years ago prisons in England were the blackest stain on our civilisation. Thanks mainly to the efforts of Howard and Lettsom, that blot was wiped out. But now they are comfortable abodes, to which persons, unfortunate enough to offend the laws, retire for a short time at the expense of society, expiate their crimes by sleeping ten hours per diem, working two; reading travels, novels, and, if they choose, light religious books; taking moderate exercise in the open air, conversing with each other, and breakfasting, dining, and supping in a way which would be envied by a Devonshire or Dorsetshire peasant, who supports himself and family on ten or twelve shillings a-week. The result everybody knows. Public opinion is setting strongly against the regimen of the philanthropists and doctrinaires. It is not impossible that the necessary rebound may even carry us again too far in the opposite direction. However, the present state of things in our gaols is as absurd as it is pernicious, and incompatible, not only with the punishment or reformation of the prisoner, but with the safety of other people. We extract from Lord Carnarvon's speech some passages on the present state of prison discipline in the Hants County Gaol:—

“The committee, appointed fifteen years ago, laid down most distinctly, that, while all proper means of moral reformation ought to be tried, yet that it was essential that every prisoner should undergo a certain amount of penal discipline before those moral means of reformation were to be used. For this purpose, the prisoners were divided into four classes—those serving their first month, to whom was allotted a minimum of eight hours' hard labour a-day, it being provided, that over and above that they were to receive what instruction they could obtain from the schoolmaster and chaplain; the second class, those serving the second month, were to be employed six hours a-day in hard labour; the third class, serving their third month, were to be employed four hours a-day in hard labour; and the fourth class, who had served three months, were to be so employed three hours in each day. What is the case now? The first class, instead of receiving a minimum of eight hours' hard labour a-day, receive a maximum of three and a-half hours; the second, the third, and fourth classes, instead of receiving respectively a minimum of six, four, and three hours, receive a maximum of about two hours a-day. Well, then, I ask, is it not idle to talk of sentencing a prisoner to hard labour, if this is to be the state of things in the prison? As respects the prisoners, you must remember, that just as you diminish the amount of hard labour you must find some substitute for it, because you cannot take a man in the prime of life, as the majority of the prisoners are, possessing full bodily vigour, and clap him into a cell, however warm and comfortable, for the best part of twenty-four hours every day, without absolutely endangering his life; consequently, it has been found necessary to give the prisoners open air exercise to such an extent, that not only is it no punishment at all, but it tends greatly to aggravate the difficulties of carrying on the prison discipline. Let me now say a few words upon the diet, which is, as I have said, just as much a part of the sentence as the hard labour. I am not one of those who are in favour of harsh and cruel measures towards criminals. I am not in favour of a starvation diet; but I think that what has hitherto been forgotten or practically ignored hitherto, in these discussions, is the consideration that there is a medium between a starvation and an excessive diet. While I would give such a dietary as would sustain fairly the bodily vigour of prisoners, I would studiously refrain from giving anything like a luxurious diet. I certainly think that the scale of dietary laid down in 1848 did not err on the side of starvation, but even if it did that dietary has been revised, and you will find that all the changes have been on the side of relaxation, and there has been a considerable increase in the amount of the meat given to the prisoners, who now have meat five days out of the seven. But that is not all, for there exists a system of extra diet, and that has grown to such an extent that, out of 300 or 320 prisoners, the number on extra diet is no less than 59. I do not say that the extra diet is wrongly given, but I do say that we ought thoroughly to understand the principle

upon which it is given; for I assure this court, that if they compare the prison diet with the workhouse diet it will be found that the comparison is far from being in favour of the workhouse diet; and I must say, that when a poor man, without a blot on his reputation, who has, perhaps, lived a long life without the slightest shadow of suspicion attaching to him, is at last obliged, either through misfortune or through old age, to resort to the workhouse, and receives hardly sufficient to keep body and soul together, while the sturdy felon, who has been committed and recommitted over and over again, is well fed and comfortably cared for, it is dealing with guilt and innocence in a most unsatisfactory manner. (Hear.) I now come to the general changes affecting prison discipline, and I am sorry to say that I can number several cases in which the relaxation of prison discipline has led to increased evils. In the first place, the extension of the open-air exercise has been unsatisfactory. As I have said, where open-air exercise is permitted to excess, imprisonment is no longer a punishment; but you have stripped it of the very semblance of punishment by removing those restraints which prevented large numbers of prisoners being brought together for open-air exercise, because by enlarging the space you have rendered it almost impossible for the warders to prevent that which is subversive of all prison discipline—namely, a free communication between the prisoners. You allow the prisoners now to be employed in agricultural operations, especially in spade labour. If your prison system had been one of the soundest, I should not have been disposed to complain of that; but, in fact, your prison system is almost entirely made up of recreation and relaxation, not only out of doors, but in doors. Quite recently there has been an extra allowance of pudding. By the old rules a prisoner was allowed a rug, a sheet, and a blanket, which latter, being large, could be doubled down. He is placed, remember, in a cell only 12ft. by 8ft. in width, which is warmed by hot air, and which he himself has the power of ventilating as much as he pleases. You have now allowed him in the daytime an additional waistcoat, and at night an additional blanket, and not only that, but in order to keep his feet off the asphalt floor, and save him from any draughts that may creep through the exceedingly well-fitting door of his cell, I perceived, on a recent visit to the gaol, that you have actually accommodated him with a footstool. (Laughter.) Then, again, in order to provide for his amusement and instruction, I observe you have a very admirable library, one-half of which is composed of works of purely religious instruction and of a serious character, and the other half is made up of works of fiction and works of entertaining, interesting, instructive, and amusing knowledge—(laughter)—such books, certainly, as are far beyond the reach of the poor. I do not wish to throw any slight at all on the system of having a prison library; on the contrary, I think there ought to be one, but I certainly did not expect to find such books in it as those I saw in the county gaol. I find works on history, on ancient Egypt and Greece, treatises on modern astronomy and astro-theology (laughter); books of fiction, such as ‘Frank Leverton’ and the ‘Dairyman's Daughter;’ books of travels, such as Dr. Livingstone's ‘Travels in Africa;’ and, lastly, popular poems and prize essays. Now, I do not want to cut off from these unfortunate persons anything which I think might be fairly allowed them, or to make their existence more miserable than crime has made it, but I think it very questionable how far you should allow prisoners to withdraw from the library works of the description I have named for the purpose of relieving the tedium of the prison, which, with the single exception of restraint on their personal liberty, now remains the only part of their punishment left, and thus to render their condition far better than the poor, but honest labourer.”

UNIVERSITY OF OXFORD  
NATURAL SCIENCE EXAMINATION.

FIRST EXAMINATION FOR THE DEGREE OF  
BACHELOR OF MEDICINE.

*Mechanical Philosophy.*

1. Explain the terms inertia, resultant, centre of gravity, centre of oscillation, centrifugal force, moment of inertia, centre of pressure, metacentre.

2. Define the metre, gramme, and litre. Reduce the centigrade temperature 16.5 to Fahrenheit's scale.
3. Explain the methods of determining the specific gravity of a liquid. How may bodies be accurately weighed in a balance whose arms are of unequal length?
4. State the law of expansion of air by heat. Explain the methods of determining the specific heats of solids. Describe the phenomena of latent heat. How is the dew point determined? What are the methods of producing cold artificially?
5. State the facts which prove the existence of two electricities, and explain how the law of attraction has been discovered. Enumerate the best insulators and the best conductors. Explain the action of a Leyden jar.
6. Describe the voltaic combinations of Daniell, Smee, and Grove. How is it proved that a circulation of electricity takes place in an active battery? Describe apparatus for giving a shock with a single cell when (1) two coils of wire are used, (2) when a single coil of wire is used.
7. State the law of ordinary refraction of light; and describe its analysis by a prism. What is meant by the interference and fluorescence of light? Explain the construction of the camera lucida, and of the Galilean and astronomical telescopes.
8. Specify the various means of procuring a beam of polarized light. Draw the appearances presented by thin plates of calc spar and nitre when viewed between polarising and analysing plates. State the phenomena of circular polarisation exhibited by certain liquids. Describe Haidinger's brushes.
9. How are electro-magnets constructed; and what discoveries have been made by their use? What force does a straight conducting wire exert on a magnetic needle?
10. Give an account of Du Bois-Reymond's discoveries in animal electricity. Give his explanation of the so-called induced or secondary contractions.

*Chemistry and Botany.*

1. Mention the acids which agree with those of arsenic in their physical and chemical properties, and relate what you know of the principle to which this agreement is referred.
2. Into what parts of the body does phosphorus enter; and how may its presence be determined?
3. State Davy's theory with respect to chlorine and the bodies related to it; and explain why it is preferred to the one previously introduced by Berthollet.
4. Account for the effect of nitrate of silver in blackening the skin; and explain why it may be administered internally without giving rise to those corrosive effects which it produces on the surface of the body.
5. State the chemical composition of urea, the bodies isomeric with it, and the methods of detecting its presence.
6. How far can animal heat be explained on chemical principles; and what facts might be alleged in support of the idea, that it is in some degree a vital phenomenon?
7. State the nature of vinous fermentation; and explain the differences between an alcohol and an ether, regarded as generic terms.
8. Give an account of the different sorts of urinary calculi, of the modes of detecting them, and of the treatment pursued in each kind, so far as it is founded on chemical principles.
9. State the differences between animal and vegetable respiration.
10. Explain so much of the physiology of plants as may furnish you with a reason why, as in the cinchona tribe, medicinal properties principally reside in the bark; or, in other cases which may be enumerated, in the root.
11. What is the supposed use of the Stomata; and where do they generally reside? State the exceptions to this rule.
12. State the characters of the Umbelliferæ; and mention in what organs their medicinal properties reside. Name some of the plants of this tribe which act injuriously or otherwise on the animal economy.

PRACTICAL EXAMINATION.

*Chemistry and Botany.*

1. Name the substances present in the solutions contained in phials 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, and 12; and mention the tests by which you have determined their presence.
2. State the natural families to which belong the plants ticketed A, B, etc.; describe the general characters of each family, as well as its medicinal qualities, and enumerate some of the plants belonging to it which are admitted into the *Materia Medica*.

1. Enumerate and describe the several varieties of epithelium which are found lining the digestive and genito-urinary tracts.
2. How is it that in hemiplegia the intercostal and abdominal muscles, together with the diaphragm, retain their physiological functions?
3. What are the different nerves which have been shown experimentally to exercise an influence on the secretion of the saliva?
4. What do you know of pigmentary deposit as a physiological occurrence?
5. Give an account of the natural history and of the structure of the trichina spiralis.
6. What are the characteristics of the human fœtus at six months?
7. Give an account of the course and relations of the sub-clavian arteries.
8. Describe the intrinsic muscles of the human larynx; and give an account of the nerves and bloodvessels of that organ.
9. In what way, and to what extent, do the several conditions of food, age, sex, and labour act upon the constituent elements of healthy urine.
10. Give an account of the microscopic structure of arteries, veins, and capillaries.

PRACTICAL EXAMINATION.

*Anatomy.*

1. Give a detailed account of the different structures exposed by dissection in the subject placed before you.
2. Make such a dissection of the heart put before you as will expose its mitral and aortic valves and the commencement of its coronary arteries.
3. Place under the microscope some of the inner coat of the aorta, and describe in full the appearances it presents.
4. Describe Prep. No.

NOTICES OF THE

SURGICAL, MEDICAL, AND OBSTETRICAL INSTRUMENTS IN THE INTERNATIONAL EXHIBITION OF 1862.

By JAMES REEVES TRAER, Esq., F.R.C.S., etc.  
Superintendent of Class 17.

If I had not already occupied so much valuable space in this journal, I would willingly prolong my series of notices; but I feel obliged to bring them to a close, with the following remarks, although I shall have left undescribed many objects of considerable interest. Mr. Matthews (to the contents of whose case I have already alluded) exhibited his improved tracheotomy canula. This instrument (Fig. 1) is deficient

FIG. 1.

above and below, and consists of two blades, fixed to an ordinary guard-plate, which are capable of being pressed together, so as to form a wedge, the point of which is not thicker than the back of an ordinary scalpel. Compressed in this way the canula is easily introduced; the blades then spring apart, and retain the tube *in situ*. The inner, a complete tube, is now introduced, and the instrument tied as usual. There is an opening on the laryngeal aspect of the inner tube, so that there is no obstacle to the respiration, when it assumes its natural direction. This canula has been frequently used with success; and the only objection to its employment which suggests itself to me, is the possibility of any evil resulting from the pressure of the external elastic tube on the mucous membrane of the trachea. Aluminium and silver are the metals employed in its manufacture.

The same maker exhibited some excellent lithotrites, in

which the bulk of the stem and handle was considerably reduced. One of them was of the size of a No. 4 catheter.

Fig. 2 represents the forceps sponge-holder, and Fig. 3 the caustic holder, for application to the interior of the larynx, as made by Mr. Matthews. These instruments, which can be easily used in connexion with the laryngoscope, are very ingeniously contrived, and practically answer the purposes for which they are constructed.

Mr. Matthews also showed the instruments ordinarily employed in ovariectomy. This operation, despite the scepticism of a few men, who, notwithstanding the gradual and sure advance of its claims to be considered of much less danger than some of the so-called "capital operations," has now most deservedly earned for itself a position among those proceedings which not only *may*, but *ought* to be carried out by the Surgeon. The same maker exhibited the different instruments employed in the operations for the various vaginal fistulæ, and a variety of specula for the ear, vagina, uterus, and rectum—those for the vagina being of a very low price. In his case were many splints of useful form; among which were to be noticed Mr. F. Mason's ingenious appliance for employment after resection of the elbow-joint, which combines the four movements of extension, flexion, pronation, and supination; and Mr. George Parkinson's splint for the treatment of cases of resection of the knee-joint.

The catheters made of steel, tinned inside, and covered with a coating of vulcanite, which Mr. Matthews exhibited, combine the three advantages of strength, cleanliness, and cheapness, and must have commended themselves to the favourable notice of all who saw them.

As might have been expected, Mr. Matthews' case contained a good array of his well-known saws for aiding in the extirpation of the upper jaw, and in operations on other parts of the osseous system; his bone-nippers are also of excellent construction; and an improvement which he has added to some of the varieties of forceps, merits a special description. The teeth (see Fig. 4) resemble those of a shark, inasmuch as they are directed backwards, and, as a consequence of this peculiarity, the hold of the instrument is so strong as to preclude the possibility of any tissue slipping from its grasp, when it has once been fairly seized. This principle (which is entirely the invention of Mr. Matthews, and for which he deserves great credit), is peculiarly applicable to the construction of sequester forceps, as well as those employed for dissection, for the extraction of polypi, and for all other purposes where great prehensile power is required.

Messrs. Ferguson, of Giltspur-street, exhibited a case, the contents of which were remarkable for excellence of manufacture, and, in many instances, for considerable ingenuity. Among them I may notice Ferguson's fissure needle, which was devised in order to facilitate the application of a ligature in a confined and limited space. It consists of a handle and staff; to the extremity of the latter, a needle, of ellipsoid curve, is attached by means of a hinge-joint (see Fig. 5). When pressure is made on the compound lever (seen in the illustration) which is placed at the side of the instrument, and is connected with the needle, the latter moves in a direction indicated by the dotted line. When the edges of a fissure have been pared in the usual manner, the Surgeon is enabled to pass his silk or wire ligature through both sides with ease; this is accomplished by thrusting the needle bearing the silk, so as to perforate one of the edges of the wound, and by subsequently pressing the handle of the lever so as to carry it through the other. The silk or wire being seized by a pair of forceps, the removal of the pressure exerted on the lever allows the needle to resume its former position, leaving the silk in the desired situation. The needle may then be withdrawn, re-threaded, and, if necessary, reapplied.

The same makers also showed Mr. Hutchinson's large trocar for emptying ovarian cysts, and also his clamp for securing the pedicle. This latter (Fig. 6) consists of two bars of steel, gilt, in order to prevent them from becoming rusty, and united by a hinge at one extremity. Their inner surfaces are jagged, in order that they may retain the divided tissues with security, and prevent the pedicle from slipping. When brought together, the two bars may be secured and retained in position by the small screw, and the handles of the instrument removed by pressing the side-springs. The smaller illustration represents the clamp when applied.

In order to diminish the injurious results of the entrance of air into the cavity of the pleura during paracentesis thoracis, Mr. Thompson, of Westerham, has devised a trocar of

peculiar construction. By referring to Fig. 7, it will be seen to consist of a cylindrical (silver) canula, of about four inches in length, and of the diameter generally used for this operation; into this opens a short silver tube, to which is attached, by means of a screw, an India rubber tube, about a foot in length. A solid steel piston, with a trocar-point, plays on the canula, and is of such a length that, when pushed forwards, its extremity protrudes sufficiently from the surrounding tube, and of such a diameter as to close the canula completely and occlude the lateral tube. By means of the screw at the extremity of the handle, the piston can be withdrawn (after the puncture has been made), so that the lateral opening becomes patent, when the pus or other liquid will readily flow into a conveniently placed receptacle, without any risk of any air being admitted into the pleural cavity. That this instrument is ingenious, no one can doubt, and I am very far from being inclined to deprecate its use; but I have a strong conviction that British Surgeons have an exaggerated fear of the bad effects of the entrance of air into the pleural cavity; it being always understood that I refer to such a quantity of air as is likely to gain admission during the performance of paracentesis thoracis with the ordinary trocar and canula.

Messrs. Ferguson also exhibited the simple instrument, suggested by Mr. Luke, for the ablation of the tonsil. It consists, as shown in Fig. 8, of a steel plate, attached at one end to a handle, and perforated at the other to receive the tonsil. On the surface of this plate, in two lateral grooves, a cutting edge plays, so that, by simple pressure of the thumb, any requisite quantity of the tonsil can be removed, if it be previously drawn through the opening in the instrument by means of an ordinary pair of forceps.

In the same case, Mr. Hutchinson's modification of Dr. Buchanan's staff (described in my last "Notice") was to be seen. This alteration consists of the addition of a central canal, so that the instrument can be employed as a catheter, and clearly increases the value of the instrument. Messrs. Ferguson also showed an ingeniously-constructed instrument devised by Mr. Coleman, for the administration of chloroform through the nostrils. It is ingenious, and likely to be very useful in certain operations on the jaws and teeth. Mr. Armstrong Todd's inhaler was also exhibited by the same makers: this instrument, like that of Dr. Sansom (shown in Mr. Matthews' case), has been devised with the intention of procuring the gradual inhalation of an atmosphere charged with a limited amount of chloroform vapour.

The class stethoscope of Dr. Davies was among the instruments shown by Messrs. Ferguson. It is intended to facilitate the practical study of auscultation in clinical classes. By means of a flexible tube (see Fig. 9), attached to the side of an ordinary stethoscope, two persons can simultaneously listen to the same sounds, and the Physician can practically instruct the student as to their precise nature and meaning.

There were many more Surgical instruments and appliances of great interest and importance in the late Exhibition, to which I am sorry to be unable to refer: indeed, I have been furnished with many illustrations which I have not had an opportunity of using. Before I quite conclude, however, there is one subject on which I wish to say a few words, which at some time or other must come under the notice of the Surgeon. I allude to the form and mode of construction of the majority of boots and shoes that are worn in the present day. Were young children carefully attended to in this matter, there would be less distortion of the foot and ankle than there is at present; and, although a painful corn or bunion may seem to be a trifling ailment, it is quite severe enough now and then to prevent anything like active locomotion, and may produce discomfort for days, or weeks, or even months. As this kind of annoyance can usually be remedied by discarding a badly-made boot, and wearing one manufactured on a sensible plan, I was pleased to observe that one boot-maker, out of the many who talk of "scientific principles," had succeeded in producing what I consider to be the proper covering for the foot. Mr. Lanagan, of Brownlow-street (to whose productions I now refer) has invented an instrument for measuring distorted feet. It enables the boot-maker to read off from a graduated plate the extent of the different curves of the foot; it also marks the precise distance from the heel to the most prominent point of the instep; and, should there be any enlargement at the metatarso-phalangeal joint of the great toe, its precise position can be indicated by sliding rules. By the aid of such measurements as these, a much more accurately

FIG. 3.

FIG. 6.

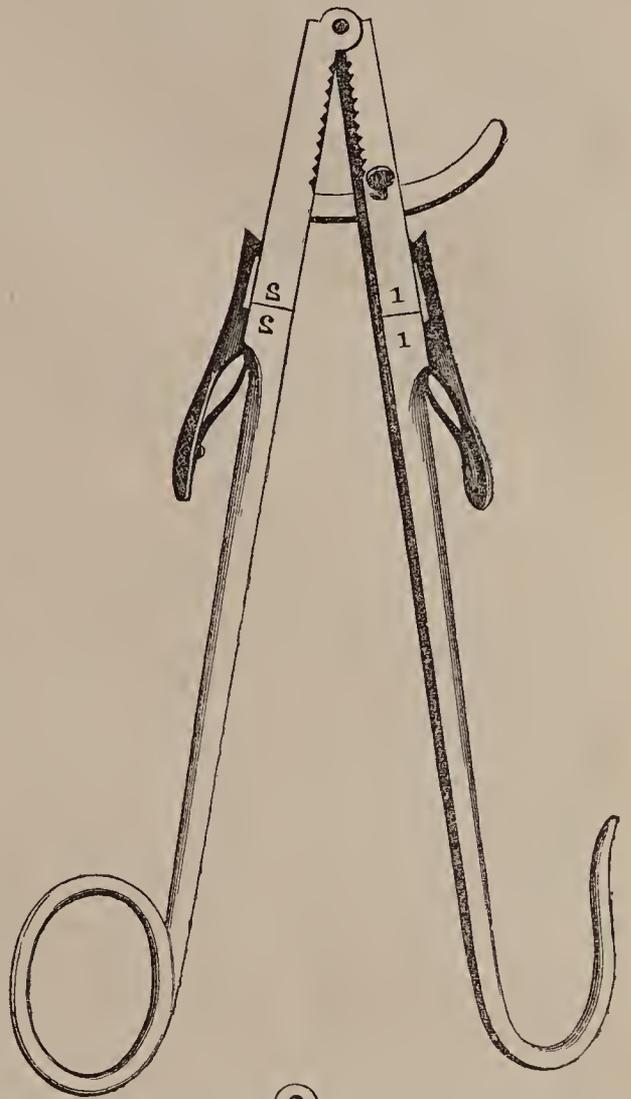

FIG. 7.

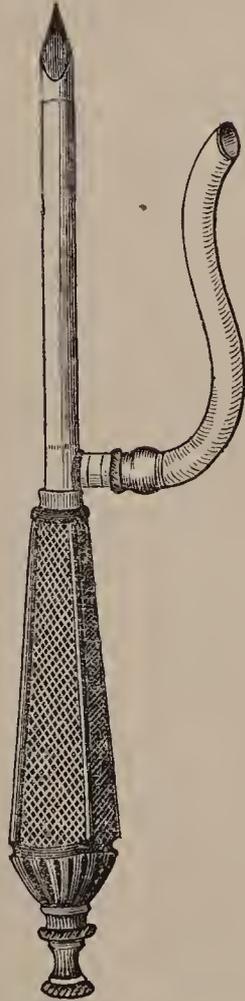

FIG. 5.

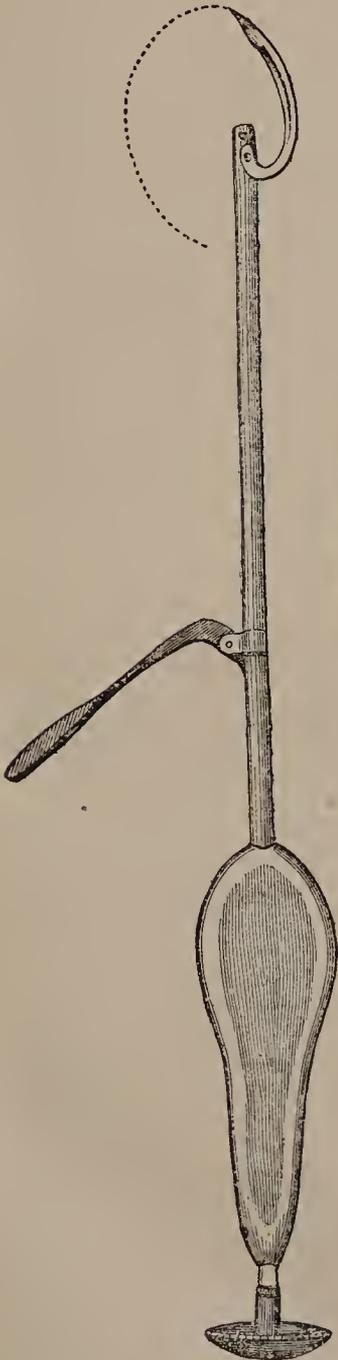

FIG. 4.

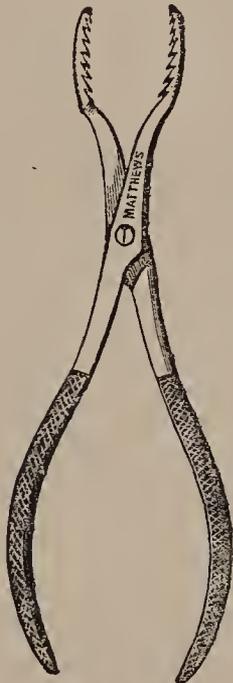

FIG. 8.

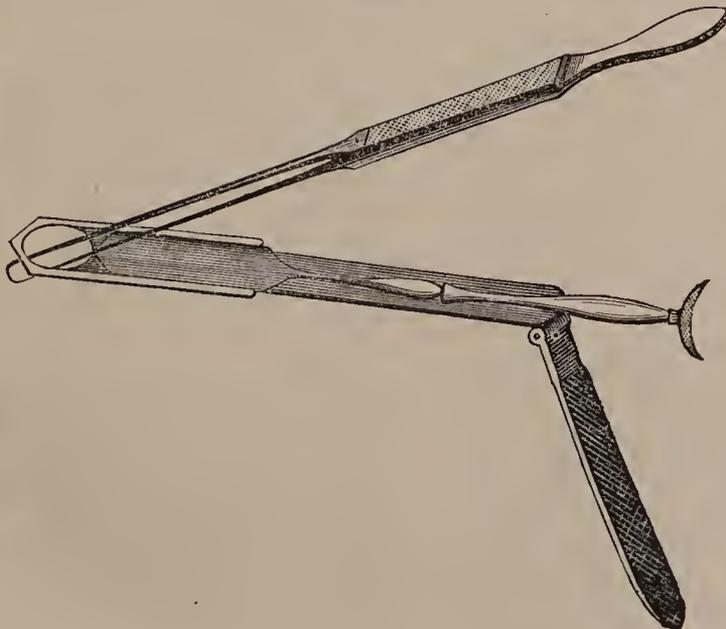

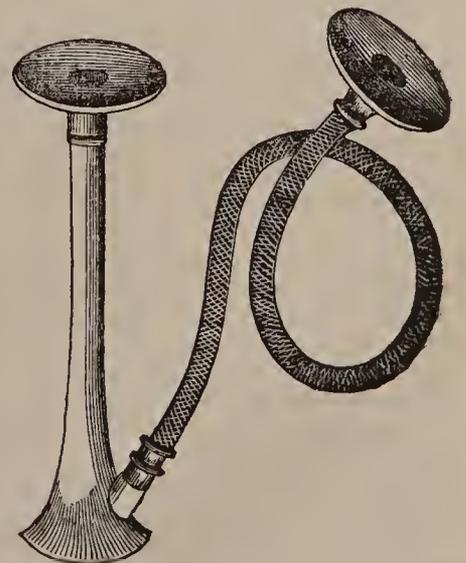

FIG. 9.

fitting, and hence more comfortable boot, can, undoubtedly, be produced. The least reflection must convince any one of the truth of the statement, that boots and shoes, as now worn, must inevitably tend to distort the foot,—indeed, an adult foot of natural form is now rarely to be found. Mr. Lanagan exhibited many varieties of boots and shoes made on his principle; and I think he deserves great praise for introducing to the notice of Medical men, and the public generally, so valuable an improvement.

In conclusion, I wish to express my thanks to the exhibitors for the wood-blocks they have furnished me; for I have been able to illustrate my series of "Notices" very fully, and to render many points clear, which, I fear, my verbal descriptions might have otherwise left in confusion.

47, Hans-place, S.W.

## FOREIGN AND PROVINCIAL CORRESPONDENCE.

### FRANCE.

PARIS, December 19, 1862.

#### ON DRINKING-WATER.

ON Tuesday last, M. Bouchardat read a very interesting paper on the above subject before the Academy of Medicine, and a short abstract of which will probably be acceptable to the readers of your journal. He commenced by stating that the best method of studying the different kinds of drinking-water was not by chemical analysis, but by rigorous Medical observation; for, if chemistry had done much to instruct us as regards the composition of the anorganic substances contained in drinking-water, it had done very little indeed to enlighten us as to the causes of the injurious effects of certain waters upon the system. He then entered into the question of the quantity of water necessary to man within the twenty-four hours, which varied very much according to age, exercise, temperature, the degree of moisture of the atmosphere, etc. The mean quantity, however, necessary for the adult might be taken at four pounds per diem. It was much better for the preservation of health to ingest habitually this quantity, which was required for the normal functions of the body, than to take more or less. Although the inconveniences produced by taking too much or too little might be often feeble or none, or remain unperceived, or become only manifest in the long run, and by close observation of the state of health of the person concerned, it was, nevertheless, advisable to keep the *juste-milieu* in this as in other points.

M. Bouchardat then discussed the influence of the principal substances of which the drinking-water is composed on the health of man, and considered successively oxygen, nitrogen, carbonic acid, and ammonia. He said that the presence of air in drinking-water was generally admitted by the writers on this subject to be necessary for health; but this point ought not to be exaggerated. Water containing air had, no doubt, a more pleasant taste than that which did not contain any, and that was certainly of importance; but we were scarcely justified in believing that this air played a great part in the system. The Chinese did not take any water but such as had been previously boiled, without any trouble resulting from this habit. The air contained in the water of rivers was generally richer in oxygen than the atmosphere; and Humboldt and Gay-Lussac had found in Seine water 33 per cent. of oxygen. It was generally believed that water containing air was more digestible and palatable than distilled water; but M. Bouchardat believed that the taste of ordinary water was more due to the salines contained in it than to air, and that the greater digestibility of water containing oxygen was a mere assertion which had constantly been repeated, but for which no satisfactory proofs had ever been advanced. He was, however, glad of finding oxygen in drinking-water, not on account of some special action on digestion, but because the presence of oxygen, in any considerable quantity, was incompatible with that of certain noxious organic substances. The presence of carbonic acid gas in water was a desirable circumstance; it gave the water sapidity, promoted the appetite, and seemed to favour digestion. All flowing waters, and, in fact, every drinking-water, contained a very small quantity of compounds of ammonia; the ammonia was collected from the atmosphere by the rain, or proceeded from

spontaneous decomposition of nitrogenous matter undergoing putrefaction in the water. The presence of ammonia in drinking-water was, therefore, frequently the sign of unfinished putrid fermentation; but although we must attribute a decided part in the injurious effects of water to organic substances, yet it would be hasty to conclude that a water was insalubrious from the presence of a few milligrammes of ammonia in a litre of fluid. When the decomposition of the organic substances was finished, or when these substances had indifferent effects, which was most frequently the case, the water might be quite healthy in spite of its containing a little ammonia.

With regard to the influence of the fixed constituents upon the quality of drinking-water, M. Bouchardat remarked, that the water of rivers and rivulets generally contained from  $\frac{1}{10000}$ th to  $\frac{3}{10000}$ ths of fixed matter. A water might contain even  $\frac{5}{10000}$ ths of solid constituents, and yet be considered not only a good drinking-water, but also suitable for most other purposes. Water which contained a higher percentage of salines was a medicinal mineral, and no drinking-water. Amongst the several solid constituents of ordinary water, silica was of importance. In a litre of river-water, one-half to three centigrammes of this substance were generally contained. It was not improbable that water containing a large amount of silica might give rise to caries and loss of teeth, so very common in certain districts, as the excess of silica determined a rapid formation of tartar, by which the teeth were rendered friable and carious. Phosphates were found in all flowing waters, although they were seldom mentioned in analyses. The same was the case with carbonates; and the presence of a moderate quantity of earthy carbonates was always useful. Chlorides were likewise "good salts," but their quantity was very insignificant, if compared to that daily ingested by us with the food. A very small quantity of iodine and bromine in drinking-water was desirable; but if their quantity should amount to one centigramme in a litre, the water would no longer be suitable for habitual use, but be a mineral water. Fluorine was found in the mineral substance of the bones and the enamel of the teeth. M. Bouchardat had discovered traces of hydrofluoric acid, or of fluorides, in the gastric juice of fowls. Fluoride of calcium, which was necessary to the system, was found in the usual articles of food, and also in drinking-water. Nitrates seemed to exist in every drinking-water, but generally in such a small quantity, that they could not exert any appreciable influence on man. But if nitrates were not directly noxious, they might indirectly serve to excite our suspicion, as they habitually accompanied dangerous organic substances. Moreover, water containing nitrates might, if kept in leaden cisterns, attack this metal, and become impregnated with it.

Amongst sulphates, it was chiefly the sulphate of lime which was met with in drinking-water; and it seemed to play quite a different part from that attributed to the bicarbonate of lime. It had not, as this latter saline, the property of giving off a gas favourable to digestion, and very little liable to decomposition; moreover, it could not, by its decomposition, furnish a basic element useful for acidity of the stomach. At the same time, water might dissolve a sufficiently considerable quantity of it to acquire a sweetish and exceedingly unpleasant taste. Finally, it was, as all other sulphates, prone to decomposition under the influence of organic substances. Sulphuretted hydrogen was, thereby, set free, and this was a bad element for such water as was, on account of an impediment to its course, exposed to a prolonged sojourn upon the soil. If we added to this, that it decomposed soap, and had incrustating properties, we were bound to admit that the presence of a somewhat considerable quantity of sulphate of lime in drinking-water was an unsatisfactory circumstance. If water contained more than  $\frac{1}{1000}$ th of compounds of lime in solution, it was considered unfit for the ordinary purposes of life; it was then called "hard." Nevertheless, water might still be drinkable, even if containing  $\frac{2}{1000}$ th to  $\frac{3}{1000}$ ths of compounds of lime, provided that no other noxious substances were found in it, and that its taste was pleasant. One ten-thousandth of bicarbonate of lime was not only not unfavourable, but, on the contrary, gave a useful element to the water. Incrustating calcareous waters were generally feared, as being able to give rise to gravel, urinary calculi, etc.; but this was an error which should be combated, as there was no single fact which would go to prove such an etiology of gravel; and, moreover, several mineral waters containing such substances were useful for preventing

the formation of gravel, consisting of uric acid or oxalate of lime. The compounds of magnesia, if found in such quantity as not to impart any taste to the water, might, although they could scarcely be called useful, yet be considered inoffensive, in spite of the accusations of which they had been the object. Small quantities of the compounds of soda and potash might be considered useful, rather than injurious, provided that they did not impart a peculiar taste to the water. Alumina was met with in water, bound to phosphoric, sulphuric, and carbonic acid. The quantity was mostly insignificant, but in some wells much of it had been discovered. Such water had an abominable earthy taste. Of iron, only a very trifling amount was met with in drinking-water, as such waters which contained somewhat less than half-a-grain of bicarbonate of iron were considered chalybeates.

With very few exceptions, those waters which contained a notable amount of organic substances were liable to rapid putrefaction, whereby they acquired "organo-leptic" properties dangerous to health. The part played by organic substances in drinking-water was the most important, and the most difficult, question in the hygiene of water. Mineral matter was comparatively innocuous in drinking-water, while organic substances were injurious to man, although useful for the development of plants. This might be considered the general rule, which had, however, many exceptions. In studying the influence of organic substances upon the quality of drinking-water, we must distinguish those matters which were merely suspended, and those which were dissolved in it. The former acted as ferments, and rapidly putrefied the latter, in rendering them insoluble; while the latter, by themselves, might remain latent, provided that no germ or insoluble organic matter induced their decomposition.

The organic substances which were contained in drinking-water might have a different origin: they might come from spontaneous decomposition of animals and animal parts, or of vegetables and vegetable parts. Until now, the influence of *animal* matters in a state of decomposition on the quality of water had been chiefly studied, but from a mistaken notion; because, when their quantity was at all considerable, they gave organoleptic properties to the fluid by which this was made undrinkable; while water containing organic substances due to the decomposition of *vegetable* parts, might still apparently preserve the principal qualities of drinking-water, and, therefore, exert a great influence on the health of populations drinking of them. It had been asserted, and M. Bouchardat was inclined to corroborate this assertion in certain cases, that water impregnated with organic matters arising from the decomposition of animal matters, might determine diarrhœa and dysentery. As regards diarrhœa, this opinion was rather based on unanimous consent, than on accurate observations. It was said that strangers newly arrived in Paris "paid their tribute to the Seine;" and this was explained by the presence of a certain amount of organic matter in the water of that river. Without denying this influence, M. Bouchardat thought that there were other circumstances which had to be taken in account, such as a changed mode of life, changed food, etc. Moreover, accidents of the kind mentioned were less frequent than they were commonly believed to be, and occurred just as well in persons who had not drunk Seine-water as in such who had. In the same manner it could not be regarded as settled that dysentery was produced by drinking water containing decomposed animal matter. M. Blondeau had stated that the apparition of dysentery at Rhodéz coincided with the use of such waters, and other authors had given similar data; nevertheless, M. Bouchardat was far from being satisfied that this view was quite justified by the facts of the case. Great caution was also necessary in determining whether, as had been stated, typhoid fever was produced by the use of such waters. At the same time, it was wise not to partake of water impregnated with such substances.

M. Bouchardat then entered into the question, how we should find out that water was fit for drinking or not? Good drinking-water should be absolutely devoid of smell; its taste should be very slight, agreeable to the palate; it should be limpid, fresh, light, and contain oxygen; it should dissolve soap without forming too much curd, and should cook beans, peas, and other leguminous seeds without hardening them. Moreover, it was necessary that a long-continued use of the water, and observations continued with perseverance, should have demonstrated its innocuity.

M. Bouchardat wound up his paper by commenting on the

principal methods of analysing water now-a-days adopted by chemists, and promised, on a future occasion, to enter into the diseases caused by the use of bad drinking-water.

## EDINBURGH.

January 5.

THE new year has come in blowing and blustering in a way unsuitable to its youth. Weary, melancholy 1862 died like a cruel giant: we are none of us sorry to part with him, and of his boisterous offspring we know so little as yet, that we can only hope he will be brighter and cheerier than his parent.

I cannot flatter myself that there is much to write about. Our Session is only tolerably well attended, but the students are as usual a gentlemanlike, steady set of young men; and, already, the dreaded preliminary examinations seem to have weeded the few tares from our autumnal harvest.

The Infirmary has not presented anything very striking in the Surgical wards. Professor Syme removed the scapula, and Mr. Spence a large tumour from the cheek, as a sensational commencement. The latter required careful dissection, but was successfully accomplished, and both operations were perfectly satisfactory in their results. Dr. Gillespie has been associated with Mr. Spence as Clinical Lecturer, and Dr. Struthers appointed one of the Acting Surgeons, so there are now three Acting and one Assistant-Surgeon, Dr. Watson. This appears a very good arrangement, as, while Mr. Spence ceasing to lecture would have been a serious loss to the Clinical Surgery department, Dr. Struthers' position as a very popular teacher made it almost an absurdity that he should continue to perform the nominal duties of Assistant-Surgeon. The only want is material. The visitor, on going through the spacious wards of the Infirmary, cannot help heaving a sigh that even railway accidents are provokingly rare, and that stones are becoming as scarce as rose-amethysts.

The societies have opened with such attendance of members as is to be expected when the wind blows a hurricane, and you leave rain in one street to meet hail in the next, where, between the wind and the water, there seems only the alternatives of swimming and flying, walking being but a euphuism for a mixture of both. The students' societies here are the Royal Medical and the Hunterian; the former, a time-honoured institution, where some of our greatest men gained their first laurels, and where now very many clever young fellows wage a wordy war every Thursday evening. There is great hero-worship there, too; and how the youngsters settle disputed questions in practice! Ah, my dear Sir, have you any doubts on the proper treatment of some disease? Come to our Royal Medical Society, and you'll go away, perhaps, a little deafer, but certainly a wiser man. The Hunterian is a good working society, and, I hear, is less burdened by laws and fines than the other, which has many of the elements of a club, including a library and excellently snug reading rooms.

I have heard a rumour, and I trust it is something more, that there is a movement towards building a students' hall and chambers here. It is a disgrace to Edinburgh that, while it derives such solid advantages from the students attending its various educational establishments, the young men are left at the mercy of persons who, with some few exceptions, are under the necessity of screwing them in every possible way, and are entirely ignorant of what a young man, sometimes delicate in health, sometimes fastidious in habits, requires. If this discomfort begot either hardihood or economy, far be it from me to object; but it is not cheap by any means, and certainly not healthy. And all this in a town where ample variety of food can be obtained very cheaply, and plenty of light and fuel! Why, then, should a student's room be dark and dingy; and why should his diet be so constantly the same that it seems almost part of the curriculum to eat down one side of a sheep and up the other, until he has consumed the academic number of chops.

So long as the student was of the traditional type, such an arrangement might do very well; but for the youths who come up now, many of them perfect gluttons for work, and priding themselves on that abnegation of self one cannot help admiring, something must, and, I trust, is about to be done. Of course, there will be a Dr. Pangloss or two, who, in his faith in "this best of all possible worlds," will "pooh! pooh!" the movement; but not many, I trust.

I happened to be in St. Andrews lately, when the M.D.

examination was going on, and, as I knew some of the examiners, had the *entrée* of the Town-hall and University Library, where the boards were sitting. I am afraid to say from memory how many hundred men of all ages have taken this degree this year—all ages: the white-haired man pored over his questions, and wrote slowly and with apparent difficulty, beside the youngster fresh from the schools, whose pen danced over the paper. But each one fared alike, for Dr. Day is no respecter of persons, and seemed nervously anxious lest any should creep through, and so do injustice to abler men. Your correspondent would not have liked to try his hand at that examination, inasmuch as he believes he would have been plucked. Unlike other Universities, St. Andrews calls its examiners from all parts, and on this occasion teachers from Edinburgh and Glasgow, and elsewhere, met. Not one of them had the least interest in the passing or plucking of a candidate, but all had one common feeling—that no one unworthy of the letters “M.D.” should pass. No doubt, in this condition of things, some who might have passed were rejected. Again, I say, if any one asks me to go up for that examination I must decline. Craigie is too erudite, Seller too smilingly severe, Wilson and Paterson too much impressed with possible obliquities of their fellow creatures’ characters, even at birth; then Heddle is bad enough; but Penny!—he who nearly hanged Madeline Smith—fancy testing for anything except escape when under his glittering eye! Struthers, too, is “little bether nor a traythur;” and Haldane is too accurate, let alone that light-haired man, fondling some diseased bones and scribbling faces on the University’s foolscap.

The above, Sir, was contributed to me by a gentleman who went to Fife lately, and returned nothing the worse apparently, and but little the better.

So Knox is dead! that sad life is ended; the die that stamped its best lines on some of our greatest men is broken. Knox is dead! You, in England, cannot see the reason why that has been so often said to even *me* within the last few days. I trust that many an unkind and undeserved word has been repented of by some who, in the natural order of things, must soon, also, go on the same journey. All allow how brilliant he was as a teacher; how true and kind a friend to his pupils; how his powers of communicating knowledge drew young men from all parts of the world to the dingy purlieus of Surgeons’-square; how he sat on but a ricketty throne, as all men do who trust only to their own powers, and how two drunken Irishmen tumbled him from it. Then it was fine times for the smaller people, and how jolly it must have been to kick the lion; but he got up again. Heigh-ho! there is no one of us but may be upset as he was, in our small way; let us try to leave behind us such living monuments of good and talent and industry as he has left, with this memorandum, which, no doubt, he, too, added in his latter years: “Except the Lord keep the city, the watchman waketh but in vain.”

I was glad to read in the *Courant* newspaper a kind and gentlemanly article on the dead teacher of our greatest living teachers—on him who first led Owen to ponder over the vestiges of an earlier world, who first placed a scalpel in Fergusson’s unfaltering hand, and lit that lamp which has never since been extinguished—still shining in Goodsir’s student-room.

The small-pox and typhoid fever have been more than commonly met with for the last few months, and the question of re-vaccination has been much discussed. It does seem hard that, with such natural advantages as this town possesses—its total want of an excuse for not being well drained, it is the worst drained town conceivable. Go through a by-street—say a street within a stone’s throw of where I am writing, and you will find heaps of human fæces; heaps of rotten fish; children doing what elsewhere is done in secret, but in modest Scotland is done in broad daylight. Children!—great girls and boys of twelve and upwards. Now, Sir, all this is within a few yards of the most important citizens’ noses. But we place a great deal of responsibility on Providence here; and unless Dr. Littlejohn, in whom I have every confidence, sets to work, to use an expression I once heard in a boarding-school, “we’ll catch it.” It is hard to believe in this almost intentional beastliness when one walks to any elevation, whether on street or grassy hill, and looks down on the beautiful city, and away to where the storm cone is apex down on Leith Pier, and the collier ships are cowering in to their moorings, like frightened birds, behind Inch Keith. How full of health seems this sharp breeze, cutting your nose into

Scotch collops! How hopeful are the rosy tints on the snowy sides of the Ochils! But still night comes, and we must descend—and where to, pray? Into a vapour-bath of poisonous vapours. Give your orders, gentlemen. We have here potted small-pox—and typhus in the next room, if you will open the window. We will not guarantee the sample, but we will do our best to give you cholera, dysentery, and anything else you please. It seems extortion to take your money, because, in a walk through the old town and some cross streets in the new, any one with moderate respiratory powers can inhale enough for himself and family.

## GENERAL CORRESPONDENCE.

### THE PRESENT EMPLOYMENT OF SYPHILISATION AT CHRISTIANIA.

LETTER FROM Dr. L. BIDENKAP.

To the Editor of the Medical Times and Gazette.

SIR,—The fairness of your review of the work of M. W. Boeck, “*Recherches sur la Syphilis*” (published at the expense of the Norwegian Government, not of the Swedish, as you say), induces me to write a few words upon the inoculability of the syphilitic virus. In this review you have already mentioned some experiments made by me in the Hospital of Christiania, tending to prove the auto-inoculability of the infecting chancre. But there is much wanting yet before the conclusions, to which these experiments have brought me, shall be generally adopted by authors. The majority of modern syphilographers delight themselves in declaring the impossibility of this transmission. And, lately, your distinguished fellow-countryman, Mr. H. Lee, in some lectures published in the *Lancet*, has held that the inoculation of the two kinds of chancre gives rise to results essentially different. In going over the account of his experiments, we find that he has only obtained that which, according to M. Ricord, we are accustomed to call “*pustules abortives*,” whilst I have nearly always succeeded in producing the “*pustule caractéristique*,” forming specific ulcers, which reproduce themselves in many generations. I will not attempt here to fathom the causes of these different results, but I am convinced that repeated and persevering experiments, conducted with the greatest possible care, will produce results analogous to mine. And I must say that at times there is need of great perseverance in these experiments.

It has happened to me that I have inoculated an indurated chancre from day to day without any effect, but, after persevering for a month or more, the time has arrived at which inoculability has manifested itself. I have, up to this day, repeated and varied my experiments, of which the number now is pretty great, and they invariably prove that inoculability is the rule, and failure a rare exception.

That which convinces me, however, that the truth, some time or other, and, perhaps, at no very distant date, will triumph over the common error, is, that lately a distinguished syphilographer and former pupil of M. Ricord, M. Melchior Robert, of Marseilles, has published some experiments, of which the results are similar to my own. We find these results and conclusions in his great work upon “*Syphilis*,” and in a small tract, “*Quelques Considerations sur l’Auto-inoculabilité du Chancre Infectant*,” etc.; Marseilles, 1861. But in admitting that which must sooner or later be acknowledged—the auto-inoculability of the infecting chancre, as well as of the non-infecting—we destroy the fundamental argument of the theory of the double virus, which has played so great a part in modern syphilography; and besides, in other respects, these facts are of great importance. Syphilisation will be cleared of the gravest charge hitherto made against it, that of being an “inoffensive playing with soft chancres.” I must not omit to state that, during the last two years, the virus of the infecting chancre has been constantly used for curative syphilisation in the Hospital of Christiania. Probably from this cause the effects have been quick, the time of treatment shorter, and relapses more rare and slight.

Will you permit me to add a few words upon the actual practice of this mode of cure in Norway? At the Hospital of Christiania, in the “service” of M. W. Boeck, it is the only cure which is administered in cases of constitutional syphilis (not treated before). In the other “service” for venereal maladies, of which Dr. Hjort is the “chef,” syphilisation is adminis-

tered in the greatest number of these cases, and more particularly in those in which the first appearance manifests an obstinate and severe affection of the organism; and also as an extreme remedy in some cases treated before without success by more simple methods, as abstinence or derivation. Mercury is never employed. In the town the majority of the syphilitic cases are treated by M. Boeck, or some of his pupils—among whom I have the honour to reckon myself—by syphilisation. The Practitioners, who are not “syphilidologues,” or who have not sufficient patience or zeal to administer the cure themselves, transfer the cases which come before them to M. Boeck, or to others who practise syphilisation. A very small number, I assure you, are treated by other methods more or less expectative; and there is scarcely one single Practitioner in Christiania who at this moment employs mercury against syphilis. So, you see, syphilisation is more flourishing than ever, and has gained the confidence of the public as well as of the Physicians who have taken the trouble to study it. I would add, that never in the course of the two years and a-half that I have filled the office of Assistant-Physician to the two “services” of the Hospital, has any accident or inconvenience attending syphilisation come under my observation, either in the Hospital or in my private practice.

Accept, Mr. Editor, &c. &c.

L. BIDENKAP,  
Assistant-Physician to the State Hospital  
at Christiania.

The State Hospital, Christiania.

### REPORTS OF SOCIETIES.

#### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, DECEMBER 3, 1862.

Dr. TYLER SMITH, President, in the Chair.

The following gentlemen were duly elected Fellows of the Society:—Dr. Charles Campbell, Kingston, Jamaica; Mr. Walter Chapman, Lower Tooting; Dr. E. Ellis, Fitzroy-street; Dr. J. Frain, South Shields; Dr. C. C. Hayman, Eastbourne; Dr. Kirkpatrick, Lying-in Hospital, Dublin; Mr. F. Prince, Sawston, Cambridgeshire; Mr. I. S. Shillingford, Peckham; Mr. G. F. Spry, Staff Assistant-Surgeon, Fort Gomer, Alverstoke; and Mr. T. Taylor, Birmingham.

Dr. TANNER, after making some preliminary remarks on the duty of recording even solitary examples of rare or complicated diseases, proceeded to give the following account of a CASE OF MULTIPLE MEDULLARY CANCER COMPLICATED WITH PREGNANCY.

He said—“On July 29, 1862, I was requested by Dr. Thane, of Hart-street, Bloomsbury, to see with him Mrs. C. L., aged 39, residing in Drury-lane. The poor woman was the wife of a very respectable working man, and was in comfortable circumstances for her station in life. She had always enjoyed remarkably good health. None of her relatives had ever suffered from cancer; but there was probably a slight family tendency to phthisis—that is to say, all her half-brother’s children had died from pulmonary consumption. She had been married ten years; and was about five calendar months advanced in her third pregnancy. The first child had been born on October 12, 1854. While suckling this infant pregnancy again took place, and on weaning the child at the beginning of 1856, she aborted, being three months advanced in gestation. After this accident the general health continued very good until May 2, 1861, when her child died from an attack of croup; and she was rendered so miserable by the loss that she may be said to have been neither happy nor well since. The catamenia had been quite regular until February 25, 1862; but this was the last day of their appearance. At the commencement of the present year (1862) a small swelling, about the size of a hazel-nut, was first discovered in the abdominal walls, just to the right of the umbilicus. There was no other symptom of disease appreciable to her husband or herself at this time. The growth gave rise to no annoyance until a few weeks ago, when it commenced enlarging, and became the seat of lancinating pains. Similar swellings also then began to form in other parts. On July 29, at my first visit, I found her much reduced in flesh and strength. The appetite was good; but, as she suffered much from indigestion and

flatulence, she was afraid to eat, although the remedies prescribed by Dr. Thane had given great relief. The sleep at night was very disturbed. In the abdominal parietes, just to the right of the umbilicus, there was a well-defined tumour, about the size of a large walnut. Adjoining the lower part of the ensiform cartilage of the sternum, there was a more extensive mass, also seated in the abdominal wall. In the left groin there was likewise a flattened growth, about two inches and a-half in diameter. On examining per vaginam, a very firm growth was discovered projecting into the canal, feeling as if it had its origin from the lower part of the sacrum, though, in reality, it was entirely seated in the recto-vaginal septum. It was clear that this mass would soon block up the vagina, and Dr. Thane assured me that it had much increased in size during the last fortnight. As before mentioned, she was five months advanced in pregnancy, and both the uterine souffle and the foetal heart could be plainly distinguished. The liver was much enlarged, and this enlargement, combined with the size of the uterus, occasioned a wearying feeling of distension, as well as some dyspnoea. Taking all the foregoing circumstances into consideration, it seemed certain that the poor woman’s comfort would be increased, even if life were not prolonged, by inducing premature labour—a proceeding which did not appear contra-indicated by any feeling for the child, as it was certain that a live infant could not be given birth to through the natural passages. The propriety of waiting, and ultimately effecting delivery by the Cæsarean section was discussed; but such a plan of treatment was regarded as not applicable to the present instance. Consequently, on July 30, the membranes were punctured, and about half-a-pint of liquor amnii withdrawn. On August 1, labour pains of fair severity set in; but the os uteri was still very rigid on the following afternoon; and, as the patient was getting tired and exhausted, and, moreover, as the mass of cancer in the recto-vaginal septum reached to within almost an inch of the pubes, it was evident that nothing could be gained by further delay. I, therefore, slowly tried to dilate the os uteri; and, this being partially effected, the foetus was broken up with a pair of forceps, and removed piecemeal. No difficulty was experienced with the placenta; the discharge of blood was very slight; no injury was done to the uterus or vaginal walls, and the poor woman was left tolerably comfortable. For some few days she continued to progress favourably; but on August 10 a severe attack of diarrhoea set in, aphthæ formed on the tongue and gums, and for the first time in her life she became jaundiced. It would only be tedious to give an account of the way in which she daily lost ground; suffice it to say that matters gradually progressed from bad to worse until the morning of August 26, when death took place from exhaustion. At the autopsy, fourteen hours afterwards, the body was found greatly emaciated. In the abdominal parietes, to the right of the umbilicus, there was a deposit of firm medullary cancer the size of a walnut, together with a larger growth just below the ensiform cartilage. These were separate tumours, and not infiltrations. The liver was enlarged to about three times its natural size, and studded with medullary masses, varying in size from a pea to a small orange. There was likewise several deposits of cancer in the great omentum, in the spleen, in the walls of the colon, and one large mass binding the sigmoid flexure of the colon to the tissues of the pelvis. In the pelvic cavity there was a separate deposit, extending chiefly down the recto-vaginal septum, and completely blocking up the vagina. The inguinal glands on both sides were enlarged and infiltrated with medullary cancer. The uterus, considering the time which had elapsed since delivery, was of its normal size, and healthy. At the apex of the left lung there was a small deposit of tubercle, which had undergone calcareous degeneration, while at the same part of the right lung there were several small tubercles. The heart was healthy, but its walls were flabby. The kidneys were healthy.” The paper concluded with observations as to the different modes of treatment which might be resorted to in such a case as that detailed, together with the reasons which led to the adoption of that practised.

A paper, by Mr. WALTER CHAPMAN, was read on a CASE OF RETENTION OF THE CATAMENIA, FOR MORE THAN TWO YEARS, IN A MARRIED WOMAN.

The history of this case, prior to its coming under the care of the author, was reported as the fifth case of cure of vesico-vaginal fistula, in the *Lancet* of November 24, 1860, by Mr. I. B. Brown. This lady, in her third confinement, was

delivered with instruments of a still-born child, and soon afterwards was found to be the subject of a vesico-vaginal fistula. She was operated on twice, and was cured; the last operation being in the middle of June, 1860. This patient was first seen by Mr. Chapman on September 26, 1862. She was sitting up, able to superintend her domestic affairs and walk about, and presented the aspect of health. She was of robust stature, rather short, with a superabundance of fat, and forty years old. She complained of great irritability of the bladder and stomach, and of severe pain in the lumbar and sacral regions. When in bed, on external examination of her abdomen, no difficulty was experienced in determining the existence of a large tumour, resembling the gravid uterus at about the sixth month. She had no reason for supposing herself to be pregnant, but said she had not menstruated since the operation. On a vaginal examination, it was found that the cervix was lost in a general enlargement of the uterus, the mouth of which could not be detected. The speculum revealed the spot where the os uteri had existed, but it was now hermetically sealed. Mr. Chapman stated his opinion that the symptoms resulted from a retention of the catamenia. Dr. Tyler Smith examined the patient, and confirmed the diagnosis. It was agreed that an opening should be made into the uterus for the evacuation of the fluid. This was done by the author, on October 5 (assisted by his friend, Mr. Thomas Harvey Trent), by passing the index finger of the right hand through the spot which could be detected by the touch as having been the site of the os uteri. Its withdrawal was instantly followed by the escape of ten or twelve ounces of a treacly fluid, of a dark claret colour, perfectly free from any unpleasant odour; and much more gradually flowed away. She was kept in bed, but became very ill on the third day, the symptoms resembling those of peritonitis. From this attack she appeared to recover, and went on tolerably well for some days; but on the morning of October 16, after a night of sickness, she became prostrated, and died at two p.m. No post-mortem inspection could be obtained.

Dr. TYLER SMITH thought the case must be considered either as one of pyæmia, abscess bursting into the peritoneum, or the passage of some of the retained menstrual fluid into the peritoneal cavity. The latter was the most probable, because it was an accident known to occur in such cases, and to produce similar symptoms to those which had been detailed. It was remarkable that, when the uterus was distended with the menstrual secretion, no escape through the tubes occurred; but this sometimes took place when the uterus was partially emptied, and a free exit had been obtained through the os. The regurgitation of fluid through the Fallopian tubes sometimes happened after labour, during abortion, and in some cases of menorrhagia. It was evident that the treatment of cases of retained menstruation required great care and circumspection.

Mr. OWEN thought that the cause of death might be attributed to the admission of air into the uterus in its relaxed and enlarged condition. After the gravid uterus is emptied of the fœtus and secundines, it immediately contracts to nearly its natural size; but here that reaction was not likely to follow, whilst the daily injection of water which had been employed exposed the organ afresh to contact with the air through the artificial opening, which latter presented no obstruction like that of the os and cervix uteri.

Dr. GRALY HEWITT remarked that the chief question to be determined was the cause of the fatal result in this interesting case. He considered that it was probably due, as suggested by Mr. Owen, to pyæmia. At the last meeting of the Society, he had alluded to the occasional circumstance of a fatal result following the evacuation of the uterine contents in cases of menstrual retention by subsequent passage of some of the blood into the peritoneal cavity. The explanation of this curious circumstance he had then attempted he still thought the most probable one, and that it was due to the contractions of the uterus becoming more forcible as its bulk diminished. However that might be, it did not seem that in the case now before the Society any such occurrence had taken place. He considered that the best course to adopt in treating such cases would be to make a minute opening, and to allow the fluid to escape as it had collected, gradually; further, that it was decidedly expedient to avoid anything, such as the use of injections of water into the uterus, likely to be the means of conveying air into the cavity of that organ.

Dr. MEADOWS exhibited a

CASE OF MONSTROSITY,

in which the two lower extremities were absent, and a caudal appendage about four inches long substituted; the body, gradually tapering off, ended in this pointed process; there were no external genital organs, and no anus. Dissection showed that the bowel ended abruptly at the sigmoid flexure of the colon. There were no kidneys or bladder, nor any trace whatever of any urinary apparatus. The supra-renal capsules were present, and were of large size, but there was very little proper structure in them, being chiefly two membranous sacs. An ovary and a somewhat convoluted Fallopian tube lay on either side of the pelvis, but there was no trace of a uterus or vagina. The liver, spleen, and other abdominal organs were normal, as were all the thoracic viscera.

Mr. SQUIRE noticed the absence of the kidneys as of more interest than the external deformity; that intra-uterine life and growth should go on to the degree here seen without those organs was very remarkable, especially as they are not inactive during the fetal state, as was shown by the occurrence of concretions of uric acid in the kidneys before birth; and he related the case of a still-born male child that he had the opportunity of examining, where the calyces and pelvis of the kidneys were filled with numerous uric-acid calculi, some of the size of small peas. The parents of the child were known to him; the father had been operated on for stone, and was then passing uric-acid calculi by the urethra. He was a continual sufferer from marked symptoms of the uric-acid diathesis.

Mr. OWEN, many years ago, delivered the wife of a respectable farmer in Essex of a well-formed female child, in which the os coccygis was prolonged into a caudal appendix about three or four inches in length, tapering off, and in every respect resembling the tail of an animal, being curled up on the back when at rest, and frequently moved in other directions. The mother attributed this growth to a strong impression made on her mind during pregnancy, for three or four months of which period she had fed a young pig, the beauty of whose tail she constantly admired. Mr. Owen, by the express desire of the mother, removed it by a ligature gradually tightened for a week. The child lived (but never walked without the aid of crutches) for nine years, when she died of hæmoptysis. The parents would not allow an examination. The tail, along with a minute description, was placed in the museum of Guy's Hospital by the late Mr. Bransby Cooper.

Dr. W. TILBURY FOX read a paper on

THE INFLUENCE OF THE MOTHER'S HEALTH IN THE PRODUCTION OF RICKETS.

The paper commenced with an analysis of the pathological changes in the rickety subject, from which it appears that the leading feature of the disease is simply a deficiency of lime-salt in the early nutrition of the child; and the object of the paper was to point out what appeared to be a tangible cause for such a deficiency—viz., the occurrence of menstruation during the greater period of lactation. A table of examples was given, as exhibiting the matter in its several details and aspects; and in most of the cases which came under the author's observation, it was noticed that, whenever mothers had freely and repeatedly menstruated during lactation, the child was rickety, unless the latter had been artificially fed with food (such as milk), and thus furnished with bone-forming material; and the degree of rickets appeared to be in direct ratio to the amount and degree (both as regards frequency and duration) of this condition, exceptional cases being accounted for in the fact of the mother not wholly suckling her infant. The *modus operandi* of the influence of menstruation upon the composition of the milk was discussed briefly; and, though little is known upon the matter, yet it appeared, on comparing together the analyses of Simon on the one hand, and Becquerel and Vernois on the other, that the percentage of salts is much lessened in nurses who menstruate during lactation, and hence, the child wholly fed upon the milk of the latter would probably become rachitic. The author thought it likely that rickets is produced in the majority of cases in this way. The paper then contained some remarks upon the use of certain kinds of food in very general use which conduced to the production or evolution of the disease—for example, Brown and Polson's, the Oswego, and the Maizena so-called corn-flours, these being oftentimes merely starch, contrasting them with such as the semola of Bullock and Reynolds, which was rich in gluten or flesh-forming sub-

stance; and attention was drawn to a new preparation, the saccharated wheat-phosphates, which might take the place of sugar in the food of children, especially those who are rickety. In conclusion, the author stated that he had introduced the subject as a provocative, rather than as a certainty of opinion.

Dr. GRAILY HEWITT believed that there was a very general impression amongst the Profession, and he thought also amongst the public at large, as to the inadvisability of allowing lactation and menstruation to go on in the same individual. The theory now propounded by Dr. Tilbury Fox would give an explanation as to the reasonableness of this impression. The subject was so novel that it would hardly be expected that the Fellows of the Society could properly discuss the paper so as to do it justice. Each must observe and collect facts on which to decide *pro* or *con*. in reference to the matter. He would ask Dr. Fox one question: How are those cases to be explained where children, the subjects of rickets, do often, after being apparently successfully treated, relapse long after any evil connected with lactation has ceased to be in operation? Such relapses were, he had observed, by no means uncommon.

Dr. GERVIS wished to ask the author of the paper how, on his theory, the occurrence of rickets in children wholly brought up by hand, or in children whose mothers did *not* menstruate during lactation, was to be explained? The fact also of the children of mothers who menstruate during lactation in many cases certainly not proving rickety, would appear to militate against Dr. Fox's view. Dr. Gervis was inclined to consider that the occurrence of menstruation during lactation was not, *par excellence*, the cause of rickets, though possibly influential in its production just so far as it proved injurious to the mother's health.

Dr. Fox, in reply, begged the Society to remember that the matter had been brought before them, not because the observations were conclusive, but for the purpose of courting inquiry. The mode of causation pointed out was not the *sole* one; for, as Dr. Graily Hewitt had observed, rickets might ensue after the weaning of the child. In this case the disease was due to, or the tendency to it worked out by, the use of foods deficient in certain constituents. So far, however, as his (Dr. Fox's) observation went, it appeared that most rickety children belonged to mothers who had menstruated during lactation; and if the paper should appear in print, the Fellows would find, in the list of cases, instances of rickets affecting one member only of a family, all the concomitants of the rearing of the children being the same, with the exception that the mother menstruated regularly and freely when nursing the rickety child, and then only. In reference to Dr. Druitt's remarks, it might be observed that the leading pathologists held that all that is necessary to the production of rickets is a deficiency of lime; and this conclusion seems inevitable if we glance at the intimate structure of the rickety bone, in which all the cellular components are fully developed, and in which the only unusual condition is an absence of calcareous matter. Dr. Gervis may possibly find in the exceptional cases mentioned by him, where children are not rickety, though nursed by mothers menstruating, that some such cause as artificial feeding explains the apparent contradiction. In reply to a question from the President, as to how rickets occurring during intra-uterine life could be accounted for, Dr. Fox remarked that the worst case he had met with was that of a child whose mother menstruated during pregnancy.

## MEDICAL NEWS.

### ARMY MEDICAL DEPARTMENT IN INDIA.

The following extracts are from a letter by an Assistant-Surgeon of the Indian army, published in the *Delhi Gazette* of November 25, 1862. They represent feelings of discontent, not confined to India, but common in the whole Medical department of the army, and which, we regret to add, are only too well founded:—

"It can be shown, that under the Royal Warrant of 1858, and the act of the annexation of India to the Imperial Government, we must look upon service in India as a loss and a hardship.

"In consequence of India coming under the Home Government, the valuable and acceptable allowance of head-money for the Medical charge of troops, landed in India, was stopped without giving the slightest equivalent.

"The stoppage of this allowance has indeed been a sad loss; and when to this deprivation we reflect on the improved rates of pay of Medical officers serving at home, service in India must be considered, especially by Assistant-Surgeons, unsatisfactory in the extreme.

"To be obliged to linger on on the pay of a subaltern (256 rupees), (minus company allowance, which most lieutenants of any standing draw), at the mature age of an Assistant-Surgeon of six years' service, and yet withal pay entrance and regimental subscriptions at the rate of pay of a higher relative rank, is, I conceive, an unbearable injustice, and one under which wretchedly paid Assistant-Surgeons have had to contend for the last three years without the slightest prospect of amendment.

"Allow me here to ask, who sits between the Government and the Pension List, on Invaliding Boards, Condemning Boards, and committees of all kinds, where honour, knowledge, and ability are of paramount importance to the Government? And yet the men who are called on to perform these, and a thousand other duties of even greater moment, are openly and continuously wronged, and their utmost efforts to gain redress are useless.

"The memorialists should state, that the Medical officers of her Majesty's army consider they are fairly entitled to increased pay, and to the pay of their relative rank, from the date of the grant of such increase to the Medical officers serving at home; from the date when the head money for the Medical charge of troops landed in India was discontinued, under the plea that we then came under the rules of home service; and from the date when we had entrance and regimental subscriptions charged according to the rates of pay of a warrant in all other ways ignored in India. The application for this pay will, I firmly believe, be honourably met. There is not a combatant officer, from the Himalayas to Cape Comorin, who will not freely admit that we are fairly entitled to this just remuneration. I have frequently heard the question discussed, and I think I am right in saying, that this honourable feeling is universal amongst the regimental officers serving in India.

"It would be well also to ask for a discontinuance of the gazettement of Assistant-Surgeons to regiments in India, as such merely entails on the Medical officer an expenditure of nearly £50 (for entrance fee, subscriptions, and uniform), for, on the regiment being ordered out of India, the third Assistant-Surgeon is, on being marched to the ship, which is to take home his regiment, hurriedly bid 'good-bye,' and directed to purchase a new uniform, and to join a new regiment.

"This treatment is not received by the other supernumerary officers of the regiment, all of whom are fairly carried home.

"It is said, that the Medical officer receives this treatment, because his services cannot be dispensed with; if, then, he is so valuable, why mulct him of £50 for having served with a regiment for a short period?

"It is for such reasons, as this indicates, that the circumstances of Assistant-Surgeons are indeed slender. Most officers are glad to see their names in the *Gazette*, as it brings promotion, without loss of regiment, uniform, or entrance fee; not so with the Medical officer, who loses all, even without promotion.

"One of the effects of the painfully manifest apathy on the part of the Indian Government towards acting justly by its Medical officers, is the distrust with which Royal Warrants, although published under the sacred name of Majesty, are now viewed by the students of the Medical Schools of the United Kingdom—a distrust which will tell sadly on the army when in urgent need of a supply of Medical officers.

"This want will, on the outbreak of a war, be still more trying and evident, in consequence of the reduced number of Assistant-Surgeons now with regiments out of India. Should the Government not be wise in time, this crisis will, I doubt not, be taken advantage of (as in the Crimea) to represent the many acts of injustice under which we serve, with the view to their redress."

UNIVERSITY OF ST. ANDREWS.—List of gentlemen on whom the Degree of Doctor of Medicine was conferred on December 20th, 24th, and 31st, 1862:—

Joseph Dixon Adams, M.R.C.S., L.S.A., Martock, Somerset; Patrick M. Allan, L.R.C.S. Ed., Arbroath; Henry George Allanson, M.R.C.S., L.S.A., Sheffield; John Anderson, M.R.C.S., L.A.C., Grantham; George A. Angier, M.R.C.S., L.S.A., Ipswich; George Morris Ashforth, M.R.C.S., L.S.A., Westmill, Herts; Charles Owen Aspray, L.S.A., London; Thomas John Aubin, M.R.C.S., St. Clement's, Jersey; Mackenzie Bacon, M.R.C.S.

L.S.A., Norfolk; John J. Ball, Dublin; William W. Ballard, M.R.C.S., L.A.C., Tunbridge; Richard Bangay, M.R.C.S., Corbridge; Alfred J. H. Banks, M.R.C.S., L.A.C., Stafford; Edward R. Barker, M.R.C.S., Denbigh; Thomas H. Barnes, M.R.C.S., L.M., Clare, Suffolk; Barnabas Barrétt, M.R.C.S., L.A.C., Liverpool; John T. Barrie, L.F.P.S. Glasg., Newarthill, Lanark; Thomas Samuel Barrow, London; Joseph Barwise, L.A.C., Wigan, Lancashire; Abraham Bate, L.R.C.S.I., L.M., Donegal, Ireland; Henry Beattie, M.R.C.S., L.A.C., Waltham Abbey; Walter Thomas Beeby, London; Joseph S. Belcher, M.R.C.S., L.A.C., London; James Edward Bennet, M.R.C.S., L.S.A., London; Henry Benson, L.R.C.S.I., Dublin; Charles Bevis, London; Charles Henry Biddle, M.R.C.S., L.S.A., Leeds; Rowland Blennerhassett, L.R.C.S.I., L.R.C.P.E., Co. Kerry, Ireland; William Bloxam, M.R.C.S., L.S.A., London; Andrew Bolton, M.R.C.S., L.S.A., Newcastle-on-Tyne; Lionel Booth, M.R.C.S., L.S.A., Greenwich; Samuel Booth, M.R.C.S., L.S.A., Huddersfield; Josiah A. Bowen, L.F.P.S. Glasg., Bretherton, Lancashire; William Philip Brabazon, L.R.C.S.I., L.K.Q.C.P., Liverpool; William S. Bramley, M.R.C.S., L.A.C., St. John, Wakefield; J. Brecknell, M.R.C.S., L.S.A., Durham; John M. Bright, M.R.C.S., L.A.C., Forest-hill, Kent; Augustus Brown, M.R.C.S., L.A.C., Islington; John R. Brumwell, M.R.C.S., L.A.C., Burnley; William Henry Fleetwood Puckle, L.S.A., Royal Mint; Ebenezer Bucknill, M.R.C.S., L.S.A., London; Edward C. Bury, M.R.C.S., L.A.C., Wisbeach; Robert Lyons Campbell, F.R.C.S. Lond., L.R.C.P. Lond., Inverness; John Candy, M.R.C.S., L.A.C., Alstonefield, near Ashbourne; John Cannell, Peel, Isle of Man; George L. Carrick, Edinburgh; J. F. Chittenden, M.R.C.S., L.S.A., London; A. G. Clarke, Calcutta; James Cleghorn, Caithness; William Cooper, M.R.C.S., L.R.C.P. Ed., L.S.A., Bury St. Edmunds; David Dunlop Costine, Liverpool; Henry Joseph Coulton, L.R.C.S.I., L.M., Dublin; Robert Cowan, L.F.P.S. Glasg., Glasgow; Thomas Creed, M.R.C.S., L.A.C., Greenwich; Nathaniel E. Cresswell, M.R.C.S., L.A.C., Canterbury; Samuel Crompton, M.R.C.S., L.A.C., Manchester; William Cross, Liverpool; William G. Curgiven, Plymouth; George C. Dale, F.R.C.S. Eng., L.S.A., London; Robert Alexander Davis, L.R.C.P. Ed., L.S.A., Stafford; David Davies, M.R.C.S., L.A.C., London; Horace Day, M.R.C.S., H.M. Bombay Army; James Bathgate Dickinson, M.R.C.S., L.S.A., Howden-on-Tyne; Patrick William Dillon, M.R.C.S., L.S.A., Ennis, Ireland; Ebenezer Diver, London; George Douglas, M.R.C.S., L.A.C., Gateshead-on-Tyne; William B. Dow, L.R.C.P. Ed., L.F.P.S. Glasg., Fife-shire; Thomas Downie, L.R.C.P. Ed., L.F.P.S. Glasg., Blantyre; Edward Dowson, M.R.C.S., London; William Dunderdale, M.R.C.S., L.S.A., L.M., Boulton-le-Fylde, Lancashire; John Edwards, M.R.C.S., Birmingham; Daniel Elias, L.S.A., Southport, Lancashire; John Ellerton, M.R.C.S., L.S.A., Wakefield, Yorkshire; George Stokoe Elliot, Southwell, Notts; William Alfred Ellison, M.R.C.S., L.S.A., London; William Erskine, L.F.P.S. Glasg., Dunfermline; Charles Eves, M.R.C.S., L.A.C., London; James Ewing, L.R.C.P. Ed., L.F.P.S. Glasg., New Lanark; Henry R. Fawcus, M.R.C.S., L.A.C., S. Charlton, Northumberland; Richard Fegan, L.R.C.S.I., L.K.Q.C.P., Belfast; Alex. J. Ferguson, L.F.P.S. Glasg., Perth; John Ferguson, M.R.C.S., Cove Nigg; Edward Fernie, M.R.C.S., L.A.C., Macclesfield; Charles E. Fitzgerald, M.R.C.S., Folkestone; Charles Newth Foote, M.R.C.S., L.S.A., Conisbro', Doncaster; James Ford, M.R.C.S., Barnstaple; John Frame, L.F.P.S. Glasg., Glasgow; John D. Frankish, Guy's Hospital; John Fulham, L.R.C.S.I., L.A.C., Drogheda; Charles Furner, M.R.C.S., L.A.C., Brighton; Frederic George, M.R.C.S., Cotterham, Surrey; Hugh George, M.R.C.S., L.A.C., Revesby, Lincolnshire; John Gimblett, M.R.C.S., L.S.A., Lydney, Gloucester; William Gimson, M.R.C.S., L.S.A., Witham, Essex; Richard W. Goddard, M.R.C.S., L.A.C., London; Samuel Day D. Goss, L.R.C.S. Ed., L.S.A., London; James H. Gramshaw, M.R.C.S., L.A.C., Gravesend; Adolphus Burnell Great Rex, L.S.A., Eccleshell; Michael Greene, L.R.C.S. Ed., L.A.C., Ennis, Co. Clare; Alexander Greenlees, L.R.C.S. Ed., Glasgow; Alfred Leete Griffith, M.R.C.S., L.S.A., L.M., Swindon; Griffith H. Griffith, M.R.C.S., L.A.C., L.R.C.P. Ed. by Exam., Folkestone, Kent; James Griffith, M.R.C.S., L.A.C., Smarden, Kent; Francis P. Griffiths, M.R.C.S., L.A.C., Sheffield; Owen Grimby, L.S.A., Banbury, Oxon; John Grove, M.R.C.S., L.A.C., London; William R. Grove, M.R.C.S., L.S.A., Huntingdon; Samuel T. Gwynn, M.R.C.S., L.A.C., Whitechurch, Salop; Charles Fincham Harding, M.R.C.S., Woolwich; Abraham Harris, L.R.C.P. Ed. by Exam., M.R.C.S., L.A.C., Camborne, Cornwall; Walter Harris, M.R.C.S., London; Arthur Robert Harrison, M.R.C.S., L.S.A., London; Henry Mortimer Hawkins, M.R.C.S., Peckham, Surrey; George Hayward, M.R.C.S., L.S.A., Leeds; Sidney Hayward, M.R.C.S., L.S.A., London; Edward Heath, M.R.C.S., Arklow, Ireland; Frederic Hetley, F.R.C.S. Eng., L.S.A., Norwood, Surrey; Edward Hibbert, M.R.C.S., L.M., Tunbridge Wells; Charles C. Hicks, M.R.C.S., L.S.A., Dunstable; John Daniel Hill, M.R.C.S., L.S.A., Market Harborough, Leicestershire; Alexander Hillyard, L.R.C.S.I., L.M., L.S.A., Falcarragh, Ireland; Caleb S. Hilton, L.S.A., Preston; Edward Rodolphus Hodgkinson, L.A.C., Umballoch, India; Richard Holt, London; Abney C. Hopton, M.R.C.S., London; Edward Arthur Howsin, M.R.C.S., Newmark; Ebenezer Hughes, L.F.P.S. Glasg., Liverpool; James D. Hulme, M.R.C.S., L.A.C., Wigton; Henry Hume, M.R.C.S., L.S.A., London; William Hutchinson, L.F.P.S. Glasg., Loughborough; Francis Henry Wilson Iles, M.R.C.S., L.S.A., Watford, Herts; George R. Irvine, M.R.C.S., L.S.A., Portsmouth; John W. Irvine, L.R.C.S. Ed., L.A.C., Lancaster; Felix William Isherwood, L.R.C.P. Ed., M.R.C.S., L.S.A., Hayes, Middlesex; Robert Jackson, Newcastle; Thomas Jackson, M.R.C.S., L.A.C., Scarborough; Alfred James, M.R.C.S., L.A.C., Forest Hill, Kent; James M. Johnson, L.F.P.S. Glasg., Liverpool; Thomas M. Johnson, L.S.A., Salford, Lancashire; John E. Jones, M.R.C.S., L.A.C., Dolgelly, N. Wales; Edward A. Keogh, Dublin; Charles Noyce Kernot, M.R.C.S., L.S.A., L.M., Cowes, Isle of Wight; Benjamin C. Kerr, L.R.C.S., H.M. Service; Thomas William King, M.R.C.S., London; William O. Lambert, L.F.P.S. Glasg., L.R.C.P. Lond., Sunderland; John William Lane, L.R.C.S.I., Bellaghy, Ireland; Jeremiah Lawlor, L.F.P.S. Glasg., Queenstown; Matthew Lee, M.R.C.S., Bradford; Joseph Less, L.A.C., London; John Levey, M.R.C.S. Ed., L.M.; Edwin Lloyd, M.R.C.S., L.A.C., Worksop, Notts; William Loftus, L.R.C.S., Glasgow; Charles F. Long, M.R.C.S., L.S.A., Barham, Kent; Arthur E. T. Longhurst, M.R.C.S., L.S.A., Royal Navy; Christopher C. Lynn, M.R.C.S., Newcastle-on-Tyne; James Maebirnie, L.F.P.S. Glasg., Glasgow; George V. Macdonogh, L.R.C.S.I., Sunderland; John Macgown, L.F.P.S. Glasg., Millport; Duncan Macintyre, L.R.C.S. Ed., Fort William; J. William Mackenna, L.F.P.S. Glasg., London; William J. Mackenzie, M.R.C.S., L.R.C.P., Greenwich; Christopher J. Madden, L.R.C.S. Irel., Bourton-on-Water; Martin Magill, M.R.C.S., Royal Navy; John M. Marshall, L.R.C.S. Ed., Edinburgh; Thomas E. Mason; Donald Ptolemy Masson, M.A., Edinburgh; William Matterson, M.R.C.S., L.S.A., York; James Blake Maurice, M.R.C.S., L.S.A., London; Hustor Maxwell M.R.C.S.I., H.M.S. *Pembroke*; John

Mayer, M.R.C.S., L.A.C., Macclesfield; George Mayou, M.R.C.S., L.A.C., Newport, Monmouthshire; Albert M'Diarmid, M.R.C.S., L.A.C., Rochester, Kent; Aaron George Medwin, L.S.A., London; Charles Matthias Meller, M.R.C.S., L.S.A., London; Edwin J. Miles, M.R.C.S., L.A.C., Gillingham, Dorset; Thomas Mills, M.R.C.S., Tipton, Staffordshire; William P. Mills, M.R.C.S., L.A.C., L.R.C.P. Lond., Ipswich; John Miller, L.F.P.S. Glasg., Glasgow; John R. Milsome, M.R.C.S., L.S.A., London; Robert Nathaniel Mitchell, M.R.C.S., L.S.A., New-cross, Kent; Arthur M'Kenna, L.R.C.S. Ed., H.M.S. *Hogue*; Hugh M'Lean, M.R.C.S., L.S.A., Newcastle; William Henry Moor, M.R.C.S., L.S.A., Buntington, Herts; Edwin Moore, M.R.C.S., L.S.A., Preston; Francis Moore, M.R.C.S., L.S.A., Hadham; Edward S. Morley, M.R.C.S., L.S.A., Blackburn; Peter Morrison, L.F.P.S. Glasg., Glasgow; Edward L. Moss, L.R.C.S.I., L.M., Dublin; Patrick Mulholland, L.F.P.S. Glasg., Glasgow; William L. Mumford, M.R.C.S., L.S.A., Cornard Parva, Suffolk; William Murdoch, M.R.C.S., London; Henry A. Murray, L.A.C., Evenwood, Durham; John C. Murray, L.R.C.S., Gateshead; James Neal, M.R.C.S., L.S.A., Birmingham; Frederick Needham, M.R.C.S., L.M., York; George M. Nell, M.R.C.S., L.M.; George D. Nelson, M.R.C.S., L.A.C., Bridlington Quay; George Edward Nicholas, M.R.C.S., L.S.A., L.M., Wandsworth, Surrey; Robert Thomas Nichols, L.S.A., Rotherhithe, London; Robert Salisbury Nightingall, M.R.C.S., L.S.A., London; George William Noad, M.R.C.S., L.S.A., Wokingham, Berks; Richard Norris, M.R.C.S., Birmingham; William Augustus Norton, M.R.C.S., Alderton, Suffolk; Elisha Noyce, L.S.A., London; Frederic O'Connor, L.F.P.S. Glasg., Dublin; Henry O'Flanagan, L.R.C.S., Miltoun, Ireland; Edmund O'Ryan, L.S.A., L.M., Clonakilty, Ireland; John Owen, M.R.C.S., L.A.C., Bromyard, Hereford; Henry Owens, M.R.C.S., Croydon; James Alden Owles, M.R.C.S. Eng., L.S.A., Bungay, Suffolk; Robert Paterson, L.F.P.S. Glasg., Galston, Ayrshire; Joseph Chadwick Peatson, M.R.C.S., L.F.P.S. Glasg., Manchester; Charles Howell Phillips, M.R.C.S., L.S.A., London; John Piethall, L.R.C.P. Lond., L.R.C.S., Bengal Medical Service; A. Bradford Pierpoint, M.R.C.S., L.S.A., London; Alexander Pole, M.R.C.S., L.M., Greentank, Shetland; Robert Popham, L.F.P.S. Glasg., London; John Lewis Pritchard, London; John Prythreth, M.R.C.S., L.S.A., Liverpool; Thomas Pullin, M.R.C.S., L.A.C., Sidmouth, Devon; Joseph Meredith Ramsbotham, M.R.C.S., L.S.A., London; Robert Ransom, F.R.C.S., L.A.C., L.M., Cambridge; Wynne staton Ranson, Edinburgh; William P. Rawlins, M.R.C.S., L.A.C., Kentish town; Edward Ray, F.R.C.S. Eng., L.S.A., Dalwich; Edward Reekitt, M.R.C.S., L.S.A., Wainfleet; George Reed, M.R.C.S., L.A.C., London; Samuel C. Reed, L.R.C.P. Ed., M.R.C.S., L.A.C., London; James B. Reid, L.F.P.S. Glasg., Ayrshire; Thomas Remington, L.S.A., Brixton, Surrey; Robert Renfrew, L.F.P.S. Glasg., Glasgow; Charles Rhodes, M.R.C.S., L.S.A., London; William Rice, L.R.C.P.E., L.F.P.S. Glasg., Glasgow; Henry Ebenezer Richards, L.S.A., London; C. S. Richardson, M.R.C.S., L.S.A., London; J. Ring, L.A.C., 1st Ex. M.D., Kettering, Northamptonshire; W. Ritchie, London; A. Tucker Roberts, M.R.C.S., London; John Roberts, M.R.C.S., L.A.C., Talarron, North Wales; John S. Roberts, L.R.C.P. Ed., M.R.C.S., L.S.A., Sheffield; Charles S. Robinson, M.R.C.S., L.S.A., L.R.C.P. Ed., London; Edmund Robinson, M.R.C.S., L.A.C., Birmingham; John Roche, M.R.C.S., L.S.A., Fermoy, Ireland; John Roland, M.R.C.S., L.S.A., Strata Florida, Wales; Alfred Rudyard, Macclesfield, Cheshire; John L. Rushton, M.R.C.S., Macclesfield; Arthur Samuels, M.R.C.S., L.A.C., Liverpool; Follitt J. Young, M.R.C.S., L.A.C., Bath.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise on Thursday, January 1, 1863.

George Pearse Sargent, Albany-road, Walworth; Edmund Pope, Eastern Dispensary; Thomas Churton, Pool, near Otley.

The following gentleman also on the same day passed his First Examination :—

Henry Stubbs, General Hospital, Birmingham.

#### APPOINTMENTS.

BORTHWICK, ALEXANDER, M.D. Edin., has been appointed Consulting Physician to the Crichton Royal Institute.

DICKSON, JOHN, M.D. Edin., has been appointed Physician to the Dumfries and Galloway Royal Infirmary.

USSHER, HENRY, M.B., has been appointed Medical Officer to the Dispensary, Wandsworth.

#### DEATHS.

BRAUN, DR. CARL, at Wiesbaden, on December 9.

BUCHANAN, GEORGE ADAM, M. and L.S.A. Lond., at 6, Northampton-park, Islington, on January 1, aged 61.

CADENHEAD, JOHN, A.M. and M.D. Aberd., at Union-street, Aberdeen, on December 30, aged 64.

COOPER, JAMES, M.R.C.S. Eng., at St. Anne-street, Liverpool, on January 6, aged 60.

JONES, THOMAS, at Fartherwell-house, near Town Mallings, Kent, on January 4, aged 94.

**GRATITUDE.**—Dr. Hildige, of Dublin, has just received an elaborately-chased silver salver, bearing a suitable inscription, from a lady on whom he performed the operation of iridectomy. Would that the same mind were in all patients.

**TWELFTH NIGHT AT THE PHOTOGRAPHIC SOCIETY.**—Mr. S. Highley, on Tuesday, the 6th inst., read a paper before this Society in the theatre of King's College. The subject was—"Photography in its Application to the Magic-lantern Educationally Considered" (with illustrations).

**ANATOMY USEFUL.**—Antiquaries are disputing as to the identity of a body which in the year 1828 was exhumed under the belief that it had belonged to John Hampden. According to one account the said body was that of a man; according to another, that of a woman. One party believed that some small bones found were all that remained of the shattered hand of Hampden, who is said to have died of lockjaw consequent on his hand having been severely wounded by the explosion of his pistol. The supporters of the female theory, on the other hand, came to the conclusion that the bones were those of an infant which had died *durante partu*.

**INFANTICIDE.**—In the course of some observations with reference to the death of two infants, Dr. Lankester, the coroner for Central Middlesex, stated, on Saturday last, that either the crime of infanticide was on the decrease in the metropolis, or more artful means were being taken to hide the bodies of newly-born infants. Of the first 72 inquests held by him after his appointment, no less than 12 were inquiries into the circumstances under which deserted infants had come by their death. He called public attention to that state of things, and his remarks were made known by the press. Of the next 72 cases that came before him, 6 were of the class to which he had just referred; of the following 72 only 4 were of that description; and since then he had held 250 inquests, only 6 or 8 of which were in cases of infanticide. Unfortunately, such cases were still numerous, but he thought there was a marked decrease in their number, and that to the press we might attribute the improvement.

**ANTHROPOLOGY IN ENGLAND.**—We learn that several of our best ethnologists and anthropologists, actuated by the feeling that the science which professes to treat of man, his antiquity, the physical diversities between his different races,

the natural laws which regulate his distribution over the earth, and the corporeal characters which differentiate him from the inferior animals, has not received in England that attention which its importance deserves, have determined to found a new society, to be entitled "The Anthropological Society of London," in which the modern phases of ethnology and anthropology will be discussed. The promises of support which the new society is receiving from all shades of ethnological party appear to be certain guarantees of its success. At a meeting on Tuesday last, the officers of the new society were elected, consisting of—*President*, Dr. Hunt; *Vice-President*, Captain Burton; *Hon. Secretary*, C. Carter Blake, Esq.; *Hon. Foreign Secretary*, E. Tylor, Esq.; *Council*, A. C. Blackstone, W. Bollaert, Luke Burke, Dr. Gibb, A. Higgins, Dr. Hughlings Jackson, S. J. Mackie, R. S. Poole, T. S. Prideaux, W. S. W. Vaux, and others. It was also agreed that the rules should be formed on the plan of the Geological Society. Due notice will be given of the first public meeting of the members.

**THE SUSPECTED POISONING AT LUDWELL.**—In an able letter, by Dr. W. Bird Herapath, to the *Salisbury and Winchester Journal*, he announces the fact, that he has just discovered the arsenic in the urine of a patient in the Bristol Royal Infirmary, who has been under treatment with about eighteen grains of the impure tris-nitrate of bismuth daily during the past fortnight. He remarks, in reference to the arsenic he discovered in the viscera of Mrs. Kiddle:—"Now, I do not for one moment wish to assert that Mrs. Trowbridge or any one else knowingly gave arsenic to our patient; there are abundant sources whence she might have obtained small but constant portions of such a poisonous body quite unconsciously to all around her—even the jelly she was fed upon might have contained it. I have found arsenical impurities in some specimens of jelly sold by excellent manufacturers. The gelatine of commerce also contains arsenic occasionally, and the source of the arsenic in these cases was presumed to be muriatic acid, employed to purify the clippings of cow and other hides obtained from the tanners of leather, and which, being saturated with lime, require purification with an acid to fit them for conversion into gelatine or jelly by the wholesale confectioner or other manufacturer of these articles for the nourishment of invalids. People do not know what they eat or what they drink. Other cases have been known in which the paint on the shelves on which a baker had placed his hot loaves of bread was the source of arsenic discovered by some toxicologist."

**ABSTRACT OF THE REPORT OF THE PATHOLOGICAL SOCIETY.** read January 6, 1863.—The Council of the Pathological Society, in furnishing the Seventeenth Annual Report of its proceedings, has the gratification to announce, that its career continues to be marked by unabated prosperity. Notwithstanding circumstances, the influence of which has tended, in some degree, to limit the rapid rate of progress which the Society has maintained ever since its origin in 1846, its numerical strength has never been greater than at the present time. Furthermore, its vigour has in no respect diminished; the interest of the meetings has, if possible, rather increased than otherwise; and the supply of valuable preparations, not only from our own country, but from abroad, has never been at any previous period surpassed. The financial statement exhibits a balance in the hands of the treasurer of £180. A portion of this will be added, according to the usual custom, to the Society's funded property, which now amounts to £129 6s. 7d. The following are the Officers and Council of the Pathological Society of London, elected for the year 1863. The gentlemen whose names are marked with an asterisk (\*) did not hold the same office during the preceding year:—*President*.—\* Prescott G. Hewett, Esq. *Vice-Presidents*.—William Jenner, M.D.; Sir John Liddell, M.D., C.B., F.R.S.; \* A. B. Garrod, M.D., F.R.S.; \* Geo Johnson, M.D.; Wm. Coulson, Esq.; \* John E. Erichsen, Esq.; \* John Hilton, Esq.; \* Geo. D. Pollock, Esq. *Treasurer*.—Richard Quain, M.D. *Council*.—Thomas A. Barker, M.D.; George Budd, M.D., F.R.S.; Andrew Clark, M.D.; William D. Chowne, M.D.; George Harley, M.D.; \* Stephen J. Goodfellow, M.D.; John W. Ogle, M.D.; James E. Pollock, M.D.; \* George D. Gibb, M.D.; Richard Barwell, Esq.; Bernard E. Brodhurst, Esq.; W. White Cooper, Esq.; William H. Flower, Esq.; J. Gregory Forbes, Esq.; Timothy Holmes, Esq.; John Pyle, Esq.; Samuel J. A. Salter, Esq.; \* Thomas Bryant, Esq.; \* John Whitaker Hulke, Esq.; \* Edward Ray, Esq. *Honorary Secretaries*.—J. S. Bristowe, M.D.; Henry Thompson, Esq.

**IRISH MEDICAL ASSOCIATION.**—A meeting of the members of this association was held on Tuesday night, in the dining-room, at the Limerick Junction Station, for the purpose of taking into consideration the provisions of the proposed bill for the Registration of Births and Deaths, and also to consider certain necessary amendments in the Medical Charities Act, with a view to obtaining a higher rate of salary, and also a retiring allowance, for Medical men employed under that Act and in connection with the Poor-law system. The chair was taken by Dr. Jacob, the President of the Association. Amongst those present were—Dr. Jacob, Maryborough; Dr. Mackesy, Waterford, President of College of Surgeons; Dr. Quinan, Dublin; Dr. Harvey, Cork; Dr. Bradshaw, Bansha; Dr. Armstrong, Cork; Dr. Martin, Portlaw; Dr. Bennett, Bruff; Dr. O'Brien, Ennis; Dr. Russell, Thurles; Dr. A. H. Jacob, Dublin; Dr. Brodie, Limerick; Dr. Darby, Bray; Dr. Kennedy, Thurles; Dr. Ffolliott, Askeaton; Dr. Ryan, Pallas; Dr. Hanley, Thurles; Dr. Morrissy, Tipperary; Dr. Hewett, Tipperary; Dr. Power, Cappawhite; Dr. Clarke, Mountrath; Dr. Elliott, Waterford; Dr. Stokes, Cahir; Dr. Callaghan, Cork; Dr. Reardon, Bruff; Dr. Mullaly, Templemore; Dr. Sullivan; Dr. Wycherly, Cork; and Dr. Fitzgibbon, Clonmel. After dinner, Dr. Quinan having been appointed secretary to the meeting, the chairman briefly addressed the meeting in reference to the subjects which were to be brought before them that night. With respect to the registration of births and deaths, he contended that no men could supply the necessary statistics except the members of the Medical Profession, and he expressed his regret that a measure was about to be introduced into Parliament which would not only deprive Medical men of their rights, but prevent the public from obtaining the information that was required. The bill provided that the constabulary should be employed, under the Registrar-General, as collectors and registrars of the statistics of births and deaths; and if that clause became law the necessary result would be, that members of the Medical Profession, who, from their education, the position they held, and the duties which they performed, were the only persons who could supply the required statistics, would be debarred from holding situations which seemed of right to belong to their Profession. But, in selecting the constabulary, the very worst body of men who could be entrusted with such important duties had been deliberately chosen. Already the constabulary had enough to do, and did not always perform their work satisfactorily. And yet now it was actually proposed to add to their manifold occupations another and most difficult one, that of collectors of statistics. (Hear, hear.) He had no intention of saying anything disrespectful of the police, but he was there to maintain and prove that they were quite unfit to discharge the new and onerous duties which would be imposed upon them, should the clause he complained of become law. He hoped that Medical men would set their faces against the measure, and do what they could, in a constitutional and legal manner, to prevent its becoming the law of the land. It was their duty to do so, not only for their own interest, but for the interest of the people of Ireland. (Hear, hear.) Dangerous results might be expected if the Government persisted in putting the constabulary into a position for which they were altogether unqualified; but he hoped that, if fair and straightforward opposition were offered by the members of the Profession, no government would be found to persist against such opposition. In conclusion, the chairman briefly referred to the other points to be considered by the meeting—namely, certain deficiencies in the Medical Charities Act, and in the law respecting vaccination, which required attention, and which should be brought under the consideration of the legislature. In the course of the evening, resolutions were passed advocating the employment of Medical Practitioners as registrars of births and deaths; that the minimum salary of dispensary Medical Officers should be £100 per annum; and that it was just and equitable that dispensary Medical Officers should be provided with retiring allowances.

### METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer .. .. .	29.607 in.
Mean temperature .. .. .	43.8
Highest point of thermometer .. .. .	52.3
Lowest point of thermometer .. .. .	33.5
Mean dew-point temperature .. .. .	40.6
General direction of wind .. .. .	S.W.
Whole amount of rain in the week .. .. .	0.57 in.

### NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

*Dr. W. T. Martin.*—Hansard's, Great Turnstile, Holborn.

*Tyro.*—1. We believe the lectures are preparing for publication. 2. The Brompton and Victoria Park Hospitals.

*Respirators.*—Consult Dr. Richardson on the "Hygienic Treatment of Pulmonary Consumption," p. 18.

*Medical Vacancy.*—The office of House-Surgeon to the Lock Hospital, Dean-street, Soho, will shortly be vacant.

*Arminius.*—Poor-law Medical Officers must have a double qualification. We believe that the Membership of the College of Surgeons alone is not sufficient.

*R. C. B.*—A paper, on the "Concurrence of Measles and Scarlatina," was read by Mr. W. B. Kesteven, at the Epidemiological Society, and was published in the *Journal of Public Health*, October, 1856. An abstract also appeared in the *Association Journal*, December 13, 1856.

*Rupture of the Liver.*—Bradford. — We remember a paper by Mr. Prescott Hewett on "Rupture of the Liver by Violence," though we cannot lay our hands on it at a minute's notice. Mr. Prescott Hewett showed, if we recollect rightly, that patients may survive such injuries if quiet and other rational means be adopted to prevent inflammation and hæmorrhage. Hence, it is quite possible that the liver may have been ruptured by a kick on Saturday, and yet that no fatal symptom may have set in, till a state of great excitement ensued on the following Wednesday.

*Jugged Hare.*—The following is another instance showing how our Profession is exposed to ridicule through the exaggerations of chemists and sanitarians, who argue *à priori*, forgetting that, in all that pertains to human life, experience is the only safe guide. It is said that Dr. Hill, the food analyst for Birmingham, summoned a game dealer before the magistrates, on the ground that he had in his shop hares which were putrid and unfit for food, and which were, therefore, condemned and ordered to be destroyed. When the defendant came before the bench, fourteen days afterwards, the Doctor is said to have deposed that "all meat that had undergone any process of decomposition was very unwholesome and poisonous; he did not think fire destroyed the poison of decomposition, nor hid the taste of it." At this point, we are told, a professional cook was called in, who produced a saucepan boiling hot, filled with jugged hare, and requested Dr. Hill to taste whether it was good. Dr. Hill did so, and replied, "It appears to me very good, but rather highly seasoned. I should not object to eat it myself." Great was the laughter when it was shown that this was one of the hares which had been pronounced by this eminent chemist as unfit for food fourteen days previously. The reporters, attorneys, witnesses, and spectators hereupon adjourned to lunch off the hare, which was placed at their disposal; and, on the resumption of business, Professor W. Sands Cox, of Queen's College, deposed solemnly that "hare is not good to eat till it does smell; fire destroys the smell; hung game is wholesome." *Solvuntur risu tabule.* The magistrate evidently repented in his soul that he had ordered the other hares to be destroyed. Every rational stomach will feel that things are coming to an alarming pass, when a dish of jugged hare shall come under the ban of the pseudo-sanitarian.

*Alleged Ill-consequences of "Diseased Meat."*—There are few periodicals which we usually take up with greater satisfaction than the *Edinburgh Veterinary Review*, and we can only regret that the Editor departs, for once, from the manly, common-sense method in which scientific matters should be treated. We, for our own part, not only have never sanctioned, but most unequivocally condemn, the use of the flesh of diseased, or self-dying animals. It is an indecency, and a thing which, if permitted, would be a most dangerous precedent. Yet that does not prevent us, as scientific men, from scrutinising the facts calmly. We have, in former Numbers, specified the cases in which the ill-effects of diseased meat are clearly proved, and those in which the ill-effects are merely matters of inference or probability. As for flesh infected with parasites, that case is notorious, and beyond doubt. Secondly, there are the cases of animals in which disease has created effusions, tending, as all morbid effusions do, to putrescence, such as abscess, empyema, etc. etc., or in which disease has advanced so far as to produce wetness. Thirdly, there are some specific diseases, such as malignant pustule, and the foot and mouth disease. We believe the milk of animals affected with the latter to be unquestionably poisonous. Fourthly, there are meat sausages, etc., in certain states of decay. It must be borne in mind, moreover, that the poisonous properties—say of milk—are not disproved because a great many people escape, for it is possible that some systems resist some poisons. But, when we have allowed for all these cases, there comes to be balanced in the scientific mind this startling anomaly:—on the one side there are many acute and able men, of whom Professor Gamgee is one of the chief, tracing out cattle disease to its causes, and impressing us with its enormous prevalence. He counted, lately, in the Dublin slaughter-houses, "scores" and "dozens" of animals slaughtered whilst labouring under pleuro-pneumonia. We must accept it as a fact from Professor Gamgee, that the flesh of pleuro-pneumonic beasts is largely used as food. We have learned the same from other sources ourselves; and we believe it to be

the fact, that most shrewd cattle-owners, the moment they observe traces of the disease, send the patient to the butcher. So far, then, we agree. But now for the other side of the question—where are the ill effects? In order to learn these, we must go—not to cattle breeders, nor to sanitary officers, nor “sensation” chemists, who tickle the public ear, but to Medical Practitioners and families. Who are the most likely purchasers of indifferent meat, such as we presume the flesh of pleuro-pneumonic beasts to be? The mistresses of boarding schools, the contractors for workhouses, gaols, and charitable institutions; the masters of shops who keep large numbers of epicene counter-skippers, and milliners’ girls; the tradesmen who advertise for two apprentices, and say they shall be treated like one of the family. We want to know, then, from the Medical Practitioner—have any symptoms yet been traced to the use of pleuro-pneumonic meat? Are the young people at large shops ever seized with any peculiar symptoms after their dinner of uncooked and bloody meat? What are the facts, facts, facts, Mr. Professor? What are the diseases that people contract? You must be consistent. You prove so much on one side of the case, that we look for better evidence on the other.

The following is a corrected list of the late Dr. Knox’s published works;—

- Béclard’s General Anatomy.
- Cloquet’s Anatomy.
- Manual of Human Anatomy.
- Translation of Milne-Edwards’ Zoology.
- Knox’s Artistic Anatomy.
- Fau’s Anatomy for Artists.
- Anatomist’s Instructor.
- Engraving of the Arteries after Tiedemanu.
- “ “ Bones after Sue and Albinus
- “ “ Ligaments after Caldani.
- “ “ Muscles after Cloquet.
- “ “ Nerves after Scarpa.
- Man: his Structure and Physiology Popularly Explained and Demonstrated.
- The Races of Men.

*Errata.*—In the remarks appended by Dr. Ramsbotham to the last collection of cases published in this journal, for “Douglas and Denman thought,” read “Denman thought.” Dr. Douglas was the first to refute Denman’s description of the process of the “Spontaneous Evolution.”—Page 689 of our last volume, in the Rev. W. Graham’s letter on the discussion as to the invention of Butcher’s saw, for “bone saw,” read “bow saw.”

A CORRECTION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the Index of your last number, December 27, I find, under the name of Dr. T. B. Moriarty, of Limerick, “On the Organisation of Medicine at Rome, 74.” Although a matter of little importance, still I beg to inform you of the mistake, as the observations alluded to on Medicine at Rome are mine, and dated from Dieppe.

I am, &c. STEPHEN S. MORIARTY, M.D.

Dieppe, Faubourg de la Barr, January 1.

DRS. FOWLER AND MAYNE—THE CHARGE OF PLAGIARISM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—On a suggestion, that notification should have been made in the journals of a reference to Professional gentlemen of the dispute between Dr. Robert Fowler and myself having been entered into, I beg leave to state that Dr. T. B. Peacock, 20, Finsbury-circus, has been named by Dr. Fowler as his referee, and Dr. A. Meadows, 9, Cavendish-place, Cavendish-square, has kindly consented to act as such for me.

I am, &c. R. G. MAYNE.

Leeds, January 6.

MEDICAL AND SURGICAL QUALIFICATIONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you be good enough to answer the following in your Notices to Correspondents?—

Mr. A., Member of the College of Surgeons, and registered, attends a patient with hepatic colic. He sends in a reasonable charge for “Medical attendance” only. Is not A. entitled to recover in a court of law by virtue of being on the Register?

This is merely a hypothetical case, but opinions down here differ. Clause 31 of the Medical Act, although using the words, “according to his qualification,” in one part, yet *not* in the other, after “recover in any court of law,” and clause 32, both read to me, that, by virtue of being registered, he is entitled.

I am, &c. F. T. H.

Queen-street, Deal.

[The Act in clause 31 makes a clear distinction between Medicine and Surgery, for it uses the words, “Medicine *or* Surgery, or Medicine *and* Surgery, as the case may be.” It also says that every registered person is entitled to recover “according to his qualifications.” That is our opinion; but our correspondent must be aware that the effect of no Act of Parliament is ever known until it has been tested in a court of law, and determined by the judges.—Ed.]

DISTRICT VACCINATORS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am a M.R.C.S.L., registered. Can you inform me—1st. Would my having only one qualification be any objection to my being appointed a vaccinator? 2. Is it usual in country districts where the Union Medical Officer is doubly qualified, to appoint others as well as himself to act as Vaccinators? 3. To whom should I apply for the appointment?

I am, &c. DUB.

[1. No. 2. It depends on the size and populousness of the district. We know a parish in which there are 700 births per annum, to a population of 30,000, and in which the vaccinator has at times the greatest conceivable difficulty in keeping up the supply of lymph by weekly vacci-

nation. In this parish the number of poor is estimated at 12,000. We know another parish in which there are 1500 births annually, and in which the vaccinator has also great difficulty in keeping up the succession, when any cause, such as bad weather, or Christmas intervenes to diminish the attendance of the patients. 3. The Guardians of the Poor.—Ed.]

APPOINTMENTS FOR THE WEEK.

January 10. Saturday (this day).

Operations at St. Bartholomew’s, 1½ p.m.; St. Thomas’s, 1 p.m.; King’s, 2 p.m.; Charing-cross, 1 p.m.

12. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark’s Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.  
MEDICAL SOCIETY OF LONDON, 8½ p.m. Clinical Discussion. Mr. Bishop, “On the Artificial Stand of Seignor Gallegos;” and other Cases.

13. Tuesday.

Operations at Guy’s, 1 p.m.; Westminster, 2 p.m.  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Mr. John Dix, of Hull, “On the Wire Compress, a Substitute for the Ligature.” Dr. A. B. Buchanan, of Glasgow, “Case of White Fibro-Serous Discharge from the Thigh.”

14. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary’s, 1 p.m.; Middlesex, 1 p.m.  
HUNTERIAN SOCIETY, 8 p.m. Mr. Hutchinson, “On Herpes Zoster—a Pathological Riddle.”

15. Thursday.

Operations at St. George’s, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopaedic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.

16. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.  
WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON, 8 p.m. Mr. Jones, “On Some Points in Connexion with Cerebral Hæmorrhage.”

EXPECTED OPERATIONS.

King’s College Hospital.—The following Operations will be performed on Saturday (to-day) at 2 p.m. :—

By Mr. Fergusson—For Painful Cicatrix; Prolapsus Uteri; Necrosis of Tibia; Removal of Osseous Growth from Femur.

By Mr. Henry Smith—Removal of Tumour from Thigh; Removal of Tumour from Lip.

Westminster Hospital.—The following Operations will be performed on Tuesday next, at 2 o’clock :—

By Mr. Hillman—Resection of Head of Humerus; Lithotomy.

**PARHYDOR, or IMPERMEABLE SILK, for Surgical Purposes, &c., &c. (Patented.)**

It is free from smell and adhesiveness in Tropical climates, warm rooms, &c. Will stand the test of being boiled in water. Free from spontaneous combustion, although packed in large quantities. Not irritating to the skin, or otherwise injurious when in use.—Sold Wholesale and Retail by Messrs. SAVORY and MOORE, 143, New Bond-street, W.; 29, Chapel-street, Belgrave-square, S.W.; 1, Lancaster-terrace, Hyde-park, W.; and 220, Regent-street, W.; and Messrs. CURTIS and CO., 48, Baker-street, W., London; and Wholesale by Messrs. MAW and SON, 11, Aldersgate-street, London, E.C.; and Messrs. LANGTONS, SCOTT, and EDDEN, 226, Upper Thames-street, London, E.C. Sold Retail by the principal Chemists and Druggists and Surgical Instrument Makers.

Manufactured by the Patent Waterproofing Company, 3, Great Winchester-stree, London, E.C.

\* \* \* Paper and Fabrics of Linen and Cotton Waterproofed in the same way.

*Pulvis Jacobi ver, Newbery's,*

is the ORIGINAL & GENUINE, was ESTABLISHED A.D. 1746,

And is Prescribed, with the greatest success, "by the highest authorities," for

Fevers, Ague, Cerebral Congestion, Rheumatism, Chills, Influenza, &c. &c.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.;  $\frac{1}{4}$  oz., 3s. 4d.

**CHLORODYNE.—R. FREEMAN, Pharmacist, Kennington-road, London, S.,**

informs the Profession and Trade that he has for years made and extensively supplied CHLORODYNE, in 1oz. and 4oz. Stopped Bottles, at 1s. 6d. and 5s. each. He guarantees it to be uniformly and properly prepared and superior to any other makers', though their charge be ever so exorbitant; and he is glad to find the low price which he sells it allows the Profession to use it in common practice and public institutions, so that its extraordinary beneficial effects are enjoyed by the poorest sufferers. R. Freeman almost daily receives letters from Members of the Profession, and also the Trade, who speak highly of his Chlorodyne. He publishes the following by permission:—

"I duly received your sample of Chlorodyne, and I liked it so well that I ordered more through my Wholesale Druggist. I think it in every way as good as any I have used, and it has the recommendation of being cheaper—"B. J. BOULTON, M.D., Surgeon Horncastle Dispensary, &c., Horncastle."

"I have administered to several of my patients your Chlorodyne, and I consider it a valuable remedy. It has succeeded perfectly in those cases in which I have used it. In its action it is uniform, and in its effects most efficacious.

"DAVID EASTON, M.D., Medical Officer Rhins of Galloway Poorhouse, &c., &c., Stranraer, Wigtonshire, Scotland."

"Having been in the habit of using Mr. Freeman's CHLORODYNE for some time past, I have much pleasure in stating that it has never failed to have the desired effect in whatever case it has been administered.

"C. SWABY SMITH, M.R.C.S.E., Surgeon to the Berks and Hants Extension Railway Works and Pewsey Union, &c., &c."

"I have had several parcels of your Chlorodyne, and the Medical men who have used it find it equally efficacious with that which is double the price, both having been tried on the same patients with similar results.

"W. GRAHAM CARR, Pharmaceutical Chemist, Berwick."

**TOWLE'S CHLORODYNE.**

Presenting the advantages of KNOWN COMPOSITION and UNIFORM MIXTURE, combined with moderate price.

DOSE, 5 to 20 DROPS.

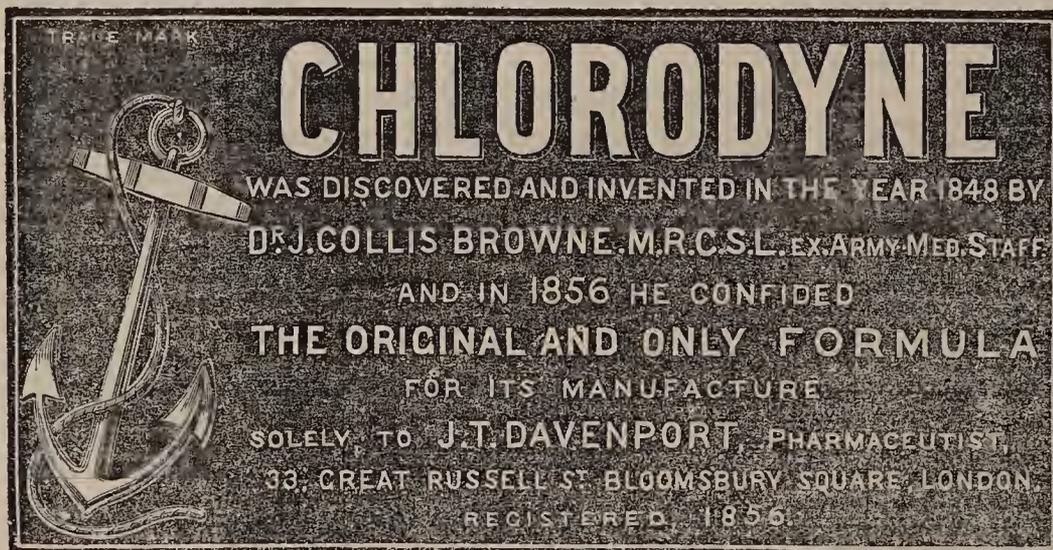

Medicinal Properties:—

Anodyne, Diaphoretic, Sedative, Anti-Spasmodic, and Astringent.

IMPORTANT LETTER, PUBLISHED BY PERMISSION.

From Dr. C. KIDD, Author of standard works on Chloroform:—"Sir,—I think if you would advertise your 'Chlorodyne' more than you do, you would help to beat the other *secret* compounds out of the market. Of the value of Chloroform given internally, I have no doubt; it appears to me in that form an anodyne *svi generis* that no other anodyne can approach. I have resolutely opposed the use of *secret* compounds of Chlorodyne, and in every way I can encourage the use of the 'Chlorodyne' (if we must have it at all) that is made by you, as you state that its composition is known. Many Medical men think with me and recommend your compound, but will never prescribe a *secret* remedy. (Signed) CHARLES KIDD, M.D., and Surgeon, Sackville-street, Piccadilly, London, April, 1862."

Sold in bottles, 1 oz. 1s. 6d., 2 oz. 2s. 6d., 4 oz. to 20 oz., 1s. per oz. Prepared, Wholesale and Retail, by A. P. TOWLE, Chemist, &c., Ardwick, Manchester. May be had from Barclay and Son, Farringdon-street; or through any Wholesale House.

**CHLORODYNE**  
 WAS DISCOVERED AND INVENTED IN THE YEAR 1848 BY  
 DR. J. COLLIS BROWNE, M.R.C.S.L. EX-ARMY-MED. STAFF.  
 AND IN 1856 HE CONFIDED  
 THE ORIGINAL AND ONLY FORMULA  
 FOR ITS MANUFACTURE  
 SOLELY TO J. T. DAVENPORT, PHARMACEUTIST,  
 33, GREAT RUSSELL ST. BLOOMSBURY SQUARE, LONDON.  
 REGISTERED, 1856.

**NOTIFICATION.**

The attention of Medical Men is directed to the Piratical application, by some parties in the Trade, of the term "Chlorodyne" to various mixtures compounded of Chloric Ether, Opium, Indian Hemp, and Peppermint, in Imitation of the ONLY Genuine preparation of this name.

The dangerous expedient of encouraging or advocating the assumption of a name specifically indicating a particular property or remedy—such as *Chlorodyne* is to spurious imitations and substitutions—ON THE GROUND OF CHEAPNESS, is a subject of surprise and grave reproach, supremely so, when the adulteration, sophistication, and tampering with Drugs, becomes so serious and important a consideration in the successful practice of Medicine.

The fact of these Piracies must fully convince the Profession of the extraordinary efficacy of the Genuine *Chlorodyne*; whereas the sad results and disappointment arising from the use of spurious compounds cannot be expressed.

Each Genuine Bottle bears a Red Stamp, with the words, "Dr. J. COLLIS BROWNE'S CHLORODYNE," in White Letters.

To be obtained from all Wholesale Druggists in 1oz., 2oz., 4oz., and 8oz. Bottles.

## ORIGINAL LECTURES.

## CLINICAL REMARKS

ON POINTS IN

## PRACTICAL THERAPEUTICS.

DELIVERED AT THE

ROYAL INFIRMARY, EDINBURGH,

AT THE CLOSE OF THE SUMMER SESSION OF 1862.

By THOMAS LAYCOCK, M.D.

Professor of the Practice of Medicine and Clinical Medicine ;  
and Lecturer on Medical Psychology and Mental Diseases in the  
University of Edinburgh.

*The Difficulties of Therapeutical Inquiry and Observation—Experience the Best Foundation—The Method of Analogy in Therapeutics—Difference between Pathological and Therapeutical Diagnosis—Local and General Action of Drugs apt to be Confounded. TONICS: their Nature—General Tonics—Bitter Tonics—Tonics in “Addison’s Disease,” or Melasmic Anæmia. STRYCHNINE: its Relations to other “Bitters”—Dangers of These—Nervine Tonics in Diabetes Melitus. QUININE: in Hemoptysis—Influence on the Blood through the Spleen? IODIDE OF POTASSIUM: in Syphilitic Cases—Combined with Colchicum. MERCURY: in Syphilitic Psoriasis by Fumigation—In Iritis—In Abdominal Inflammation—And of Mucous Membranes—Salivation not Necessary. PODOPHYLLIN: Doses and Uses.*

GENTLEMEN,—I propose to call your attention, by way of summary, to a few of the results we have arrived at in the treatment of disease, and some of the methods and means we have adopted to that end, during the past session. Practical therapeutics being of the very essence and business of clinical Medicine, is one of its most important departments; yet it is too apt to be lost sight of in the more interesting and easy study of pathology, or the theory of disease. I say, more easy, because the difficulties which interfere with investigations into the effects of remedies and of remedial agents are so numerous, in too many instances so insuperable, and in all cases so troublesome and perplexing, that the more impatient minds in the Profession either lose all reliance on practical Medicine, and subside into what the Germans call “nihilism,” or do-nothingness, or else abandon all attempts at science, and yield up their judgment to a gross empiricism.

After pointing out some of the difficulties in the way of accurate therapeutical observation, and showing that a large experience of remedies is the only safe guide in practice, Professor Laycock proceeded to say:—

When experience has enabled us to deduce general principles of therapeutics, we apply them to individual cases by the method of analogy. We inquire whether the morbid state we have to combat is like some other morbid state (or establish our nosological diagnosis) in which certain drugs or remedies have been found useful already. Now this entire process is therapeutical diagnosis. But therapeutical diagnosis is often confounded with pathological diagnosis; and hence, practical mistakes of a very gross kind arise. Thus, for example, pathological diagnosis is much the same for almost all varieties of pneumonia, in so far, at least, as physical methods are used; but the therapeutical diagnosis is as different for the varieties of pneumonia, as if they were wholly different diseases. Hence, when the treatment of “pneumonia” by various means is discussed, with the pathological diagnosis only in view, there are no true analogies to guide the inquiry, and the results are simply a mass of contradictory and conflicting statements, which practically are worse than useless. If, on the other hand, we class the varieties of pneumonia, with reference to a therapeutical diagnosis, it will be found that there is really very little difference in the experience of careful and observant Practitioners, and sound rules of treatment for each variety can be laid down. Now, it is in therapeutical diagnosis, rather than the physical or pathological, that the skill of experience is most shown. It is easy to diagnose a pneumonia, but not always so easy to decide upon the kind of treatment which experience has shown to be best; for this, indeed, experience is needed, both of the varieties of pneumonia and of the operation of remedies in each, such as tartar emetic, bleeding, chloroform, inhalation, wine, etc.

The same method of analogy can be applied to the selection of remedies. If we can determine what is the action of a class, we can, by analogy, take individual drugs of the class. Thus, terebinthinate acts especially on the mucous membranes; consequently, we can select a terebinthinate drug which acts curatively on the mucous membrane of the bladder or intestine, and prescribe with a view to its action on the mucous membrane of the bronchi; or we can substitute one terebinthinate for another, as copaiva for tar, Chian turpentine for spirit of turpentine, and the like. These points I have often illustrated at the bedside. But I think it may be safely affirmed, that all drugs and remedial means act upon, not one, but several, tissues or organs; and we have, therefore, to determine, in each case, which of these are specially or predominantly, and which consecutively, affected. This is, however, one of the most difficult problems in therapeutics; and hence the chief lesson we derive from the general principle is, that we cannot be too cautious in our deductions as to the *modus operandi* of remedies, feeling sure, indeed, that these must be imperfect, however cautiously drawn from carefully-observed phenomena. For example, to take a common case, what is the influence which certain drugs exercise upon the nervous system through the stomach by local action thereon, and what on the blood, the nervous system, and the viscera in general, when carried along with the current of the circulating blood? The so-called “stomachics” are believed to act chiefly on the stomach; yet there is reason to believe that this class of bitters at least really influences the nervous system in the first instance, and the digestion through this. On the other hand, it is very probable that various stimulants, as the alcoholic, act primarily on the stomach and on the nerve-centres through the gastric nerves, and consecutively on the nerve-centres and tissues through the blood. In practice, this local action of wine and alcoholic stimuli is of importance, inasmuch as we must regulate the extent of dilution, the dose, and the frequency of repetition accordingly.

Perhaps we shall best illustrate our views by noting the influence of *tonics* of various kinds. These are drugs which strengthen the body. Now, the body may be strengthened in very various modes. If weak from want of food or of fresh air, or from over-fatigue, then nutritive food, pure air, and rest are the most certain tonics. If the blood be defective in certain ingredients necessary to health, we add these. Thus, in convalescence from fever, cholera, and other diseases, in which the salts of the blood have been wasted, chloride of sodium, the phosphates, and the nitrates are *tonics*. Digestion may be imperfect, from imperfect innervation of the digestive organs, and thus chylication is hindered. Then defective blood results, and this re-acts morbidly on the nerve-centres, intensifying the primary cause. Hence, tonics must often be compound in their nature, because intended to be multiform in their effects. When we give bitter ale or beer as a tonic, we give a very compound thing, and, *quâ* the bitters, a “tonic” not to be trifled with, from their action on the nerve-centres.

The cases treated in the Infirmary being, for the most part, asthenic and cachectic, give great scope for the observation of tonic remedies. Bitter drugs, chalybeates, “kitchen physic,” and wine, have been freely used in the wards, either singly or in conjunction. A good diet (“kitchen physic”) is often all that is needed in many of the cases we admit, and hence a source of fallacy when estimating the effects of drugs of this class. Of the bitters, we have chiefly used quassia, gentian, chamomile, quinine, and strychnine, and all these are, I conceive, nervine tonics; that is, stimulate digestion, and give strength by primarily acting on the nerve-centres. Quinine, strychnine, hop, and wormwood are acknowledged nervines; and it is probable that other vegetable bitters, even such as aloes and colocynth, belong to the same category. Hence, the tonic value of aloes in non-purgative doses. These were rarely administered singly, as the blood was usually in a morbid state, as well as the nervous system; hence, we combined bitters with chalybeates and cod liver oil. When this last cannot be taken, glycerine seems to be a useful substitute. A combination of quassia, sesquichloride of iron, and glycerine (a), was found useful in various cachectic states, as anæmias, cardiac and renal dropsies, and the like. One man who came in with all the pathognomic symptoms of the anæmia or asthenia known as “Addison’s disease,” quickly rallied under this combination, with a gene-

(a) The formula used is as follows:—℞ Tinct. ferri sesquichlor. ʒij. glycyrrhinae, infusi. quassia, āā ʒiv. ; two tablespoonfuls thrice a-day.

rous diet as an auxiliary, and went out, in six weeks, convalescent. At first he added half a stone to his weight in a week. Five years ago a similar case was under my care in the clinical wards, and, after taking good diet, wine, and chalybeates without benefit, recovered as rapidly as this man did under the same remedies. I do not pretend to say that in these cases there was structural disease of the supra-renal capsules; but most certainly there was that discolouration of the skin and mucous membrane of the mouth, that asthenia and those nervous symptoms, which Dr. Addison and others have observed to be associated with such structural disease. That the melasma occurs without structural disease of the supra-renal capsules is certain; but this observation does not exclude functional disease of them as a cause, which may, in fact, pass away altogether, leaving the melasma as a permanent thing. A more conclusive objection is, that structural disease of the capsules is found without the accompanying melasma; but, then, in physis there are no single causes at work, and it is probable that a lesion of the blood and nervous system, especially of the skin, must be superadded to the capsular disease. In the absence of a satisfactory pathology, it would, perhaps, be better to take the leading symptoms as a guide, and term the disease a melasmic anæmia—an anæmia with a sort of melanosis, in fact, in which the epithelial cells of the skin and mucous membrane are the chief seats of the melanotic deposit.

*Strychnine* is a valuable nervine tonic of the bitter class, and may be said to be generally available in all cases in which there is defective innervation of the pneumogastric system. I always begin with  $\frac{1}{40}$ th of a grain as a dose thrice a-day. We have found it useful in cases of bronchitis in which the cough is more or less spasmodic, in phthisis with much bronchorrhœa, and in the convalescent stage of febrile pneumonia. The chief objections to its use are, the danger of an overdose from careless compounding or administering, and the rapidity with which its physiological effects are sometimes manifested. I am inclined to conclude, however, from frequent observation, that it does not stand alone in this respect, and that other "bitters" exercise an analogous and often as dangerous an influence on the nervous system. I have known bitter beer excite twitchings, and urgent head symptoms result from taking the "bitters" of the dram shop; and I suspect the liqueur or "sirup" termed "absinthe" owes all its mischievous effects to the bitter drug it contains.

Strychnine and other nervines were tried in two cases of diabetes. The valuable and sedulous observations of Mr. Smart as to the progress of these cases, enable us to judge as to the effects of both drugs and diet on the production and elimination of sugar and water. The administration of strychnine, Mr. Smart reports, in doses progressively increased until the physiological effects became incipiently apparent, was followed by progressive and commensurate decrease in the amount of urine and sugar. Chloroform, and the chloric and sulphuric ethers, increased it. I think nervines are most likely to be available in diabetes, for all the most recent researches into the pathology of glycosuria point to the nervous system as the primary seat of disease. In one of our cases the glycosuria was periodic, occurring every fortnight for about ten days, the interval of four days being free. This periodicity is, I suspect, less commonly observed than it occurs.

*Quinine* holds its place as a powerful nervine tonic. Perhaps it is in this way that it is so serviceable in cases of splenic disease, or of blood diseases consecutive thereto. In one case, in which hæmoptysis was associated with splenic disease, in a discharged soldier, returned from India, we found the blood-corpuscles, when examined under the microscope, to be highly crenated. This appearance is very decisive of splenic disease, and is readily altered, in some cases, by quinine. In the case alluded to, the hæmoptysis ceased, and the crenation of the blood-corpuscles disappeared, after the rapid administration of two-grain doses of quinine. Perhaps it is by its action on the nervous system that quinine facilitates the action of purgatives. You have seen how much the activity of the sulphate of magnesia is increased by combination with the drug; a scruple of the salt, combined with a grain of quinine, repeated a few times, at intervals of three or four hours, acts as an efficacious laxative.

*Iodide of potassium* has been frequently prescribed. I have had experience of this drug in the treatment of syphilitic diseases for the last twenty-eight years, and am satisfied it is one of the most reliable of anti-syphilitic remedies. Its value

was shown in two cases in which the diagnosis pointed strongly to a syphilitic cause, although absolute certainty was not attainable. The one was that of a youth with bronchitis, first acute and then persistent, who had been exposed to contagion, and confessed to a "running." He improved immediately and rapidly under the drug. The other was that of a woman, with the syphilitic physiognomy, and with a sad family history of debauchery and violence on the part of her husband. She had had attacks of hemiplegia, first of one side, then of the other, from which she recovered, except a ptosis of the left upper eyelid, from paralysis of the third nerve, but with a tendency to vertiginous attacks. She had had abortions and several deaths of infants. As the case resisted all the usual remedies, she was prescribed the iodide of potassium, and very shortly signs of improvement were observed in increased power over the paralysed eyelid, and less frequent recurrence of the vertiginous attacks. In ward I. there was the case of a man with chronic syphilitic cachexia of twenty-two years' standing; the numerous circular scars and cicatrices scattered over his face and limbs illustrated well the true character of cutaneous syphilitic ulceration. He came in with neuralgia and weakness of the left arm, which quickly yielded to full doses of the iodide. I shall not attempt a theory of the *modus operandi* of the drug, but would remark, that in syphilitic periostitis, whether of the cranium or other bones, occurring in persons of a decidedly rheumatic or gouty diathesis, I have observed that the efficacy of the remedy is much increased by the combination with it of colchicum; I usually order five minims of the tincture of the root with five grains of the salt. And this combination is also useful in chronic rheumatism and lead neuralgiæ, especially those of the joints which simulate rheumatism. The iodide of potassium has a tendency to irritate the mucous membrane in some persons. Thus, severe coryza is sometimes quickly induced by it, or an annoying gastritis, or a sort of pyalism, as in the case of a man in ward I. I do not think it suits such persons at all, and should, therefore, be discontinued when the results are of this kind. The bitter taste in the mouth which it causes is felt by all who take it, and is, I think, due to the direct contact of the drug with the palate, to which it is brought in the current of the circulation. This bitter taste is, therefore, a proof, both that the drug is taken, and is genuine. It should always be administered immediately after food, to prevent any irritation of the stomach; and when there is gastric irritability a grain or two should be the dose, with an equal quantity of the bromide of potassium. It may be safely increased, in some persons, to ʒss. thrice a-day.

*Mercury* has not been found necessary in many cases; the majority have been too cachectic, or in other respects unsuitable. We tried mercurial fumigation in a case of syphilitic psoriasis which long resisted ordinary treatment:—First, full doses of iodide of potassium were freely tried, and, failing this, arsenic; while taking this drug, however, the disease progressed rapidly, the crusts becoming both thicker and more numerous. We then reverted to the iodide, and, at the same time, adopted the method of mercurial fumigation recommended by Mr. Henry Lee. Two spirit-lamps were used, fed with methylated spirit; over the one a metallic plate was placed, upon which ten grains of calomel were laid, and over the other a small cup of water; over these was placed a cane-bottomed chair, upon which the patient sat down naked, and was then enveloped—chair and all—in a blanket, for a quarter of an hour; he was then rolled in the blanket, and went to bed. The drug acted as a tonic. In a few days, visible improvement in the health took place, and in about five weeks he was cured of the psoriasis. I have detained him a few days to show him to you. He experienced no salivation, nor any other ill effect. The bichloride of mercury is sometimes a useful tonic in these chronic syphilitic diseases of the skin, and has the advantage over other drugs of rarely causing salivation.

We tried the iodide of potassium in the case of a woman in ward XI., with syphilitic cachexia, but she did not bear it well, having very irritable mucous membranes; then she got iritis, with slight keratitis, and, being reluctant to give mercury, I tried quinine in the first instance, but with so little good result, that, finally, calomel and opium were prescribed. The inflammation then yielded, leaving, however, a slightly irregular pupil. I think, in this kind of case, mercury is the most certain remedy, but it must be watched, so that pyalism shall not result. Is mercury a tonic or

stimulant in other diseases? We have tried calomel in a case of supposed gall-stones, with probably cystic inflammation; the pain was terrible, the vomiting incessant. Opium was at first tried alone, together with leeches over the right hypochondrium, where was a tumour the size and shape of a large egg projecting from the margin of the liver—midway. Only temporary relief followed. I then ordered quarter-grain doses of calomel, mixed with two grains of sugar, to be placed on the tongue every two hours; in a few hours relief of the pain was experienced, and copious bilious evacuations followed, then convalescence. In all these acute abdominal affections with incessant vomiting, especially of grass-green stuff, calomel, according to my experience, thus administered, is a valuable drug. But I must remind you of the plan that I told you, when at the bedside, should be adopted when treating these cases by calomel and opium, or by either singly, namely, so to administer them that they cannot be rejected. Thus, in spasmodic colic or ileus, with obstinate vomiting, the opium should be prescribed in one or two grain doses of the solid opium, as a small pill, and the patient should have a draught of water before the pill, that he may vomit it, and so empty the stomach; then administer the pill, and allow nothing to be drunk for half-an-hour. In this way its transit downwards should be secured. The calomel should be administered with the same precaution.

Grain doses of blue pill, combined with two or three grains of Dover's powder in pill, is a useful remedy in certain forms of acute bronchitis and other mucous inflammations. We have not, however, had any suitable case this summer for showing the value of the combination. In one case of pneumonia of a severe type, we administered calomel in combination with antimony. This is an old method of combining these two most powerful drugs, and is specially available in those acute inflammations in which you desire to bring on mercurialisation rapidly. They are of very rare occurrence here, and the case I allude to was hardly a typical example. I do not think it was of any use to the man. Mercury, like opium, antimony, arsenic, colchicum, digitalis, and the like, is one of a class of powerful and valuable drugs, which require a large experience for their safe and satisfactory administration; so that the observation of cases in which they prove to be useless, or worse than useless, is really as valuable to the student as the observation of those in which they are beneficial. Speaking generally, mercury should never be given so as to affect the mouth; and all that class of persons in whom inflammation of the mouth is readily induced by it, derive little or no benefit from it. These have already a red line on the gums, decayed teeth, etc.

We have used the new drug podophyllin with varying success. It is undoubtedly a very useful cathartic, but should not be prescribed incautiously, on account of its uncertain action. The safest and most effectual plan is to order from one-sixth to a quarter of a grain every three or four hours, guarded with a carminative, until its purgative action is shown. We have seen that this commonly takes place, at latest, by the time a grain or a grain and a-half has been thus taken. But with patients easily acted on by purgatives, an eighth or twelfth of a grain repeated at intervals is enough. There is certainly less tendency to constipation after its use than after senna, colocynth, and the like.

LECTURES ON THE  
BLOOD OF VERTEBRATA.

DELIVERED AT THE

Royal College of Surgeons of England,

DURING THE SESSION 1861-62.

By GEORGE GULLIVER, F.R.S.

Professor of Comparative Anatomy and Physiology to the College.

LECTURE IX.—On Animal Heat—Relation of the Red Corpuscles to the Respiratory Demand—Theory of Black, Lavoisier, and Crawford—Difference between the Heat of Arterial and Venous Blood—Rise of Temperature in Vegetables—Temperature of Fishes—Temperature of Birds—Electricity—The Oxygen conveyed by the Red Corpuscles to produce Carbonic Acid and Heat—Isomerism—Agency of the Nervous System.

HAVING described the colour of the blood, with the causes of modifications in that colour, and the agency of the red cor-

puscles as carriers of oxygen to maintain the power of the contractile tissues, of the nervous tissues and brain, and of the nutritive processes, we come to consider the office of these corpuscles in connection with the generation of animal heat.

*Relation of the Red Corpuscles to the Respiratory Demand.*—Ever since chemistry has been capable of attempting or affording any explanation of the cause of animal heat, the red corpuscles were generally admitted as mainly concerned in the process in connection with pulmonary respiration; or rather, perhaps, we should say the red part of the blood, as the earlier observers were either ignorant of, or but little acquainted with, the corpuscles. We have already mentioned the great merit of the observations made in 1669 and 1674, by our excellent countrymen, Lower and Mayow. As explained in Lecture V., there is, *ceteris paribus*, an increase of the mass of the red corpuscles with a like tendency to an increase of the sum of their surface by minute multiplication or subdivision of them, in relation to the respiratory demands of the animal, and *vice versa*. The exceptions may be rather apparent than real. Science is not sufficiently advanced to enable us to estimate the value of the disturbing circumstances; for the result is not comprehended under a single factor, but is influenced by others not yet known, or only so dimly seen as to require more light. We cannot, for instance, move a step without a correct knowledge of the relative proportions of the red corpuscles to the liquor sanguinis, to say nothing of those peculiarities of habits and organisation with which we are at present unacquainted. Even fishes would probably appear less exceptional were we less ignorant of their physiology; and we shall soon show, however little expected, that the abundance and smallness of the red corpuscles, and the strength of the heart, are in harmony with the relation in question in certain warm-blooded members of this most abject class of vertebrates. In the highest class again, nature might compensate for a comparative deficiency of red corpuscles, extending the sum of their surface by a suitable subdivision of them; and when that surface would otherwise be in excess, she might prevent it by keeping them larger.

You see by the diagrams how much larger the corpuscles are in man than in the horse. Now, merely to make our meaning plain, suppose the proportion of the corpuscles of these animals relatively to the rest of the blood preserved, and the size of the corpuscles exchanged. They would then probably be quite unequal in the brute to perform their functions, and in man might present such an excess of surface beyond what is required of them, as to carry too much oxygen. In the pig, one of the hottest of *Apyrenæmata*, the proportion of red corpuscles is immense, and their size not large; and, though the experiments of Nasse show a much smaller proportion of these corpuscles in the sheep and goat than in the dog and ox; no wonder, considering the comparative minuteness of the corpuscles in the two former animals, that Dr. Davy found their temperature even rather higher than that of the two latter. Thus, whenever we consider the corpuscles in relation to respiration and its consequences, we must connect their individual size with their aggregate proportion to the liquor sanguinis. They are larger in hot birds than in cooler *Apyrenæmata*, but abundant in proportion; and in cold fishes so small as would indicate a higher temperature than two or three degrees above the medium in which they live, but for their scanty proportion to the other parts of the blood.

*Theory of Black, Lavoisier, and Crawford.*—Soon after the discovery of oxygen by Priestly in 1774, the very time of Hewson's death, just a century after the publication at Oxford of Mayow's tract, and seventeen years subsequent to the discovery of carbonic acid by the eminent Dr. Black, a consistent, or at least plausible, theory was formed on the subject. Black observed that carbonic acid is produced during respiration and combustion, and the chemical theory of the cause of animal heat made rapid progress. In short, that respiration is essentially a combustion of carbon, which combines in the lungs with oxygen, and forms carbonic acid, and at the same time produces the animal heat, was the prevailing doctrine—indeed, the exclusive one on the subject. And no wonder, seeing that this conclusion was supported on the Continent by such eminent authorities as Lavoisier and Laplace, and in Britain by Black and Crawford. Recently, even Liebig, like some old writers (see Needham, "De Formato Fœtu," cap. vi., 12mo, London, 1667; and Ray's "Letters," by Derham, p. 294, 8vo, London, 1718),

seems to maintain the same view when he attributes animal heat to the burning of the carbonaceous part of the food, especially fatty matter, in the lungs.

But a host of experiments and observations in our day, and before, show that the blood in the lungs cannot be the centre or furnace for the production of all the animal heat, whatever may be the importance of that blood as a carrier of support and fuel for the combustion or other chemical changes concerned in the production of that heat. Mr. Hunter, Sir Benjamin Brodie and Mr. Cæsar Hawkins, have given conclusive evidence, that respiration in the human subject may be preternaturally slow or imperfect while the body is acquiring and maintaining a preternatural heat; and it is well known to practical Surgeons, that the limb in which the artery has been tied for the cure of aneurism, may be for a while hotter than the other limb, which is still receiving its usual supply of arterial blood. That arterial blood is warmer by one or two degrees than venous blood has been clearly proved by Dr. Davy; and he has also proved that the relative capacity for heat of arterial and venous blood is really so little different as not to be deserving of the importance attached to it by Dr. Crawford. Yet, one of Davy's own experiments, in which the pyloric compartment of the stomach of the ox, containing food, was  $104^{\circ}5$ , while the blood in the left ventricle was only  $103^{\circ}$ , gives an excess of heat in the stomach certainly not derived from the lungs. Ludwig and Spiess found the temperature of the saliva which flows when the nerves of the submaxillary gland are galvanised,  $1^{\circ}8$  higher than the blood of the carotid artery of the same side; and they conclude that the work of secretion produces a notable increase of temperature, with a diminution in the formation of carbonic acid, the venous blood of the gland being almost as red as arterial blood. Nay, further, we have well-attested cases of an actual rise of temperature in the human body, unconnected with putrefaction, during the first hours after death, and, therefore, quite independently of the immediate agency of the nervous and respiratory functions. Dr. Bennett Dowler, of New Orleans, has reported cases of this kind in bodies dead of cholera, yellow fever, and sun-stroke; and, though Dr. Davy, in his excellent work on "Diseases of the Army," has some doubt about these results, they have been confirmed, as far as regards cholera subjects, by M. Doyère, in Paris. And now, within our own immediate knowledge, thanks to the interesting experiments conducted by Dr. Sclater and Mr. Bartlett, we have the great female python at the Zoological Gardens producing and maintaining a great increase of temperature during the act of incubation; and this, though taking no sort of food for upwards of a month. It would be curious to know how Professor Liebig would attempt to reconcile these unquestionable facts with his theory. Certain it is, that here there has been no food, no fuel put into the reservoir of the stomach to be burned up for heat in the lungs, during this remarkable elevation and maintenance of temperature in the body. Perhaps it might be suggested that the fuel was laid in before, as coal is now being collected in certain places for worse purposes, and kept unaltered in its repository, to be burned when needed for the special use in question. Yet the weight of the python should have been often noted during these observations, as there was probably increased functional activity, and waste of substance, as in a fever. In short, animal heat is certainly produced elsewhere than in the lungs, whatever heat may be generated there, and however important they may be as receptacles for the elaboration of materials, to be distributed to initiate or assist in the chemical processes for the production and maintenance of that heat throughout the body.

*Difference between the Heat of Arterial and Venous Blood.*—We have already seen that Dr. Davy has proved that blood acquires heat in passing through the lungs—in other words, that the blood of the left ventricle is hotter than the blood of the right ventricle in the living body, the difference of temperature being from  $1^{\circ}$  to  $1^{\circ}5$  of a degree, a like difference existing between the blood of the veins and arteries, though somewhat diminishing as their distance from the heart increases. He has further shown that venous blood agitated in a bottle with oxygen, acquires an increased heat of about  $1^{\circ}$ , and this by combining with the oxygen without the production, or at least evolution, of any carbonic acid. Hence, he infers that animal heat is caused by the fixation and condensation of oxygen in the blood, by its conversion from venous to arterial blood in the lungs, and by the combination of this oxygen in its course through the body in connexion with secretion and other changes.

*Rise of Temperature in Vegetables.*—Indeed, the facts generally at present known concerning the production of heat in organised bodies, whether animal or vegetable, tend to prove that it is more or less connected with changes or combinations in which that potent agent, oxygen, is concerned. This is certainly the case in the germination of seeds, as in the process of malting; and in some species of the Arum family, during the flowering time, the rise of temperature is a well-established fact, which De Saussure observed to be connected with the formation and evolution of carbonic acid. Thus, in these examples in vegetables, there is still a consumption of oxygen, though quite unconnected with any corpuscles of the blood; but this by no means proves that the red corpuscles, among other offices, may not be special agents, mediately or immediately, for the production and regular support of heat in the higher animals. We require some exact observations on the changes during the heating of hay, refuse tan-bark and muck, in any of which the temperature may much exceed that of animals, and maintain itself for several days. I found the heat of a hay-stack upwards of  $200^{\circ}$ , and that a tan-bed generated and kept up a temperature varying between  $89^{\circ}$  and  $134^{\circ}$  for a fortnight in February. The gardener can modify the warmth of his hotbed; and, could he further exactly suit the supply to the waste, preserving all the conditions under which a given heat is produced and maintained, he would only be imitating the perfection of organised nature in this process.

*Temperature of Fishes.*—And that the red corpuscles really do supply oxygen, among other purposes, for the production of animal heat, might be inferred, independently of the facts already detailed, from many others—such as the proportional quantity of these corpuscles in certain warm and cold fishes. As described in a former lecture, the red corpuscles are by far the heaviest part of the blood; hence, their proportion, relatively to the other proximate constituents of this fluid, may be, to a certain extent, deduced from its specific gravity. Accordingly, Dr. Davy instituted experiments of this kind. Certain fishes of the Scomber tribe, as the bonito and pelamys, he proved to have warm blood, varying from 7 to 19 degrees above the water in which they live; while, from very particular inquiries made of persons engaged in the tunny fishery, he believes that the tunny is also warm-blooded. The specific gravity of the blood of the tunny was 1.070, while the blood of the colder fishes with which he made the comparison, only a little exceeded the serum in density, the specific gravity of the blood of the picked dog-fish (*Squalus acanthias*), for example, being but 1.030, while its serum alone was 1.027. And the contrast between these warm and colder fishes was equally remarkable when the large and powerful heart, the abundance of blood and its red corpuscles, the large gills and apparatus of branchial nerves of the warm *Scomberidæ*, were compared with the diminution or reduction of all these phenomena in the colder fishes. He also found the size of the red corpuscles to the same effect,—all much smaller in the rich blood of the tunny, of the pelamides, and of the sword-fish, than in the poorer blood of the colder fish,—a fact only of weight in connexion with the other circumstances; and it has already been explained how, *cæteris paribus*, the tendency of the corpuscles is to be smaller, so as to multiply or extend their surface in a given proportion, according to the activity of the respiratory function.

Having noticed these exceptional temperatures in fishes, it may be mentioned that these animals generally are not absolutely, but only relatively, cold-blooded. As an old angler, I have for many years taken every opportunity of ascertaining their temperature by a delicate thermometer, made for the purpose for me by Mr. Adie, and the results are confirmatory of the earlier observations of Mr. Hunter, Martin, and Dr. Davy. I have experimented thus on numerous river fish, particularly on different species of *Salmonidæ*, *Percidæ*, *Cyprinidæ*, *Esocidæ*, *Murenidæ*, *Petromyzidæ*, and with the result of finding them from three-quarters to three and a-half degrees warmer than the medium in which they live. I could not ascertain any marked variation in their temperature during the breeding season, nor in the different streams and lakes of England, Scotland, and Ireland. The result of thirty-one experiments on the salmon gives its mean temperature at  $2^{\circ}4$  above the water in which it lives.

*Temperature of Birds.*—The high temperature of birds, another class of the pyrenæmatous vertebrates, has never been satisfactorily accounted for; but in them we find, as we always do in connection with the development of much heat

in the vertebrate animals, a large proportion of red corpuscles. Dr. Davy found the specific gravity of the blood of a turkey exceeding that of the human blood. There is probably, too, great activity in the organic functions of birds. Whether the nucleus of the red corpuscle has any share in the production of this increased heat, or, indeed, what may be the specific use of that nucleus, are yet subjects for inquiry. It has been thrown out as a conjecture that the vesicle and nucleus, containing and contained part, may be in the electrical relation to each other of positive and negative; and Dr. Davy has proved that the white and yolk of the egg of the common fowl are in this state. As to the objection, that cold fishes have red corpuscles containing nuclei, these corpuscles are so scanty that this constitution of them might still be required. Whether the high temperature of birds depends entirely on the carbonic acid formed and expired, is yet questionable. From the experiments of Treviranus and Müller, it would appear that birds expire more of this acid in proportion to their weight than *Apyrenæmata*; but Allen and Pepys obtained contrary results on the guinea pig and pigeon. The peculiar clothing, the urine, and other circumstances, would have to be taken into an account of the heat of birds.

*Electricity.*—Whatever may be the agency of electric action in the production of animal heat, we cannot estimate or value it in the present state of science. Professor Carlo Matteucci, whose experiments on electricity in animals have been so numerous, concludes that the property of the muscles immediately connected with their electric currents, is identical with that which was long ago denominated by Haller irritability, but which is at present more usually designated by the term contractility; and he ascribes the development of this muscular electricity to the chemical actions which are attendant on the process of nutrition of the muscles, and result from the contact of arterial blood with the muscular fibre. Now, we know that MM. Bequerel and Breschet had long before demonstrated that there is actually a development of heat during muscular contraction; but whether the electricity and heat in this case are in the relation of cause and effect is a subject for further inquiry. At present we are only concerned about the red corpuscles; and this experiment might be objected against their agency in the production, mediately or immediately, of the increase of temperature during muscular contractility. But the objection would have little weight, unless it should be also proved that there is not an increased circulation of blood in, and, consequently, a greater supply of the red corpuscles to, the muscles during their contraction. We have already seen how these corpuscles, charged with oxygen, are capable of restoring the contractile power of muscles even after post-mortem rigidity,—in short, of actually reviving and re-animating these dead muscles. Dr. Davy observed that the electrical fishes are of low temperature, and the blood corpuscles of the torpedo large and few; and I found them also scanty, but smaller, in the *gymnotus*.

*The Oxygen Conveyed Mainly by the Red Corpuscles to form Carbonic Acid.*—We have shown that, while healthy serum has such a very high solvent power over carbonic acid as to be capable of absorbing even more than its own bulk or volume of this acid, oxygen is scarcely or not at all capable of absorption by the serum; and, in fact, that the oxygen is absorbed by the red corpuscles. And that the carbonic acid is not merely an excrementitious substance, results directly from Dr. Brown-Séguard's observations, that the contractive tissues of vertebrate animals can be stimulated or excited by blood charged with this acid. He relates an experiment in which the pregnant womb of a dead bitch was made to contract and expel its contents by the stimulation of carbonic acid. But now, having produced the chief points in the evidence as to the concern of the red corpuscles in the production of animal heat, conclusive of their potent agency in this respect, we must leave to chemistry the explanation of the multifarious means by which the oxygen they undoubtedly convey, may mediately or immediately act to this end. The formation of carbonic acid, and consequent evolution of heat by combination of oxygen with carbon, is a leading fact. We have already noticed the high temperature generated and maintained for a while by certain living vegetables, and by such dead things as hay, dung, and tan; and that animal heat is also simply the result of chemical agency, can scarcely be doubted.

*Isomerism.*—But if the chemist has not yet been able fully to explain the phenomena in these lifeless heaps, no wonder he should fail to follow and determine exactly all the steps

throughout the complex organism and manifold processes of the living animal; more especially when we consider the increased difficulties arising from such relations as isomerism and polymerism, which make the transition of one compound to another depend merely on contact, as in assimilation and dissimilation. Thus, the recent and beautiful observations on amyloid substance in the liver, and many very different organs, and its relation with sugar on the one hand, and with proteic azotized compounds on the other, would appear to be intimately connected both with dissimilative and assimilative processes, as Dr. Robert M'Donnell, of Dublin, has so well observed. And, as I shall show to you in a future lecture, a membranous cyst may be produced in serum by a process of spontaneous coagulation at the temperature of the air, and some days after that serum has been kept apart from the blood in a jar, quite independently, too, of life, or of red corpuscles of the blood or cells of any kind, or of the evolution of ammonia; so that it would be difficult to reconcile this one simple fact with either the doctrine of Mr. Hunter, of Professor Schwann, of Dr. Richardson, or of Professor Grant. But the whole of this interesting branch of our subject will come under consideration when we treat of the fibrin of the blood.

*Agency of the Nervous System.*—Having mentioned the large size of the apparatus of branchial nerves in the warm-blooded *Scomberidæ*, reminds us of the doctrine of Sir Benjamin Brodie, that the integrity of the nervous system is in some way necessary to the production of animal heat. Undoubtedly so, as far as regards the conditions for the regular maintenance of that heat. This eminent physiologist ("in his younger days," as honest Izaak Walton said of some of Sir Walter Raleigh's best work) proved that in the most convincing manner; and though he was surely wrong in ascribing the heat mainly or fundamentally to nervous action, and some of his minor facts have been questioned, and his leading conclusion somewhat modified; we shall soon see that the chief details stand now, as ever, a model of experiments so ingeniously devised, so skilfully and carefully executed, so novel and striking and true in their results, as must at once have shown the capacity of the author for the eminent career which he has subsequently pursued. We have already seen how he and Mr. Cæsar Hawkins, like Mr. Hunter, had observed that animal heat, contrary to the then universal doctrine, could not be altogether and immediately dependant on respiration. We need only, on the present occasion, allude to some of Brodie's central experiments and results, as it forms no part of our design in this course of lectures to treat of the functions of the brain and nerves. It had before been shown by Cruickshank (another illustrious disciple of, and successor to Hewson in, the brilliant Windmill-street School), and by Bichat, that, when the brain is destroyed, the action of the heart only ceases because respiration is suspended; in other words, that the brain is not directly necessary to the action of the heart, though the lungs are so to that action in the higher animals. And so, the circulation of the blood may be kept up by artificial respiration, for a while, after the functions of the brain have been annihilated, either by mechanical means, or by such vegetable poisons as woorara and the essential oil of bitter almonds.

Accordingly, Brodie removed the brain of dogs or rabbits, after having duly secured the arteries of the neck, and maintained the action of the heart thereafter for two or three hours, when the bodies were found to cool even faster than the bodies of other animals killed at the commencement of the experiment, and laid in the same room for comparison. Yet the blood of these decapitated animals, thus made to breathe artificially, underwent the usual changes, just as in a living animal. The dark venous blood acquired the florid arterial hue in its passage through the lungs; as usual, too, oxygen was absorbed and carbonic acid evolved. Here, then, allowing for all possible errors in the observations and calculations, was sufficient experimental proof that the then universal doctrine, of all the animal heat being produced in the lungs, must be abandoned; that specious and beautiful theory, so beloved by its authors, so long and fondly admired and cherished by its embracers, had to be discarded; but this not without many a challenge for further proof or confirmation,—not without more than one new trial.

So the experiments were repeated, and the evidence reviewed by Dr. Chossat and M. Le Gallois on the Continent, and by Dr. Wilson Philip in England, but without the effect of disturbing essentially the original verdict. All the additional facts elicited only amounted to this:—During artificial

respiration in the dead animal the loss of heat may not be uniform—in some instances greater, and in some less—in the animal under artificial respiration, than in the animal killed and laid by for comparison. And it is remarkable that this new inquiry amply confirmed the truthfulness of the first experiments and observations; for Dr. Wilson Philip showed that the small discrepancies in question were explicable by a calculation of the differences in the quantities of air blown by the bellows into the lungs. For example, in a rabbit in which the lungs were inflated about thirty times in a minute, the loss of heat was greater than in the dead rabbit; but when the process was repeated, only twelve times in a minute, the animal cooled somewhat slower than the dead one placed by for comparison. In short, in the earliest experiments, such an excess of air had been blown in as to produce a certain excess in the cooling process; but not a tittle of evidence was adduced to show that the regular animal heat can be kept up by artificial respiration, when the influence of the brain is removed. And so the conclusion becomes irresistible, that animal heat, whatever share the oxidation of the blood in the lungs—and some share it would appear to possess—may have in its production there, must be generated also elsewhere in the body; and this, as we have before seen, is just what all the best subsequent and independent observations have peremptorily proved. And, indeed, with these observations, and especially the experimental researches of Dr. Davy, which attribute the generation of a large share of the animal heat to the consumption or agency of oxygen, and different chemical processes in other parts of the body besides the lungs, Sir Benjamin Brodie's experimental results have always appeared to me to be in concord; and Mr. Hodgson's conclusion is to the same effect. Chemical changes, so far as they are dependant on the organic functions, in vertebrate animals, are under the presidency of the nervous system, or at least some part of that system; and as by these changes the heat is generated, the immediate or exciting agent of which is the oxygen distributed by the red corpuscles, the two independent sets of observations seem to illustrate each other, and this by that very beautiful harmony of contrast which Coleridge has so admirably described.

## ORIGINAL COMMUNICATIONS.

CASE OF

### VESICO-UTERO-VAGINAL FISTULA CURED AT ONE OPERATION.

By T. SPENCER WELLS, F.R.C.S.  
Surgeon to the Samaritan Hospital.

THE interesting paper on "Vesico-Uterine Fistula," by Mr. James Lane, published in the last Number of the *Medical Times and Gazette*, induces me to bring the subject of "Vesico-Utero-Vaginal Fistula" also before the Profession.

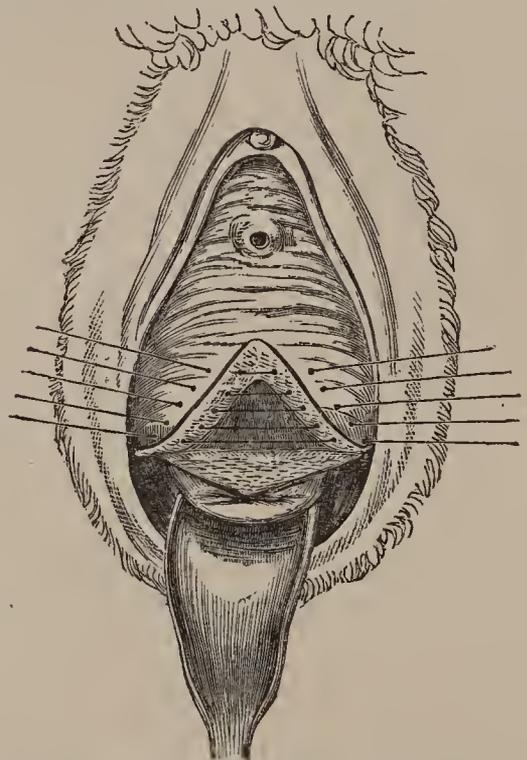

In Mr. Lane's case of vesico-uterine fistula a cure was effected by closing the os uteri, but the patient was thus rendered sterile; and, at each menstrual period, the bloody fluid from the uterus passed away through the bladder, mixed with the urine. As his patient was 45 years of age, these conditions could not be considered as objections to the proceeding which he adopted; but they would render it altogether unjustifiable in a young woman, provided a cure could be effected without any such consequences. That it may be so effected, the following case is sufficient to prove. I am indebted for the notes to Mr. E. Parson, House-Surgeon to the Samaritan Hospital, a most intelligent gentleman who has just obtained the gold medal in Midwifery and the Diseases of Women, at the M.B. Examination for Honours of the University of London.

"J. W., aged 39, was admitted to the Samaritan Hospital on March 29, 1862. She was married fifteen years ago, and has had nine children. The last was born three years ago; it was of an immense size. The labour lasted a whole day and night, and the child was born dead after the use of the forceps. The next day the urine began to pass through the vagina, and has continued to do so ever since, the usual misery connected with this condition rendering her quite unfit for her duties.

"On admission, her general health appeared to be good; but the labia, thighs and nates were much excoriated, and coated

with phosphatic deposit. The urine was ammoniacal, and contained much mucus. At the distance of two inches and a-half from the orifice of the urethra there was an opening in the vesico-vaginal septum. A curved sound, passed through the urethra, was readily carried through this opening into the vagina, and a finger passed into the vagina went very readily beside the sound into the bladder; but the opening was hardly large enough to admit two fingers. It was triangular in shape, the apex towards the urethra. Its base was formed by the anterior lip of the cervix uteri, which was split into two portions by a fissure which connected the cavity of the bladder with the canal of the cervix for a distance of about three-quarters of an inch from the os. By careful washing of the external parts, the use of oil, and frequent syringing of the vagina and bladder, the state of the urine was much improved in a few days, and the parts became much less inflamed, so that on April 7 Mr. Wells proceeded to close the fistula by operation.

"Chloroform was not given. The patient was told to ask for it if the pain became so great that she wanted it, but she bore all without a single cry. She was placed in the semi-prone position recommended by Dr. Sims, and the fistula was brought into view by his speculum. Mr. Wells first passed three silver sutures through the vaginal borders of the opening, using the wires to draw down the edges while he was paring them. This he did partly by a small knife and partly by scissors. While using the latter one of the sutures was accidentally cut; it was replaced, and a fourth and fifth passed. The annexed cut shows the appearance of the pared edges before they were brought together.

"The wires were all passed after the fashion of Dr. Sims, by a needle-holder and short needles carrying fine silk, by which the wire was afterwards drawn through. The edges of the fissure in the cervix uteri had been pared at the same time as the vaginal mucous membrane was removed, so that when the sutures were fastened—which was very readily done by simple twisting of the wires—a longitudinal line of union along the vagina came into contact with a slightly curved transverse section of the anterior lip of the uterus, as shown in the annexed cut. The apposition was so close that it seemed hardly necessary to apply a suture, but one was carried, as shown by the dotted lines in the cut, through each side of the vaginal line of union and through the cervix.

"Dr. Sims' catheter was introduced as soon as the operation was completed, and the patient was allowed to lie on either side, or on her back, as was most comfortable. The vagina was syringed twice a-day; the catheter was changed and cleaned night and morning. No urine passed by the vagina. On the ninth day Mr. Wells examined, and finding union perfect, he removed all the stitches, but kept the patient in bed for five days longer. When she got up she could retain the urine for two hours at a time, the whole passing

by the urethra. After she had been moving about for a week, M. Nélaton carefully examined the woman with Mr. Wells, and found that union was perfect. In order to see if any small opening might still remain between the bladder and uterus, the bladder was injected with warm water till it was full; but though it overflowed by the urethra beside the catheter, not a drop escaped into the vagina. Still, after this experiment, she was for several days unable to retain the urine for more than half an hour at a time. On May 13 the note is: 'Can retain the whole of her urine one hour. If she does not pass it then, there is a little dribbling from the urethra.'

"May 21.—She was discharged, the power of holding the urine gradually increasing.

"A letter, dated September 29, speaks in most grateful terms of the comfort she now enjoys compared with her former miserable condition. She is able to walk about all day without any inconvenience; but when she is lying down in bed, if the bladder becomes distended, she is obliged to get up, otherwise she could not avoid wetting the bed. This slight inconvenience is probably due to the bladder not having quite recovered its original size, and may be expected to disappear in time."

It is not uncommon to meet with cases of vesico-vaginal fistula in which the cervix uteri forms the upper border of the opening; but these do not become examples of vesico-utero-vaginal fistula unless there is a communication between the bladder and the cavity of the uterus or the canal of the cervix. I have only met with one other case of true vesico-utero-vaginal fistula besides that reported above. This was in 1857. I succeeded in closing a considerable portion of

the opening, taking great pains to avoid closure of the os uteri; but a small opening still remained, after several operations, in the cervix uteri, and the patient fell into the hands of a person who has acquired some notoriety by his treatment of vaginal fistulae. He operated, but was so ignorant of what he had done, that he boasted of having cured a case in which I had failed; and even after it was proved to him, by the fact of the menstrual fluid passing through the bladder, that he had closed the os uteri, he published his egregious failure as a successful case. This patient was a young married woman, yet her os uteri was closed quite unnecessarily,—as the first case above alluded to sufficiently proves. The annexed diagram, which shows how the uterine and the vaginal borders of a vesico-utero-vaginal fistula were brought together without interfering at all with the os uteri and cervical canal, and the successful result of only one operation, it is to be hoped will induce Surgeons to pause before they render a young married woman sterile who may be cured without any such damage.

Two practical details in relation to the cure of vaginal fistula deserve a word of passing notice—the material of the sutures, and the use of the catheter. Since this case occurred I have been gradually arriving at the conclusion that fine strong silk answers even better than wire. It is passed much more easily and with finer needles, causes less irritation of neighbouring parts, and is removed much more easily, while union takes place quite as well as when wire is used.

With regard to the use of the catheter, a most troublesome part of the after treatment, I believe it may be dispensed with altogether. The catheter certainly need not be left in the bladder, and I believe it need not be used to empty the bladder. At any rate, in one of my later cases, it was never once used after the closure of a fistula by five silk sutures, and perfect union resulted with less inconvenience to the patient than I had ever seen before. That the use of the catheter is not altogether free from danger, is proved by the frequency of catarrh of the bladder, persisting occasionally for months, after a fistula has been cured; and by one case of death which occurred at Brussels, where, although the fistula was cured, the patient died of peritonitis caused by the point of the catheter having caused ulceration, and perforated the fundus of the bladder.

Upper Grosvenor-street.

CASE OF  
DIABETES SUCCESSFULLY TREATED BY  
THE SACCHARINE METHOD, AND  
REMARKS THEREON.

By HENRY USSHER, B.A., M.B., L.R.C.S., L.M. Ed.

OBADIAH S., 31 years of age, was, two years ago, as fine a specimen of an active railway navvie as could anywhere be found. His present illness is of nine months' duration. He was discharged from Hospital as an incurable, dying man, and I certainly thought so on my first visit to him, that took place on April 3, and the following was the condition in which I found him:—He was in bed; face very much flushed; eyes glazed; tongue hanging from the mouth; lips covered with sordes; skin harsh and dry; intense thirst; inability to sleep or take a morsel of food; sternal pain severe and constant; bowels constipated. I hardly recognised the man, so attenuated was he; and he expressed his case to be hopeless. ℞ Spt. juniph. ʒj; liq. hydrarg. bi., ʒiv.; tr. opii, ʒj.; inf. tileæ Europ., ʒij. (blossoms of the lime tree, and a most excellent diaphoretic); inf. juniph. ad ʒvj.

April 7.—Pulse 96; breathing regular and more easy; sternal pain gone; eyes less glazed; lips covered with sordes; passing three pints and one-half in twenty-four hours; odour of the urine all through the house. Six months ago he had a strain, but no ill effects remained. Specific gravity of urine, 1.033; no albumen present; effervesced with nitric acid, gave off fumes of ammonia; has slept somewhat since the medicine was given to him, and made less water after the use of it. Previous to his getting worse, he had occasional vomiting, and, thinking that the man might be suffering from sarcinæ, I prescribed the following, the sugar suggesting itself in a paper I had read of Dr. Budd's:—℞ Sod. hyposulph., ʒij.; glycerinæ, ʒij.; acet. zinci, gr. xij.; aq. ad ʒvj. M. s. coch. amp. ter. die. Now, there was a marked increase in the quantity of urine voided, viz., April 8, 4 pints; 9th, 4½; 10th, 6; 11th, 8 pints. The first improvement was in his appetite, and I furnished him with a dietary, but it requires an unusual amount of self-denial from persons in this class before they will adhere to it. I think he did so generally. His sleep was middling; more thirst complained of; and his water scalded him.

11th.—Omitted the acetate of zinc, and substituted the mixture:—℞ Quinæ dis., gr. viij.; ferri am. tart., gr. x.; acid. nit. dil.; tr. hyoscyami, āā ʒj.; glycerinæ, ʒij.; aq. ad ʒviij. M. s. c. a. 4tis hōris. ℞ Pulv. Doveri nocté.

12th.—Urine paler, less smell; sp. gr. 1.035; bowels slightly opened; slept better.

14th.—Passing eight pints in twenty-four hours. Repeat mist. with ʒss. of the dilute acid.

15th.—Had a copious and satisfactory diaphoresis for the first time; urine still scalds; his tongue is cleaning, and not so dry; appetite increases; there is visible improvement; face not flushed; pulse 104, steady, and not full.

17th.—Pulse 92. Omitted the Dover's powder, and he did not rest or perspire. Specific gravity of urine 1.030, very much paler, and whitish looking; smells like whey; decomposes much sooner; crowded with crystals of uric acid. Nitric acid causes a slight fawn colour. Rep. mist. c. gr. xij. sod. bicarb.; continue the powders likewise.

18th.—Pulse 72.

19th.—Able to sit to his dinner of roast mutton, vegetables, and coffee. He is gaining flesh, but rather down in heart at his wife's illness, which turned out to be typhoid fever of a severe type, and which the child also contracted. Tongue cleaning. Passes less water. Clouds of mucus in urine. Specific gravity, 1.032.

20th.—Specific gravity 1.035.

22nd.—Still gains flesh. Makes more water at night, which I attribute to the disturbed state of his mind, then more at ease for reflection. ℞ Quinæ dis., gr. vj.; ferri am. tart., gr. x.; tr. chiretæ, acid. nit. dil., āā ʒj.; glycerinæ, ʒij.; aq. ad ʒviij. M. s. c. a. ter. hōris.

25th.—Met him out walking; he goes with the aid of a stick. Tongue losing its slimy coating. Urine gets darker, and the wheyey smell vanishes. Sweating copiously day and night. Made rather more water last night. Specific gravity 1.040.

28th.—When the urine stands some hours, clouds of

mucus float in it, looking like a fine gelatinous substance, and moving with the fluid. These clouds contain visible crystals of uric acid. The glycerine was now omitted, and the tartrate of iron increased to ℥j.

29th.—He ate some salt pork on Sunday, which brought on purging, and to-day he is voiding ten pints in twenty-four hours. I have told him to measure accurately, to see if the iron increases the quantity. Now the wheyey smell is gone, and the urine gets more of an amber colour. Specific gravity 1·037. He is much depressed in mind at his family troubles, and the consequent pulls on his diminished exchequer.

May 2.—Weighs 9 stone 6½ lbs., the former weight in health being 12 stone 11 lbs. Since the glycerine was omitted, the quantity of sugar has increased, and also the amount of urine passed, viz., fifteen and a-half pints in twenty-four hours, which plainly shows the former decrease was not due to the iron. He complains of great weakness, but looks wonderfully well, and uses a small amount of white bread and a little wine when he can get it. Now that the anxiety about his wife and child has abated, I should expect some improvement in him.

4th.—Increased thirst.

8th.—He again reverted to the glycerine, having been without any medicine for two days. Thirst gone; quantity in twenty-four hours reduced from ten pints to three; pulse 80; tongue healthy and clean.

13th.—Specific gravity 1·033; gained 3 lbs. in weight; walked to the village over one mile distant. Has again eaten some salt beef, and is purged—℞ Pulv. Cret. c. op. gr. v., sumat si opus sit. o. secund. hōris. ℞ Ol. jec. aselli coch. min. omni mane sumend.

18th.—Passed four quarts in twenty-four hours, consequent on the use of the salt meat and unguarded drinking of water. To-day his weight is 9 stone 13 lbs., showing an increase of 6½ lbs. since May 2. Urine still shows traces of sugar, turning yellow with Barreswill's solution, and when evaporated it yields a syrupy residue. Moore's test also indicates sugar, but I found the Liq. potassæ contained lead.

19th.—℞ Ferr. am. tart., ℥j.; liquoris strychniæ, gr. j. ad ℥j. ʒj.; quinae dis., gr. vj.; acid. nit. dil. ʒj.; aq. ad ʒviiij.

20th.—Again omitted the glycerine, and increased the quinine and iron, with minute doses of strychnia. It will be remembered, that on May 8, when he was without medicine, and had taken large doses of iron, it was attended with the best results, and I have continued it with the most signal benefit. I think it has some influence in arresting the elimination of sugar, perhaps in the same manner as it did albumen in the cases of my respected teacher, the late Dr. Cathcart Lees.

23rd.—The quantity now passed in twenty-four hours is a little over three pints. He eats well, looks hearty, and his only complaint is of weakness in the legs.

26th.—Weighs 10 stone 1 lb., being an increase of 2 lbs. in nine days; his average of water passed is about five pints in twenty-four hours; urine still pale by day and very clear, but of an amber colour in the morning, and smells natural; there is a very trifling shade of sugar in the urine. ℞ Fer. am. tart., ℥j.; quinae dis., gr. vj.; acid nit. dil., ʒj.; liq. strych. ʒij.; aq. camp. horæ ad ʒviiij. S. c. a. 4tis hōris. I fear he occasionally recurs to his old habit, and will not forego the beer. I have to add this fact, viz., that his illness was immediately subsequent on fright. He was jumping on burning brambles, to prevent a hedge taking fire, and after the excessive heat sat in a shady shelter, cooling rapidly; then he felt himself completely unstrung, and became worse from day to day.

His diet was a mixed one, and liberal; he took little bread. The amount of sugar, as indicated by the "companion phial" method, varied thus, during my attendance, at the following specific gravities, and an equal temperature:—April 19—1·033, 21 grains in the ounce; 1·035, 17 grains; 1·032, 17 grains. April 27—1·035, 18 grains in the ounce; 1·035, 7 grains. Here I had the misfortune to break my urinometer, and, not having a Garrod's glucometer, my observations on this head were suspended.

June 5.—Weighs 10 stone 6 lb., being a further increase.

6th.—Liq. strychniæ, ʒij.; tr. ferri mur., ʒj.; quinae disulph., gr. vj.; aq. dest. ad ʒviiij. M. sumat. coch. amplum 4tis hōris.

16th.—Continued improvement manifested; the mixture is repeated with the addition of an alterative pill. He looks well; has walked from his house to Canterbury, nearly three miles; sleeps very well; passing an average quantity of

four pints in the twenty-four hours, of which quantity about two pints are voided at night-time; no thirst continues; breath still smells melleous; pulse 96, good; has motions, two or three in the day, formerly constipated; tongue a little slimy, and somewhat sore from the alterative pills, which are discontinued; appetite better; skin acts well; diaphoresis takes place when he drinks hot coffee; flesh getting firmer, and more muscle; hair falling off. ℞ Acid. nitr. dil., ʒj.; liq. strychniæ, ʒij.; tr. ferri mur., ʒj.; quinae disulph., gr. vj.; mist. camphor ad ʒvj. M. s. c. a. 4tis hōris.

December.—The last I saw of him a few days back he was working on the South Eastern Railway; and, although he complains of languor, still I should say, from his appearance, that he was able to do a fair day's work with any one.

Remarks.—The conditions under which sugar makes its appearance in the urine, seem to be reducible in most cases to defective nervous energy, when reaction is unequal to the shock,—e.g., a patient, after much exposure and wet, secretes diabetic urine; or after great mental shock and utter prostration, the same thing obtains, an arrest of function as clearly taking place as in typhus or any other functional disorder. To which of the organs are we to attribute this change? Examination of the urine detects nothing but sugar; no evidence of decay is discoverable in any of the other organs that subserve the purposes of life. If there is any faith to be placed in the experiment that detected sugar in the hepatic veins, and the absence of it in the portal, I think we have one starting point for reflection. The presence of an hepatic organ, or its counterpart, is, I believe, almost universal in nature. It is the largest solid body in our organism; and this would seem a strong argument *à priori* in favour of its duties being manifold. Subject to excessive changes in the circulation, it enjoys a great power of adaptability: its proximity to the surface of the body, and connexion with the skin, make it highly probable that their uses are co-ordinate, illustrations of which abound both in disease and therapeutics. Practical Physicians well know how much of disease may be fairly attributed to the arrest of nervous power—that link, the severance of which terminates in death; and of its action in the body, each one is cognisant of for himself, and sees the effects in others. Constant interference with this power as surely develops disease as if it was introduced from without. If the influence is everywhere observable over mind, why not equally true of matter? Who can doubt that cancer of the stomach and heart disease are often correlatives, and even coetaneous with the "*res angusta domi?*" It is a well-known fact, that injuries of the head, and the excitement of the floor of the fourth ventricle at particular situations, influence the production of sugar in the system. This very correlation, it seems to me, may be as effectually produced through the medium of the cerebral circulation, constantly congested by the requirements of an intensely busy brain. Look at the concentrated force of the cerebral circulation, as it must be in those large vessels which compose the circle of Willis. All this is carried on close to the fourth ventricle, and a choroid plexus enters the cavity: what, let me ask, can prevent emboli acting as the source of irritation here, with precisely the same result as if mechanical means were employed? Here, I humbly conceive, we have an approximation to the truth. Lately, I was the subject of much mental worry, and became temporarily diabetic. The attack commenced with a severe pain in the right hypochondria, and remarkably severe and constant in the right shoulder. The skin was harsh and dry. I passed an unusual quantity of water; had a sweet taste constantly in the mouth, and excessive languor, thirst, and an irresistible desire to sleep, most evident on Sunday, which symptoms preceded the appearance of sugar in the urine; and, had not chance led me to examine it, I should have remained in ignorance. When the cause was removed, I returned to my original state of perfect health. External sensations will produce internal changes,—e.g., vomiting, and the suppression of singultus by fright, etc., etc. How often is the advent of typhus predicted by a sudden invasion of the nasal faculty, which then and there marks the commencement of disease, or the arrestment of function perhaps never to be reinstated? Cold, the most common of all external influences, acts thus, I believe, to determine the formation of sugar. As a necessary conclusion, then, I conceive that sugar is present often when least suspected, and that its presence is of no more moment than the hepatic disturbance that has caused it; both are evanescent. Under the

influence of mechanically obstructed respiration, sugar makes its appearance in the system, and Dr. Pavy considers this due to hepatic pressure. If this be a correct explanation, then we should expect the same results in severe cases of empyema, diaphragmatic and other pleurisies; and if this were ascertained to be so, we might have a valuable aid to diagnosis at hand. I am myself persuaded that the sugar itself causes an obstruction in the respiration, as may be seen in the worst cases of this disease. Lehmann has pointed it out in the saliva and expectoration; and the melleous odour of the breath shows that the circulating air is charged with it, and the persons afflicted are sensible of a sweet taste in the mouth. The diabetic expends largely of azotised material in the formation of sugar, and draws, in a corresponding manner, on the supply of other organs. To furnish him with this sugar in the quantities that he can appropriate, will stop the downward progress as it did in this case; while the other constituents of glycerine will help to restore the general decadence. It is, no doubt, an expensive medicine when the best quality is used; but I am sure it would soon recommend itself by economising the stay of the patient in the Hospital, reducing it from months to weeks, and thereby saving a very considerable amount of pabulum and space for others.

Canterbury.

## THE USE OF ARSENIC IN PHTHISIS.

By ARTHUR LEARED, M.D., M.R.I.A.

Physician to the Royal Infirmary for Diseases of the Chest.

It cannot be questioned that, under certain circumstances, arsenic possesses a singular power in restoring health. It is used in some countries, as is well known, for the purpose of improving the outward appearance of men as well as of horses, and its efficacy in malarious diseases and skin affections is perfectly established. Liebig's theory, that it acts by delaying the retrograde [metamorphosis of tissue, is plausible, and may be true. If, then, as appears from many indications, this metamorphosis is peculiarly active in phthisis, an agent capable of controlling it might be expected to prove valuable.

But it must be admitted that great therapeutic hopes should not be founded on mere theoretical grounds. The direct contributions of science to the improvement of therapeutics have been exceedingly small. Experience is the only safe guide; and, even in certain cases where the connexion between cause and effect in relation to the action of a remedy seems proved, we have much to unlearn. Take, for example, the universally received opinion, that we cure anæmia by giving iron because a material is supplied to the blood in which it was deficient. It is certain, however, that in some cases of anæmia arsenic will restore the complexion and the strength as effectually as iron itself. Omitting the class of direct nutrients, as cod-liver oil, manganese, and probably other remedies, possess more or less of the same power. It is also known to every Practitioner that iron often fails in curing anæmia, which goes to prove that mere chemical supply is not a sufficient explanation of its beneficial action.

In the nine following instances arsenic was used in the treatment of phthisis. The cases occurred amongst the patients of the Royal Infirmary for Diseases of the Chest, but were in no way selected. Cod-liver oil and sedatives were conjoined, as it did not seem justifiable to omit them; but most of the patients had been taking oil before admission:—

*Case 1.*—July 17, 1860.—J. H., aged 23 years, tall and very thin; ill two years. Marked dulness on percussion, and deficient respiration beneath right clavicle; profuse night sweats and troublesome cough; never had hæmoptysis. R Sol. arsen. potass.,  $\text{mij}$ .; tinct. camph. co.,  $\text{mxx}$ .; mist. camph.,  $\text{ʒj}$ , ter. in die sumend post cibos.

Under this treatment he gradually improved up to August 21, when he stated that his cough had quite disappeared—that pains in the chest which used to trouble him had vanished, and that he had now nothing to complain of but “shortness of breath.”

He went on well, the treatment being continued, until September 30, when copious hæmoptysis came on, that being the first time of its occurrence. This made him very weak, and the treatment was discontinued.

*Case 2.*—July 31, 1860.—H. C., a delicate, slightly-made man, aged 23 years; health began to fail upwards of three

years ago. Hæmoptysis in small quantities every few days for a long time; cough very troublesome; night sweats; great loss of flesh and strength.

Dulness on percussion, with very moist crepitation beneath both clavicles, but most marked on right side. Ordered the same as in previous case.

He took the medicine for two days only, when hæmoptysis to the extent of a teacupful occurred.

Died September 10.

*Case 3.*—July 31, 1860.—R. C., a tall man, of large build, aged 36; has been in failing health for six months; has had hæmoptysis. All the signs of a large cavity beneath left clavicle. Sol. arsen. potass., etc., as in former cases.

August 7.—Says he feels medicine is doing him good; is stronger; has less cough and expectoration.

September 4.—Cough not so well, but otherwise improving. Says that the night perspirations which used to saturate his shirt have been removed by the medicine.

11th.—Spat nearly half-a-pint of blood two days ago; omit cod-liver oil, but continue mixture.

18th.—Feels stronger; appetite very good; no sweating; but cough is troublesome.

October 12.—Good deal of hæmoptysis lately. Omit medicine.

*Case 4.*—August 3, 1860.—Mrs. B., aged 24 years; cough for twelve months; has lost flesh notably within the last few weeks; has had slight hæmoptysis; sweats much at night. Dry cavity in upper part of right lung.

17th.—Expectoration streaked with blood; says medicine increases her appetite.

21st.—Says the medicine has increased her appetite very much.

September 11.—Had taken, through misapprehension, only half the dose of medicine until a week ago; diarrhœa came on a few days since. The diarrhœa was controlled by small doses of morphia, but the arsenic could not be continued.

*Case 5.*—August 14, 1860.—Mrs. B., aged 40 years; out of health three years; bad cough, loss of flesh, night sweats. Has had copious hæmoptysis. Dulness on percussion under right clavicle, also fine crepitation. Medicine as in the other cases.

25th.—Does not think the night perspirations lessened; but “heat and flushing of the face,” to which she was subject, are much better, and she attributes it to the medicine. Cough not better, but expectoration less.

*Case 6.*—September 14.—Mrs. D., aged 45 years; losing flesh for five months; profuse night sweats, &c.; second stage of phthisis well marked. Medicine, as in the other cases, discontinued in a few days, owing to its causing pain in the bowels.

*Case 7.*—August 21, 1860.—Mrs. S., aged 32 years; in failing health for several months. Left infra-clavicular region dull on percussion, with moist crepitation there. Slight hæmoptysis several times. Medicine as in the other cases.

24th.—Feels better in general, but bowels rather relaxed. Omit arsenic.

*Case 8.*—August 24, 1860.—R. H., aged 22 years; healthy until last three months; slight cough; loss of flesh and strength; never spat blood; dulness on percussion below right clavicle, and well marked sub-mucous crepitation. Medicine as in other cases.

31st.—Cough not so well; but says the medicine has almost entirely stopped the perspirations.

September 28.—Going on well until a few days ago, when he appears to have caught cold. The sweating has not returned, however. Medicine changed.

*Case 9.*—September 14, 1860.—H. M., 37 years of age, says that he has been in bad health for eleven years, but much worse for about nine months. Large vomica in upper part of right lung. Medicine as in other cases. Discontinued after a few days, as he experienced a sinking sensation at the epigastrium, accompanied by faintness.

It will be observed that nearly all the patients were in an advanced stage of disease, when the irritability of the stomach, as well as the general susceptibility of the system, were likely to interfere with the medicine. Four were obliged to discontinue it after very short trials; but it is probable that hæmoptysis, which was the cause of discontinuance in one instance, and occurred in two other cases, was simply a coincidence. Of the remaining four, three affirmed the cough or expectoration to be improved, one that pains of the chest were removed, two that night-sweats had been arrested, one that

flushing of the face was much relieved, and one that appetite was greatly increased.

It seems from these cases that arsenic would be useful in phthisis by virtue of its action on the respiratory system, as well as its tonic properties, but that it is not easily borne by the digestive system, even when combined with sedatives. If anything is to be effected through the chemico-vital action spoken of, it will only be early in the disease, when the vital power is comparatively unimpaired and capable of repelling any injurious effect of the drug.

It may be mentioned here that, in consequence of a very favourable report presented to the French Academy, of the use of arsenic in doses of one-seventieth of a grain for dyspepsia, I gave the proposed remedy a fair trial, but without any good results.

I mean on a future occasion to detail my experience as to the use of arsenic in some forms of dyspnoea.

12, Old Burlington-street.

## REPORTS OF HOSPITAL PRACTICE

IN

### MEDICINE AND SURGERY.

#### ROYAL INFIRMARY FOR CHILDREN.

##### NOTES ON SCARLET FEVER.

(By Dr. WILKS.)

In this Journal for November 29, 1862, we gave a series of cases showing some of the complications and sequelæ of scarlet fever. As these cases excited some interest, we now follow up the subject. At our request, Dr. Wilks has supplied us with the following very interesting remarks. In an early Number we shall report a series of cases of scarlatinal dropsy:—

*The Scarlet Fever "Poison" more Virulent by Concentration—*

*Cases Suddenly Fatal—The Renal Affection Connected with the Exanthem, and not Secondary—Sequelæ, Sloughing of the Neck, Otorrhœa, and Deafness—Connexion of Scarlet Fever with Rheumatism—Scarlet Fever as a Cause of Heart-Disease—Secondary Fever: its Nature.*

In the neighbourhood of the Infirmary, the district being a poor one, scarlatina is always prevailing, and with more or less severity, but during the last year it has been more than usually rife and fatal in its character. There can be but little doubt that the poison (to use the common expression) becomes more virulent by concentration, and thus it is that, when the disease is prevailing in any district, or has taken up its abode for awhile in any small street or court, its victims are numerous; and it always augurs ill for any fresh patients when two or three deaths have already occurred in the same house. It would, therefore, be a boon above all medicines could the poor children, when first attacked, be removed at once into a pure atmosphere. The marked changes which are so constantly noticed in fever patients, after removal to the large ward of an Hospital, can be only due to the beneficial effects of the comparatively purer air.

When the disease is rife, and the poison thus concentrated, patients are often struck down in a most remarkable manner,—children who are well in the morning being dead at night, the only suspicion as to the nature of the ailment being the presence of the epidemic in the neighbourhood. With reference to these cases, further investigation is needed, in order to discover whether this speedy and fatal result is owing, as was formerly thought, to the scarlatinal poison concentrating itself upon the blood or upon the brain, instead of displaying itself upon the surface of the body in the more ordinary manner; or, whether the effect be not due to the simultaneous implication of the kidney,—the latter theory being supported by the fact, that the convulsions and coma, which so commonly exist in the cases of which we speak, are the symptoms ordinarily met with in renal suppression. There are, also, other cases occurring in neighbourhoods where scarlatina exists, and where the presence of the exanthem in the same house or street can alone throw a light upon their nature. For example: lately, a man, living near the Waterloo-road Station, was seized with acute pleuro-pneumonia, which was rapidly fatal; but that it was set up by scarlatina was very clearly proved, by the condition of the pharynx and surrounding parts, as seen after death.

With regard to the rapidly fatal cases, and their connexion with the kidney, there appears to be a gradually increasing opinion, that the scarlatinal renal affection is intimately connected with the exanthem, if it be not a necessary part of it, and must not be regarded as a simple secondary affection or sequela. Thus, it has been said, that, in scarlatina, three parts of the body are more especially affected—the skin, the throat, and the kidney; that, in ordinary cases, or in *Scarlatina simplex*, the rash is prominent, the fauces are inflamed, and the kidney also affected; but the latter passes unobserved. In other instances, however, the throat may be the part more particularly selected for the operation of the disease, and then the case is styled *S. maligna* or *anginosa*. Or the whole virulence of the poison may display itself upon the kidney; a suppression of its important function takes place, and death occurs through the brain in a very few hours; such a case is one of *S. renum*. Supposing, however, that the throat be unusually affected, an extensive inflammatory and sloughing process may be set up, continuing long after the subsidence of the original exanthem; in the same way, if the kidney be more than usually affected (but to a less extent than in those cases where death is speedy), an inflammation or nephritis ensues, and this continues, as albuminuria or dropsy, long after the original disease has departed. A difficulty in determining the presence of renal disease is often very great, and especially in those cases where a knowledge of it is most needed. As the urine is not always albuminous, the microscope may be used for the detection of casts; but, at the very onset of scarlatina, these will not be present, and the mere appearance of a few epithelial cells can scarcely be satisfactory evidence.

One of the most frightful of the sequelæ of scarlatina is the sloughing of the neck; the sores resulting therefrom continuing open for many weeks in scrofulous children. For these we generally use the iodine lotion. Occasionally, they may be the cause of death, as in a case lately at the Infirmary, where the jugular vein was laid open, and the child died of hæmorrhage.

Another fearful consequence is the effect on the ear, causing otorrhœa and deafness. In a child now attending amongst our out-patients at the Infirmary, hearing is quite destroyed, and there is purulent discharge from both ears, and exfoliation of parts of the mastoid process. When the disease exists to this extent it may be looked upon as one of the sequelæ of scarlatina, in the same manner as the throat affection or the nephritis, but, like those affections, probably exists to a slight degree in all cases. Where we have had an opportunity of judging from post-mortem examination, the inflammation of the pharynx has been found to proceed upwards into the Eustachian tube, and, therefore, in all probability, there is, in all cases of scarlatina, some inflammation of this tube and the tympanum, and the pain in the ears is an indication during life that such is the case.

There remains another condition in which many patients succumb in connexion with scarlatina, and this is intimately associated with the rheumatic affection, which is well-known to accompany the exanthem. This condition is very frequently styled pyæmia, but it appears to be one due rather to a peculiar state of the blood which prevails in this disease. The simple rheumatic affection in connexion with scarlatina is of a most interesting character: it is sometimes spoken of as rheumatism following scarlatina, and sometimes as pseudo-rheumatism, but it appears to be very like the ordinary, well-known joint affection, and to be intimately associated with the exanthem.

In both these diseases there is a hyperinosis of the blood, and in both a tendency to the deposition of the fibrin of the blood in the capillary system of the viscera, and on the valves of the heart; and thus endocarditis is frequently met with in both affections. The disease occurring in the tropics, styled *Scarlatina rheumatica*, is sufficient to show that their close relationship is recognised. In several cases, where a fatal result has followed scarlatina, and the patient has suffered from pains and swellings in the joints, we have found the fibrinous deposits in the spleen and kidneys, with or without vegetations on the heart; but we have not found, as sometimes suspected, a pyæmic condition arising from a purulent absorption from the neck.

This connexion between scarlatina and rheumatism has been known ever since our acquaintance with the practice of Medicine; for, more than twenty years ago, we have heard Dr. Barlow, at Guy's Hospital, state that, when seeking for a

history of rheumatism, as, for example, in a case of heart disease, we should often be told of a scarlatina having preceded the attack; or, on the other hand, if seeking for a history of scarlatina in a case of albuminuria, we should be frequently told that it followed rheumatism. In such instances, probably, both diseases had existed, but the one had been more prominent and appreciable than the other.

Such cases as this are of daily occurrence, as, for example, within a few days, the two following cases came to the Infirmary:—

Jane L., aged 5, had swelling and pain in all the joints, evidently of a rheumatic character. Ten days before she had scarlatina.

Robert S., aged 11, came to the Infirmary with a loud systolic, cardiac bruit, indicative of mitral disease. The child was said never to have had rheumatism, but had not been well since a severe attack of scarlatina three years before; at that time the mother remembers that he complained of great pain in his limbs.

The form of disease, however, which led to these remarks, and which has carried off many patients, has been a kind of secondary fever, associated with which there has been some tenderness and swelling of the joints, but the cases have never assumed a decidedly rheumatic character. It appears as if a secondary poison had been set up in the system, or that the state of blood, which is a necessary part of the scarlatinal process, continuing in full force, the patient died from that condition after the other effects of the exanthem were over. The cases are mostly of this kind, that after the child has had the disease, and the worst appears to be over, a secondary fever is set up with typhoid symptoms, and to this the child succumbs. The following is an example:—

A little girl, 3 years of age, was taken ill on March 23. The rash was out on the next day, and the throat became swollen. The child was very ill, but at the end of the week the eruption had disappeared, and the throat was better; there was, however, a discharge from the nose and from the ears. She then became worse again, and took to her bed; the skin became dry and harsh, and the whole surface mottled as if the scarlatina were about to appear again, the tongue was furred, and sordes appeared on the lips. This was on April 1. On the next day roseolous patches appeared, and some of these were livid, as though disposed to become purpuric. The child then remained in this so-called typhoid state for several days, the wrists and other joints appearing somewhat red and swollen. She was quite conscious, there being no cerebral or pulmonary symptoms, and the urine was healthy; in fact, there appeared to be no defined affection to treat, but she seemed as if she were suffering from a mere poisoned state of the blood. A large amount of nourishment was given, together with ammonia, quinine, and chlorate of potash. The mottling rash, which at times went away, at others reappeared, and, at one time, much resembled measles, when, towards the close, the spots became petechial. The child died on April 9, and was, on that day, for the first time, unconscious, shortly before death. There was no post-mortem examination; but there was never any indication of any organic disease; probably, fibrinous clots might have been found in the viscera; but, if so, these could only have been regarded as results indicative of the peculiar morbid state of the blood. The child is thus seen to have been ill seventeen days from the commencement of the illness.

(To be continued.)

### ST. BARTHOLOMEW'S HOSPITAL.

#### UNUNITED FRACTURE OF THE LOWER JAW, OF FIVE WEEKS' DATE, WITH PARTIAL NECROSIS—PERFECT UNION UNDER TREATMENT.

(Case under the care of Mr. WORMALD.)

For the particulars of this case we are indebted to Mr. Vernon, House-Surgeon.

J. W., a stout Irish lad, aged 26, applied at St. Bartholomew's Hospital, in October last, for an injury to his lower jaw, the result of a fall upon the pavement five weeks previously. His face was much distorted and swelled on the left side; articulation imperfect; mouth opened with great pain and difficulty. Careful manipulation discovered a fracture through the thickness of the body of the jaw, between the canine and bicuspid tooth on the left side. The two fragments were very movable upon each other; and the fragment holding the molar teeth was displaced upwards,

and bulging into the mouth; the gums were bleeding and swelled; the under surface of the chin was much swelled, and two or three sinuses were discharging offensive matter. The probe passed directly to the seat of fracture, and entered the mouth between the cheek and gums. He had been a patient at another Hospital; but, from his own account, had had no very strict treatment.

A loop of wire was fixed around the bicuspid tooth, and the ends were brought down and out beneath the chin, and were there fixed to a pad, with the effect of bringing the fragments in thorough apposition. The whole jaw was encased in a gutta-percha splint.

During the next fortnight small spiculæ of bone were discharged; the discharge became more healthy and gradually ceased. The wire was removed on the fourteenth day after his admission; union evidently had taken place to some extent. He left the Hospital five weeks after his admission, with thorough repair of the injury; and in a month from this date he showed himself, and said his "mouth was as sound as ever it was."

### WESTMINSTER HOSPITAL.

#### UNUNITED FRACTURE AND NECROSIS OF THE LOWER JAW, AND FISTULA, FROM OLD GUNSHOT INJURY—OPERATION—SATISFACTORY RESULT.

(Under the care of Mr. CHRISTOPHER HEATH.)

Cases of gunshot injury are of rare occurrence in the London Hospitals, except, as in the present instance, in the case of soldiers who apply for relief after being discharged from the army. Although simple fractures of the jaw ordinarily unite readily enough, the frequency of ununited fracture of the lower jaw in cases of gunshot injury has been noticed by several authors, and, amongst others, by Dr. Williamson, of Fort Pitt, in his "Notes on the Wounded from the Mutiny in India," from which we extract the following:—

"The lower jaw is well supplied with blood, so that necrosis to any great extent does not generally follow severe comminution; still, callus is not thrown out so copiously for the repair of fracture as in the long bones of the extremities. Ununited fracture of the lower jaw does not seem to have been of such frequent occurrence amongst the wounded from the Crimea as those from India.

"Six were admitted from India with fracture of the lower jaw. Of these, three were invalided, two sent to duty, and one to modified duty. Of these six cases, three were instances where the fracture remained still ununited, although the fractured ends of the bone were in contact. In one case the ball struck one side of the lower jaw, and was cut out on the opposite side one month after, fracturing the bones on both sides. In one, the ball was cut out from below the tongue. In one case, from a shell wound, there was a double fracture, one on the right side of the ramus, and also another near the symphysis, with great laceration of soft parts, and resulting deformity; the first-named fracture remained ununited. In another case there was a double fracture from a musket-ball; the fracture at the entrance of the ball still remains ununited; that at the exit has become united. In one case, from round-shot, the whole of the left ramus of the lower jaw had been extracted at the time, or came away by exfoliation, leaving a large chasm and great deformity on this side of the cheek from laceration of the soft parts. In one case there was a fracture on the left side, at the angle of the jaw, still ununited."

For the particulars of this case we are indebted to Mr. Beadles, the House-Surgeon:—

James P., aged 32, was admitted, August 19, 1862, into St. Luke's ward, under the care of Mr. Heath, for necrosis of the lower jaw.

*History.*—In March, 1860, when in the 64th Regiment, and whilst marching through Central India, he was struck on the right side of the lower jaw by a spent bullet, fired by some hill robbers. He was stunned for a few moments, and had hæmorrhage for half an hour. He went to the rear, but was able to continue the march. The following day he went into camp Hospital, under the regimental Surgeon, at which time the parts about the wound were much swollen. The wound was bathed with warm water, and the swelling was rubbed with soap-liniment. At this time he was able to open his mouth and eat on the left side without pain; but three weeks afterwards, having attempted to eat on the right side, he felt

a grating sensation and much pain, and told the Surgeon his jaw was broken; but the Surgeon did not believe him. The last molar tooth was found to have been displaced, and to be lying horizontally, and attempts were made to extract it, but unsuccessfully. It gave him extreme pain, and the Surgeon then admitted that the jaw was splintered. A gutta percha splint was now moulded on, and a bandage applied for eight days, the wound having by this time closed. On April 9, 1860, he was admitted into the Kurrachee Hospital, and another splint was applied, and kept on three or four days, when a large abscess formed. It was opened, and a large quantity of matter discharged, and the wound then healed. Another abscess began to form immediately behind the opening, and just below the original wound; and this also was opened and poulticed, and has never closed. The regiment arrived at Dover on August 6, 1861, and the man was doing duty; but the cold weather coming on, the wound inflamed and swelled up again, and he was sent into Fort Pitt on May 14, 1862. During the whole of the time he felt a numbness over the chin and all round the mental foramen. Various attempts had been made to extract the last molar tooth, which Dr. Longmore removed with some difficulty. After the patient had been in the Hospital for twenty-one days, he was, on June 26, 1862, invalided and discharged from the service.

*Present Condition.*—There is an open sinus on the right angle of the jaw leading down to dead bone and into the mouth, and he can blow air through the aperture. He can bite perfectly with the left side, and can open his mouth as wide as most people. He does not complain of any pain in the part, and his general health is good. He has never had syphilis. A small piece of bone has worked out into the mouth since admission. On looking into the mouth, a good deal of swelling about the ramus of the jaws is seen. The second molar tooth is *in situ*, but loose.

*Operation, August 26th.*—Chloroform having been administered, Mr. Heath proceeded to enlarge the external opening, and removed, with the gouge, several pieces of necrosed bone. He found that the jaw had been fractured, that it had not united, and that the upper fragment was tilted forwards by the temporal muscle, thus causing the projection in the mouth before noticed. The wound was filled with lint, and a compress applied.

28th.—Face considerably swollen, but pain slight; wound discharging freely; can blow air freely through the wound from the mouth.

Sept. 10th.—Wound has much decreased in size; two or three small particles of bone have worked out through the mouth.

20th.—The last molar tooth of the right side being quite loose, was extracted.

28th.—Says that the opening from the mouth has appeared larger since the extraction of the tooth, so that he is unable to hold fluid on that side of his mouth; external wound very much diminished in size.

November 4th.—The wound having degenerated into a small fistula, and there being no evidence of further disease of the jaw, Mr. Heath determined to attempt to close it. For this purpose, he introduced a narrow knife into the opening, and, by rotating it, pared the surface, including the skin, and then brought the edges together with a curved needle and twisted suture, over which collodion was applied.

7th.—One end of the needle having cut its way out, it was removed altogether. The wound was not united. The edges were now brought together with a strap and pad and bandage.

14th.—Wound much diminished in size; the edges touched with nitrate of silver.

22nd.—No fluid now passes through the fistula, and he says that he can feel with his tongue that the internal wound has healed.

26th.—External wound closed.

December 9.—Discharged cured. The movements of the jaw are much freer than they were, and he can eat on the wounded side without pain or inconvenience. The false joint does not appear to affect in any way the powers of mastication or articulation.

### ST. MARY'S HOSPITAL.

#### CASE OF PARALYSIS (NEUROLYTIC) OF THE EXTERNAL RECTUS OF THE RIGHT EYE—CLINICAL REMARKS.

(Under the care of Dr. HANDFIELD JONES.)

Mrs. P., aged 48, very fat and stout-made, was admitted

July 24, 1862. The catamenia had ceased ten months ago. She had had ten children, the youngest six years old.

Her first attack of head symptoms was in October, 1861; the second in April, 1862. She did not lose consciousness in either, but had pain at the top of the head, and at the "back of her eyes." From the first she recovered in six weeks; from the second she still suffers. Before the first attack she had leeches on her head a good deal. Cupping has been performed, but did harm. Was always a weakly nerved person. Her urine, which at the beginning of the attacks used to be very copious, is much less so. She complains now of burning heat at the top of the head, and of pain there at times with great heat. She has some numbness in both her hands, along the back of the fingers. Her head is not tender.

She has double vision, the right external rectus being paralysed to a considerable extent; she has to turn her head to the right in order to see properly. The pain in the head is increased in the recumbent position. Pulse apparently of good force. Bowels open; tongue clean; appetite good; and she does not feel very weakly. She has had boils lately about the pudenda. Urine clear; a week later it was examined, and found free from albumen, sp. gr. 1022.

During the first week iodide of potassium, with tincture of cinchona and infusion of chiretta, was given, but without any benefit. She was then ordered—

R Strychniæ, gr.  $\frac{1}{6}$ ; ferri et quinae citr., gr. viij.; acidi citrici, gr. viij; aq.,  $\mathfrak{zj}$ ., ter. die.

25th.—She is much improved; vision much better; action of eyes much more symmetrical.

September 8.—No double vision now, but has pains and "numby feelings" at times. Suffers with bleeding piles, and loses a good deal of blood thereby. To continue the mixture; sulphur electuary every night, and alum lotion.

The bowels were subsequently disordered with a kind of lenty, which yielded to tannin and opium internally, and she was last seen much improved October 23.

*Clinical Remarks by Dr. Handfield Jones.*—This case is well worth study in various respects. First, it may be contrasted instructively with one recorded in the *Medical Times and Gazette*, January 29, 1859, where paralysis of the left external rectus appeared to depend on the presence of a bit of dead bone in the left thumb. The paralysis in that case was of inhibitory character, and essentially similar to reflex paraplegia. In the case just related the presumption is fair that it depended on simple debility of the nervous centre, and might be designated, therefore, as simple or neurolytic. Such cases are even more proving than post-mortem examinations as to the possibility of the occurrence of dynamic paralysis without any organic change. Secondly, the difficulty of diagnosis is worth remark. The absence of marked debility, the quality of the pulse, the increase of pain in the recumbent posture, were against the view of neurolytic paralysis; while the copious diuresis, the bad effects of cupping, the bodily habit, and the somewhat intermittent character of the symptoms, might have been set down as in its favour. It was not ascertained till a later period that there was hæmorrhage from piles, and it is not at all known whether this had preceded the attacks. On the whole it seemed only prudent to commence treatment with a trial of the iodide of potassium on the supposition that the paralysis might depend on some rheumatic inflammation of the dura-mater and the fibrous sheath of the nerve. This, however, was of no avail, while direct nerve tonics produced speedily a good effect. There are many instances of a like kind, where a judicious trial and observation of the action of remedies will do more to determine the true nature of a disease than any other mode of examination. Apart from this, as it were, chemical testing, it may be laid down as a good rule, that the greater the amount of general derangement the more hope there is that the paralysis is not dependent on irremediable organic change; whereas, when the functions are all duly performed and the health good, it is but too probable that any existing paralysis is the result of some local lesion.

JUNIOR MEDICAL SOCIETY OF LONDON.—The next meeting of this Society will be held at the Whittington Club, Arundel-street, Strand, on Tuesday, the 20th, at 8 p.m., when a paper will be read by Mr. H. Cooper, of St. George's Hospital, on the "Treatment of Fever."

# Medical Times and Gazette.

SATURDAY, JANUARY 17.

## RIPE OR ROTTEN.

THE story of a jugged hare, which appeared in our last Number, is a capital illustration of that cardinal defect in Medical reasoning which the *Medical Times and Gazette* finds its special vocation in correcting (a). There are, as is well known, two ways of laying down the law. The first belongs to the *doctrinaire* or rationalistic school; the second, to the humbler-minded men, whom we will call practical, and whom the Greeks called *εμπείρικους*. The first method consists in stating some general law, and predicting certain consequences as following of necessity from its operation. The second consists in collecting the results of experience, and using them for precedents. The first, or *a priori* method, is the most perfect in itself (when applicable), and the most gratifying; but, unluckily, it is of too high an order for so imperfect a branch of knowledge as Medicine. We, who practise Medicine, must, for a long time to come, be content to gather up facts, and leave the evolution of general laws to future generations.

We find in actual life that the men who have enjoyed the largest experience are always the most careful to appeal to that experience, and not to run the hazard of enunciating general laws. On the contrary, amateurs, women, clergymen, chemists who do not practise Medicine, and young men fresh from the schools, are singularly fond of propounding dogmas *a priori*. One dogma that has gained considerable currency is that which pronounces all substances in a state of decomposition to be hurtful. There is even a school of quackery (an antiseptic school), whose main creed is that diseases proceed from decomposing food, and whose panacea is charcoal. This, we are told by the advertisements, will preserve "a sound mind in a sound body," and even a religious sanction is claimed for its use. So thoroughly is the amateur Medical mind imbued with this notion, that one of the early tracts of the Ladies' Sanitary Association, "On the Influence of Wholesome Drink," was literally founded on the notion that fermented liquors ought to be abstained from because fermentation is a kind of decay, and all decaying substances are, *ipso facto*, deleterious.

The subject is sufficiently practical to deserve a few remarks.

When we begin to investigate it by the light of experience, we shall find that it is very far from being the law, that food and drink, to be wholesome, must be in a *stable* (i.e., undecomposing) condition, or that a state of decomposition *per se* is unwholesome. In the first place, it seems to be the fact, that all moist organic substances, unless at very low temperatures, and unless they have been subjected to some special antiseptic process, are in a state of silent, but ceaseless change,—a change tending, however slowly, to reduce them to their ulti-

mate elements. In the case of fruit, there is no line of demarcation between full ripeness and incipient rottenness. The quantity of water diminishes, the acids diminish, the green rind, which gave out oxygen, is succeeded by the red or purple, which gives out carbonic acid; and, as is well known in the case of the apple and of the medlar, what is called ripeness in one is rottenness in the other. One of the best known instances of decay is the alcoholic fermentation. This is employed in the manufacture of bread. A certain portion of the sugar and starch of the flour is converted into carbonic acid, and a certain small portion of the nitrogenous matter is possibly consumed to regenerate the leaven or yeast. Hence, persons who have an interest in unfermented and aerated bread attempt to alarm the public by representing the fermentation of bread as a process both wasteful and noxious. But, for our own parts, if we compare a good fermented loaf with any specimen of unfermented bread we have ever yet seen, we become conscious of the intense privation which must be inflicted on the children of Israel during the days of unleavened bread. We have lately examined some aerated bread, and find it to be first-rate in sweetness, flavour, and colour, wofully deficient in *firmness*,—the quality, *par excellence*, which fits it to satisfy a hungry stomach, and is a proof of the goodness of its nitrogenous constituents. Assuming, then, that the non-fermented bread and the fermented are both made of equally good flour, we can but conclude that fermentation—in other words, a certain measure of decomposition—renders bread not only more palatable, but more satisfying; not only does not destroy, but develops and improves those qualities which should be conspicuous in good wheaten bread.

Of all the articles of food, milk is that whose *sweetness* we are accustomed to consider most essential to its wholesomeness. But we must not forget that in almost every part of the civilised world, except England, dishes of milk, in various states of sourness, are amongst the most popular luxuries—from the Icelanders with their skier and the Russians to the Arabs. Even in England milk is used when slightly soured, and set with rennet. Perhaps, cheese furnishes the strongest proof that certain articles, in a state of active decomposition, and yielding intensely fœtid products, may yet be not only safe or wholesome, but specifically beneficial as food. In those counties which yield much good butter, the cheese is, of necessity, poor. That of Dorsetshire, for instance, when first made, is a white, insipid curd, very pure, but we should think utterly indigestible; then it sets into a material as hard as stone, and tough as gutta percha. After this it dries and cracks, becomes pulverulent, and impregnated with a minute vegetable growth, in which stage it is called "*blue vinny*" by the natives, and is eatable and relishing, though rather dry. But in its further or prime stage it softens into a mass of the consistence of clay, with an odour which some call fine, others insufferable. They who like it call it ripe; the majority of mankind would call it abominably rotten and putrid. Not only would no London servant eat it, but even the rats in a well-bred house turn up their noses at it. But, put it before a Dorsetshire labourer, and you will see a commentary on the Homeric phrase—"*γηθήσε δε πίμπην.*" "The conscious swain, exulting in the sight," knows that this is the stuff which gives warmth to his stomach, and force to his limbs, and enables him to digest his clammy bread, and to do work which would overtax the powers of many a beefeater. If we refer to that Chapziegar cheese, whose odour has procured it the name of "*pieds des voyageurs*," it will be confessed that the distinction between fragrance and fœtor, like that between ripeness and rottenness, is not always easy to draw, and that fœtor is no proof of poison.

Butcher's meat, that is to say, the flesh of the ox, sheep, calf, and pig, as well as the flesh of domestic poultry, is insufferable to an English stomach if it have the least *taint*; yet there is no doubt that it does not acquire its full *flavour*

(a) See leading article on "Therapeutics," *Medical Times and Gazette*, 1861, vol. ii. p. 8.

till the *rigor mortis* has passed off, and that *tenderness* has succeeded which is the first stage of decay. The phrase, "*well-hung*," applied to a joint of meat, is as simple and expressive as an epithet of Homer's. As for the flesh of wild animals, the best qualified appetites pronounce that it can scarcely be kept too long; and there is many a man who enjoys the flavour of his roast pheasant or jugged hare, who would have been disgusted had he superintended the process of plucking and trussing.

As a proof that the fondness for decaying flesh is no evidence of effeminacy and sophistication by the arts and luxuries of civilised man, Bishop Colenso tells us that those innocent and unadulterated savages, the Zooloos, at whose conversion he so energetically laboured, not only greedily devour half putrid flesh, which they call *ubomo*, but that they regard this delicacy as the type and climax of all beatitude, ghostly and bodily; insomuch that missionaries have no other term than "*eating ubomo*," wherewith to describe the ineffable joys of Paradise.

Fish, as a rule, and especially oily fish, is best fresh. But the London epicure knows that there is a certain stage in the history of a turbot when its flavour is fullest, though it might have been ignorantly rejected, had it been smelled by one of the antiseptic school before it went into the fish kettle.

As for cod-fish, the man who began dinner with hare-soup, and intends to eat his way through half-a-dozen *entrées*, a roast joint, a bird, a jelly or cream, and a bit of Stilton, and to moisten the mass with two or three kinds of wine, prefers it fresh, no doubt. Not so the hungry peasants on the Scotch coast, who tell you that it is not good to eat "till it shines in the dark." The same poor creatures ferment their oatmeal into "sowens," in order to prove that man in fermenting his food obeys an universal instinct, spite of pseudo-sanitarian law, and that it is possible to wring something like a luxury even out of oatmeal.

We will refer, in passing, to the hay which is made of fermented grass, and which is not mere flavourless dried grass, but contains odours generated by decay; to the tobacco, whose flavour is developed by fermentation; and to the tea, wherewith the writer of the tract for the Ladies' Sanitary Association refreshes herself, but which yet would be dull and flavourless had not the leaves been fermented when green.

Thus far we are, we think, justified in our assertion, that a *stable*, or *fixed*, or *non-decomposing* state is not essential to the wholesomeness of food, and that all products of decay are not deleterious. Like most general laws, that against decomposition is premature and unwarranted. Experience shows that some states of decay are pernicious, and some products of putrefaction poisonous; and it is left for man's industry and acuteness to find out, in daily life, which are the instances that come under either head. Within a very few years, champagne used to come under the ban of the silly sanitarian and amateur doctor who wrote books on diet, because it was a fermenting liquid, and "it is a general law that all substances in a state of fermentation," etc., etc. So they used to forbid pie-crust, and roast goose, and crab, and duck, and pork, because they were "oily," and "it is a general law that all oily articles," etc., etc. Now, however, under the guidance of experience, the true practical Physician, the *εμπείρικος*, has learned that champagne is one of the lightest and wholesomest of wines, and has imitated the poor Dutch, and the Manchester mechanics, in their use of train oil for scrofula and chronic rheumatism.

The fact is, the stomach of every adult working animal craves for flavour. Instinct and experience have shown that flavour is an incident or product of decay, and has determined what kinds and stages of decay shall yield useful products, and be called *ripeness*, and what shall be noisome and *rotten*. The odorous matters which come into existence during various stages of the decomposition of animal and vegetable

matter, are probably more than can be imagined. Their distinctive qualities can only be learned by that use which has taught us that decaying rose leaves yield an agreeable perfume, and rotten cabbage an odious stench. But the difference between perfume and stench is subjective and conventional only. Sometimes, the anatomist, in opening an old preparation bottle in his museum, comes across a rare musky perfume, which he would think even nice did he not know that it resulted from a slowly decaying piece of man's anatomy; and they who know how to appreciate the flavour of a well-kept country ham will not wonder that our forefathers, when they translated the relics of some mediæval saint, were sometimes surprised at finding a mysterious odour proceeding from the half-dried fragments, or a fragrant oily liquid exuding from the bones. They looked upon these as instances of divine favour, which permitted the relics of the saints to exhale an "odour of sanctity," and refreshed their mouldering bones with the "oil of gladness."

### THE WEEK.

#### THE COMMITTEE OF THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY ON CHLOROFORM.

THE Committee of the Royal Medical and Chirurgical Society appointed to investigate the effects produced by the administration of chloroform, consider that the co-operation of the Profession is necessary to enable the Committee to pursue their investigations in a satisfactory manner, and they are, therefore, desirous it should be generally known that their primary object is to inquire into the use of chloroform by inhalation, and its results: (a) in the treatment of internal diseases, such as tetanus, delirium tremens, asthma, epilepsy, and infantile convulsions; (b) in Surgical operations; (c) in obstetric practice. The points on which the Committee at present especially desire and ask for information are the following:—(1) Reports of any unpublished cases of death during the administration of chloroform, or of any other anæsthetic. (2) More complete reports of fatal cases already published. (3) Notes of any accidents with chloroform in which death has been threatened, but averted. (4) Facts as to the effects of chloroform employed by inhalation as a remedial agent in disease; the mode of its administration, the quantity used, and the results both immediate and subsequent. (5) Notes as to the comparative results of operations before and since the introduction of anæsthetics. Gentlemen who may be disposed to oblige the Committee by furnishing information on these subjects, are requested to address their communications to Mr. Callender, Reporter to the Committee, Royal Med. Chir. Society, 53, Berners-street, W.

#### THE PROCEEDINGS OF THE METROPOLITAN BOARD OF WORKS.

THE proposition on the part of the Board of Works to pour one-tenth of the whole sewage of the metropolis into the Thames near Cremorne, to which we lately drew attention, has rightly excited general condemnation. Whilst we regard the whole of the present main drainage scheme as a huge blunder, we really did not expect that the Metropolitan Board of Works would have thus proposed to stultify itself, by neutralising its own resolutions and relinquishing one of its main objects, the purity of the river. We extract the following from an article which appeared in the *Times* of the 14th inst. :—

"We admit that the area to be thus relieved of its sewage is but thinly peopled in comparison with other districts; that the sewage thus discharged into the Thames would be less than a tenth portion of the whole sewage of the metropolis, and that even this is to be carefully deodorised first in a reservoir prepared for the purpose. These qualifications of the proposal will, no doubt, be pressed on our notice, and we have no wish to disguise them, but they will have, in reality, little effect in modifying the result. Though the western area

of the metropolis contains at present only a comparatively small population, it is precisely the district in which the population may be expected most rapidly to increase. Its extent is great, and it is the quarter to which London is gravitating. In a few years it may be closely inhabited; and in such a scheme of drainage as that now in hand, which is to cost us millions, we may surely ask that the exigencies of the future should receive some consideration. Then, again, although the sewage to be thus poured into the Thames is but a fractional portion of the whole flood for which provision is to be made, it is still an enormous body of refuse in itself. It is all very well to talk about 'one eleventh' part, but this part amounts to no less than 10,000,000 gallons daily. As to the previous deodorisation, it is hard to think with what face such a plan could be brought forward by the Metropolitan Board. They have already been told that they are either wrong at this point or wrong at all others. If sewage matter can be so completely divested of all noxious qualities as to render it harmless to the river even in these enormous quantities, and if the work of purification can be conducted without injury to the neighbourhood, why was not so simple and inexpensive a principle applied to the whole scheme of the main drainage? Why were all those gigantic sewers constructed on their several levels at so immense a cost for the mere purpose of intercepting the sewage from the river, if a little chemical manipulation would have secured the desired object? Why, in short, should we put ourselves to such prodigious expense in taking nine-tenths of the metropolitan sewage down to Barking, there to be out of harm's way, if the remaining fraction can be safely disposed of at Battersea? One of these plans must needs be wrong. Either the western drains at Cremorne must be injurious to the river and the population, or the discharge of the other drains at such a distance must be a gratuitous piece of folly."

It appears, however, that public remonstrance is likely, in this case, to have good effect. Mr. Thwaites has already written a letter to the *Times*, stating that a Committee of the Board have unanimously recommended that body to rescind their resolution of the 29th of June, 1858, which directed the formation of the deodorising works at Fulham; and that they have further advised that the sewage of the western area be carried into the low level sewer, to be conveyed to Barking-creek. He adds that there is little doubt but that the Board will approve of the recommendation.

#### COMBATANT AND NON-COMBATANT.

THE just complaints of the Medical officers of the army, which have lately attracted public attention, are only the latest fruits of the old jealousy of the so-called civil element which has long been fostered at the Horse Guards. Admittedly, the Doctor is a non-combatant officer, although instances are plentiful where valuable services, even in the way of fighting, have been rendered by our Professional brethren. The Royal Duke now at the head of the army owed his life, at the battle of Inkermann, to the bravery of a Medical officer; and we all remember how that type of an army Surgeon, the late George James Guthrie, taught his men, in the Peninsula, to defend themselves against cavalry by placing their backs against the bullocks of their baggage-waggon, and how he, on one occasion, attacked and captured a gun. Still, it is the business of the Surgeon to save, not to take, life. But, actual killing apart, we maintain, that the army Surgeon is a military officer, in a sense which cannot be affirmed of the chaplain or the commissary. His duties are at least as military as those of the engineer, and his services are constantly required and rendered under the hottest fire, and in the most exposed situations of the battle-field. Guthrie used to assert, that the Surgeons of the Fusilier Guards in Spain were under more fire than half the general officers of the Army. If personal bravery, coolness, and endurance be military virtues, it may well be asked whether, in any branch of the service, they are more necessary than in the Medical? The pluck required to arrest hæmorrhage from a wounded artery, when balls are whizzing about

the operator, is greater than that necessary to lead a forlorn hope. The bravest men are nervous when going into action, but, in a very short time, all thought of personal danger is lost in the wild excitement of the scene. Yet this very excitement, which gives vigour and dash to the soldier, would be fatal to the clear head and steady hand of the Surgeon. On the battle-field, as in the sick ward, he must not only seem, but be "a calm intelligence." He dares not permit himself to be carried away by the overwhelming interest of the game which is occupying all around him. We repeat, it requires more moral courage to dress the wounded under fire, than to have ridden with "the six hundred" at Balaklava. It is necessary that these facts should be borne in mind when an attempt is made to diminish the privileges and lessen the standing of Medical officers on the part of those in power, on the pretence that the original Royal Warrant has given too much prominence to, and conferred too much authority on, a civil branch of the army. If the military Surgeon is anything he is a military officer, educated in the art of healing, who devotes himself to the care and cure of his fellow soldiers. Reduce him to a mere civilian attached to the army, and you take away one of his greatest incentives to excellence by depriving him of his *esprit de corps*. It is admitted on all hands, that the efficiency of the army could not be maintained for a single week without its Medical department. It is, therefore, a suicidal policy to take every opportunity of lowering the status of the army Surgeon in his own eyes, and in the eyes of his brother officers. Last week we said that such short sighted proceedings must, and will, deter men from entering the service. If the Medical students of Great Britain are true to themselves, and to their Profession, they will refuse a service where no faith is kept, and in which a Royal Warrant can be set aside at the caprice of the military authorities. It is a noticeable fact, that the *Gazette* of last week contained an announcement of the retirement of no less than four Medical officers: amongst them is Dr. P. Frank, to whose able report on Ophthalmic Surgery we had lately to direct attention. We know nothing of the circumstances which have led to the retirement of these gentlemen; but at the present juncture the fact is highly ominous. Urged by the remembrance of the disasters of the Crimea, the Medical department were assigned by Government an honourable position and rank, and a remunerative pay; but with the return of quiet times it appears to be the intention of those in power to rescind one by one their privileges, and to reduce them to the position they held before Scutari and Balaklava. Public opinion, in the event of war, would not allow such a policy to be pursued for a day. It belongs to a class of wrongs which are pre-eminently the "cankers of a quiet world and a long peace."

#### "HOSPITALS AND THE STAFFS OF HOSPITALS."

AN able article, an extract from which has been going the round of the daily papers, has appeared under the above title in the *Social Science Review* of last week. The writer states his argument forcibly and clearly, and with an appearance of fairness which goes far to carry with him the ordinary reader. We fully agree with him in the general conclusion, that the staffs of Hospitals employed in the out-patient departments are not large enough to do the work required of them. But, at the same time, exception may be fairly taken to certain of his premises. In the first place, we entirely dissent from the assertion, that a change of sentiment is taking place in regard to Hospitals. We believe, that never did these institutions stand higher, nor more justly so, in the appreciation of the public. Of this fact, their increase, and the enormous sums which are being yearly expended in their support, are the best proofs. It may suit enthusiastic *doctrinaires* like Mr. Rawlinson to state, "that Hospitals are a mark of a degraded civilisation," and Dr. A. Uytterhoeven to brand them as

“antechambers to the graveyards;” but common sense will set down such assertions as paradox, and will consign them to the limbo of things new, but not true. In reference to the main question discussed,—viz., the sufficiency of the staff of Hospitals for their work, the Social Science reviewer draws the following lively picture of the afternoon labour of a conscientious Physician who endeavours to do his duty by 224 out-patients who presented themselves in his waiting-room:—

“We once calculated this work up in a particular instance. In this case, at half-past six in the evening, an Esculapian bee was putting on his overcoat to return home. He had taken his seat in a wooden-bottomed chair at one p.m. of that day. For the intervening five and a-half hours he had sat there, ringing his bell, calling out ‘Come in,’ examining his patients, and writing prescriptions, without a break. In the course of that period he had counted 4480 strokes of the heart, listened to 86 chests, looked at 190 tongues, asked 1120 questions, written 336 separate receipts, 11 certificates for clubs, 3 certificates of death, and brief notes in the Hospital books of 29 new patients, giving their ages, sex, occupations, duration of illness, residence, and disease. Altogether, he had given advice, gratis, to 224 people, and remarked that he fell short of his usual number. Shall we describe the man at the end of his day’s work? The description is worthy of record. He was so pale that he might have played Ghost to Hamlet in broad sunlight. He was a little deaf on one side from the frequent use of the stethoscope; one of his fingers was sore from percussing; his eyes were wearied; his back ached intensely; his head was heavy; and his voice was hoarse and tremulous. He had a misgiving that, at the close of his work, he had written a prescription for one patient on another patient’s letter, and was dreadfully put out to find that, right or wrong, the patients had gone off with their medicines. As he passed out of the Hospital, nine persons whom he had never seen in his life waited to ask him privately his solemn opinion as to cases some of which had not been before him for weeks, and of which he had no more recollection than of Adam. His face of white despair now became terrible, conveying to the anxious listeners meanings of which he had not the remotest conception; and when he got away from them all, there were still three long miles yawning between himself and his dinner and his easy chair.”

There can be no doubt that the sketch, highly coloured though it be, has a real substratum of truth. But it must be remembered that our friend “the bee” has done his work voluntarily, that he expects sooner or later—directly or indirectly—to reap a return for it, and that he does reap that return in the experience which he gathers. It is not, as a rule, at the large endowed Hospitals, but at the free Hospitals and Dispensaries, that such unmanageable crowds of out-patients present themselves—institutions of which it is no wrong to say, that in most instances they have been founded and maintained, in great measure, as fields of Medical and Surgical practice. And rightly so: the young Surgeon and Physician must obtain experience, and if, as in many instances, he has no chance of getting a footing in an established Hospital, he rallies his friends around him, and they, partly out of charitable feeling for the poor, and partly out of friendly feeling to himself, start a Dispensary or Hospital. The public find their account in it: not only are the ailments of the poor attended to, but themselves are provided with a body of Medical men possessing an amount of practical experience which formerly was limited to a very few. The system of free admission of patients has its evils, like everything else. People come to the Hospital to gossip and waste their time. The poor, huddled together in the waiting-room for hours, contaminate each other with their filth and poisonous effluvia. Children catch scarlatina, measles, and whooping-cough, and occasionally, in particular cases, there is no doubt that more harm than good results. But the picture has its opposite side, and we firmly believe that, in the long run, the good overbalances the evil. One of the assertions made by the writer of this article is manifestly a mistake. He says that an average of four minutes should be allowed to each out-patient. For certain cases five times that time would

not be too much; but it may be safely asserted that out-patients can be seen and prescribed for honestly and conscientiously by the practised Physician at a quicker rate than fifteen an hour. With regard to the gratuitous nature of the services of the Medical officers of Hospitals and Dispensaries, it is doubtless, on many accounts, a thing to be deplored. Formerly, the Medical officer of a Charitable Institution received an *honorarium*, and we believe it is so now in some of the large Hospitals, such as St. Bartholomew’s and St. Thomas’s, and in some of the older metropolitan Dispensaries, such as the Bloomsbury. But the thing appears to have arisen necessarily from the circumstances of the Profession—from the fact that it has been becoming every year more strictly a profession and less a trade. The Practitioner does not now rely upon the medicines in his surgery, but upon the knowledge and skill which he possesses; and he has found it his policy to sacrifice time and labour in order that he may increase his stock. Gratuitous Medical services have, indirectly, at least, made many a fortune; and if the system has grown into an evil, it is an evil for which we have ourselves to thank. One of the most crying evils in the system of free Hospitals and Dispensaries is to be found in the fact, that they tend to injure the Practitioners in the neighbouring district. The same objection does not so much apply to institutions where the sick are required to produce a letter of recommendation from a governor. But even then charity is too often abused. Undoubtedly, the first reform needed in our Hospital system is the exercise of some check on the shoals of *quasi*-respectable people who, well able to pay the general Practitioner his fees, present themselves under the garb of pauperism as proper objects for Medical charity.

---

THE LATE MR. JOHN GUNNING, C.B.

MR. JOHN GUNNING, formerly, and for many years, Surgeon to St. George’s Hospital, died on Sunday morning at his house, No. 52, Rue de Colisée, Paris. He had attained the great age of 90, and we believe him to have been the oldest Fellow of the College of Surgeons, his diploma of membership dating 1793. A distinguished Army Surgeon, he served on the Staff as long ago as 1792, and at Waterloo held the rank of Deputy-Inspector General of Hospitals. Whilst absent with the army under Lord Wellington, his place at the Hospital used to be filled by his then junior, the late Sir Benjamin Brodie. After the peace, Mr. Gunning returned to London, was promoted to the rank of Inspector, resumed work at the Hospital, and received the appointment of Surgeon Extraordinary to the King. After the battle of Waterloo it fell to his lot to amputate Lord Raglan’s (then Lord Fitzroy Somerset) arm. The operation was performed at the Duke’s quarters, in the village of Waterloo, in a room where Alexander Gordon lay dying, and the Prince of Orange lay wounded. The Prince used to recount that not a word announced Lord Raglan’s entry or presence till he heard him call out, in his usual tone, “Hallo, don’t carry away that arm till I have taken off my ring!”—The ring was the gift of his wife, whom he had shortly before married. About the year 1824, Mr. Gunning retired from London practice, and took up his residence in Paris. He resided there until his death. A correspondent of the *Express* writes:—

“His house was a joyous *rendezvous* for his own countrymen, at which he delighted to mix with young people, and promote their amusement. There was scarcely anything of the old man about him. His sight, hearing, memory—all his faculties, indeed—were perfect to the last, and his friends confidently predicted that he would live to a hundred. On New Year’s-day he had a dinner party; and cards for one of those little friendly dances which he loved to see were issued so lately as last week. An attack of bronchitis prevented him from receiving his friends on the day expected. His Medical attendant, Dr. Davison, thought it serious; but it

got better, and within the last two or three days he was considered to be out of danger. On Sunday morning, however, he expired in his arm-chair without pain, and with scarcely any previous symptoms to denote an approaching end. His daughter, Mrs. Bagshawe (the wife of the Queen's counsel), and two of his granddaughters, were with him at the time of his death."

## REVIEWS.

*Lectures on Surgery, delivered in St. Bartholomew's Hospital.*  
By WILLIAM LAWRENCE, F.R.S., Sergeant-Surgeon to the Queen, and Surgeon to the Royal Hospitals of St. Bartholomew and Bethlem. London: John Churchill and Sons. 1863. 8vo. Pp. 632.

THIS handsome volume does not embrace the whole of Surgery, but rather those parts of it which may be called its general principles. Nearly one-third of it is devoted to inflammation and its consequences, about one-sixth to wounds and other injuries, whilst the remaining half of the book is divided between the specific diseases, as scrofula, gout, rheumatism, syphilis, cancer, and the other varieties of so-called "malignant" disease.

The work has for its original basis the celebrated lectures on Surgery formerly published in the *London Medical Gazette*. It is now, however, divided into chapters instead of lectures, although, as the author observes, the language still retains traces of lecturing, which he has not thought it necessary to efface. We may say, in a few words, that it is an admirable book, and one adapted to the wants of all ages, ranks, and classes in the Profession. It forms a valuable set of first lessons for the young student, and a charming recreation for the senior, whose eyes will be delighted by its clear type. Its characteristic is common sense—that kind of common sense which belongs to a man of great natural power, refined education, immense experience in his Profession, and equal knowledge of men and manners. It contains the finished work of the prime of life, re-cast with the help of all those corrections and suggestions which have resulted from the author's subsequent experience.

Proceeding from a father in our Profession, the opinions advanced are not so much to be criticised as to be reviewed. We must open the book with some of that feeling of veneration with which we one and all regard its author; and we naturally read it without any disposition to carp either at the theories or practice of the writer. We shall, therefore, content ourselves, and we are certain that we shall satisfy our brethren, by stating, in Mr. Lawrence's own language, some of the views which he holds upon matters of practical interest.

First, then, in respect of the moot question of the utility of blood-letting in inflammation. Mr. Lawrence evidently is no friend to the "change of type" theory; neither does he admit the notion that countrymen bear bleeding better than Londoners:

"A notion has prevailed that the inhabitants of London and other large cities do not bear bleeding, and that the depletion which is advantageously employed for removing inflammation in the residents of the country is neither safe nor proper in Londoners. This view, which is not set forth as a deduction from experience or argument, seems to be one of the commonplaces handed from one writer and teacher to another, without direct inquiry or examination. The inhabitants of London, from the highest to the lowest, for the most part, indulge their appetites like the rest of the world, and they who live in the country do the same. Nowhere is the consumption of animal food and fermented liquors more general than in our metropolis. These habits, of which the injurious effects are aggravated in many instances by sedentary occupations or indolence, produce their natural results,—a plethoric state of system, and abundance of inflammatory diseases, both of which will soon be detected by the attentive observer in all classes. I am convinced that inflammations are as numerous and violent among cockneys as among countrymen, and I know that they can only be counteracted by the same means, which are just as necessary and safe in the one case as in the other. . . . It would require long and close observation, with careful examination of corresponding classes in cities and the country, to determine whether there is any real difference between them in the respect above mentioned. I have not met with any allusion in reference to the capital

and great cities of France or of other European countries. My own experience does not lead me to accept the notion above mentioned, or to believe that there is any essential distinction in pathology and therapeutics between town and country. We must direct our practice, in either situation, not by any abstract principle, but by careful consideration of each case."—Pp. 87, 88.

We suspect that, whilst Mr. Lawrence has remained unchanged, Professional opinion may veer round to him:

"General bleeding may sometimes, not frequently, be resorted to with advantage when it is important to subdue active inflammation quickly, or to check it decidedly. Such occasions are afforded by serious and alarming inflammatory disorders of the respiratory apparatus, whether in the throat or chest, by similar attacks of the cranial contents, or those of the abdomen.

"The same course of proceeding, or the use of such local depletion as may be equivalent to general bleeding, may be necessary to prevent injurious changes of structure in parts delicately organised—as the brain, eye, or ear—or where the function is important, and requires a perfect state of the structure, as in a large joint or the hand. In the latter case, I have often seen the greatest advantage and relief from opening a vein at the elbow."—Pp. 81, 82.

"It has been objected to the large bleedings which we sometimes find necessary that they weaken. They certainly do so in one sense; that is their object. We think that the patient has too much blood, and that the heart is acting too powerfully; that is, too strong, if those circumstances are the criteria of strength. The object, however, is to stop the inflammation, to do it effectually, and, at the same time, safely. I cannot doubt that these points will be most completely secured by employing active means in an early stage. One large bleeding generally suffices. I never saw a patient labouring under a serious inflammation injured by one venesection, however large."—Page 84.

We are surprised to find that erysipelas is not included in his volume, as the author once took a prominent share in a controversy respecting incisions.

As to the treatment of delirium tremens, he writes thus: "The treatment of delirium tremens turns on two points, the use of stimuli and that of opiates. The former is the most important in the early stage, when it may possibly supersede the necessity of resorting to the latter. When, however, the want of sleep has come on in the full development of the complaint, opium must be resorted to, and must be used freely, as the nervous system is less amenable to its influence than under other circumstances." After recommending the combination of tartrate of antimony with this medicine, he proceeds:—"It is certainly advisable to avoid the large and repeated doses of opium which have sometimes been necessary in the treatment of this affection." He then notices the use of tincture of digitalis, the sovereign remedy of the late Mr. Jones, of Jersey. "This plan of treatment," he writes, "has been followed by others without doing harm in any case, but not with invariable success. To a female, about fifty, with a bad fracture of the leg, by whom two or three large doses of laudanum had been taken without effect, I gave three drachms of the tincture, which quieted her immediately and permanently, inducing a tranquil state of the circulation, under which recovery went on most favourably."—P. 297. Let us add, that the success of Mr. Jones with this medicine in the form of the disease met with in Jersey, where spirits are cheap, and where it usually immediately succeeds prolonged debauch, was most marvellous. Such as have, like ourselves, been privileged with watching the practice of this talented and accomplished man—Surgeon, Physician, and Accoucheur—have all been strongly impressed with the value and importance of his discovery. He informed us that he never lost but one case since accident opened up to him this method of treatment; and in the Hospital practice of Jersey cases of delirium tremens were of daily occurrence.

The subject of syphilis occupies one hundred pages of the volume. The views of the author upon the question of mercury or no mercury in its treatment are thus summed up:—

"Although the researches of Mr. Rose, supported as they have been by other concurrent evidence, entirely overthrew the long-established doctrine, that the cure of syphilis without the use of mercury is impossible, and thus proved that repeated and injurious courses of the remedy are quite unnecessary, they do not, and were not intended by that gentleman to show that the remedy ought to be altogether discarded,

that it has no special power over the disease, or that it ought not to be still retained, under proper management, as the principal means of treating a large portion of venereal affections. I must, therefore, express my entire dissent from the opinions of a distinguished teacher, the late Dr. John Thompson, Professor of Pathology in the University of Edinburgh, who entirely abandoned the use of mercury both in primary and secondary syphilis, considering, not only that patients recover much better without it, but that many of the affections regarded as the secondary symptoms of syphilis, especially in their more aggravated forms, are owing to the use of mercury. For many years before his death, he trusted entirely to the simple decoction of sarsaparilla, in all forms and stages of the disease. It is likely enough that too free use of a remedy under an exaggerated notion of its powers, should be followed by the opposite mistake of disbelieving its real efficacy. These errors are gradually corrected by time, and thus it has been found necessary, in numerous instances, to resume the use of mercury after it had been entirely abandoned."—P. 565.

Mr. Lawrence notices briefly the treatment of the constitutional or secondary forms of the disease by syphilisation, as practised by M. Boeck at Christiania, and by others of his school, without expressing any opinions of his own upon its value. As regards one use of syphilisation, however, all right-minded men will agree with him:

"If I am not mistaken (he says) the notion has also been entertained that healthy persons might be rendered insusceptible of syphilis by this process of syphilisation. We cannot be surprised that the French Academy of Medicine, after a long debate, should have recorded its entire disapprobation of the whole scheme. I have heard of one instance in which the plan has been attempted in London, with results too well calculated to discourage any repetition of the experiment. I trust that this example will not be imitated, and that the inoculation of syphilis will be entirely discontinued."—P. 441.

And now, after giving our readers a taste of its contents, we close the book. Mr. Lawrence is a Surgeon of the old school, but when it is recollected for how long a period the views he re-announces upon these general topics were held, and for how long they influenced practice, it is well that we should, through the medium of such a work as this, look back upon the opinions of our predecessors, and ask ourselves whether, after all, in a few cases at least, we may not, in avoiding Scylla, have fallen upon Charybdis. Blood-letting and mercury, at all events, have not been thrown aside as harmful agents by the veteran Surgeon, who now reproduces his old teachings for our renewed instruction.

## FOREIGN AND PROVINCIAL CORRESPONDENCE.

### FRANCE.

January 10.

LOOKING over the published records of Medical science, and watching Hospital experience, in France, I do not find many brilliant discoveries or remarkable observations during the past year. There has been wanting neither patient investigation on the part of the distinguished members of the Faculty, nor any deficiency of reports from the institutions that furnish the public with the narrations of that which is passing. There is a steady march towards improvement.

The Medical School of Paris opened this year in the month of November, under the auspices of some of the most acute and experienced Professors that this country has ever known; still the number of foreign and provincial students has been somewhat diminished of late. English searchers after knowledge do not find the same necessity for this termination of their studies as they formerly did. The great Schools of London now furnish them with all the means of acquiring sound Professional information, and they are no longer compelled to come here for anatomical science. Subjects are, under the regulation now in force in London, quite as easy of acquisition as they are here; indeed, at the present time, more so; for, of late, the deficiency has been remarkable. The fee required in November from each student was 60 francs; but, up to this moment, very few have been placed on the dissecting table, and those, for the most part, in so mutilated

a condition, and without injection, so as to be, in many instances, almost useless. The prospector—for so is the demonstrator called—comes late into the dissecting-room, seems scarcely to trouble himself about individuals, and pays attention only to the general accommodation: he does not attempt to point out to the student the object which is to be kept in view, nor the means by which he is to gain information, but leaves him entirely to the anatomical volume that lays down the ordinary rules. In fact, there seems to be a carelessness which rather disheartens the student than excites him in his labours. The general accommodations of the dissecting-room, too, are altogether on an inferior scale to those that are found in the established Schools of London.

The session opened in the month of November at the *École de Médecine*, with one of those storms which essentially belong to the Schools of Paris. The pupils have never been, within the memory of man, on good terms with any of the governments of the country: looking, perhaps, to the perfectibility of the human species, they are never satisfied with things as they are, but exhibit their impatience for something better whenever they have an opportunity. Dr. Rayer, the Dean of Faculty, a man of considerable influence, and remarkable for scientific study, best known in England by his work on the "Diseases of the Skin," took his seat as President amidst a storm of noise, a volubility of exclamations, and reiterated hissing, because he had been nominated by the Emperor. When calm was re-established, which did not take place until the police had removed some individuals more noisy than the rest, the Dean delivered, with much energy of manner, an address, such as was worthy his position, and could not but be acceptable to the pupils. This was followed by a lecture from M. Gosselin, who pronounced an eulogy upon a lately-departed colleague, M. Moreau, whose conduct he called upon his audience to imitate when they commenced their Professional career. It was somewhat long and prosy: the young men took it, however, in good part, and seemed to forget their political feelings, only again to exhibit them when the opportunity presented itself of greeting with acclamation M. Nélaton, who is at the present moment their idol, not so much for his skill as a Surgeon, as a professor of liberal political principles.

The Academy of Science holds its regular meetings, at which subjects of scientific value are nightly brought forward and discussed, of which I hope to be enabled occasionally to furnish you with details. The last two meetings have been devoted to the formation of bureaus, and election of officers for the ensuing year. The only paper read at the last was by Dr. Fournie, upon the "Laryngoscope, and the Employment of Remedies to the Affections of the Air-tubes." He gives the result of his employment of different caustics; he approves of solutions of nitrate of silver; discourages the employment of gargles; and prefers the application of caustics to the amputation of the tonsils. There is considerable simplicity in the laryngoscope, and its use seems likely to become popular.

Béclard has lately added to his reputation by the production of an elementary treatise on "Human Physiology," the fourth edition of which is just issued. "A Clinical Examination of the Diseases of Women," of considerable value to obstetric science, has appeared from the united labours of Bernetz and Goupil. The Hospitals continue to be sources of most important information. Dr. Trousseau daily adds to the stock of Medical knowledge by his clinical lectures. The Hôtel Dieu has of late furnished him with some cases, which would require to be laid before you in detail did space permit. He lately gave a most admirable view of hydatid cysts in the liver: his diagnostic and prognostic skill is equal to that of any of the greatest Professors of the past or present day; and if English science claims excellence in the treatment of disease, it may fairly be said that the French School surpasses all others in its mode of ascertaining the nature and the probable effects of the maladies. M. Villeneuve still tries, at the Hôtel Dieu, the effects of various remedies, and gives most satisfactory explanations of the views that lead him to the numerous experiments that he tries in cases that enable him to form accurate judgments. One of the most valuable means of obtaining information as to the state of the general health of this city is a monthly report, presented by M. Lailler to the Medical Society, on the sanitary state of the Hospitals. It enables Practitioners to judge of the epidemics that exist, and of the character of the affections that are most predominant. Thus are obtained the observations of the most active men at the Hospital. Some changes occur always at this time amongst

the Profession at the different institutions; the Surgeons are removed from one Hospital to another. The only one I have yet heard of as decided is M. Cusco, who leaves the Midi for the Hospital Saint Louis: the Hôtel Dieu remains unchanged.

Adolphe Béclard, one of the favourites of the day, opens a course on "Fractures and Lacerations" on the 13th of this month. The Corvisart prize is offered for the best dissertation on "Hyoscyamus, Datura and Belladonna." The fashionable amusement of the day is the smoking "hachich, the hemp." M. de Luca has followed the example of Dr. Lallemand, and given a curious history of the effects of the drug. He took, at nine in the morning, at the laboratory of the College of France, two scruples of the paste as brought from Turkey; its effects upon the senses were most singular. On leaving the establishment, and walking in the street, he appeared to himself magnified, and as if he were walking in the air, whilst those he met were diminished in size; the houses appeared to run away from him; sounds were scarcely audible; distances much increased. Upon reaching home, he threw himself on his bed, and was speedily immersed in feelings of contentment and ease. All the transactions of his past life floated before him, but with such rapidity that he could retain no idea that presented itself. For four hours he was in a state of extraordinary cerebral affection, which, gradually diminishing, left him in the state of previous health.

## LIVERPOOL.

January 12.

ALTHOUGH I have already occupied some of your space with observations as to the effects of the cotton famine on the health of the people, I think that some further information about the same subject may be, especially just now, of interest to your readers. In order to obtain reliable information, I have communicated with a number of gentlemen practising in the localities in which the pressure of the distress is most severely felt, and, in order to be able to see for myself, and to describe the kind of relief which is afforded, and to see the morbid results of the distress where alone they are alleged to exist in any intensity, I paid a second visit to Preston.

I think that if I give first an epitome of the information which has been so kindly furnished me by Medical men in the suffering districts, and then some account of what I saw and heard at Preston, I shall convey a just idea of what the general sanitary condition of the county is now, and has been, during the last three months.

From Bolton, Mr. Carruthers writes to say that the health of the operatives and lower classes, in general, is satisfactory. The complaints most prevalent are bronchitis, pneumonia, pleurisy, and some croup and measles in children. About twenty cases of typhoid fever apparently originated from infection conveyed from Liverpool. A child, whose mother died of fever in Liverpool, went to Bolton, sickened, and recovered; but eight of the family into which the child was received were struck down, and two died. Two nurses who attended the family were attacked, and one died; and other cases occurred in the same locality. Mr. Carruthers had heard of no cases of relapsing or "famine fever," and believes the health of the town to be not below the average. From the same town, Mr. Garstang writes that, with the solitary exception of the family just referred to, there had not been any but sporadic cases of fever, arising from accidental causes, and by no means of an infectious character.

At Burnley, I hear, from Mr. Thomas Brown, there has been an increase in the amount of illness among those receiving parish relief. There has been a good deal of influenza, and a few cases of typhoid fever have been met with; but this disease is not prevalent. Mr. Coultate states that the amount of disease of all sorts now prevalent at Burnley is not above the usual average, and that, from the care exercised by the relief committees, any disease fairly ascribable to want has been prevented.

At Over Darwen, which was visited in 1861 with a terrific epidemic of typhus, I am informed, by Mr. Wraith, there is some rubeola and scarlatina, which are the only prevalent diseases of this class. The fatality is not great; but patients recover slowly, and most diseases appear to be more complicated and difficult of cure.

Mr. Clark, of Farnworth, says that up to the present time

(December 27) there has not been any epidemic disease attributable to the distress.

From Heywood, Mr. Brown writes that neither in public or private practice has he had a single case of fever, and that the common diseases have been coughs, colds, whooping cough, and infantile remittent fever.

At Leyland, Mr. Berry says there has been an increase of the usual style of complaints, catarrh, bronchitis, etc. He has seen but one case of fever, and that terminated favourably; and believes that what disease has occurred has not been due to scarcity of food or clothing, all being pretty well supplied by the District Relief Committee.

At Manchester, I hear from Mr. Evan Thomas that cases of maculated fever are on the increase; but that all such cases admitted into the Workhouse Fever Hospital have come from infected houses, thus showing, as far as this circumstance goes, that the disease is not epidemic. No scurvy; a few cases of purpura within the last week or two. The general appearance of the people is more anæmic than in better times. Mr. J. O. Fletcher also reports an increase of typhus, though not to any great extent, during the last four months. There has been scarlatina and hybrid rubeola, with a tendency to fall into a typhoid state, among children. Rheumatism among adults, owing to deficient clothing and the employment in farm labour, etc., of those who have always been used to work within the factories. Mr. Roe states that, in his district of the Barton-upon-Irwell Union, the number of sick has been nearly doubled during the last six months, but that the character of the complaints is not serious; catarrh, bronchitis, whooping-cough, and diarrhoea the most prevalent. Of 188 new cases occurring in the quarter ending December 24, there were only 8 deaths: 1 from fever, 1 from paralysis, 4 from bronchitis, and 2 from phthisis. In the Salford Union Workhouse Mr. Brownbill tells me there have been rather more cases of fever than there were a month or two since, but not more than is usual at this time of the year; that it has all been synochus, not typhus or typhoid. Chest affections prevalent as usual at this season.

At Middleton, Mr. T. B. Knott has noticed an increased amount of cases suffering from debility, attributable to insufficiency of food, but no increase of fever. At Mossley, I am informed by Mr. Schofield that the amount of sickness has been less than usual, and the deaths below the average, but that, within the last few weeks, fever of a continued type has made its appearance.

At Rochdale, Mr. Collingwood states that, up to the end of October, the health of the district was remarkably good; from that time to the middle of December there was an increase of sickness, followed by a decrease; so that, at the beginning of this month, disease was rather below the average. The death-rate of the past quarter has not been at any time above the average. There have been a few cases of typhus and typhoid fever, which he had no reason to ascribe to the cotton famine. At the Rochdale Dispensary, Mr. T. F. Green has seen some mild cases of typhoid; few deaths from this cause. No typhus. Heart disease much aggravated and fatal. Phthisis and other lung diseases not above the average. Exanthemata—only a few isolated cases of variola, of a mild type. Scabies very prevalent.

Mr. Brierly, of Staleybridge, informs me that, out of between six and seven hundred cases attended by him in the last three months, there have been—of typhus, 2; catarrhal fever, 16; gastric fever, some cases putting on a typhoid type, 16; scarlet fever, 14; measles, 33; itch, eczema, etc., 73; acute rheumatism, 9; the rest being made up of the cases ordinarily met with in the routine of parish practice.

At Stockport, Mr. J. Blackshaw says, we are free from epidemics; a few cases of scarlatina, measles, and fever, but not more than usual at this time of year. The Medical orders during the past year have been about 1000 more than usual; many have been for very trifling cases.

At Warrington, Mr. Spinks says, there is no disease but that which is incidental to the season; not one case of fever in his district, or in the Union Hospital, and that several Medical men in the neighbourhood give the same report.

At Wigan, Mr. Macloghlin, Surgeon to the Dispensary, finds that the health of the poor remains as it was in September, and no more fever exists than is generally expected to present itself at this time of year.

Next, as to Preston, whither I went on January 5. My first visit was to the central clothing depôt and soup kitchen, in Crooked-lane.

Here an iron warehouse, belonging to Messrs. Smith and Grime, and kindly lent by them, is now a kitchen and dining-room on the ground floor, a blanket-store, second-hand clothes stall, and work-room on the first floor, while higher up are tailors and shoemakers, and bedding and bedstead manufacturers. At the time of my visit, the dining-room was still gay with the festoons and wreaths put up in honour of Christmas. On the side furthest from the door a row of gigantic cauldrons were boiling and bubbling, and the atmosphere was fragrant with the odour of the meat, potatoes, and onions which they contained; while, on the other side, were tables surrounded by men, women, and children unanimously feeding, not with the savage energy of ravenous hunger, but with the leisurely satisfaction of people who are enjoying their dinner. They were mostly poorly dressed, some ragged, but clean and orderly. There was a policeman present, but the only duty I saw him perform was that of handing soup. In the centre of the room is a sort of office for the distribution of bread, and at one end a *quasi* butcher's shop, where a benevolent gentleman, who has made his fortune in that craft, kindly gives his time and experience to the supervision of the meat. From this establishment bread, meat soup, sweet soup, and potato hash, *alias* "lobscouse," are given in exchange for the relief committee's tickets. These articles of diet are made as follows:—Meat soup—beef, 130 lbs.; barley, 150 lbs.; meal, peas, rice, and onions, 30 lbs. each; carrots and turnips, 40 lbs.; salt, 12 lbs.; curry powder,  $\frac{1}{2}$  lb.; and water, 175 gallons. A penny ticket obtains a quart of this. Sweet soup—barley, 120 lbs.; rice, 48 lbs.; sago, 28 lbs.; meal and treacle, each 40 lbs.; salt, 12 lbs.; and pimento,  $1\frac{1}{2}$  lbs. This is a halfpenny per quart. The "scouse" is composed of mutton, 30 lbs.; onions, 12 lbs.; and potatoes, about 240 lbs. This is given twice a-week.

At 21, Great Stone-street, is the sick kitchen, whence cooked meat, beef-tea (1 lb. of beef to 1 quart of water), arrowroot, sago, gruel, tea, and wine are given on the orders of Medical men. Upstairs are employed a small army of sempstresses, tailors, and shoemakers, repairing, etc., the cast-off clothes, boots and shoes sent to the relief committee. The blankets, as, in fact, all the things which I saw, were of the best kind, and conspicuously stamped with the word "lent," to prevent them from being pawned. The beds are made of the ordinary ticking, and filled with chopped straw, which is as soft as chaff, and much cleaner and far softer than the whole straw. The straw cutting is easily managed by two or three of the ordinary machines worked by a small steam-engine. The bed, bolster, and chopped straw to fill them are supplied to the ward committee at from 5s. 6d. to 7s. Full suits of clothes for men, 8s. 6d. to 10s. 6d.; for boys, 4s. to 5s. 6d.; print dresses for women, 1s. 6d. to 2s. 8d.; stuff, from 3s. 6d. to 6s.; men's boots and shoes, new, 3s. to 4s.; women's, 1s. to 3s. I mention these money details to show that it is difficult to estimate the amount of relief actually afforded by the amount of money expended on the poor.

I noticed carefully the general aspect of the people, both at the soup-kitchen and in the streets, and, as far as such observation went, I could not perceive any difference in look from that of any miscellaneous assemblage of poor people.

To turn now to the more strictly Medical part of my inquiries, I was informed by Dr. Brown, of the Dispensary, that, after making all allowance for the fact, that many persons who in prosperous times pay a doctor have been obliged to apply to the Dispensary or the parish, that the number of patients attended by the Union Medical officers and by those of the Dispensary, has been, during the last six months, considerably above the average. At first, the effects of a diet, defective both in quantity and quality, were shown in the amount of anæmia, diarrhœa, and general debility which was met with. The increased liberality in the relief has checked considerably this class of maladies, and the convalescence from acute diseases has been rendered less protracted than it would otherwise have been, in consequence of proper articles of diet having been provided for the destitute sick from the sick kitchen.

In the latter part of the summer, typhus made its appearance, and from the beginning of October up to Christmas there was a steady average of 24 new cases a-week, according to the returns of the Union and Dispensary Medical officers; a marked decrease, however, has occurred during the last two weeks of the past year. This outbreak, unfortunately,

found the town completely unprepared with adequate accommodation: the House of Recovery was soon overcrowded, patients died, nurses and others in the house sickened at so alarming a rate, that it became evident that the House of Recovery was far from justifying its name. A temporary Hospital was, therefore, erected, and, after some inexplicable delays, the patients were transferred to it.

Through the courtesy of Dr. Ridley, under whose charge this Hospital is now placed, I had the opportunity of visiting it. The building is entirely of wood, with light iron girders in the roof, and it is placed upon a foundation of brick. Its plan is extremely simple, there being two sheds, 120 feet in length, running parallel with each other, separated by a partition which reaches only a little more than half way to the roof, so as to allow a free current of air from side to side. The total breadth is 50 feet; the height to the angle of the roof, 18 feet 6 inches. There are windows on each side, and ventilators, guarded by plates of perforated zinc, above and below each. The temperature is maintained by means of a triple row of hot-water pipes running round the building. The whole was put up in about ten days. The cases which were there at the time of my visit were almost, if not all, true typhus; those which had been recently admitted, and of which I could judge myself, were well-marked examples of this disease, with very distinct rash.

Cases of typhoid fever have occurred, and their proportional amount may be inferred from the fact, that of deaths from fever there were, in—

	Typhus.	Typhoid.
September . . . . .	4	1
October . . . . .	18	0
November . . . . .	21	4
December . . . . .	10	9

The mortality of the fever cases appears to have been at least 23 per cent.

I would make but one comment in conclusion, that there are many points to be carefully weighed before we take it as fully proved, that the disease now existing in a few spots of the cotton districts is due to deficient food or clothing, one of these being the remarkable fact, deduced by Dr. Beddoe, of Bristol, from the Registrar-General's report, that the mortality of Lancashire, for the summer quarter of 1862, was below the average, and that the whole of this diminution took place in the cotton districts; and, further, that the proportional increase of zymotic disease has been, during the past quarter, more decided in Liverpool, where the pressure of the cotton famine is not so severely felt, than in any of the most suffering places, with the single exception of Preston.

## GENERAL CORRESPONDENCE.

### THE PRESENT STATE OF THE ARMY MEDICAL DEPARTMENT.

[To the Editor of the Medical Times and Gazette.]

SIR,—At the last competitive (?) examination for the above department, the number of vacancies exceeded the number of candidates; and, as a preliminary to that of February next, we have the Medical journals strongly advising young Professional men to turn their attention elsewhere!

Nor is this all. We find leaders, comments, and letters, very much in unison in their tone, appearing in various portions of the press, daily, military, and Medical. To complete the picture, the *Gazette* of January 9, contains the following resignations, on the part of those who have long tasted the sweets of the department, and found them, it is to be presumed, only to leave a bitter savour in the mouth:—Assistant-Surgeon Dr. Macartney; Assistant-Surgeon Dr. Frank; Assistant-Surgeon Hyde; Assistant-Surgeon Frazer; all resigned.

Shortly after the appearance of the Warrant of 1858, for the first time in the history of the Army Medical department a post in it was sought by some of our best men. How is this? The causes are not far to seek. Not only has that Warrant become a dead letter, but the department has steadily and surely retrograded ever since the lamented death of Mr. Alexander.

During his reign there was a manifestly hopeful and satisfied tone prevailing amid the members of the department, and those who are best conversant with it now can state how this

has been replaced by distrust, dissatisfaction, and dislike. The latest occurrences at home and abroad would seem to have been applied as a test of how much the back of the Army Medical camel could bear.

If the Army Medical department is to be respected as a body—if its members are ever to take their stand upon the ground of regulations common to every other officer, something must be done now.

There is one only sure mode of attaining the end. It resolves itself into a simple question of ordinary business. So long as vacancies are filled, so long, depend upon it, will things not only remain, but become worse. If the pile of unfilled vacancies can only be made to accumulate rapidly upon the official backs of the Government horses, the just claims of the department must be ceded; and this is the only way, probably, in which they ever will be.—I am, &c.

January.

THE ACTION OF DIGITALIS.  
LETTER FROM MR. W. B. KESTEVEN.

[To the Editor of the Medical Times and Gazette.]

SIR,—Attention having recently been directed to the effects of digitalis, it may not be uninteresting or unimportant to your readers to have their attention directed to the opinions expressed in Dr. Fuller's recent work on "Diseases of the Chest." Dr. Fuller is well known as a man of sound practical judgment, and one who does not express an opinion without having duly weighed all the facts on which it is based. It is urged by Dr. Fuller, that the general notion of the danger attending the administration of digitalis in dilatation of the heart is incorrect, inconsistent with fact, and founded on the erroneous impression, that digitalis exercises a depressing influence over the action of the heart, and, therefore, leads to accumulation and coagulation of the blood in its cavities, if not to actual paralysis of its muscular structure. Dr. Fuller affirms, that digitalis stimulates the muscular fibres of the heart, and augments the contractility of the capillaries; that when it kills, it is not by paralysis, but by tonic contraction and spasm of the heart; that, such being the case, it is a valuable remedy in dilatation, and dangerous only when administered in hypertrophy. The grounds given by Dr. Fuller for these opinions are thus stated by the author (p. 592):—

"1st. During many years, I have observed, that the cases of heart disease most benefited by digitalis have been those in which the heart has been weak and dilated, and the pulse feeble and irregular. In these the pulse has become stronger and steadier, and less frequent under its action.

"2nd. In the only cases in which I have known death to occur suddenly during the administration of digitalis, the heart has been hypertrophied and firmly contracted. This may have been a coincidence, but, viewed in connection with the results of experiments to which I shall presently refer, it is, at least, a suspicious fact.

"3rd. Dr. Dickenson has pointed out (*Med.-Chir. Trans.*, vol. xxxix.), and I have repeatedly verified his observation, that digitalis, if given in full doses, induces violent uterine contraction, and checks uterine hæmorrhage; and, inasmuch as its action in staying menorrhagia and uterine hæmorrhage is permanent, it seems fair to conclude that it gives tone to the capillaries, and increases their contractility.

"4th. This view is borne out by what I have long since observed relative to its action in arresting hæmoptysis, viz., that, whilst effecting the object required, it does not weaken but rather increases the force of the pulse, though it lessens its frequency.

"5th. When patients die of delirium tremens, the pulse is usually rapid and fluttering before death, and the heart is found weak, flaccid, and distended with blood afterwards. These are just the cases in which, on the commonly-received doctrines as to the action of digitalis, the drug ought necessarily to prove fatal, and yet modern experience has shown that in these cases it is tolerated, even in excessive doses. My impression is, that its remedial action in these cases depends on its stimulating the heart, subduing its irritability, and increasing the tonicity and contractility of the heart and capillaries, so that the brain is better supplied with blood, and the effusion of its more fluid parts, which gives rise to the "wet brains" of habitual drunkards, is avoided.

"6th. It has been proved by experiments on animals (Dr. H. Jones) that when death is induced by digitalis, the heart is not flaccid and distended with blood, as is commonly supposed, but, on the contrary, empty, contracted to the utmost, and in a state of tonic spasm. All these facts confirm my view as to the action of digitalis; and if it is correct, its practical importance in relation to the treatment of cardiac dilatation can hardly be over-estimated."

The preceding extract places before us so clearly all that can be said on the action of digitalis, that, although long, it will not, I believe, be found too long to claim the careful attention of your readers. Having myself observed the clinical facts stated by Dr. Fuller, I would, with much deference, beg permission to endorse the practical views thus put forth on the therapeutic value of digitalis. I am, &c.

Upper Holloway, January 6.

W. B. KESTEVEN.

THE KING AND QUEEN'S COLLEGE OF  
PHYSICIANS IN IRELAND AND THE TITLE OF  
"DOCTOR."

THE following correspondence has been sent us for publication:—

(Copy.)

King and Queen's College of Physicians in Ireland,  
Dublin, November 10, 1862.

Sir,—In reply to your letter of April 4, I am directed to forward you a copy of the opinion of the Attorney-General for Ireland, from which you will see that, as a Licentiate of the College, you are legally entitled to assume the title of "Doctor"; and I am further instructed to inform you, that if any authority or individual desire to try the question legally, the College is prepared to defend the privilege of its Licentiates.

The College being in recess prevented an earlier reply to your letter. You are at liberty to make any use you please of this communication.

I am, Sir, your obedient servant,  
LOMBE ATTHILL, M.D., Fellow and Registrar.  
J. Styrap, Esq., M.D., Shrewsbury.

"King and Queen's College of Physicians in Ireland,  
Dublin, November 24, 1860.

"Sir,—I am instructed by the President and Fellows of the King and Queen's College of Physicians in Ireland to forward to you, for your information, the subjoined copy of the opinion of the Right Hon. her Majesty's Attorney-General for Ireland, as to the power of the King and Queen's College of Physicians to confer the degree of Doctor of Medicine.

"I have the honour to be, Sir, your faithful servant,

"WILLIAM MOORE, M.D., Fellow and Registrar.

"The two Charters of the College, and the several Acts of Parliament bearing thereon, having been submitted to the Attorney-General, his opinion was requested on the following query:—

"Whether the Licentiates, as such, of the King and Queen's College, are entitled to the degree and title of Doctors in Medicine, and to use the abbreviation or initial letters M.D. after their names?"

(Answer.)

"I think the Licentiates and Fellows, as such, of the King and Queen's College of Physicians, are entitled to the degree and title of Doctors in Medicine, and to use the letters M.D. after their names. (Signed)

"November 21, 1860."

"R. DEASY.

CASE OF SUSPECTED POISONING IN IRELAND.—A case of suspected poisoning is just now occupying public attention in Ireland. The supposed victim was a young lady, named Cary, aged 18, and the suspected person is domestic servant to Dr. Courtenay, Medical Officer of the Galgorn Dispensary, who attended the deceased in her illness. The body has been exhumed, and a coroner's inquest held. The viscera were healthy, with the exception of the stomach, which was said to be livid and in a state of gangrene. There was also slight congestion of the brain. The stomach and its contents have been sent to Dr. Hodges, of Belfast, for chemical examination.

## REPORTS OF SOCIETIES.

## WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, DECEMBER 19.

DR. BARCLAY, President, in the Chair.

A PAPER was read, by Dr. EDWARD HARVEY, on CONTINUED FEVER, AS IT APPEARED AT ST. GEORGE'S HOSPITAL DURING THE LAST SEVEN MONTHS.

The author remarked that, since the time of Jenner, no better opportunity than the present outbreak had occurred for studying this disease and its treatment. What is fever? That no eruption need accompany it is quite admitted, other organs manifesting its various symptoms; but as a disordered organ may produce the symptoms of fever, its diagnosis requires great attention. This care is needed, for the statistics of the years 1855 and 1859 differ materially at St. George's and the Fever Hospital. Can this be due to an epidemic varying widely in different parts of the town? The post-mortem book of St. George's shows that, from 1852 to 1861, the deaths from fever average 9 a year,—15 being the highest number, and 3 the lowest. Now in this year 16 have already died. Of these 16 cases, 4 were not examined: of the 12 that were, 3 had ulcerated bowels; 3 patches of congestion, but the glands natural; and in 6 the bowels were healthy. Thus, of those examined, 25 per cent. had ulcerated bowels, whilst it was 70 per cent. in former years. As to symptoms: 1. The eruption on the skin.—One of the 3 with ulcerated intestines had no eruption; 2 had rose-spots going away on pressure; the 6 with healthy intestines had mulberry or measles eruption; of the 3 with patches of congestion, 2 had mulberry spots, and 1 only petechiæ. The connexion between the mulberry eruption and healthy intestines—between the rose-spots and ulceration—is evident.—2. During life, ulceration of the bowels and diarrhœa co-existed. Of those who died with ulcerated bowels, 2 had mild, and 2 severe diarrhœa; 7 the bowels well open; and 2 costive. In the 8 cases of typhus fever this year, diarrhœa existed, and at the Fever Hospital it is about 1 in 5; whilst the last nine years, ending 1859, give at St. George's a percentage of 11·4. Of the 58 cases lately in the Hospital, 41 had eruption, 10 rose-spots, and 31 mulberry or measles. Of those without eruption, 2 were typhoid, 3 typhus, and the rest febricular. The total of typhus was 34, of typhoid 12, and of slight fever 12. All the typhoid had confusion of thought, but no active delirium; 10 out of 12 had diarrhœa. One-fourth of those who died had typhoid fever. Of the typhus cases, the brain was clear in 5, slightly delirious in 11, and severely so in 18. The bowels were costive in 11, quiet in 10, relaxed in 8, and given to diarrhœa in 5. Of the 58 patients, 26 came from the neighbourhood of the Hospital; 6 became infected in the Hospital. There is no instance of a typhus and a typhoid case coming from the same house. From May to December, most were admitted in July, and least in August. The treatment has, for the most part, been to support the patient by beef-tea, wine, brandy, etc., opiate and other injections being used, if necessary, for the bowels in the typhoid cases, and purgative, with care, in the typhus. The treatment of Dr. Fuller differed from the ordinary, and consisted of an emetic at the outset, with a scruple of quinine every hour for three doses, and, subsequently, quinine in smaller doses. This treatment, in 6 out of 8 cases, caused considerable temporary depression and deafness, due to the quinine. Patients on this plan mended on the ninth day, and on the seventh with the ordinary treatment.

THE HUNTERIAN ORATION.—The biennial oration in memory of the immortal genius of John Hunter will be delivered in the theatre of the Royal College of Surgeons, on Saturday, the 14th of February, by George Gulliver, Esq., F.R.S., a Member of the Council of the College.

## MEDICAL NEWS.

## UNIVERSITY OF ST. ANDREWS.—EXAMINATION FOR HONOURS.

*First Class.*—Wm. Bloxam, London, and Edward Ray, Dulwich,—Equal.  
*Second Class.*—John M. Bright, Forest-hill; John L. Pritchard, London; Charles H. Phillips, London; John W. Irvine, Lancaster; James Steele, Wishaw.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a Meeting of the Court of Examiners on the 13th, 14th, and 15th inst., and, when eligible, will be admitted to the Pass Examination:—

J. B. Brown, T. F. Lloyd, R. T. Freeman, T. Wilson, J. Mathews, G. H. Whidborne, H. W. A. Mackinnon, G. Griffiths, W. Hughes, C. F. Bullmoore, C. Adcock, F. W. Adams, R. J. Lupton, H. W. Jackson, J. A. Woodhams, H. J. Dwelly, W. C. Penn, A. Charles, A. W. Walls, E. Hyde, F. E. Chambers, J. C. Robinson, E. H. Ruddock, E. J. Hardwicke, A. Tuxford, J. R. Dowman, W. McCandlish, M. Wright, F. Sutton, J. Drust, E. Cheatle, J. Loane, C. H. Weld, R. Bonice, T. Smallhorne, D. J. Canny, S. Morton, R. W. Henderson, H. O. F. Butcher, J. Morris, R. Hay, E. B. Pearson, R. Willmot, G. R. T. Phillips, W. Wigmore, J. Shackleton, W. E. Loffe, J. Stedman, S. H. L. Murray, G. V. Wright, F. S. Taylor, H. McK. Parkes, P. K. Picard, J. Demaine, W. P. Dukes, J. P. Hewley, G. Penrudocke, C. E. Coekertau, and E. T. C. Ellis.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise on Thursday, January 8, 1863:—

Frederick Waghorn, 34, Soho-square, W.; Henry Beazeley Trimmer, Gloucester; William Thelwall, Farndon, near Chester; Allen Græme Cheek Mann, Guy's Hospital.

## APPOINTMENTS.

DAVIES, JOHN SIDES, M.R.C.S. Eng., has been elected Coroner for the borough of Shrewsbury.

GRABHAM, G., M.R.C.S. Eng., has been appointed Senior Assistant Medical Officer to the Surrey County Lunatic Asylum, Wandsworth.

HUGHES, WILLIAM HUGH, M.R.C.S. Eng., has been appointed Medical Officer to the Chorlton Union Workhouse, Withington, Manchester.

## DEATHS.

BROWN, JOHN, M.D. St. And., at Quadrant-villa, Lower-road, Islington, on January 5, aged 51.

CAMERON, EVAN P., M.D., at New Amsterdam, Berbee, on November 30, aged 53.

FENNIE, WILLIAM, Staff Surgeon-Major, at 19, Kew-terrace, Glasgow, recently.

GERRARD, JAMES, M.R.C.S. Eng., at Aboyne, Aberdeenshire, on December 26, aged 29.

GUNNING, JOHN, C.B., at Paris, Inspector-General of Army Hospitals, on January 11, aged 90.

HARWOOD, JABEZ, M.R.C.S. Eng., at Eckington, on December 28, aged 39.

HOLLAND, WILLIAM, Surgeon, in practice prior to 1815, at Over, Cheshire, on January 3, aged 69.

JONES, GEORGE HAINES, M.D., J.P., at Ashling-house, Hambledon, Hants, on January 3, aged 72.

KINGDON, WILLIAM, F.R.C.S., at Abbey Weod, Kent, on January 8, aged 74, late of New Bank-buildings.

M'DOUGAL, J., M.D., at Leith Hospital, on January 4, aged 25.

MOTT, CHARLES, M.R.C.S. Eng., at Church Stretton, Shropshire, on January 11, aged 73.

NEWINGTON, CHARLES E. H., M.D., at the Vineyard, Ticehurst, Sussex, on January 6, aged 50.

RATLIFF, RICHARD, at sea, off Bermuda, Senior Assistant-Surgeon H.M.S. *Melpomene*, on December 8, aged 34.

RITCHIE, JOHN, L.R.C.S. Edin., at Tean, near Cheadle, Staffordshire.

THOMAS, WILLIAM, L.R.C.P. Ed., at Pembroke Dock, on December 25.

GAROTTING.—Mr. George Cooper, F.R.C.S., Surgeon to the Bloomsbury Dispensary, has addressed a letter to the *Morning Post*, calling attention to a case of garotting at his own door. The subject of the assault was a poor widow, who was returning home from nursing a lady, with her money concealed in her bosom. Two men, dressed like gentlemen, assaulted her in Woburn-place, Russell-square. She was rendered unconscious by a blow on the head, and was then plundered of her wedding-ring and money—£7 10s. The woman sought shelter at Mr. Cooper's door, and has been under his care ever since. He adds:—"About the time mentioned [nine p.m.], I was engaged in visiting some patients in the immediate neighbourhood, when, on passing along the northern side of Russell-square, I noticed a policeman engaged in conversation with a man-servant at an area-gate for at

least a quarter of an hour, he being similarly occupied on my return home. My residence is only a short distance from the spot alluded to; consequently, at this period a poor woman was being thus maltreated whilst a policeman was idling his time, instead of patrolling the streets and protecting the public."

**ETHNOLOGICAL SOCIETY.**—At the meeting of this Society, held on Tuesday last, John Crawford, President, in the chair, a paper was read by the President on the "Com-mixture of Races of Man in Africa." In the course of his paper, Mr. Crawford discussed the causes which influenced the civilisation of Ancient Egypt. He observed that—"Egypt is a country in which foreign blood has been inter-mixed with native in greater abundance and variety, perhaps, than in any other part of the world. The aborigines were a peculiar race, differing from the rest of mankind physically and intellectually, even from their nearest neighbours, the Arabs and Phœnicians. Favoured by the peculiarity of the Nile, which almost spontaneously irrigated and fertilised their small country—for the Egypt of the Nile is little more than one-half of the size of Ireland—the Egyptians attained an earlier and a higher material civilisation than, perhaps, any other people, unless, perhaps, we except the Hindoos and Chinese, whose great rivers conferred upon them benefits similar to those which the Nile conferred on the people of Egypt. The late Mr. Buckle ascribed the early civilisation of the Egyptians to the capacity of their country for the production of dates,—a wild and groundless hypothesis, for it is certain that no people feeding on fruits, on roots, or the farinaceous pith of trees, ever attained a decent measure of civilisation. Some one cereal or another seems indispensable to the growth of civilisation. A people without corn never, for example, invented the art of writing. Wheat has been the chief instrument for this purpose in the temperate regions of the Old World, rice in intertropical Asia, and maize in America. The civilisation of the Egyptians, however, was of a feeble and effeminate character. Their government was an unmitigated despotism, and, in the language of Gibbon, their superstition was, of all others, 'the most contemptible and abject'—of such a character that even tolerant Rome could scarcely endure it. The Egyptians wasted their strength in building huge tombs and temples to nameless kings and deified oxen. They wanted the courage to defend themselves, and, while their wealth attracted invaders, every invader became a successful conqueror. They themselves subdued only poor tribes in their vicinity; and even so small a nation as the Jews, when they found a leader of genius, were able to baffle them, and escape from the bondage in which they were long held." Papers were also read by W. Bollaert, Esq., F.R.G.S., on a "Human Skeleton found in a Fissure at Kellet, in Lancashire," and on "Indian Antiquities from Ecuador." The latter were derived from a stratum underlying seven feet of marine clay, and represented large apes, and human beings with the crania artificially deformed. Observations were offered on the subject by Mr. Carter Blake, Mr. S. J. Mackie, Mr. Christy, Sir Charles Nicholson, and Sir John Davis. The next meeting of the Society will take place on the 20th inst.

**ST. THOMAS'S HOSPITAL.**—Mr. McWhinnie, of St. Bartholomew's, has addressed a sensible letter to the Editor of the *Morning Star*, on the subject of the future of St. Thomas's. He advocates the establishment of the Hospital near its old site, and also the erection of a country branch Hospital in some healthy open locality. We extract a passage from his letter:—"In most of our Hospitals, the vacant beds, excepting those which are reserved for casualties, are, on a certain day in the week, filled from amongst the numerous applicants, many of whom, of necessity, cannot obtain admission. Such selection, for many reasons, is often a very painful task. One of my colleagues—the Physician of the week—would recollect, whilst sharing the duty with me, saying, 'On these occasions, one ought to have a heart of stone, in having to reject so many distressing cases.' Now, not a few of these cases are constantly turned away, not on account of the insufficiency of bed accommodation, or that their complaints are of a trifling nature, but are refused, and constantly refused, because the air of our wards is judged unsuitable to them. Some of these poor persons may have been sent up expressly from the country, and thither they are recommended at once to return. Now, what a boon it would be, as I have frequently remarked, to the almoners in

the admission-room, for our Hospital to be able to command, for properly-selected cases, a few beds, in a convenient and healthy spot, there to receive some of the advantages they enjoy when sent by us to a sea-side Infirmary, while they would be more within our reach and continued supervision. There are other cases of a description more especially Surgical, whose treatment might, not only with safety, but even advantage, be postponed for time and season. One single illustration may be allowed for my argument. An operation of comparatively modern date, and which originated with an English Surgeon, Mr. Park, of Liverpool, consists in relieving a patient of an irreparably diseased joint without sacrificing the entire limb, which, being thus preserved to the sufferer, remains of considerable use to him afterwards. Now, the statistics of this important operation, which is considered one of the triumphs of conservative Surgery, tell much in favour, as we should expect, of its performance in the country, for the patients requiring it are frequently of a weak and scrofulous habit, and I have, for this reason, as friends associated with me know, declined on more than one occasion undertaking it in St. Bartholomew's Hospital on patients, though sent up for the purpose, and whose cases were deemed proper for this treatment; and although the operation is not unfrequently attended with a happy result in our London Hospitals—in some it is performed in more instances than in others—yet no Surgeon would affirm that a case of this description would not, with the same judicious treatment, have a better chance of recovery in pure air. The same applies to other operations: instances could be multiplied. 'Let me have,' as an eminent *confière* once said to me, 'the skill and experience of a Hospital Surgeon, with the advantages of country air and scene, and I believe that there is scarcely a London operator who would not prefer such were he himself the sufferer from a complaint of this kind.'"

**THE HOTEL DIEU.**—The Paris correspondent of the *Times* writes:—"The demolition of the Hospital of the Hôtel Dieu and its reconstruction, which the inhabitants of Paris have loudly called for during many years, are at length decided on. The place on which the new Hospital is to be erected is not yet fixed; but a decision must shortly be adopted, inasmuch as the present building is so defective. This is the second time that the Hôtel Dieu will have been displaced. The primitive position of the Hôtel Dieu was to the south of the little church of St. Christophe, nearly in the middle of the *parvis* of Notre Dame. The Seine was not then, as it is now, confined with walls, and its waters, after the least flood, washed the wall of the old city. During the excavations made in 1847 the foundation of this wall was discovered. It followed a line parallel to the river, and its position is distinctly indicated by the iron railing of the garden of the Hôtel Dieu in the Rue Neuve Notre Dame. The present building, consequently, could not have been erected until after the demolition of that wall. The opening of the Rue Notre Dame, which was accomplished in 1181, in order to facilitate the approach to the grand entrance to the church then being constructed, and which absorbed a portion of the church of St. Christophe, coincides with the destruction of the Gallo-Roman wall. Thus the appellation under which it was generally known—*Hospitale Pauperum quod est apud ecclesiam Sancti Christofori*—was beginning to be replaced by its present title, *Domus Parisiensis Dei*. The Hospital, moreover, did not in those distant ages possess the character which it subsequently acquired. It was rather a house of refuge for mendicants and foreigners. The friars, according to the ancient custom, washed the travellers' feet. It was not until the reign of Philippe Auguste that invalids were admitted. This Prince, who may be called the founder of the Hospital, built the Hall St. Denis and its additions. Blanche de Castille, his daughter-in-law, founded the Hall St. Thomas, and Louis IX. built the large hall on the bank of the river and a chapel beside the Petit Pont. The crypt, which extends under the ground occupied by the old church and by the Hall St. Thomas, and which now serves as a wine-cellar, has preserved the character of the period, and the distinct signs of the 13th century. Louis XI. decorated the two doorways opening on the Petit Pont. All the buildings on the banks of the Seine were constructed during his reign. In 1535 Cardinal Duprat constructed a magnificent building called the Legate's Hall. It occupied the place now used as a clothes store. When Francis I. heard of this munificent act of the Cardinal, he observed that the hall should be very large to contain all the people he

had ruined. It appears from the bill of the carpenter who made the beds for this hall, that a bench was placed beside each bed, called 'the bench of repose,'—that is, if the bed contained three invalids, it might be made to accommodate six by permitting three to sit on the bench while three took their turn in the bed. During an epidemic which prevailed in Paris, eight persons were placed in a bed. The buildings of the Hôtel Dieu being in a dilapidated state during the reign of Henry IV., they were repaired by that monarch. Between the years 1802 and 1804 the Hôtel Dieu was again repaired, and the building lost its mediæval character. The chapel, with its doorway, was taken down, and the architect, Clavareau, replaced the handsome and delicate work of the 13th century with a heavy peristyle."

**SALTED SLUGS.**—The author of "Life in Normandy," a book full of curious details of the customs of the Norman peasants, tells us that they add to the pleasures of their table by partaking of sea-crows, cuttle-fish, limpets, frogs, snails, and maggots. He illustrates the nutritive properties of the latter by the following:—"An Irish gravel-digger lately died near Sydenham, leaving his widow and family utterly destitute, save that he had built them a hovel against the side of the gravel-pit, which was on the common. There the widow and the orphans lived, and it was observed that, though they had no visible means of earning a livelihood, they were fatter and rosier than any labourer's family in the parish. About this time hen-roosts were robbed and sheep were stolen in the neighbourhood, and the plump widow and her rosy family were at once set down for the thieves. A warrant was granted to search her house, and the policemen found what they deemed proof of her guilt. They took her in custody, and bore with them the proof in the shape of a good-sized cask, containing, as they said, the sheep, salted and minced into morsels. The poor woman denied that the little salted morsels were of the composition of mutton, but she refused to say what they were to 'them blackguards'—the policemen. She told the magistrate, however, what they were. 'Send them fellows away, and I will tell your honour,' she said. Under the seal of secrecy she let out that they were salted slugs. She had seen them given in Ireland to a young man who was supposed to be in a consumption, and who grew fat and well on the diet; and, failing other means of subsistence, she tried the same food for her starving children. She first tried the slugs fresh; they were found to be good and nourishing; and then she took to salting them for winter consumption. Her mode was to drop the slugs into boiling water, and then to lay them with salt in a cask." The author concludes the story with the obvious moral, that no one need starve where there are plenty of black slugs to be got.

### NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

C. S. R.—Let bygones be bygones.

Dr. Abbotts Smith.—The communication shall appear. Want of space only has delayed it.

An Agriculturist.—We shall be happy to publish the letter if the author will favour us, in confidence, with his name and address.

Vacancy.—A House-Surgeon is required to the Lock Hospital, Dean-street, Soho.

To Correspondents.—All communications intended for publication should be authenticated, in confidence, by the enclosure of the author's name and address; but especially should communications be so accompanied which reflect in any way upon the character, doings, or writings of others.

#### EXTENSION OF AREOLA IN PREGNANCY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Can you or any of your readers inform me whether the following is an uncommon occurrence:—

A woman, aged 21, recently delivered with her first child, has an areola round the nipple, measuring  $4\frac{1}{2}$  inches in diameter, and of a very deep brown colour; both breasts are alike, and, as they are not unusually full or large, this circle of nearly 13 inches in circumference has a very singular appearance. The woman is rather stout, and has fair skin and hair.

Portsmouth, January 14.

M.D.

#### NITRATE OF POTASH AND THE FIBRINOUS COAGULATION OF THE BLOOD.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Dr. Basham, in his interesting lecture on the treatment of acute rheumatism by nitrate of potash (*Medical Times and Gazette*, December 20, 1862), lays it down as an ascertained fact, that "nitrate of potash, circulating in the blood, prevents the separation or coagulation of the fibrin." On December 23, I observed, in performing a post-mortem examination, a fact which must, to a considerable extent, modify the position assumed. The patient had died somewhat suddenly on the morning of the 22nd. He had long been labouring under the general paralysis of the insane, and was known to have heart disease, but presented no severe disturbance of general health until about ten days before death. He was then observed to be getting rapidly dropsical. The serous cavities and cellular tissue of his body were gradually filling and becoming infiltrated with serum, and symptoms corresponded—dyspnoea, prostration, cutaneous ulceration, etc. The urine was tested and found albuminous, and physical signs of mitral regurgitation were revealed on examination. Nitrate of potash was prescribed in the doses of gr. xii. every two hours, in combination with Spirt. eth. nit., considerably diluted, and was sustained up to the time of death. On examination the blood was found to be generally very dark and coagulated; and the heart, which was hypertrophied, dilated, and fatty, contained, especially on the right side, a large quantity of black sanguineous coagulum and masses of fibrinous clot encircling the tubercular structures of both ventricle and auricle, and continued into the large vessels.

Other pathological appearances were very interesting, but foreign to the point in question. The kidneys were severely affected with Bright's disease, and what remained of their pyramids congested.

Durham County Asylum, January 14.

#### SCARLATINA CO-EXISTENT WITH MEASLES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your Number of last week I read with much interest a short letter on the above subject; and having lately met with a case somewhat similar, I forward you a short account of it. In this case the scarlatina preceded the measles.

W. T., aged 2 years and 8 months, was taken ill on December 7. I first saw him on the evening of the following day, when there was a very distinct rash of scarlatina on the abdomen, arms, and legs. There was no eruption on the face, but the mother states that she noticed the rash on the face and neck last evening and this morning. The surface of the body was very hot. There was no swelling of the tonsils. On the 10th, the tonsils were slightly swollen. On the 13th, the rash had disappeared, and the cuticle began to desquamate; the tonsils rather more swollen. On the 16th he appeared quite well, and all swelling about the throat had subsided. On the 21st, a peculiar mottled eruption, of a dark purple colour, appeared on the face and neck (where the mottled appearance was most marked), ultimately extending to the abdomen and extremities. The eruption on the abdomen was slightly raised, and felt rough to the feel; and the day following the cuticle began to be detached in branny scales. On the 24th, the child died comatose, eighteen days from the beginning of the illness, and the fourth day from the appearance of the second rash. I may mention that on several occasions during his illness the child parted with large lumbrici.

I should be glad if some of your correspondents would give us the benefit of their experience on this subject, as so little is said about it in Medical writings.

I am, &c.

January 10.

AN INQUIRER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—If you can make room for them, the following notes of a case of co-existent measles and scarlatina, which I attended about three years since, will interest your correspondent, "R. C. B.," and possibly others, as such cases are uncommon:—

A young lady, aged 18, whose sister had just passed favourably through measles, but who was not known to have been exposed to the infection of scarlatina, was attacked with catarrhal symptoms, and, when seen the following morning, had a few spots of commencing measles eruption, and the ordinary symptoms of that disease. On the third day of indisposition, the measles eruption had but little developed, and was still confined to the face and neck, but, in addition, the diffused rash of scarlatina had also made its appearance; the tongue and throat were characteristic of the latter disease. Later in the day the throat had begun to ulcerate, the

scarlatinous eruption was more marked, the measles rash, as before, slightly so; and it became a question if the case were not simply scarlatina. The following morning, however, both rashes were well marked; the measles rash had put on the crescentic arrangement—the scarlatina was more general, and deeper in tint. My partner saw her with me, and agreed that there could be no doubt as to the co-existence of the two diseases. In the evening of this day there was a violent attack of palpitation and dyspnoea. (A bruit had previously existed, but there had been very slight results produced by the heart disease, nor has it produced much inconvenience since her recovery.) The next morning the rashes were both paler, but the measles more so than the scarlatina, which was more extensively diffused than ever. The throat and other symptoms improved. By evening the measles rash had almost disappeared; the scarlatina much as in the morning. From this time convalescence was steady. The cuticle desquamated very freely. I am, &c.

Heath-street, Hampstead, January 10. ROBERT R. FRANCE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your journal of January 3, "R. C. B." asks if any one has seen scarlatina existing with measles? and, in the same journal, "A Medical Student" doubts the rheumatic character of the acute arthritis that sometimes supervenes in cases of scarlet fever. At the present time I have one case under my care that illustrates both questions:—

A boy, aged about 8 years, was first taken ill with measles; on the going off of the rash, sore throat came on, and was followed by the rash and other symptoms of scarlet fever, accompanied with tenderness of the joints, and, at times, great perspiration. The day after the commencement of desquamation, the pains in the joints became worse; the perspiration became profuse; the tongue, which was dry and red, has become moist, with a thick white fur; pulse 144; and urine, from being abundant and clear, has become scanty and high-coloured, with lithates. There is now effusion into some of the joints, and desquamation, which was very limited, has ceased.

Without being aware of the previous history of the case, I doubt whether "A Medical Student" could diagnose the case to be anything but acute rheumatism. The boy's two sisters and mother have had the measles, and one sister has since had the scarlet fever, and is now in the desquamation stage.

It is the opinion of some, that no two poisons can exist in the body at the same time, each producing its own peculiar symptoms. The above case illustrates that measles, scarlet fever, and rheumatic fever may follow so close, one upon the other, that you cannot say that the action of one poison has ceased before that of the other has begun. I have before witnessed the appearance of the rash of scarlet fever the day after that of measles had faded. That small-pox and measles may occur together in the same subject is another fact.

A little girl, whom I recently attended, was taken ill with a mild attack of small-pox; there was an abundant crop of pustules, and on the second day of their appearance the rash of measles appeared, and she went through the two diseases together. Her brother had them separately, the measles first, and the small-pox when convalescent of the former. I am, &c.

11, Craven-hill Gardens, January 13. J. BRENDON CURGENVEN.

CHLOROFORM IN OVIOTOMY AND PARTURITION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The interest attaching to ovariotomy at present is so great, and objections are so often made to chloroform in this operation, for fear of syncope following the tapping and removal of some quarts of fluid, that it seems desirable to state the fact, that there are really very few operations where there is such and so great a "tolerance" of chloroform as ovariotomy; whilst in two or three cases (out of about thirty where I have administered chloroform for this formidable class of cases), where some faltering of the pulse came on, the immediate substitution of sulphure ether at once restored the pulse and respiration.

A very erroneous, quackish idea has got abroad, that there is some new specialism or mystery in giving chloroform so that it shall not go the "round of the circulation." And we can have parturition without pain, or chloroform in the circulatory current! as we may have the present year 1863, perhaps, without the usual 1st of April in the "round of its circulation," a day dedicated to not overwise people who believe and subscribe to everything they see in print. We do not know exactly how much chloroform is taken up by the circulation; the quantity is, however, very small, and it probably exists as a vapour in the blood (like ammonia?) and certainly not at all, as recently described in America, in shape of some theoretic new formic abstraction. It is, of course, quite absurd that we can produce anaesthesia (now more generally termed "analgesia"), as in parturition, by rapidly-repeated but interrupted impressions on the nervous system, which prevents the chloroform getting into the blood. This is as nearly nonsense as we can conceive anything to be; yet it is put forward as beyond contradiction—as the theoretic formic abstraction from America, which destroys the blood altogether.

I find some very erroneous ideas on chloroform, also, in a book of Casper, just brought out by the Sydenham Society—ideas long since exploded by the earlier experiments of our late able friend, Dr. Snow. The fact is, in fine, the use of chloroform is becoming simpler and safer every year in midwifery and such operations as ovariotomy; and safer according as its use is simpler. We only encumber it with patent Calabrian pipes and bags, and aromatic spices of nutmegs, cloves, pterocarp chips, etc., which are to anaesthetics what the infallible virtues of "puccoon" were in curing all forms of cancer when mixed with chloride of zinc and other caustics, no credit being given to the caustics themselves.

Chloroform vapour in the blood most probably lessens for a short time the peculiar nervous polarity of the cells of the grey matter of the sensorium, as this polarity is described, for instance, by Dr. Radcliffe, or the late Dr. Todd. It exists in the blood in a different state from either ether or carbonic acid; the former (ether) not only is dissolved in the blood, but it seems to dissolve out the fat of some tissues, which fat glistens in spiculae under the microscope in the blood of other patients. And as to carbonic acid and oxide, if Mr. Gulliver would try their effect on blood globules and report on it, he would astonish his readers. The action of all these agents, in fact, is well known, so that it is absurd to say in parturition no chloroform becomes mixed with the blood.

Chloroform vapour in the blood is always striving to make its exit again, having completed the entire figure 8 of the circulation. There has not been a single accident from chloroform in midwifery. This is due, as I conceive, to the active healthy state of the reflex and respiratory systems

during labour, and not at all to this new or quackish idea, so painful to be obliged thus to comment upon. I am, &c.

APPOINTMENTS FOR THE WEEK.

January 17. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.

19. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.  
MEDICAL SOCIETY OF LONDON, 8½ p.m. Dr. Richardson, "On Alcoholic Phthisis."  
ROYAL INSTITUTION, 2 p.m. Special Meeting of Members.

20. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.  
ROYAL INSTITUTION, 3 p.m. Professor Marshall, F.R.S., "On Animal Mechanics."

21. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.

22. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopaedic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.  
ROYAL INSTITUTION, 3 p.m. Professor Frankland, F.R.S., "On Chemical Affinity."

23. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.  
ROYAL INSTITUTION, 8 p.m. Professor Tyndall, F.R.S., "On Radiation through the Earth's Atmosphere."

EXPECTED OPERATIONS.

King's College Hospital.—The following Operations will be performed on Saturday (to-day) at 2 p.m.:—

By Mr. Fergusson—For Necrosis of Tibia; Removal of Dead Bone from Hand; Lithotrity.  
By Mr. Henry Smith—Removal of Tumour from Thigh.

# NEPENTHE, OR ANODYNE TINCTURE.

OBTAINED EXCLUSIVELY FROM OPIUM.

Prepared only by **FERRIS, TOWNSEND, LAMOTTE, & BOORNE**, Manufacturing Chemists and Wholesale Druggists, Bristol.

Messrs. FERRIS AND COMPANY take leave to direct the attention of the Medical Profession to a selection from various reports upon the use of this most valuable form of Opium. NEPENTHE may be used with perfect safety in every case where an opiate is indicated; and, from the peculiar process by which it is prepared, it is deprived of all constituents which render the Tinctura Opii, and most other forms of opium, in numerous instances, wholly inadmissible. NEPENTHE is always of uniform strength, and, in this respect, possesses high advantages. It may be procured direct from the Manufacturers, Messrs. FERRIS and COMPANY, Bristol, or through the leading Wholesale Druggists in London, and from most respectable Dispensing Chemists in Great Britain and Ireland. Every bottle has a fac-simile of Messrs. FERRIS and COMPANY'S Signature pasted over the Cork, to imitate which is forgery.

The price of NEPENTHE to the Profession is 8s. per lb., and the dose the same as the Tinctura Opii.

*Report from F. PORTER SMITH, Esq.*

I have pleasure in bearing testimony to the decided advantages possessed by Messrs. Ferris and Company's preparation of Opium called "Nepenthe" over other preparations of that important drug. I have used it for several years in Cancer of the Uterus, continuing it, with scarcely abated advantage, as a sedative, in one such case, for the long period of eighteen months, in doses of, at the utmost, half a drachm, which served the purpose to the end. I have used it in "Subcutaneous Injection" for Neuralgia, without producing any local irritation, such as abscess, &c. In the cases of unusually

severe "after-pains" in connexion with labour, I can strongly recommend and endorse its successful and satisfactory employment. I have never met with any unpleasant symptoms, such as sometimes occur in some constitutions after the administration of morphia, &c., during an extensive use of this valuable addition to that "Practical Pharmacopœia" which waits for no "imprimatur" from College or Council.

F. PORTER SMITH, M.B. Lond.,  
Evercreech, March, 1862. Associate of King's College, London, &c.

\*\* Fresh Reports will be published in the Medical Journals from time to time.—Bristol, 1862.

## *Pulvis Jacobi ver, Newbery's,*

is the ORIGINAL & GENUINE, was ESTABLISHED A.D. 1746,

And is Prescribed, with the greatest success, "by the highest authorities," for Fevers, Ague, Cerebral Congestion, Rheumatism, Chills, Influenza, &c. &c.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.;  $\frac{1}{4}$  oz., 3s. 4d.

### PARHYDOR, or IMPERMEABLE SILK, for Surgical Purposes, &c., &c. (Patented.)

It is free from smell and adhesiveness in Tropical climates, warm rooms, &c. Will stand the test of being boiled in water. Free from spontaneous combustion, although packed in large quantities. Not irritating to the skin, or otherwise injurious when in use.—Sold Wholesale and Retail by Messrs. SAVORY and MOORE, 143, New Bond-street, W.; 29, Chapel-street, Belgrave-square, S.W.; 1, Lancaster-terrace, Hyde-park, W.; and 220, Regent-street, W.; and Messrs. CURTIS and CO., 48, Baker-street, W., London; and Wholesale by Messrs. MAW and SON, 11, Aldersgate-street, London, E.C.; and Messrs. LANGTONS, SCOTT, and EDDEN, 226, Upper Thames-street, London, E.C. Sold Retail by the principal Chemists and Druggists and Surgical Instrument Makers.

Manufactured by the Patent Waterproofing Company, 3, Great Winchester-street London, E.C.

\*\*\* Paper and Fabrics of Linen and Cotton Waterproofed in the same way.

TRADE MARK

## CHLORODYNE

WAS DISCOVERED AND INVENTED IN THE YEAR 1848 BY  
DR. J. COLLIS BROWNE M.R.C.S.L. EX. ARMY-MED. STAFF.

AND IN 1856 HE CONFIDED  
THE ORIGINAL AND ONLY FORMULA  
FOR ITS MANUFACTURE

SOLELY TO J. T. DAVENPORT, PHARMACEUTIST,  
33, GREAT RUSSELL ST. BLOOMSBURY SQUARE, LONDON.  
REGISTERED, 1856.

### NOTIFICATION.

THE attention of Medical Men is directed to the Piratical application, by some parties in the Trade, of the term "Chlorodyne" to various mixtures compounded of Chloric Ether, Opium, Indian Hemp, and Peppermint, in Imitation of the ONLY Genuine preparation of this name.

The dangerous expedient of encouraging or advocating the assumption of a name specifically indicating a particular property or remedy—such as *Chlorodyne* is to spurious imitations and substitutions—ON THE GROUND OF CHEAPNESS, is a subject of surprise and grave reproach, supremely so, when the adulteration, sophistication, and tampering with Drugs, becomes so serious and important a consideration in the successful practice of Medicine.

The fact of these Piracies must fully convince the Profession of the extraordinary efficacy of the Genuine *Chlorodyne*; whereas the sad results and disappointment arising from the use of spurious compounds cannot be expressed.

Each Genuine Bottle bears a Red Stamp, with the words, "Dr. J. COLLIS BROWNE'S CHLORODYNE," in White Letters.

To be obtained from all Wholesale Druggists in 1oz., 2oz., 4oz., and 8oz. Bottles.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

The Best House for Second-hand Instruments,

Where there is the Largest Stock in London, is Mr. WILLIAM LAWLEY'S, 78, FARRINGDON-STREET, CITY.

Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each.

BY

SOELBERG WELLS, M.R.C.S. Eng., M.D. Edin.

Ophthalmic Surgeon to, and Lecturer on Ophthalmic Surgery at, the Hospital.

## STRABISMUS.

## LECTURE III.

GENTLEMEN,—Let us now pass on to the operation for strabismus. My time will not permit me to describe the various modes of operating which have been practised, and I shall, therefore, confine myself to the description of Von Graefe's operation, which I practise myself, and consider the best. I may mention, however, that the old operation, in which the conjunctiva and subconjunctival tissue were widely incised, the capsule of Tenon lacerated, the muscle itself, and not its tendon, divided, should never be performed. Its effect is generally most unhappy, and it brought the operation for strabismus into great disrepute.

The principle of Von Graefe's operation consists in a very careful division of the tendon close to its insertion, with the smallest possible amount of laceration of the subconjunctival tissue, and the tendinous processes of the capsule of Tenon. We diminish the power of the muscle by giving it a more backward insertion; but we, at the same time, preserve its length intact. Our object is only to weaken the muscle, and not to render it more or less impotent. Before proceeding to consider this method of operating, I would, however, recall to your mind the anatomical relations of the muscles of the eye with the ocular sheath. Commencing at the optic foramen, and loosely embracing the optic nerve, the sheath expands, and passes on to the eyeball, which it encloses. It is loosely connected with the sclerotic by connective tissue—so loosely, indeed, as to allow of the free rotations of the globe within it. At the equator of the eyeball it is pierced by the tendons of the oblique muscles, and, more anteriorly, by the tendons of the four recti muscles, with which it becomes blended; being finally lost on, rather than inserted into, the sclerotic, close to the cornea. The posterior portion of the sheath, up to the passage of the tendons, has been called the capsule of Bonnet; the anterior portion, from the passage of the tendons to its insertion into the sclerotic, being designated the capsule of Tenon. On piercing the capsule the tendons of the recti muscles become connected with it by slight cellular processes sent forth from the capsule. These processes prevent the too great retraction of the muscle after the division of its tendon, which would be followed by a great loss of power. It is, therefore, of the utmost consequence that these connecting processes should not be severed by the tendon being divided too far back, or be lacerated by rude and careless manipulations with the squint hook. Von Graefe has, moreover, pointed out that the result may be unfavourable, even although the tendon has been divided anterior to these fibres, for the sheath of the tendon becomes thickened from the point at which it passes through the capsule, and this thickening extends nearly up to its insertion. If the tendon is, therefore, not divided sufficiently close to its insertion, it is apt to retract within this thickened sheath, and this retraction will in many cases prevent its reunion with the sclerotic. In the old operation the muscle was divided far back, frequently even posterior to its passage through the capsule, and it was consequently often rendered so powerless, that the eyeball could not be moved in this direction; its opponent acquired a corresponding preponderance of power, giving but too frequently rise to a secondary squint in the opposite direction. Hence, the popular dread of the operation, "lest the eye should go the other way." But you need not fear such unfortunate results if you practise Von Graefe's operation, if you are careful in its performance, and if you are thoroughly conversant with the theoretical part of the subject. Never do too much, for nothing is so difficult as to retrace your steps, to patch up a

fault you have committed. It is far easier subsequently to increase the effect of the operation than to diminish it. Let me impress this strongly upon your minds, for by following this advice you will escape many unpleasant *contretemps*. I know of no surgical operation which is so safe and so sure in its cure as that for strabismus when properly performed. Let us now pass on to the description of Von Graefe's operation.

As it is sometimes very painful, the patient should be placed under the influence of chloroform. The eyelids are to be kept apart by the spring speculum, or, if this proves not sufficiently strong, by the broad silver elevators. An assistant should evert the eye with a pair of forceps (I am supposing that the internal rectus of the right eye is to be operated on), taking care to do so in the horizontal direction, without rotating the eyeball on its axis, otherwise, the horizontal position of the internal rectus will be changed. The operator should then seize, with a pair of finely-pointed forceps, a small, but deep fold of the conjunctiva and subconjunctival tissue, close to the edge of the cornea, and about midway between the centre and lower edge of the insertion of the internal rectus. He next snips this fold with the scissors (which should be bent on the flat, and have tolerably sharp points), and, burrowing beneath the subconjunctival tissue in a downward and inward direction, makes a funnel-shaped opening beneath the subconjunctival tissue, this being, however, done very carefully so as not to divide it to too great an extent. If the subconjunctival tissue is thick and strong, it will be better first to take up a small fold of the conjunctiva only, to open this, and then, seizing the subconjunctival tissue, to divide the latter. The squint-hook (which should be bent at a right angle, and have a slightly bulbous point) is then to be passed through the opening to the lower edge of the tendon. Its point being pressed somewhat firmly against the sclerotic, the hook is to be turned on the point and slid upwards beneath the tendon, as close to its insertion as possible, and the whole expanse of the tendon caught up. You must be careful not to direct the point of the hook upwards and outwards, otherwise it may perforate the fibres of the tendon, and only a portion of the latter be caught up; the direction of the point should, therefore, be rather upwards and inwards. When the tendon has been secured on the hook, the conjunctiva which covers its upper portion may be gently pushed off with the points of the scissors, so as to expose the tendon, which is then to be carefully snipped through with the scissors as closely as possible to its insertion. When it has been completely cut through, the conjunctiva is to be slightly elevated on the point of the hook, and a smaller hook passed upwards and downwards to ascertain whether the lateral expansions of the tendon have been divided. Should a few fibres remain, you must divide them, and again ascertain whether any others are still present. Never omit to satisfy yourselves upon this point, for sometimes the lateral expansions are considerable, the tendon spreading out like a fan, and, although a few fibres only might remain undivided, they would often suffice to spoil the effect of the operation.

If you find, on the first introduction of the hook, that it slides up to the edge of the cornea without having caught up the tendon, you may be certain that you have either not divided the subconjunctival tissue at all, or that you have passed the hook between it and the conjunctiva. If the former is the case, you must open the subconjunctival tissue, and then, on reintroducing the hook, you will have no difficulty in finding the tendon. The opening in the conjunctiva and subconjunctival tissue should be but small, and the excursions with the hook limited, otherwise the subconjunctival tissue and the lateral processes of the capsule of Tenon will be extensively lacerated, which will be followed by a too great recession of the muscle.

The after treatment is very simple. The eye, after having been well washed and cleansed of any blood coagula, is to be kept constantly moist with cold water dressing during the day of operation, so as to prevent any extensive effusion of blood under the conjunctiva. No button of granulations will form on the stump of the tendon, if the latter has been divided close to its insertion, and if the opening in the conjunctiva has been made near the upper or lower edge of the tendon, so as not to leave the latter exposed.

The effect upon the squint, which follows immediately upon the operation, will not be the permanent one. We may, indeed, distinguish three stages in the effect produced by the operation:—1st. The period immediately following the opera-

tion; 2nd. After three to four days have elapsed; 3rd. After the interval of a few months,—this being the permanent effect. During the first stage the effect will be considerable, for the eye can now only be moved in the direction of the divided muscle by the indirect connexion of the latter with the sclerotic by the lateral processes of the capsule of Tenon. As soon as the divided end of the tendon becomes reunited with the sclerotic, which generally occurs within three to four days, the effect will diminish, for the muscle now exerts again a direct influence upon the eyeball. This is the second stage. But we find that a further alteration in the position generally shows itself a few weeks or months after the operation, the effect being then again somewhat increased. This is due to the action of the opponent muscle, which, on account of its antagonist having been weakened, can now exert a greater influence upon the position of the eyeball.

A clue to the permanent result of the operation is furnished by the position of the operated eye during the accommodative movements of the eyes, when they are directed upon some near object. It is, therefore, of the greatest consequence always to test the position of the eyes during accommodation, immediately after the operation, as soon as the effect of the chloroform has gone off. We have already seen that the position of the squinting eye (convergent strabismus) may vary when the object is approximated closely to the eyes; for whilst the optic axis of the healthy eye remains fixed upon the object, converging the more the nearer the latter is brought, the position of the squinting eye may undergo the following changes:—1st. It may retain its original position, sustaining only a few oscillating, irregular, lateral movements. 2nd. It may remain completely stationary, so that the angle of squinting will diminish the more the nearer the object is brought, until, at a certain point (if the squint be not excessive), its optic axis will also be fixed upon the object, and there will no longer be any squint. If, however, the object is approximated still closer, a divergent squint will arise; for whilst the healthy eye converges still more, the other retains its position, and now deviates (passively) outwards. 3. It retains its position up to a certain point, and then, as the healthy eye moves inwards to follow the object, it makes an associated movement outwards. 4. It deviates suddenly and spasmodically inwards when the object is very closely approximated (a).

We should, therefore, immediately after the operation, ascertain whether both optic axes can be firmly fixed upon the object, when it is brought to a distance of from four to six inches from the eyes (their state of refraction being normal). If the eyes are very short-sighted, the distance should be still less. The final result of the operation may be predicted from the position which the operated eye now assumes. If it remains stationary when the object is brought up to within eight inches from the eyes, so that a passive divergence will arise on its being approximated still closer, we must expect a certain amount of divergence in the course of a few months. But this will be still more the case if the eye, instead of simply remaining stationary, makes an associated movement outwards. It is necessary to test this at short distances (four to six inches), for the eye might be able momentarily to fix its optic axes upon the object, although quite incapable of maintaining this position for any length of time. In both the above cases the effect of the operation is to be diminished by a conjunctival suture, and particularly so in the latter case. The effect of the suture will vary with its position and with the amount of the conjunctiva embraced in it. Its effect will be greatest if it be inserted in a diagonal direction from downwards and inwards, to upwards and outwards, so that the inner and outer lips of the wound are united. By giving it this direction we also prevent any sinking of the earuncle. The suture diminishes the effect of the operation by re-advancing the tendon, which is closely connected with the conjunctiva and subconjunctival tissue; the divided ends, consequently, will be more closely approximated, and the retraction of the muscle diminished. The suture may remain in for twenty-four to thirty-six hours.

The fourth position which the operated eye may assume during accommodation, viz., making a sudden spasmodic movement inwards, must make us fear that there will be a relapse,—that in the course of a few months the inward squint will again show itself; for this convergent squint, which at first only showed itself during accommodation for near objects,

will gradually extend also to greater distances. In such cases the operation is said to have been only of temporary benefit; you should, therefore, at once intimate to the friends of the patient that the squint may return, and necessitate another operation.

The extent of the operation must be regulated according to the extent of the squint. I have already pointed out to you how the amount of the latter is to be estimated.

If the squint is but very slight (1 to  $1\frac{1}{2}$  line) a partial tenotomy is indicated. We must, however, divide at least three-quarters of the tendon, or even all but a few lateral fibres, otherwise the effect will not be sufficient. Should the latter exceed our wishes it is to be diminished by a suture. If the squint amounts to from  $1\frac{1}{2}$  to 2 lines, a careful, complete tenotomy is to be made. The conjunctival opening should be small, and the hook but of moderate size. The accommodative movements must be accurately tested immediately after the operation; for, if there is the slightest tendency to divergence, when the object is brought up to 8 or 6 inches from the eye, a suture should be inserted. In a squint of 2 to  $2\frac{1}{2}$  lines, the cellular tissue may be somewhat more freely incised, and a larger hook employed. In children we find that the effect is generally more considerable, for the muscle is not fibrous, and the surrounding cellular tissue is very elastic; we may, therefore, in them easily attain an effect of  $2\frac{1}{2}$  to 3 lines by a single operation.

If the squint exceeds  $2\frac{1}{2}$  to 3 lines, we must always operate upon both eyes. We may perform either a complete tenotomy in the squinting eye and a partial one in the other, or divide the tendon completely in both eyes. In this we must be guided by the amount of squint left after the affected eye has been operated upon. I advise you, as a general rule, never to operate upon both eyes at the same time, except the squint is very considerable, exceeding  $4\frac{1}{2}$  to 5 lines. For, if both muscles have been divided at the same time, you cannot accurately test the accommodative movements directly after the operation, and you thus lose the only clue to the permanent effect. It is, therefore, far safer to operate first upon the affected eye, and then, after a few days have elapsed, and the divided tendon has again reunited with the sclerotic, to ascertain how much of the squint is still left. The amount still remaining will guide you as to the extent of the operation necessary upon the healthy eye. If, after having operated upon the latter, you find that the effect somewhat exceeds your wishes, you can always diminish it by a suture. It certainly is far more brilliant to operate upon both eyes at the same time, and thus rid the patient at once of the squint, but then you run the risk of the unpleasant contingency of the eyes subsequently "going the other way." You should always remember that the cure is to be permanent, and not temporary. In some exceptional cases, however, you must run this risk—if, for instance, the time of the patient is limited, or a second visit impossible. If the squint exceeds five lines, you may, particularly in adults, operate safely upon both eyes at the same time. It may be occasionally necessary to operate not only upon both eyes, but even to repeat the operation upon the squinting eye, before we can cure the affection. This generally occurs only in cases of excessive squint, or if the strabismus has existed for a long time, and the muscle has become fibrous. This second operation upon the affected eye requires considerable care, for the effect of the correction will exceed the extent of the retraction, as the influence of the muscle upon the eyeball diminishes in proportion to the backward position of its insertion.

In divergent squint we may be somewhat bolder, particularly as to operating upon both eyes at one sitting. The effect of the operation is generally less, and has often to be increased by subsequent treatment. If we desire an increase in the effect, the patient should be made to look in the opposite direction, which will cause an increased retraction of the divided tendon, so that its reunion will take place further back than would have occurred if the eye had maintained a median position. If the abductor of the right eye has been divided, and we desire to increase the effect of the operation, the patient should be directed to look, as far as possible, towards his left side. The easiest way of attaining this is, by making the patient wear spectacles, the right half of each glass being covered with a piece of court-plaster, for he will in this way be obliged to look to the left. They should be worn during the first three or four days after the operation. Von Graefe points out the fact that, occasionally, though rarely, we meet with cases in which the operation is followed

(a) At page 402 (October 18, 1862), a misprint occurs to the effect that the eye moves spasmodically "outwards;" it should be "inwards."

by no effect, either upon the position or mobility of the eyeball, and yet no lateral fibres of the tendon have remained undivided. In such cases there is a second connexion of the muscle with the sclerotic further back, near the equator; in one case, indeed, he found it even posterior to the equator.

If the operation for squint be carefully performed, there is no fear of any but the slightest sinking of the caruncle. A little sinking will occasionally occur, whatever mode of operation be employed; indeed, I know of no method which can guarantee a *perfect* immunity from it. Von Graefe thinks that the sinking does not depend so much upon the gaping of the conjunctival wound, and retraction of its inner lip, as upon the cicatrization of the connective tissue situated between the muscle and conjunctiva, by which the movable caruncle is retracted. The further back this cicatrization extends, the more will the caruncle sink. Hence, the danger of incising the tendon too freely, and of any considerable sweeping about with the hook, and consequent extensive laceration of the subconjunctival tissue.

## ORIGINAL COMMUNICATIONS.

### ON THE ACTION OF CERTAIN SUBSTANCES UPON PHTHISIS.

By RICHARD PAYNE COTTON, M.D.

Fellow of the Royal College of Physicians, London; Physician to the Hospital for Consumption and Diseases of the Chest, Brompton.

#### No. X.—SESQUICHLORIDE OF IRON.

THE sesquichloride of iron is, I believe, a very old remedy for phthisis; and, although there may be few Medical Practitioners whose experience of its use has not enabled them to form their own conclusions on the matter, I was, nevertheless, anxious to compare its effects with those of other agents. As in my previous experiments, therefore, I administered it in twenty-five cases of uncomplicated phthisis furnished by my own wards in the Consumption Hospital. Of this number, eight were males, and seventeen females. Eleven were in the first, four in the second, and ten in the third stage of the disease. None of the cases presented any very remarkable feature, all of them being examples of the ordinary run of patients affected with chronic consumption, care having been taken to exclude those in whom there existed either any special complication or secondary affection which demanded a different treatment.

The dose consisted of ten or fifteen minims of the Tinctura ferri sesquichloridi administered in water two or three times a-day, and was continued for periods varying from three weeks to four months. Cod-liver oil was also taken sometimes by a few of the patients; but, as a general rule, this substance was avoided, at least temporarily, with the view of not complicating the result.

Twelve patients improved greatly, five improved slightly, and eight experienced no relief whilst under treatment. Ten of the seventeen more or less improved cases did not take any cod-liver oil; but, by subsequent observations, it was sufficiently evident that the greatest good was brought about by the combined influence of these two substances.

Were I to be asked from which of the ten medicinal agents already experimented upon, I had observed the most benefit, I should unhesitatingly fix upon the sesquichloride of iron. For some years, indeed, I have been in the habit of using this substance extensively, both in private and Hospital practice, and some of the most happy results I have met with in the treatment of phthisis have certainly taken place during its administration. In no instance have I seen any reason to connect with its use the occurrence either of hæmoptysis, or any other active symptom. In passive hæmoptysis, indeed, I have often found it a very useful remedy; whilst it often helps to check excessive secretion, whether from the skin or the mucous surfaces.

A great disadvantage inseparable from Hospital practice is, that we generally lose sight of our patients at the very moment when their cases begin to be instructive. Circumstances have enabled me, however, to watch the continued progress of three out of the twenty-five cases treated with the sesquichloride of iron; and, as they are marked instances of its success, I shall briefly relate them.

*Case 1* was that of a dressmaker, admitted into the Brompton Hospital six years back. She was well known to Dr. Arthur Farre, who had watched her case, as that of a private patient, from the very commencement, and who agreed in the opinion that it was one of advanced phthisis, with a cavity of moderate size under the left clavicle. The pulse was about 100, and the general health at a low ebb, although there were no symptoms of immediate danger. She was ordered fifteen minims of the tincture of sesquichloride of iron in water, two or three times a-day, with cod-liver oil and good diet. After remaining four months in the Hospital, during which time she took the steel very regularly, but the oil only occasionally, as it sometimes disagreed, she became very much better, and shortly afterwards returned to her employment. Dr. Arthur Farre and I have seen this patient occasionally up to the present time. She has continued, with a few short intermissions, both the steel and cod-liver oil; and although, perhaps, it might be going too far to say that she is cured of her disease—since we know only too well how frequent and how fatal in such cases is a relapse—her general health is fairly good, her pulse is quiet, and her cough gone; and she is now following pretty actively her business as a milliner. The physical signs in this case are not uninteresting. The thoracic wall over the original seat of the cavity has sunken considerably; there is considerable dulness there, and where the respiration was cavernous it is now simply very weak and harsh, but unattended with rhonchus. Dr. Arthur Farre has repeatedly said that he considers this case one of the best illustrations of arrested phthisis he has ever witnessed.

*Case 2* was that of a governess, who was admitted into the Brompton Hospital four years back. She had all the symptoms of advanced phthisis; the pulse was over 100; the breathing oppressed; the cough severe; and there was considerable emaciation. Cavernous breathing, with loud gurgling rhonchi, unmistakably announced the stage of the disease. Under the continued influence of tincture of sesquichloride of iron, with cod-liver oil, and an opiate, chiefly at night, to check the cough and promote sleep, with ample diet, her health was gradually restored; and, after six months' perseverance with the treatment, she left the Hospital in fair health, greatly increased in weight, and able to undertake some light occupation. She was re-admitted into the Hospital the following winter, having continued the steel and cod-liver oil during the interval. She had lost a few pounds in weight, and her cough had returned, but her pulse was quiet, and there had been no recurrence of any active symptom. After leaving the Hospital a second time greatly improved, she went into the country, and for some time I heard very good accounts of her condition, the last report mentioning that she still continued both the steel and oil. For the last few months, I have been unable to ascertain particulars of this patient; but for more than three years I had ample evidence of her satisfactory progress. Mr. Edwards, the Resident Medical Officer, watched this case through the whole of its Hospital career.

*Case 3* was that of a page, aged 17, admitted into the Hospital two years ago. It is unnecessary to say more than that both the general and local symptoms told of phthisis in its third stage; the humid crackling rhonchus, and cavernous breathing, respectively announcing tubercular softening and the presence of a cavity. The hurried pulse, with dyspnoea, and a very anxious countenance, led us to form an unfavourable prognosis. Under liberal diet, with the use of the sesquichloride and occasionally cod-liver oil, this patient left the Hospital in four months greatly improved in health, and with all his symptoms in abeyance; and I have continued to see him every two or three months since his discharge. He has perseveringly taken, with some few intermissions, both the steel and oil, and is now in tolerable health, and nearly a stone heavier than he was a year back; whilst the physical signs, as in *Case 1*, are indicative of the quiescent condition, and the greatly reduced size of the cavity, the chest-wall in that region having fallen inwards, and the respiration being very feeble and harsh, with occasional subcrepitan rhonchus. My friend and colleague, Dr. Stone, who happened to see the case lately during my absence, considers it a good illustration of checked phthisis, with a contracting cavity.

From the foregoing facts, coupled with preceding observations upon the effect of iron upon phthisis, I have arrived at the following conclusions:—

1. That iron is a very valuable remedy in consumption—

perhaps more valuable than any other with which we are at present acquainted.

2. That of the numerous preparations of iron, the sesquichloride is the best, its astringent nature being generally well suited to many symptoms of the consumptive patient.

46, Clarges-street, Piccadilly.

### CASE OF GUN-SHOT WOUND.

By M. F. MANIFOLD, Surgeon to the 34th Regiment.

Two cases of gun-shot wounds were treated during the past year, neither of which, I am happy to say, proved fatal, although one was a very serious and complicated case, the particulars of which are as follows:—

P. G., 34th Regiment, an Irishman, aged 31 years, seven years' service, of which four years have been passed in India, a man of intemperate habits, was admitted into the Hospital on the night of July 26, 1861, in consequence of having attempted suicide, by shooting himself with a double-barrelled rifle.

He was conveyed to the Hospital in a dhooly, between nine and ten o'clock at night, and presented the most frightful spectacle I ever beheld. He was bleeding profusely at the time from the mouth and throat, the blood being brought up in mouthfuls, flowing over, and covering his whole person.

His face, at the left side, was literally blown away, together with a portion of the upper and lower jaw at the same side: the ball, entering a little to the left of the symphysis of the chin, and passing through the hard palate, exposing the inside of the mouth and tongue, escaped superiorly through the floor of the orbit, carrying with it the eye, and displacing the malar bone, which was subsequently removed.

Assisted by Dr. Smith, I immediately proceeded to arrest the hæmorrhage by tying several vessels, while, at the same time, I removed all the loose pieces of bone that could be found, or seized with the forceps or my fingers; after which the soft parts were brought in apposition, and secured by sutures, water dressing, and a bandage.

Next day (27th), silver wire sutures were substituted for the silk, which latter were removed; and the day following, assisted by Dr. Burn (Royal Artillery) and Dr. Whisham, who kindly gave me the benefit of their advice, I proceeded to remove the malar bone, which was so much displaced and broken as to render its removal necessary. Having made an incision about three inches long, parallel with the zygoma, and reflected the flaps, the removal of the bone was easily effected with Liston's bone forceps. The parts were brought together, and union took place by the first intention. Not so the other soft parts, which sloughed, together with the eye, and profuse suppuration followed. Several loose pieces of bone were subsequently removed, and the case seemed to be doing well, when maggots made their appearance, in spite of every precaution used to prevent them, and quickly consumed every vestige of cheek that remained. The maggots, getting into the antrum, nose, and orbit, were with difficulty removed. All this time the patient was fed from a child's feeding bottle, and supported

by a liberal allowance of wine, brandy, and eggs, his fine constitution remaining firm and unimpaired. He was, however, subsequently attacked with crysipelas, which was with difficulty arrested under the use of bark, ammonia, and stimulants. At last, healthy suppuration was established, and on November 15 the wound presented the appearance so faithfully delineated in the accompanying engraving.

With the view to remove the existing deformity, and, if possible, close up the opening so

kindly assisted me), on November 19 I commenced by breaking up the old adhesions, detaching the puckered skin from beneath the eye, dissecting and loosening the lower cicatrix of the wound, and endeavouring, by this means, to bring the angles of the lips together; but this was found impossible, the contractions were so firmly bound down, and attended with so much loss of skin.

I, therefore, found it necessary to make a free incision beneath the chin, as recommended by Mr. Syme, elevating the skin as it became loosened, until by degrees, and with no little difficulty, I was enabled to bring the parts together, and secure them in position with hare-lip pins.

The operation, as will be seen from the accompanying sketch, was perfectly successful, an opening scarcely large enough to admit the shank of a pipe remaining, which has since been closed (a).

Sutopore, Oude.

### PROFESSOR PETTENKOFER'S RESEARCHES ON RESPIRATION AND THE CHEMISTRY OF LIFE.

(Concluded from page 572)

The experiments on respiration hitherto made by Professors Pettenkofer and Voit, were all undertaken on a dog, who, immediately after having been fed, was placed in the cage contained in the respiration apparatus, where he remained for twenty-four hours. The general results were, that the elimination of carbonic acid by the skin and lungs is subject to considerable variations, the smallest quantity being 289.4 grammes, which was observed after the animal had not taken any food for ten days, and the largest amount being 840.4 grammes, after a very considerable quantity of food had been allowed, viz., 1800 grammes of pure meat and 350 grammes of fat. The proportion in the numbers thus obtained is as 1 to 2.9. The excretion of nitrogen is not proportionate to that of carbonic acid; the variations in the excretion of urea being much more considerable, viz., from 8.3 to 180.8 grammes, that is, as 1 to 21.8. Although it has appeared from investigations undertaken at a later period, that the carbonic acid expired is no standard for oxidation in the system, it may yet be concluded, from the large variations observed, that the quantity of heat generated in the same individual, in consequence of decomposition, may vary from one to three. It has, however, been shown by experiments undertaken by Dr. Ranke on himself in the same apparatus, that in man the exhalation of carbonic acid varies not nearly as much as it does in animals, the smallest quantity being 660 grammes, and the largest 860. A dog, which has only half the weight, eliminates about as much carbonic acid as man, if a large quantity of food is given, but double the quantity of urea; while, if no food is allowed, the quantity of carbonic acid, as well as that of urea, is only half that excreted by man under the same circumstances.

In the further course of these investigations the important facts were elicited, that the quantity of carbonic acid eliminated can no longer be considered as a standard for the consumption of oxygen within the system; and also that hydrogen is not the substance with which oxygen always combines next to carbon. The results previously obtained by Messrs. Regnault and Reiset differ from these, which is probably to be explained by the circumstance, that the French physiologists did not observe the different states of nutrition so long as the Munich professors. Regnault only studied the

(a) I am indebted to Lieutenant Pearson, Bombay Engineers, for these sketches.

altered condition of animals to whom no food was given for two days, while Pettenkofer and Voit withdrew food for ten days consecutively. Moreover, Regnault's animals were much smaller than those employed in the Munich laboratory; and, finally, Regnault always experimented in the same volume of air, while in Pettenkofer's respiration apparatus the air was continually renewed. In fact, the minimum of air that was carried to the dog amounted to 8000 litres per hour, which must necessarily produce a considerable difference. In the investigations which are to follow, Professors Pettenkofer and Voit intend working with four pumps simultaneously, in order to search for hydrogen and carburetted hydrogen in the air that enters as well as in that which leaves the apparatus. They also purpose to extend their observations on patients suffering from various complaints, so that we may at last arrive at a satisfactory insight into the general metamorphosis of matter in health as well as in disease.

## REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

### GUY'S HOSPITAL.

#### DISEASE OF THE SUPRA-RENAL CAPSULES WITHOUT BRONZING OF THE SKIN.

(Case under the care of Dr. GULL.)

In this Journal for January 10, p. 32, we recorded a case of disease of the supra-renal capsules, in which there was no discoloration of the skin. Mr. Hulke, under whose care the patient had been in the Middlesex Hospital, thought that "the probably short duration of the capsular disease, inferable from the generally firm, lardaceous character of the organs, and the presence of vestiges of their proper tissues, might account for the absence of bronzing." But, in the case we are about to relate, the disease was so extensive, that the functions of the capsules, whatever they may be, must have been annihilated. It is supposed by some, that disease of the renal capsules alone is not the cause of the symptoms of Addison's disease, but that it is disease spreading from them to the contiguous semilunar ganglia and solar plexus. But, in the following case, "the semilunar ganglia were more than usually involved. The right one was actually embedded in the capsule." Here, then, is a well-marked case of disease of the capsules, affecting also the great ganglionic centres in the abdomen, and yet the most marked symptom is wanting. This case will, doubtless, be cited by those who do not believe in Dr. Addison's views, as an instance contradictory to his theory. But although the discoloration of the skin is the most marked symptom, it has never been considered the most characteristic. Dr. Wilks says, in a paper in the last Number of *Guy's Hospital Reports*, "the discoloration of the skin, although a striking feature of the complaint, was not the main one insisted on by Addison; but since it is that which can be portrayed in a drawing, and, consequently, apt to strike the eye on turning over the pages of a monograph, it is not surprising that it was at once regarded as the most remarkable part of the complaint, and would, therefore, be especially dwelt upon in our ordinary mode of communicating to one another the facts relating to the disease, until, at last, the erroneous opinion would be reached that Addison's disease and discoloration of the skin were convertible terms." In the same article, Dr. Wilks relates a case (Case 8 of his series) in which there was disease of the capsules, and no change of colour of the skin. Yet a most characteristic symptom, "an utter prostration of strength," was not absent.

Dr. Harley considers that disease of the supra-renal capsules is not fatal; but, he says, disease may extend from them to the semilunar ganglia or solar plexus, or may excite such an amount of irritation in them as to induce secondary disease, which, and not the contemporaneous affection of the capsules, may cause death. He states that a rat, from which he had removed both capsules, lived in good health three years after the operation, and died at the end of that time of old age. He says, that in all cases in which the animals have died after removal, it is clearly due to the effect of the operation, and not to the loss of the capsules. The fact that rats, in which the capsules are loose and easily removed, generally

recover, whilst guinea-pigs and rabbits, in which they are intricately involved in the abdominal plexuses, frequently die, tends to favour the idea, that death is due to the operation alone.

In the article already referred to, Dr. Wilks writes, "the symptoms cannot be due simply to a destruction of the organs, since this must have happened, in many instances, long before death occurred, and is one reason, as before said, to suggest some implication of the organic system of nerves." In the case we are about to relate, as in Case 8 of Dr. Wilks' series, before alluded to, the disease was in an early stage. Dr. Wilks says (*op. cit.*, p. 13):—"A sufficient number of cases have now been observed to suggest whether the change in the skin does not depend on the chronicity of the disease; and that, if it should progress rapidly, no discoloration of the skin would be observed, the symptoms being merely those of asthenia."

William T., a publican, aged 31, was first seen at home by Dr. Gull on December 26. The case being a very obscure one, the patient was sent to the Hospital, and admitted December 27. He died on the 29th, before he had been seen a second time by Dr. Gull. As far as could be learned he had been ailing about four months, or, at least, there was no symptom to attract attention before that. He then began to get weak, pale, and thin. A Medical man was called in, who gave him medicines with varying effect; and it was his opinion that he was consumptive. At this time he often had sickness, his appetite was bad, and he also at times complained of pain in his back. He had also various nervous symptoms, which were differently described; it being stated that he had lost sensation on one side of his face, and could not eat so well on that side; and that he had numbness in his legs, and that he could not hold his water perfectly. He still continued at his employment. About a month before his death he became much worse, with all the above-named symptoms, and he then went to Greenwich for change of air. He still became worse, however, the pain in his back becoming more severe. He returned home, but was obliged to ride from the railway station to his house, a short distance. On December 26 Dr. Gull was requested to see him, and advised his removal to the Hospital. He was admitted the next day, December 27. He was so weak that it was necessary to carry him to the ward. He then brought up all the food he took, but rallied somewhat the next day. The next day Mr. Stocker saw him, and found him dying, after having vomited. Mr. Stocker said, that from this, his only visit to the patient, he did not know whether he was suffering from stomach, cerebral, or supra-renal disease.

The man's face was sallow, or of a yellowish cast, such as is seen in cachectic persons, but not sufficiently well-marked to attract attention. His wife said that his skin was sallow, but that no one had voluntarily remarked any change of hue.

The patient, on admission, stated that he had been ill six weeks, this being the time in which he had been incapacitated for work.

*Autopsy, by Dr. Wilks.*—Both supra-renal capsules were converted into large masses of an albuminous substance. They were larger than any which had yet been found at the Hospital, and were composed of a material of a much more recent formation than had been before observed. They had contracted adhesions to the parts around, as to the liver, etc., from which the right one had to be torn. The right capsule was also adherent to the vena cava, and the coats of the vein were involved. On opening this vessel, there was seen a raised rough patch where the coats had actually been destroyed; and the disease was penetrating their interior. There were also contiguous lymphatic glands enlarged. The diseased organs, or the masses of material which took their place, were not weighed, in consequence of their non-removal from the kidneys, but they, probably, would have weighed as much as two-thirds the size of the kidneys to which they were attached. The substance composing the diseased organs was a softish material, of a white colour, of the consistence of tallow or lard. It cut with a smooth surface, but was easily friable, and could be rolled up into a softish mass. It was of the same character as had been met with in previous cases, but not, as in them, associated with any yellow or so-called tuberculous or cretaceous material. In fact, there was no deposit within them indicating that the disease was of any age, as it had not undergone those changes which time brings about. The deposit had, no doubt, been formed in a comparatively short period. The diseased masses were so contiguous, and the material

forming them so encroached on surrounding parts, that the semilunar ganglia were more than usually involved. The right one was actually embedded in the capsule, and many of its nerves passed into it. The left was in contact, and its nerves merely involved.

### ST. THOMAS'S HOSPITAL.

#### DISEASE OF THE SUPRA-RENAL CAPSULES, WITH FRENCH MILLSTONE-MAKERS' PHTHISIS— CLINICAL REMARKS.

(Under the care of Dr. PEACOCK.)

THOUGH, in the following case, the patient died after leaving the Hospital, and there was no examination of the body, yet, Dr. Peacock says, the diagnosis appears so clear, that it is worthy of being placed on record.

W. W., aged 36, was admitted into Edward ward, St. Thomas's Hospital, on January 16, 1861. He stated, that he had been apprenticed to the trade of a millwright, but at 23 years of age he commenced to work at the French millstone-making in a London shop, and had continued to do so, with the exception of leaving for a few days at a time, till he became so unwell as to be incapable of any longer following his occupation. He, however, enjoyed good health till about sixteen months before his admission into the Hospital. He was of a healthy family, and free from any hereditary predisposition to phthisis. His father was living, at 80 years of age; his mother had recently died, at 83; and five brothers and one sister were all living, older than himself, and healthy. He acknowledged, however, to have taken much beer and spirits when in work. His illness commenced with rheumatic pains, and a cough and expectoration, which he ascribed to cold, and for which he became an out patient, under Dr. Peacock, and, though relieved, he had never been well since. The cough and expectoration had continued; and he found, soon after the commencement of his illness, that his complexion was becoming much darker, and this had gradually increased. He also suffered from dyspeptic symptoms, and, while not severely ill, lost both flesh and strength.

When admitted into the Hospital, he was found to be of a dark brown colour in all parts of the body. The discoloration, though everywhere marked, was much darker in some parts than in others, and especially about the forehead, at the front and sides of the chest, below the axillæ, at the backs of the shoulders and arms, and at the front of the thighs; and the dark portions did not terminate abruptly, but shaded gradually into the lighter. His hair was dark brown, but his eyes blue; and the contrast between the bluish-coloured glassy conjunctivæ and the skin was very marked. The skin in the roots of the hair was not affected. On the backs of the hands, the forearms, and the front of the chest, there were many small lines or patches of a white colour in the darker skin, and these were accompanied by numerous bluish-black spots, such as are common in those parts in millstone-makers, and result from the imbedding of particles of metal thrown off from the tools with which the siliceous stones are worked. The lighter spots, he said, marked the situations in which the metal had excited inflammation and ulceration; and a careful examination showed that they consisted of small cicatrices.

His general health was much impaired; he had a troublesome and somewhat paroxysmal cough, and expectorated a considerable quantity of sputum, partly viscid and glairy, and partly muco-purulent, but he had never spat blood; his appetite was capricious, and his digestive organs much out of order; the tongue furred; the bowels confined; and he not unfrequently vomited the food which he took. He was considerably emaciated, had a somewhat quick and feeble pulse, and was much prostrated; he complained of pains and weakness in the loins, and the joints of the fingers were swollen and livid. On examining the chest, the movements were found to be very imperfect, especially at the upper parts, where, also, the resonance, on percussion, was much impaired. At the right apex there was decided dulness on percussion, with falling in and deficiency of movement, and the respiration was bronchial; there was unduly loud cough resonance, and subcrepitation at the end of a deep inspiration; the urine was examined and found free from albumen. From the general history of the case, no hesitation was felt in diagnosing it to be one of supra-renal capsular disease, with

commencing millstone-maker's phthisis. While in the Hospital, his condition varied greatly at different times. Upon the whole, he suffered less from the cough and expectoration, but the dyspeptic symptoms were never materially relieved; his appetite was extremely variable, and every few days he had attacks of vomiting, and rejected everything which he took; he sometimes suffered from diarrhœa, and he steadily became more emaciated,—indeed, the emaciation and prostration of strength were altogether out of proportion to any evidences of disease which could be detected in the lungs. The discoloration did not make any very great progress, but became, upon the whole, more marked, and it varied considerably at different times. When he was tolerably well the discoloration appeared less; when he was collapsed it became considerably darker. The local signs also progressed, but not rapidly; the dulness became more marked, the respiration more bronchial, and the subcrepitation more distinct. He, however, thought himself better during the fine weather of the summer, and requested to be discharged; he was, therefore, discharged, and left the Hospital on June 20.

Shortly after his discharge, however, he went into the country, and died in Oxfordshire, and the information was not given till it was too late to procure an autopsy; but there can, Dr. Peacock thinks, be no doubt that the case was one of supra-renal capsular disease. It is further interesting as showing the occurrence of the pulmonary disease caused by the millstone-making in a person, all the other members of whose family were healthy, and who was not brought up to the trade, and did not commence the work till he was grown up, and when he might be supposed to be more capable of resisting the injurious influence; yet in his case the disease was developed after a period of about twelve years, and, like almost every one in the trade, he died before attaining the age of forty.

### HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

#### CASES OF PHTHISIS—ARREST OF THE DISEASE, AND REMARKABLE GAIN IN WEIGHT—CLINI- CAL REMARKS.

(Cases under the care of Dr. POLLOCK.)

CASE 1.—M. N., aged 17, a servant, residing at Stepney, admitted to Montgomery ward, August 25, 1862, under Dr. Pollock. Father died of phthisis. Ill two years, cough constant, but very moderate expectoration. Never had hæmoptysis; has lost much flesh; night sweats last three months. Complains of pain in right side and back, much debility, dyspnœa, vertigo, tinnitus aurium, and dim vision. Pulse rapid, small; tongue clean; appetite good; catamenia had appeared once only, six months ago.

*Physical Signs.*—Right: dulness from the clavicle to the third rib; blowing on inspiration and expiration, and large dry crackle. Same signs in supra-spinous fossa. Base clear. Left: expiration much prolonged, and rough respiration throughout.

The girl stated that she had lived well, had had meat daily, and had not been overworked. She was ordered a dessert-spoonful of cod-liver oil twice daily, and five grains of citrate of iron in infusion of calumbo. The latter was changed a month later for a mixture of citrate of iron and quinine. Full diet consisting of four liberal meals per diem, one of them of meat *ad libitum*, and wine.

The following is her weight table:—		The progressive increase has been:—	
	st. lbs.		lbs.
Sept. 1.	7 0½	1st fortnight gained	6½
„ 15.	7 7	2nd „ „	3
„ 29.	7 10	3rd „ „	4½
Oct. 13.	8 0½	4th „ „	4½
„ 27.	8 5	5th „ „	2½
Nov. 10.	8 7	Last three weeks	6
Dec. 1.	8 13		

Total gain in 91 days . 27

Cod-liver oil had been regularly taken for three months before admission.

On November 12, the following were the physical signs on the right side:—Dulness, as before; dry, leathery, creaking sounds have replaced the crackling under the clavicle; below

this is heard a whiffing, dry inspiration; no moist sounds anywhere; the catamenia are still absent. This patient expresses herself as much relieved, and seems not to have much the matter with her. The night sweats ceased long ago.

*Remarks by Dr. Pollock.*—This seems to be a case of chronic tubercle in one lung, derived hereditarily, with little activity of the constitutional mischief, and arrested before softening had occurred to any extent, and before the isolated deposits had coalesced to form a cavity. On the eve, as it were, of such occurrence, the disease stopped short, the tubercle tending to dry, local irritation ceasing, and the nutritious processes of the body proceeding rapidly to replace the waste undergone by the tissues. It is important to observe that this patient was not taken from poverty and placed in the midst of plenty, for her living had been previously good; but it is equally important to remember that she was taken from a life of daily labour and anxiety, and placed where there was no necessity for any exertion of mind or body, and where every want was cared for. The remedial influences were, therefore, many in addition to those purely medicinal. She had taken cod-liver oil for three months before admission.

The following case presents many points of similarity:—

*Case 2.*—M. A. G., aged 15, tailoress, admitted under Dr. Pollock, August 26, 1862, Harewood ward. Has always lived at home; the family being in comfortable circumstances, had had meat daily. Of middle height, chest pretty well shaped, hair light brown; of lymphatic temperament. Her father, mother, and several maternal uncles and aunts, died of phthisis. Ill three months, cough constant for that period, with slight expectoration. No hæmoptysis; catamenia established at 13, now absent for five months; no sweatings; complains of cough, debility, flushing; appetite indifferent; tongue clean; pulse quiet.

*Physical Signs.*—Left: dulness on percussion; humid crepitus over the whole front and axilla; also in supra-spinous fossa; rough respiration at base posteriorly. Right: percussion slightly dull; clicking sounds in supra-spinous fossa, and along spine; posterior base pretty clear. She has considerably lost flesh.

The following is her weight		The progressive increase has	
table:—		been:—	
	st. lbs.		lbs.
Sept. 1.	6 13		
„ 15.	7 4	1st fortnight gained	5
„ 29.	7 8	2nd „ „	4
Oct. 13.	7 13	3rd „ „	5
„ 27.	8 1	4th „ „	2
Nov. 10.	8 6	5th „ „	5
„ 24.	8 7½	6th „ „	1½
		Total gain in 85 days	22½

This girl is also now in a very comfortable condition, coughs little, sleeps well, and expectorates scarcely anything. The catamenia have not been re-established.

The physical signs in this case underwent an alteration coincident with the improvement in health. On November 12, a careful examination gave rough, dry inspiration, and prolonged expiration over left side, instead of the humid crepitus formerly noticed.

The points of resemblance in the two cases (Dr. Pollock said) were:—In both the disease was hereditary; occurred at the period of growth; in neither had there been hæmoptysis; the absence of fever, and the similarity of temperament (the lymphatic); the moderate amount of expectoration; the unimpaired condition of the digestive functions; the suspension of uterine activity; the limited amount of disease in the lung; and the characters of, and changes in, the physical signs denoting a deposit in the lung undergoing alterations rather of an absorptive than of a softening nature. A theoretical view of the two cases implies that, a slight injury having been sustained by the lung, not only did the deposit undergo changes indicating a tendency to dry up, and leave behind merely the inorganic elements of tubercle, but the still more important fact, that the impairment of nutrition, in which the morbid changes originated, had ceased, and that the tissues of the body were again being built up of healthy material. Such a condition may fairly be called an “arrest” of diseased action, and exhibits, hopefully to the Practitioner, clear evidence of the reparative powers and tendencies of the system.

## HOSPITAL FOR SICK CHILDREN.

### DIPHTHERIA — TRACHEOTOMY — CALOMEL INTERNALLY — TRACHEOTOMY-TUBE FINALLY REMOVED FIFTEEN DAYS AFTER THE OPERATION—ALBUMINURIA EIGHT DAYS—RECOVERY —CLINICAL REMARKS.

(Under the care of Dr. HILLIER.)

M. A. G., aged 4½ years, a tolerably healthy child, was in usual health till Sept. 5, 1862, when, towards evening, her mother observed “a wheezing at her chest” and slight cough. She passed a restless night, tossing her arms about. The next day she seemed better, till towards evening, when she again became worse, and her breath appeared tight. There was no heat of skin or thirst, and no pain.

On the afternoon of the 7th she first complained that her throat was sore, and had some difficulty of breathing; threw her arms about, and stretched her head backwards. An antimonial emetic was given to her, but towards evening she got worse, and passed a very restless night, with great difficulty of breathing and noise in her throat.

On the 8th she was ordered by a Physician some ipecacuanha wine and carbonate of ammonia. The next day she was brought to the Children’s Hospital. The mother stated that the child had been getting worse since the previous day, the difficulty of breathing had increased, and she had frequently complained of pain in her throat. Bowels relaxed to-day, having been previously confined. (In the same house in which she lived a little boy died of croup on August 30, and a girl died in the opposite house, on September 2, also of croup.) She was admitted an in-patient, under the care of Dr. Hillier, at 4 p.m., when the following notes were taken by Mr. T. Jones, the Registrar:—The prominent symptom is difficulty of breathing, with moderately loud laryngeal inspiration. There is recession of all the soft parts (supra-sternal and clavicular, intercostal spaces and ensiform region) during inspiration. Pulse 160, quick, soft; respirations 50. The arches of palate, uvula, tonsils, and pharynx are of a dull red colour, and covered here and there with yellowish-white exudation. Small but distinct membraniform patches are seen on the sides of the uvula; on the posterior wall of the pharynx a larger patch is seen. The exudations and surrounding parts were carefully brushed over with strong hydrochloric acid and syrup in equal proportions, and a strong mustard poultice applied to the throat. At 5.30 a powder containing a grain of calomel was ordered to be taken on alternate hours, with one consisting of a grain of calomel and a quarter of a grain of compound ipecacuanha powder. A mercurial belt was applied round the body. Diet, milk and beef-tea.

Towards night the laryngeal symptoms became worse, the recession of soft parts of the chest-walls had much increased, and the little patient was extremely restless and distressed for want of air. The consent of the friends was now obtained for the performance of tracheotomy, which was decided on by Dr. Hillier as affording the best chance for the child. It was accordingly performed by Mr. Gee, the House-Surgeon, at midnight. The head was thrown back, with the neck and shoulders raised, and a line in ink was traced from over the centre of the cricoid to the middle of the sternal notch. A fold of skin over the trachea, the middle of which corresponded to a point half an inch below the cricoid, was transfixed; the subcutaneous fascia was then divided; the muscles were then seen and separated; the plexus of thyroid veins and the isthmus of thyroid body were then seen. The isthmus was kept up and the veins kept out of the way by blunt hooks. A sharp hook was then passed into the upper part of the trachea, and the point of a scalpel was pushed in below, and made to cut up to the hook. A tracheotomy forceps was then introduced to the wound, and artificial respiration was kept up by compressing the lower part of chest for a few seconds until the child took a full inspiration, and the breathing then became easy. A full-sized double canula was introduced, and fastened by a tape round the neck. The diameter of the inner tube was  $\frac{3}{16}$ ths of an inch. The colour of the cheeks, which had been livid, now rapidly improved, and the child was evidently comfortable. The pulse soon after the operation was 160, and respirations were fifty in the minute. The bed was now placed near the fire, and blankets were put over the bed, supported by rails, and forming an enclosed tent. The air was kept constantly moist by a steaming apparatus. Care was

taken not to let the temperature rise above 70°, and the side of the bed near the fire was frequently open for ventilation. After the operation, considerable quantities of thick yellow mucus were coughed up through the tube. Beef-tea was given *ad libitum*, as well as milk. In an hour after the operation the patient was comfortably asleep, and slept at intervals through the night, occasionally sitting up to drink beef-tea.

10th.—Breathing easy; skin warm; pulse 146; respirations 48. The calomel has been continued. In the twenty-four hours since admission eight grains have been given. The powders are now to be taken every six hours only. Urine yesterday was not albuminous.

11th.—Pulse 124, respirations 44. Passed a quiet night. Every now and then coughed up some thick mucus, and the inner tube required to be frequently cleared. Bowels have acted once; stool slimy and offensive. Urine last evening contained a trace of albumen. A small patch of exudation is now visible on the left tonsil. The powders now to be taken night and morning. From the operation until the tube was finally removed, the patient was incessantly watched by Mr. Gee, or else by an experienced and able nurse. The greatest difficulty in the treatment was to induce the child, who was very obstinate, to take sufficient nourishment. It was given very frequently.

12th.—Passed a quiet night. Has coughed up, this morning, some thick mucus, tinged with blood, and a small piece of membranous exudation, whitish, a quarter of an inch square; continues to take beef-tea and milk; is now ordered, for the first time, wine, three ounces in twenty-four hours; gums rather spongy; tongue clean, moist; urine, to-day, free from albumen. 3 p.m.—Coughed up another piece of false membrane, three quarters of an inch long by half an inch wide. Calomel powders three times a-day.

13th.—Passed a comfortable night. Tube was removed to see if patient could breathe through the larynx, but it was necessary immediately to reintroduce it, as little or no air appeared to enter by the natural passage. The edges of the wound were, this morning, covered with a film of diphtheritic exudation, and touched with nitrate of silver; has taken six ounces of wine in twenty-four hours; takes more nourishment than she did; her spirits are good; intimates that her throat feels better. A larger tube was introduced to-day, the inner tube being nearly a quarter of an inch in diameter.

14th.—Pulse 124, stronger; respirations 30; much mucus expectorated through tube; wound looks more healthy; calomel omitted, and a mixture, containing ten minims of liquor cinchonæ, ordered to be taken every four hours; a saturated solution of chlorate of potash to be applied to some aphthous spots on lips and gums. On closing end of tube, a little air passes through larynx on full expiration. Urine slightly albuminous.

15th.—Passed a good night. Has had several beef-tea enemata yesterday and to-day. Urine more albuminous. Five minims of dilute muriatic acid added to mixture.

16th.—Pulse 120, firm, and of good volume; urine less albuminous.

17th.—Had more difficulty in expectorating mucus through the tube than usual last night. The mucus is, however, much thinner than it was. Was sick once in the night. Beef-tea injections are continued every eight hours, and they appear to cause a tendency to relaxation in the bowels. The bed is still converted into a tent by blankets, and the temperature is kept at about 70°, and the air moistened by occasional steaming.

18th.—Last night was the best since the operation. The tube was taken out, and the wound brought together by plaister. The patient breathed through the larynx with difficulty, and coughed up a little mucus. As the dyspnoea continued, the tube was replaced. Ordered quinae disulph., gr. ij., with dilute sulphuric acid, every four hours.

19th.—Has eaten fish yesterday and to-day. The tube is to-day again removed. The sides of the wound in the trachea came together on removal of tube, and seemed quite free from irritation. It became necessary again to introduce the tube.

21st.—Has eaten a good meat dinner.

23rd.—Tube again removed. Patient can expire, but cannot inspire through the larynx. A smaller tube now inserted.

24th.—Tube finally removed; breathing partly through the larynx and partly through opening in trachea, which is small. Spoke for the first time since the operation.

25th.—Seems languid to-day. To take four grains of the ammonio-citrate of iron, with tincture of calumba, three times a-day.

27th.—Has not taken her food so well lately. Wine increased to four ounces daily.

October 1.—Continues to improve, but slowly; was sick twice yesterday.

3rd.—Pulse 132; respirations 34; was sick again yesterday, bringing up a quantity of thick mucus; still requires much coaxing to take food; there is still a small fistulous aperture into the trachea, through which a little air escapes.

4th.—Was very sick for several hours, from four to eleven o'clock last night; after that was ordered ʒiiss. brandy every hour, since which she is better; is now ordered a calomel and rhubarb powder.

6th.—She got up and was dressed for the first time to-day; she is dull and languid.

8th.—The beef-tea injections have been again resumed, as she takes too little nourishment by the mouth; no air now comes through the wound, which is nearly healed; is more cheerful than she was.

13th.—Slowly improving; she was sick again on the night of the 11th; can now stand without assistance.

20th.—Improving; now runs about the ward; to take *Ol. morrhue*, ʒj., and quinine, three times a-day.

27th.—Improvement has continued since last note; no sign of paralysis anywhere; there is now only a small cicatrix where the trachea was opened; sent to Brighton for change of air.

*Remarks by Dr. Hillier.*—This case may be taken, together with one reported in the *Medical Times and Gazette* (July 5, 1862), in which tracheotomy was performed for diphtheria in a child, as a proof of the expediency of resorting to this operation, in certain cases of diphtheria, even in children. In this case, as in the other, there was no probability of the child surviving more than a few hours unless the air-passage was opened. The older the child, the greater the chance of a successful result, owing to the greater size of the trachea, and the less danger of collapse of the lung, which so often occurs in young children. In cases of considerable rickets, I would not advise the operation, owing to the great flexibility of the anterior walls of the chest, and the consequent danger of pulmonary collapse. In this case, there was some tendency to spread of the disease below the seat of operation, as manifested by the false membrane coughed up; I believe this was arrested by the use of calomel. It does not appear to me to be true, as stated by M. Trousseau, that the operation of tracheotomy in itself has any tendency to arrest the progress of exudation; and one of the most frequent causes of death after tracheotomy is the extension of exudation into the trachea below the wound. This exudation I know of no way of arresting except by the use of mercurials, which may with great advantage be resorted to in most cases. The remedy is one, of course, which must be used with great discretion and caution.

A few years ago this case would have been called croup; but now, as there was some exudation on the uvula and back of the fauces, and the dyspnoea set in gradually, we call it diphtheria. The two diseases cannot, I think, be distinguished. The occurrence of two fatal cases of "croup," one in the same house, and the other in the immediate neighbourhood, just before this child was attacked, is interesting. The successful results in these two cases were due very mainly to the extreme care, assiduity, and skill of Mr. Gee, the House-Surgeon, by whom both the operations were performed, and under whose eye they were incessantly kept. The convalescence was, as is always the case in diphtheria, protracted, but the debility was not greater, nor the after symptoms more serious than in other cases of the disease which have I seen treated by tonics and stimulants in large amount throughout. It will be observed that stimulants were not used to any great extent, but only as the debility of the patient appeared to demand them. I am inclined to think that the profuse employment of stimulants in this disease favours the renal congestion and albuminuria with which so many of the secondary symptoms are connected.

#### YORK DISPENSARY.

#### CASE OF CROUP COMING ON AFTER THE CURE OF SCABIES — EMETICS OF SULPHATE OF COPPER—RECOVERY—CLINICAL REMARKS.

(Case under the care of Dr. SHANN.)

ON Saturday, November 21, 1853, about 11 a.m., Dr. Shann

was sent for to see a girl, 4 years of age. She was breathing with difficulty, with a noisy, croupy respiration; the pulse feeble and irregular both as to rhythm and force and fulness; the countenance pale, and more or less mottled, with a livid hue, and the limbs hanging loosely on her mother's lap, in an attitude of extreme muscular prostration, the head and hair bathed with perspiration.

The child had been under Dr. Shann's treatment for scabies at the Dispensary for some weeks; in truth, she had had the complaint upwards of two years, the real character of the complaint never having been discovered. The usual treatment cured this affection; and when she came to the Dispensary on the Monday, she was said to be suffering from a cold and cough; but at that time there was no apparent threatening of croup. On the Friday, her mother thought her better, the cough having entirely left her; but, in the afternoon of that day, the difficulty of breathing came on.

When Dr. Shann first saw her, there was manifestly great obstruction to the passage of air through the larynx, but the breathing had not that shrill ringing sound often met with in the sthenic form of croup. There was, however, so much narrowing of the larynx, that little or no air could be heard entering the lungs, only here and there a deep droning r le in some of the larger bronchial tubes. The sound heard on placing the stethoscope on the back of the neck indicated clearly the larynx and upper part of the trachea as the seat of obstruction. Having seen the patient an apparently strong child at the beginning of the week, and considering the collapsed state the result chiefly of threatened asphyxia, Dr. Shann ordered five leeches to the upper part of the sternum, and gave a mixture containing the potassio-tartrate of antimony, desiring it to be given in quantity equivalent to half-grain doses of the antimony till it produced vomiting, and then to be reduced. Dr. Shann ordered, at the same time, a grain of calomel and four grains of grey powder every hour; and to apply steamed flannels to the feet and legs, and hot fomentations to the throat.

On seeing the child at 10 p.m. in the evening, there appeared to be some slight improvement; the leeches had bled pretty freely, and the vomiting afforded considerable relief for the time. The child dozed at intervals, and the respiration was not quite so noisy. Ordered a tolerable-sized blister to the back of the neck.

Sunday morning, 9 o'clock.—The child had varied much during the night; the respiration sometimes very difficult, at others less so; the blister had taken hold well. The respiration was certainly less noisy, but the whole surface was more livid, the fingers especially so; the chest generally was less resonant than it should be, and no air could be heard to penetrate the lungs, so far as examined, at the upper part of the front of the chest. A mixture was now ordered containing a grain and a-half of sulphate of copper and a small quantity of syrup of orange-peel in each tablespoonful, to be given every half hour till free vomiting was produced. The mixture contained ten grains of the sulphate, and the whole was taken. As soon as this had had its full effect, she was to take a stimulating mixture containing aromatic spirits of ammonia and spirits of nitric  ther every hour or two; to have large mustard plasters applied to the legs, and also hot steamed flannels. 5 p.m.—The effect of the emetic had proved most satisfactory; the breathing was comparatively free, and the obstruction in the larynx, as indicated by croupy respiration, much less strongly marked. The cough, which now reappeared when she was disturbed, was slightly ringing, but the air could be heard to traverse the lungs freely.

23rd.—The improvement still continued. The patient had slept at intervals and seemed refreshed, and had taken some tea. Previously, she could not be induced to take anything except cold water. Ordered some more nourishment to be given.

24th.—The child was in every respect better; had taken nourishment, and was much improved in appearance. The countenance of a natural hue, although the hands and arms still retained a mottled, rather livid colour. Had a constantly troublesome short cough, but the croupy sound was quite gone. Ordered a mixture of compound infusion of roses, nitric ether, and sulphate of magnesia.

27th.—Found the child convalescent.

Remarks by Dr. Shann.—Croupy affections are often met with in connexion with acute skin diseases, scarlet fever, measles, erysipelas, and not unfrequently originate about the time of the declination of the eruption. I cannot but believe

that in this case there was a close connexion between the disappearance of the long-continued chronic disease of the skin—scabies persisting for one-half of the child's life—and the setting up of this croupy form of disease. The treatment by sulphate of copper is recommended by a German—Dr. Schwabe—and is mentioned in Braithwaite's "Retrospect," vol. viii., 1843. I had formerly tried it in similar affections, but not with the same satisfactory results. Where time was allowed for the use of mercury, I should not be disposed to trust to the copper till the action of mercury in modifying such affections of the mucous membranes had first been brought to bear on the complaint; but where, as in this case, immediate suffocation is threatened, I conceive the remedy may prove very valuable in removing, by its emetic action, the morbid secretion obstructing the air-passages, and possibly in modifying the action of the secretion itself. In this congestive form of the complaint, the secretion is of a soft, albuminous, rather than a fibrinous character.

## THE HULL INFIRMARY.

### TRACHEOTOMY FOR FOREIGN BODY IN THE AIR PASSAGES—DEATH—AUTOPSY.

(Under the care of Dr. KING.)

[Reported by Mr. EVANS, House-Surgeon.]

CATHERINE S., aged 1 year and 9 months, was admitted, at 11 a.m., on February 18, 1862, having, an hour or two previously, swallowed a pea. It had lodged, apparently, in its windpipe. The breathing was laboured and wheezing, and there was evidently some obstruction to the free entrance of air into the lungs. The finger, passed as far back in the mouth as possible, met with no foreign body. The chest sounds indicated that the foreign body was situated in the right bronchus or one of its branches. The symptoms were not very urgent, but the child was sent up into a ward.

At one o'clock she was seen by Dr. King, and an emetic of sulphate of zinc was administered. While the throat was being explored by the finger, symptoms of suffocation came on, and it was necessary to open the trachea at once. There was a good deal of bleeding, and before an opening could be made in the windpipe the child apparently died; but by compressing the chest, however, for a little while, after Marshall Hall's method, respiration was restored. During the operation a portion of what appeared to be a pea came up, and a few minutes afterwards a quantity of brown viscid fluid, containing portions of peas, was ejected from the stomach. The child continued pretty well during the day, the inner tube having frequently to be removed for the purpose of being cleaned. Milk was taken freely. About the middle of the night respiration became laboured, with mucous r les all over the chest, and the countenance pale. Ordered one-fourth of a grain of tartar emetic in solution every two hours. The symptoms became aggravated, and death took place at 4 p.m. on the 19th, twenty-seven hours after the operation. She took a little wine previously.

Autopsy.—The whole of the larynx, trachea, and thoracic viscera were removed entire. Both lungs were much congested, especially the right; mucous membrane of larynx not congested, that of trachea and bronchi redder than natural. In the right bronchus (which was shorter than natural), close to its commencement, was lodged a portion of pea, and in one of its primary divisions another smaller portion was found. No pieces were found in the left lung. The stomach contained a quantity of solid, white, curdy matter (coagulated milk), with a little fluid, but no peas or portions of them.

CATCHING EELS.—One morning a man was missing, and could not be heard of for a fortnight. His wife was in such distress that when at last his body was found in a fishpond near the house no one liked to tell her, more especially as the discovery of the body was accompanied with what people thought would shock her dreadfully—namely, that when it was pulled out of the water a great quantity of eels fell on the grass from it; the body was, in fact, full of them. At last some one had the courage to tell the widow, and to add the circumstance about the eels. The widow replied, amid her tears, "Send home the eels—and set him again. I am very fond of eels."—*Life in Normandy.*

SATURDAY, JANUARY 24.

### THE PURIFICATION OF THE THAMES.

LAST week we stated the probability that the Metropolitan Board of Works would, at the recommendation of their committee, abandon the plan of pouring the more or less deodorised sewage of the western area of London into the Thames at Fulham. What was expected has taken place, and both eastern and western sewage are now to be conveyed by intercepting tunnels to Barking Creek, there to be discharged. The plan of deodorisation being thus given up, it remains to be seen in what degree the present proposal will accomplish the main end to which the Board has pledged itself—the purification of the Thames. The atrocious waste involved in the entire scheme is patent to every one. Parliament and the nation have determined to throw away wealth to the amount of £500,000 per annum, or the interest of £10,000,000 of capital. The London sewage would amply suffice to raise the annual value of 50,000 acres of land £10 per acre. This enormous amount of material must now go to form a fresh stratum in the estuary of the Thames, which, in ages to come, may yield an interesting field of research to a future development of geologists, but will be irrevocably lost to the English nation.

Leaving, however, except as a secondary consideration, the question of profit and loss, we, on the part of the Profession most deeply interested in the health of the metropolis and the purity of its river, are bound to examine how far the entire project is likely to benefit the one and to secure the other. In a small town it may be allowable to mix the rainfall with the sewage, and to carry them away together, though such a proceeding is open to grave objection on economical grounds; but in the case of the vast area of London, such an admixture is itself a blunder which must defeat alike the ends of the sanitarian and the economist. It requires no argument to show that the purity of the Thames will be best secured by diverting from it the sewage, and by directing to it the rainfall to aid its scour. This was pointed out by Mr. F. O. Ward in an able letter to Mr. Coningham as long ago as 1858 (a). The Metropolitan Board have chosen to ignore the necessity of keeping these two objects separate. By adopting the plan of mixing the sewage with the rainfall, they render them both useless for the purpose for which nature destined them—the maintenance of the fulness and pureness of the river and the fertilisation of the soil. The sewage spoils the rainfall by pollution—the rainfall the sewage by dilution. In the letter above referred to, Mr. Ward describes the sewage of London as consisting of the 50,000,000 gallons of water supplied by the water companies, enriched by the matters which this water takes up in the dwellings of the

people. Estimating the latter at two ounces per diem for each man, woman, and child, it would represent a daily total of 139 tons, containing, at 17 per cent.,  $23\frac{1}{2}$  tons of nitrogen, equal to  $28\frac{1}{2}$  tons of ammonia, of the value of £1597. The weight of the sewage proper thus calculated is only 223,000 tons, an amount, Mr. Ward observes, only requiring a couple of moderately sized sewers (not several colossal tunnels) to convey it away, and which might be pumped this way or that by steam power as easily as a lady pours tea into this or that cup at her pleasure.

Turning now to the rainfall, if the area of London be taken at only  $59\frac{1}{2}$  square miles, and if due allowance be made for evaporation and absorption, it may be set down as 80,000,000 or 90,000,000 tons annually—an amount about equal to the annual total of sewage. But the rain does not come down equably; it only falls on 152 days, and two-thirds of it in about one-eighth of the entire year. It must also be remembered that the rain of any day is not uniformly diffused over its twenty-four hours; it frequently descends in a very small part of the time, so that, for instance, 7,000,000 tons of rain—equal to a month's sewage—will at times fall on London in a single hour. The mixed streams of rain and sewage liable thus to be increased are too enormous to be diverted from the river; and there is no mechanism at our disposal which could direct them to the soil. In the great sewage tunnels which are now being built, Mr. Ward argues that the current will, in rainy weather, be torrential; in dry, a slender streamlet, too weak to scour the containing culvert, and to prevent the accumulation of putrescent material.

The accumulation in the underground cesspools and sewers of London, Mr. Ward estimates at twelve months' excreta, or an amount equalling one day's evacuation of the entire population of Europe and Asia, numbering 800,000,000. Suppose that a sudden rain-storm sweep into the river eight or nine days of this accumulated filth, it would be equivalent to polluting it with one day's excrement of the entire population of Great Britain. The money-loss of every such occurrence will, in ammonia alone, be nearly £16,000, whilst the river, as far as the tide extends, will be discoloured, and, in hot weather, putrescent for days. The proposed plan of deodorisation has been most rightly relinquished, but the new one will add enormously to the evil. In avoiding Scylla, the Board have rushed into Charybdis. Twenty-five more miles of rain-gathering surface have been added to the area, to make the days of overflow more frequent and the masses of filth discharged vaster.

It is at the point where the pipes conveying the rain from roof and area, and the sewage from closet and sink, meet, that the grand error is committed. Whilst the two streams are separate they can be each used—the one for scouring the river, the other for enriching the land. Mingled, they are unmanageable and useless, and, directly or indirectly, become the fertile source of pestilence and death. If the silver stream of our poets and dramatists is to be restored to the nation pure and full as it was in the days of the Tudors and Stuarts, it must be done by modest tubes bearing to it the unadulterated showers of heaven, not by gigantic tunnels deluging it with the offal, the mire, and the excreta of London. But mankind are seldom convinced by argument: experience is a more severe, but a more successful, teacher; and from it the rate-payers of London, and the nation at large, will learn that public interest is not always represented by a cabal of engineers, and that the teachings of nature and common sense are identical with those of the highest social and sanitary science.

### THE WEEK.

#### ST. THOMAS'S HOSPITAL.

The Governors of St. Thomas's Hospital have met, but have left the question of the site of the new Hospital still undecided. Six sites have been submitted to their consideration

(a) "Purification of the Thames: a Letter, by F. O. Ward, Esq., addressed to William Coningham, Esq., M.P." Second Edition. London: H. Renshaw.

—viz., the ground now occupied by Bethlehem Hospital, a piece of land belonging to the Fishmongers' Company on the eastern side of the Walworth-road, the Surrey Gardens, a tract of open ground at the back of Newington Church, Myatt's ground at Camberwell New-road, and a piece of land about to be reclaimed by the proposed southern embankment opposite the Houses of Parliament. It seems to have been the general opinion of the meeting that the site of Bethlehem would be the most suitable were it not for the enormous expense of removing the Lunatic Hospital and rebuilding it elsewhere. Next to Bethlehem, the ground near Newington Church appears to have obtained favour. The grand committee have finally abandoned their intention of a country Hospital supplementing a town one, and have come to the determination to have a central Hospital in a central spot, without division either of the establishment or school. The report, which was only passed after considerable discussion, contained a long exculpation of the committee from the charges, during the past year, constantly reiterated against them. Mr. Tite, who was the principal spokesman on their part, made the following statement in reference to the chief accusations. In this it will be seen that he directly contradicts the assertions that they had wasted money in litigation, and had refused an offer from the Charing-cross Company of a larger sum than the Hospital ultimately obtained:—

“It had been stated in the public press that the grand committee had been litigious; but, speaking on their behalf, he declared that there had never been any feeling of litigation in their minds. All they desired was to be left alone, and that no railway should be permitted to interfere with the Hospital (hear, hear). It was further asserted that they had wasted 30,000*l.* in prosecuting their parliamentary opposition, whereas the fact was that they had spent only 3000*l.* on that account, and that was forced upon them and unavoidable. The cost of reference was 8500*l.*, but a great portion of that would be borne by the railway company. So, too, with the Chancery suit, the costs of which came to 828*l.*; a portion of that would likewise fall upon the company. They were also charged with employing an unheard-of number of counsel in opposing the company's bill; but, in truth, they had employed no more than they were advised they ought to have; and surely if the railway company deemed it right to have three counsel to support their interests the Hospital had a right to be represented by an equal number. Then, with regard to the number of witnesses who were called, the company had not less than ten surveyors in that capacity; and how were they to be met but in the same way? Whilst, however, the company called ten, the counsel for the Hospital called only six. He appealed to the meeting, therefore, whether there was any ground for the accusations that had been heaped upon the committee (hear). There was one other statement which he should notice before concluding. It had been said that, in some mysterious way or other, the company had intimated their readiness to pay the Hospital an infinitely larger sum than it got. When the matter was before parliament the company had a valuation made for the whole Hospital; and he knew what was the amount of that valuation, and that it was consistent with the character of the evidence given before the umpire. Now, the highest valuation made by anybody on the part of the company was that of his friend, Mr. Shaw, and it was 179,550*l.* for the land. Mr. Norton's amounted to 175,000*l.* Mr. Ryde's to 149,000*l.* (he was the adviser of the company), and Mr. Snook's 126,000*l.* On the other side Mr. Hunt's valuation was £267,000, Mr. Marrables' £286,000, Mr. Gurney's £297,000, his (Mr. Tite's) £296,000, and Mr. Clifton's £306,000. The umpire had been censured for the decision he had arrived at; but he had known Mr. John Stuart for forty years, and there was not an abler or more honourable man in the kingdom; and he contended that there was nothing unreasonable in the judgment which that gentleman had come to upon the figures that were placed before him (hear). With reference to the value of land in that neighbourhood, he had his own notions upon the subject, and perhaps it was not fair to cite the value of land let to a bank as a guide to the price of land required for a railway; but he took upon himself to say that, in this instance, the land which the company wanted to take was, the whole of it, of the character of the land which the bank had taken. This showed, therefore, that when the

grand committee refused the offer, they only did their duty in following the recommendations of those to whom they were bound to listen; for if they allowed the Hospital to be interfered with by the railway, it must be destroyed. He had entered into these explanations in order that the public might thoroughly understand that the committee had no motive in the course which they had pursued but that of a desire to do their duty in a situation of extreme difficulty, and fraught with enormous danger to a charity with which many of them had been connected for the greater part of their lives. In conclusion, the hon. member moved, ‘That the report be received, and that the several sites mentioned in the surveyor's report, produced this day, be referred back to the grand committee for further consideration, with a view to obtain more particulars and information in reference thereto, and again to report thereon to this court.’”

In the discussion which followed,

“Mr. Deputy Elliot characterised the whole of the report to page 9 as a ‘brief for the defendants,’ and declared that its statements were but imperfectly true, and ought not to be accepted as a full and fair record of the proceedings of the grand committee. He had been requested by one of their Medical officers, Mr. Simon, to state that he considered the grand committee to have made a singularly unfair and disingenuous use—a use which very closely bordered upon misrepresentation—of his letter written, in 1856, to the treasurer. This was a protest from one of their Medical officers, and, if time had admitted, he believed there would have been a protest from nearly all of them, as to what they regarded as an unfair use of their communications to the treasurer, by giving only portions of what they had written instead of the whole.”

Many people think, and with reason, that allowing themselves to be written and talked out of the plan of having a country Hospital, in addition to a town one, is not the smallest error into which the committee have fallen.

#### ALCOHOL FROM COAL GAS.

M. COLETTE, of Paris, has recently announced a process by which he manufactures alcohol from coal gas. It is said that it can be effected at a very cheap rate—so cheap, indeed, as to permit of its commercial competition with alcohol derived from saccharine substances. Of this, however, the only proof to be afforded will be the results of the manufacture upon an extensive scale. We will take an early opportunity of laying the details before our readers. At present the possibility of this mode of producing alcohol is simply proclaimed as the result of experimentation in the laboratory. The subject will doubtless attract the attention of innumerable chemists. Should anything come of it, and the price of spirit be cheapened in consequence, we shall not be disposed to regard the discovery as an unmixed good.

#### PHYSICIANS' FEES.—CASE OF GIBBON v. BUDD.

THE Medical Act and the new by-laws of the College of Physicians have together had the effect of unsettling the previously-received principle on the subject of physicians' fees, at least, as regards the members of the London College. We confess that we think this is to be regretted. We know that it is the opinion of a large body of practising Physicians that fees should be strictly *honoraria*, and should not be reduced to the level of charges to be haggled over and disputed in courts of law. We believe it to be better for the Physician to put up with an occasional loss than to forsake the 'vantage-ground' which his position, with regard to remuneration for his services, has hitherto given him. Yet, on the other hand, there are so many cases in which unfair advantage is taken, that we readily concede that those who adopt the opposite view have some ground for their opinion. The case of “Gibbon v. Budd,” which will be found in our “Legal Intelligence,” is one in which a departure from the rule might be almost said to have been forced upon the plaintiff. The patient, a rich miser, dies, and his executor, who comes by his decease into half a million of money,

actually refuses to pay Dr. Gibbon the sum of twenty guineas for visits to the deceased, on the ground that, there having been no special contract, Physicians are unable to recover under any circumstances by the by-law of the College. That by-law, however, only refers to Fellows, and the plaintiff's case, it was therefore argued, was not affected by it. For our own part, we hold that, in so framing the by-law, the College committed an error. If it befits the dignity of Fellows that their fees should be strictly honorary, the non-extension of the law to members may be supposed to place them in a different position as Professional men. Mr. Baron Bramwell seems to doubt whether, under the Medical Act, which provides "that Physicians registered under it may recover reasonable charges subject to such by-laws as might be passed by the College of Physicians," that College "has a right to make a by-law referring to one portion of their body only." It certainly was never the intention of the Fellows of the College to place the whole body of members, a rank through which alone they themselves arrive at their present dignity, in another *status* outside the College. The law should, we think, if enacted at all, have comprehended both divisions. In the present instance, Dr. Gibbon gained a verdict, leave being reserved to the defendant to move the court above as to the construction to be placed on the Medical Act. It is, however, a good thing, apart from the question at issue, that such cases should occasionally be brought to light. The general public are little aware of the injustice and ingratitude which too frequently are meted out to the Medical Practitioner. But we repeat that, in our opinion, the old principle was the better. The position of the Bar would be manifestly lowered if fees to Queen's counsel *only* were *honoraria*, and the remuneration of the junior barrister were reduced to the same category as the attorney's bill.

#### THE MEDICAL DEPARTMENT OF THE UNITED STATES ARMY.

THE annual report of the Surgeon-General of the United States' Army for the year ending June 30, 1862, has appeared in a recent number of the *American Medical Times*. The number of general Hospitals is thus seen to be 150, and the total number of patients in them 58,715. During the past year the health of the troops has been remarkably excellent. No epidemics of any severity have appeared among them, and those diseases which affect men in camp have been kept at a low minimum. Scurvy has been almost entirely prevented, and yellow fever, from which much was feared, has had but few victims. This immunity is due, says the report, to the excellent hygienic arrangements instituted, and to the cordial manner in which generals in command have co-operated with the proper authorities. At present, the total number under the charge of officers of the Medical Department is not short of 70,000, and immediately after the battle of Antietam it was over 90,000. In the discharge of their duties, Medical officers have been very much aided by the contributions of the people of the country, and by the efficient co-operation of the sanitary commission and relief associations. The Surgeon-General is satisfied that never before were the sick and wounded of an army so well cared for as are those who have suffered for their country in the present rebellion. He considers the Hospitals to be a credit to the nation. He informs us that, prior to June, 1862, in the examinations for admission into the service, the standard of attainments required for success was much lowered, and that out of eleven candidates only two were rejected. At the present time the standard has been raised, and he adds that the gentlemen now entering the Medical staff have been found fully competent to undertake the important trust with which they are charged. Appended to the report is a series of recommendations calculated to increase the efficiency of the department, the necessity for which, together with the confession as to the admission

of candidates, goes far in our mind to neutralise the rose-coloured account of the manner in which the unfortunate sufferers from the war have been hitherto cared for. First, he recommends the establishment of a Hospital and ambulance corps, after the model of those in the European armies. Secondly, an increase of the Medical corps, since the service in Hospitals has been hitherto filled by the employment of "contract" Physicians. Thirdly, he wishes to do away with the five years' probation as assistant, before promotion of an officer to the full rank of Surgeon; adding, that the number of Medical cadets is altogether too small for the necessities of the service. Fourthly, he recommends the institution of a corps of Medical army inspectors. Fifthly, an annual grant for an army Medical museum, and the establishment of an army Medical school. Then follows a series of recommendations as to an increase in the number of Medical storekeepers; an improvement in the laundry arrangements of the Hospitals, etc.; and one to the effect, that the Medical department should be charged with the duty of building the Hospitals which they have to administer. He tells us that, in the matter of transportation, the interests of the service require that the Medical department should be independent. Much suffering has been caused by the impossibility of furnishing supplies to the wounded, when those supplies were within a few miles of them in great abundance. Passing on to the recruiting and equipments of the army, we are informed, that the minimum age for recruits is now fixed at eighteen years, and it is not uncommon to find soldiers of sixteen years old. Youths of these ages are not developed, and are not fit to endure the fatigues and deprivations of military life. They soon break down, become sick, and are thrown upon the Hospitals. As a measure of economy, then, he recommends that the service age of recruits be fixed by law at twenty years. The present manner of supporting the cartridge-box is, he says, productive of hernia; and he recommends that, instead of being carried by a belt round the waist, it should be supported by a shoulder-strap.

#### VENTILATION OF NEW BUILDINGS—A FIX.

THE editor of the *Builder*, a journal heartily devoted to sanitary progress, informs us that a district surveyor, of twenty-five years' standing, has been suspended for three months by the Metropolitan Board of Works—a punishment equivalent to a fine of £100—for non-performance of his duties, under the following circumstances:—The 29th section of the Building Act requires, that unless all the rooms of a new house can be lighted and ventilated from a street or alley adjoining, it shall have in the rear, or at the side thereof, an open space exclusively belonging thereto of the extent of at least 100 square feet. This provision is habitually evaded by persons constructing buildings of a low class, and it so happened that an attempt of the kind was recently made. Two small houses, it appears, each having two rooms on a floor, front and back, were erected at Stepney, with a large open area behind. When the houses were built, the enclosure walls at the back were put up in such a way as not to give to each house the requisite area of 100 square feet. The district surveyor complained to the builder, and, in consequence, he removed the doors by which the front and back rooms communicated, and made an opening of about 4 feet 6 inches in width, so as nominally to turn the two rooms into one "lighted and ventilated from the street." The district surveyor ought to have carried this case before the magistrate, but did not do so, because the builder had complied, if not with the spirit, yet with the letter of the Act, and for this failure of duty he was suspended. The Metropolitan Board, then, who have the control of their officers, interpret the Act as any other reasonable people would, and insist on the object of the framing of the clause referred to being maintained. But suppose the officer had proceeded criminally

against the builder. He would have been met with the argument, that this was a penal clause, and must, therefore, be strictly and literally interpreted, and, before the magistrate, he would most certainly have lost the day. This is no imaginary result. "Magistrates have already stated, that although the Act requires rooms to be lighted and ventilated from a street or alley adjoining, the clause is not contravened if the back room be so lighted and ventilated through the front room." In the case of the district surveyor of Bethnal-green against Baum, who had not provided the required area at the back, Mr. Hammill, the sitting magistrate, suggested that the builder should remove the partition which divided the front room from the back room on the different floors, so as to meet the requirement of the Act, and this was done. In a more recent case, in Marylebone, the district surveyor having summoned a builder for not providing the proper area, the sitting magistrate suggested to the builder to get over it by substituting a glass door for the deal one between the two rooms." Still, while we think that the district surveyor in Stepney ought to have proceeded in his duty, in spite of these adverse decisions, we are of opinion that the fault he committed would have been fully met by a reprimand. At the same time, with magisterial decisions such as have been referred to, it is clear that, if this most wholesome law is to be carried out, no time should be lost in the ensuing session in obtaining such an amendment of its provisions as will prevent evasions of this kind for the future being sanctioned by the magisterial bench.

#### THE POPULATION OF MEXICO.

THE expedition to Mexico, and the avowed intention of the Emperor to restore to the Latin race on the other side of the Atlantic all its strength and *prestige*, by erecting a Mexican monarchy, have turned thither the eyes of all Europe. A Medical journal, the *Gazette Hebdomadaire*, has lately published an admirable series of letters from M. Buez, *Aide-Major* attached to the expeditionary force, descriptive of the Medical aspect of the country. The fourth of this series contains a graphic description of the population. From every paragraph may be gleaned matter favouring Dr. Knox's cherished faith in the immutability of race, and the impossibility of superseding and supplanting autochthones by foreign immigration. The modern Mexican is the Spaniard deteriorated. He has retained all the faults of his European ancestor—his vanity, his sloth, his poverty, and indifference, but, with them, something of his gallantry and his abstemiousness. Civil war and gambling are his only passions, and, the latter, the only honest institution which is honestly practised. The Mexican gains or loses with an *insouciance* remarkable, never uttering a sound. After his last coin is gone he will stake the gilt serpent which garnishes his sombrero, and the silver buttons adorning his nether habiliments. All lost, he borrows a few piastres with an air of *dignité* that it is impossible to resist—it must be added, that he will scrupulously repay when the fickle goddess proves favouring. The Mexican *senorita* is inactive, slothful, and an unbridled coquette. Visiting, cigarettes, and *les bains* are her only occupation. But yet she, at times, can exhibit noble qualities. Often has M. Buez admired the courage and devotion of the wife of the *arriero* under a burning sun and the fatigues of a frightful route. But the only working population are the children of the soil—the primitive Indians. It is they who bring to the towns the produce of the country. On market-days, they come in, men, women, and children, with feet and legs bare, carrying their large baskets, fastened in front by means of a girdle, the mother bearing her infant suspended at the side of her pannier. Often, for the sake of a few piastres, do they accomplish five or six leagues, under these conditions. Prescott, in his "Conquest of Mexico," relates the marvellous feats of walking performed by the couriers of Montezuma: the same qualities of endurance

and docility are exhibited by their scattered and degraded descendants. The Indian's respect for religion and its ministers is extreme. As soon as he hears the tinkling of the bell which announces the transport of the host to some sick man, he prostrates himself, and continues kneeling until the sound has died away in the distance. The Indian mother hastens with her recently-born infant in one hand, and an enormous candle in the other, to dedicate her child to heaven. This veneration, which spent itself in the gorgeous worship of the Teocalli, is still to be recognised under the leaf-covered huts of the aborigines of Anahuac. Forms of religion and forms of government change but little the enduring lines, moral and physical, which nature has imprinted on the races of Man.

#### PROVINCIAL CORRESPONDENCE.

##### GRADUATION WEEK AT ST. ANDREWS.

BY ONE WHO WAS THERE.

ON December 24, 1862, I found myself once more in Edinburgh—once more looking at its castle,

"Grey in arms, and marked with many a seamy scar,"

loitering near *that* monument, peeping into the dingy closes of the High-street, "cannily keekin ben," and dreaming of the glorious suppers of long, long ago! I climb the Calton-hill, my heart panting, towards the crags, Arthur's seat, and Antony's chapel, and proudly looking on this, Scott's own romantic town, could not keep from exclaiming—

"Where's the coward that wouldn't dare to fight for such a land?"

But from high poetics to the dull, common prose of life there is but one step. The train starts at half-past two, and I must be off to St. Andrews. Of course, you know this same St. Andrews is situated in the kingdom of Fife, North Britain, and washed by the waters of the German Ocean; that its university is a very ancient seat of learning, and the town and neighbourhood closely associated with the early history of Scotland; and tales of thrilling interest hang around its crumbling walls! Here, some of the best and the worst men Scotland ever knew drew their first intellectual breath; here, the men of the Covenant did their bloodiest deed (?); but our business at present is with the living and not with the dead; so, if you please, we will say—

"The knights are dust, their swords are rust,  
But their souls are with the saints, we trust."

Here we are at the station called St. Margaret's, a motley crew drawn into this little point, as a focus, the Medicals being recognisable at once by, shall I say, our jaded, missionary look, martyr's eye, and lofty scorn of external appearance. The voyage to Burntisland is made in safety, "that lonely spot by the sea," and we are in the heart of Fife, rushing past the "lang town" Markinch, and other villages associated with the wanderings of the eccentric James V., who, as the guid man o' Ballengeoch, did higgelty-piggelty justice there!

Hitherto, we have been a black mass of human beings moving to St. Andrews, but individual peculiarities are beginning to appear. Here is a beardless young man, not quite finished at Guy's, who has come up, like a trump, determined to take his degree, and not lose this last chance.

Yonder man, with the portly frame and great gold chain, talking so loud and sonorous, is a well-known London quack. Of course, he thinks the *thing* is to be bought, and has brought lots of *tin* with him; but is astonished to learn that there really is to be an examination. "Who is Penny, and Struthers, and Buchanan?" he is continually asking. "Why, I thought Day was to do it all." "Oh, not at all; it is a very stiff examination. Heddle is worse than Penny; fifteen were plucked yesterday." And so our fat fellow traveller is left to draw comfort from the fifteen of yesterday, and to mark more clearly the shadow that is beginning to fall around his huge form.

Here is a quiet man who tells me he comes from Wigan, and who is silently listening to the Babel that rattles around. It is clear that he does not like all this, and has more than once looked sternly at a swarthy young man who is making a Jack of himself; but he, from the land of the sun, scorns advice, and swaggers on with defiance in his eye.

"Thornton," shouts the guard—"Thornton," and into our

already choked compartment presses a wayworn traveller from Crewe, who had missed his track in the morning, and been carried round by Perth, and now, at the last hour, has joined the great body of recruits for St. Andrews.

The first time one sees and carefully looks at a particular person, we endeavour to index the inner from the form and expression of the outer man. We are all continually doing this, and continually failing, because man is a complex being, and has springs of action unknown even to himself. The soul is too subtle to be measured by anything material, and all attempts to arrive at but a very general idea of what a man is by looking at him, have failed, and must fail. Notwithstanding, we cling to our habit, and peer into men's faces, and look into their eyes, which poets say are the windows of the soul, and imagine we see truth and beauty—a life devoted to virtue, reflected from those wonderful orbs; or fastening on a lip, grasping a hand, staring at a neck encompassed it may be with "a white choker," we declare the unfortunate possessor of the thick lip, stumpy fingers, and short neck, highly dangerous to society—an inflammable mortal little above the brutes that graze the field. It is needless to say that in all this we err much, and frequently do grievous wrong to worthy, most excellent people, and should not be guided too much by these first impressions. The worst man I ever knew was a plausible scoundrel, with a fair face and handsome exterior; and some of the best men I have met—large-hearted, noble fellows—were dumpty and most unpromising at first look. However, I must confess "some souls by instinct to each other turn," and we three, that is, the gentlemen from Wigan and Crewe and myself, who were entire strangers, agreed to lodge together, and a few minutes more found us, as old friends, over a towsey tea, in excellent quarters at the Post-office, St. Andrews. One sentence more before the curtain drops for the first night. At the Post-office we found an Irishman, also a candidate, who gave us a hundred thousand welcomes to the ancient city. He had lived in it three days, and was full of information concerning the coming struggle. But love is the soul of a neat Irishman, and with one or two of Moore's songs, and a glass of *poonsh*, we drowned all cares, and went to bed as happy as kings!

Christmas morning broke beautifully: the atmosphere was clear and bracing; and the streets of St. Andrews, clean and shining, animate with the black-coated strangers, gave the old town quite a gay appearance. Among the first persons we met, on emerging from our lodgings, was the portly gentleman from London. He had been to the secretary, Mr. McBean, and was evidently disconcerted at the reception. Things were beginning to assume rather a serious aspect, and the joke was becoming a little painful. There was to be an examination after all, and no mistake! Two days ago, a military gentleman, covered with clasps, had got plucked. The most aged among us must submit to this ordeal: really it is too bad to bring middle-aged gentlemen so far and use them thus; why, it is shameful!! "I go back to London," said the man of pills, "but Day shall hear from me!" and, saying this, he drew a long breath! In vain I looked admiringly at the gold chain! In vain I attempted to "smooth the raven down of darkness till it smiled." It would not do. Hope came not here that comes to all. In vain I rested my eye on his round corporation, and splendid pectoral region, assuring him his appearance was sufficient to make him pass, and that such a jolly-looking fellow had no cause to fear; all would not do. "Go in," I exclaimed, "it is glorious to fail!" but my fat friend had no idea of such glory, and, looking unutterable things, he waived adieu, and we parted never to meet again!

On reaching the secretary's, we found a host registering, and Mr. McBean quietly and methodically doing his work, handing to each gentleman a card containing a programme of the examinations, which, upon reading, looked formidable enough, and made "the boldest hold his breath for a time." It now became apparent to the most thoughtless that there was work to be done; that those who had prepared for it were alone likely to succeed; that the stray waifs and incapables were sure to go to the wall; and that those who came here, believing it to be an asylum for the destitute, would very soon awaken from their dream. To the strong and healthy, this was rather invigorating; for what is a victory without a struggle? Sandford, on looking at his card, muttered, "On, Stanley, on!" while Barwise more philosophically exclaimed—

"Come what may,  
Time and the hour run through the roughest day."

Our Christmas dinner at the Post-office went off cheerily, for our chairman, the good man from Queenstown, was lively as Sheridan and brilliant as Burke; and while the wine-cup shone in light, with the songs of Moore and Burns, and libations to distant friends, the night passed gloriously, and we thought not of the morrow.

The ball opened on Friday morning, in St. Mary's Hall, by each candidate being admitted in the alphabetical order of his name; and, on walking forward, I found my address distinctly written at a seat in the front rank, with a request that I was to keep it during the examination. The large hall soon filled, and the "Chemistry" paper was before us. For the first five minutes I could do nothing; the seats swam around me, and I could only hear a rustling of paper and the noise occasioned by gentlemen taking their seats behind. Presently I began to look at the paper, for my neighbours on both sides were busy at it. The first question, "What compounds does hydrogen form with nitrogen, with chlorine, and with sulphur?"—Give the processes for the preparation of these compounds," appeared very beautiful, and not very difficult, and I knew who constructed that question. But still I could not go on with it; my hand trembled; I could not think, and once more I looked up to see what was passing around. The examiners were moving about, silent as ghosts, handing papers, and assisting men to find their places. There were among those examiners strange faces, but others I had seen before. That little man, whose hand, no doubt, drew the questions we were to answer, is one of the great chemists now living: as a teacher, I do not know his equal; and as a toxicologist, Taylor alone may be named before him! That other gentleman, with a fresh and ruddy complexion, has an historical name, and, if you look carefully at his face, you will be reminded of a remarkable man, who bore the same appellation, whose phiz is well known to the readers of "Ebony." He is the worthy son of an honoured sire, and well qualified to take part in this examination.

That venerable old gentleman, with the long flowing beard, I do not know; he is evidently a descendant of some of the cardinals—perhaps of John Knox himself.

There is Tulloch, with sunshine in his look, and a spring in his walk, which gives the world assurance of a man.

Who is this gentleman with the pale, womanly face and spreading forehead, so calm and still in his motions? That is Struthers, a well-known name in Surgery, under whose mild exterior lies a nerve of iron. Other men of mark are moving about, but we will speak of them again.

The venerable gentleman with the beard has just been saying, "There is but half an hour left to finish the first paper," and I see some of the candidates have already got it finished, and are busy at the one on "Materia Medica."

The tremulous feeling has now subsided, and each man is doing his best to answer the questions. All is orderly, not a *wish* is heard, and the work goes on. The Latin paper reaches me at last: by this time some had got it over and left the room; and with it closed a long round of three and a-half hours. On getting into guid bruid daylight, who should I run against but an old fellow-student from Fort William, whom I had not seen for many years, when we congratulated each other on round No. 1. I was the first of our lot who arrived at the Post-office: Joseph was too exhaustive in his replies; and the others, like myself, had felt a little queerish, but had stuck in to the last; so, with old Jack Falstaff, believing in a cup of sack, I warmed my heart until their arrival, consoling myself with the thought—"He that does his best, does well, acts nobly—angels can do no more." The other gentlemen soon arrived; and, after mutual congratulations, we prepared for bout No. 2, which passed off with less excitement than the first, and consisted of the Anatomical and Physiological papers, with the questions on "Surgery," and extended fully over two hours.

In the evening, along with a batch of others, I found myself, by special request, waiting on Dr. Day, in a crowded room of that gentleman's residence. Each man held in his hand his diploma, or evidence of it; and as, one by one, we drifted into the presence chamber, there was a pause as though some of us had suddenly sunk out of sight or passed into some dangerous vortex. It was curious to observe how the various gentlemen conducted themselves on emerging from the scrutorial chair, one declaring Day had treated him most savagely, lacerating his muscular system, tearing through the arteries, and making sad havoc at the base of the brain. From this description I was made to fear that a bear

was in the other room. The next arrival would tell us how gentlemanly and kind Dr. Day was; while a third would say, "Why, he did not ask me many questions; I told him I had not studied 'comparative anatomy,' but was familiar with the workings of the microscope, and he was kind enough to pay a compliment to the educational institutions of my native town." And so, after many departures, my turn came at last. I found a middle-aged gentleman, evidently an invalid, partially reclining on a couch, who, with searching eye, scanned me as I entered, courteously inviting me to take a seat. Dr. Day is a practised hand at operations of this kind, and I need not say how very soon he dissected me, making the humble narrator of this interview once more acutely feel the truth of Bacon's aphorism, "Knowledge is power." With a smile he bade me "Good night," and I felt I was not quite killed, nor inclined, like an unfortunate fellow-traveller, to run away. One poor fellow, who had waited in the ante-room for some hours, and found at last that he was not wanted, but that he ought to have been with Drs. Heddle, Craigie, etc., in the hall at the university, became fearfully agitated, and in despair asked me "where he could get a refreshment?" I pointed to an hotel over the way, and he vanished from my sight. Next day I saw him in a still more pitiful plight. Evidently he was a doomed man, for there he was, hat in hand, gravely talking with the examiners in the body of the hall, while the written questions were being answered. Now, it was clear he was no longer one of us; and, no doubt, the two p.m. train saw him on his way for the great metropolis, sadly thinking—

"Hither, as to their fountain, other stars  
Repair, and from those urns draw golden light."

Saturday morning found us at the "Practice of Medicine" papers, and we finished the day with those on "Midwifery." Many gentlemen had taken their departure "in sorrow, grief, and woe;" and pale, anxious faces were to be seen about South-street, dreading that fatal letter, and trembling lest Fletcher should honour them with a visit. It came to I do not know how many, but certain the rejections were numerous, and, I believe, some good men were plucked—great lament being made for a promising young man from a metropolitan Hospital.

Sunday gave us a breathing space. Wandering among the ruins of the cathedral and Cardinal Beaton's palace, inhaling the saline breezes, and "wondering what the wild waves were saying," the day passed. Monday brought the orals. There I met, for the first time, Dr. Sellers, a mild, benignant man, with whom I spent a very agreeable quarter of an hour; passed to Dr. Buchanan, and from him to Dr. Keiller, a gentleman evidently of high Professional acquirements. At last I found myself sitting opposite my old master, Dr. Penny, who blamed me much for forgetting my chemistry, and was only prevented from murdering me outright by the shortness of the hour,—

"Glad to escape, I stumbled to the door—  
Confound your symbols and your atoms more."

And so ended my "heckling" at St. Andrews.

The rest of the day we spent lounging about Fletcher's, where considerable excitement was kept up by hearing of these fatal letters, the report being "still they come;" and as no man could say one of these little billets might not come to him, each was asking others the news, and looking out for the wounded and the fallen, and those who were likely to go.

A rollicking sailor, fresh from the *Hogue*, once splendid at a dissection or an examination under Moses, now full of health and mirth and jollity, would come up into our lodgings and alarm us all by the terrible work that was going on, telling us old Dr. Craigie was biting like a snapping turtle; that nothing but the crotchet and perforator were used by Wilson; that that white-haired fellow, Edwards, was scalping them, and Heddle finishing the work with oxalic acid! "No doubt," continued Arthur, "the deaths are numerous, and, gentlemen, the mortality will be great." The big fellow would then extend his sides and roar like a hippopotamus.

This, and some things more, brought Tuesday, but "the havoc did not slack," for Arthur was still swearing, "'Tis as bad as the cholera,—every third man is plucked who goes in to-day." However, calling on Mr. McBean, he desired us to sign the oath—and so, we had passed.

The capping took place on Wednesday, December 31, at three p.m., in the large hall, when not less than 130 gentlemen received the honourable title of "Doctor Medicinæ," after a

protracted examination extending over eight days, the feeling among each and all of us being that we had been thoroughly tested, and that the gentlemen who passed as men of honour and ability are themselves a guarantee that no man received the degree that day who did not deserve it. And now, fellow graduates, farewell. We can never all meet again; most of us will never see each other more; but each of us have a certain influence as individuals, and that influence is for good or for evil. Every profession is affected, to a certain extent, by the character of each individual member of it. Let us, then, under all circumstances, endeavour to do the right, so that St. Andrews may not be disgraced in our persons. Let us, above all—

"To ourselves be true,  
And it must follow, as the night the day,  
We cannot then be false to any man."

## GENERAL CORRESPONDENCE.

### DISSECTION WOUND — TWENTY - ONE DAYS AFTERWARDS, INFLAMMATION AND SUPPURATION OF MIDDLE FINGER OF RIGHT HAND; SUBSEQUENTLY PALM OF LEFT HAND—RECOVERY.

LETTER FROM DR. CHARLES DRYSDALE.

[To the Editor of the Medical Times and Gazette.]

SIR,—The following case of dissection wound is so singular, from the long period of incubation, that I have thought it, perhaps, not unworthy of insertion in your pages:—

On November 11, 1862, in company with Mr. L., a brother Practitioner, I made a post-mortem examination of a young woman, aged 23, who, during life, had suffered from albuminuria with anasarca, upon which disease symptoms of phthisis latterly supervened, leading to emaciation, and, immediately before death, to peritonitis.

*Post-mortem Examination Twenty-four Hours after Death.*—Notes:—Rigidity well marked; body emaciated; on pressing the abdomen, there are felt hard, roundish bodies, about the size of a hen's egg, in the epigastric region. On opening the abdomen, these bodies are discovered to be enlarged mesenteric glands. The mesentery, from the number of them, presents the appearance of a hen's ovary. There is about a pint of fluid in the abdominal cavity; no adhesions of intestines. Kidneys enormously enlarged, weighing together one pound eight ounces; on section, the tubular portion presents the feather-like appearance common in such cases. Thorax.—Both lungs have their apices consolidated with recently-deposited tubercle; each pleural cavity contains a small quantity of fluid. Pericardium and heart not abnormal.

Twenty-one days after this post-mortem examination, at which Mr. L. pricked his finger, the finger began to swell.

December 2.—Mr. L. showed me his finger; it was much swollen, and threatened deep abscess. I advised incision, and Mr. Allingham opened the swollen part, pronouncing the case to be a dissection wound.

6th.—Finger suppurates freely; red line along the course of the right axillary vessels; pulse 90; tongue clean; appetite good; rigors.

11th.—Palmar surface of left hand is inflamed, and there is a deep abscess; pulse 95; tongue clean; Mr. L. has an anxious look, and is thinner.

15th.—Mr. Allingham opened the abscess in the left hand; small pustules near the inflamed part; Mr. L. is very weak; pulse 95, weak.

19th.—Confined to bed; left hand much swollen, and suppurating very slowly; pulse 95; haggard.

30th.—Much better; wound closing.

January 10.—Convalescent; fingers stiff; health excellent.

The treatment of the case was simply analeptic, with a moderate amount of stimulants. I have not found in works upon necroscopic poisons any instance of such a long interval (twenty-one days) between the inoculation and the outbreak of symptoms; and would be glad to hear if this has been observed.

I am, &c.

CHARLES DRYSDALE, M.D.,  
M.R.C.P. Lond., F.R.C.S. Eng.,  
Hon. Sec. to Harveian Society, London

## THE ARMY MEDICAL DEPARTMENT.

## LETTER FROM AN ARMY SURGEON.

[To the Editor of the Medical Times and Gazette.]

SIR,—The Medical officers of the army will feel a debt of gratitude to you for bringing their grievances before the students, as it is only by pressure which can be brought to bear on the Horse Guards, by no candidates offering themselves for the appointment of Army Surgeon, that justice will ever be done to the Medical service.

The columns of the Military and Medical papers have all of them frequently expressed how the authorities have, in every possible way, thrown over the Warrants of 1858, and how they have seemed to delight in snubbing their Medical department by all means in their power. It is well known that in every rank of the Medical department there is deep dissatisfaction; in fact, that Medical officers of fifteen or twenty years' service cannot now afford to throw away their service, or they would resign in large numbers. I well recollect, about a year ago, that a petition was signed by nearly all the officers of the Medical department, to memorialise the Secretary at War concerning the abrogation of some of the benefits conferred on us by the Warrants of 1858. This was laid before the Secretary at War by General Peel, who, as a former Secretary at War and a military officer, was not likely to espouse a cause that he did not consider was just and fair. A short time after this, the *Globe* and other daily papers stated, that all the grievances of which we then suffered were to be redressed, and the *Globe* published a leader on the subject. As this paper is supposed to be the Government organ, the department felt convinced that what it stated was true, and took no more steps in the matter. From that time to this, nothing has been done; and, as you justly remark, the whole body of Medical officers is disgusted, and feel that faith has been broken towards them.

Whether it is advisable that so large and useful a body of gentlemen should be thus insulted and discouraged, I think is a matter worthy of the attention of the public; and I hope, as soon as Parliament meets, that steps will be taken, so that, without delay, some pressure may be put upon the Horse Guards, and our rights at once be granted. But, above all, we look to your columns to lay before the Medical students and young Surgeons the manner in which we have been treated, and how they may expect to fare when they have once donned the now degrading costume of the army Medical officer. Let them recollect that, not content with qualifications that are sufficient for a man to rise to the highest position in civil life, special acquirements are insisted upon; besides which, before an Assistant-Surgeon can obtain his next step, he must undergo a second examination; and then let all aspirants for military surgeoncies ask themselves whether the "game is worth the candle?"

I am, &amp;c.

AN ARMY SURGEON.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 13, 1863.

Dr. BABINGTON, President, in the Chair.

A PAPER, by Mr. JOHN DIX, was read, on the

WIRE COMPRESS: A SUBSTITUTE FOR THE LIGATURE.

The wire compress—the subject of this paper—is a modification of the method of arresting hæmorrhage devised by Dr. Simpson, of Edinburgh, and introduced by him, about three years ago, as a substitute for the ligature. This "acupressure," as it is called, has been tested by but few Surgeons of note; and in London, especially, it is almost unknown and ignored. Although, probably, a real improvement on the ligature, it undoubtedly labours under certain inherent disadvantages, most, or all, of which (it is believed) are obviated by the use of a fine wire of iron or of silver, instead of the steel needles of Dr. Simpson. This idea was first promulgated in a paper on "Acupressure," published in the *Medical Times and*

*Gazette* of June 2, 1860; and first put to the proof in a case of amputation of the finger, September, 1860. In this operation two arteries were secured by wire, which was removed on the third day. The case did well: there was no bleeding, and very slight suppuration. In the next case—Chopart's amputation, performed April 26, 1861—five wires were applied on as many arteries: four of these were removed in forty-eight hours, and the other on the fourth day. It was found that the wire was easily applied, as easily withdrawn, and entirely effectual for the purpose it was intended to serve, namely, the arrest of the bleeding from the cut vessels. This patient, being the subject of constitutional syphilis, did badly. There was sloughing of the entire surface of the wound, and the flap was totally destroyed, notwithstanding which there was no hæmorrhage; but she died, on the thirteenth day after the operation, of pyæmia. Case 3 (September 21, 1861).—In an amputation of the thigh, done after Mr. Luke's method, there were seven bleeding arteries. Upon five of these the wire was used, and, with the femoral artery, the femoral vein was intentionally included; two very small branches were treated by torsion. This case did well. Seventy-two hours after the operation, four of the *presse artère* wires were withdrawn with perfect ease and without bleeding. The one on the femoral remained five days, when it, too, was removed without any difficulty and without a trace of blood. There was but little suppuration, and an excellent stump was the ultimate result. These cases prove that this mode of securing arteries is practicable, efficient, safe, and manageable. It is also believed to possess a certain positive superiority over the ligature, as the following comparison shows:—A ligature in a wound impedes union and induces suppuration. Cure, by primary adhesion, of a large wound—as, for instance, an amputation—is an event of extreme rarity, and this because of the ligatures. A thread of silk is, in fact, a miniature seton, and the whole number required in an operation make up one of considerable size, and can scarcely fail to lead to the formation of pus. Again, the ligature of necessity excites ulceration of the artery upon which it is tied; it cannot in any other way be got rid of. This is another unhealthy process, antagonistic of repair. In applying a ligature, the end of the artery is drawn out from its sheath, by which its natural connexions are disturbed, and its vasa vasorum broken up; its coats also are lacerated and bruised. The ligature remains for an indefinite time, long after it is useful or necessary, and it is not unfrequently pulled at by the dresser before it has become detached. Its knot, often deeply buried between the flaps, cannot be withdrawn without tearing through adhesions, or damaging the granulations. All these are serious obstacles to the healing process both in the stump and in the artery itself, and must protract the period of cure. Moreover, the following is an interesting and noteworthy formula: Pyæmia is the offspring of purulent secretion, of which the ligature is an efficient and probable cause. Bleeding arises solely from ulceration of an artery, of which again the *primum mobile* is the ligature. From one and all of these objections to the ligature the "wire compress" is almost or altogether free. Thus, in accordance with a well-known pathological law, it, being a metallic substance, is freely tolerated by the living body, and has little or no tendency to excite suppuration or irritation. Neither does it cause ulceration of the artery. This is positively affirmed from actual observation of its effect as witnessed in the sloughing stump before alluded to. It is applied without interference with the natural relations and vital connexions of the vessel. It is removed at any time, according to the will and judgment of the Surgeon, without disturbance to the reparative action going on in the artery and in the rest of the wound, without futile premature attempts, and almost without pain to the patient. It is not liable to lose its hold, or to become detached too soon, as not unfrequently happens to a ligature applied upon a brittle or sloughing artery. Twigs of nerve accidentally included in the embrace of the wire are not injured and excited as by the tight strangulation of the ligature, and, if thought advisable, the veins are easily and safely occluded, along with the arteries. Although this has been spoken of merely as a modification of acupressure, yet it is believed to be a decided and important improvement on "Simpson's skewers," as the needles have been irreverently called, and which are fairly open to the following objections:—When several of them are required, the stump resents, as it were, being thus pierced through and through in various directions. From the injury thus inflicted, and from the

obstruction to the capillary circulation caused by the pressure of the unyielding steel, arise much tension, œdematous swelling, and great pain; the pain, especially, has been found a very serious evil. Again, their projecting ends, and the puckering they cause in the substance of the flaps, interfere very much with that accurate adjustment of the cut surfaces and edges which so greatly aids the chances of union by adhesion. The wire is free from all these shortcomings. It is thus applied:—Take a piece of Surgical wire six or eight inches long, and thread each end thereof upon a straight needle. Seize the bleeding mouth of the artery with forceps, and pass one of the aforesaid needles close on each side of the artery just mentioned, about a line above the point of the forceps, directly down through the substance of the flaps, so that they emerge at the cuticular surface, about half an inch distant from each other. Draw them both through together till the curve of the wire compresses the artery on the face of the flap. Now get rid of the needles by clipping through the wire close above their eyes, and also detach the artery forceps. Place a piece of cork, cut for the occasion, upon the skin, between the points of exit of the wire, and over this twist the wire tighter and tighter until the bleeding is arrested. Lastly, cut off the superfluous wire. All which is done quicker than described. Two or more arteries lying near together may be embraced by one wire, and, as has been said, the veins may be included or excluded at will. The wire should be either of silver, or, what is much cheaper and equally manageable, of the finest and softest passive iron. The generality of wire as used for sutures is too hard and stiff. The needles are about three inches in length, straight, and three-edged, with an eye adapted for carrying wire. Special care is necessary in threading the wire that it is kept perfectly free from all twisting. The forceps are used, not to draw out the artery as when a ligature has to be applied (this, indeed, is to be particularly avoided), but merely as a guide to mark the exact position and course of the vessel. The cork is necessary to protect the skin from the pressure of the wire. The withdrawal of the wire, which at first sight appears an insuperable difficulty, is perfectly simple and easy. It is thus effected:—Clip the wire close to the edge of the piece of cork, and straighten out the curve it has formed, at its exit from the skin. Remove the cork, and apply instead the tip of one finger, with which press firmly upon the flap, making traction gently and gradually upon the other end of the wire. If this were roughly and hastily done, it might break up the adhesion which it is presumed has taken place between the surfaces of the flaps, and it is quite possible that a flexure in the wire might lacerate the artery in passing over it; but it is certain that none of these evils need happen with ordinary care and tact. As to the period of withdrawal, further observations are desirable; but it has been clearly shown in numerous cases of acupressure, that for small vessels a few hours of compression is sufficient, and for the largest arteries a much less time than might be supposed. However, as a general rule, it is not desirable to disturb a wound in any way for from twenty-four to forty-eight hours; at the end of which time all wires commanding the secondary branches may be safely removed, and probably also from the large arteries; but, as a matter of prudence, it is well to keep a check upon such a one as the femoral for three or four days at least. The descriptions hitherto given apply particularly to amputations; but the wire is equally applicable to many other operations. In a postscript to this paper was related a case of excision of the testicle, in which it was used most satisfactorily upon the vessels of the cord. Two wires were required, and they were removed on the fourth day. Also a case of excision of the breast, in which three wires were applied, and removed in twenty-four hours. The wound, which was six inches long, healed kindly and rapidly—almost without suppuration. Suppose the femoral artery needs to be secured for popliteal aneurism. The wire would be passed under the artery by means of a tubular aneurism-needle made for the purpose, brought out through the integument at a convenient situation, and then twisted upon a cork in the usual way. This same artery, cut in amputation, is securely closed in three or four days by the action of metallic pressure; consequently, in three or four days the wire might be removed. Meanwhile, it has not caused suppuration, or impeded the union of the wound, which ought, therefore, by this time, to be completely healed; and more important still, the artery is not cut through, as by the ligature, but its coats remain intact, and bleeding is

impossible. It will probably be found that the pedicle in ovariectomy may be conveniently dealt with by this method, the arteries being secured individually, and the entire stump also fixed to the abdominal wall by another wire. This idea has been already promulgated by Mr. Spencer Wells. The paper was illustrated by models.

Mr. FERGUSSON said that the author's paper ought not to pass without remark, as the subject was novel to the Society, though not new to the Surgical department of the Profession. The paper (he said) was very interesting and very clever, and yet the materials of it were not sufficient to prove the author's point, as five cases only were reported. These, if the subject had been quite new, might have been brought forward. From the cases adduced, he had not learned that there was, in the smallest degree, any advantage over the ligature, which, as a practical Surgeon, he was not disposed to set aside. It had been brought forward by a gentleman of great talents, but he (Mr. Fergusson) had not seen, nor heard, nor found anything to induce him to imagine this process superior to the ligature. The cases related were very few, whilst ten times that number of the employment of other means might be brought forward. As regards the amputation of a finger, every one knew that such cases would do perfectly well with the ligature. In the case of partial amputation of the foot, he did not suppose that the sloughing was due to the wire; but the fact, that there was no hæmorrhage, did not prove that the wire was better than the ordinary method of securing bleeding vessels. As to the plan adopted with regard to the thigh, that was not new. Professor Handyside had tried this method. The history of the case did not vary from the ordinary run of such amputations. He had tried this plan repeatedly, but should require much greater proof of its value than he had yet heard before he should attempt to secure large arteries, as the femoral or the brachial, on this plan. He noticed that in this paper, as also in many others on the same subject, there was a constant attempt to decry the ligature, one of the grandest things in Surgery. Great pains had been taken to test the value of the ligature, and he thought that the question had been set at rest. One point urged against it was, that it gave rise to suppuration, and thus favoured pyæmia. Of this he was doubtful, as he had often observed that patients, after operation, had feverish symptoms which gave rise to great anxiety, but which passed off as soon as suppuration set in. In fact, he always calculated on suppuration as a relief to the patient. He thought that the ligatures acted as vents for the discharge of pus; and, as regards their preventing healing by first intention, he would say that the advantages of this kind of union were overrated. Suppose the stump did heal by first intention, it could not be used for weeks—for months, as it was, in a great measure, new material, which would not bear pressure. In fact, the ligatures were of advantage in this way, that they prevented the patient using his limb too soon.

Mr. BARWELL said that the great compression the tissues must necessarily undergo would interfere very much with the circulation of the part, and in the case of partial amputation of the foot recorded by the author, he feared that the sloughing might be due to strangulation. Pyæmia might follow without the previous local formation of pus. He had tried acupressure in small vessels, and had found it as useful as the ligature, but would not like to try it with such arteries as the superficial femoral.

Mr. HOLMES said that the great advantage the author hoped to gain by his method was a freedom from suppuration, and yet in not one of his cases was this result obtained. He thought as Mr. Barwell did, that the wires would tend to strangulate the tissues included in their loops.

Mr. MAUNDER said that he was not aware that cases of pyæmia occurring without the existence of a breach of the surface of some part of the body had been undeniably observed, and, therefore, thought that, until such fact was established, and while pus was deemed to be a fruitful source of pyæmia, any means suggested to favour the closure of wounds by primary union should be willingly accepted and tested by the Profession. He had always been taught that the early healing of wounds was a great desideratum, by saving time, pain, and inconvenience to the patient, and by diminishing the risk of pyæmia, erysipelas, etc. The author's arguments in favour of the wire, and in preference to the silk ligature, were, at any rate, theoretically sound, and based upon indisputable physiological and pathological grounds. Notwithstanding the preference for the silk ligature which

had been expressed by the first speaker, he (Mr. Maunder) was of opinion, that the principle of controlling arterial hæmorrhage, advocated by the author, whether needles or wire were used, was a good one, and should be fairly and honestly tried.

Mr. BARWELL would refer Mr. Maunder to "Virehow's Pathology" for facts in support of his opinion, that suppuration did not necessarily precede pyæmia.

Mr. SPENCER WELLS trusted that the respect with which Fellows of the Society must receive the remarks which fell with such authority from so experienced an operator as Mr. Fergusson would not induce them to regard the suggestion of Mr. Dix as either unimportant or unworthy of a full and fair trial. The tendency of modern Surgery was towards simplicity in all things, and as compression seemed to be a simpler mode of stopping bleeding than the ligature, by all means let us see if it were equally effectual. In the treatment of aneurism nobody thought of using the ligature in a case where compression could be used, unless compression had failed. It was much simpler to stop the current of blood in an artery than to destroy ever so small a portion of the coats of that artery; and, if this were true in the case of aneurism, it was equally so in the closure of a divided artery. If compression for twenty-four hours were enough to seal or plug up a divided artery, it must surely be better simply to close it in that way, without the additional complex process of destruction and separation of the strangulated portion of the vessel which necessarily followed the use of the ligature. The objection raised by Mr. Barwell, and supported by Mr. Holmes, seemed to him (Mr. Wells) to be very unimportant, for it must be perfectly easy to apply such a degree of pressure as would compress a vessel enough to stop bleeding, without the slightest fear of injuring any of the parts pressed between the vessel and the skin. It was probably of little or no importance whether wire or silk were used; and silk would seem to offer many advantages over wire, especially as to the facility of removal. At any rate, Mr. Dix had brought sufficient evidence before them to render a fair trial of his method not only advisable, but necessary. If not on man, this was a case in which experiments might with perfect propriety be made on the lower animals. The subject was too important to be passed over without a careful investigation, by experiment, whether the advantages of the compression over the ligature were or were not real.

Mr. DIX said that he rose with much diffidence, and especially so because his reply must be chiefly directed to the remarks of Mr. Fergusson. "Of course (he said) I feel myself quite unable to cope in Surgical discussion with so great a Surgical authority; nevertheless, it is somewhat encouraging to find that such an opponent, though uncompromising and inclined to be severe, finds so few real and substantial objections to the subject of my paper. His lengthened argument amounts simply to this, that he is content with the ligature. In support of this position, he tells us that he thinks it a matter of little moment, whether a wound heals by primary union or by suppuration. In fact, of the two, he seems to prefer the latter. Sir, I have come a considerable distance to attend this meeting, and I certainly shall not return without having gained a new idea. This doctrine is altogether novel to me. It is utterly subversive of all I was taught as a student, and is entirely opposed to my own somewhat extensive observation and experience. I think it will find but few supporters in this room, or amongst the Profession at large. We have been told that, as regards the time at which a stump becomes useful, little is gained by primary union, and, in the same breath, it is somewhat inconsistently stated that suppuration is inevitable—that an amputation cannot be healed without it. This, Sir, is a fallacy. Primary union is rare, no doubt, but not impossible. I have seen it myself, and others have here and there met with an isolated case. About five years ago I amputated the leg just below the knee. In this case, although ligatures were used, there was never a trace of pus; in about six days this stump was entirely and soundly healed. I must say that I thought this a very good thing, and, with all deference to the great authority in opposition, I must still retain my humble opinion, that it is far better than a suppurating stump. I am fully persuaded that the chief reason why this good result does not oftener occur is, that those Surgeons who doubt its possibility do not adopt the best means to favour its occurrence. He who hopes most and attempts most will attain most, and I have given reasons for believing that there is no surer step in this direc-

tion than the disuse of the ligature. Pyæmia, we have also been told, is not necessarily connected with the presence of pus. This may be so. It may be that there is such a disease as idiopathic pyæmia, but it is a doubtful point and difficult of proof. A far more certain thing it is that pyæmia can mostly be traced to a pyogenic source, and it is well-known by fatal experience that it occurs most frequently in conjunction with an unhealthy suppurating stump. Hence I have argued in favour of endeavouring to prevent or to lessen the duration of suppuration. My cases, I grant, are few, because my opportunities are not frequent, but I may claim for them that they have been carefully and anxiously worked out under considerable difficulties and with a weighty responsibility; and I am perfectly convinced that they afford good ground for believing that this little device is likely to be of real practical utility, or I should not have appeared here to-night. But I plead not guilty to the charge of having exaggerated the evils of the ligature, or of having made too much of my own cases. I have expressly and emphatically stated that I have as yet obtained no better results than might have been obtained by the use of ligatures, though I hope ere long to do so. That the ligature is an old friend, well-tried and trustworthy—has been successfully used for years, and does well enough—that somewhat similar attempts to find a substitute for it have failed—belong to that kind of reasoning by which all abuses are defended, and all attempts at improvement are ignored and abolished; they are not of much weight on the present or any other occasion. Mr. Barwell also seems to have a friendly leaning towards the ligature; but his dread of sloughing, from the strangulation produced by the wire, is, I can assure him, purely imaginary. If he will try the experiment, he will probably be surprised to find how little pressure is needed to stop the bleeding from even a large artery. The needles of Dr. Simpson do produce injurious and inconvenient compression, but the wire compress does not, and it is one of the advantages I have claimed for it over the needles. I have fully shown that it is safe, and effectual, and manageable; and I have no doubt, from the attention which has been given to my humble efforts to-night, and from the ventilation which the subject has here received, that the wire compress will soon be put to the proof by others who have better and more frequent opportunities than I have; it may be, perchance, to the advancement of the science of Surgery, and to the benefit of suffering humanity."

## THE PATHOLOGICAL SOCIETY.

TUESDAY, DECEMBER 16.

Dr. COPLAND, President, in the Chair.

Dr. GIBB showed the drawing of

A SPLEEN WEIGHING FIFTEEN POUNDS, REMOVED FROM A LIVE DOG

in the year 1850. This was exhibited in consequence of the suggestion made at the previous meeting by Mr. Spencer Wells, of removing enlarged spleens from the human subject. The animal from which Dr. Gibb removed the tumour was five years old, and was narcotised with sulphuric ether in a few minutes. The splenic artery and fifteen other vessels were tied. Very little hæmorrhage occurred. The dog lived five days, and died from cold. The tumour consisted chiefly of coagula within a large cyst formed by the capsule of the spleen, probably originating in a kick; the gland itself was embedded in its upper part. Dr. Gibb remarked that Dr. Crisp and others had removed the healthy spleen from dogs, and there was no reason why the diseased organ should not be so also.

Dr. GIBB also exhibited a sketch of

PARALYSIS OF THE LARYNX AFTER DIPHThERIA, PERMITTING OF A VIEW OF THE BIFURCATION OF THE TRACHEA.

The patient was a man, aged 33, who contracted diphtheria from his three children, one of whom died. He subsequently had more or less general paralysis, and possessed the nasal twang; fluids came through the nose; the limbs tottering; he was a little deaf, and had anæsthesia of the fauces. There were ulcers on the tonsils and pharynx. The laryngoscope showed the larynx much expanded, the vocal cords completely relaxed, and the trachea seen throughout its length,

terminating in the bifurcation, which was quite distinct. The tube above the left bronchus was bulged inwards. He recovered well.

Mr. HUTCHINSON inquired whether the patient's ocular accommodation was not also defective?

Dr. GIBB replied that it was, and that the man could only see objects held at considerable distances. In reply to another question, Dr. Gibb stated that in cases of operation for the removal of growths from the larynx he always prepared the patient by administering the bromide of ammonium. The dose used was from fifteen grains to a scruple every four hours for a day or two before the operation. It usually had the effect of inducing the patient to complain of numbness in his tongue and palate. It was, however, difficult to extinguish the irritability of the epiglottis.

Dr. GIBB also showed a

FIBRO-CELLULAR POLYPUS OF THE LARYNX, THE SIZE OF A PEA, SUCCESSFULLY REMOVED

from a gentleman, aged 42, with dysphonia and hoarseness for ten years. He had had rubeola at 24, pertussis at 30, and variola at 40. The voice was a sort of hoarse whisper and constrained, as if the trachea was tied. The laryngoscope showed this to depend upon a polypus, the size of a pea, growing immediately below the origin of the two vocal cords. This was removed with the most satisfactory results on December 10.

Mr. HULKE exhibited the

RIGHT HIP JOINT REMOVED FROM THE BODY OF A PATIENT WHO HAD RECENTLY DIED IN THE MIDDLESEX HOSPITAL,

where he had been many months, under Mr. Moore's care. He always lay on the left side, with the right thigh strongly flexed and adducted. Whether the joint was ankylosed was not positively determinable without chloroform; but the extreme suffering which the gentlest examination gave him rendered a slight mobility probable. Behind and below the great trochanter were two sinuses, which discharged a large quantity of pus. In August he was for a short time in Mr. Hulke's charge, who, thinking suppuration was kept up by the presence of a sequestrum detained in the acetabulum, would have removed the upper end of the femur, had not Surgical interference been forbidden by the enlarged state of the liver (at the post-mortem it was found to be lardaceous, and weighed 7 lbs.) The preparation showed the femur acutely flexed on the pelvis, adducted and rotated inwards, so that the lesser trochanter was lying against the ilio-pectineal eminence. The head and neck of the femur were absent. The great trochanter covered in the acetabulum, and prevented the escape of several sequestra, which had been thrown off from the floor of this cavity, and were floating upon, or lying embedded in, granulation tissue. Some of these were thin films of bone, but two or three involved the whole thickness, and there were corresponding perforations which communicated with a large subperiosteal sinus on the pelvic side of the innominatum. Outside the hip-joint were several sinuses which emptied into those below the great trochanter, and also communicated with other sinuses running into the pelvis along the tendon of the external obturator muscle, through this muscle and the fascia, closing the foramen ovale; along the tendon of the internal muscle of the same name, through the lesser sciatic foramen; and along the tendon of the iliacus internus muscle. Inside the pelvis these sinuses were connected with abscesses in the muscles just named. The muscular tissue was wasted and in an advanced stage of fibrous and fatty metamorphosis. The tendon of the iliacus internus contained a bony plaque, where it turned over the brim of the pelvis, and there was a second large piece of bone within a dense fibrous mass in the situation of the insertion of the pectineus and adductor brevis muscles. The back of the femur in connexion with the sinuses of outlet was studded with osteophytes. The formation of abscesses in the pelvis by the extension of suppuration from the hip-joint along the tendons is the interesting feature in this case. These abscesses were quite distinct from those caused by perforation of the acetabulum.

Mr. HULKE also showed a specimen of

OVARIAN CYST REMOVED BY OVARIOTOMY.

The specimen had, he said, no special pathological interest, but he brought it forward because, as the case had ended fatally, he did not wish to come under the criticism sometimes made, that operators made public their successful cases, but concealed their fatal ones.

Mr. CALLENDER showed a specimen of

FRACTURE OF THE BASE OF THE SKULL.

The man from whom it had been removed had been under the care of Mr. Paget, in St. Bartholomew's, and had died with all the symptoms of severe concussion and fractured base on the eleventh day. During life, considerable quantities of clear fluid had escaped from his left ear. At the autopsy, a starred fracture was found passing across the foramen magnum, and in several directions into the adjacent bones. It crossed the internal auditory canal, and involved the aqueductus and hiatus Fallopii; it also crossed the course of the eighth pair of nerves. Nowhere was there any separation of the fractured portions, the injury consisting of a fissure without laceration of the dura mater. The latter point was of great importance, and was carefully made out both by Mr. Paget and himself. They felt quite certain that the fluid which escaped from the ear had not proceeded from within the skull, since the dura-matral investment of the bones was everywhere entire. It could, therefore, only be supposed that the fluid in question was the perilymph or liquor Cotunnii.

Mr. HUTCHINSON exhibited an

OVARIAN CYST WITH EXTRA-CYSTIC GROWTHS.

The specimen had been successfully removed by ovariectomy from a woman aged 65. Its peculiarity consisted in the development, external to the large cyst, of a considerable number of smaller ones, and also of numerous pedunculated solid growths. The solid growths looked like small masses of cauliflower buds, being developed in minute lobules. Under the microscope they showed numerous cells arranged after the pattern of glandular growths. They were quite solid and very firm. Some of the extra-cystic cysts were large enough to contain an egg, others much smaller, and within these, in many instances, were solid growths resembling those just described. During the operation, one of these cysts on the outer wall of the parent had, at first sight, been mistaken for an adherent coil of intestine, which it remarkably resembled in appearance. The tumour consisted chiefly of one large, thick-walled cyst, which contained a dark-brown dense fluid. At the back of the larger one numerous secondary cysts were found.

Mr. HUTCHINSON also showed a specimen of

DISEASE OF THE KNEE-JOINT.

It had been removed by amputation from a lad of seventeen, who had suffered relapses of inflammation for five or six years. Persevering attempts had been made to save the limb, and also to avoid resection of the joint, and the lad had been for more than a year under care in the London Hospital, with a few months' interval at Margate. At one time he had greatly improved, and ankylosis was hoped for; but a relapse occurred, and indications of periostitis of the femur became developed. It was at length determined to excise the joint, and then amputate or otherwise, according to the state of things disclosed. This was done. On opening the joint, the ends of the bone were found completely denuded of cartilage, but everywhere covered by granulations, and firm and quite free from earies. Thin sections were now sawn from the ends of the femur and tibia, and in both bones above the epiphysal line (which was still represented by a thin layer of cartilage) a condition of extensive red softening was found. In the case of the femur it almost amounted to abscess, the soft cancellous bone being infiltrated with lymph, almost resembling pus. The epiphysis itself in each bone was hardened and whitish, the diseased condition commencing immediately above it. In both bones there was evidence of periostitis of the shaft beginning just above the epiphysis, and causing thickening of the membrane and the deposition of rough layers of new bone. Such being the condition of things, amputation was at once performed.

The lad had made a good recovery.

PROFESSIONAL PHOTOGRAPHS.—The Council of the Medical and Chirurgical Society have determined to add to their valuable library a collection of photographs of subjects having Professional interest, to be mounted in suitable portfolios, and accompanied by descriptions of the cases or preparations thus illustrated. The Assistant Librarian of the Society (53, Berners-street) will receive any contributions towards so valuable and interesting a collection from members of the Profession.

## LEGAL INTELLIGENCE.

(Sittings at Nisi Prius, at Guildhall, before Mr. Baron BRAMWELL and a Common Jury.)

GIBBON v. BUDD.

THIS was an action brought to recover the sum of £21 as Physician's fees. The defendant pleaded never indebted.

Mr. Serjeant Parry and Mr. H. T. Cole appeared for the plaintiff, and Mr. Dowdeswell and Mr. Shaw represented the defendant.

A question of great importance to the Medical Profession arose during the trial. The plaintiff was a Physician residing in Finsbury-square, and the defendant was the executor of a Mr. Henry Budd, now deceased, formerly living at Albany Chambers and 45, Piccadilly. According to the plaintiff's case, Mr. Budd, having met with an accident to his foot, consulted him upon the subject, as well as with reference to his general health, which was much impaired. Mr. Budd died in January, 1862, upon which the plaintiff sent in his charges for attendance to his executors, who disputed the amount.

Mr. Dowdeswell, at the conclusion of the plaintiff's case, submitted that there was no case made out on the part of the plaintiff. Previous to the passing of the Medical Act, the 21st and 22nd Victoria, cap. 90, sec. 31, the universal rule was, that Physicians were assumed to attend gratuitously, for which they expected an *honorarium*; they could not recover the amount of their charges for attendance unless there was a special contract. In the case of "Veitch v. Russell" (3 Queen's Bench Reports, page 936), Lord Denman, in delivering judgment, said: "It must be assumed as clear, that Physicians and counsel usually performed their duties without having a legal title to remuneration. Such has been the general understanding. To prevent that from operating, some express agreement must be shown; but, in considering whether such an agreement existed, we cannot lose sight of the general understanding." The Act of Parliament enacted that Physicians registered under it might recover reasonable charges, subject to such by-laws as might be passed by the College of Physicians. Now, the College of Physicians had passed a by-law which directed that they should not recover, even if there were a contract; so that Physicians were unable to recover under any circumstances.

Mr. Baron Bramwell: You say that the Act of Parliament has merely put a further difficulty in the way of a Physician's recovering the amount of his charges for attendance?

Mr. Dowdeswell replied in the affirmative, contending that such a course had been adopted for the purpose of rendering the payment of the Physician's fee immediate.

Mr. Baron Bramwell: I should think that the Act was drawn up by a person who was no lawyer.

Mr. Cole pointed out that, although the Act of Parliament stated that the right of the "Fellows and members" of the College of Physicians to recover the amount of their charges should be subject to by-laws to be drawn up by that body, the by-law in question only referred to the Fellows, and not to the members, and, therefore, did not apply to the present case.

Mr. Baron Bramwell: Does not that give rise to a curious question, whether under the Act the College has a right to make a by-law referring to one portion of their body only? I am sure I do not see any great magic in the word "Physician," which should distinguish him from the General Practitioner, so far as to prevent him recovering the amount of his charges. The Act states that all reasonable charges are to be recovered, which could not relate to charges to be made under a contract, and, therefore, it must be supposed that the intention of the Act was that the Physician was to recover the charges for his attendance like any other professional man. If the statute meant merely to say that, if registered, you shall have a title to sue in cases where you could otherwise sue, it would have merely said, "You may sue," in place of saying, "You may recover reasonable charges." By the word "reasonable" being used in the place of the word "fixed" charges, one would think that the Act meant to take away the disability that Physicians formerly laboured under. However, I think that there is sufficient difficulty to make it right to reserve the question, the difficulty of which is much increased by the manner in which the Act of Parliament is drawn up.

Mr. Dowdeswell observed that his client as executor felt it to be his duty to protect the estate by taking the opinion of the court above upon the matter.

Mr. Serjeant Parry: Why, your client is a legatee under the will to the extent of half a million. (Laughter.)

Mr. Dowdeswell then addressed the jury on behalf of the defendant, and observed that there was no proof beyond the plaintiff's own word that he had attended upon the deceased as a Professional man. He should call witnesses who would prove that the deceased was a man of miserly disposition, who would not have thought of paying a Physician a guinea a visit; that during the time Mr. Budd was ill he was attended by other Medical men; and that during a portion of the time when the alleged visits took place no Medical attendant whatever saw him.

Several witnesses were called in support of the defendant's case.

The learned counsel having addressed the jury on behalf of their respective clients,

His Lordship, in summing up, left it to the jury to say whether in their opinion the plaintiff had established his case. Was the plaintiff attending the deceased as a Professional man or as a friend?

The jury returned a verdict for the plaintiff for the amount claimed, leave being reserved to the defendant to move the court above as to the construction to be placed upon the Medical Act.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary Examinations for the Diploma, were admitted Members of the College, at meetings of the Court of Examiners, on the 20th and 21st inst. :—

Edward Chandler, L.R.C.P. Lond., Chester-place, Kennington; James Lattey, Upper Phillimore-gardens; Thomas Franklin Baker, Doncaster; George Huristone Elliott, Chichester; James Dixon Roberts, Shipley, near Leeds; Philip John Simpson, Gower-street; John James Saville, Sunderland; Archibald Megget, Scarborough; Edward Ellis, M.D. St. Andrews, Fitzroy-street; Edward Benjamin Randell, Carshalton; Joseph Willes, Brighton; Thomas Smallhorn, Dublin; William Arthur Bracey, Birmingham; William Matthews Bobart, Ashby-de-la-Zouch; Arthur J. Graham Cross, New-street, Spring-gardens; J. Blount Fry, Edgbaston, near Birmingham; Eltham Wood, M.D. Toronto, Toronto; Chas. Spurway, Tiverton, Devon; John Wilkins Williams, Paddington; John Wilson, Musselburgh; John Mottershead, L.S.A., Macclesfield; Isaac Baker Brown, Connaught-square; James Bruce, Islington; Thomas Lewis Brittain, M.D. Edin., Chester; George Albert Miskin, M.D. St. Andrews, Yerk-road, Lambeth; George Pearse Sargent, M.D. St. Andrews, Camberwell; Thomas Cargill Nesham, Newcastle; William Montague Hall Welby, L.S.A., Newark, Notts; Henry Cartmel, Manchester; Samuel Rains, Manchester; Thomas Lawson, Craister, Leeds; Frederick Robert Clarkson, Leeds; Thomas Leigh, Chiswick; William Row, Clapham-road; George Vint Wright, M.D. Edin., Edinburgh; John Davies, Coleshill, Warwickshire; Samuel Edward Walker, Warwick; Arthur Newman Turner, Bermondsey-square; Robert Hay, M.D. Queen's Univ. Ireland, Belfast; Richard Thorne Thorne, Leamington; Robert Sidney Stone, Bath; Alfred Agassiz, Bradfield, Essex; Henry Ebenezer Richards, M.D. St. Andrews, Sloane-street, Chelsea; Henry Albert Pattinson, Penrith, Cumberland; Charles Addams Buckmaster, Piccadilly; John Reddrop, Tiverton, Devon; Alfred Wadsworth, Leeds; and Albert Meeres, Thame, Oxfordshire.

NAVAL SURGEONS.—The following gentlemen passed their Examinations for Naval Surgeons, at a meeting of the Court of Examiners on the 20th inst. :—

Thomas Williams Hughes, diploma of Membership dated June 13, 1856; William Roche (B.), of the Royal Naval Hospital, Plymouth, May 24, 1858; Thomas Dunlop Allison, M.D. Glasg., M.R.C.S., June 25, 1858; Patrick Keelan, of H.M.S. *Neptune*, M.R.C.S. Irel., November 4, 1858.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise on Thursday, January 15, 1863 :—

John Reynolds, St. Bartholomew's Hospital; George Eugene Yarrow, 8, Central-street, E.C.; Benjamin Whitehead Parker, Farington, near Preston, Lancashire; Henry Corpe Selwood, The Hospital, Birkenhead; George Stokoe Elliot, Southwell, Notts; Edward Leeds, Stretford, near Manchester.

The following gentleman also on the same day passed his First Examination :—

Carey Pearce Coombs, St. Mary's Hospital.

## APPOINTMENTS.

BELL, J., M.D., has been appointed Assistant-Surgeon to the Eye Infirmary, Edinburgh.

EASTLAKE, HENRY E., has been appointed Physician-Accoucheur to the St. Marylebone General Dispensary.  
 EVANS, CALEB, M.R.C.S. Eng., has been appointed Surgeon to the Hospital, Birkenhead.  
 FOX, WILSON, M.D., has been appointed Assistant-Physician to University College Hospital.  
 HARLEY, GEORGE, M.D., has been appointed Assistant-Physician to University College Hospital.  
 PALFREY, JAMES, M.D., has been elected Physician to the Surrey Dispensary, Great Dover-street.  
 PETTIGREW, DR. JAMES, has been appointed Assistant in the Hunterian Museum, Royal College of Surgeons, England.  
 SELWOOD, HENRY CORFE, M.D., M.R.C.S. Eng., has been elected House-Surgeon to the Hospital, Birkenhead.  
 SPANTON, W. DUNNETT, M.R.C.S.E., has been appointed Assistant to the House-Surgeon, Sheffield General Infirmary.  
 WRIGHT, FREDERICK, W., M.R.C.S.E., has been elected Resident Surgeon to the Birmingham and Midland Counties Lying-in Hospital.

## DEATHS.

BRIGGS, JOSEPH, at Maesteg, Glamorganshire, on January 10, aged 33.  
 CHALMERS, ANDREW, M.D., at Tavistock-buildings, Port Adelaide, South Australia, on October 5, 1862, aged 42.  
 GARDINER, ROGER GILBERT COOPER, M.R.C.S. Eng., at St. Leonard's-on-Sea, on January 17, aged 51.  
 HARRISON, T., M.R.C.S.E., of Lancaster, on January 4, aged 57.  
 HARVEY, HENRY HOPE, at Melbourne, Australia, on November 10, formerly of Bristol.  
 LANE, THOMAS BAGOT, A.M., M.D., Dublin, at Sidney Avenue, Blackrock, Dublin, on January 16, aged 86.  
 MOIR, GEORGE D., at Dudley Colliery, Northumberland, on January 2, aged 24.  
 ROSS, REV. R., M.D., at Sydney, Australia, on November 2, 1862, aged 71.  
 SCOTT, ROBERT T., M.D. Edin., at Leuchars, Fifeshire, on January 7.  
 SMITH, RALPH, M.D., at Yankalilla, on September 22, 1862, aged 54.  
 STUCKEY, HENRY, M.R.C.S.E., at 50, Wellclose-square, London, on January 12, aged 36.  
 SYKES, JOHN, at New Swindon, Wilts, late of Leeds, on January 12, aged 74.  
 TURNER, THOMAS WILLIAM, M.R.C.S. Eng., at Deddington, Oxfordshire, on January 8, aged 62.  
 WARBURTON, THOMAS J., L.R.C.P. Edin., at Market Drayton, Salop, on January 1, aged 37.  
 WHITFIELD, FREDERICK F., M.R.C.S.E., at Thornleigh, Longford, Tasmania, on October 10, 1862, aged 49.

THE COLLEGE LECTURES.—Professor Huxley, F.R.S., will commence his course on "Comparative Anatomy," in the theatre of the College, on Tuesday, February 17, at 4 o'clock, when he will deliver an inaugural lecture on the "Skeleton of a *Glyptodon*," recently presented to the Museum of the Royal College of Surgeons by Senor Don Maximo Terrero. The lectures will be delivered on Tuesday, Thursday, and Saturday, at 4 o'clock.

A ROYAL ACKNOWLEDGMENT.—Mr. Grove, the Medical student who was fortunate enough to render assistance to her Royal Highness the Princess of Hesse when she was thrown from her carriage in the Isle of Wight a few weeks since, has been presented with a valuable memento of the adventure—consisting of a gold pin and a set of studs.

THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND, AND THE TITLE OF "DOCTOR."—We understand that the University of Dublin, acting on the opinion of Sir Hugh Cairns and Dr. Twiss, is about instituting proceedings by which the right of the College of Physicians in Ireland to confer the title of "Doctor of Medicine," will be submitted to the decision of a competent legal tribunal.

DR. HARLEY, Professor in University College, London, has just been elected Corresponding Member of the Royal Academy of Sciences of Bavaria. This is the second time, in the course of the last twelve months, that Dr. Harley has had an honour of this kind conferred upon him, having, within a few months, been made Corresponding Member of the Royal Academy of Medicine of Madrid.

UNIVERSITY OF ST. ANDREWS.—At the recent examinations at this institution 379 candidates presented themselves for the degree of M.D., of which number 336 passed, and 43 were rejected. The amount of fees, at £26 5s. each, arising from those who were *capped*, amounted to the large sum of £8820; and if to this amount be added the four guineas forfeited by each of the rejected candidates, making another sum of £180 12s., and added to the larger amount, it will give a grand total of £9000 12s.

NEXT in importance to the inaugurative meeting of the Pathological Society, and the address of Mr. Prescott Hewett, the Chloroform Committee of the Medico-Chirurgical Society seems to progress in its very useful labours. A large number

of most useful documents not previously published have been sent this week to the Secretary, so that it is expected the subject of the administration of chloroform, and its various uses in Surgery, Medicine, and Midwifery, will undergo a very complete examination, and chiefly in a practical point of view, as the more abstract physiological speculations as to anæsthesia, apnœa, asphyxia, have already been exhausted, or nearly so, in France, Germany, and America. The committee, we hear, were engaged this week chiefly with the practical views of Dr. Richardson on apnœa, anæsthesia, etc.; and some very interesting facts were also elicited as to the uses of chloroform in Midwifery, eye Surgery, amputations, and general Surgery, during a congressional discussion or examination of views of Dr. Charles Kidd in a *vivâ voce* series of questions to that gentleman, by Mr. Paget, Mr. Curling, Dr. Priestley, Mr. Bryant, and others of the committee. We are told that a visit of Mr. Marion Sims to the Societies this week has proved very opportune, as the recent experiences of chloroform in the war in America, and notably of ether, such a favourite in America, have been made incidentally available.

THE HUNTERIAN MUSEUM.—From the annual report of the conservator of this collection to the council of the College of Surgeons, and which is just published, it appears that, owing to the large concourse of persons from the country and abroad, attracted to London during the past season by the International Exhibition, the council had ordered the Museum to be opened on additional days and hours, and had thus afforded unusual facilities for viewing the collection by 6825 persons against 3669 visitors in the preceding year. It is gratifying to add, that the conservator, Mr. W. H. Flower, had not discovered any instance of damage to the delicate and costly preparations. The new edition of the very interesting "Synopsis of the Contents of the Museum," prepared by the conservator, has been of great use to the visitors, who had purchased upwards of 500 copies. Mr. Waterhouse Hawkins, so deservedly well known as the restorer of the extinct animals in the Crystal Palace at Sydenham, has been engaged by the council to reconstruct the skeleton of one of those gigantic forms of the animal life of the ancient world, now only represented by the diminutive armadillo of South America. This unique specimen consisted of many thousand fragments of fossil bones, which Mr. Waterhouse Hawkins has, with singular facility, called out of chaos, collated and re-united in their natural form and relative situation. This work is nearly completed, much to the satisfaction of the council and the palæontological section of the scientific world, who have taken great interest in this noble donation of the Chevalier Terrero, who is the son-in-law of the Dictator Rosa, of Bolivia, now residing in dignified retirement at Southampton.

LONGEVITY.—On Monday evening last, the first of two lectures was delivered in the Metropolitan Hall, Dublin, by the Right Hon. James Whiteside, on "The Life and Death of the Irish Parliament." It is an interesting fact, that the chair was, on that occasion, occupied by Sir Thomas Staples, Bart., who himself represented the borough of Knocktopher in the Irish Parliament. He has thus survived the legislature, of which he was a member, by upwards of sixty-two years. Though in his eighty-eighth year, Sir Thomas walks the streets of Dublin with a quicker pace and a more elastic step than many men by sixty years his junior. He is, moreover, still a keen and active sportsman. The only other former member of the extinct Parliament who yet survives is the Earl of Charlemont, who sat in both Houses: in the House of Commons as Viscount Caulfeild, for the county of Armagh, and, after the death of his father, the "great" Earl of Charlemont, on August 4, 1799, in the House of Lords. Lord Charlemont, who is in his eighty-ninth year, is, owing to the infirmities of age, now seldom seen beyond the precincts of his demesne. The Right Hon. Thomas Lefroy, Lord Chief Justice of the Queen's Bench in Ireland, was called to the Irish Bar in Easter Term, 1797, and still presides daily, during Term, much to the advantage of the suitors in his court.

PROFESSIONAL "CARTES DE VISITE."—The employment of *cartes de visite* is extending every day. Every one has his album; and we now find the Dean of the College of Doctors at Prague issuing a circular, stating that the Faculty of Medicine of that city have determined to establish an album of all living members, and requesting any of these who have not already done so to forward their *cartes de visite* to the Deanery at Prague, before the end of April, 1863. Surely,

this is carrying the thing to an absurd length; for, however desirable it may be to have the effigies of celebrated characters or personal friends, what useful end can be served by collecting a huge book of nobodies?

**EPIDEMIC ERYSIPELATOUS OPHTHALMIA AT VIENNA.**—For some time past there has been observed a great number of cases of catarrhal ophthalmia at the Vienna Eye Clinic. There is a slight swelling of the eyelids, and ecchymosis of the ball of the eye, accompanied by the usual symptoms of catarrh. Professor Arlt regards the affection as an epidemic due to atmospheric influences, and believes it intimately connected with erysipelas, which has also been unusually prevalent. He refers to the fact, that one of Beer's forms of ophthalmia is termed "*ophthalmia catarrhalis erysipelatos.*" At all events, Beer's description of erysipelatos ophthalmia exactly agrees with that of Arlt's epidemic, catarrhal ophthalmia. The affection is rapidly cured by the application of a solution of nitrate of silver, five grains to a drachm of water.

**A MARTYR TO SCIENCE.**—The Jamaica papers announce the death of one of our best rising geologists, under circumstances of the most peculiar and painful nature. Mr. Lucas Barrett, F.G.S., Director of the Geological Survey of the British West Indies, with a view to carry on scientific observations at the bottom of the sea in the harbour of Port Royal, descended in a diver's dress. Contrary to the advice of his servants, he neglected to attach the rope round his body, but preferred to retain it in his hand. After the lapse of about twenty minutes, the negroes were horrified by seeing the corpse of the deceased floating on the surface. Life had been long extinct. Mr. Barrett was well known as the original discoverer of the evidence of bird remains in the greensand of the neighbourhood of Cambridge. His name will, however, survive, imperishably linked with that of the remarkable fossil *Hippurite*, from the limestone of Jamaica, described by Mr. S. P. Woodward, F.G.S., who named it *Barrettia monilifera*. This shell, although essentially that of an aequalous mollusk allied to *Hippurites*, yet by its peculiar radiated structure would have lead almost any person to consider it to be a coral. Many other interesting fossils owe their discovery to the late Mr. Barrett, whose untimely death has filled geological society in England with a universal sentiment of regret.

**LIFE OF AN IRISH DISPENSARY DOCTOR.**—A correspondent of the *Dublin Medical Press* gives the following graphic account of an incident in the life of an Irish Dispensary Doctor. An article in our First Volume for 1862 will show what the trials of these gentlemen are, and likewise what are the dreaded "scarlet-runners":—"To give some idea of the constitution necessary for a Dispensary Medical slave, I will just mention what occurred on yesterday in my neighbourhood, much more to the sunny south than Drumshanbo. At ten a.m. a Medical Officer received a scarlet-runner, running him six miles to a midwifery ease, the woman two days ill. On making an examination, he found the head well-descended, quite free, and unimpacted. He told them that the sooner the woman was delivered the better chance of saving mother and child. The women or friends would not consent. After some hours, finding matters had not improved, he again impressed on them the danger to both mother and child by further delay. All to no use: 'God was good,' and he should not be in a hurry. He then said he should return home to see other patients and get some refreshment, as he had breakfasted at eight o'clock, and that he would be back in the evening to deliver the woman. No, he should stop and look on until the woman was dead or better, but use an instrument he should not. After spending the day in close confinement, and fearing he should pass the night in the same state, he wrote a line with pencil on the cover of a note, requesting I would go and liberate him, sending back the ear and driver he had taken out in the morning. I started at 8 p.m., the night foggy and bitter cold. I arrived there at nine, and confirmed the opinion of the poor prisoner, that the woman would be lost if she was not promptly delivered; then, indeed, we should wait until they would send two or three miles for a clergyman to give her the last rites of the church. I told them that they had time enough to do that, but that I could not nor would not wait, and that on my way home I would report the matter to the police, and have them made accountable should anything go wrong. They then consented, and the woman was delivered very promptly and without any trouble, but the

child was dead, and had been so for some time; thus, after a fast and confinement of fourteen hours, the Doctor was set free! We then set out, to walk about a mile of a lane, all sloughs and ruts, frequently half-leg deep in the mire, to where the car was on the high road. We got back our six miles, as well as a jaded and starved horse and driver could. I then assisted down the victimised Medical Officer, who retired with a heavy heart and an empty stomach; but as it was past midnight, he might take a light breakfast to prepare for the next day's work. Some may suppose this to be a rare and exaggerated case; but I assure you it is neither the one nor the other."

## BOOKS RECEIVED.

## NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

*Dublin.*—Dr. Quinlan's paper is in the printer's hands.

*Answer.*—Write to the President of the University of Medicine, Paris.

*An Omission.*—In the last St. Andrews graduation list, for "Thos. Stainthorpe, M.R.C.S., L.S.A.," read "Thos. Stainthorpe, L.R.C.P. Ed., M.R.C.S., L.S.A."

*Y. Y. Y.*—Quain and Sharpey's "Anatomy," which, besides descriptive anatomy, gives a full account of the microscopic anatomy of the tissues, including the dental.

*Weston.*—The account received of the point at issue between the Surgeons and Governors of the Weston Dispensary, as it only gives one side of the case, and that imperfectly, does not furnish the data necessary to give an opinion.

*A Meat Pudding* writes to us in rather a greasy hand, complaining of certain slanders that have appeared in a weekly Medical journal of eminence, against his near relative, a meat pie. If, as the pudding justly observes, a pie is poisonous (as is alleged) if it have no hole in the crust, how is it that the pudding, if well boiled, is so nutritious, and savoury, and deservedly popular? The alleged "hole in the crust" must surely be in the head of the person who makes the accusation.

*Death from Burning?* (Mem. from a correspondent.)—Carbonic oxide is a poisonous gas, and one that makes the blood preternaturally florid; it produces death quickly, and it exists where carbonised matters are highly heated with insufficient oxygen. Surely, then, Mr. Buzzard is in error in ascribing the deaths of those children in Portland-street to burning; for burning would not kill so many persons right out: carbonic oxide is quite capable. Ask Mr. Buzzard to reconsider the question.

*Medicus, F.R.C.P., etc.*—There is no doubt but that the present fee system is horribly illogical, inconsistent, and absurd in theory, but that it works well, where it is applicable. But, like every thing else, it has its limits, and out of these is, as may be expected, a ridiculous failure. Of course, it can only work well in a highly-refined and wealthy society, where the Medical attendant is looked upon as a gentleman, and not as a tradesman, and where the patients have plenty of ready money, and are in the habit of spending it freely. It is advantageous to the Phy

siciau, inasmuch as it gives him payment promptly, in a gentlemanly form, without the trouble of book-keeping, the risk of bad debts, and protracted payments, and the unpleasant feelings which always attend the commercial element of transactions, the counting up the visits, and comparison of the sum charged with the value received. If patients were classified, we believe they might be ranged into two grand kingdoms:—1st. The solvent, *i. e.*, those who pay or are presumed to pay. 2nd. The insolvent, including the large and increasing class of Dispensary and out-patients of Hospitals, etc. The first kingdom comprises two grand orders:—1. Those who pay *gratuities*; and 2, those who liquidate *accounts*. Of order 1, we have genus *a*, the people who present a fee at each visit; *b*, they who send a cheque at the end of an illness; *c*, they who ask the Physician to name the amount of his fees at the end of an illness, or after a certain lapse of time. But in each case the sum received is a gratuity, is accepted as such with thanks, and no stamped receipt is required. Even if a Physician for valid reasons sees fit not to accept the whole amount of his usual fees; if, as is sometimes the case, he may choose to devote unusual time, pay unusually frequent visits, or take extra trouble, either to satisfy his own spirit of scientific research, or to satisfy the claims of humanity, it makes no valid difference. The other order of patients make their own arrangements, and pay accordingly. But either order may be afflicted with a kind of moral *mange*—a desire to get what they can, and evade payment. The Physician, who receives *gratuities*, is thus left on his beam-ends: the Practitioner, who sends in a bill, can appeal to law. But the hardship to the Physician is less than it would seem at first sight. A man may be cheated once or twice in his life, rarely oftener. Then it may be a question whether it may be a duty to society to pillory the offender by means of an action; yet most prudent men will pocket the affront. The instances which usually come into court are usually those of Physicians who practise as General Practitioners; or else who practise amongst a class of people to whom one Doctor is the same as another, and the gratuity system is incomprehensible. The rule is always to have an understanding with your patient. If Mr. Grubb, who is taken ill at an inn, tells the waiter to fetch a Doctor, how is Grubb to know whether it is a Physician, who receives gratuities, or a Practitioner, who sends in a bill? The Physician should take care to let Grubb know what gratuities he expects, and not have to bring in a bill for guineas against a poor devil who would think a visit dear at 3s. 6d. After all, the present system is so based upon personal character, that even if Physicians were able to recover reasonable and usual charges, matters would go on pretty much as they do now.

*Puckett Fund*.—Mr. Griffin requests us to state that he has received from A. Keppel Read, Esq., Garrison and Civil Surgeon, Attock, India, £22 13s. 4d., as a subscription towards the Puckett Fund, from the following subscribers:—

	Rupees.		Rupees.
Baillie, Assistant-Surgeon . . .	10	M. M. R. . . . .	3
Blackall, Mrs., Attock . . .	10	Morrison, Mrs. . . . .	3
Blackall, Capt., Attock . . .	5	Morland, Lieut., Murree . . .	5
Church, Murree, Offering Fund .	35	Olpherts, Col., Murree . . .	5
Carleton, Col., Royal Artillery .	5	Powell, Mr., Murree . . .	3
Colton, Sir S., Major-General .	10	J. B. C. . . . .	5
Dyer, Mr., Murree Brewery . .	5	Reed, A. K., Assistant-Surgeon.	21
Drake, Lieut., 32nd N.I. . . .	5	Reade, J. B., Assistant-Surgeon	5
Elliott, Capt., 94th Regt. . . .	16	Stuart, Rev. Kilbee, Murree .	15
Finn, Mr., Public Works . . . .	2	Sandilands, Major, Attock . .	10
Green, Mrs., Mean Meer . . . .	5	Urniston, Capt . . . . .	5
Green, W., Esq., Punjab Police .	5	Ware, Capt., 51st K.L.I. . . .	5
Heyland, Capt., A.D.C. . . . .	10	Wright, Jas., Esq., C.E. . . .	10
Kindlerides, Lieut.-Col., R.A. .	16		
Langmore, Capt., Bk.-Master . .	5		
March, Lieut., Sappers & Miners	5	Total Rupees . . . . .	244

Mr. Griffin wishes us further to state that the list is now closed, £1074 8s. 10d having been received, and the handsome provision of £52 per annum made for the widow, the capital ultimately to be divided amongst the children.

IS QUININE (SULPH.) APERIENT OR PURGATIVE, "PER SE?"

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Dr. Laycock, in his lecture on "Points in Practical Therapeutics," alludes to the action of "quinine on the nervous system facilitating the action of purgatives." I should like to ascertain from Dr. Laycock, or any of your correspondents, whether he has found quinine, *per se*, act as a smart purgative? I have had lately an attack of neuralgic lumbar pain, and I determined on trying the effect of quinine, combined with Dover's powder. I took one night 3 grains of the former, with 6 grains of the latter, and, next morning, the bowels were freely acted on. The next night I took 5 grains each of quinine and Dover, and the following morning I was briskly purged, the dejections containing large quantities of bile, and with relief to the pain from which I had been suffering.

*Quere*.—Was it the quinine which thus acted, no aperient having been taken? I am, &c. M.D.

REMARKABLE CASE OF APOPLEXY—CONDITION OF THE PUPILS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg to send you a few notes of a case of apoplexy, which occurred to me last month, for publication in your Journal, if you should deem it worth that consideration:—

I was called, on December 10, 1862, at 11.30 p.m., to see Mrs. T., Gilmour-street. The history which I got of her was, that she had a fit of apoplexy two years ago, which had left the left side of her body almost completely paralysed. On the evening I saw her, she had been sitting on a chair, speaking to a neighbour, about eight o'clock, when she suddenly fell from

the chair; she was lifted up, undressed, and put to bed, being, all this time, quite insensible. No twisting of the face was noticed. When I saw her, she was lying in bed on her back; pulse moderately strong, and 75; breathing stertorous; surface cold; and the patient quite insensible. On examining her pupils, the right iris was found to be completely paralysed, the pupil being very large, irregular, and not affected by light. On examining the left pupil, it was found to be very much contracted; and, on the application of light, it dilated considerably. On closing the eyelids for about a minute, and again examining the pupil, it was found to have regained its original contracted size; but, on a reapplication of the light, it again dilated. This process of contraction and dilatation was repeated about six or eight times, when the pupil seemed to lose its power of dilatation, and remained contracted. I ordered the patient to be kept quite quiet, with cold applications to her head. I called again next morning early, but found she had died a short time after I had left her. No autopsy was allowed. I am, &c.

Edinburgh, January 15.

R. LAWSON TAIT.

THE LIQUOR QUESTION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Truly may it be said that "the spirit of the age" is *pro bono publico*. Science, art, philanthropy, religion, are all brought to bear upon the problem—how can the people be made better? By common consent we sustain a crusade against social evils of every description; and drunkenness being recognised as a very potent one, much credit is due to the social reformer for his efforts to remove or mitigate it. But however desirable the success of his mission, it does not necessarily follow, that the means intended for its accomplishment are entirely unobjectionable.

The political and commercial bearings of the present scheme of highly intelligent and humane temperance reformers, *i. e.*, to seek the aid of the legislature in their efforts, I profess never to discuss, nor care for; but as a member of the Medical Profession, of somewhat lengthy experience, I feel justified in expressing opinions, founded upon the observation of fact, not to all unimportant in considering the question of suppressing by statute the trade in liquor.

I believe that, up to the age of 45 or 50, except under especial circumstances, alcohol as a beverage is not a necessity; but after this period it very frequently becomes indispensable to security against defective nutrition; whilst in old age, health can be materially insured, and life protracted, by the daily discreet use of alcohol as a beverage: that in practice cases are constantly occurring when life depends upon the prompt administration of alcohol in its more potent forms, for which we possess no substitute; such instances are frequently emergencies, and the alcohol has to be supplied to the patient at the nearest public-house: that, for the successful treatment of the zymotic fevers, typhus, typhoid, scarlet, small-pox, &c., we have no agent equal to brewers' yeast; further, that in those diseases it is an unfailing antidote.

Bearing upon the question under consideration, the following facts, well known to all those who have investigated the subject, may be advanced. Whenever the use of German yeast has superseded brewers' in the making of bread, etc., a marked increase in digestive derangement has followed; further, I have seen innumerable cases of a peculiar form of secondary indigestion directly referable to the use of German yeast.

Surely it is not unreasonable to ask the advocates of compulsory abstinence from alcoholic beverages, previously to depriving the working man of his beer—what is he to drink? I am, &c.

January.

L. F. CRUMMEY.

CASE OF PSORIASIS INVETERATA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The following case of psoriasis of seven years and four months' duration, may not, I trust, be undeserving a place in your columns. It may be interesting to your younger readers, and its publication may, perhaps, influence the Profession to pay greater attention to the cause as well as to the treatment of this class of diseases, which, in many instances, have the effect of disfiguring the beauty of the human face and of shattering the strongest constitution, in consequence of being so much subjected to mental disquietude. The history of this class of diseases is also important, as they not infrequently appear to be indicative of a scrofulous diathesis.

*History of the Case*.—A gentleman, aged 25, consulted me in March last for a scaly disease of the face and forehead. The disease had also extended to the head, and, in consequence of the falling off of the hair, a periwig had been worn for the past two years; and the feet, particularly from the knees down, were covered with scaly patches; similar spots were diffused over the chest and arms; while the cuticle on the hands and feet resembled tanned leather in hardness, as well as in colour. The disease first appeared as a spot on the left cheek, next on the forehead; after some time it appeared on the head, and then it became diffused over the body. During the period of his illness he received a merely temporary relief from consulting some of the ablest men in this country, amongst whom I may enumerate that bright ornament of our Profession, the late Sir P. Crampton, as well as a host of provincial Physicians. Recourse, too, had been had in no small degree to Turkish bath institutions. I am aware that forty of these baths were taken in succession. It might here be a fit subject of inquiry, if this novel method of purification or of cure is as deserving of that degree of praise which the general public, as well as some members of our Profession, are willing to assign to its use—men who, while they are ready fairly to extol, do so without taking into consideration that the majority of those who use, or accustom themselves to their use, have no need to use them at all; and, while forming a hasty conclusion, they, perhaps, venture to deprive nature of her own remedial powers. *En passant*, I must remark, from my own experience as well as from the opportunities I have of judging of others, that I am a sceptic regarding their curative powers: whether on good grounds or not we may hereafter have an opportunity of deciding. This case of psoriasis was not improved by their use; and I have reason to believe, if their use had been persisted in, that hypochondriasis would have been the result. The disease seemed to have a kind of periodicity in its attack, usually appearing in spring, while it abated (but never got well) during the summer season, to reappear with October's chilly blasts. The beginning of the attack was ushered in with all the symptoms of dyspepsia, flatulence, acid eructations, feeling of lassitude, etc. After the administration of a warm antacid draught and rhubarb aperient, I began to give ten minims of Fowler's solution, four times a day, in an infusion of gentian, together with six grains of quinine. I directed a mild caustharadino liniment to be applied with a feather over the seats of the disease. This treatment was persisted in for three weeks, at the end of which time the quantity of Fowler's solution was reduced to six

minims a-day, while the quantity of quinine was increased to twelve grains, together with the use of the hot bath every second day; sherry wine was given as a drink. At the end of the sixth week I dismissed my patient, ordering him to take a few alterative pills every week, and twenty minims of liquor potassa, twice a-day, in broth or milk. Some weeks afterwards he writes, in quaint terms, to tell me that he is as "good as new." I saw him in September, when there was no other trace of the disease than those indelible stains on the feet; the hair on the head was sufficiently abundant to dispense with the wig.

From long observation, I have come to the conclusion, that the only medicines deserving of a trial in this disease, as well as in lepra, are Fowler's solution and quinine. In all the cases I have ever seen, a distressing flatulency had been complained of. We are told by writers that flatulent dyspepsia may generate scrofula. It is from this fact that I am induced to remark, that the occurrence of this disease is indicative of a scrofulous diathesis. I have given a fair trial to creosote ointment, oil of tar, tincture of cantharides, and most of the other carbo-hydrogens, but I forego their consideration in consequence of the beneficial results obtained from the use of Fowler's solution and quinine. If carbo-hydrogens are useful at all (and I doubt much their individual utility), they will be found useful in combination with the hot bath. I have never seen those black stains, alluded to by Professor Laycock (*Medical Times and Gazette*, June 20, 1862), so well marked as they were in this case, particularly those on the feet. On the whole, this dinginess was best marked on the left half of the body.

The interest attached to this class of cases may, I trust, serve as an excuse for engaging so much of your columns. I am, &c.  
Limerick, January 17. T. B. MORIARTY, A.B., M.D., etc.

#### THE COMPOSITION OF MILK.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The *Lancet* of the 3rd of this month contained an article on the above question, evidently written by Dr. Hassall himself, as it is a counterpart of his letter in the *Times* of the 5th, relative to Dr. Boedecker's supposed discovery, that the evening's milk of a cow was, as a rule, the richest, and which Dr. Hassall claims to be the discoverer of in 1851. Knowing that others had mooted the subject a considerable time before either Drs. Hassall and Boedecker had written on it, and that it was by no means to be depended upon, I wrote the following to the *Lancet*, which I hope you will do me the honour of publishing, as I consider it has done me an injustice by not publishing it, at the same time making strictures on my communication, which you will at once see are at variance with the truth: for instance, I did not call in question the "scientific accuracy" of either Dr. Hassall or Professor Boedecker; I merely stated that they were not the first observers, and that, as a rule, it could not be depended on, and gave my authorities; yet the *Lancet* has the assurance to state that my letter, "though strong in assertion, is singularly destitute of facts and proofs in support of his position."

I think, Sir, in the mind of any unbiassed reader, it will be at once seen that I gave authorities sufficient to support my position without the necessity of (as I am entirely an obscure and unknown man) making my own name public. I could have multiplied and given ample "numerical results" from other men's labours had I desired to have encroached on their space; but I thought that my giving names and dates of those who had been working in the same field as Drs. Hassall and Boedecker would be sufficient to have insured the insertion of my communication, though "shielding myself from all responsibility under the shelter of an assumed designation." I may mention that neither my own cows, nor those whose milk Dr. Voelcker analysed, were "artificially fed."  
January 12. I am, &c. AN AGRICULTURIST.

"TO THE EDITOR OF THE LANCET.

"SIR,—I am a member of the Medical Profession, but, for the last fourteen years, have been practically pursuing agriculture and agricultural chemistry; but as I like to know what is going on in the Profession I still take in the *Lancet*, and through it must beg to inform you that Drs. Boedecker's and Hassall's assertion with regard to the morning's and evening's milk does not hold good as a rule; and that, so far from either the one or the other having discovered that the morning's milk is richer than the evening's, I may mention that it was noticed, not as a positive fact to be depended upon, but as a variable occurrence, by Boussingault, the eminent French chemist and agriculturist, in the *Quarterly Journal of Agriculture* for, I think, 1840. My own observations will not at all testify to the truth of Drs. Boedecker's and Hassall's statements, as it varies from such a variety of causes, that it would be next to impossible to lay down any law on the subject. My experiments are not at all satisfactory, being about evenly balanced upon a very considerable dairy stock, which are changed from time to time, and their milk analysed under every variety of circumstance and condition; so much depends on the state of health of the cow, age, distance from the time of calving, whether frequent, and what period of her gestation, food, and time of giving it before milking, which would take up too much of your space to detail. However, I am corroborated in my deductions by Dr. Voelcker, professor of chemistry to the Royal Agricultural College: he states, taking thirty-two samples of milk which he analysed, that in eight the morning's milk was poorest, in four it was richer, and in the remainder there was no perceptible difference between the quality of the morning's and evening's milk; and he goes on to state that he believes the quality of the milk is affected by the food and the time at which it is given the cows, and that he could not say in a general way that the morning's was richer than the evening's, or that it was poorer—that it was impossible to generalise or come to any definite conclusion on the matter (a).

"Again, I recollect, in the year 1848, being the first year I became an agriculturist, hearing Mr. Hodson Rugg, a Surgeon, give a most interesting, eloquent, and thoroughly practical lecture on the adulteration of milk—the proper method of feeding cows, with regard to producing the constituent elements of milk in their entirety. At the same time he entered into the question of the morning's and evening's milk, and distinctly stated that no practical fact could be arrived at, giving, to my mind, most conclusive reasons why it could not; at the same time mentioning several labourers in the same field as himself, and who had arrived at similar conclusions.

"Dr. Hassall states that he made the singular discovery that the composition of milk varies still more at different periods of the same milking. This, Sir, has been practically known ever since cows have been milked; and, without troubling you with any lengthened account of why

it is so, I will merely mention that Dr. Schütter, many years before Dr. Hassall made his observation, ascertained that the first-drawn milk contained only five, the second eight, and the fifth seventeen per cent. of cream. Besides, the last-drawn milk, or the strippings, has been from time immemorial practically known to have very much the largest percentage of cream. I hope, in justice to other scientific observers on this most important subject, you will, with your usual liberality, and in the system of fair play, allow both sides of the question a place in the columns of the *Lancet*.

"I am, &c.

AN AGRICULTURIST."

## APPOINTMENTS FOR THE WEEK.

January 24. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.  
ROYAL INSTITUTION, 3 p.m. W. S. Savory, Esq., F.R.S., "On Life and Death."

26. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.  
MEDICAL SOCIETY OF LONDON, 8½ p.m. Mr. W. C. Calthrop, "On Spontaneous Closure of the Axillary Artery after Division (by a Gun-shot Wound), with Final Recovery of the Patient."

27. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Dr. Buchanan, of Glasgow, "On a White Fibrous Discharge from the Thigh." Dr. J. A. Marston, "On Syphilis as a Constitutional Disease."  
ROYAL INSTITUTION, 3 p.m. Professor Marshall, F.R.S., "On Animal Mechanics."

28. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.  
HUNTERIAN SOCIETY, 8 p.m. Dr. McDonnell, "On a Case of Disease of the Knee-joint, with Abscess and Necrosis of the Tibia."

29. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopaedic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.  
ROYAL INSTITUTION, 3 p.m. Dr. E. Frankland, F.R.S., "On Chemical Affinity."

30. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.  
ROYAL INSTITUTION, 8 p.m. Cardinal Wiseman, "On the Points of Contact between Science and Art."

## EXPECTED OPERATIONS.

King's College Hospital.—The following Operations will be performed on Saturday (to-day) at 2 p.m. :—  
By Mr. Fergusson—Lithotomy (two cases); Removal of Epulis.

## ORIGINAL LECTURES.

LECTURES ON THE

## BLOOD OF VERTEBRATA.

DELIVERED AT THE

Royal College of Surgeons of England,

DURING THE SESSION 1861-62.

By GEORGE GULLIVER, F.R.S.

Professor of Comparative Anatomy and Physiology to the College.

LECTURE X.—*History of the Coagulation of the Blood.*

ALTHOUGH physiological literature has long been full to overflowing about the red corpuscles, I found it, with the exception of a few short and excellent notices by Dr. Davy, an absolute chaos in the year 1846 as regards the coagulation of the blood. This seems the more remarkable in our country, where Mr. Hunter had been so strongly urging that the fibrin is the most important part of the blood, while his contemporaries and immediate successors were all, save Hewson, wedded to his views. Hewson, indeed, by whom the leading physical properties of the coagulable lymph had been previously and more exactly described, was more or less forgotten, and there was a general ignorance of the labours of their predecessors in the path of truth as concerns this subject. Even our own countryman, Richard Davies, was so utterly unknown that he was never mentioned as a worthy forerunner of Hewson in displaying the three parts of the blood; and this while Denis in France was asserting his absurd claim to the discovery of the fluid state of fibrin in living blood; Müller in Germany making experiments to prove, as if any such demonstration were wanted in Britain, that the red corpuscles are not essential to coagulation; and the Hunterian Professor, in reply, assuring us that it was not known, before Hunter discovered it, upon which part of the blood its spontaneous coagulation depended!

Indeed, we shall find this subject affording one of the saddest, most strange, and curious chapters in the great book of physiological history. We shall have to search for truth and justice long hid under such successive heaps of bewilderment and delusion as could scarcely be found in any other department. Let any one who may pursue science for the mere sake of fame—"that last infirmity of neble mind"—behold here what may be his fate, and accordingly resolve to go on his course supported by higher motives, and then he may, at all events, rejoice on his way, and make sure of the "fair guerdon" afforded by the virtue and pleasures of the occupation.

The ancients had more correct notions on the coagulation of the blood than those which prevailed in Britain and on the Continent during more than the first half of the last century. I say prevailed, because truth had peeped out and even walked abroad sometimes, only to be sent back to obscurity, scorned, neglected, or drowned by the Babel of rivals,—and so left to bide her time. Those errors remained longer on the Continent, where correct views had first appeared, than in Britain, where Truth, after all, was revived and established, though sorely bespattered and disguised at times.

Aristotle knew that the concretion of the blood is owing to a fibrous part, since he remarked, if this be removed the blood will not set. And his master, Plato, was acquainted with these fibres. Harvey described the blood as composed of a red portion; of a white, fibrous, tough part uniting the rest; and of an ichorous or serous one, in which the coagulum is wont to swim; adding that these parts severally have no existence in living blood. Dr. Willis, eight years later, described the filaments of the crassamentum as joined together or concreted into a parenchyma; and Lower gave a tolerably good account of the "glutinous fluid" to which the coagulation of the blood and some of its morbid appearances are owing.

In the year 1666, Malpighi obtained the fibrin separately, and of a whitish colour, by washing away the red part of the blood-clot in the same manner as we are now wont to do. He correctly insisted that the so-called polypi of the heart are composed of this fibrous matter, and not of coagulated serum, as was then generally supposed. He examined this matter with the microscope, both from the crassamentum and the polypi,

and found them both made up of a fibrous texture or network; adding that the buffy coat of the blood has probably the same structure. And to him we owe the discovery of the red corpuscles of the blood. Thus we have the first approach to an accurate description of the blood-clot; and that in the memorable year of the great fire of London, and of the institution of the French Academy of Sciences at Paris.

But the observations of Borelli, published in his posthumous works just fifteen years afterwards, that is to say, in 1681, were still more precise. He described the compound nature of the clot, and of the serum: the clot as consisting mainly of white fibres, or reticulated membranes; the serum of matter partly coagulable by heat, and partly of water impregnated with salts. He examined the fibrin and capillary vessels microscopically, concluded that it is liquid in the living body, and described it as the white, glutinous, and spontaneously-coagulable matter of the blood. These just opinions prevailed for a few years afterwards in Italy, where Gulielmini and Michelotti distinguished the whitish tough fibres from the red globules of the clot, and as a result of microscopic examination. Meanwhile, Bidloo, in Holland, figured and described the tough and tensile network of fibrils and the red corpuscles in a drop of blood, and called the corpuscles "globose vesiculæ." This was in 1685.

In the same year Dr. Samuel Collins's great book of Anatomy was published in London. He gave such an excellent description of the blood clot, of the nature of the so-called polypi of the heart, and of the arrangement of the parts in buffy blood, as shows that he must have carefully examined the subject. He may have been more or less indebted to Malpighi and Borelli, but, undoubtedly, realized the facts by his own observations. This, then, is the advent of correct knowledge of this subject in England, at least, in a comprehensive form; for though Harvey, Willis, and Lower had described the fibrin here, the red corpuscles were unknown to them; or, at least, imperfectly by Lower. Collins's work appeared just thirty-four years after the publication of Harvey's observations. And yet, as if to assert the impotency of truth, when Bidloo's plate before mentioned was repeated by William Cowper, he disputed its accuracy, considered the fibres as accidental, and described the blood as consisting only of two parts, the serous and globular. This was in the year 1737, fifty-two years after Collins had given his correct descriptions, thirty since Ruysch had described and displayed the fibrin collected on twigs, and about the time when the delusions of hypothesis were obscuring the truths which had been so well demonstrated by Malpighi, Borelli, and Collins. We all know the Ruyschian membrane, how he whipped it out of the blood by sprigs of a plant, and had engravings made thereof and published in 1707. And it is probable that our forefathers, long before his time, had practised the same means of keeping the blood fluid for the purposes of domestic economy.

But the truth which even this simple and familiar experiment might have taught, and which, as we have seen, was proved, not only in Italy, but also in England, was about to be hid both in Britain and on the Continent, with certain illustrious exceptions presently to be noticed. In short, for a long while the fibrin was either lost sight of or confounded with the serum, and the coagulation of the blood attributed to an aggregation of the red corpuscles. I am disposed to attribute this error in great measure to the influence of Leeuwenhoek; for though he wrote a few years before the Ruyschian membrane was described, he had the advantage of such predecessors as Harvey, Willis, Lower, and, above all, Malpighi, and so should have avoided the error of regarding the red corpuscles as the spontaneously coagulable part. But this error he did hold, and seems only to have considered the blood as composed of the globules and serum.

And this opinion, modified in one way or other, prevailed, or was more or less current in Britain, for, at least, the first sixty years of the last century. Let any one read the writings of such men as Keill, Jurin, Thos. Morgan, John Cook, Arbuthnot, Langrish, William Northcote, Marmaduke Berdoe, and Huxham, all published in London from the year 1717-72, and he will find the coagulation of the blood considered simply as caused by a running together of the red corpuscles. And either this opinion or something more vague rules in the writings of Keill, Drake, and Verheyen, published in London during the year 1714, in the third and last volume of the "Bibliotheca Anatomica." In Edinburgh, Martine and Dr. Francis Home, and even Dr. Butt, partook of the prevailing

errors. The terms "serum" and "lymph" were often used synonymously by the best authors in London and Edinburgh; and though Butt described the coagulable lymph, and so termed it, he confounded it with serum and with the white of egg.

We have already alluded to Leeuwenhoek's speculations as the root of so much error. His observations were published in London, in the *Philosophical Transactions* of 1675, and afterwards; and a select version of his works was edited by Hooke in 1800, not at all improved as regards the coagulation of the blood. Indeed, it seems marvellous that the sharp-sighted and justly-celebrated micrographer should have overlooked the fibrin, and not described its fibres as the bond of the blood-clot, more especially after the exact and emphatic observations on this point by Malpighi and Borelli. But on the Continent, as well as in Britain, the errors were held by the best authors, such as Boerhaave, Van Sweiten, Haller, Marherr, Sauvages, and De Haen; and may be found also plentifully in the "Dictionnaire Raisonné d'Anatomie et de Physiologie," published at Paris in 1766. Yet some correct views peep out occasionally, especially in Quesnay's "Principes de Chirurgie," which appeared in 1746.

Indeed, as already hinted, there were more remarkable and illustrious exceptions at this dark period. In France, Petit and Senac, from the years 1732 to 1749, gave correct accounts of the formation and structure of the blood-clot, and of the agency of the fibrin, which they called the lymphatic part or coagulated lymph. Petit was remarkably accurate; while Senac retained a leaven of error, part of which he corrected after the publication of Hewson's "Inquiries." So perfect were Petit's views, that he even described the disposition of the parts of the blood in the heart and great vessels after death, and thus accurately observed, as Mr. Paget has lately done, that the relative situation of the fibrin and the red part might indicate the position in which the dead body had lain when the blood coagulated.

In England, William Hunter was acquainted with the three parts of the blood at the end of the year 1759, but certainly not before; and in 1762 his knowledge of the properties of the coagulable lymph in inflammatory exudations was crude or imperfect. He calls it a "mucus . . . a glutinous concretion or slough." The term "mucus" was then and had long been current in its modern restricted sense. By "lymph," he understood "the interstitial fluid of living bodies." Like Borelli and many others afterwards, he termed the spontaneously coagulable matter "gluten," and asserts that it was "formerly falsely called 'fibrous.'"

When then, and by whom, was the foundation laid in this country of a revival of the old and correct observations of Malpighi, Lower, Borelli, and Collins? Who established among us, and from open and direct proofs, the leading difference of the three parts of the blood, and especially of the fibrin, as taught and extended by Hewson, Fordyce, and John Hunter? This honour belongs to Dr. Richard Davies, whose "Essays to Promote the Experimental Analysis of the Human Blood" were published at Bath, in 1760, with a post-script dated March 1, 1759, and a statement that he had drawn the principal lines of these Essays full twenty-five years before; that is to say, when Dr. Hunter was only thirteen years of age, Mr. Hunter a still younger boy, and before Hewson was born. And, independently of Dr. Davies' statement, there is public proof that he was experimenting on the blood at least as early as the year 1748, in his "Tables of Specific Gravities," published in the *Philosophical Transactions* of that year, including his observations on the comparative weights of the serum, buffy coat, and crassamentum. He was old, it may be inferred, in 1760, when his Essays were published, as he expresses a hope that they may engage younger eyes and younger minds in such studies. We have seen that a correct knowledge of the subject was obscured by a general gloom long before, and for some time after, that date, which not even the fitful and beautiful lights of the eminent French physiologists, before mentioned, had been sufficient to dispel; but it was at last dispelled, and the current errors exposed, by the clear proofs of Davies, and the true outline of the facts thus fairly established again in Britain by this obscure, neglected, and excellent observer; and that after they had been forgotten, or put out for more than half the century which had passed since the time of Malpighi, Borelli, and Samuel Collins. I have found no notice whatever of Davies by any one of his contemporaries or successors; and yet he must have been a man of no mean position in his day, for he was a Doctor

of Medicine at a time when any or every "M.D." did not pass current here, and was of Cambridge, as he describes himself "late Fellow of Queen's College" in that University. Why he has so long been consigned to oblivion, that it was left to me alone to rescue him from this indignity, and to solicit for him the common justice of that meed of praise to which he is fairly entitled, it might be vain or painful to inquire. There is a copy of his Essays in the library which Dr. Hunter left to the University of Glasgow, and another in the library of our College.

Dr. Davies having, as we have said, laid and proved the outline of the facts, and that at a time when there was a general ignorance of them in England, it yet remained to fill up, complete, and extend the subject, by such fair, simple, and plain experimental proofs as could not fail to convey conviction to the understanding of any physiologist who might undertake to repeat them. This was done by Hewson ten years afterwards, and he was then unrivalled, and has never been surpassed for the sagacity and skill with which he prosecuted the inquiry. His work on the "Properties of the Blood" is a model of its kind, in which point of view alone it would possess great value; for it has the high merits of experiments nicely devised, well executed, and clearly told; often original, ever instructive, and such a happy combination of perspicuity, precision, and simplicity, that the reader cannot fail to comprehend the importance and accuracy of the leading conclusions, and to feel the pleasure of learning from such a master.

With a tea-spoon he skims off from inflammatory blood the colourless fluid, and shows how it coagulates when thus completely removed from the red corpuscles, an experiment of great importance at a time when the coagulation had so long been attributed to a mere aggregation of them; and accordingly he varies it, ties up the veins of an animal just dead, lets the corpuscles sink, and then removing the clear, colourless, supernatant fluid, witnesses its coagulation as before. He retards the coagulation of human blood by neutral salts, and again proves that the clear, colourless fluid upper stratum, will coagulate at the temperature of the air, and quite independently of the red corpuscles. And he demonstrates in the most unequivocal manner, that these remain entire and unaltered in the clot, and that their form is preserved by the saline matter of the serum. Now, if any more perfect, conclusive, or better evidence than this has ever been produced, that the spontaneous coagulation of the blood is alone dependant on the fibrin, and that totally independent of the red corpuscles, you would be glad to know where to find it—not for the want of further proof, but merely as a physiological curiosity.

But there was an old and discarded hypothesis entertained by Sydenham, Quesnay, and Bordenave, that the fibrin of the blood is formed of the colourless matter of the red corpuscles, or, at least, at their expense; a doctrine which has appeared again within the last twenty years from the independent observations of some of our best physiologists. Besides, in the Croonian lectures for 1818 and 1820, Sir Everard Home and Mr. Bauer had revived it in the more specious form, that the fibres of fibrin and of muscle are composed of rows of the nuclei of the corpuscles divested of their coloured envelopes. And when you look at the diagrams of the rolls of the human corpuscles in strings, and of the relative size of the same corpuscles deprived of the colouring matter, you will perceive how readily such an error might have arisen and been embraced then, and how pretty and seductive it must have been. And so no wonder that a similar doctrine was soon afterwards promulgated in France by Prevost and Dumas, supported by Professor Milne-Edwards, and adopted by such other eminent men as Dutrochet and Béclard. But it never was adopted, much less took root, in Britain; where, although Davies was unknown or forgotten, the accurate conclusions of Hewson remained current in the schools and among our best independent observers: while valid objections to the new doctrine were advanced by Tiedemann and Burdach in Germany, and even in France by De Blainville.

Still, it seemed as if the delusion never would cease on the Continent. So widely and deeply had it spread there, that, besides the writers before-named, Professors Müller, Wagner, and Milne-Edwards, three of the most illustrious foreign physiologists, state, that it was generally believed that coagulation was produced by a running together of the red corpuscles, before Berzelius had announced that the fibrin is liquid in the flowing blood, and becomes solid in the clot.

How very old and very new this last and correct opinion was when that distinguished chemist advanced it as a novelty, we have already shown; but it seems hopeless to expect that it will ever be known as a fact established long ago; for we find an excellent French physiological chemist seriously proclaiming, in 1838, that he was the first to admit the liquidity of the fibrin in the circulating blood!

And so no wonder Müller was led, in 1832, to discover the facts again, so often discovered here and abroad before, but so long hid in the prevailing darkness on the Continent; this, too, in spite of the universal acceptance in Britain of the correct doctrine of Davies and Hewson; as well as of Dr. Babington's term "liquor sanguinis" for the spontaneously coagulable matter, as distinct from the red corpuscles. Müller witnessed anew the coagulation of that liquid apart from those corpuscles; but, as might have been expected, added nothing to the exactness or completeness of Hewson's demonstrations, and, indeed, only gave a needless confirmation of them. Hewson's "Inquiries" were completed and published in the *Philosophical Transactions* of 1770, the very year of his marriage to Mary Tickell; and he died within three years afterwards. Twenty years passed before Hunter's death, in 1793, when his great work on the "Blood" was in the press, the publication of which was superintended by Sir E. Home and Dr. Baillie in 1794. There is no reason to suppose that Mr. Hunter ever claimed for himself the discovery, either of any one of the chief parts of the blood, or that its coagulation is due to the fibrin. On the contrary, his great and generous mind would, doubtless, have revolted from any such injustice; for, whatever might have been his ignorance of the earlier writers, it is certain that he was well acquainted with Hewson's observations. But, as a final proof of the potency of error, and of how "confusion then had made his masterpiece," in 1835, the Hunterian Professor, referring to that posthumous book of 1794, seriously asserts that it was not known in Hunter's time upon which of the constituents of the blood its act of coagulation depended, claiming accordingly the discovery for him, and this on the credit of a mere repetition of one of Hewson's experiments; an error scarcely equalled even in this perplexed subject, and the more deplorable, as still standing, without correction by its author, in the preface to the concluding volume of the last edition of "Hunter's Works."

## ORIGINAL COMMUNICATIONS.

### CLINICAL MIDWIFERY.

By FRANCIS H. RAMSBOTHAM, M.D.

Physician-Accoucheur to the London Hospital, etc.

(Continued from page 5.)

I HAVE already related in these reports those cases of hæmorrhage before delivery, forceps, craniotomy, and transverse, which I was called upon to treat during the five years embraced between January 1, 1840, and the last day of December, 1844; and I will now proceed to detail those cases of convulsions and other indications of oppressed brain, which I witnessed within the same dates. The following three occurred in my practice during the three first months of the year 1840:—

#### *Apoplexy at Five and a-half Months of Pregnancy—Twins.*

*Case 172.*—On February 5, at 7 p.m., a Medical friend requested me to see Mrs. A., Artillery-place West, five months and a-half advanced in her second pregnancy. Two months after the birth of her first child she caught the small-pox; her infant took it from her and died. She had never been strong or healthy since. For a week before I saw her she had complained of intense pain in the head and frequent vomiting; however, on the 2nd she was able to receive a number of friends who had been invited to dinner, although she felt very ill; and her doing so was most injudicious. On the next day she was quite jaundiced, and kept her bed; the whole of the day before I saw her she was dull and stupid, in a semi-comatose condition, and only spoke in answer to questions; towards the evening she could not hold anything in her hand, and she gradually became more and more insensible till 2 a.m. on the 5th, from which time she never uttered a syllable. When I saw her I was told by the friends that "she had been in a sweet sleep all day;" but instead of that I found her apoplectic, with deep, stertorous

breathing. Every now and again she gave indications of painful sensation, which was due to uterine action. The os uteri, indeed, was dilated to the size of half-a-crown; and the pains were coming on every three or four minutes. Twenty ounces of blood were immediately taken from the arm with some benefit; for some spasmodic twitchings and startings, which had been frequent before, entirely ceased. The os uteri opened rapidly, and before the lapse of an hour I was able to bring down the foot of one child which presented, rupturing the membranes at the time. I delivered this child most easily. There was a second, also presenting with the feet, which I extracted as readily. The placenta passed almost immediately. After her delivery she seemed more tranquil, and the stertor ceased; but she never became conscious, or spoke, and she continued gradually getting worse till 6 a.m. on the 6th, when she died. Each fœtus breathed for a few minutes. An inspection of the head was not allowed; but there is reason to believe that effusion of serum was the cause of death.

#### *Convulsions before and after Delivery.*

*Case 173.*—On February 25, 1840, at 4 a.m., I was sent for by a Professional friend to Mrs. H., Hackney, a strong, hearty woman, aged 35, in labour of her first child. She had been in very full health during her pregnancy, living highly, and taking scarcely any exercise. She had also much neglected the state of her bowels. She had been much harassed with false pains from the morning of the 21st. The os uteri began to dilate about noon of the 24th, and the labour progressed very well, though slowly, until 11 o'clock at night, when, without the least warning, she was seized with a violent convulsion. She was bled immediately to sixteen ounces; but this made no impression on the pulse, and apparently but little, if any, on the system. She became gradually conscious, however, after the cessation of the fit, but in an hour she had another equally severe as the first. When that ceased, she remained quite comatose, and suffered one every twenty minutes until my arrival. I found her perfectly insensible, the breathing very stertorous, the pupils much contracted, and dilating always on the application of light. The fits were as violent as any I ever witnessed. She was bled again to nearly twenty ounces. The pulse, which was hard and bounding before, now became softer and more natural, and the lips slightly pallid; but the coma remained as deep as before. With great difficulty she was made to swallow ten grains of calomel, and some strong purging mixture. The os uteri being entirely dilated, I was proceeding to turn the child, with the intention of delivering; but at the moment I was passing my hand into the vagina, which was preternaturally rigid, for that purpose, a very strong contraction took place, the membranes suddenly broke, the whole of the liquor amnii, very small in quantity, was evacuated, the head came to press strongly against the pelvic brim, and the funis prolapsed by its side, its vessels not pulsating. As, under these circumstances, it would have been difficult and dangerous to endeavour to introduce the hand with the intention of bringing down the feet, especially as the patient was very restless, throwing herself about on the bed in every direction, yet, as delivery was urgently called for, in consideration of the fœtus being already dead, I perforated the skull at once, and extracted the child with not more difficulty than I expected to meet. She seemed better after the child's birth, and, though still insensible, no fresh fit occurred for more than an hour. After that, they again came on every twenty minutes. Directly after delivery a turpentine enema was exhibited, which speedily acted, and brought away an immense quantity of very offensive fæces. The fits continued more or less frequent till 8 p.m., when they ceased; there must have been nearly sixty in all. She still, however, remained insensible. At my visit, 3 p.m. on the 26th, I found she was sensible enough to swallow by voluntary efforts, though she had never spoken, nor shown any other signs of consciousness. The bowels had been freely purged; but the abdomen had become tympanitic; at 8 p.m. she was evidently sinking, and she died at 8 a.m. on the 27th. No urine could be saved to ascertain whether albumen existed in it or not.

#### *Convulsions before Delivery—Twins.*

*Case 174.*—On March 26, 1840, at 7.30 p.m., a Professional friend requested me to visit Mrs. T., Old Street-road, at the close of her first pregnancy. I found that she had been seized at noon of the same day with a strong convulsive fit, without any premonitory symptoms, and that about sixteen ounces of blood had been taken immediately, with but little benefit; for,

although she regained her consciousness between the attacks, the fits returned, becoming gradually more frequent, while in the intervals she became less conscious; twelve leeches were, therefore, applied to the temples. When I saw her, she was quite comatose, the fits were recurring every fifteen minutes, there was a slight sanguineous discharge from the vagina, and the os uteri was the size of a sixpenny piece, but there were no indications of uterine contractions. It was agreed that she should be bled again to the amount of sixteen or twenty ounces; ten grains of calomel were put on her tongue, and she was made to swallow some purgative medicine. After the second bleeding the attacks were less frequent, and also less strong. Uterine action was well established at 10 p.m., and she was delivered of one child at half-past one in the night, and of a second in twenty minutes after; both presented with the head, and both were born dead; the second was putrid. She had a fit whilst the head of the first was passing into the world, but none after. I saw her at 7.30 the next morning, when she was still comatose, but she had swallowed naturally, though she had not spoken; the bowels had acted copiously. From this time she gradually regained her consciousness, and the next day answered questions quite rationally. The uterus, however, was large, very painful, evidently congested, and there was no lochial discharge. Leeching, fomentations, and warm water injections, relieved these symptoms, and she gradually recovered.

N.B.—There are three circumstances connected with this case that are worth notice. The first, that it occurred under a twin gestation. Now, it is an established fact, not only that convulsions are comparatively more frequent when there are more children than one in utero, but that twin gestation predisposes to many other of the dangers to which lying-in women are exposed, particularly hæmorrhage; this might, indeed, have been expected, from the larger surface of placenta in contact with the uterine walls. But the inflammatory and other diseases of the puerperal condition are also more frequently found to follow plural than single births. The second is,—that it was a first labour. Women bearing first children are peculiarly liable to convulsive seizures. Thus, out of 127 cases reported by Clarke, Merriman, Collins, Meigs, and my father, 100 of them were first births; and of 111 cases of puerperal convulsions which I have myself personally attended, 79 were first births. These proportions are large. The third circumstance is, the occurrence of a congested or inflamed state of uterus. It has been remarked by Denman and Collins, that abdominal inflammation is a common sequela of puerperal convulsions, and Gooch gives a case in point. Indeed, Denman goes so far as to say, that in almost every case which he had seen there was evidently after delivery a greater or less degree of abdominal inflammation. Although it has happened to myself to meet with a few instances of peritoneal and uterine inflammation subsequent to puerperal convulsions, the number has not been by any means so great as to impress my mind with an idea that either of the latter diseases had any connexion with the former; nor would it have occurred to me to imagine such a connexion, had the remark not been made by high practical authorities. Perhaps this may be accounted for by its being the practice now to take blood more freely for the subdual of these frightful attacks than was the case when Denman wrote.

8, Portman-square.

(To be continued.)

*Erratum.*—In the remarks appended to the last collection of Dr. Ramsbotham's cases published in this Journal, for "Douglas and Denman thought," read "Denman thought." Dr. Douglas was the first to refute Denman's description of the process of the "spontaneous evolution."

NOTES ON CAUSES OF EARLY MORTALITY.

By J. WHITEHEAD, M.D.

No. IV.

DEATH-RATE IN INFANCY.

As was assumed in the case of the intra-uterine tenant, so, also, would it seem to be in that of the independent being in regard to the uncertainty of its existence, namely, that its tenure of life is precarious in proportion to its helplessness, and the extent to which its supply of sustenance depends upon the skill and moral integrity of those around it, influenced, of course, by the nature and sufficiency of the means

available. This law operates with a force proportioned to the degree of intellectual torpidity of the creature, the progressive steps of early development lessening its stringency as the faculties become awakened to a knowledge and appreciation of functional promptings and requirements.

Among those born alive, the highest rate of mortality occurs during the first few days—probably on the first, the day of birth; from which date it steadily decreases week by week during the first month, and month by month, with striking regularity, to the end of the first year; standing, for the first month, twice as high as for the second and third together; and as high for the first three months as, and sometimes much higher than, for the whole of the remaining nine months of the first year, as shown below.

Table representing the average death-rate at different periods during the first year of life, for the six years ending with 1844, in England:—

Months.	Deaths to 100 Births.		
	Males.	Females.	Total.
0 to 1 . . . . .	2.68	1.96	4.64
1 to 2 . . . . .	0.97	0.76	1.73
2 to 3 . . . . .	0.48	0.54	1.02
3 to 6 . . . . .	1.59	1.27	2.86
6 to 9 . . . . .	1.31	1.05	2.36
9 to 12 . . . . .	1.17	1.02	2.19
	8.20	6.60	14.80

To express the above results more concisely, they may be conveniently arranged in two groups, for the first three and the following nine months respectively, thus:—

Months.	Deaths (first year) to 100 Births.		
	Males.	Females.	Total.
0 to 3 . . . . .	4.13	3.26	7.39
3 to 12 . . . . .	4.07	3.34	7.41
	8.20	6.60	14.80

Showing how nearly the respective events approximate in number for these two unequal periods of the first year.

The relative proportions here given, however, for the two periods specified are constantly fluctuating from year to year; but the item for the first period (first three months) is seldom so low as that of the preceding statement, although frequently much higher. The causes of such variation are not always sufficiently explicable.

It does not appear that the rate of infantile mortality has thus far been favourably affected by the praiseworthy efforts which have of late years been made with a view to improve the sanitary condition of towns and dwellings, and to better the material status of the people, as the item representing the first year's death-rate, as above quoted, for the sexennial period ending with 1844 (viz., 14.80) stands lower than that, fifteen years later, for the three years ending with 1860 (viz., 15.29), the most prosperous period that England has for many years known. The estimate was, of course, higher during the four years ending with 1849—the years of the Irish famine—than that of 1860; but even then the disparity was not very remarkable, except for the populations occupying the north-western division, where the scourge was much more severely felt than elsewhere in England.

To offer, in passing, a brief comment upon the character of this visitation, it may be remarked that, although the failure and deterioration of the crops began to be noticed in 1845, their effects upon the material condition of the populace were not inconveniently experienced until the year after, when the death-rate at all ages exhibited a considerable augmentation, and continued to be much above the general average throughout the three years following. The results denoting the effect of the panic upon infant life for these four years respectively stand as follows:—

Months.	Deaths (first year of life) to 100 Births.		
	Males.	Females.	Total.
1846 { 0 to 3 . . . . .	4.70	3.56	8.26
{ 3 to 12 . . . . .	4.44	3.64	8.08
			=16.34
1847 { 0 to 3 . . . . .	4.68	3.56	8.24
{ 3 to 12 . . . . .	4.48	3.68	8.16
			=16.40
1848 { 0 to 3 . . . . .	4.55	3.48	8.03
{ 3 to 12 . . . . .	4.05	3.28	7.33
			=15.36
1849 { 0 to 3 . . . . .	4.59	3.50	8.09
{ 3 to 12 . . . . .	4.30	3.55	7.85
			=15.94
			Mean . . . . . 16.01

In illustration of the extent to which vicissitudes of this kind are liable to influence the death-rate in infancy, it may be convenient to compare the issues on this subject, of this and two other remote epochs, each contrasting, in a manner sufficiently striking, with the others in regard to circumstances which specially affect the health and well-being of the people at all times,—namely, the productiveness of labour, the price of provisions, and the quality of the articles consumed.

The first of these epochs represents a trade panic of at least three years' duration, comprising, indeed, the years 1839 to 1842, during which term employment was scarce, the price of provisions high—though unaccompanied by deterioration in quality,—wages low, with a state of chronic political agitation throughout the country. The second refers to the epoch comprised within the dates of the preceding table, and which was a veritable famine such as had not prevailed in this country for many years, attended by a pestilential infliction upon the health of many located within the sphere of its influence—the immediate result of a succession of faulty harvests, which were not only deficient in yield, but of bad quality. The third is an epoch of unwonted prosperity and abundance. The rate of infantile mortality for these three epochs respectively stands thus—both sexes included :—

	Deaths (1st year) to 100 Births.		
	0 to 3 mo.	3 to 12 mo.	Total.
1840, 1841, 1842 . . .	8.45	6.25	14.70
1846, 1847, 1848, 1849 . . .	8.57	7.56	16.13
1858, 1859, 1860 . . .	8.55	6.74	15.29

In contrasting the first and last items of the preceding table, and taking into account, at the same time, the prevailing circumstances of the labouring population under which they were furnished, the conclusion seems inevitable, that abundance of means is not necessarily conducive to the amelioration of the death-rate in infancy; seeing that the average fatality for the three prosperous years ending with 1860, is .59 per cent., higher than that of the period of difficulty, comprising the three years ending with 1842. There was not, so far as I know, any unusually severe epidemic prevalent amongst children during either of the years comprised in the third—the prosperous epoch—which could account for the high rate quoted. The results for the respective years of this epoch certainly differ materially one from the other,—being, for 1858, 15.60; for 1859, 15.41; and for 1860, 14.86; showing a remarkable decrease of the early death-rate during these three years. But the year 1860, the most favourable of the three, was notably prosperous as well as healthy; yet was its death-rate for the first year of life higher by .16 than that of the crisis ended 1842.

Hence it would appear, that mere limitation of means, provided this does not extend to actual and continued deficiency, and provided also the articles of common consumption be of sound quality, cannot be regarded as a chief cause of an increased mortality. This position is forcibly sustained by events which are now passing. It is especially noteworthy, for instance, that, during the present season of privation and depression, the class of diseases commonly met with in early childhood amongst the indigent, and brought under notice at public charities, have been both fewer and milder in character; and the death-rate, judging from the comparatively few fatalities which have occurred among the patients treated, within a limited experience, during the past twelve months, will probably be, for this year, below the general average. This cannot be owing to climatic agency, for the seasons this year (1862) have been even less genial than usual. The cause must, therefore, be elsewhere sought for, and may possibly be found among the attributes of domestic and personal hygiene.

Faulty diet and repletion, together with the intemperance of parents both in eating and drinking—vices which are most prevalent in times of prosperity—are much more pernicious in their effects upon infantile health and life than the spare and simple regimen which straitened circumstances impose: provided always, as before stated, that the quality of the food be sound, and want avoided.

The fatal pestilence which prevailed in the north-western division of the empire during the Irish famine crisis, was mainly due to the diseased quality of indigenous alimentary products, and not to actual deficiency alone, as a liberal supply of grain and other substitutes began to be poured in from foreign countries so soon as the want was made known; the prohibitive duties having been providentially removed,

thanks to the efforts of a small knot of energetic philanthropists, during the early pressure of the panic.

It is to be regretted that the Registrar General's tables furnish no means whereby to estimate the actual amount of fatality, during this epoch, among illegitimate children as compared with that of those born in wedlock. Doubtless, the influence of badness, and at the same time of scantness of food, would tell with great severity upon such as were also deprived of the maternal sustenance. Even under ordinary circumstances, the death-rate of illicit offspring during the first year of life, according to the French records, is more than double that of the legitimate, and must be much higher in seasons of dearth and during the prevalence of devastating epidemics.

The rate of mortality in infancy, as well as generally, is referable to many causes, one of which, though not the only, nor even the chief, agent in this work is, according to general belief, overcrowding in the dwellings of the poor. The following table, bearing on this subject, represents the death-rate during the first year of life in each of the ten registration divisions of England (that of London being excluded), and the density of population, as indicated by the number of persons per acre in each division, ranged in the order of the preponderance of deaths :—

Divisions.	Deaths (first year) to 100 Births.			No. of Persons to the acre.
	Males.	Females.	Total.	
North Western . . .	9.36	7.26	16.62	1.46
York . . . . .	9.09	7.12	16.21	.55
Eastern . . . . .	8.42	6.52	14.94	.36
North Midland . . .	8.61	6.27	14.88	.36
South Midland . . .	8.49	6.28	14.77	.40
West Midland . . .	8.37	6.42	14.79	.63
England . . . . .	8.32	6.44	14.76	.52
Northern . . . . .	7.70	6.22	13.92	.33
Welsh . . . . .	7.44	5.87	13.31	.25
South Western . . .	7.09	5.37	12.46	.37
South Eastern . . .	7.00	5.39	12.39	.45

The influence of agglomeration, however, will be better understood, when examined in connection with the death-rate of town populations, an inquiry which must be deferred for an occasion hereafter. Suffice it to say in this place, that the agency in question—albeit demoralising and unwholesome—seems to hold in reality a less important rôle than is commonly assigned to it. It may be remarked, in passing, however, in reference to the share which over crowding undoubtedly has in the augmentation of mortality, that the division in which the highest death-rate occurs, namely, the North Western, has a population more than twice as dense as any other in England—London alone excepted; and the metropolis ought to be placed, when instituting comparisons of this nature, in juxtaposition with towns only.

(To be continued.)

### CASE OF MALIGNANT PUSTULE.

By JAMES EDMUNDS, M.D., etc.

A FINE, tall, bulky man, 50 years of age, who had led an active business life, lived freely, and suffered from gout, and from symptoms which had been referred to disease of the muscular texture of the heart, was occupied on the 16th of last December in superintending the construction of a conservatory in his grounds at Hackney, and at 10 p.m. he took supper, and went to bed "as well as possible."

At midnight, he was seized with a rigor, and with severe pain across the lower part of the loins and through the hips. At 3 a.m. he found his "tongue greatly swollen," and his articulation very difficult; he became rapidly worse, and, early in the morning, sent for me, but I was unable to visit him directly.

At 11 a.m. I found him in bed, with a countenance indicating considerable distress and profound toxæmia. The mouth was open, the saliva was running over the lower lip, and the tongue was thrust upwards by a remarkable swelling in the sublingual space; there was the greatest difficulty in utterance, but no huskiness of the voice; the pulse was weak, and he was very feeble when out of bed. Only the under part of the tongue was visible, but, by means of a table-spoon, I managed to see that the roof of the mouth, the palate, and the pharynx were unchanged in appearance, as also were the

lips, the cheeks, the gums, and the tongue itself. The tongue had a "dried beef" look about the tip of its upper surface, and, with the swelling beneath, looked as if it were mounted upon a small thick muffin, about as big as itself, and of the colour of the mouth. The swelling was symmetrical, and it completely filled that space within the lower jaw which is usually occupied by the tongue. The mucous covering was not obviously altered, but close inspection discovered an indistinct pallid mottling, analogous to that change of surface which precedes ordinary gangrene. Upon applying a finger the mass was not very sensitive; it was soft and yielding, as if it might contain pus infiltrated through its texture, but it was not quaggy, it did not pit, and it was utterly destitute of that brawny feel which attends ordinary carbuncular inflammation. Beneath the lower jaw there was some swelling and considerable tenderness.

I could scarcely believe that the patient had arrived at this condition in less than twelve hours; but he emphatically assured me that he "went to bed as well as I was."

Ten years' active practice had not previously presented a similar case to my observation; and beyond considering it as gangrenous cellulitis, I was at a loss for a designation; and beyond the risky procedure of making a free incision beneath the tongue, I was also at a loss for any effectual treatment.

I explained the nature of the case to the patient and family, and particularly guarded the latter against infection. I directed the patient to wash out the mouth frequently with a solution of nitro-muriatic acid, and to take a full dose of carbonate of ammonia immediately; and it was arranged by telegram for Dr. B. W. Richardson to meet me in consultation at two o'clock. At this visit the patient looked worse, and the submaxillary swelling and tenderness were greater, although the mouth and the utterance were about the same, and there was neither affection of the pharynx, nor huskiness of the voice. The only clue which we could obtain as to the origin of the malady was the fact that, three and four days before, the patient had eaten some jugged hare which was "high," and that beneath the tongue a ragged tooth in the lower jaw had produced a sore, through which a putrid infection might have occurred, and near to which he remembered that some of the meat had lodged until the next day. We decided that, at all hazard, a free incision must be made into the mass, and Dr. Richardson further suggested that some solution of iodine should be inserted into the incision on pledgets of lint, so as to permeate the diseased textures, and, if possible, prevent, by chemical action, any further blood poisoning. Our recommendations were at once acquiesced in, and a long bistoury was plunged by the side of the frænum linguæ downwards and backwards into the mass for an inch and a-half, when its point was turned outwards so as to emerge upon the end of the finger beneath the root of the tongue, and the knife was drawn forwards so as to cut its way out, and produce a most effectual incision. No bleeding ensued, and a corresponding incision was instantly made under the other side of the tongue. The mass did not cut like ordinary flesh, nor in the least like carbuncle, but like soft flesh, or ripe Stilton cheese; no pus exuded; and the cut surface presented a mottled pale and pinkish appearance. Pieces of lint, soaked in a solution of compound tincture of iodine diluted with three parts of water, were thrust into the opening, and were to be changed every hour; the surface of the mass and the contiguous parts were also to be frequently swabbed with the solution by means of a small sash brush. The room contained a good fire, and the windows were thrown open. Some fragments of iodine also were placed about the room to exhale into vapour, and, as Dr. Richardson thought, to produce an ozonising, and, perhaps, disinfecting effect upon the atmosphere. The patient was to take large doses of carbonate of ammonia, and champagne *ad libitum*.

At 10 p.m., Dr. Richardson and myself held another consultation. The patient's countenance was much improved, and he said he felt better. Articulation was easier, the tongue more movable, and the incisions were discharging copiously. There was no huskiness of voice nor affection of the pharynx, and the pulse was better. We congratulated ourselves and the family upon the possibility of recovery, as, notwithstanding the wonderfully rapid advent and increase of the disease, it appeared to have made no progress during the last seven hours. The treatment was to be continued, and we were to hold another consultation at 8 a.m.

In the night, however, a cab was sent for me, and, on arriving, I found that the patient had just died. I learnt

that a second rigor had occurred at midnight, and that he became rapidly worse; the discharge was more profuse from the mouth, and began also to come from the nostrils; the swelling under the jaw increased enormously, and extended backwards to beneath the ears; the voice became husky and the breathing difficult; he became very restless, turned across the bed on to his back, and died at 3 a.m. The discharge was never really black (Dr. Richardson termed it sepia-coloured), and the odour, although exceedingly disagreeable, was never gangrenous. The throat swelling, which came on so rapidly after the second rigor, was examined by me just after death, and it precisely resembled, in external outline, the enlargement which accompanies the deadly forms of scarlet fever. There was, however, no rash upon the skin, and the commencement and location of the first symptoms had nothing in common with that disease. The body ran rapidly into putrefaction.

The room was disused, the linen burned, and other precautions were adopted. The patient's wife, who attended closely to him, was very prostrate and ill for a week or two afterwards, and she ascribed this to having "caught a whiff of his breath." The son, however, who applied the iodine and changed the pieces of lint, and helped the patient about in bed, is quite well, and no member of the family has since suffered in any way like the patient.

The onset of this frightful malady was marked by the midnight rigor, and at 3 a.m. appeared the difficulty of utterance. Precisely as midnight recurred there was a second rigor, and this again was followed by rapid extension of the local symptoms, and death at the recurrence of 3 o'clock. Profound toxæmia from the first stamped death upon this gentleman's countenance; and the immense scarlet-fever-like enlargement of the throat, which came on after the second rigor, only aided, by mechanical pressure upon the larynx, that vital prostration which had, as it were, already mixed up death with life.

Although I have classed this with cases of malignant pustule, yet it materially differs therefrom—while points of resemblance and analogy are presented by many other diseases, *e.g.*, scarlatina maligna, some rare cases of typhus, the plague, and cases of animal or venomous poisoning. I doubt not that many readers would like to have a paper from Dr. Richardson upon this case. I have not myself had time to look up the literature of the subject; but I have thought it well to at once put upon record as clear an account of the facts as I am able, and just to summarise, as remarkable points, the supposed origin of the malady, the deadly rapidity of its course (twenty-seven hours), the exact diurnal recurrence of the rigor and of the local exacerbation, the utter impotence of remedial means, and the impunity which attended the incisions. Although not unaccustomed to use the knife, I must say that, remembering the frequency with which free incisions in carbuncular cases are followed by troublesome bleeding, I did look with much anxiety upon the risk of cutting deeply into the sublingual space; but, in future, I shall have no hesitation in freely opening such a mass, inasmuch as in this case the incision was only attended with trifling pain, and was followed by no bleeding, and I am inclined to ascribe the temporary arrest of the symptoms to the use of the bistoury and the solution of iodine.

35, Finsbury-circus.

## REPORTS OF HOSPITAL PRACTICE

IN

## MEDICINE AND SURGERY.

### ROYAL INFIRMARY FOR CHILDREN.

#### NOTES ON SCARLET FEVER.

(By Dr. WILKS.)

(Continued from page 63.)

*On the Diagnosis of Scarlatina and Measles: Are they Distinct Diseases?—Illustrative Cases.*

ANOTHER feature of interest in this disease, and one which is constantly presenting itself before us, is the diagnosis between scarlatina and measles. At one period in Medical history the two affections were confounded, but since that time a very broad line of distinction has always been made between them, and, as a rule, no difficulty exists in their separation.

Every Medical man must, however, at times have been puzzled in his attempt to declare to which exanthem the particular case belonged; the difficulty arising from the apparent mixture of the two diseases rather than from the mere mildness of the case, although this constitutes a difficulty of another kind; for those who have witnessed an exanthem in a public school must know how differently children are affected, and how, in several cases, unless from a knowledge of the existence of the disease in the institution, they would scarcely have recognised the true character of the affection.

We now allude rather to cases where the patient is very ill, and the symptoms well marked, but partaking of characters belonging to both scarlatina and measles, so that it is with difficulty a decision can be arrived at concerning the true nature of the illness. A question, therefore, has often arisen whether Sydenham did right in drawing so distinct a line between the two affections—whether, indeed, they be not modifications of one another, or whether they may not be often combined. Some have thought, and such theory is held by many German writers, that the disease which constitutes the difficulty, and which is apparently made up of scarlatina and measles, is, in fact, a third affection of an altogether distinct character, and that three exanthemata should be recognised—scarlatina, morbilli or measles, and rubeola, the latter being the name given to the affection of which we are now speaking.

The method to be taken in forming a conclusion would be probably of the same kind as that adopted with respect to the controverted theory of the distinctions of continued fevers—that if belonging to the same species one would propagate the other, and the two would be found associated, but, if belonging to different species each would produce its like, and very distinctive characters would be preserved to them. So if it be found that the exanthemata of which we are speaking are found variously intermixed, occurring in all forms in the same localities or the same houses, it would be a strong argument in favour of their identity. If, on the other hand, they are found distinct, it would be almost a proof that they had a nature *sui generis*, and this, we think, will be found to be the case with respect to these diseases. Measles or morbilli is one form of disease, and scarlatina another, whereas, in all probability, the rubeola is a third affection, distinct from both, and thus explaining the difficulty arising from the apparent combination of the two, and explaining also the fact of the re-occurrence of measles or scarlatina.

Dr. Copland states that some authors believe rubeola to be a specific contagious disease. Some consider it a variety of one or other of the diseases which it so closely resembles—of either measles or scarlatina. Some consider it a variety of scarlatina, others allied to measles, and others that there is no essential difference between measles, scarlatina, and rubeola. According to this, rubeola should be regarded as the connecting link between measles and scarlatina; and Dr. Copland himself rather thinks that it is a combination of both, and not a disease *sui generis*.

The disease of which we speak may be characterised, in short, as an affection having the eruption of measles, with the throat of scarlatina. Our own attention was drawn to the subject many years ago, when attached to the Surrey Dispensary, and a difficulty occurred to us long before we knew that any similar trouble had been met with by others; as, for example, on visiting a child, and finding its skin covered with a measly rash, and, at the same time, a cough existing, with wheezing, coryza, and the general aspect of measles, we were just on the point of pronouncing the case to be measles, when the neck was observed to be swollen, and, on looking at the throat, it was seen to be injected, and the soft palate tumid, as in scarlatina. Always having been in the habit of regarding the throat affection as the most important feature of such a case, we changed our diagnosis to one of scarlatina, but then were rather annoyed to hear that the child had already had this latter disease, which was described in such an unmistakable way that there could be no doubt of the fact. The same difficulty has since often occurred; also the statement that children have had measles and scarlatina twice; as well as the announcement which one is obliged constantly to hear, of one disease rapidly following the other, as only lately, where we were told of the case of a child who was said to have had scarlatina before the rash of measles had entirely disappeared,—a most unlikely circumstance.

At the Infirmary for Children, our experience being gained mostly from the out-patients, an opportunity for seeing the diseases at their height is not so great as for witnessing its

effects or the sequelæ; but in these we can every day see that the subject of which we speak requires further elucidation; for example, in the following cases:—

A child, 2 years old, was brought to the Infirmary with discharge from the ears, and enlarged glands in the neck. On making inquiries as to scarlatina, the mother stated that, four weeks before, the child had a fever, but which the Doctor said was measles. Was it not rather this third disorder, the apparent combination of the two, or rubeola?

A child, 8 years old, came to the Infirmary with renal dropsy; the mother said that a month before she was covered with a rash, like that of measles, and she had a cough; but, at the same time, the neck was much swollen, and the throat was sore. Soon afterwards the skin desquamated. Was this merely a mistaken diagnosis, or was it a case of rubeola?

A boy, aged 5, was brought to the Infirmary, with large suppurating glands in the neck, just as seen after scarlet-fever. On making inquiries as to the occurrence of this disease, the mother said that a month before the child had what was called measles. There was a cough, and a running from the nose and eyes. The mother said that the child had had measles before, and this was the second attack.

A girl, aged 5. Nine days before she was taken with a cough and cold, followed by rash, which both the Doctor and the mother considered to be measles. In a day or two there was great swelling of the throat. When she appeared at the Infirmary, there was no desquamation of the skin; but the neck was very much swollen, just as after scarlet fever, and there was some bronchitis, and in a few days there was discharge from the left ear.

The case showed an apparent combination of the two. Was it not rather an instance of a third disease?

A girl, aged 4, came to the Infirmary very ill, wasted, skin harsh, mouth aphthous, and lymphatic glands in neck much enlarged. There was ulceration of the gums of the lower jaw, and a portion of the alveolar process was exposed. This was subsequently removed, and the two incisors of the lower jaw fell out. The whole history suggested scarlet fever, but the mother said that the child had had measles three weeks before, and that one child in the house had died of it.

Although most Medical men would consider it an insult to suppose that they were unable to recognise a case of scarlatina or measles, yet the relationship of these two diseases remains in such obscurity, that we would suggest that some unprejudiced person, with a large field of experience, should commence the study of the exanthemata in children *de novo*.

## GUY'S HOSPITAL.

### MENORRHAGIA TEN MONTHS—DILATATION OF CERVIX UTERI—DISCOVERY OF POLYPUS—REMOVAL—RECOVERY.

(Under the care of Dr. J. BRAXTON HICKS.)

S. R., aged 36, single, servant, was admitted, under the care of Dr. Braxton Hicks, on September 17, 1862. She menstruated normally till ten months before admission. During the last ten months the periods have lasted fourteen days. She was found to have a rather bulky uterus; the cervix and os were healthy. Various styptics were given, but these were found to be useless. Secale, in small, continued doses, was also employed, but no benefit resulted, and the menorrhagia became more persistent. This state of things continuing, and no external cause having been found, Dr. Hicks thought a polypus might be the cause of the hæmorrhage. He determined, therefore, to dilate the os uteri. This was attempted by means of the stem of *Laminaria digitata*, recommended by Dr. Sloan, of Ayr. To a certain extent, it answered; but, after its application, irritation was produced, which subsided in a day or two after its disuse. Upon examining, a week after, a polypus was discovered protruding through the os, which was dilated to the size of a florin. After waiting a week for its further descent, which, however, did not take place, Dr. Hicks removed it by his wire-rope écraseur whilst within the uterus. It was about two inches long, by one inch, at its greatest diameter, composed of fibrous tissue, and was tightly grasped by the uterus. It was found necessary, in order to pass the rope round the root, to use the guides. A slight irritation followed, but it soon passed off, and she left the Hospital quite well in about three weeks after the operation.

In this case the effect of the dilator was rather to provoke the uterus to force down the polypus, than directly to bring it into view, as the os was not dilated more than one-third of an inch by it.

## THE ROYAL PORTSMOUTH HOSPITAL.

### REMITTENT FEVER, WITH EPILEPTIFORM ATTACKS—CLINICAL REMARKS.

Communicated by J. W. MOORE MILLER, M.D., M.R.C.P. Lond., Physician to the Hospital.]

G. D., aged 19, a Danish sailor, who had been attacked with rigors and fever during a very rough voyage from Dantzic to this port, was admitted into the Hospital under my care on October 31, 1862. He was of spare habit, and appeared to be labouring under general debility and depression, without any other marked symptoms. He stated that he had been ill ten days, and that he had received no other treatment than a saline draught, which was administered to him by the captain of the ship. His previous health had always been good.

The next day, while in the sitting posture, he suddenly fell down on the floor in an epileptic fit, in which he continued twenty minutes. When he recovered he was incoherent and sleepy. Several other attacks of a similar character followed in a few hours, and these left him unconscious and exhausted. I saw him a short time after—he was then insensible, lying on his back; if spoken to, he could be aroused for a moment. His pupils were somewhat dilated; pulse 100, and full; skin generally warm; tongue somewhat dry, very tremulous, and coated on the dorsum. The bowels and bladder having been freely evacuated, two grains of quinine and a quarter of a grain of extract of belladonna were prescribed every two hours. The head was ordered to be kept cool, and he was placed upon a diet of beef-tea and port wine.

November 2.—No return of the epileptic fits, but he has been very delirious and restless throughout the night. The febrile symptoms are marked by indistinct remissions.

3rd.—Patient has been very restless and occasionally violent. Pupils much dilated; voice husky; tongue dry; pulse 110, and soft; skin still variable, sometimes extremely hot. Head was now ordered to be shaved, and cold lotions applied. Quinine and chlorate of potash were given internally, and the bowels stimulated by a turpentine enema.

5th.—Delirium and restlessness continued the prominent symptoms yesterday. A blister was applied to the nape of the neck. This morning, about 4 a.m., a profuse perspiration broke out over the whole body. He became tranquil, fell into a sleep for some hours, and then awoke refreshed. From this time his recovery was complete, and exhibited nothing worthy of recording.

*Remarks.*—During the development and progress of fevers and other acute diseases, there is frequently a temporary susceptibility to convulsive seizures. A state of "increased reflex excitability" is induced, partly by the morbid condition of the blood, and partly by the congested state of the nervous centres. This was the associating link between the epilepsy and the fever in the case above. At the onset of the disease, the base of the encephalon, and the medulla oblongata—the centres of reflex action—were excited; but, with the increasing constitutional derangement, the irritation extended to the cerebral hemispheres, and produced a disturbance of those faculties which are manifested through them. The profuse sweat which occurred during the last stage of the fever, and which immediately preceded a marked abatement of all the symptoms, appears to have been one of the old-fashioned "critical evacuations."

During a residence of many years in Calcutta, this form of remittent fever, ushered in with epileptiform convulsions, came repeatedly under my observation; and, as a general rule, I have found quinine and stimulants, freely and persistently administered, to be the safest and most successful remedies.

## HOSPITAL FOR SICK CHILDREN.

### CASES OF EPILEPSY IN CHILDREN RELIEVED BY THE EXPULSION OF WORMS.

(Under the care of Dr. DICKINSON.)

A GIRL, 8 years of age, was brought to Dr. Dickinson, on May 29, for fits, of which she had had eight in three weeks.

Dr. Dickinson saw her in one, of an evidently epileptic character, in the out-patients' room. Treatment for worms was adopted, although there was no actual evidence of their presence. Dr. Dickinson directed that the child should go without food from breakfast-time until the next morning, and then take six grains of santonine in castor-oil. After the operation of this, quinine was to be taken. The draught brought away a large quantity of thread-worms.

A week later the patient still passed many worms, but had had only one slight fit. An enema, made with the tincture of the sesquichloride of iron and lime-water (in the proportion of half an ounce to the pint), was ordered to be used every night, and a little castor-oil was given occasionally.

A great number of these worms were passed after the injection. Except a slight feeling of faintness, she had no further fit, so long as she was under observation—*i.e.*, up to June 30.

In reference to the treatment of worms in children, Dr. Dickinson said that he adopted the following methods:—The injection of the sesquichloride of iron and lime water in cases of ascarides, the administration of santonine in round worm, and the oil of male fern in tænia.

A girl, aged 11½ years, pale, but looking fairly healthy, was admitted an out-patient on July 31. She had had fits for about two months. They began, the child said, by "a darkness," but there was no loss of consciousness until the end of the attack. She fell, and was much convulsed, but did not bite her tongue nor foam at the mouth. It was followed by sleep and headache.

She had a good appetite, but suffered pain in the epigastric region. Her bowels were constipated, but worms had never been noticed; there was no albumen in the urine. Santonine was given in the same way as in the other case.

On August 4, she was brought again. She had not passed any worms, and had had one fit, which, however, differed from the other, being, apparently, hysterical in character. Quinine, with valerian, was now given, and, on the 17th, another dose of santonine, with castor-oil. Having, after this dose, passed a small piece of tape-worm, she was ordered, on the 25th, a draught, consisting of half a drachm of the ethereal oil of male fern, two drachms of turpentine, and two drachms of castor-oil. This expelled a long tape-worm. She had no more worms or fits as long as she was under observation,—*viz.*, to September 11.

## HOSPITAL FOR THE EPILEPTIC AND PARALYSED.

### CONVULSIVE SPASMS OF THE RIGHT HAND AND ARM PRECEDING EPILEPTIC SEIZURES.

(Case under the care of Dr. HUGHLINGS JACKSON.)

THE following case is of interest as showing how slight may be the first symptom of a very serious case. If a patient were to consult us for symptoms so trifling as this patient had at first, even if we, as Medical men, suspected its very serious nature, as a part, so to speak, of an epileptic paroxysm, we should have difficulty in persuading the patient to agree with us. In very many cases of epilepsy, and especially in syphilitic epilepsy, the convulsions are limited to one side of the body; and, as autopsies of patients who have died after syphilitic epilepsy appear to show, the cause is obvious organic disease on the side of the brain, opposite to the side of the body convulsed, frequently on the surface of the hemisphere. Yet in this case the patient had good general health, and there was no evidence of syphilis. It has a general resemblance to the next case, in which there was a more definite history. Probably in few cases does syphilis produce nervous disorders by general impairment of the nutrition of nervous tissue, but rather by some obvious lesion, as deposit in the membranes on the surface of the brain, or in the brain itself.

The fact, that there is often an aura in these cases, is not contradictory to the idea that there may be organic disease, as an aura from a limb is present in epilepsy from tumour of the brain; and again, when there is obvious lesion, as in injury to the spinal cord in artificially-produced epilepsy in animals. It is not supposed that this organic disease produces epilepsy directly, but rather that it is some change of nutrition secondary to it, possibly in the medulla oblongata.

Seth W., a carpenter, 33 years of age, was admitted under the care of Dr. Hughlings Jackson, November 10, 1862.

When sixteen or seventeen years of age, a chisel thrown at him struck him on the sacrum. He was ill with pain and weakness in the back for three weeks, and then felt no more of it. Eight or nine years later, at the age of 25, he had one day a feeling of pins and needles in the index finger of the left hand, and the finger "worked." Very naturally, he took no notice of it. It soon passed off, but came on again now and then. Soon it affected the whole hand, and gradually the arm as well, and at length the face on the same side. He has since had about one of these attacks every three or four weeks, but only five or six times has he become insensible. The first time was six months after the cramp in the hand. The fits in which he is insensible are always preceded by the symptoms above described, and it is clear that they will last for some time before he becomes insensible—on one occasion for half-an-hour.

He says that all the fingers of the left hand shake, and are gradually drawn into a sort of cone. Next the arm is drawn, and then the face, and "if it gets worse it causes a pain like tearing the sinews." Still to use his own words, "if the pain gets so that he cannot bear it," he falls insensible, and is convulsed, and in this condition he used always to bite his tongue on the left side; recently he has prevented this by putting a piece of wood in his mouth.

Sometimes he will have these cramps in the hand, arm, and face for two hours. It will "fly from the face to the arm, and then back again."

This patient is a clear-headed, intelligent man, but he says that his memory has failed "terribly" lately; yet he is able to attend to his business as well as ever.

### METROPOLITAN FREE HOSPITAL.

#### SYPHILIS, FOLLOWED BY UNILATERAL CONVULSIONS FOUR MONTHS AFTERWARDS—TEMPORARY HEMIPLEGIA—PARALYSIS OF THE SIXTH NERVE ON THE SAME SIDE—RECOVERY.

(Under the care of Dr. HUGHLINGS JACKSON.)

BENJAMIN P., aged 32, was admitted an out-patient, under the care of Dr. Hughlings Jackson, on April 11, 1862. Eight months before he had a chancre, for which he was treated for nine or ten weeks; he then got well. Eight or nine years ago he had some kind of venereal disease. He says it was only a running, but it was followed by sore throat. He had, on admission, a suspicious-looking rash, which had come out recently.

He came on account of fits, the first of which occurred four months before. It began one day, whilst he was walking in the street, by a trembling in the right leg, which gradually extended to the arm, then, to use his words, "to the jaw and the sight as well." Probably, the confusion of sight was due to a spasm of the external rectus on the same side, as it was afterwards more permanently affected—the spasm passed into paralysis. He next fell insensible, and was convulsed, his mother said, on the right side only. He never bit his tongue. He had had eight or nine altogether, all preceded by an aura from the arm or leg. After each of the fits he felt weak, but was only paralysed after the last, which was a month before admission. He was, he said, in the fit for five hours, and for fourteen days he lost the use of the right side of his body, and, since, his sight had not been so good.

He came to the Hospital on account of pain chiefly in the right side of the head and face, not distinctly localised to any nerve trunks. It was worse at night. There was no pain at the vertex; no tenderness. He had a good deal of giddiness, and attacks of *petit-mal*, in which he would fall. At nights he slept badly. The right external rectus was paralysed, and it was to this, and not to the retina or cerebral part of the sense, that the defect in sight was due, as it was found that he could read small print easily, and see well in the distance with each eye. There was no difference of sensation on the two sides of the face. There was no notable paralysis of the limbs, but he thought the right arm and leg were weaker than the left, and at a future visit he said that the right leg "felt dead."

He was ordered fifteen grains of iodide of potassium three times a-day. He attended until September 5. The paralysis of the sixth nerve was quite gone, and he then felt well in every respect. The future progress of a case like this is very doubtful; probably he will have, if not epilepsy, further cerebral symptoms.

## Medical Times and Gazette.

SATURDAY, JANUARY 31.

### THE FEVER PANIC.

AMONG the many fearful results of the want of food, fever holds a most conspicuous place. Death from actual starvation is rare, even in the poorest and the most destitute localities, but the train of diseases induced by deficient nourishment sweeps off a multitude of victims, who are thus mercifully spared the lingering pains of a gradual extinction of the vital powers. The poison of typhus, whatever may be its nature or essence, appears to be generated from the bodies of the dead or the dying, or from the exhalations of persons crowded together in unhealthy and ill-ventilated localities, and this poison, which is even noxious to the human system in a healthy and well-nourished condition, is especially malignant to those whose vital energies are depressed by poverty, mental anxiety, want, or dissipation. Under such circumstances, the blood, exhausted of its solid constituents, and wasted by the excess of excretion over repair, readily absorbs the poisonous miasmata floating in the surrounding atmosphere, or exhaling from infected sources, and thus typhus is communicated to an indefinite extent, and assumes a contagious or epidemic character. In proportion as a community becomes prosperous, cleanly, and sober, does typhus disappear, and under the opposite conditions it decimates the population it attacks. The fearful epidemic of this disease in Ireland at the time of the potato famine, and the more recent experience obtained from the military annals of the allied armies in the Crimean war, have tended clearly to point out both the sources of the malady, and the best measures to be adopted for its prevention.

Such being the causes of typhus fever, it might naturally have been expected that the appalling destitution which has visited many of the manufacturing districts of this country, would be accompanied or followed by an outbreak of this formidable epidemic, and too much praise cannot be bestowed upon the Government, for instituting inquiries upon the subject, and appointing a Medical Commissioner to visit the distressed districts, and to report upon the sanitary condition of the inhabitants. For this service Dr. Buchanan has been appointed, and a better choice could hardly have been made, for he is, from long experience, thoroughly well acquainted with the phenomena of fever, and is, besides, a zealous and energetic Physician. He has, accordingly, visited the localities where the distress was most urgent; he has instituted inquiries upon all matters connected with public hygiene; and he has presented a report, which has obtained the prominent notice which it merited, by the importance of the subject itself, and by the abilities and good faith of the reporter.

In a leading article in the *Times* of the 3rd inst., the writer endorses the facts and reasonings presented in Dr. Buchanan's

report, and very properly and humanely urges upon the benevolent to continue their contributions to the Lancashire Distress Fund, on the plea that the relief afforded is not yet sufficient to procure an adequate supply of food to the starving operatives for such a lengthened period as to secure them from an epidemic visitation of typhus. It is alleged in Dr. Buchanan's report, that this fever has broken out among the population of Lancashire for the first time since 1847, when it was nearly as fatal in that county as in Ireland during the famine. In Preston and Manchester, typhus, which appeared only in isolated cases during the summer, is said to have increased in the autumn, and to have assumed the epidemic form in the winter. Dr. Buchanan also states that in twelve of the chief manufacturing towns, including Manchester, Preston, Stockport, and Bolton, he has noticed among the cotton workers an evident loss of strength, colour, and flesh, and that these external signs indicate a readiness to sink under the first attack of disease. In fact, he leads us to suppose that a fatal epidemic of typhus is now raging in the manufacturing districts, and that those who have not yet taken the disease may very soon do so, unless speedy and energetic steps are taken to obviate the calamity.

Without having the least desire to arrest the current of public benevolence to our distressed fellow-creatures in Lancashire, and without the slightest wish to impugn the good faith and accuracy of Dr. Buchanan, we venture to ask the questions, whether this zealous and accomplished Physician has not, perhaps unconsciously, somewhat exaggerated the facts laid before him, whether the testimony of other independent observers entirely corroborates his own, and whether, indeed, his own statistics wholly bear out the views which he advances? In adopting our present line of argument, we conceive that we are allaying a rather unnecessary apprehension in the public mind by showing that the distress in the cotton districts has not yet produced such disastrous consequences as might have been feared, and that the contributions already made have served not only to sustain life, but to ward off the attacks of epidemic disease. What the future may have in store for the people of Lancashire it is not for us to tell, but we must deal with the facts at present before us.

In a letter printed in the *Times* of the 23rd inst., and signed by the chairman and the honorary secretaries of that admirable Sanitary Association in Manchester, Dr. Buchanan's facts and figures are very temperately criticised. It is admitted that, between midsummer and November of last year, twenty fatal cases of typhus occurred in Manchester. "But," it is asked, "do twenty cases in a population of nearly half-a-million, scattered over five months, constitute an epidemic?"

It is also admitted that no epidemic of typhus has occurred in Manchester since the years 1847 and 1848, but it is stated that sporadic cases have never been altogether absent, nor is the latter circumstance remarkable, considering the number and density of the population of Manchester. The Sanitary Association regard Dr. Buchanan's cases as also sporadic in their character, for "how otherwise," it is asked, "can we explain the still heavier mortality from typhus, which we find specially referred to by the registrars as having taken place in the six months preceding midsummer?"

It is, then, shown that in the months of October, November and December, 1861, 187 deaths were registered in Manchester and Salford under the generic name of fever, of which number 17 were set down as typhus. In the first three months of 1862, there were 133 cases of fever, 23 being typhus, and in the next three months the numbers were respectively 89 and 10. By pursuing the same reasoning, founded on statistics, it is shown that, during the six months when the famine epidemic is said to have prevailed, it carried off only 23 victims, while, during the six preceding months, it sacrificed no less than 31. It also appears that the total mortality from all causes in Manchester and Salford during the first six

months of 1862 was 5979, while during the last six months it was only 5409, so that the number of deaths was actually less during the alleged epidemic of typhus than it had previously been. In another letter, which appeared in the *Times* of Thursday last, the same writers state the pregnant fact, that during the last six months of the year 1861, 17 cases of typhus fever occurred in the fever wards of the Manchester Infirmary, whilst during the last six months of the year 1862 there were only 14 cases, or three less. In the course of each year, precisely the same number (eight) have died in the wards from the same variety of fever.

Those who have perused the interesting letters of our Liverpool correspondent will perceive that his results are in accordance with the views expressed by the Sanitary Association of Manchester. In one of his letters, written in May of last year, he states that he had begun to institute inquiries into the sanitary condition of the Lancashire operatives, in connexion with the distress which was beginning to prevail among them, and the conclusions at which he then arrived were in favour of the view, that no increase of disease had then accompanied the cotton famine. In another letter, written in September, he pursued the same course of investigation, and with the same general result; and, in order to arrive at greater accuracy, he communicated with gentlemen holding official appointments in public charities in seventeen districts, asking them to favour him with reports as to the condition of the poor, and especially as to any increase of fever or tubercular disease, or to any aggravation in the type of disease in consequence of want. The answers were almost universally to the same effect,—namely, that no perceptible increase of fever, or of any other disease, could be discovered, and, on the contrary, some of the districts were more healthy than usual.

In October, our correspondent reported that, although most of the other towns in Lancashire were in a healthy condition, yet that Liverpool had seriously retrograded in that respect, typhus and typhoid fevers being both unusually prevalent. But it must be recollected, that Liverpool is not, strictly speaking, a manufacturing town, and is not, therefore, subjected to the same depressing circumstances as most of the other large centres of industry. In January, he resumed his investigations into the sanitary condition of several large towns, including Manchester, Stockport, Wigan, Warrington, Bolton, and Rochdale, and, while finding that the deficiency of employment was producing a great amount of suffering, he did not ascertain that there was any appreciable increase of epidemic fever. We cannot too highly commend the industry and impartiality of our correspondent, whose testimony, as an independent observer, is of the highest value.

We are compelled to believe, therefore, that the distress in the manufacturing districts has not been hitherto attended with such disastrous results, in a sanitary point of view, as might have been feared, and as, indeed, judging from previous visitations of famine and distress, might have been reasonably anticipated. Why we should experience so agreeable a disappointment is an interesting question for the politician and the philanthropist, no less than for the physiologist and the sanitarian. As we have just remarked, it would be presumptuous in us to declare that fever, in its worst forms, will not follow in the wake of famine; all we assert is, that at present it has not done so. This gratifying result may be due to several causes, among which may be enumerated the benevolent efforts which have already been made to alleviate the existing distress, and which, though perhaps falling short of accomplishing all that might be desired, have nevertheless had the effect of saving a vast amount of human life, and preserving a moderate degree of health. To this may be added the increased sobriety of the operatives, from their inability to procure the means of obtaining drink; their release from the confinement entailed by their employment, and their conse-

quently greater exercise in the open air; and the greater care bestowed by the mothers upon their children, consequent upon the women having no labour to perform.

As to the amount of food absolutely required to sustain life and to preserve health, the question is an important one, but is too wide in its scope to enable us at present to discuss it. But it is manifest, as the result of experience, that different qualities of food are necessary for different persons, not only under differing hygienic conditions, but under different employments. The forthcoming papers of Professor Haughton will show this in figures. The agricultural labourer would seem to require less food than the weaver, and the man who works with his hands less than he who works with his brains. It may possibly be argued that the Lancashire operatives, being out of work and taking exercise in the open air, may be adequately sustained upon a smaller amount of nourishment than would suffice for them if they resumed their usual occupations. Common observation in the agricultural districts proves that the labourer in the field is sustained, and apparently adequately sustained, upon an amount of food, the scantiness of which would astonish a weaver or a miner. A letter written by "One who has Followed the Plough," and printed in the *Times* of January 27, alleges that the writer, when a boy, actually subsisted on *two shillings a-week*, almost his whole food being bread, meat and beer being totally unknown to him; his only taste of animal food being a small weekly taste of bacon!

These matters are all pregnant with interest, and they deserve and will receive attention at our hands.

---

#### THE WEEK.

##### THE "PHYSIQUE" OF CANDIDATES FOR EMPLOYMENT ON RAILWAYS.

THE Report of the Medical Officers of the Great Western and its Associated Railways' Provident Society for 1862, contains information of general interest as to the physical condition of candidates presenting themselves for railway employment. Of 530 candidates 201 were rejected. The rejected and passed being ranged under their respective counties, although the numbers are too small and too unequally distributed as regards the counties, to allow much weight to inferences drawn from them, it yet appears that a greater proportion of rejections occur amongst candidates from counties containing large seats of manufacturing industry, than from the purely agricultural; and again, that, classifying the candidates according to their previous occupations, nearly one-half of general labourers and porters are rejected, whilst about four-fifths of the agricultural labourers and gardeners pass. So far, then, the evidence is in favour of the superior *physique* of the tiller of the soil. The chief causes of rejection were small and malformed chest (in 92 cases), disease of lungs and heart, hereditary phthisis and scrofula, and near-sight. The number rejected—38 per cent.—is about the same as amongst army recruits, if allowance be made for special causes of rejection of soldiers, such, for instance, as loss of front teeth, which, although it unfits for biting cartridges, does not incapacitate for the railway. One class of imperfection, however, affects the railway *employé* peculiarly; it is near-sight. Twelve rejections occur under this head. The pecuniary loss of the companies, on account of mis-sent packages, is far too large to permit any laxity here; and the danger of employing near-sighted persons as switchmen or policemen is obvious. It has been surmised that railway accidents have arisen, in some instances, from signalmen being affected with colour-blindness. Nothing like an approach to it was found in the 530 candidates examined; and, from the rarity of the defect, it is highly improbable that such a notion has hitherto had any foundation in fact.

##### NICOTINE IN TRAUMATIC TETANUS.

WE are sure our readers will not accuse us of any leaning towards Hahnemannism when we assert that the doctrine of specifics is looking up. When we were a student, five-and-twenty years ago, we were taught by our excellent Professor of Therapeutics that there were but two remedies at all worthy of the name, to wit, quinine for ague, and mercury for syphilis. If new researches, such as those of Dr. Boeck, should lead us to discard the latter, the value of quinine in ague remains still undisputed. And are we not on the road to the discovery of others? The path we are following is that which has led to the discovery of undoubted counter-poisons. It is true, we may as yet count all these upon our fingers, but science is progressive, and we must hope and work. What if our first steps are empirical? they are not always so. At the recent meeting of the Surgical Society of Ireland, Mr. Tufnell brought forward a case of "Traumatic Tetanus, following upon Compound Fracture of the Forearm, which was Successfully Treated by Nicotine," the introduction of which into recognised practice is due to the Rev. Professor Haughton. The cases in which this line of treatment has proved successful in the hands of Professor Haughton have already been referred to in this Journal. In the present instance the nicotine used had been prepared under the direction of Professor Haughton, the strength of a single drop being equivalent to 23.3 grains of Virginian Cavendish tobacco. The case was a severe one. The first symptoms of tetanus appeared on March 12th. The nicotine was first administered on the 16th. The first dose of one drop induced remarkable perspiration, and an immediate relaxation of the spasms. This amendment being transient, it was repeated every two hours, and the dose was increased to two drops. After two days, the patient becoming un-governable and scarcely able to swallow, two drops were injected into the rectum, and again the spasms relaxed, and, though delirium set in, the man had acquired full voluntary power over the muscles of the arms and legs. This practice was continued for three days longer, and on the 22nd the fifty-sixth drop and last dose was administered, the countenance being placid, and no spasm having occurred for some hours. After the 31st his recovery was progressive; other remedies were used in the course of the treatment; nourishment, some fomentations of decoction of tobacco over the abdomen, purgative enemata, chloroform, etc. Idiopathic tetanus has proved amenable to a variety of remedies, but they have failed woefully in the traumatic form. The best acknowledgments of the Profession are due to the acute and courageous reverend Professor Haughton. He has shown nicotine to be a manageable remedy; let us, then, in future, take heed to the maxim—"Principiis obsta." No one need now be alarmed at its well-recognised activity.

---

##### POISONING BY MILK.

A NUMBER of persons occupying two of the principal hotels at Valletta, Malta, were seized, on the morning of the 17th inst., with symptoms of irritant poisoning. The *Malta Times* states that—

"All the sufferers were seized within twenty minutes to two or three hours after breakfast; and as the only article of diet common to all was milk, and as on other occasions of similar seizure the cause was clearly traced to that article, it is reasonable to infer that in the present instance the milk used for breakfast contained the poisonous ingredient. This conclusion becomes almost a certainty when it is known that several persons, living in the same hotels, who had not taken milk that day, escaped, while, without one exception, those who had taken it were seized with the alarming illness described. Several families in Valletta, it is said, were attacked in like manner the same morning, after partaking of milk for breakfast; even a cat, which had taken some, showed the same symptoms of having been poisoned. Towards the end of last year a number of exactly similar cases happened

at Sliema, where the whole family of a field officer, with one exception, was poisoned, evidently by goat's milk; and about the same time other cases occurred among the officers and men of her Majesty's ships *Marlborough*, *Algiers*, and *Firebrand*, but with no fatal consequences. We have also heard of other cases occurring from time to time. Poisoning by milk, therefore, appears to be not an uncommon occurrence in Malta; but we are not aware if experiments were ever made by scientific men to ascertain beyond doubt the real cause of the milk assuming this dangerous character. The natives attribute it to the goats browsing on a particular plant belonging to the natural family *Euphorbiaceæ*, or spurge-worts, which they call *tenhuta*, and which, they say, possesses the property of rendering the milk poisonous to human beings, without inflicting any serious injury on the animal itself. On the other hand we have heard this popular belief ridiculed by some of the more learned Maltese Physicians, although we must confess we never could perceive upon what grounds. We are glad to learn that his Excellency the Governor has ordered a searching inquiry into the matter, and we hope the result will be the adoption of means, if possible, to prevent such serious endangering of life by a common article of daily food for the future."

It is well known that the *latex* of most of the plants belonging to the order *Euphorbiaceæ* has acrid and purgative properties; and it has also been observed that in certain districts of America the milk and flesh of cows have been rendered poisonous by particular pastures, without the health of the animals being affected. Like instances of numbers of people being poisoned by milk have been noted in various parts of the continent; amongst others, at Aurillac, in France, and at Hereford, in Westphalia. The latter cases have been long popularly attributed to the cattle having fed on the *Euphorbia esula*. Such a notion has, nevertheless, been negatived by continental toxicologists, on the ground that cattle refuse the *Euphorbia* as long as grass and other wholesome vegetables occur in their pasturage; yet this may be only the cause why such accidents do not occur more frequently. It is a mistaken idea that the instinct of ruminants in the choice of herbage always leads them to refuse poisonous plants. Oxen will eat the berries and leaves of the yew, and frequently die in consequence, either from the immediate effects of the poison on the nervous system, or subsequently from inflammation of the alimentary canal.

#### THE CHARGE OF PERJURY AGAINST A SURGEON AT MANCHESTER.

WE have received from a correspondent, at Manchester, the following account of the Medical facts of the painful case which has, during the past week, attracted general attention. As the defendant is to appear before a higher tribunal, on a charge of perjury, we shall for the present reserve any comment:—

"At midnight on January 5, Mrs. Mary Ann Bell, from Bassenthwaite, in Cumberland, arrived, by appointment, at the Cathedral Hotel, Manchester, to consult Mr. Evan Thomas, a Surgeon of considerable repute. On the following morning, Mr. Thomas called to see her, and was conducted to her room. An examination of the patient was made directly, after which Mr. Thomas states that she was seized with an epileptic convulsion, and immediately expired. Mr. Thomas forthwith communicated the result to the borough coroner, by whose directions he made a post-mortem examination of the deceased, assisted by Mr. Braddon, a Professional friend; and on the evidence given by Mr. Thomas, before a coroner's jury, the latter returned a verdict of "Death from epilepsy." Nothing that afterwards occurred has shaken in the least the correctness of the verdict. A telegram, communicating the circumstances of the death, was sent by Mr. Thomas to Cocker-mouth, where it reached ultimately the hands of Mr. Musgrave, clerk to Mr. Waugh, the deceased's attorney. It appears, from the evidence, that there was at Cocker-mouth a gentleman who suspected that the deceased lady, who had been nine years a widow, had been to Manchester some time previously for the purpose of procuring abortion, and this circumstance immediately connected itself in his mind with the death of the deceased. Acting on this suggestion, Mr.

Musgrave next day came to Manchester for the purpose of making inquiries. On his arrival, he called on Mr. Thomas, and heard from him the circumstances attendant upon the death of the deceased.

"On the following day, he went to see the coroner, and, in the afternoon, this functionary held a second examination, at which several witnesses gave evidence upon oath, and a second post-mortem examination was ordered, conducted this time, however, by Mr. Heath, House-Surgeon to the Royal Infirmary. Mr. Braddon, who had assisted Mr. Thomas in the first post-mortem inquiry, was also examined. The evidence of these two gentlemen completely rebutted the idea of death having been caused by abortion, or of any attempt at the latter having been made, and was quite consistent with the verdict already returned. It, nevertheless, appeared that, either from Professional repugnance to expose the character of a patient, or from some other motive not yet explained, Mr. Thomas had been led to make in his evidence some important suppressions, and which resulted in his being placed before the magistrates on a charge of perjury. The previous unblemished character and Professional repute of the accused excited strongly the interest of the public, and the court-room was crowded.

"The charges of perjury founded on the statement made by Mr. Thomas before the coroner were,—first, that he had stated that there was a tumour in the womb, when there was no tumour; second, that the brain and membranes were congested, when the brain was not even examined; and third, that he had never seen the deceased before her arrival in Manchester, when it would be proved, by his own admission before the coroner on the second inquiry, that he had seen her previously.

"Mr. C. H. Braddon said: I am House-Surgeon at the Manchester Workhouse. On the 6th of January the defendant called upon me. He said he wished me to assist him in making a post-mortem examination. We went to the Cathedral Hotel. Mr. Thomas produced the key of deceased's bed-room, and opened the door. We proceeded with the examination. We examined the heart and lungs. The right side of the heart was full of dark blood, but otherwise healthy. The brain was not examined. I cut open the uterus, and found a fœtus and its membranes about five-months old. The liver appeared healthy. There was no tumour in the womb, but there was a cystic tumour in one of the ovaries. It was not of much consequence.

"Cross-examined by Mr. Higgin: In making the post-mortem examination, I observed that the blood was liquid, and ran out freely. The cavity of the chest was filled with blood. I should think it probable that the filling of that cavity would relieve the brain of an overflow if there had been one. I examined the cervix uteri. I did not find the slightest symptom that anything like abortion had been attempted. There was nothing inconsistent with the notion that this lady had died of epilepsy. The deceased's pregnancy had nothing whatever to do with the cause of death. I think it quite impossible for death to have ensued so quickly if there had even been an attempt to procure abortion. The head was not opened, though Mr. Thomas asked me to open it. I replied that I thought it would be unnecessary, as he had seen the woman die, and probably nothing would be found there. It is possible that epilepsy might follow the use of a certain instrument with which the defendant told me he had made an examination.

"Mr. William Heath said: I have been for three years House-Surgeon to the Manchester Royal Infirmary. Upon a coroner's order, I made a post-mortem examination on the 9th instant on the body of Mrs. Bell. I found that a previous post-mortem examination had been made. The head had not been examined, nor had the kidneys. The other parts of the body had been examined at a previous post-mortem examination. The witness described his examination in detail, the effect of which was that all the organs were perfectly healthy.

"Cross-examined: Supposing the deceased had died from epilepsy, I should not have expected to find anything more than I did. There may be no abnormal appearances in a person dying from epilepsy. From the appearance of the body alone, I should not be able to predicate the cause of death. In such a case, it would be necessary, in order to ascertain the cause of death, to have the evidence of some person who was present at the death. I found very slight congestion of the brain or membranes. I did not find any indications that the first post-mortem had been performed otherwise than as I myself should have performed it.

"The above is the Medical evidence bearing on the case.

"Mr. Higgin, barrister, who appeared for Mr. Thomas, said he had matters to submit which would take a very long time, as they were matters of law. As to the question of fact, at this stage of the case, he was bound, as they were all bound, by the statement of facts upon the part of the prosecution, because at that time he was not in a position to call any witnesses to controvert those facts; but, supposing them to be true, then grave questions of law arose, and he was quite sure that, speaking as he did before gentlemen of very vast experience, still, in such a case, they would ask themselves whether they were bound to decide questions of law. He knew well what their answer would be on such a subject. There was, again, another question which the bench would naturally ask,—whether there was the slightest prospect of any jury in the world convicting; if not, then what was the good of sending the man before a jury? On the other hand, if they thought it was a case deserving of further inquiry, then he would not make a speech. He believed he would be able to prove to the justices, and to any candid mind, that Mr. Thomas had been guilty of the suppression of the truth—that that was the whole extent of his guilt; and, to the mind of any man, Mr. Thomas's motives were deserving of the highest possible praise, and not of the censure which was attempted to be cast upon him. If the bench would tell him that, in their opinion, it was a case to be further inquired into, he was bound to be satisfied; but he was also bound, in justice to his client, to be silent.

"Mr. Ellison: We are of opinion that this is a case that ought to be further inquired into; and we, therefore, commit the defendant to take his trial.

"The bench admitted the defendant to bail."

#### NEW PAMPHLETS (a).

AN able contribution to the literature of the pathology of the liver has appeared from the pen of Dr. F. N. Macnamara, of the Indian Medical Service, in the *Indian Annals*, and has since been circulated in a separate form. The chief point on which Dr. Macnamara insists is, that the form of liver abscess which most commonly accompanies dysentery, commences not with inflammation, but in the degeneration and death of the tissue; and he concurs in Dr. Budd's explanation of the common association of dysentery and hepatic abscess,—“That the portal blood becomes contaminated with morbid matter, and that this, arrested in the degenerated liver substance, commences the abscess, yet not always by setting up inflammation, but by destroying the nutrition of the part, and thus causing death.” Before the formation of abscess, patches of degeneration show themselves—paler, and having a softer consistence than the surrounding parenchyma. In the next stage they have become larger—of the size of a walnut, and contain, in the centre, liquescent or completely fluid tissue, which, however, although puriform, may not present a single pus corpuscle on the most searching examination. Hitherto, there is no sign of inflammation, no congestion, no redness. In the next stage of the abscess, however, a halo of congestion is observed. Dr. Macnamara's observations will well repay the short time a perusal of his paper requires. An anonymous pamphlet on the “Evils Resulting from Rising too Early after Childbirth” is one of those semi-popular tracts which members of our Profession benevolently print, from time to time, for the benefit of a benighted public. It contains very good advice, and we would recommend the Ladies' Sanitary Association to distribute it freely amongst monthly nurses and mothers of the working class. Dr.

(a) “On the Pathology of Hepatic Abscess.” By F. N. Macnamara, M.D., Assistant-Surgeon B.M.S.

“On the Evils Resulting from Rising too Early after Childbirth.” By Obstetricus. London: J. W. Davies. 1862.

“On the Situation, Form, and Capacity of the Gall-bladder in the Vertebrata; on its Absence in Certain Animals; and on the Colour of the Bile.” By E. Crisp, M.D. From the “Proceedings of the Zoological Society.”

“Large Scrotal Tumour: New Plan of Operation for Large Tumours.” By J. M. O'Ferrall, M.D. Dublin: printed by J. M. O'Toole and Son.

“Third Annual Report of the Cranley Village Hospital.”

“Statement of the Medical Officer of the Cranley Village Hospital.”

“Defects in the Moral Treatment of Insanity in the Public Lunatic Asylums of Ireland.” By John A. Blake, M.P. London: Churchill and Sons. Dublin: Fowler.

Crisp's paper on the “Gall Bladder of the Vertebrata” is of great interest. The Hippocampus controversy having subsided, it is refreshing to learn that a new anatomical difference has been discovered between man and the “Yahoo” genera—*Pithecius* and *Troglodytes*. Dr. Crisp says that, in six anthropoid apes which he has examined (three ourangs and three chimpanzees), “the gall bladder was of a twisted, irregular shape—a fact of importance now that some zoologists are giving these brutes, as I believe, an undue elevation in the vertebrate scale.” It has been asserted that the gall bladder is present in the hollow-horned ruminants, but absent in the *Camelidæ* and *Cervidæ*. Dr. Crisp has, however, found it present in the musk deer (*M. moschiferus*) and in two species of *Cervus*. In many of the *Antilopidæ* it is present—in many absent. Dr. J. M. O'Ferrall has reprinted, from the *Dublin Hospital Gazette* of February 15, 1845, an account of the removal of a large scrotal tumour. He adds, in a note, that the reprint was suggested by the adoption, without acknowledgment, of the principle on which his operation was conducted. The tumour, which measured from the pubis to the fundus, 28 inches, and in circumference about its middle, 22.5 inches, was a fibro-cellular growth, presenting on its surface none of the warty and tuberculated appearance which distinguishes elephantiasis scroti. It appeared to have its origin in the cellular tissue of the left spermatic cord. The cord on the left side was lost in the substance of the tumour, and the testicle was atrophied and buried in it. The penis was also enveloped in the tumour, just as in cases of elephantiasis. The right testicle could be felt about three inches below the corresponding ring; it glided up and down freely under the integuments, and was evidently healthy. Repeated and alarming hæmorrhage from an ulcer on the surface of the mass necessitated the operation. The mode of proceeding which Dr. O'Ferrall adopted, and on which he insists in commenting on the case, was to place the patient on his back, and to have the tumour poised for sufficient time to empty the vessels before operating. He thus lessened the chance of enormous hæmorrhage, an accident which proved fatal in the case of Hoo Loo, a Chinese operated on in London in 1831, and also very nearly killed Liston's patient. In the operation the patient was placed in the lithotomy posture, and two straight incisions were made in the perineum, at an angle salient towards the anus. These were then carried round the under and lateral surfaces of the tumour. The tumour was then allowed to descend to a nearly horizontal position, and the operation was completed in front by two straight incisions carried downwards from the groins, and meeting at an angle, so as to include a portion of integument capable of covering the urethra, and fitting into the incisions previously made below. Two short incisions connected the limbs of the two angles previously made. The tumour was then detached by a few strokes of the knife. The right testicle and penis were left uninjured, and, after getting through an attack of erysipelas, the man ultimately recovered. From the report of the Cranley Village Hospital, and the statement of its Medical Officer, it appears that uninterrupted success has attended the experiment. Of the thirty patients admitted during the year, several required operations, and many were cases which could not be adequately treated at their own homes. The statistics of the Hospital show but one death (from consumption). Amongst the Surgical cases was one of amputation of the thigh. We quote one sentence from Mr. Napper's statement. “The modest plan on which this little Hospital is conducted, may be gathered from the balance-sheet, made up to October, 1861, by which it appears that the whole expenses of the year were only £140 9s. 7d., whilst the receipts were £177 7s. 11d., a state of things which many of our larger Hospitals might envy.” Mr. John A. Blake has done good service by calling attention to a deficiency in the treatment of the insane in the Irish public asylums. From evidence given before a Royal Commission in 1856, it appears that there has been a great want of system and appliances to

supply suitable occupation and amusements for the patients. Mr. Blake, from personal inspection of nearly a dozen asylums, finds that the state of things continues much the same as at the period of the report of the Commissioners. The chief instance of improvement has been at Belfast, where a musical band, drill, and regular walks in the country have been introduced. Generally speaking, the Irish asylums contrast unfavourably with the English in their prison aspect—their leading features being safeguards against escape. The exercise yards are surrounded by high walls, and the patient has nothing to look at but the gravel beneath his feet, the sky overhead, and dead wall or grated windows. The female patients are entirely idle; and of the male, a small proportion may be employed in field work, or in one or two trades, such as shoe-making and tailoring, but for by far the larger proportion there is nothing to interrupt the tedium of confinement or to break the thread of distraught fancy. Mr. Blake confirms Dr. Conolly's observation, that Irish patients, as a rule, improve more speedily than English. At Hanwell, Dr. Conolly observed that the form of insanity amongst the Irish was frequently pure excitement, rapidly allayed by quiet, temperance, and an orderly regimen. Mr. Blake's essay commences with a very well compiled review of the history of improvement in the treatment of the insane. We extract from one of his notes the process adopted as the best curative method by the great Chancellor, Sir Thomas More:—"Another was one who, after he had fallen into these frantic heresies, soon fell into plain frenzy—albeit, he had been in Bedlam, and afterwards, by beating and correction, gathered his remembrance. Being, therefore, set at liberty, his old frenzies fell again into his head. Being informed of his relapse, I caused him to be taken by the constables, and bounden to a tree in the street before the whole town (Chelsea), and there striped him till he waxed weary. Verily, God be thanked, I hear no more of him now."

## FOREIGN AND PROVINCIAL CORRESPONDENCE.

### ITALY.

LEGHORN, January 6.

#### ON LEGHORN AND VIAREGGIO AS HEALTH RESORTS.

It is curious to observe the changes which, from time to time, take place in the direction of the currents of tourists. At first sight, they seem as unaccountable as atmospheric or submarine currents; yet, if Buckle be correct in asserting that, although the individual may be a comparatively free agent, the actions of mankind in general are ruled by fixed and unalterable laws, we should be justified in searching after the causes of such phenomena. To ascribe them to the caprices of fashion would be moving in a vicious circle, fashion itself being left unexplained. The English health-and-pleasure-seeking public have for a long time been adhering to certain traditional rules, and which have become almost venerable by age, in mapping out their continental routes, and in choosing their winter quarters. A considerable amount of prejudices and fallacies has thereby been engendered, and the initiative of some original and inquiring mind would be necessary for inducing people to revise their judgment on these and similar questions. Although this need not, necessarily, lead to a thorough change of fashion and habits, it might save many of the poor erratic strangers great disappointment, by preparing their minds for a juster appreciation of both the advantages and drawbacks which await them in their temporary homes. But nowhere do we meet with such difficulties as if we attempt discussing the nature and action of climatic health-resorts. On the part of the observer himself, there is the tendency to generalisation and to dogmatism, while the public have an unreasonable craving for so-called "positive" information, which frustrates all efforts to approach the truth. A silly sight-seer, who catches a cold in a picture-gallery, and leaves Italy, disgusted with her climate, often becomes a missionary of error. Nor do the statements of Medical men

deserve much credit, as long as they allow their judgment to be overruled by partiality or interest. Moreover, to stem or divert the fashionable currents of strangers, it would be necessary to bring the weight of a celebrated name to bear upon their *vis inertiae*. If they change their course, nevertheless, it is scarcely ever by the force of reasoning, but rather by that of circumstances and necessities. The political condition of Naples, for instance, and the various more or less well-founded apprehensions thereby created in the minds of the less adventurous part of the public, have effected greater changes in this respect than any scientific treatise on climate could have done. Thus, in 1860, it became a necessity to seek for a safer, but equally pleasant, climatic health-resort, as a substitute for Naples, and such a one was easily found in the now fashionable villages and towns of the Riviera. Dr. Lee's pamphlet drew particular attention to Mentone; and even Nervi, which has, as yet, hardly one inhabitable house to boast of, is now on every tourist's lips; while Sorrento is almost forgotten, and even Ischia, with its inestimable mineral springs and natural baths, unduly lost sight of.

Leghorn and Viareggio have had their share in this redistribution of public favours; and we shall endeavour to show that both are not quite unworthy of the boon which was so unexpectedly conferred upon them. This year, however, Nice and Rome have carried off the palm. They are fuller than ever—Nice, in spite of its annexation; Rome, in spite of its non-annexation. And, if we consider that even invalids cannot live on climate alone, but that they require some social or artistic pleasures, we can only congratulate the public on the present state of its predilections. After these two queens of fashion, places like Leghorn and Viareggio can only be mentioned with modesty and reserve. They are, however, both blessed with an excellent winter climate. Leghorn has all the resources proper to a commercial town, *plus* those of a sea-port, neither more nor less. Viareggio has none of these; but it has what neither Naples, nor Ischia, nor Palermo, neither Nice nor Mentone, have, *viz.*, a magnificent sandy beach. I doubt whether, with the exception of Ravenna, another beach of this kind is to be found in Italy. It extends for about ten miles on either side of the town, and the surf, as may be imagined, is magnificent. In addressing Professional readers, it is unnecessary to dwell on the advantages of such a bathing-place. Siliceous sand is a bad radiator of heat; and the sandy seam of this coast being very broad, it is sufficient to influence the local climate of the place by lessening the dew, which, even in midsummer, renders the Italian nights so chilly. The long pine plantation, which extends many miles parallel to the coast of Viareggio, shelters the place against the land winds; while the Carrara mountains, in its rear, impart uncommon beauty to the scenery. Between these and the pine forest, there are some rice-fields, which, in former times, compromised the salubrity of the neighbourhood. But an improved system of drainage and irrigation seems to have rendered them perfectly harmless. A gentleman, who had for years been suffering from malaria, and who could hardly be prevailed upon to make a trip to Viareggio, has now been residing there for the last eighteen months with perfect impunity, and even with advantage to his general health. Since the opening of the railway, the number of season visitors, but especially of stationary residents, has been steadily increasing. Some good hotels and one or two English boarding-houses, besides a number of private lodging-houses, offer sufficient accommodation. Nevertheless, it should be borne in mind that, however beautiful its scenery and its beach, Viareggio is an intensely dull place; and if it deserves a word of praise, it is merely because it has something which cannot possibly be found anywhere else in Italy. For scrofulous children I know of no better place either in or out of Italy; and the Italian Government seem to have been fully alive to this advantage, when they chose Viareggio as the best place for the erection of a so-called *Ospizio marino*, or Hospital for children affected with glandular diseases.

Leghorn, although not more than twenty-four miles distant from Viareggio, differs considerably from the latter both topographically and as regards the climate. Its beach is rocky, and it is much further from the mountain-screen which encircles Viareggio. Hence it has more hygroscopic moisture in the night, and is more exposed to blasts. It has the valuable although negative virtue of being perfectly healthy, and free from all evil geni *epidemi*. Even small-pox is scarcely ever met with. It

has a more genuine and unsophisticated maritime climate than most seaports, it being situate on a convex coast which bulges out considerably: while at Spezzia, for instance, the sea-air is carried to the shores by one wind only, viz., the scirocco, it is wafted into Leghorn from nearly two-thirds of the compass. It is owing to this ventilation that, notwithstanding the scarcity of shade, one suffers less from mid-summer heat at Leghorn than in many apparently cooler places. The bathing is somewhat irksome on account of the rocky nature of the ground. The town is handsomely built; the architecture of the houses and the pavements betray the wealth of the inhabitants, and it is not necessary to search beyond its walls for villas, gardens, and rural seclusion. Although perfectly uninteresting to the sight-seer, it rarely fails to fascinate the comfort-loving stranger, who, moreover, finds there a nucleus of stationary English residents. Some years ago a form of typhus fever broke out in some streets lining the coast, and enjoying, hygienically, the best possible position; but the cause of the mischief, viz., the blocking up of one of the sewers which run into the sea, was soon removed. The drinking water, which reaches Leghorn by means of a subterranean aqueduct, comes from the hills of Montenero, and is very good and wholesome. Something more ought to be done for a certain mineral spring, called the Puzzolente, and situate in a charming solitude some four miles from Leghorn. Its waters are strongly hydrothionic, and enjoy a good, although only local reputation. Some years ago an omnibus plied between the centre of the town and this place, and I am in hopes that the communication will soon be re-established. At present, there is nothing on the spot but the Naiads' own temple sheltering the spring, another small house, and an unenclosed natural garden of bushes, groves, and meadows, fenced in by some distant hills.

### GRADUATION WEEK AT ST. ANDREWS, FROM ANOTHER POINT OF VIEW.

BY A SECOND WHO WAS THERE.

EARLY on the morning of December 25, I left England for St. Andrews, to undergo the ordeal for the M.D. degree of the ancient and, in more respects than one, "renowned" University of that place, merely, I may confess at once, because I could not gain admission to examination for the degree at any other British university. On the evening of the same day, the train, conveying myself and a hecatomb of candidates, deposited us at a terminus situated in the midst of a desert in a small way. I saw, on peering from this terminus, two "busses" in waiting for the purpose of conveying candidates to the chief inns of the town—no cab or hansom to gratify the partiality of a very ordinary swell—no porters to rudely snatch your portmanteau, and ask which place you propose to patronise—but, to repeat, two busses, in all the stern reality of country busses. These vehicles were soon filled inside, and I, together with my companion, scrambled by the wheels to the top of one, which was, in a very short space of time, fully occupied. The driver dilated on the subjects of examination, the wished-for number of candidates, the state of affairs at his master's hotel, and so forth; and, after a ride of ten minutes through the so-called desert, we were put down in South-street, opposite the chief hotel of St. Andrews.

My friend and I found, on inquiry for quiet lodgings, that the beadle of the university, who combines with his duty that of bookseller and stationer, was the man to whom candidates would do well to apply. We went across to the beadle's. That beadle, melancholic and uncommanding as he seems to be, possesses a reputation in St. Andrews worthy of a celebrity! If you wish to know privately what kind of examination you are likely to have, go to him. If you desire to know how you have got on in your *written*, go to him. If you are anxious to know that you have been "spun," he is the man to tell you; and if, again, you want quiet lodgings, he can secure them for you. Well, we went across to this beadle's, and were recommended by him to rooms which, at an exorbitant price, satisfied us. We were no sooner ensconced in the apartments, than our landlady informed us, that all the gentlemen—charity knows how many—who had ever lived in her house had passed, excepting one, who appeared a second time, and departed again defeated.

On the following morning, December 26, I went to the Town Hall for the written examination a number of candi-

dates having been posted thither, another number to the United College, and another to the University Library. The questions were, to say the least, difficult, and the time for answering them extremely limited. It became evident to me, that the examiners were determined to fathom the knowledge of each candidate in Latin, Chemistry, *Materia Medica*, Anatomy, and Physiology. On the following day, papers were given on Practice of Medicine, Surgery, and Midwifery, and, as on the preceding day, the time for returning answers was extremely limited.

I cannot pretend to say how gentlemen were supervised at the University Library, or at the United College, or even at the fore part of the room at the Town Hall, for I occupied a seat on a bench in the rear; but I must say that candidates who sat near me were pretty much at liberty to act as reason dictated to them, and, judging from the approximation of heads in different directions, an observer would naturally come to the conclusion, that nature had recommended a muffled and constant use of the vocal chords.

Well, thought I, after the *written*, the University of St. Andrews will rise very considerably in public estimation. The *vivâ voce* will pull down those who have gained information in the room by tasting, very superficially, of the Pierian spring. Altogether I began to entertain a very favourable opinion of my future *alma mater*.

I ascertained from the beadle that batches were to be examined, *vivâ voce*, hour by hour, until the day of capping. During the three days which elapsed before my turn came, what was my astonishment to find that the ancient university had provided a cap to make men Doctors of Medicine who had never attended a regular course of lectures on the principles and practice of Physic—that students of two years had been admitted to the degree for which I had been at the trouble of wandering so far north—and, worse than worst of all, that one of the newly-fledged Doctors had been metamorphosed from the state of a druggist, and has, since his graduation, combined the business of a druggist with the Profession of which I have the high honour to be a member!

After my *vivâ voce*, which lasted about an hour, and embraced all the subjects of the written examination except Latin, I was at a loss to know how the men to whom I have so particularly alluded could have passed through the trial. I could not consider it possible that a man who had never attended lectures on the subject could have satisfied Dr. Craigie on Practice of Medicine; nor could I see how students who had not fulfilled the curriculum of study should have been admitted.

Nevertheless, the bare fact, that these men had passed, was before my face; and, when the cap which had donned the head of the retailer and dispenser of drugs had made me a *bonâ fide* Doctor, I felt regret that the University of St. Andrews, at a time when public estimation begins to rise in its favour, should have foolishly thrown away the chance of gaining a *status* equal to that of other universities.

### GENERAL CORRESPONDENCE.

#### GRATUITOUS MEDICAL ADVICE TO INSURANCE COMPANIES.

LETTER FROM MR. SPENCER WELLS.

[To the Editor of the Medical Times and Gazette.]

SIR,—The enclosed correspondence appears to be worthy of the attention of your readers. The Liverpool and London Insurance Company has hit upon a new mode of asking for gratuitous Medical advice, which, I trust, will be received by the Profession as it deserves to be received.

I feel certain that if Medical men would always refuse a fee from a patient in such cases, and induce him not to insure in any office which refuses to pay for the advice it asks for, the gratuitous system would soon come to an end. A few fees more or less in a year may be of little or no consequence to many of us, but it may be of serious consequence to others; and it is worth while to take a little trouble for our poorer brethren, though we would not on our own account.

I am, &c.

T. SPENCER WELLS.

3, Upper Grosvenor-street, January 23.

It will be noticed that the following letter, though sent from

the office, and directed to be returned to the secretary, is signed by the gentleman whose life is proposed for assurance:—

(No. 1.)

“Private Medical Report.

“January 17, 1863.

“Sir,—Application having been made to the directors of the Liverpool and London Fire and Life Insurance Company, to effect an assurance on my life, I have given them reference to you as my Medical attendant usually and of late, and as being fully competent to give satisfactory and complete information respecting my habits, conformation, and general health; and I have to request the favour of your transmitting to them, at your earliest convenience, answers to the several queries annexed hereto.

“I need not remind you that the validity of the policy, if issued, will depend on the absence of reservation in your replies; and that communications of this nature are always received and regarded as strictly confidential. I shall, therefore, be obliged by your furnishing the directors with all the information necessary to enable them to decide on the proposal.

“Should your replies not be received by the company within a week from this date, I understand it will be assumed that you consider my life ineligible for the purpose of assurance.

“I am, sir, your obedient servant,

“T. C.,

“To Spencer Wells, Esq.,

“London.

“3, Upper Grosvenor-street,

“London, W.

“To the Directors of the Liverpool and London Fire and Life Insurance Company.

“Gentlemen,—In compliance with the request contained in the annexed letter, I beg to give you, in answer to the several queries at foot hereof, all the information I possess regarding the habits, conformation, and general health of Mr. T. C., by whom the letter is signed.

“I am, gentlemen,

“Your obedient servant,

“\_\_\_\_\_”

[Here follow fifteen questions in the usual form of Life Assurance offices.]

No. 2 is a copy of the letter which I addressed to my patient:—

(No. 2.)

“January 22, 1863.

“Dear Mr. —,—I received yesterday, from the Liverpool and London Insurance Company, a paper, called a ‘private Medical report,’ containing a printed form, which the company have induced you to sign, requesting me to give them a great deal of information respecting your ‘habits, conformation, and general health,’ and informing me that this information is necessary to enable the directors to decide on the proposal of insurance.

“As a friend and patient, it would, of course, give me great pleasure to oblige you in any way, and it would give me far less trouble to fill up the paper sent to me than to write this letter; but there is a principle of great importance to the Medical Profession involved in this matter, which I will explain to you.

“Some years ago most insurance companies obliged all who made proposals of insurance to come provided with a Medical certificate, and also to submit to an examination by their own Medical officer. But, as the companies gained very large profits, other companies were started, and competition had the good effect of lowering the rates of annual payments, and of dividing the whole or part of the profits of the company among the assured. But the tables are still so calculated as not only to insure the company against loss, but to secure so large a profit that a very considerable sum is paid yearly by every office as a commission to agents and others who bring in business—in other words, who introduce persons wishing to insure their lives. It is clear that the profit or loss of any office must depend, in a great measure, upon a judicious selection of lives; and equally clear that the directors must be guided in their selection by the reports of their own Medical officers, and of the Medical attendants of the assured. Nearly all the oldest and most respectable offices have gradually been brought to

acknowledge that they should pay for the information by which their acceptance or refusal of a risk is decided. A few still hold out, and argue that, as they pay their own Medical officer, the assurer should pay his; and this would be fair enough if the engagement were one of mutual obligation—if the assurer were as anxious to insure his life in one particular company, as the company is to obtain business. But when there are not only one or ten, but twenty or fifty thoroughly respectable, rich, well-established companies competing for business, and perfectly willing to pay a fair or moderate remuneration for the information they require, no assurer of ordinary intelligence would make his proposal to an office which obliged him either to incur expense, or to ask a favour of his Medical man, when he might go to equally good offices who impose no such condition, but are perfectly ready to pay for the information required.

“I know nothing whatever of the Liverpool and London company; but of all the shabby modes of evading payment for necessary information, and of obliging assurers to obtain this information, that adopted by this company is the shabbiest I ever heard of.

“You, as a lawyer, would very properly resist any attempt of any public company to cut off the proper emoluments of your Profession, and will feel that I, as a Medical man, by exposing the artifice of this Liverpool and London company, am only doing for my class what you would do for yours. I am quite ready to furnish you with the names of twenty companies who offer quite as many advantages to assurers as the ‘Liverpool and London’ can possibly do, and who are not driven to the expedient of begging for gratuitous Medical advice.

“Believe me to be, dear Mr. T.,

“Very truly yours,

“T. SPENCER WELLS.”

No. 3 is the reply of my patient, who, although already insured in the “Liverpool and London,” has made a proposal of insurance to one of the oldest companies in the kingdom, instead of increasing his insurance in the Liverpool company as he intended:

(No. 3.)

“Inner Temple, January 22.

“Dear Mr. Wells,—In reply to your letter of this morning, I enclose you a copy of one I have just written to the Secretary of the London and Liverpool Insurance Company, which runs as follows:—

“‘Dear Sir,—Since I was at your office in Liverpool the other day, I have seen Mr. Spencer Wells, my Medical attendant, and having learnt from him that the letter I signed there, and which was addressed to him, is such as to exonerate the London and Liverpool Insurance Company from paying the usual fee, and as he refuses to take any fee from me for his services in this matter, I must decline to insure my life again in your office on such terms, much preferring to insure in an office which properly remunerates Medical men for their advice.

I am, sir, your obedient, etc.’

“Had I been aware before that what you have stated in your letter was the case, I should not have insured my life in the London and Liverpool Insurance Company, as I have already done; and I am very much obliged to you for the clear manner in which you have explained the matter.

“I am, yours truly,

T. C.”

#### THE RECENT APPOINTMENT OF CERTIFYING SURGEON AT OLDHAM.

[To the Editor of the Medical Times and Gazette.]

SIR,—I venture to address you on a subject which is, at present, engrossing the attention of the Medical Profession in this town, and which, I have reason to believe, is not indifferent to the general public.

You are, no doubt, aware that there are, in Lancashire, numerous Medical appointments in connexion with the staple manufacture, cotton, of considerable value, these being held for life, as under the Poor-law, or during the “good behaviour,” as it is called, of the incumbent. They are Government offices, and in the gift of the Inspector of Factories for the district in which a vacancy occurs. Those who hold them are denominated “Certifying Surgeons to the Factories,” because all children, under the age of 16, have to undergo Medical inspection before they can be employed as factory operatives. The direct pecuniary value of these appointments varies from

£100 to £400 per annum, and, indirectly, as a means of introduction to much Surgical practice, considerably more. In the town of Oldham, there are two such appointments,—one, the largest in the country, I am told, is supposed to yield between £400 and £500 per annum; the other, from £250 to £300. It is with the latter I have to do.

You may naturally suppose that whenever a vacancy occurs there is much emulation amongst the Medical residents to gain the prize, especially as the duties pertaining to the position are by no means onerous, and perfectly compatible with the conduct of a large general practice. It has been customary for the Inspector, when called upon to discharge this public trust, to nominate some Medical gentleman of established reputation resident in the town, and possessing the confidence of the public. During the past week, the death of Mr. Earnshaw, one of the certifying Surgeons here, has placed at the disposal of Mr. Alexander Redgrave, the Inspector for the district, the appointment of a successor. Judge of the surprise of the Profession when it was announced that, ignoring age, reputation, and *status*, he had violated his trust by nominating a non-resident young gentleman, who has just completed his education, the son of a sub-inspector in a neighbouring district. Is it matter of surprise that all here view this proceeding as a deliberate insult and a gross piece of official jobbing? We are anxious to take such steps as may manifest this opinion, having in view either the annulling of this appointment, or the prevention in future, here and elsewhere, of a similar injustice. It has been determined, therefore, to call a meeting of the Profession in the course of a few days, and it would much aid their object to be fortified by the support of the Medical press. It is to the interest of all of us that nepotism should be strangled in its birth.

Oldham, January 27. I am, &c.

BETA.

## REPORTS OF SOCIETIES.

### THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 6.

Dr. COPLAND, President, in the Chair.

MR. THOMAS SMITH showed, for Dr. Wilson, of Clay-cross, the SAC OF A SPINA BIFIDA WHICH WAS SUCCESSFULLY REMOVED BY OPERATION.

The child from whom the sac was taken was a fine, and, in other respects, well-formed boy, the first child of young parents. The tumour was pyriform, the size and shape of a ten-ounce necked cupping-glass. It hung from the upper dorsal region of the spine, was flaccid, and only partly filled with fluid; the integuments over it were very thin, indeed, translucent, and over the most prominent part of the swelling were two small excoriations. At the base of the tumour could be felt a deficiency in the bones beneath, corresponding with the third and fourth dorsal vertebræ. There was no paralysis or other symptom of deficiency of nervous power. From the time of birth Dr. Wilson applied pressure to the base of the tumour, so as to isolate it from the spinal canal as far as possible. To relieve the tension of the integuments which had become extreme, on the twentieth day after birth it was punctured, and eight ounces of fluid were drawn off. During the next twelve days it was tapped four times, each time about two ounces of fluid being drawn off. A steel clamp was applied to the base for five days before removal, and, on the thirty-third day, the sac and integuments were shaved off at the base of the tumour, which was grasped by a pair of circumcision forceps. The cut edges of the spinal membrane were lightly touched with a red-hot needle, sutures were applied to the wound, and pressure to the base of the tumour. Twenty days after the operation the wound had entirely healed. Two months after the operation the chink in the vertebræ was found to be closed by a solid mass which projected somewhat beyond the neighbouring spines, and appeared to be formed of bone. The sac, as Dr. Wilson says, consists of thin integuments covering the dura mater, to which it is unadherent; this is lined internally by a layer of epithelium resting on a basement membrane, coated on its free surface by a more or less organised exudation of lymph. The dura mater is quite an independent coat in this tumour, and is in no way connected with the integuments: the sac contains no nerves. The fluid in this case was situated in the sac of the arachnoid,

and not, as is usually the case, in the sub-arachnoid space. The tumour (Mr. Smith said) had been examined by Dr. Cornelius Black, of Chesterfield, by Mr. Savory, and by himself, and all coincided with Dr. Wilson in his account of its structure and connexions with the spinal membranes.

Mr. HULKE asked if the fluid contained sugar? He had been told by a German friend that sugar was always to be found in the fluid drawn off; and he had since found it in every instance in which he had operated.

Mr. THOMAS SMITH said that there was no mention of any examination for sugar.

Dr. HARLEY said that eight years ago a French Surgeon proposed to determine whether fluctuating swellings over the spine communicated with the spinal canal, by examining the fluid drawn off for sugar. It was well known (he said) that the cerebro-spinal fluid contained sugar during digestion, but not during fasting.

Mr. HUTCHINSON remarked that this case had been very correctly described as the first successful one of its kind in English practice. It was not, however, by very far the first in which a similar plan had been tried. All the others had ended fatally, and he (Mr. Hutchinson) found in this fact a very strong argument against the measure. We must not be misled, by the successful result of a single case, into adopting a practice which, in the long run, would destroy many lives. He gave a strong opinion against all operative interference with spina bifida, stating that he had witnessed many operations of very various kinds for the cure of this deformity, but every one of them had been followed by the same result. In several of these there was every probability that, had the operation not been performed, the patient might have grown up. He had seen several adult patients the subjects of spina bifida which had been wisely let alone in infancy.

Mr. CURLING said that a great deal would depend on the state of the integuments. When they were healthy and thick an operation would not be justifiable, but when they were thin, and ready to burst, an operation might give a slight chance of averting death.

Mr. SPENCER WELLS presented

#### TWO OVARIAN TUMOURS REMOVED BY OVARIOTOMY.

The first was removed on the 15th of December from a married woman 42 years of age. There were very firm parietal adhesions, but the patient had thoroughly recovered, and left the Hospital three weeks after the operation. The tumour consisted of one very large cyst, and of a group of smaller cysts about the size of a doubled fist. The second tumour was removed on the 23rd of December from a single lady, 53 years of age, who was now convalescent. It had been surrounded by many pints of ascitic fluid, and consisted of a mass, of the size of a large adult head, presenting all the characters of adenoma. Mr. Wells said that, although ovarian tumours of this character presented many of the appearances of soft cancer, and resembled malignant tumours in the great rapidity of their growth, yet they offered the important practical difference, that they showed neither tendency to invade neighbouring parts nor to return.

Mr. SPENCER WELLS exhibited

#### A THIGH AND LEG REMOVED BY AMPUTATION AT THE HIP-JOINT,

on account of a malignant tumour developed in the substance of the biceps muscle, and obliterating the femoral artery. The tumour was first observed by a young married woman last March. It increased rapidly, and was removed by Mr. Wells last June. It was distinctly capsulated, and was entirely removed. It proved, on examination by Mr. W. Adams, to be true encephaloid. Growth very soon recommenced in the same spot, and the foot and leg began to suffer from want of circulation. The foot and outer part of the leg had previously been anæsthetic, owing to the division of the sciatic nerve at the removal of the tumour. Two months ago the patient fell and fractured both tibia and fibula on the diseased limb. After this the tumour grew more rapidly, the general health began to suffer, and it was determined to remove the limb at the hip-joint. Mr. Wells performed the operation on the 29th of December. Very little blood was lost, and the patient had gone on remarkably well ever since. About half the wound had healed by first intention, and the remainder was granulating. The tumour was a well marked example of encephaloid. Part of it surrounded the femoral vessels in the middle of the thigh, and about three inches of the artery were completely obliterated, although the vein was pervious. The

sciatic nerve terminated at the point where it had been divided in a bulbous enlargement. Some blood taken from veins in the immediate neighbourhood of the tumour contained cells, differing from blood globules in their irregular size and outline, and closely resembling those observed in the juice of the tumour. Mr. Wells remarked that it was probable the extension of cancer from the surface to internal organs took place in this way by means of the blood.

Dr. OGLE referred to a case in which branches of the vena porta were plugged by cancerous matter.

Dr. HARE mentioned a case in which the inferior cava was similarly plugged.

Mr. CÆSAR HAWKINS said there was a specimen in the museum of St. George's Hospital of cancer of the liver, which blocked up many portal and hepatic veins.

Dr. WILLIAMS said it was generally acknowledged, since Cruveilhier had shown the fact, that the blood vessels might be invaded by cancerous growths.

Mr. FERGUSSON said that the question raised by Mr. Wells was a very different one. He spoke of cancer juice or cancer cells circulating in the blood. If this were so, they ought to be seen in the blood of cancer patients during life.

Dr. WILKS said it was an accepted fact, that cancer invaded and destroyed blood vessels in its neighbourhood; but the fact, that cancer cells might be carried in the blood and deposited in distant parts of the body, was not accepted, although he believed it must be the fact. If Mr. Wells had demonstrated it in this case, it was for the first time.

In reply to a question by Mr. Hulke, Mr. WELLS said that Mr. W. Adams had not found cancer in the tibia or fibula.

Mr. LEE alluded to experiments of Langenbeck, that when cancer-cells, whilst warm, were injected into the veins of a dog, cancer of the lungs was developed.

Dr. DICKINSON exhibited a specimen of

#### RUPTURE OF THE HEART, WHICH WAS ATTRIBUTED TO DIRECT VIOLENCE.

The subject from whom it was obtained was a child, 5 years of age, who was knocked down and run over by a cart. When brought to the Hospital she was quite dead. There was no mark of injury upon any part of the body. At the post-mortem the pericardium was found to be full of blood, which had issued from a transverse rent across the apex of the heart, which cut off all but a sort of fringe on the anterior aspect. Both ventricles were laid open. The muscular substance was torn to a greater extent than the pericardium. The spine and ribs were unbroken, and there was no injury to any other organ. It was obvious that the injury to the heart had been occasioned by the accident. A sudden spasmodic action, from terror or exertion, even if sufficient to rupture the perfectly healthy heart of a child, which is highly improbable, could scarcely be supposed to tear both ventricles in exactly adjoining situations. Moreover, when the heart is ruptured spontaneously it is almost always found that the rent is considerably higher up the wall of the ventricle than in the present case. Dr. Dickinson concluded that the cart had passed over the back of the child, and compressed, without breaking, the yielding structures of the thorax, so as to squeeze off the apex of the heart by means of some prominent bone, probably a rib. It must be noted that the rupture commenced on the posterior aspect of the heart.

A case was then related of a patient, thirty-five years of age, whose leg had been crushed by a gate falling on it. The leg was amputated; the man died suddenly some days afterwards. The right ventricle was found to be ruptured, probably, in this case, from mental emotion.

Mr. HUTCHINSON mentioned a similar case. In it a child was knocked down in the street, and died on its way to the London Hospital. There was no mark of bruise on the chest nor any fracture of rib, but the heart was found ruptured; the right lung near its root was also torn. The evidence was conflicting as to whether or not the wheel had passed over the child, but in all probability it had done so. The elasticity of the walls of the chest in children might account for the non-occurrence of fracture of ribs, and the fact that death took place from sudden and complete arrest of the heart's action, for the entire absence of bruising or ecchymosis.

Dr. BRINTON said that rupture of the heart would follow the most severe accidents, for instance, a blow on the head. He could scarcely accept Dr. Dickinson's theory of the cause of rupture in his specimen.

Dr. C. J. B. WILLIAMS alluded to great contraction of the walls of the ventricle in the specimen exhibited.

Dr. LEARED related a case in which a man died suddenly after the fall of part of a wall on him. The pericardium was full of blood, and there was a jagged rupture of the ventricle.

Mr. SPENCER WELLS related a case in which a sailor, having been struck on the chest by an officer, walked away and died shortly afterwards, whilst vomiting. There was a small aneurism of the aorta, which had been ruptured. The question raised on the trial was, whether death was due to the blow or not?

Mr. CROFT exhibited, at a previous meeting, a specimen of

#### VILLOUS CANCER OF THE INTESTINE.

The subject of the disease was a male, aged 63. He had suffered from intermittent attacks of constipation for several years, and at such times he had complained of a fixed pain behind and to the right side of the umbilicus. The final and fatal attack commenced on September 1, 1862, and lasted over a period of ninety days. It was characterised by persistent pain over the seat of the tumour, and alternations of obstinate constipation, accompanied by faecal vomiting and diarrhoea. After death, a tumour was found in the right half of the transverse colon. It projected across so that it blocked up the canal of the intestine, and the intestine was dilated on the proximal, whilst it was collapsed on the distal side of the seat of disease. The mucous membrane on each side of the disease was marked by tendency to redundancy of villous growths; and from the opposite side to that of the larger tumour a small, slenderly pedunculated one, of essentially villous character, was found hanging on to the canal. The larger tumour measured about two inches in breadth, and one in depth; it was seated on the lower segment of the intestine, and had caused constriction at that part. When the mass had been divided in half, the base and central portions were found to have sprung from the mucous coat, and to be seated on the muscular coats of the intestine. Several small cysts, containing mucus, were found in the base and central portions, and the intervening structures were seen by the microscope to consist chiefly of blood-vessels and connective tissue. The periphery of the mass consisted of a villous investment to the base and central portions, the villi in some places springing deeply from the centre. The villi themselves were very beautiful microscopical objects, being of all dimensions. Some were extremely fine and long, and made up almost entirely of delicate loops of capillaries; whilst others appeared almost papillary in their structure and dimensions, consisting of loops of capillaries invested by basement membrane supporting a perfect arrangement of columnar epithelium. In the examination of the seat of disease there was not discovered any particular feature of cancer; and, at the general examination of the body, the various viscera and the lymphatic system were observed to be free from disease.

Mr. HUTCHINSON remarked that he believed a very similar case was recorded by Mr. Birkett in the Society's *Transactions*. Mr. Gowlland had recently, at St. Mark's Hospital, operated in three cases of large villous growths in the rectum. One of these operations he (Mr. Hutchinson) had witnessed; and although the growth was firmer, and much less shreddy, than those met with in the bladder, yet it, like the others, was undoubtedly villous in nature.

Mr. HOLMES stated that the specimen shown by Mr. Croft appeared to him to be much more of a solid growth than true villous tumours are. He had seen some from the intestine in which the prolongations of the villi were very long; and adverted to one case in which the tumour grew from the lower tract of the rectum and was removed on many occasions.

Mr. HENRY THOMPSON agreed with Mr. Holmes in doubting whether the term "villous" could be correctly applied to Mr. Croft's specimen. He thought we ought carefully to restrict that term to examples of growth in which the prolongations were very long, and bore resemblance to those of the chorion. He referred to several from the bladder, very different, indeed, in appearance from Mr. Croft's specimen, which showed little or nothing of the villous character.

Mr. HUTCHINSON differed from the last speaker, and considered that the difference between a villous growth from the bladder and one like that now before the Society was of degree rather than kind. He suggested that the reason why good specimens of villous growths were rarely met with except from the bladder was, that in the latter instance the villi grew in fluid, a condition very favourable to them, whilst in the interior of the colon it might easily be understood that the slender villi would be crushed off by the passage of faecal masses.

## OBSTETRICAL SOCIETY OF LONDON.

ANNUAL MEETING, WEDNESDAY, JANUARY 7.

Dr. TYLER SMITH, President, in the Chair.

AFTER the ordinary meeting, the business of the annual meeting commenced.

The report of the Auditors of the accounts of the Treasurer for the year ending December 31, 1862, was then read, from which it appeared that the balance in the hands of the Treasurer is £204 9s. 2d., and that during the year a sum of £400 had been invested in the Funds in the names of the Trustees of the Society. The balance-sheet read by the Secretary showed that the Society had received during the year £478 15s. as subscriptions from Fellows, and £48 9s. 3d. as proceeds of the sale of the *Transactions* of the Society.

Dr. GREENHALGH, in moving the adoption of the Report of the Auditors, alluded to the satisfactory condition of the funds, and also to the fact, that the sum received during the past year in subscriptions exceeded that of any previous year, the respective amounts received during the years 1859, '60, '61, and '62 being, £336, £413, £445, and £478; while a total sum of 100 guineas had been paid into the Society's hands in respect to the proceeds of the first three volumes of the Society's *Transactions*. He also congratulated the Society on the promising condition of the library.

Dr. MEADOWS seconded the resolution, which was carried unanimously.

Dr. RICHARDS moved, and Mr. MITCHELL seconded, the following resolution, which was carried by acclamation:—

"That the best thanks of the Society be and are hereby given to the President and officers of the Society for their services during the past year. That the best thanks of the Society be in an especial manner given to the retiring President, Dr. Tyler Smith, and to the retiring Honorary Secretary, Dr. Tanner: to Dr. Tyler Smith for the able and efficient manner in which he has presided over the meetings of the Society for the past two years; and to Dr. Tanner for his valuable and zealous services as Honorary Secretary from the commencement of the Society, four years ago, until the present time."

Dr. TYLER SMITH and Dr. TANNER respectively returned thanks.

The list of donations during the past year was read, from which it appeared that 605 volumes had been presented to the Society by Sir Charles Locock, Bart., Dr. Clay, of Manchester, and others.

The following gentlemen were elected officers of the Society for the year 1863:—

*Honorary President*: Sir Charles Locock, Bart., M.D. *President*: Dr. Oldham. *Vice-Presidents*: Dr. J. Hall Davis, Dr. Druitt, Mr. Fergusson, Mr. Robert Hardey (Hull), Dr. G. Swayne (Bristol), and Dr. Tanner. *Treasurer*: Dr. Barnes. *Honorary Secretaries*: Dr. Graily Hewitt, and Dr. Braxton Hicks. *Other Members of Council*: Mr. H. Woodruffe Bailey (Thetford), Dr. Clay, (Manchester), Dr. Wm. Fred. Cleveland, Dr. Chas. Drage (Hatfield), Dr. Gream, Dr. Greenhalgh, Mr. F. Seymour Haden, Dr. Harley, Mr. Isaac Harrison (Reading), Mr. Henry James, Dr. J. C. Langmore, Dr. Alfred Meadows, Dr. Madge, Mr. Joseph Thos. Mitchell, Dr. W. Tyler Smith, Mr. Fred. Symonds (Oxford), Dr. Alfred Joseph Tapson, and Dr. Jas. Geo. Wilson (Glasgow).

The PRESIDENT then delivered the

## ANNUAL ADDRESS.

The first point dwelt upon in the address was the financial and numerical prosperity of the Society. The success of the volume of *Transactions* for 1862 was then briefly referred to. The additions made to the library during the year, the unique value which would attach to a large collection of purely obstetrical works, and the need which existed for appointing a librarian, and making some arrangement which should render the books accessible to the Fellows, were next alluded to. The loss of Fellows by death during the year was stated to be unusually large, including the names of Dr. Metcalf Babington, Dr. Waller, Mr. Jessop (of Cheltenham), Mr. Smith (of Crawley), Mr. Rowland (of Wrexham), and others. The trials which had occurred during the year, in which persons practising midwifery were accused of malpraxis, were commented on, and especial notice was taken of the case of Mr. Robinson, convicted of manslaughter at the Central

Criminal Court. It was shown that in many of these cases the charge of malpraxis arose out of the attendance of midwives in the first instance; and the anomaly, that midwives, without any special training or qualification, are allowed to attend in cases often involving the question of life and death, was commented on. The progress of ovariotomy during the year, and its evident connexion with obstetric practice, were noticed. The recent discussion respecting the genealogy of the Chamberlens and the discovery of the forceps, was alluded to, and reasons were adduced for giving the merit to Mr. Peter Chamberlen, surgeon-accoucheur, of the City of London, and the first of the family of whom we have any record. The address was concluded by the retiring President thanking the Society for the kind support which he had received during his tenure of office.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having undergone the necessary Examinations for the Diploma, were admitted Members of the College, at a meeting of the Court of Examiners, on the 22nd inst.:—

William Clement Daniel, M.D. Heidelberg, Kennington; John Lovell Arnott, M.D. Edin., Cheltenham; William Frank Smith, Nottingham; Philip Henry Pye Smith, Hackney; Charles Henry Butlin, Camborne, Cornwall; Denis Joseph Canny, Dublin; Thomas Thomson Dick, M.D. Edin., Ayr; John Edward Thornburn, Cokermonth; George Smith, Hampstead-road; George Gregson, Harley-street; Robert Meadows, M.D. St. Andrews, Ipswich; William Cooper, L.R.C.P. Lond., Beaumont-street, Cavendish-square; Horsley Thomas Mapleson, Westbourne-place; Jacob De Leon, Jamaica; and Arthur John Farwell, Chipping Norton.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, January 22, 1863:—

Henry Addison Hobbs, Croydon; George Edward Walker, Wigan, Lancashire; Thomas Cargill Nesham, Newcastle-on-Tyne.

## APPOINTMENTS.

ANDERSON, DR. ALEXANDER, M.D. Edin., has been elected a Director of the Royal Lunatic Asylum, Gartnewel, Glasgow.  
DE MORGAN, CAMPBELL, F.R.C.S.E., has been appointed Consulting Surgeon to East Grinstead Dispensary.  
EADE, DR., has been appointed Lecturer on Materia Medica at Melbourne University.  
EARLE, JAMES NEALE, M.R.C.S.E., has been appointed Surgeon to the Royal South London Dispensary, Lambeth.  
EDWARDS, DR. MORGAN JOHN, M.D. St. And., has been appointed House-Surgeon to the Glamorganshire and Monmouthshire Infirmary, Cardiff.  
FLEMING, DR. JOHN G., M.D. Glasg., has been elected a Director of the Royal Lunatic Asylum, Gartnewel, Glasgow.  
GAIRDNER, PROFESSOR WILLIAM T., M.D. Edin., has been appointed Medical Officer of Health for Glasgow.  
HARVEY, DR. ALEXANDER, M.D. Edin., has been appointed Surgeon to the Aberdeen Ophthalmic Institution.  
LAPRAIK, DR. THOMAS, M.D. Glasg., has been elected Surgeon to the Glasgow Asylum for the Blind.  
LOCOCK, SIR CHARLES, Bart., has been elected Honorary President of the Obstetrical Society of London.  
OLDHAM, DR. HENRY, has been elected President of the Obstetrical Society of London.  
PAGAN, DR. JOHN MACKENZIE, M.D. Edin., has been elected a Director of the Royal Lunatic Asylum, Gartnewel, Glasgow.  
SANDERSON, DR. JOHN BURDON, has been elected Additional Assistant-Physician to Middlesex Hospital.  
STAMPER, JAMES FENTON, M.D. St. And., has been appointed Resident House-Surgeon to the Tunbridge Wells Infirmary.  
STEVENTON, DR. WILLIAM, has been appointed a Member of the Executive Council of the Island of Montserrat.  
WARD, CHARLES PARKER, M.R.C.S.E., has been appointed one of the Visiting Surgeons to the Royal South London Dispensary, Lambeth.

## DEATHS.

ALDIS, RICHARD, at Suffolk, on January 15, aged 71.  
BOULT, EDMUND, L.R.C.P. Edin., at Bath, on January 24, aged 48, late of the H.E.I.C.S.  
BOWMAN, EDWARD, L.R.C.S. Edin. (of Carlisle), at Kingston, Jamaica, whither he had gone for the benefit of his health, on December 24, aged 51.  
BURMAN, HENRY, L.S.A., at Ketton, Stamford, Lincolnshire, on January 8, aged 56.  
CRIGAN, RCV. ALEXANDER, M.D., Vicar of Skipwith and Ricall, Yorkshire, at Sidmouth, on January 25, aged 82.  
EARNSHAW, J., M.R.C.S.E., at Oldham, Lancashire, on January 20, aged 51.  
FOWKE, FREDERICK, M.R.C.S.E., at Wilton House, Ryde, Isle of Wight, on January 24, aged 57.

JONES, WILLIAM, M.D. Aberd., at 10, Lower Seymour-street, Portman-square, W, on January 26, aged 52.

KNOWLES, S., of Horley-hill, Ashton-under-Lyme, on January 4, aged 54.

RAMSAY, DAVID, M.D., R.N., at the Royal Naval Hospital, Simon's Bay, Cape of Good Hope, on December 16, late Surgeon of H.M.S. *Gorgon*.

RICHARDSON, JAMES, at Queen-street, Stirling, on January 10.

ROBERTSON, J., M.D., at Woodside, Paramatta, New South Wales, on November 17, aged 40.

SMITH, GEORGE THOMAS, at 32, Clement-street, Leamington, on January 19.

**THE MIDDLESEX HOSPITAL STAFF.**—A correspondent of the *Times* is premature in announcing that Mr. Lawson has been elected the successor of Mr. Mitchell Henry at the Middlesex Hospital, no vacancy having yet been declared. In a few days it is expected that another vacancy will be declared in the Staff of this Hospital by the resignation of the lecturer on Midwifery, as it stated that Dr. Priestly will succeed Professor Farre at King's College.

**VACCINO-SYPHILITIC INOCULATION.**—At a meeting of the Royal Medical and Chirurgical Society, on Tuesday night, Mr. Henry Lee mentioned that he had now under his care at St. George's Hospital a case of vaccino-syphilitic inoculation. As the existence of such cases had been doubted, Mr. Lee mentioned that he should be happy to show the patient to any gentleman who might feel interested in the subject, on Tuesday next, at one o'clock.

**MEDICAL SOCIETY OF LONDON.**—A course of three Lettsomian Lectures, "On the Surgical Diseases of Children," by Mr. Thomas Bryant, F.R.C.S., Assistant-Surgeon to Guy's Hospital, will be delivered, February 9, 16, and 23. Lecture I. "On the Differences between the Physiological and Pathological Processes in Children and in Adults, and on some Congenital Deformities, as Hare-lip and Malformations of the Rectum." II. "On the Differences between the Surgical Diseases of the Nervous, Respiratory, Circulatory, Digestive, and Urino-genital Systems of the Child and the Adult." III. "On the Diseases of the Osseous System, and on Tumours," etc.

**APPOINTMENT OF DR. FURNARI AS PROFESSOR OF OPHTHALMOLOGY IN THE UNIVERSITY OF PALERMO.**—Dr. Furnari, well known by his works on Ophthalmological Medicine, and who, during his exile, had acquired golden opinions in Paris, has, on the recommendation of Professor Matteuci, been appointed Professor and Director of the Ophthalmological Clinic in the University of Palermo.

**TESTIMONIAL TO PROFESSOR MATTEUCI.**—In order to perpetuate the remembrance of the services rendered by Professor Matteuci (while Minister of Public Instruction) to the cause of Medical education, the entire body of the Professors of all the Universities of the new kingdom of Italy has entered with enthusiasm into a subscription, in order to present him with a large honorary medal. On the one side is the portrait of the Professor, with the inscription—"To Charles Matteuci, 1862." On the obverse is inscribed—"For having established unity in instruction." On the exergue are the names of the 201 Professors.

**HONOURS CONFERRED ON THE FRENCH JURORS AND EXHIBITORS OF CLASS 17 IN THE INTERNATIONAL EXHIBITION.**—Among the Jurors, MM. Balard and Nélaton have been promoted to the rank of Commanders in the Legion of Honour; MM. Barrall, Bella, Demarquay, and Wurtz are made officers; and MM. Masson (the Medical publisher) and Lecorché (who acted as Medical attendant upon the exhibitors during their stay in London), Chevaliers of the Legion. Among the exhibitors, MM. Charrière, jun., Lüer, and Mathieu have been nominated Chevaliers.

**CROCODILES IN THE OLD RED SANDSTONE.**—A paragraph has been inserted in several of our contemporaries, announcing that the remains of a crocodilian reptile had been derived from the old red sandstone in the neighbourhood of Elgin. We have only to remark that the bed in question, whence the *Leptopleuron lacertinum* was derived, appertains to the triassic age, and that remains of a thecodont reptile, with crocodilian scales (*Steganolepis Robertsoni*), from the locality are in all our public collections.

**NETLEY HOSPITAL.**—The arrangements for the removal of the invalid establishment at Chatham, together with the Medical staff, Professors, and other officers connected with the Army Medical School at Fort Pitt, to the new Hospital at Netley, near Southampton, are expected to be completed in the course of a few weeks. The entire Medical staff at the

General Hospital, Fort Pitt, as well as the staff of the invalid establishment and pay-offices, will quit Chatham for the new establishment at Netley. The responsible appointment of Governor of Netley Hospital has been conferred on Col. R. Wilbraham, C.B., the present Governor of the General Hospital at Woolwich.—*Times*, January 27.

**THE Senatus Academicus of the University of St. Andrews** announces that the examinations for the degree of Doctor of Medicine will, under the new regulations, be conferred annually on ten registered Medical Practitioners above the age of 40 years, and on payment of the increased fee of fifty guineas. The next examination for the "M.D." will take place during the last week in April, on which occasion the examinations will also take place for the degrees of Bachelor of Medicine and Master in Surgery. During the last three months the Council of Medical Education and Registration have registered 262 Practitioners, twenty-six of whom have just been "capped" at St. Andrews. It may be regretted that persons still continue to be registered without any qualification, merely on their statement of having been in practice before 1815; consequently, these Practitioners, assuming they were in the practice of the Profession at the early age of 20 years, would now be 68 years of age. A correspondent, however, draws attention to a case in the West of England, where one of these Practitioners so registered is little more than 50 years of age.

**ROYAL MEDICAL COLLEGE, EPSOM.**—A printed appeal has lately been issued by the Council of the Medical Benevolent College, calling upon the Profession to aid in increasing the number of Foundation Scholarships, and in rendering their maintenance independent, at least in part, of the precarious support of annual subscriptions. From the following extract it will be seen that the Council look forward to an important change in the mode of election of candidates:—"Hitherto there has been an objection, on the part of many Medical men, to contribute to what is essentially their own institution, from a fear that their money would be sunk in bricks and mortar. The building is now on the point of completion, so that this fear will soon cease to have any foundation; moreover, any donor, or subscriber, may prevent such an application of his contributions absolutely, by intimating a wish that they should be added to the Endowment Fund. When this fund has reached a certain point, it is earnestly to be desired, that the admission of the Foundation Scholars may no longer depend upon the present harassing and expensive method of a general canvass of all the governors, but take place by a competitive examination of the candidates, or some similar proceeding, which may at once render it a reward and a stimulus, while it takes from it that purely eleemosynary character which now surrounds it."

**ROYAL COLLEGE OF SURGEONS.**—Professor Gulliver will, early in June, deliver six lectures on "Blood, Chyle, and Lymph," in continuation of his former course on "Blood;" and Professor Samuel Solly, F.R.S., will deliver six lectures on the "Brain and Some of its Diseases." The annual election of Fellows into the Council will take place, as usual, in July. The next Primary or Anatomical examination for the membership of the College will commence on Saturday, April 4, and the Pass or Surgical and Pathological examination on April 18. An examination for the Midwifery licence will take place on Wednesday, the 11th proximo. The following prizes, offered by the Council of the College, are open for competition by the Fellows and Members of the College, viz.:—The subject of the Collegial Triennial Anatomical Prize, of fifty guineas, is on "The Structural Anatomy and Physiology of the Lymphatic Vessels and Glands (the Anatomical Distribution not being required); the Communications (if any) between the Lymphatics and the Blood-vessels to be demonstrated; and the Influence (if any) which the Lymphatic Vessels or Glands exercise on the Fluid they transmit, to be elucidated. The Dissertation to be illustrated by Preparations and Drawings." The essays must be sent in on or before Christmas-day, 1864. The subject for the Jacksonian Prizes of twenty guineas, for the present year, 1863, are on "The Pathology and Treatment of Diseases of the Larynx: the Diagnostic Indications to include the Appearances as seen in the Living Person; the Dissertation to be illustrated by Drawings and Preparations;" and, "The Normal and Pathological Anatomy of the various Synovial Bursæ connected with the Muscles and Tendons of the Upper Extremity, and the Treatment of their Diseases; the Disserta-

tion to be illustrated by Preparations and Drawings." The essays must be sent in on or before Christmas-day next. The terms and conditions may be known on application to the Secretary.

**COMMON RESIN AS A SPECIFIC FOR WHOOPING-COUGH.**—A writer in the *Australian Medical Record* for September 24, recommends the use of common resin as a specific in whooping-cough. The dose for a child is one or two grains three times a-day, and four to six grains for an adult. He is in the habit, apparently, of combining with the resin both opium and belladonna,—not a very philosophical practice, by the way, considering the established antagonism between these drugs. Nor do the sixteen cases adduced impress our mind at all forcibly as confirmatory of the value of the practice. Still, when we consider some recent observations upon the pathology of whooping-cough, we are disposed to advise our readers to make a trial of the remedy. At any rate no harm can come of it.

**MELBOURNE LOGIC AND MELBOURNE LUNATICS.**—We learn from the journal just referred to, that Dr. McCrea, who, we believe, is the Health Officer for Melbourne, certainly one of the best-informed Practitioners there, and highly respected by the Profession, has got into a little trouble, for daring to step beyond the bounds of routine practice. It appears that a Mr. Turner, who showed evidences of mental disturbance, was committed to the Western Gaol on May 26, and was seen there by Dr. McCrea. He was not violent, but on the night of the 29th became so, and from fighting with the other lunatics was much bruised. Half an ounce of tincture of digitalis was ordered him. This calmed the excitement; and on June 4 he was apparently well. At subsequent periods, on the recurrence of violence, the medicine was repeated with good results; and on the 18th he was transferred to the Yarra Bend Asylum. Dr. McCrea's practice was based on the belief that the early symptoms were those of delirium tremens. The patient never had more than an ounce of the tincture in the twenty-four hours. No one in his senses can blame Dr. McCrea, with the facts now before the Profession illustrative of the value of this medicine in delirium tremens. The case, however, ultimately became one of intermittent mania. The digitalis was no longer given, and three or four weeks after the last dose the man died from his injuries and from pericarditis. An inquest was held, and the coroner told the jury that, even if they found him guilty of manslaughter, he would not commit Dr. McCrea for trial. Whatever may be thought of this, it is clear that Dr. McCrea, whose practice was successful as far as it went, could not be fairly censured. As to "poisoning" Mr. Turner, the thing is simply ridiculous. Who ever heard of a man being poisoned with a large dose of digitalis, and not dying from the effects of the dose until a month had expired? Besides, how is it that the characteristic signs of the "poisoning" were not observed at any time? Mr. Phillips, who saw Mr. Turner last, says: "In my opinion, the cause of death was, first, pericarditis and exhaustion, induced by acute mania, accelerated by the sloughing sores on the trunk of the body." The comment of the editor is worthy of reproduction: "What else could be expected from placing twenty lunatics and two wardsmen in a ward 22 feet by 15 feet, than that some of them should be injured? If those in authority continued the system of crowding lunatics into a place of this kind, in spite of the repeated representations of Dr. McCrea, Mr. Turner's death was caused by their supineness." What year of our Lord is it just now in Melbourne?

**RARITY OF BAYONET WOUNDS IN WAR.**—We extract from Dr. Detmold's first lecture on "Military Surgery," delivered at the College of Physicians and Surgeons at New York, the following observations: we do so without comment:—"Almost all the wounds that will be brought under your notice will be gun-shot wounds. You hear a good deal about bayonet charges, and crossing of bayonets, but I have been through a great many of our hospitals, and have seen thousands of wounded, but do not recollect to have seen a single bayonet wound. The only bayonet wounds I ever saw were inflicted in a sham fight. I was attached at the time to the Royal Hanoverian Grenadier Guards, and in the sham fight our regiment was to make a decisive bayonet charge; the opposing regiments, according to the programme, were to give way, but a good deal of jealousy existing against the guards, the line regiments did not heed the programme, and the men actually crossed bayonets. On that occasion I saw a good many, in fact, the only bayonet wounds, and a good many

men were maimed for life."—*American Medical Times*, Dec. 20, 1862.

**ACCLIMATISATION IN AUSTRALIA.**—A New Zealand journal, speaking of the two white swans presented by the Queen to this colony, and which were placed on the North Shore Lake, says that they were sitting on no fewer than eighteen eggs. The swans had been hatching alternately for three weeks. One of the Canadian geese, which came with the swans, and from the same royal donor, flew away some time after being placed on the lake, but the remaining bird took up with the common geese, and the result has been a magnificent cross. The divers are doing well. In Victoria, measures are in progress for the speedy introduction and acclimatisation of roe deer, partridges, rooks, hares, sparrows, and song-birds, from England; deer, Cashmere goats, and black partridges, from India; ostriches, pheasants and partridges, and antelopes, from the Cape of Good Hope; for all of which the money has been remitted by the Acclimatisation Society. A letter was recently received by the Acclimatisation Society of New South Wales from Mr. Black, of Miami, enclosing a sample of wool from an Angora goat descended from those that were imported some years ago into this colony. Mr. Black, who has paid much attention to improving the breed of goats, states that their wool and fat are exceedingly valuable; that their flesh is in no way inferior to mutton, but rather resembling venison; that the females breed twice a-year, producing generally two at a birth; that they require very little shepherding, and thrive well where nothing else could be kept with profit.

**TOWERS OF SILENCE.**—"There exists in Bombay, on one of the fairest spots of Malabar-hill, a wide extent of ground, allotted to one of the vilest purposes which it ever entered into the heart of man to conceive. Here we have in modern times the vulture preying upon the dead body, as in heathen mythology the bird is reported to have done on the living! The 'Towers of Silence' are immense structures of varied diameter, raised twenty, thirty, or more feet from the ground, in the centre of which is a well, covered by an iron network, frame, or grating. On the latter are placed the corpses of the Parsee population, and before the mourning relatives have left the grounds hundreds of carrion birds, of voracious vultures and hungry crows, are quarrelling, fighting, clawing, like so many ornithological devils, at the specimen of humanity exposed to their ravages. The delicate Parsee female, the portly merchant, the withered sexagenarian, are all thus disposed of, and we are credibly informed that two hours after the deposition of any body in the 'Towers of Silence,' bones alone are to be found, which are eventually thrown down into the well enclosed in the tower. At the same time the loathsome carrion birds, with their bald heads and hideous claws, arrange themselves in rows on the summit of the towers, bloated and surfeited from their ghoul-like feast, secure in the knowledge that, by waiting where they are, a repetition of the festival will take place to-morrow! But the blood, bones, and fluids of the body must escape the voracity of the carnivorous birds, and, gravitating downwards within the tower, there undergo the inevitable process of decomposition, rising thence in pestiferous gases, which are only less hurtful than the miasma of the graveyards, simply because the altitude of Malabar-hill allows the free breezes of the ocean to sweep them off into infinite space. We are, however, credibly informed that neighbouring residents are not unfrequently annoyed by the 'Towers of Silence,' and this not only by pestiferous effluvia, but even in a more demonstrable manner. Thus, we have heard it rumoured that it occasionally happens that feathered bipeds may be seen pursuing one another, and quarrelling over pieces of the human form divine! Nay, more—tales of our intrusive friends, the crows, hopping into verandahs with digits in their beaks, have before now been related. The Parsees, who owe not only their wealth but their very location to the British, must not be longer suffered to carry on such a nuisance in the fairest part of Bombay. They, equally with all sects, must remove their 'Towers of Silence' without the island, and, having been made to take this step in advance, it may reasonably be expected, with a race so 'Europeanised,' that they will eventually hit upon some less loathsome method for disposal of their dead."—*Bombay Saturday Review*.

**HOW TO COOK HEDGEHOGS.**—"We have for supper this evening (said the gipsy) only a hedgehog, which was found in the hedge-row, and it is very little for so many. . . . Hereupon I placed a crown in the old woman's hand to buy

a fowl with. . . . The next point was to cook it; and the gipsies have a peculiar mode of doing that: a square piece of turf was removed, and a hole dug in the opening, which was filled with small wood. In the meanwhile, the fowl's toilette had been made: this consisted simply in removing the entrails, and rolling it, feathers and all, in a paste of clay. This done, it was laid on the sticks, arranged so as to burn easily, and the piece of grass was placed over all as a lid. This mode has sundry advantages. In the first place, from a culinary point of view, it is excellent; and then it has the great merit in the eyes of the gipsies of concealing their dinner preparations. . . . After some little time the lid was removed, and the fowl taken out still wrapped in the clay, which was broken with a hammer: the feathers came off of themselves, and it was served up on a wooden dish. The chief of the tribe took from his pocket a formidable knife, and divided the plunder impartially. Next came the turn of the hedgehog, cooked precisely in the same way. This gipsy dish, thus prepared, is by no means to be despised; the skin and prickles of the steaming animal are removed by the mere act of breaking the clay."—*The English at Home, Alphonse Esquiros*, pp. 177, 178.

## BOOKS RECEIVED.

### PAMPHLETS.

- A Brief Report of Indian Drugs as contributed to the London Exhibition of 1862. By Kanny Loll Dey. Calcutta. 1862. Pp. 14.

## NOTES, QUERIES, AND REPLIES.

*He that questioneth much shall learn much.—Bacon.*

L. L. G. F.—1. Yes; 2. No.

Mr. L. F. Crummev.—The omission was intentional. We do not think that the argument has a basis in fact.

A. Z.—We hear that a German translation of Mr. Toynbee's work on the "Ear" has just been published.

F.R.C.S.—We must repeat, that all communications containing the slightest reflection on the personal character or works of any member of our Profession must be authenticated.

We cordially concur in the object of the promoters of the cricket ground in Victoria-park, and trust that their petition to the Commissioners of the Board of Works may be successful.

A Father asks of us to pronounce an opinion on a case of which we have only heard one side. As a general rule, we condemn the use of the speculum in the case of unmarried women, unless there are ample reasons for suspecting some organic disease which cannot be diagnosed without visual examination.

A correspondent sends us the following advertisements, copied *verbatim* from the *Daily Telegraph* of Wednesday, January 23:—"For Sale: A Medical Diploma to be disposed of. For price, etc., send a directed envelope to J. A., care of Bookseller, 3, Spur-street, London, W.C."—"An original Medical manuscript to be disposed of. It is a first-class production, and will bring both profit and *prestige* to the purchaser. Address, for interview, to Medicus, 3, Spur-street, London, W.C."

*The Invalids' Dinner Table, Earl-street, Lisson-grove.*—The Third Annual Report of this really useful little charity has come to hand. Since its establishment three similar institutions have sprung up, one in Pimlico, another in Bayswater, and a third in St. Pancras. We have had personal experience of the good done by one of these amongst the out-patients of one of our Hospitals. The balance sheet of the Lisson-grove Dinner Table shows that, with an income from all sources of £159 7s. 6d., 3045 dinners of meat, vegetables, bread and beer have been furnished to the sick poor, although one-third of the said income has been necessarily spent in rent, furniture, salaries, printing, &c. Such a charity deserves support.

*The Nightingale Fund.*—At the suggestion of Miss Nightingale, a portion of the available surplus income of the fund has been applied to the purpose of training midwifery nurses for the poor, who are to be employed, not as midwives to replace, but as nurses to supplement the Medical man. For this purpose the Committee have made arrangements with the Council of St. John's House, and with the Committee of King's College Hospital, the one to train the nurses, the other to supply wards for the purpose. A certain number of beds for poor married women in their confinement are to be maintained in the Hospital at the expense of the fund, and the training of the nurses is to be conducted under the direction of the Physician-Accoucheur and the Assistant-Physicians for the diseases of women and children. Five persons are now training, and the report states that they have had the advantage of lectures delivered to them twice a-week by Dr. Meadows, one of the Assistant-Physicians. Those of us who attend midwifery amongst the poor know full well that it is as difficult to obtain good monthly nurses for them as good nurses in ordinary sickness. The movement thus commenced bids fair to be a boon not only to patients but to Practitioners.

*Erratum.*—In the prescription of Dr. Laycock's, quoted in a foot note at page 53 of the *Medical Times and Gazette* of January 17—*R̄* Tinct. ferri sesquichlor., ʒij; glycyrrhinae, infus. quassia, āā ʒiv.; two table-spoonfuls thrice a-day—for "ʒiv.," read "ʒiv."

### ST. THOMAS'S HOSPITAL.

The following has been forwarded to us by a Physician of eminence:—

"To the Governors of St. Thomas's Hospital.

"Gentlemen,—The Governors of St. Thomas's Hospital would be entitled to the gratitude of the sick poor of London for generations to come, if they would take a liberal and extended view of the great charge entrusted to them.

"The object of the founders of these great institutions was to afford the greatest amount of relief to the greatest number of sufferers. That object would be best attained by removing the pale and debilitated invalid to the country, as soon as he was capable of removal. The rich seize on the first opportunity of acting on this principle, where they are personally concerned.

"To accomplish this would not be difficult; the Hospital has ample funds; it could maintain two establishments, each capable of receiving 200 patients, one in town and another in the country. Casualties and urgent cases of all kinds would be received in the lower Hospital, where pupils might attend lectures, and have other instruction.

"When the great London institutions were first founded, locomotion was difficult; now space and distance are practically annihilated. A train—nay, a single invalid carriage, daily, would accommodate the sick in transit to the country house, while passes by any train would enable the Medical officers, students, and patients' friends, to go a distance of five or six miles in twice as many minutes. The advantage to the sick poor of the metropolis would be manifest. Thousands living in close courts and alleys, who never in their lives slept out of town, would thus breathe the pure country air, and by that means, partly, be restored to health and usefulness. It would be a work of supererogation to dwell on the greater salubrity of an open country situation, as compared with a densely-populated city; suffice it to say, the mortality in Hospitals in towns is much greater than it is in rural establishments. The principle advocated here is already in operation in respect to many Hospitals, lunatic asylums, and sanitariums, both in London and in other large cities—indeed, its adoption bids fair to become universal; and it is hoped the Governors of St. Thomas's Hospital, looking to the real interests of the poor, will follow it up in such a manner as to do themselves honour, and secure the gratitude of thousands yet unborn. I am, &c.

"Gower-street, January. M.D."

### CASE OF ABSENCE OF ABDOMINAL PARIETES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—If you deem the following of interest to your readers, I will feel obliged if you will give it a place in your Journal:—

At the end of last month a male child was born in this parish without any covering to the abdomen, except the peritoneum; the intestines could be seen quite plainly; the child was otherwise perfect, and the bowels and bladder acted regularly; but, although taking nourishment freely, it gradually wasted and died at the end of three weeks.

I am, &c. JOSEPH HAZARD, M.R.C.S. Eng., etc.  
Litcham, Norfolk, January 21.

### MIDWIFERY DIPLOMATA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg leave to set "L. M.D.," right upon one part of his letter to you, which appeared in your valuable Journal of December 27, 1862. He there states, "that no midwifery licence or diploma is recognised by the Medical Act, nor will they be registered." Now, in refutation of this, if

he will only refer to the registry, he will see that midwifery diplomata are registered, but not certificates; consequently, Mr. Talbot was not "legally entitled to attend a midwifery case."

Within the last few days, the certificate from the Dublin Lying-in Hospital was refused as a qualification by a dispensary committee; and the gentleman was obliged to go in for the midwifery diploma of the College of Surgeons before he was permitted to become a candidate for the appointment of Medical attendant to the district.

I am, &c.

Dublin, January 21. A REGISTERED MIDWIFERY DIPLOMATIST.

MALPOSITION OF THE HEART AND LIVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the report of the meeting of the Royal Medical and Chirurgical Society for November 25, 1862, I see a case of malposition of the heart and liver recorded. As there is at present in this city a living instance of a similar case, and as the gentleman himself makes no secret of it, I see no impropriety in my referring to it. His heart is undoubtedly and congenitally placed in the right thoracic region; and he is fully persuaded himself that his liver occupies the left hypochondrium. The subject of this *lusus nature* is a small, but most active man, is one of our most eminent men here, is a specialist, and holds a very high and important position in our Royal College of Surgeons. He enjoys excellent health.

I am, &c.

Dublin, January 21. F.R.C.S.I.

GIBBON v. BUDD.—PHYSICIAN'S FEES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Allow me to correct a trifling inaccuracy in the report of this action, as it appears in your Journal, and to state that I did not attend the late Mr. Budd for a Surgical injury to the foot, but was called in four months after the accident by his Medical attendant, in reference to the extreme debility and head symptoms from which he was suffering. Had I had anything to do with the treatment of the Surgical disease it would, assuredly, have been pleaded against me; for the defendant left no stone unturned and spared no money in order to quash my claim. In other respects the report is one-sided, especially in not giving the evidence adduced on my behalf. As to the plea that I attended as a friend, the only pretext for it was that I had a passing acquaintance with Mr. Budd; indeed, I proved that he had once paid me for previous Professional services. Unfortunately for me, my attendance on him was abruptly terminated by an attack of typhoid fever, which obliged me to leave London for a considerable time in the autumn of 1861, when other Medical men took charge of the patient up to the time of his decease.

My legal title to recover fees under the new Medical Act will be decided in a few days by the Exchequer Court, as it was stipulated not to carry the question to a Court of Error, on account of the heavy expense it would entail upon the parties.

It may be a mistake, as you say, in a College of Physicians to enact conventional distinctions between the different members of their body; but it would surely be a greater mistake for the Fellows to impose legal disabilities on the members and licentiates without their consent.

With every respect for the opinion, or rather feeling, which you appear to share with a majority of the Fellows of the London College,—that the Physicians' fees had better be regarded as a "gratuity" than as "wages," for the most important and valuable services one man can render to another,—I must confess, after due consideration, that I cannot agree with you. If there be a moral claim, one would naturally suppose that there ought to be a legal title to remuneration for the inestimable services that we, as Physicians, render to our fellow-men. In a Professional point of view, we need only to determine whether of the two is the more just and the more politic,—the "honorarium" or the "merces" principle of payment. Now, it is difficult to conceive how any injustice can be inflicted either on the patient or his Physician by the "merces" principle, but it is constantly done under the "honorarium" system. In some instances, rare I admit, the Physician obtains, either through ignorance or excessive gratitude on the part of the patient, a much larger fee than his services warrant, or than his conscience would accept, were it not for this "honorarium" superstition. But in the far greater majority of cases he receives no remuneration whatever, or a very inadequate one, for services rendered at the cost of much time, skill, and labour. I more than suspect that the "honorarium" practice is partly the cause of nearly the whole of the public Medical service, in this country, being "honorary." Now, although this is done (except under the Poor-law) in the name and under the cloak of charity, I believe that you, with most other Medical gentlemen, denounce it as unjust and iniquitous.

With the exception of the case of our Hospital out-door patients, perhaps this system inflicts no injustice or injury on the public, for, unlike the barrister, the Physician is not paid his fee, or gift, until after he has performed his work: he cannot pocket any number of fees in the morning, on the understanding of seeing cases in the afternoon, and wholly neglect two-thirds of them, or send a junior to them to be paid by the patient. Moreover, the Physician can be, and often is, mulct in heavy damages for any want of skill or care he may exhibit in the treatment of his patient; but an unfortunate client has no remedy against the ignorance or carelessness of his advocate.

Turning to the question of policy, it is obviously to the interest of the Bar to keep up a system, enacted, strange to say, by some Roman Emperor, to control the rapacity of Doctors and lawyers, which enables a few to rapidly accumulate fortunes and to escape all responsibility. But what advantage is it to a Physician? It neither fills his pocket nor protects him from being legally responsible for his treatment. If there had been any value in it for such a purpose it would surely have been pleaded in Dr. Semple's case the other day.

Although I do not see it, there may be something in the opinion you express, that "honorarium" upholds the dignity of the Profession better than the "merces" principle of payment would. To take the case of the late Sir Benjamin Brodie, who, during the later period of his life, practised more as a Physician than a Surgeon—do you believe that the dignity and estimation of his professional character were lowered in the eyes of the world by the fact of his holding a legal title to remuneration for his services? The wealth of the Bar (i.e., of its more eminent members) is increased, but I doubt whether its dignity is increased by the "honorarium" system. The dignity of a calling is proportionate to its influence and usefulness to the community. I have yet to learn that the dignity of a cabinet minister, an ambassador, a bishop, a judge, a surgeon or dentist, an architect or engineer, is compromised by his accepting wages for his toil as "merces" rather than

"honorarium." It has always appeared to me undignified in Physicians to link themselves to barristers in this matter of fees, when the relation they bear to their respective clients is so different, and help to sanction a system of remuneration which, in the case of the Bar, is universally condemned as unjust.

Your fears that, if we established a legal title to fees, the fee would not be paid at the time, or as soon as practicable, are, I trust, groundless; at least, the consulting surgeon, the dentist, the architect, and the engineer are, as a rule, paid as soon as their work is completed.

The main question to be decided is, whether the remuneration of Physicians would be less if their fees were made recoverable at law. I hold the opinion that it would, in the long run, be much greater. If you hold the contrary opinion, you will do good service in convincing a large number of Physicians.

I am, &c.

3, Finsbury-square, E.C., January 27.

SEPTIMUS GIBBON.

[We cannot endorse our correspondent's argument. The fee system, as pursued hitherto, has been undeniably to the advantage of Physicians; they are not so often cheated as the General Practitioner. If their remuneration is to be no longer honorary, but is to be canvassed and squabbled for in a court of law, it is certain that the rate of fees will be lowered. What common jury, or even special jury, of tradesmen will be able, for instance, to conceive the propriety of paying a Physician his fee per mile for a railroad journey? The law values the special jurymen's time at a guinea a-day, and allows a fee not exceeding three guineas for the day's attendance of a Medical man at assizes. What chance of success would the Physician have who claimed fifty or a hundred guineas for a journey not occupying a longer time? The Consulting Surgeon's fee is considered honorary by the public, as is the Physician's.—Ed.]

IS QUININE (SULPH.) APERIENT OR PURGATIVE, "PER SE?"

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Allow me to suggest to your correspondent "M.D.," the propriety of testing the above question in his own person before requiring a solution of it from his Professional brethren. Opium invariably acts as a "smart purgative," when taken by the writer of these lines—may it not have a like action on M.D.?

I am, &c.

January 26.

ANOTHER M.D.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In answer to "M.D.," I think that most of us must conclude that the rationale of his case is purely depending upon idiosyncrasy.

I have a case at present of a robust and healthy child, one year old, who lately suffered from a periodic weed every day at 3 p.m. He was put upon two grain doses of sulphate of bicarbonate daily, which stopped the weed, but moved the bowels, which were habitually costive. Since then, the nurse has always found two grains of bicarbonate the best aperient she ever used for this child.

I am, &c.

Liverpool, January 26.

THOS. SKINNER, M.D.

MENSTRUATION AND CONCEPTION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—At what, if any, period after menstruation, is conception impossible? Dr. Prosper Lucas, in his admirable work, "*De l'Hérédité Naturelle*," states, in the most unqualified manner, that "there is no day, however distant from menstruation, at which a woman may not and does not conceive."—Vol. ii., p. 917. Dr. Carpenter, however, in his "*Human Physiology*," is quite disposed to limit the period of possible aptitude for conception, and can only adduce one instance, from his own experience, in which conception followed connexion occurring so long as seven days after menstruation. (P. 1004, note, 4th edition).

Can any of your readers contribute a single case in which conception certainly took place subsequently to the twelfth day after menstruation had ceased, and not immediately prior to its return? Are there any works or contributions to the journals in which this important question is discussed in addition to those referred to by Dr. Carpenter? (*Op. Cit.*, p. 998, 1004.) It is to be hoped that in the forthcoming edition of his "*Physiology*" Dr. Carpenter will be able to arrive at a definite conclusion upon the subject.

I am, &c.

January 24.

A SUBSCRIBER.

[All such evidence is hearsay, but on such evidence we know one case in which conception occurred on the tenth day after menstruation.—Ed.]

FOLLICULAR CONJUNCTIVITIS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In a recent Number of the *Medical Times and Gazette*, this somewhat rare, but highly interesting morbid condition of the conjunctiva is very instructively noticed in a review of Dr. Frank's "Report" and of Dr. Marston's pamphlet.

We should be the more especially grateful to these gentlemen for their description of the complaint by reason of the fact, as indicated by their reviewer, that no previous description of it has been given by our systematic writers on the subject.

I confess, that from what I have recently observed, I am inclined to extend the application of the sago-grain-like bodies or obstructed follicles, as proximate causes of ophthalmia, beyond the sphere of regiments or where persons dwell together in large numbers.

The condition, however, of the palpebral conjunctiva in the sporadic cases, as in the detailed, is modified in degree when compared with the typical form which these gentlemen have portrayed; or rather, it would seem that in those cases where there has been no exposure to miasmatic or unhygienic influences, the diseased condition of the conjunctiva stops short of that in which, besides follicular prominences, the connective tissue becomes studded with the grain-like bodies.

A gentleman, between 30 and 40 years of age, complained of what at first sight looked like a rather painful case of catarrhal ophthalmia, or of irritation from a foreign particle in the right eye. No cause could be assigned, and no trace of intruding substance could be detected. He had once before suffered from "a cold in the eye." The sensation of grains of sand under the lid had been marked for three days; there was slight swelling of the lower lid; considerable injection of the conjunctival vessels generally; lachrymation and intermitting periods of much intolerance of light. Vision, *per se*, was unimpaired. Search was at first made for a foreign body, but none could be found. The conjunctiva of the lower lid

was deeply reddened and roughened with distended and projected vessels. The patient seemed confident that there existed some fixed cause of irritation; and I was inclined to ascribe it to a villous projection of the mucous membrane. When, however, I had kept the lower lid everted for some little time, I perceived an indistinct opalescence in two or three spots towards the outer angle. Instead of applying a fine point of caustic to the roughened membrane, as I had intended, I scarified, with a narrow knife, these whitened follicles, producing, as the patient expressed it, instant relief, and, subsequently, an unusually speedy recovery of the eye.

Believing these facts to be suggestive of treatment, I beg to submit them to your pages. I feel satisfied that there was no disposition in the case to the formation of pustule, or of minute abscess in the lid; and I feel equally certain that the lesion described would, in all probability, have escaped my notice, had I not employed both time and patience in seeking it out.

I am, &c.

Birkenhead, January 28.

ESSEX BOWEN, M.D.

#### GROANS OF AN ASSISTANT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—While it is held that the Medical Profession is one of the noblest that can by any possibility engage the thoughts or occupy the mind, it is to be regretted that some of its members act in a most disgraceful manner; for instance, two Medical men, holding a large union, club, and private practice, residing in a town in —, have engaged a dispenser the last month; but what, think you, has been his previous experience? Was it in a druggist's shop? No; but he was an errand-boy in a draper's establishment; and these two worthy Medical men have now employed this young lad, aged 18, without any experience whatever in compounding, and pay him the miserable salary of £30 a-year, out of which he has not only to support himself, but also assist a poor widowed mother.

May I ask, is this the way to support the honour and dignity of a Profession which they have sworn to maintain? And it is to be regretted that every dispenser employed by these gentlemen has nearly been of the same stamp as the one they have now. Of course, when the dispensers get a sufficient knowledge of compounding, they leave them, and they see no reason why they should not become members of the Profession themselves, just like the last dispenser they employed, who, after over two years' hard work for a miserable salary, commences lectures next winter at one of our London schools. Of course, the poor dispenser looks to his own interest, and, as soon as he considers himself competent, looks out for a better shop, which, heaven knows, he can easily get. By acting as these two Medical men do, they admit men into the Profession who never otherwise would have a chance of getting in. Of course, they would not give them a certificate of apprenticeship. However, any one who is acquainted with the regulations at the Hall must be aware that it can be easily got over, as it is only required to have a certificate of having served after the manner of an apprentice.

You will say, perhaps, these Medical men cannot afford to give a fair salary, so as to employ a really competent assistant. I say, with truth, that they have one of the best practices in —, and one of them I have alluded to was, some years ago, lecturer at one of our London schools. I trust they may read this letter, as they cannot contradict a word I have stated. Some principals care not if their dispenser was starving, so as they get the work done; no thought whatever of his comforts; and if they could get a dispenser to work for nothing, they would gladly do so. Indeed, there resides a certain M. D. in — who boasts of kicking his assistant, but he often finds that more than he can manage.

As long as Medical assistants are treated badly by employers, and Medical men employ grocers' and drapers' boys to compound medicine—this, together with Medical men injuring each other by every mean act, lowering fees, etc., makes one ashamed to belong to such a Profession.

I am, &c.

A WELL-TREATED ASSISTANT.

[We may sympathise fairly with the misfortunes of assistants, but the laws of political economy will not be set aside; and whilst there are a large number of persons willing to do the work for little or nothing, their position cannot be improved.—Ed.]

#### CHILDREN SUFFOCATED IN BED.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As a preventive measure for this class of fatality, I wish to direct your attention, and that of your readers, to an apparatus called the "Nursing Basket," invented by Mr. C. E. Wright, of Birmingham. It has been highly approved by the Medical Profession, but not sufficiently made public. I am so well convinced of the value of the basket, that I have ordered several of them, and they are now in use among the poor of this town. A child, when laid in the basket—which is very light and portable—and placed by the side of the mother's bed at night, or on the bed, would be warm and safe, and not liable to be overlaid or suffocated, which is so often the case when mothers and nurses are in the habit of going to sleep with an infant on the arm. By the use of this admirable contrivance, safety, cleanliness, health, and comfort are promoted. It has many other advantages, some of an industrial kind, to the mother, of which I cannot now stay to speak. I merely add, that a specimen of the "Nursing Basket" may be seen at South Kensington Museum, at the Economic Museum, Twickenham, and at Madame Caplin's Museum, London. It is a subject worthy of the profound attention of the Medical Profession and of all philanthropists, not only to discover the true causes of such accidents, but to devise some efficient measures for their prevention.

I am, &c.

Brighton, January 23.

M. A. B.

#### A SINGULAR CAUSE OF ASPHYXIA OF A CHILD DURING BIRTH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The occurrence of such accidents as the one recorded below is, I am inclined to believe, very rare in obstetric practice, because I do not find in the works upon obstetric subjects any mention of it, excepting in Burn's "Principles," where mention is made of the membranes being carried forward by the head of the child—"like to a cap or cover"—forming, I suppose, the once valued caul. Nor have I been able to ascertain that it has been met with in the obstetric practice of some of my friends. From these circumstances, as well also from the medico-legal interest attached to the case, I am induced to suppose that a report of the case is not undeserving of a space in the pages of the *Medical Times and Gazette*, and thus ensure the attention of the Medical jurist.

It has occurred to me on other occasions, owing to several causes—e.g., toughness of the membranes, etc., to find the child's life in jeopardy at

the birth; but I have never met with a case of a child, quickly and easily born, cut off from life owing to a portion of the membranes being carried forwards with it, and closely applied over its head, face, and neck, like to a tightly-fitting oiled silk cap, so as completely to exclude the air from entering the lungs through the mouth or nostrils, and thus preventing the first inspiratory efforts being made.

Had this accident occurred to an illegitimate child, the mother, although anxious to avoid exposure, yet not altogether indifferent to the well-being of her child, certainly not desiring its death, would be exposed to serious suspicions. For supposing the birth to be sudden—almost unexpected, as in this instance—did she, when recovered from the shock, endeavour to ascertain the condition of the child and remove the membranous bag from the head and face, she would, if early, probably ensure the child's life; but if, as in this case, some minutes had elapsed, its death would be certain, and no statement the woman might make would secure her from the suspicion of infanticide.

May not some of the cases of presumed infanticide find an elucidation from the occurrence of accidents similar to this? If so, it must be confessed that such cases are deserving of consideration.

Mrs. W., married, required my attention January 17, 1863, she being in labour of her third child.

I may here remark that this patient has hitherto experienced lingering labours, owing to some slight deformity about the sacral prominence: on the two previous occasions she experienced severe pains, accompanied by the discharge of much fluid two or three days before actual labour commenced.

On January 15 I received notice of her condition, she having, whilst at dinner, experienced considerable pain a short time; during the continuance of this pain she felt something give way within her, and much watery fluid escaped from her. The remainder of the day she passed comfortably in her room, and when I saw her on the evening of the 16th she was moving cheerfully about, and was comparatively easy. On the evening of the 17th she became rather more distressed, and, experiencing some three or four decided and sharp uterine pains, I was at once sent for, she having now resumed her couch. I reached her at ten or twelve minutes, and found her on the bed in the usual obstetric condition. I was surprised to learn, in answer to some queries as to her state, that the child was born, and that it had been so almost before she could properly dispose herself upon her bed; it was very quiet, but it had moved its feet slightly once or twice.

Concerned as to the extreme silence of the child, I at once proceeded to ascertain its condition, and found the infant all but fully born, lying upon its back, motionless, warm, and perfectly white; the face, head, and body covered with sebaceous matter, but looking very smooth and glistening, as if varnished; the mouth and eyes firmly closed, and the lips very pale in colour. On feeling for pulsation over the region of the heart, and finding it absent, the cord was appealed to, and about an inch or so from the body the umbilical arteries could be felt distinctly, but slowly and feebly pulsating. That the child was in a condition of asphyxia was evident, but from what cause was not so evident, for there was no exclusion of air by the pressure of the clothes, nor had any restraint been imposed on the child from the position of the mother: the cause was allowed to remain unexplained for a time, and endeavours were at once employed to restore life to the child. Hot and cold water were both abundant and at hand.

As a preliminary to the employment of measures to effect the restoration of suspended animation, I proceeded to cleanse the child's face with a sponge from warm water, and was surprised to meet with some difficulty about the mouth, the entrance of my finger being resisted by the interposition of a very transparent membrane, which, puckering up about the chin, enabled me to seize it and to draw it from off the entire face and head, to which it had been closely applied, giving to the surface a glistening appearance, and completely cutting off the air to the lungs through the mouth and nostrils. On removal of this membrane from off the child's head and face, endeavours were made to recall life by the employment of the Marshall Hall method: hot and cold water, the introduction of the tracheal tube—these and other expedients proving futile after twenty-five minutes had elapsed, no respiratory movement being excited in the child, and it having become cold, and the pulsation of the cord having ceased through its entire extent, the connexion between the placenta and child was divided, a few drops of blood, dark coloured, escaping. The placenta was readily removed in twenty minutes later. The mother subsequently did well.

In conclusion, it is to be regretted that her nurse was absent, an inexperienced friend being only present at the birth. I have also to deplore my absence, for, had I been in time, the membranes would have been much earlier ruptured, so as to have permitted the child's head to have entered the world entirely free from them.

Jermyn-street, S.W.

FREDERICK HALL, M.R.C.S., etc.

#### ON THE TREATMENT OF DIABETES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the *Medical Times and Gazette* of Saturday last appears a "Case of Diabetes Successfully Treated by the Saccharine Method," contributed by Mr. Ussher, of Canterbury. In connexion with this case there are one or two points concerning which I, and possibly some others of equally dull apprehension, would like some more information, as, on reading and re-reading the contribution, I cannot light on a single word or passage touching the administration of sugar, which, in this instance, is set forth as the curative agent by the author. Of this, however, more hereafter; and, in the meantime, I would beg to inquire what was really the condition of the patient when first seen? Under what particular disease was he labouring so heavily that "he was in bed; face very much flushed; eyes glazed; tongue hauging from the mouth; lips covered with sores; skin harsh and dry; intense thirst; inability to sleep or take a morsel of food; sternal pains severe and constant; bowels constipated?"

From this enumeration of symptoms, apparently so fatal, are we to understand that the man was dying of diabetes; and that by a combination of "spt. junip., liq. hydrarg. bi. chl." with "inf. tilæ Europ.," he was happily restored to life even when in the jaws of death? At the risk of being considered impertinently curious, and even disgustingly hypercritical, I would like to have some light thrown on the therapeutic effects of this combination of remedies—as to how the "spt. junip." (by which, I presume, is meant the spt. junip. co.) with the "inf. tilæ Europ." (by which is probably indicated inf. tilæ) and the "liq. hydrarg. bi. chl.," acted so well together in bringing round a patient apparently dying of diabetes. In my humble opinion this mode of treatment savours much of the motto—"Similia similibus," etc.—But there are such strangely ingenious

remedies turning up now-a-days, that we can only open our eyes, and express our thanks for all the mercies.

The patient was, no doubt, diabetic, and no doubt he was, as reported, restored to comparatively good health by a highly-varied system of tonics, and by a proper and nutritious dietary, including glycerine; for I take leave to question whether this substance contributed to the cure in any other way than by supplying nourishment, just the same as, though in a less degree than, cod-liver oil would.

If glycerine be claimed as the chief remedial agent in this case, and as illustrating, as it is evidently meant to do, the saccharine mode of treatment, I would beg to ask in what way it can exert any curative influence further than by supplying nutrition to a wasting body? Does it, sugar of oils though it be called, go to supply the place of the grape sugar, which is being rapidly eliminated from the diabetic patient? I cannot subscribe to the notion that the exhibition of glycerine is an illustration of the "saccharine method" of treatment. "To furnish him," says Mr. Ussher, "with this sugar in the quantities that he can appropriate will stop the downward progress as it did in this case; while the other constituents of glycerine will help to restore the general decadence." I would beg to inquire, what are the constituents of glycerine that remain after the appropriation of the sugar; and in what manner these constituents "will help to restore the general decadence?"

The pathology of diabetes is, doubtless, hard to be understood; but, thanks to the talented Pavy, whose researches on this subject are worthy of all praise (though I do think it has been meted out to him rather niggardly), it is becoming more intelligible; and he who would spin fine theories on the dogma—that the normal function of the liver is to form sugar, either ignorant of, or wilfully ignoring, Pavy's most conclusive experiments, ought to be "sent to Coventry."

I am, &c.

HYPERBOREUS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your valuable Journal of the 17th inst. a case appeared, which "is a capital illustration of that cardinal defect in Medical reasoning which the *Medical Times and Gazette* finds its special vocation in correcting." The case I allude to is one by H. Ussher, M.B., of "Diabetes Successfully Treated by the Saccharine Method, and Remarks thereon." The writer terms his method the "saccharine," but from first to last not a particle of sugar, or of anything allied to sugar, was administered. Glycerine is, no doubt, sweet, but so is hyposulphite of silver, and also sugar of lead, but yet no one ever dreamt of applying the term "saccharine" to either of these two latter substances. Glycerine has no resemblance whatever to sugar of any form, but is, in reality, an alcohol of the teratomic type, its formula being  $C_3H_5O_3$ , whereas all true sugars possess an equal number of equivalents of hydrogen and oxygen. But even granting that glycerine is or contains sugar, as asserted by the writer, it does not at all follow that the good effects observable were due to it alone; for, in addition, the patient got a regular hotch-potch of quinine, iron, nitric acid, hyposulphite of soda, acetate of zinc, cod-liver oil, chiretta, hyoscyamus, strychnia, Dover's powder, alterative pills, and, lastly, a regulated diet.

Some of the prescriptions in this case are so peculiar as to deserve a passing notice. Take, for instance, the following:— $\mathcal{R}$  Quinae dis., gr. viij.; ferri am. tart., gr. x.; acid. nit. dil.,  $\mathcal{z}$ j.; tr. hyoscyami,  $\mathcal{z}$ j.; glycerinae,  $\mathcal{z}$ ij.; aq. ad  $\mathcal{z}$ viiij., M. Now, in this most of the iron will be thrown down as sesquioxide, in consequence of the decomposition of the salt by the acid, so that the mixture will be, to say the least, inelegant. But six days later we find a far greater blunder committed, viz., the adding to this acid mixture gr. xij. sodæ bicarb. In order to ensure the whole of the iron being converted into as inelegant and inert form as possible, we find a new remedy introduced into a precisely similar mixture, viz., tincture of chiretta, the proper and peculiar action of both the acid and chiretta being thus impured. On May 19 we find a prescription which nothing but a very decided predilection for homœopathy could have induced him to write.  $\mathcal{R}$  Ferri am. tart.,  $\mathcal{O}$ j.; liquoris strychniæ, gr. j. ad  $\mathcal{O}$ j.  $\mathcal{z}$ j.; quinae dis., gr. vj.; acid. nit. dil.,  $\mathcal{z}$ j.; aq. ad  $\mathcal{z}$ viiij. How this is to be taken is not stated, but taking it like the preceding, at the rate of  $\mathcal{z}$ ss. ter. die, the strychnia in each dose would be exactly 1-2560th of a grain; so that it would require at least fifty-two days before the patient would have ingested the amount of one ordinary dose (1-16th gr.), even allowing that this drug is cumulative in the highest degree.

As to the method by which the writer estimated the amount of sugar, it is one which has been repeatedly proved to be so variable and fallacious in its results, that the figures stated by him cannot be relied upon. In many cases, indeed, the "companion phial" will not yield even an approximation to the truth. Thus, on April 27, the specific gravity of the urine was 1.035, yet in two specimens of it the amount of sugar per ounce was respectively eighteen grains and seven grains. Now, it would be hard to account for this great difference except by supposing that some very great increase of urea had occurred, which would, of course, keep up the specific gravity, though scarcely to such an extent as would reconcile the writer's results with those of experience.

In the remarks which follow, there are one or two curious assertions made, which it would be interesting, as well as instructive, to have more fully elucidated. Thus, the connection of the liver with the skin has not, I believe, been noticed by any anatomist up to the present time. Nor does it appear from observation that proximity of any organ to the surface of the body renders it co-ordinate in use to the skin, so that the "numerous illustrations" of this fact as regards the liver would be extremely valuable.

In the last paragraph but one of his paper, Dr. Ussher, not content with asserting glycerine to be a sugar, states "that the other constituents will help to restore the general decadence." This manifestly implies that glycerine consists of sugar and certain other flesh-producing and calorific materials,—a fact previously as unknown to chemists as the connection of the liver and skin to anatomists. These being the chief points of interest in this curious case, and a apologise for the length of this communication,

I am, &c.

APPOINTMENTS FOR THE WEEK.

January 31. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.  
ROYAL INSTITUTION, 3 p.m. W. S. Savory, Esq., F.R.S., "On Life and Death."

February 2. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.  
MEDICAL SOCIETY OF LONDON, 8½ p.m. Dr. Cockle, "On the Conditions of the Aorta Simulating Aortic Insufficiency." Mr. Streeter, "On Disease of the Brain by Extension from the Ear." Dr. Greenhalgh, "On a New Metrotome." Dr. Richardson, "On Nitrate of Amyle." Communications from Drs. Gibb and Thudichum, Mr. Baker Brown, and others.  
ODONTOLOGICAL SOCIETY OF LONDON, 8 p.m. Meeting.

3. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.  
ETHNOLOGICAL SOCIETY, 8 p.m. Mr. Dunn, "On some Observations on the Psychological Differences which Exist among the Typical Races of Man."

4. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.  
OBSTETRICAL SOCIETY OF LONDON, 8 p.m. Mr. Baker Brown, "On Vesico-Vaginal Fistula—the Results of Fifty-five Operations at the London Surgical Home." Dr. Shortt, "On the Medical History of Woman in India."

5. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.

6. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.  
MEDICAL SOCIETY OF LONDON, 8 p.m. Meeting of Council.  
WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON, 8 p.m. Practical Evening, for the Narration of Cases and the Exhibition of Specimens.

EXPECTED OPERATIONS.

King's College Hospital.—The following Operations will be performed on Saturday (to-day) at 2 p.m. :—

By Mr. Fergusson—Lithotrity; for Vesico-Vaginal Fistula; Necrosis of Lower Jaw.

By Mr. Henry Smith—For Hare-lip; Nævus.

By Mr. J. Wood—Plastic Operation upon Neck.

COMMUNICATIONS have been received from—

HYPERBOREUS; Dr. J. LANG; Mr. J. HAZARD; A REGISTERED MIDWIFERY DIPLOMATIST; L. L. G. F.; F.R.C.S.; A. B.; A WELL-TREATED ASSISTANT; MR. LE GROS CLARKE; F.R.C.S.I.; A FOURTH YEAR'S MAN; M.D.; MR. F. HALL; Dr. HOOG; OLDHAM; A FATHER; ANOTHER M.D.; A SECOND WHO WAS THERE; MANCHESTER; Dr. G. JOHNSON; Dr. BARRIE; MR. STONE; Dr. GIBBON; Dr. ESSEX BOWEN; Mr. F. L. CRUMMEY; THE SECRETARY OF THE LONDON MEDICAL SOCIETY; Dr. E. ELLIS.

# NEPENTHE, OR ANODYNE TINCTURE.

OBTAINED EXCLUSIVELY FROM OPIUM.

Prepared only by **FERRIS, TOWNSEND, LAMOTTE, & BOORNE**, Manufacturing Chemists and Wholesale Druggists, Bristol.

Messrs. FERRIS AND COMPANY take leave to direct the attention of the Medical Profession to a selection from various reports upon the use of this most valuable form of Opium. NEPENTHE may be used with perfect safety in every case where an opiate is indicated; and, from the peculiar process by which it is prepared, it is deprived of all constituents which render the Tinctura Opii, and most other forms of opium, in numerous instances, wholly inadmissible. NEPENTHE is always of uniform strength, and, in this respect, possesses high advantages. It may be procured direct from the Manufacturers, Messrs. FERRIS and COMPANY, Bristol, or through the leading Wholesale Druggists in London, and from most respectable Dispensing Chemists in Great Britain and Ireland. Every bottle has a fac-simile of Messrs. FERRIS and COMPANY'S Signature pasted over the Cork, to imitate which is forgery.

The price of NEPENTHE to the Profession is 8s. per lb., and the dose the same as the Tinctura Opii.

### Report from F. PORTER SMITH, Esq.

I have pleasure in bearing testimony to the decided advantages possessed by Messrs. Ferris and Company's preparation of Opium called "Nepenthe" over other preparations of that important drug. I have used it for several years in Cancer of the Uterus, continuing it, with scarcely abated advantage, as a sedative, in one such case, for the long period of eighteen months, in doses of, at the utmost, half a drachm, which served the purpose to the end. I have used it in "Subcutaneous Injection" for Neuralgia, without producing any local irritation, such as abscess, &c. In the cases of unusually

severe "after-pains" in connexion with labour, I can strongly recommend and endorse its successful and satisfactory employment. I have never met with any unpleasant symptoms, such as sometimes occur in some constitutions after the administration of morphia, &c., during an extensive use of this valuable addition to that "Practical Pharmacopœia" which waits for no "imprimatur" from College or Council.

F. PORTER SMITH, M.B. Lond.,  
Evercreech, March, 1862. Associate of King's College, London, &c.  
\*\* Fresh Reports will be published in the Medical Journals from time to time.—Bristol, 1862.

## *Pulvis Jacobi ver, Newbery's,*

is the ORIGINAL & GENUINE, was ESTABLISHED A.D. 1746,

And is Prescribed, with the greatest success, "by the highest authorities," for Fevers, Ague, Cerebral Congestion, Rheumatism, Chills, Influenza, &c. &c.

**FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.**

Prices for Dispensing—1 oz., 9s.;  $\frac{1}{4}$  oz., 3s. 4d.

### WALTERS' INDIA-RUBBER URINALS.

F. WALTERS having originally invented these Urinals, begs to warn the Profession of the many bad and useless imitations which are now sold, and he would advise them, before purchasing, to look that they are stamped with his name; as, unless that be the case, he cannot guarantee them.

These conveniences are made for those who require them only occasionally, during a long journey, as well as for those invalids who use them always. Mr. WALTERS has much improved them by making them of *Etherised India-Rubber*, which adds very greatly to the strength of the India-Rubber, at the same time that it prevents its sticking together; by this means he is enabled to make them less stiff and harsh than hitherto, and yet to retain all the advantages of that stiffness. There is a patent valve which prevents the return of the fluid; and they may be worn either sitting, walking, or lying, without the slightest inconvenience, and without being perceived by any one.

WALTERS' CONVENIENCES FOR LADIES will be found particularly useful during pregnancy. They are perfectly soft and flexible, and may be worn with perfect comfort.

*All Orders must be accompanied by a Post-office order or reference.—Entrance for Ladies at the private door, where a Female attends.*

**MANUFACTURER OF ELASTIC STOCKINGS, BELTS, &c.**

16, MOORGATE STREET, NEAR THE BANK, LONDON, E.C.

TRADE MARK

## CHLORODYNE

WAS DISCOVERED AND INVENTED IN THE YEAR 1848 BY  
**DR. J. COLLIS BROWNE, M.R.C.S.L. EX-ARMY MED. STAFF**  
AND IN 1856 HE CONFIDED  
**THE ORIGINAL AND ONLY FORMULA**  
FOR ITS MANUFACTURE  
SOLELY TO **J. T. DAVENPORT, PHARMACEUTIST,**  
33, GREAT RUSSELL ST. BLOOMSBURY SQUARE, LONDON.  
REGISTERED, 1856

### NOTIFICATION.

The attention of Medical Men is directed to the Piratical application, by some parties in the Trade, of the term "Chlorodyne" to various mixtures compounded of Chloric Ether, Opium, Indian Hemp, and Peppermint, in Imitation of the ONLY Genuine preparation of this name.

The dangerous expedient of encouraging or advocating the assumption of a name specifically indicating a particular property or remedy—such as *Chlorodyne* is to spurious imitations and substitutions—ON THE GROUND OF CHEAPNESS, is a subject of surprise and grave reproach, supremely so, when the adulteration, sophistication, and tampering with Drugs, becomes so serious and important a consideration in the successful practice of Medicine.

The fact of these Piracies must fully convince the Profession of the extraordinary efficacy of the Genuine *Chlorodyne*; whereas the sad results and disappointment arising from the use of spurious compounds cannot be expressed.

Each Genuine Bottle bears a Red Stamp, with the words, "Dr. J. COLLIS BROWNE'S CHLORODYNE," in White Letters.

To be obtained from all Wholesale Druggists in 1oz., 2oz., 4oz., and 8oz. Bottles.

## ORIGINAL LECTURES.

A CLINICAL LECTURE  
ON THE  
DIAGNOSIS OF HERNIAL AND OTHER  
TUMOURS OF THE GROIN AND SCROTUM.

DELIVERED AT THE  
Westminster Hospital.

By CARSTEN HOLTHOUSE,

Surgeon to the Hospital, and Lecturer on Anatomy in the Medical School.

GENTLEMEN,—From what we know of the anatomy of the parts in the groin, it should follow that inguinal hernia would occur most frequently in the male, and femoral hernia in the female, and this is fully borne out by the statistics of the two affections; indeed, so true is it, that, knowing the sex, we are apt to prejudge the nature of the hernia, and sometimes erroneously, as happened in the following case, with which most of you are familiar. A man, 47 years of age, was lately admitted into Luke ward with strangulated hernia, supposed to be inguinal. A tumour of an oblong form occupied the left inguinal region, its long axis was parallel with Poupart's ligament, and it projected a little above this structure. It differed, however, from an inguinal hernia in the following important particulars:—1st. Its outline was more defined. 2nd. It was more prominent. 3rd. It was more superficial. An inguinal hernia in this situation must have been wholly or in part within the inguinal canal, and, therefore, beneath the aponeurosis of the external oblique, which, owing to its unyielding nature, would have prevented such a prominence and such a definition of the tumour as was here apparent; but the decisive test for determining whether it were an inguinal or a femoral hernia, consisted in carrying the finger into the inguinal canal. This you saw me do: invaginating a portion of the skin of the scrotum on the end of my forefinger, I passed it into the inguinal canal, and found this passage free, and the tumour lying in front of my finger. There could be no doubt, then, that this was a femoral hernia, —one of those cases I have before spoken of to you, in which the hernia, having presented itself at the saphenous opening, and continuing to increase, takes the course in which it meets with the least resistance, viz., upwards. The taxis having failed to return the hernia, the usual operation was performed, and the patient, as you know, left the Hospital well a few days ago.

In the female, the demonstration of the variety of hernia is less perfect than in the male; this arises from the impossibility of carrying the finger into the inguinal canal, owing partly to the absence of any lax skin like that of the scrotum, partly to the small size of the inguinal canal, and partly to the existence of a large quantity of subcutaneous fat; this is so abundant in some women, that the different outlets through which a hernia may protrude are with difficulty made out. In these cases, you must be guided in your diagnosis chiefly by the duration, position, and size of the hernia: a recent one could not be situated *above* Poupart's ligament, unless it were inguinal, and in this case it would be small, ill-defined, and little prominent, causing a fullness rather than a tumour; while a small and recent hernia *below* that structure (Poupart's ligament) would show it to be femoral. A large and old femoral hernia might, as already seen, turn up over Poupart's ligament, and so occupy the inguinal region, but it would produce no alteration of the labium pudendi of the same side; whilst, on the other hand, a large and old inguinal would pass down into the labium, and produce a marked contrast between it and its fellow. There is, however, a variety of inguinal hernia which descends into the thigh instead of into the scrotum or labium, and so resembles a femoral hernia; but this is so rare an affection, that I need do no more than call your attention to the fact that such a hernia has been described. Its diagnosis from a femoral hernia might probably be established by a careful examination of the tumour and by the history of its origin and progress.

I now come to the second and more important part of my subject, viz., the diagnosis of hernia from other swellings which bear some resemblance to it, and these may be classed under two heads:—1st. Those situated in the neighbourhood of the

groin, including the region immediately above and below Poupart's ligament; and 2nd. Those met with in the scrotum or labium. Among the tumours in the former situation may be enumerated enlarged glands, abscesses, imperfectly descended testis, hydrocele and hæmatocele of the cord, adipose tumour of ditto, the fibrous tumour of the iliac fossa of M. Nélaton, occurring, for the most part, only in females, aneurism, dislocation of the femur upon the pubes. The three last of these may be fairly dismissed from our consideration, as their characters are too well marked to be likely to be confounded with hernia. The tumours in the scrotum or labium which bear some resemblance to hernia, are hydrocele, common and encysted, hæmatocele, varicocele, sarcocele, and other tumours of the testis or cord; and, in the female, cysts and chronic abscesses of or in the labium.

Enlarged glands have been mistaken for hernia, and *vice versa*. Here are two casts, one of a direct inguinal hernia, and the other of a chronically enlarged gland, and, as far as appearances only are concerned, they certainly bear a very close resemblance to each other; but there was no other point of similarity: the one was reducible or disappeared on pressure, the other did not; the one was soft and elastic, the other hard and unyielding; the one had an impulse communicated to it on coughing, the other had not; the one first appeared suddenly, the other had been slowly growing. And here I must caution you against relying implicitly on the statements of patients. A widow, 66 years of age, presented herself among the out-patients, when I was Assistant-Surgeon to this Hospital, with a tumour in the left groin, which she called a rupture. She said she first observed it about nine months ago after carrying a heavy load, and that till quite lately she had been able to reduce it; she was now unable to do so, and, therefore, came to the Hospital to have it reduced. On examination, I found a large red, irregular-shaped tumour, evidently composed of a mass of diseased glands, and on further investigation I discovered that the source of this enlargement was carcinomatous ulceration of the uterus and vagina: yet so prone is poor human nature to deception, and so loth to be undeceived, that this patient went away dissatisfied that her so-called rupture was not returned, and, as I afterwards learnt, she declared that her case was not understood.

Abscesses, one would imagine, could scarcely be mistaken for hernia, did we not know by experience that the contrary is the fact. You have all, I believe, seen a case now under my care, in which this mistake was committed. The patient, a mariner, 29 years of age, presented himself at the Surgery, with an oblong swelling, extending obliquely from near the right anterior superior spine of the ilium to the spine of the pubes; the skin over it was of a natural colour, but it was slightly tender on pressure, especially towards its iliac extremity; it distinctly fluctuated, no impulse was communicated to it on coughing, and it could not be made to disappear on pressure. The history the patient gave of the tumour was the following:—About two weeks ago, on going aloft, he felt some stiffness in the hip-joint, and, on examining his groin, found a small swelling, as large as a walnut. He immediately consulted a Medical man, who told him it was an enlarged gland, and prescribed accordingly; but, at his next visit, on finding it larger, it was pronounced to be a rupture, and a truss was applied. This the patient was wearing when he came to the Hospital.

Only a few days ago, I was requested by a Surgeon in the country to see a female, who had a swelling in the right groin, about the nature of which he was doubtful, though he suspected it to be a femoral hernia. It was soft and elastic, and partly reducible; but it was also dull on percussion, fluctuating, and slightly tender on handling. It was a psoas abscess. But not only are abscesses sometimes mistaken for hernia, but the latter for abscesses. Some years ago, while I was Assistant-Surgeon to this Hospital, a female, 46 years of age, was sent here from the country, with a large tumour in the right groin; the skin over it and around it was discoloured, having a bruised or ecchymosed appearance, as if the tumour had received a severe blow, or been roughly manipulated. This discoloration, together with its great size, and the absence of any definite history, led the Surgeons who saw it to doubt whether it were a hernia, and one of them inclined to the opinion that it was an abscess. However, as the bowels had not acted for three days, it was determined to make an exploratory incision into it. Extravasated blood escaped from the incision, and, on cutting deeper, the sac of a large hernia was opened, from which escaped a

dirty, bloody, stinking fluid, revealing two large knuckles of distended ileum, partly gangrenous. The patient only survived the operation about six hours. Now, I have related this case for the purpose of illustrating two facts:—1st. That a hernia may so far resemble an abscess as to lead even experienced Surgeons to be doubtful of its nature; and, 2nd. That this doubt could never have arisen had a very simple test been applied, to which I shall again allude presently,—viz., percussion of the tumour. The fluctuation of an abscess is usually considered sufficient to point out its true nature; and so it is as a general rule, and in by far the greater number of abscesses; but the impression conveyed to the fingers by fluid within a cavity, and which we call fluctuation, is not always perfectly unequivocal,—it may be simulated by certain tumours of a malignant nature, or by a knuckle of intestine containing air, especially if a certain thickness of soft parts, or a stratum of fluid, intervene between the fingers and intestine; or, again, it may be absent, or, at all events, so obscure, owing to the distance of the matter from the surface, that error may arise from this cause, as happened in the following case:—A delicate female, 23 years of age, came under my care at the Lincoln's-inn Public Dispensary, in November, 1842, for a tumour about the size of a swan's egg, situated at the upper, anterior, and internal part of the thigh. It was movable, apparently solid, somewhat irregular on its surface, and felt like a fatty tumour; it was free from pain on pressure, and the skin over it was of a natural colour. Several Surgeons who saw it considered it to be a fatty tumour, and on this supposition the patient was admitted into one of our Hospitals to have it removed. During the operation, a sudden gush of matter took place; the Surgeon, while detaching the supposed tumour from its surrounding connexions, accidentally cut into it; it was the sac of an abscess—of a psoas abscess; and within a week the patient was dead.

But you will say in an abscess there is no impulse on coughing; well, this depends on its locality; abscesses in certain situations may have an impulse communicated to them on coughing; and it so happens that the situations in which this occurs are just those in which hernial protrusions take place, as the lower part of the abdomen and the upper part of the thigh; it is in the latter situation that psoas abscesses point; and as the upper part of their sac is situated within the abdominal cavity, you can easily understand how an impulse must be communicated to their lower part by coughing or straining, or by any act by which the sac is compressed between the viscera and abdominal wall. These abscesses also occasionally resemble a hernia in another respect—they may diminish or almost disappear on lying down, reappearing or becoming larger on standing up. If abscesses, then, may simulate hernia in so many important particulars, and hernia occasionally resemble abscesses, is there no other means of distinguishing them, you will ask, than by resorting to the knife? Fortunately there is; and it is so very simple that it seems almost incredible it should ever be overlooked—it is percussion of the tumour: the sound elicited on percussing an abscess is nearly always dull, while percussion of a hernial tumour, which might otherwise resemble it, is clear. I say *nearly* always, because I have met with a few exceptions in which air, as well as pus, occupied the sac of an abscess; but these were cases, either where the abscess had been previously opened and afterwards closed, and where, therefore, all doubt of the nature of the swelling had been removed; or they were anal abscesses, which are always preceded by unequivocal signs of inflammation of the part, and in no respect resemble any form of hernia.

An undescended testis has not unfrequently been mistaken for a hernia. I have seen the mistake committed more than once, and once I saw it cut down upon, in the belief that it was a strangulated hernia. A man has had one testicle in his inguinal canal all his life; he has noticed the swelling, and has fancied, or been told, that he has a rupture; he has even, in some cases, worn a truss for it. From a slight hurt or other cause, the tumour becomes inflamed and painful, and increases in size; this is not unfrequently accompanied with sickness and constipation, and other constitutional disturbance, and a Surgeon is consulted; he takes note of the above symptoms, but he does not observe that only one testicle is in the scrotum; and the case is pronounced to be a strangulated hernia. Hydrocele of the cord, whether encysted or diffused, bears some resemblance to hernia: a movable tumour, circumscribed in the one case, diffused in the other, occupies the inguinal canal, and, perhaps, the upper part of the

scrotum, and can be pushed towards the abdominal and scrotal cavities, but not completely into them, as, indeed, is the case with an irreducible bubonocoele: the difference consists in this—the hydrocele is fluctuating to the touch, and dull on percussion, whilst the hernia is either elastic to the feel, resonant on percussion, and has a distinct impulse communicated to it on coughing, in which case it is intestine; or it is neither elastic, resonant, nor fluctuating, but doughy to the feel, in which case it is omentum. The chief points in which a hæmatocele of the cord differs from a hydrocele of the same part are,—1st. The mode of its occurrence, coming on suddenly after violent exertion, or a blow on the part; 2nd. The occasional presence of ecchymosis; and, 3rd. The indistinctness of the fluctuation. In the suddenness of its appearance it is more suggestive of hernia than is hydrocele of the same part, in illustration of which I will read you the following case from Pott:—A labouring man, who had fallen down in the street, with a load on his back, was brought into St. Bartholomew's Hospital, on a suspicion of his having got a rupture in consequence of his fall, he having immediately perceived a swelling in his groin and scrotum which he had not before. The tumour seemed to occupy the whole spermatic process, which was so enlarged by it that it was impossible to feel the passage of it from the abdomen through the muscle; but the testicle below it was perfectly distinct. The appearance of a tumour, the suddenness of its formation, the distinct situation of the testicle below, and the accidental circumstance of the man's not having had a stool for two days past, inclined Mr. Freke (whose week it was) to believe it to be, and to treat it as, a rupture. He made some attempts for reduction, and, finding them fruitless, determined upon the operation immediately.

He divided the skin and membrana adiposa down to what he took to be the hernial sac; and, when he had done so, had a mind to endeavour at the return of the intestine without opening the sac. Accordingly, with his probe scissors he divided the tendinous opening in the abdominal muscle, and then again tried to reduce the gut, but to no purpose, for nothing would go up. At last, though with much reluctance, he was obliged to lay open the containing membrane. He had no sooner done this, than a large quantity of blood, partly fluid and partly grumous, burst forth, and the whole tumour subsided, leaving the process perfectly free, and containing neither intestine nor omentum.

A combination of hydrocele of the cord with incomplete descent of the testis is sometimes met with, as in the following case, which some of you may probably remember. Here is the case. It is so instructive, that I will read you some of the notes of it from my case book:—

H. B., aged 48, blacksmith, was admitted into Henry Hoare ward early on the morning of March 19, 1861, with a painful tumour in the right groin, for which he was wearing a truss, and great tenderness and distension of the abdomen. The tumour, he said, had become much larger since the 16th, and on the day before his admission he had had vomiting. His pulse was feeble, and there was considerable prostration. The House-Surgeon, believing the case to be one of strangulated hernia, placed the patient in a warm bath and tried the taxis; but the swelling not yielding to these means, I was sent for. Hearing that the taxis had been tried without success, I gave directions that everything should be got ready for operating; and, on my arrival, I found the patient already on the operating table, and the inhalation of chloroform commenced. As soon as he was under its influence, I proceeded to make an examination of the tumour, which certainly presented most of the external characters of an inguinal hernia. On proceeding to handle it, however, I was at once struck by its softness, want of tension, and mobility, clearly showing that, even if it were a hernia, it was certainly not strangulated. Then, again, it distinctly fluctuated, and was dull on percussion. On examining the scrotum, the testis was found to be absent on this side, but, on carrying the finger into the inguinal canal, a small solid body, probably that organ imperfectly developed, was distinctly felt. The patient was carried to bed, and when fairly recovered from the effects of the chloroform, the following history was obtained:—Twenty-five years ago, whilst lifting a heavy weight, and giving a sudden jerk to raise it a little higher, he felt something give in his right groin, with great pain. He continued his work, however, and did not examine the part till night, when he found a hard lump, tender on pressure, and as big as a small marble. For five weeks afterwards he had some pain in the "lump," but it underwent no change in size or consistency.

Twelve years ago he was persuaded by one of his mates to wear a truss; and he has continued to wear one ever since. From the first appearance of the tumour he has been subject to occasional attacks of pain in it, attended with an increase of its size and hardness. He thinks that it has altered to its present size and softness within the last five years only; but he is not certain on this point. He is not an intelligent man, and was not aware that he had only one testicle in the scrotum.

So much for the history of the tumour: now for the history of the symptoms for which the patient was admitted. It seems that he had been out of work for some weeks, and living very miserably. So far from there being any intestinal obstruction at the time of his admission, he was actually suffering from diarrhoea, hence the tympanitis and abdominal pain, which had been mistaken for peritonitis. Now, you will naturally ask, how came this case to be mistaken for strangulated hernia? The answer is simple. One little fact had been overlooked,—the bowels were not obstructed, and this single link wanting to complete the evidence of strangulation, all the other symptoms went for nothing. Nevertheless, it must be conceded that the tumour, the truss, the distended and painful abdomen, the prostration and vomiting, were well calculated to throw a Surgeon off his guard, and so lead to the error in question.

Very much resembling an epiplocele in the canal, especially if this be irreducible, is the fatty tumour of the spermatic cord, which, indeed, can scarcely be distinguished from it, and, perhaps, not certainly diagnosed. This is not of much importance, because, unless symptoms of strangulation are present, neither the one nor the other requires to be meddled with. In my next lecture I will direct your attention to the tumours of the scrotum and labium which resemble hernia.

(To be continued.)

ORIGINAL COMMUNICATIONS.

NOTES ON CAUSES OF EARLY MORTALITY.

By J. WHITEHEAD, M.D.

No. IV.

DEATH-RATE IN INFANCY.

(Continued from page 107.)

The French statistics bearing on this subject present some points of additional interest, inasmuch as the records are more minute for the early stages of infancy, whilst the illegitimate, in all essential points of their history, are separately distinguished.

There is one remarkable feature in the French death-rate, which is this. Although the general rate of mortality is considerably and constantly higher in France than in England, yet, during a large portion of early childhood, it is as remarkably and as constantly lower. The disparity may not be very striking in the first year's results, but will be found to be sufficiently so during the few following years. The average first year's rate, in France, for the fifteen years ending with 1831, stands at 18.24, which is very high. There is no result extant for England during the same period; but the average, thirteen years later, for the six years ending with 1844, is 14.80, being 3.44 per cent. lower than that of France. Allowance must be made, however, for improvements which may have been effected in England during these thirteen years; so that the disparity might not have appeared so great had it been possible to compare the results contemporaneously.

It is remarkable, that the preponderance in the French results occurs chiefly during the first three months of life, after which the estimates are lower than those of England to the end of the first year, and lower also, as will be shown hereafter, for several years later. Compare, for instance, the details for the two epochs referred to, as given below:

FRANCE.			
Months.	Deaths (first year) to 100 births, 1817 to 1831.		
	Males.	Females.	Total.
0 to 3	6.76	5.27	12.03
4 to 12	3.32	2.89	6.21
First year	10.08	8.16	18.24

ENGLAND.

Months.	Deaths (first year) to 100 births, 1839 to 1844.		
	Males.	Females.	Total.
0 to 3	4.13	3.26	7.39
4 to 12	4.07	3.34	7.41
First year	8.20	6.60	14.80

Showing an excess, during the first three months, of the French rate over the English, to the amount of 4.64; but, on the contrary, an excess for the remaining nine months, of the English rate over that of France, to the amount of 1.20 per cent.

Take again the respective issues for the two countries during the same term of life, at a more recent date:

FRANCE.

Months.	Deaths (first year) to 100 births, 1855, 1856, 1857.		
	Males.	Females.	Total.
0 to 3	6.01	4.70	10.71
4 to 12	3.73	3.17	6.90
First year	9.74	7.87	17.61

ENGLAND.

Months.	Deaths (first year) to 100 births, 1858, 1859, 1860.		
	Males.	Females.	Total.
0 to 3	—	—	3.51
4 to 12	—	—	6.74
			15.25

Exhibiting still an excess in the French first year's mortality of 2.20 per cent., and also an excess on this, an exceptional occasion, for the remaining nine months of .16. But it is due to observe, that the French death-rate has steadily decreased from the epoch ended 1831 to that ended 1857 to the extent of, for the first three months, 1.32, and for the whole of the first year, .63; whilst the English rate, from the first to the second of the epochs above recorded, has increased to the amount, for the first three months, of 1.12, and for the whole of the first year, of .45.

The causes of this differential fatality, and of the ever-recurring fluctuation in both countries, are numerous. Modes of nursing, tact in the adaptation of regimen, and the nature and relative sufficiency of means, are, doubtless, among the chief of them. The more favourable results in England for the first three months may, in great measure, be due to the practice, much prevalent among all classes in this country, of maternal breast-nursing during the early months of infancy at least; whilst in France it is extensively customary amongst mothers to commit their offspring, even from birth, to foster management, and that not seldom without the aid of a foster breast. This view is materially supported by the extraordinary fatality which occurs to illegitimate offspring, who, with scarcely an exception, are abandoned to the custody of strangers and the perilous infliction of artificial feeding from the day of their birth. On the other hand, the more fortunate issue for the following nine months, and for some time later, would point to a more judiciously adapted hygiene among the French during this period.

The immense preponderance of deaths during the first year, of those born out of wedlock, is painful to contemplate, and serves to illustrate how largely the life and well-being of the infant are dependant upon the natural sustenance and care which its own parent alone has the power of imparting. Any other form of aliment, however judiciously prepared, even cows' milk of faultless quality, however scientifically adjusted by approved modes of culinary preparation, are still immeasurably inferior to the maternal breast-milk, which, in the vital warmth with which it is indued when imbibed from the nipple, possesses properties which the subtlest skill of the chemist cannot supply.

It is notorious that foster nurses, both in this country and elsewhere, are chiefly supplied from among the unfortunate class of illicit mothers, whose offspring are necessarily consigned to the charge of indifferent persons, who, if not totally ignorant of infant management, are certainly devoid of many of the qualities essential to the well-being of the child, and which none but its mother possesses. Nor are these foster guardians at all times over-scrupulous as to the means they employ for the purpose of procuring repose in the event of restlessness, whether arising from disease, or from deficiency or improper quality of food. It is well known that cordials,

in the form of patent soothing nostrums and spirituous liquors, are often nefariously administered for such purposes, and possibly contribute not a little to the augmentation of the death-rate among this class of infants.

According to official returns for the year 1847(a), the comparative estimate of legitimate and illegitimate deaths at different stages of the first year of life, for the whole of France (except the department of the Seine), stands as follows:—

Age.	Deaths (first year) to 100 births in 1857.	
	Legitimate.	Illegitimate.
0 to 7 days . . . . .	2·61	5·02
8 „ 15 „ . . . . .	1·93	5·53
16 „ 22 „ . . . . .	1·15	2·80
23 „ 30 „ . . . . .	0·86	3·07
1 „ 3 months . . . . .	3·20	6·91
3 „ 6 „ . . . . .	2·78	5·28
6 „ 12 „ . . . . .	4·10	5·85
	16·63	34·46

Thus, the rate of mortality of illegitimate children during the first year is shown to be more than double that of those born in wedlock; and the comparative estimate for the first three, as compared with the remaining nine months, is still higher, as may be better understood from the following summary of the preceding table:

Age.	Deaths (first year) to 100 births in 1857.	
	Legitimate.	Illegitimate.
0 to 3 months . . . . .	9·75	23·33
3 „ 12 „ . . . . .	6·88	11·13
	16·63	34·46

It is impossible to adduce an argument in favour of maternal breast-nursing more potently convincing than that which the preceding figures supply.

In the case of the illegitimate there is another cause, whereby the rate of early mortality is materially augmented: the absence, namely, of timely medical aid in the event of sickness. This is not necessarily owing to unskilfulness on the part of the practitioner employed: it is more probably due to neglect or delay in summoning such aid when required—a resource, however, which must, no doubt, be often much influenced by scantness of means.

The importance of timely and skilful medical aid is further illustrated in the great preponderance of still births among the illegitimate, as compared with those of the more fortunately circumstanced. Illicit mothers in France are seldom, perhaps never, except in cases requiring instrumental interference, attended in their confinements by skilled medical practitioners, but by *accoucheuses*. It may be observed, in passing, however, that the French midwife is usually an intelligent woman, suitably educated for her calling, and not allowed to practise without the possession of a certificate of efficiency. But there are, of necessity, various grades of these practitioners differing widely in skilfulness and experience; and it is commonly the cheaper, and consequently the least experienced of them who are employed in such cases, especially when not in Hospital.

For Paris and the department of the Seine, the disparity between the two classes of legitimate and illegitimate is less wide, although in both cases somewhat less favourable than for the rest of the empire.

The relations of still-births of those born *in* and *out* of wedlock, for Paris and the department of the Seine, for the rest of France, and for the whole of the Empire, comparatively stand thus:

	No. of children still-born to 100 births—1857.		
	Legitimate.	Illegitimate.	Mean.
Department of the Seine	6·04	7·80	6·52
The rest of France	3·92	6·98	4·01
For all France	4·02	7·16	4·27

On the other hand, Paris, with its department, has a death-rate in early infancy somewhat below the general average. The following results copied from the official returns for 1857(b), although a little higher than those of the preceding

(a) "Statistique de la France, Deuxième Série." Tom. x., 1861.

(b) "Recherches Statistiques sur la Ville de Paris, d'après les Ordres de M. le Bn. Haussmann, Préfet du Département."

and some other years, may be taken to represent fairly the average for a few years past:

Age.	Deaths (1st year) to 100 births—Paris and the Seine.		
	Males.	Females.	Total.
0 to 7 days	1·19	0·97	2·16
8 to 15 „	1·59	1·23	2·82
16 to 30 „	1·57	1·32	2·89
1 to 3 months	1·53	1·28	2·81
3 to 6 „	1·15	0·97	2·12
6 to 12 „	2·15	1·94	4·09
	9·18	7·71	16·89

Compressed into the two periods of the first three and the following nine months, this table will stand as follows:

Age.	Deaths (1st year) to 100 births—Paris and the Seine.		
	Males.	Females.	Total.
0 to 3 months	5·88	4·80	10·68
4 to 12 „	3·30	2·91	6·21
	9·18	7·71	16·89

For London, the average result for the years 1858, 1859, and 1860, in collective numbers (the details for the several months being wanting), is—males, 8·55; females, 6·90; total, 15·45; being 1·44 below that of the Parisian rate. It must be taken into consideration, however, that the density of population is widely different in the respective cities—that for Paris, with the *banlieue*, being 80; while that for London, with the suburbs, is less than 36 to the acre.

#### AN ACCOUNT OF THE PHYSIOLOGICAL RESEARCHES OF THE REV. PROFESSOR HAUGHTON, M.D., TRINITY COLLEGE, DUBLIN.

AN elaborate series of experiments on the urine of healthy men was recently undertaken by the Rev. Professor Haughton, M.D., of Trinity College, Dublin, with the object of establishing a theory of work applied to man, considered as a machine, mechanical, and mental. Reflection and observation suggested to him that the natural and proper measure of the value of a given diet was the amount of work it would produce in a healthy animal such as man. Bernoulli was of opinion that the total quantity of daily work of which a healthy man was capable was constant, no matter in what description of labour he was employed, but the state of knowledge in his time did not admit of the development of his idea; the facts, as he understood them, were against his view, and he was obliged to give up his opinion. The view which Professor Haughton takes of the subject is as follows:—A man in health consumes per day a certain amount of food and drink, and excretes per day an equivalent amount of waste matter, supposing him to be full grown, in good health, and not gaining or losing flesh: the excretions are effected in four ways—*per habitum*, *per cutem*, *per vesicam*, *per anum*, and are more highly oxidated than the food and drink consumed. The difference of oxidation of the ingesta and excreta, converted into work, should account for, and be equal to, the total labour effected per diem. This work is divided by the Professor into four heads: (a) the effort necessary to live, or the work spent on the performance of the organic functions [*opus vitale*]; (b) the work, converted into heat, requisite to keep up the animal temperature [*opus calorificum*]; (c) the mechanical work effected by bodily labour [*opus mechanicum*]; (d) the unknown, and hitherto unmeasured work done by the mind [*opus mentale*]. Confining himself to the subjects on which he has experimented directly, viz., the excretions *per vesicam*, and the mechanical labour of body, and work of mind, of which man is capable, he takes for granted that the substances excreted by the urine of a healthy man result from the wear and tear of tissue of every kind in the body; that, in a state of health, this excretion is exactly compensated for by the assimilation of an equal amount of the same substances ingested. Aware that, in restricting this hypothesis to the urine, he differed from many physiologists, he made a number of observations on the food taken by the persons experimented on, par-

ticularly with reference to the relative quantities of nitrogen received in their food, and excreted by the urine. The close agreement between the amount of nitrogen excreted *per vesicam* and *per anum*, and the amount obtained in analyses of the food, has induced him to assume that the nitrogen used in the body is naturally excreted by the kidneys, and that the surplus taken in food, and not used or required by the body, is thrown out as a merely superfluous excretion *per anum*. The quantity of nitrogen in food, and in the corresponding urine and fæces, being determined by direct experiment, the quantity excreted by the skin and lungs is found simply by difference.

The first set of experiments were made with the view of determining the daily discharge of urea in healthy urine of man; and this course of investigations was rendered necessary by the difference between various authorities in their quantitative estimates relative to this subject. Having made preliminary trials as to the different methods in use among chemists for the determination of urea quantitatively, Liebig's volumetric process was adopted, as calculated to give the most accurate and consistent results, the test solution of nitrate of mercury being estimated by a known weight of pure urea previously.

The subjects of the observations were required to live according to their usual mode, without any deviation from their regular habits, for a period of from five to seven days, before the constituents of their urine were estimated. The urine was in all cases that of healthy men, and the quantity operated on was the excretion of twenty-four hours, considering this to be the natural period of man's cycle of labour, food, and rest. The subjects for experiment were divided into two classes—1. Well-fed, flesh-eating, wine-drinking men; 2. Well-fed, water-drinking vegetarians.

The following tables contain the results of the experiments:—

Table A.—Beef-eaters.

No.	Urea per day.	Urine per day.	Specific gravity.	Urea per fluid oz.	Solids per day.
	Grains.	Ounces.		Grains.	Grains.
1	465.09	34	1023.8	13.70	817.25
2	677.25	62	1019.0	10.11	1065.69
3	644.62	52	1018.5	12.40	998.55
4	554.06	50	1015.8	11.08	818.00
5	630.00	45	1028.2	14.00	1330.20
6	484.30	41	1024.8	11.81	1051.25
Mean.	575.87	47.3	1021.7	12.18	1013.49

Description of the subjects of experiment:—

No. 1. Age, 37; weight, 126 lbs.; occupation, walks five miles per day, studies five hours per day; food, 8 oz. fresh meat, 8 oz. white bread, 10 oz. vegetables.

No. 2. Age, 35; weight, 126 lbs.; occupation, partridge shooting, office work three hours, anxious about business matters; food, mixed diet.

No. 3. Age, 19; weight, 126 lbs.; occupation, studies five hours, walking and athletic games, two hours; won the prize for the long jump at the Trinity College foot-races; food, mixed.

No. 4. Age, 39; weight, 174 lbs.; occupation, walks two miles, office work, six hours; food mixed.

No. 5. Age, 40; weight, 189 lbs.; occupation, walks four miles, studies four hours; food, mixed.

No. 6. Age, 40; weight, 145 lbs.; occupation, walks five miles, studies two hours; food, mixed.

Table B.—Vegetarians.

No.	Urea per day.	Urine per day.	Specific gravity.	Urea per fluid oz.	Solids per day.
	Grains.	Ounces.		Grains.	Grains.
1	367.50	70	1014.00	5.25	1012.90
2	578.81	81	1014.76	7.14	1236.87
3	315.00	45	1015.23	7.00	712.50
4	366.12	56	1012.41	6.54	717.08
5	342.55	43	1017.17	7.87	775.60
Mean.	393.99	59	1014.71	6.76	890.99

Description of the Subjects of Experiment.

No. 1.—Age, 63; weight, 173 lbs.; occupation, walks 3 miles per day, office work 1 hour; food, 1 egg, 6 oz. bread, vegetables *ad lib.*, 16 fl. oz. milk, 40 fl. oz. water.

No. 2.—William Wall, 16th Regiment (2nd battalion), in Military Prison, Dublin. Age, 22; weight, 132 lbs.; occupation, 3 hours' shot drill, 1¼ hour ordinary drill, 3½ hours oakum picking; food—breakfast, 8 oz. oatmeal, ½ pint milk—dinner, 9 oz. Indian meal, ½ pint milk—supper, 8 oz. bread, ½ pint milk.

No. 3.—William Tysack, Military Train, in Military Prison, Dublin. Age, 31; weight, 146 lbs.; occupation and food, same as last.

No. 4.—Thomas M'Donald, 18th Regiment (2nd battalion), in Military Prison, Dublin. Age, 22; weight, 146 lbs.; occupation and food, same as last.

No. 5.—Same man as No. 3, a fortnight subsequent.

(To be continued.)

## THE EMPLOYMENT OF POSITION IN CONTROLLING HÆMORRHAGE.

By FRANCIS B. QUINLAN, M.D., Trin. Coll. Dublin,  
Medical Adviser to St. Vincent's Hospital.

PAIN, shock to the nervous system, and hæmorrhage may be fairly considered the principal sources of immediate difficulty and danger in the actual performance of extensive Surgical operations; and, as the all but universal employment of anæsthetic agents has, to some degree, neutralised the first two impediments, it may be of advantage to recur to a plan of diminishing venous hæmorrhage, which, employed and described in the year 1845, has since been frequently resorted to, although not always with due acknowledgment to Dr. O'Ferrall, of St. Vincent's Hospital, the distinguished Surgeon by whom this plan was first devised. It will be admitted that, while most cases of arterial hæmorrhage are susceptible of comparatively easy control, there is scarcely any bleeding so rapid, so tremendous, or so alarming in its effects as that experienced in the removal of large scrotal tumours, when the enormous tortuous veins—usually found in connexion with these growths—have been divided while in a state of repletion; and it is to guard against such hæmorrhage that the plan to which I have alluded is especially directed.

The accuracy of these statements will be easily established by a brief review of some operations of the kind which have been performed with and without having recourse to this plan.

In the first of these cases, a large scrotal tumour, weighing about fifty pounds, was removed by the late Mr. Liston, the veins being in an engorged condition. Upon the first incisions being made, the blood flooded out, to use the words of that celebrated operator, "as from a shower-bath;" the patient rolled in exhaustion and agony from the table, and the operation was completed upon the floor; the patient collapsed, and was with difficulty restored by the energetic exhibition of stimulants. In Mr. Aston Key's operation, performed upon the Chinese Hoo-Loo, the results were similar, but, from the feeble Asiatic temperament of the patient, more disastrous. The operation lasted an hour and three-quarters, and the patient, who had shown some signs of syncope during its continuance, died immediately after its conclusion. It may be observed that in both these cases the genital organs were necessarily sacrificed in an effort to hurry the operation to a conclusion, in order to save the patient from impending death from hæmorrhage.

Results of this character, occurring in the hands of some of the first operators of the day, were sufficiently appalling; and it speedily became evident that, unless some means could be devised to diminish this excessive hæmorrhage, the removal of such tumours must, like the extirpation of bronchocele, be for the present abandoned. It was, therefore, with peculiar satisfaction that the Profession learned, in the *Dublin Hospital Gazette* of February, 1845, that a method of operation had been devised by Dr. O'Ferrall, by means of which he had removed an enormous scrotal tumour (fully equal to those removed by Liston and Aston Key) without difficulty in eight minutes, and with the loss of only five ounces of blood; the genital organs being preserved, and the patient having made a good recovery, notwithstanding attacks of erysipelas and various other unfavourable circumstances. Such an announcement could not fail to be in the highest degree gratifying; and it became all the more so when it was found the importance of Dr. O'Ferrall's plan of operation was only

equalled by its extreme simplicity. Observing the great change produced in turgid varicose veins of the leg by placing the patient upon his back, and elevating the limb, and the immediate arrest of hæmorrhage from such veins which ensues upon the adoption of this position, it occurred to Dr. O'Ferrall that, if the enlarged scrotum were held up, a similar withdrawal of the vital fluid would take place, particularly as regards the enlarged and tortuous veins which were the principal sources of hæmorrhage. The result completely justified the accuracy of this expectation, — the more so as the hæmorrhage in these cases had been always observed to be principally of a venous character; the arterial hæmorrhage, in Aston Key's case, being estimated to be scarcely one-twentieth of the whole.

Since the publication of Dr. O'Ferrall's plan, a complete change has occurred in these operations, which have since been performed in rather considerable number, and with an ease and success more or less resembling that experienced in his case. I now recur to the plan, because in two instances of operation published during the present year (in one of which an Asiatic was the subject) it appears to me that the able and successful operators, although adopting the method, omitted, in their reports of the cases, to make due acknowledgment to the author; contrasting, in this respect, with Mr. South, who, in his splendid work on Surgery, gives due prominence to Dr. O'Ferrall's plan.

The application of this method is by no means limited to the removal of large scrotal tumours. On the contrary, it has been resorted to by Dr. O'Ferrall in cases of considerable innocent tumours of a vascular character; and in amputations he has obtained great advantages by loosely applying the tourniquet, elevating the limb, emptying it of venous blood by manipulation, and then tightening the tourniquet. The limb can thus be kept in a state of comparative anæmia while the amputation is being accomplished; and a loss of blood can be prevented, which, by deteriorating the general quality of the vital fluid, might have laid the foundation of subsequent disease. In fact, the value of a position by which the entrance of arterial blood into a limb will be retarded, and the exit of venous blood facilitated, is almost as useful in the performance of an operation as in the treatment of inflammation.

## POISONING WITH MORPHIA.

Communicated by Dr. ANSTIE.

CHARLES S., aged 40, of good general health, but suffering from fistula in ano, became a patient of the Chelsea Dispensary on November 3. On the evening of the 5th, the House-Surgeon, under whose care he was, supplied him with a bottle containing  $\mathfrak{v}$  of *iq. morphia*, diluted with  $\mathfrak{z}$ ss. of water, directing that two teaspoonfuls should be injected into the rectum that night, in order to quiet the pain, which was excessive. Through the ignorance and carelessness of the woman who administered it, about three-fourths of the whole (equivalent to three grains of morphia) were injected. This was at half-past eight, and, immediately afterwards, the man lay down to sleep, and his wife retired to rest in an adjoining room. At six o'clock on the following morning, she went to him, and found him insensible. On the House-Surgeon visiting him, he proved to be deeply comatose, with strongly contracted pupils, and surface rapidly becoming cold. Stimuli and friction were applied to the surface, and he was thoroughly shaken and made to swallow some hot tea, with the effect of so far rousing him that once he even answered a question. At 8.30, Dr. Anstie saw him. At this time he was quite unconscious; the pulse was exceedingly weak; pupils strongly contracted and insensible to light; muscles of the jaw strongly contracted, so that the mouth could scarcely be opened at all. Breathing loud and rattling, indicating much mucus in the bronchial tubes; lips livid. It was attempted to administer coffee, but owing to the clenching of the jaws, but little could be got into the mouth; this was, however, swallowed. Coffee was injected into the rectum, but the bowel would not retain it; in a short time, however, the spasm of the jaw-muscles somewhat relaxed, and a fair quantity of coffee was got into the mouth and swallowed, producing a slightly reviving effect. Meantime, some caffeine had been procured from Morson's, and twenty grains of this were now administered, dissolved in a little water. The effect was remarkable; the pulse, which had been scarcely perceptible,

rose to a fair strength, and beat 100 in the minute; consciousness slightly returned, and the limbs became perceptibly warmer. The improvement, however, lasted only for about an hour and a-half, at the end of which time it became evident that the patient was rapidly sinking. At a quarter to one (sixteen hours and a-quarter from the administration of the morphia) he died quite quietly. Throughout the case there was no convulsion whatever.

*Remarks.*—Two things are notable in this case: the dose which proved fatal, and the treatment adopted. Three grains of morphia is by no means the smallest dose which has been known to prove fatal, for less than a grain has been known to kill an adult; but it is a small dose, nevertheless, to produce this result, and, in fact, many instances are within my knowledge in which as much has been given to patients not particularly well used to taking opiates, without any mischief occurring. This case serves to confute signally the notion, which unaccountably prevails in a good many people's minds, that opiates do not act so powerfully when given per rectum, as when given by the mouth—an idea which is entirely contradicted by my own experience, and, indeed, by that also of some of the highest authorities.

Another point which I wish to notice is the administration of caffeine as an antidote. This plan of treatment was attended with complete success in a bad case of opium poisoning, which came under the care of Dr. Campbell, an American Physician, and which is recorded in the *Southern Medical and Surgical Journal* (U.S., 1861); and, upon the strength of this case, I determined to give it a fair trial. My own experience of the treatment with belladonna had not been so favourable as to encourage me to entertain much hope of its proving useful—at any rate, in this case. What was needed, above all, was some powerful stimulus to the action of the heart, which was rapidly failing. If this could be sustained in tolerable strength for a few hours, there was reason to hope that the effects of the poison would pass away. The teaching of all the experiments which have been made with caffeine is, that this substance has a very powerful stimulating influence upon the heart, as, indeed, we might expect beforehand, from familiar acquaintance with the effects of its diluted form—coffee and tea. The action of the heart being once roused, the languid circulation in the brain is quickened, and the patient is restored to a certain degree of consciousness, perhaps sufficient to enable him to take part in the measures adopted for his recovery. For these reasons, it appears to me that caffeine is an appropriate physiological antidote to opium—far more so, at any rate, than belladonna, towards which attention seems to have been attracted solely on account of the apparent opposition between its effects and those of opium on the pupil, which appears to me an insufficient basis for the hypothesis that the two agents are mutually antagonistic in their effects on the nervous system generally. I can speak pretty confidently as to the effect of large doses of belladonna upon the nervous system of healthy persons, as I have repeatedly witnessed the operation of enormous doses given, under Medical advice, to persons whose general health was pretty good; and in one case I had an opportunity of minutely observing the symptoms of acute belladonna poisoning, which went to the very extreme of what was consistent with recovery. The result of my observation is the conviction, that the quick beating of the heart which frequently attends the delirium of belladonna poisoning, is not the expression of a stimulated condition of the heart, but merely the consequence of general nervous prostration, such as one sees in typhoid affections, and that the cerebral circulation actually languishes, instead of being quickened during the profoundest atropism.

It must be remembered that opium kills, by causing a cessation of the respiratory movements. One of the best means to meet this danger is, doubtless, the employment of artificial respiration; but a far better way of preventing its occurrence at all is to keep the brain, and, consequently, the intelligence and consciousness, in a state of activity. If once a patient, suffering from opium poisoning, becomes thoroughly unconscious, he becomes unable to make those voluntary efforts at respiration which are far more likely to prevent its cessation than artificial processes are to restore it when once it has ceased.

Now, there can be little doubt that caffeine quickens the circulation generally; and there are some special reasons for thinking that it especially exerts an influence upon the circulation of the brain; it would, therefore, be well adapted to this particular purpose.

I have spoken with distrust of the therapeutic effects of belladonna in opium poisoning; but it must be distinctly understood that I refer only to the use of poisonous doses of that drug. What might be the effects of belladonna administered in those small doses (*e. g.*, one-sixth grain of the extract), which we give in the treatment of incontinence of urine, constipation of the bowels from want of muscular tone, etc., etc., and which, undoubtedly, act as pure stimulants to the affected part, I know not. But obviously this would be quite a different mode of treatment to that which proposes to antagonise the poisonous action of opium by means of the poisonous action of belladonna.

## REPORTS OF HOSPITAL PRACTICE

### IN MEDICINE AND SURGERY.

#### KING'S COLLEGE HOSPITAL.

##### RECURRENT FIBROID TUMOURS OF THE BREAST —TEN OPERATIONS.

(Under the care of Mr. FERGUSSON.)

[Reported by Mr. SMITH, House-Surgeon.]

*Case 1.*—Elizabeth E., aged 42, a fine, healthy-looking woman, the mother of two children; she had no appearance of cachexia, and had always had good health.

*History.*—About seventeen years ago she noticed a small swelling about the size of a marble below the left clavicle; it increased in size, was attended with no pain, and at the end of ten months it had increased to the size of a large walnut; it was then removed by the knife at the Birmingham General Hospital.

She applied again at the same Hospital at the end of seven months, and another tumour was removed from below the cicatrix of the former incision. This second appeared five months after the last operation.

Twelve months after the second operation another tumour appeared in the same place, and gradually increased in size. It was removed by Mr. Pollock, at St. George's Hospital.

After the last operation she was free for five and a-half years, when another small lump appeared in the cicatrix. This grew very rapidly, and when, at the end of a year and a-half, she applied to Mr. Fergusson, there was found to be a large tumour below the left clavicle, extending down to the mammary gland, and reaching from the sternum into the hollow of the axilla. The skin over it was tightly stretched, glazed, and of a purple colour, and at some points seemed about to ulcerate. This was removed by Mr. Fergusson on August 17, 1861, and in six weeks she was discharged well. No microscopical examination was made of the tumour.

She was admitted again into King's College Hospital, on January 8, with several small tumours scattered about the old cicatrices. These, she said, appeared about a fortnight after the last operation, and had grown very rapidly, but were unattended with much pain. They were removed on January 11, and, upon examination under the microscope, were found to be good specimens of the recurrent fibroid tumour. She was discharged well at the end of the month.

February 27.—Another tumour, the size of a pigeon's egg, was removed.

March 3.—Another small tumour was removed.

April 30.—Several tumours have appeared in the old situation since last operation; one of which, just above the nipple, was the size of a large orange. They were all examined, and found, under the microscope, to be made up of elongated, caudate cells.

In the month of May she was twice operated upon, and once in the month of June. Fresh tumours sprung up in a very few days after the operation, and rapidly increased in size. She always begged to have them removed; and, although extensive incisions had to be made, she was able to dress them herself, and generally left the Hospital about three days after the operation.

At the end of August she died, but from no cause connected with the growth of the tumours.

##### RECURRENT FIBROID TUMOURS OF THE LEG— FOUR OPERATIONS.

(Under the care of Mr. FERGUSSON.)

*Case 2.*—Thomas H., aged 43, a gardener had lived in

the country all his life, and had always had good health. He was a ruddy, strong, hearty man, with no signs of cachexia.

*History.*—About thirteen years ago he fell and hurt his left leg. Soon afterwards he noticed that there was a swelling in his calf; it gradually enlarged for four years. He was then admitted into King's College Hospital under the care of Mr. Fergusson, who removed a small fibrous tumour.

About six years after this he noticed another small tumour in the same place; this increased in size very rapidly, and, after he had allowed it to grow, the calf measured nineteen inches in circumference (in the first growth, of four years' duration, it only measured thirteen inches). The skin became involved, and when he was admitted into the Hospital, June 1, 1857, there was a large fungous protrusion. The tumour was removed by Mr. Fergusson; was found before section to be firm, and semi-transparent. He was discharged at the end of six weeks.

About three months after last operation, another tumour appeared near the cicatrix. This increased rapidly up to February 5, 1862, when it was removed by Mr. Fergusson, and found to consist of a soft, jelly-like substance, mixed up with clots of blood. Another small tumour was discovered lower down on the inner side of the calf, but this was firmer, and a good specimen of the recurrent fibroid growth.

On October 16, 1862, he was admitted again with several distinct tumours about the old cicatrices, each about the size of a walnut. These, he says, began to grow about a fortnight after the last operation. He has had very little pain, although they have increased in size very rapidly. They were removed by Mr. Fergusson on October 18. During the operation there was very much hæmorrhage, and some little difficulty in dissecting them out. These were of a firm, fibrous structure, and, under the microscope, showed the elongated, oval-shaped cells characteristic of the recurrent fibroid tumour. He was discharged cured on November 23.

##### RECURRENT FIBROID TUMOURS IN THE LEG— EIGHT OPERATIONS.

(Under the care of Mr. PARTRIDGE.)

*Case 3.*—Chas. K., aged 50, is a comb maker, a native of London; he looked a strong, hearty man, and had always had good health. About two years ago a small tumour was removed from the front of the tibia of the right leg. This had been growing six months, and, when examined, proved to be of a fibroid character. Three months after this, another small tumour was removed.

On September 13, 1861, another tumour was removed from the same place. This had been growing twelve months, and had attained the size of a hen's egg.

April 9, 1862.—Another tumour removed; this was found to involve both the skin and the periosteum covering the tibia.

July 29.—Another small tumour was removed from the cicatrix. After the operation, extensive sloughing of the flaps occurred; and, after healthy action was established, several distinct tumours sprang up amongst the granulations; these were removed three times, twice by Mr. Partridge and once by Mr. Mason.

At the end of September, he was discharged with no signs of any more growths.

#### HOSPITAL FOR SICK CHILDREN.

##### PROGRESS OF A CASE OF SUCCESSFUL EXCISION OF THE KNEE.

(Under the care of Mr. HOLMES.)

THE patient was a healthy boy; his age at the present time is 14. The operation was performed in August, 1861, on account of chronic disease of the knee, with long-standing dislocation, and the case is reported in the *Lancet* for April 19, 1862. It will be seen, by reference to that account, that, in order to get the bones into position, the section of the femur was necessarily carried higher than was desirable, so that a portion of the whole thickness of the epiphysis was removed, and the shaft cut into at one part. On this account, anxiety was felt as to the equable growth of the two limbs; and, notwithstanding the immediate success of the operation (which was most satisfactory), doubt existed as to its ultimate utility. The precise measurements, which were taken at the time of the boy's discharge from the Hospital, were unfortunately mislaid; and the report merely says, in general terms,

that the shortening was "fully two inches." Mr. Holmes' impression, however, is, that the precise measurements would have given a greater shortening.

The boy attended recently (November 29) for the purpose of showing his limb. To outward appearance, nothing could be more satisfactory. He can walk (with a high-soled shoe) actively, and with very slight limping. The operated limb bears the weight of the body in standing on one foot. He generally uses a stick, but can walk quite well without it. The limb is quite straight, and firmly soldered at the seat of operation. It does not appear more shortened than when he left the Hospital; but the measurements certainly indicate a shortening of at least three inches—the healthy limb measuring a little over 28 $\frac{3}{4}$  inches from the anterior superior spine of the ilium to the point of the external malleolus, while the same measurement on the opposite side gives only 25 $\frac{3}{4}$  inches. This shortening is partly compensated by inclination of the pelvis. No spinal curvature exists.

The boy and his friends are highly delighted with his restoration to activity; and the limb, as it now is, is certainly greatly superior to any artificial leg; still, some little doubt yet remains as to its future condition. He was accordingly requested to exhibit himself again at the latter part of this year.

#### CASE OF EXCISION OF THE KNEE-JOINT—RECOVERY—CONDITION OF THE LIMB THREE YEARS AFTER THE OPERATION—CLINICAL REMARKS.

(Under the care of Mr. THOMAS SMITH.)

This case is a valuable one, as the patient has been under observation longer than the majority of such cases; indeed, long enough (Mr. Smith said) to justify a reasonable expectation that the cure will be permanent, and long enough to afford information on the question of the influence of the operation of excision upon the growth of bones in young children. Mr. Smith remarked that resection of the knee-joint has been pronounced by many (Mr. Syme among others) to be inapplicable to the growing bones of young children, from the belief that the injury inflicted would either abruptly arrest the growth of the limb, or at all events so seriously interfere with it as to render the limb nearly useless in adult life. The results of the following case (Mr. Smith said) tends to confirm an opinion he had expressed in 1857, namely, that, provided the line of epiphysial cartilage is uninjured by the operation, the subsequent growth of the bones will continue as before.—*British and Foreign Medico-Chirurgical Review*, 1857, vol. xx., p. 313. This coincides with the results of the recent investigations of Dr. Humphry, of Cambridge, on this subject, which are summed up by that gentleman in the following words (*Medico-Chirurgical Transactions*, vol. xlv., p. 303):—"We are justified in concluding—1st. That if the epiphysial lines are sawn away in the operation of excision of the knee, the subsequent growth of the limb will be impaired; 2ndly. That if the epiphysial lines be intact, there is much probability that the growth of the limb will be fully or nearly equal to that of the other limb.

A boy, aged 9, had been suffering with repeated attacks of pain in one knee during the last three years. The first attack was attributed to a blow. When first seen, the joint was about twice its natural size, fixed and flexed at a right angle; any attempt to straighten it gave great pain, but it bore external pressure pretty well; it was elastic and puffy on each side of the patella, as if from synovial enlargement; the limb was useless; the mother stated that recently the pain had become worse in the joint, and that the boy was day by day getting thinner and weaker. He frequently awoke at night with loud screams from the pain produced by starting of the limb; there was the usual distortion of the joint, characteristic of advanced disease, the bones of the leg being drawn outwards and far backwards, beneath the condyles of the femur, and the patella being dislocated on to the external condyle.

Excision was performed on August 24, 1859, the patella and articular surfaces of the femur and tibia being removed by a short and wide semilunar incision stretching across the front of the joint. The hamstring tendons were divided, as the limb could not otherwise be brought into the straight position, notwithstanding that a second slice of the femur had been previously removed with the same object in view. A long back-splint with a foot-piece was applied, and a short, wooden splint was strapped firmly over the front of the femur, and a

large pad was placed behind the head of the tibia. No ligature was required.

The joint was found to be full of tough, vascular, and pulpy synovial membrane, and a similar structure connected the opposed surfaces of bone. The back of the condyles of the femur rested on the front of the head of the tibia. The cartilage of the femur was everywhere eroded, and about three-fourths of its surface had been removed. It had a worm-eaten appearance; the bone beneath appeared healthy; the tibia and patella had suffered in the same way to about the same extent; the whole thickness of the bone removed did not exceed an inch when put together in their natural position. In taking the second slice from the femur, a portion of the epiphysial cartilage was removed over the most prominent part of the external condyle. This piece was about the size of a shilling, or rather smaller.

For the first few days after the operation the boy suffered severely from constitutional irritation, but by the sixth day the wound had, for a time at least, healed, and he had regained his appetite and ordinary condition. Three weeks after the operation, an abscess formed in front of the resected ends of the bones, which required a drainage-tube to be passed through it before its cavity would close. At the end of six weeks from the operation the splint was first changed. Three months after the operation the boy was allowed to walk across the ward at his own request, and, from his mode of progression, it was evidently not the first experiment of the kind. The limb was quite straight, and apparently firmly ankylosed (no force was employed to test it). It was an inch shorter than the opposite, measuring from the umbilicus. There were still two small sinuses open. The whole joint was encased in gutta serena, and a firm bandage applied, and at the end of November he went to Brighton to a convalescent institution.

Dr. Humphry, who was kind enough to look after him at Brighton, wrote on February 4, five months and a-half after the operation,—“There is two inches' difference in the length of the limbs, partly accounted for by the stiff limb being ankylosed in a slightly flexed position. The boy can run and do anything.”

Mr. Smith saw the boy two years after the operation. The relative length of the limbs was the same, and, though the boy had grown much taller, there was still but two inches' difference in the length of the legs.

February, 1863.—The boy is strong and well. He can, he says, walk as well as other boys.

#### THE LONDON HOSPITAL.

#### CASE OF TRISMUS ALGIDUS—TREATMENT BY INDIAN HEMP—RECOVERY—CLINICAL REMARKS.

(Under the care of Dr. FRASER.)

[Reported by Mr. HECKFORD.]

Geo. M., 23, a robust sailor, was admitted on January 2, 1863. His previous health was good; he had never had rheumatism, worms, nor had he received any injury to the jaw, nor any wound or scratch whatever; in fact, all his organs seemed healthy. Having previously been very much exposed to wet and cold, the attack commenced six days before being admitted, by inability to open the mouth to its full extent. This inability gradually increased until his admission, when the jaws were so closely locked together, that the tip of the tongue could not be protruded. He had had no pain until that day, when he had some uneasiness in swallowing. There was no impediment to the lateral movement of the jaw, and it could also be brought forward so as to make the lower incisors project beyond the upper jaw; the left temporal and masseter muscles seemed more tense than the right, but not to any great degree. His appetite was very good, but he was able to swallow liquids only. Sleep undisturbed, and bowels regular. He said that a year ago he had had a similar attack, though not so severe. This, also, followed exposure to cold and wet. It disappeared in three weeks without any treatment. He was ordered a purge.

3rd.—He now complained of stiffness of the muscles of the neck. He was placed under the full influence of chloroform, but there was no relaxation of the spasm, considerable force being required to partially insert a gag, and on its being removed the jaws snapped together like a lock. To have a quarter of a grain of the extract of Indian hemp every hour.

4th.—The stiffness of the neck ceased, and he was able to

pass the tip of the tongue between the teeth. 2 p.m.—The dose to be increased to a grain every hour.

5th.—Was able to project the tongue about half an inch.

6th.—Mouth could be opened to the extent of three quarters of an inch.

7th.—He was able to take meat for the first time. To have three grains of the extract every hour, and its effects to be carefully watched. He commenced at 6 p.m., but showed no signs of disturbance till seven o'clock the next morning, when, on getting out of bed, he felt giddy, was unable to stand, had tremor of the hands, and occasional twitchings of the limbs, and he described his sensations as those of a drunken man. The medicine was stopped, and in the course of three hours these sensations disappeared. Altogether he had taken 115 grains of the drug.

9th.—Could separate the jaws about an inch, and it was evident that the left maxillary angle was more acute than on the right side, as if there still existed some amount of spasm. He expressed himself as being perfectly well, and left the Hospital at his own desire, having a voyage in view.

*Clinical Remarks by Dr. Fraser.*—This affection is one of the three varieties under the species "locked-jaw," viz., *trismus nascentium*, *trismus algidus*, *trismus traumaticus*. Whatever may be the remote cause of these obscure and curious affections, it operates upon the reflex excitability, and the characteristic spasms are induced totally unconnected with any influence of the brain. Before drawing your attention to the case in question, I may observe that trismus nascentium is one of the most fatal diseases of childhood; and those of you who are likely to be engaged in obstetric practice will do well to be prepared for its terrible encounter. It seldom appears before the third, and never after the eleventh day. The pathological cause is said to be inflammation of the umbilical arteries, consequent on dividing the cord. Trismus traumaticus is a subject of too large proportions to be entered upon at present, but I may say that it seldom appears before the tenth day after the injury, and that, so far as I am informed and have seen, severe cases are almost always fatal. In mild cases various remedies have been successful. In trismus algidus the result is generally favourable, and spontaneous recoveries are not unfrequent. The intellect is unaffected; the pulse not much, sometimes not at all affected; the bowels usually costive, and if the patient survives over the fifth day of the attack recovery is pretty certain. However, sometimes, in severe and prolonged cases even of trismus algidus, the condition of the patient becomes imminent, for the jaws may be so firmly locked that suction is next to impossible; and if there be no aperture caused by absence of, or broken teeth, through which to introduce a stomach tube, life may be difficult to sustain, for it is not easy to extract a tooth under such circumstances, and we must then have recourse to nourishing injections per anum, until the spasms relax.

Until we know the cause of the one set of muscles only being thrown into spasm—viz., those of mastication, including the temporal masseter, two pterygoids, etc.—our treatment can be only experimental. The muscles in question are supplied by the motor branches of the third, inferior maxillary, division of the fifth nerve. In this case the two pterygoids seemed to be unaffected. The chloroform was administered with the intention of abolishing the reflex action (this effect is disputed by Schröder Van der Kolk) consequent on irritation, from cold and wet, of the peripheral nerves, and conveyed to the inferior maxillary branch of the fifth, or, according to Dr. Radcliffe, to a withdrawal of nerve power. This latter opinion is entirely at variance to all our previous convictions. No appreciable relaxing effect followed the employment of the chloroform. Romberg, in his work on "Diseases of the Nervous System," vol. ii., p. 115, gives a case in which no effect was produced by chloroform, but in which benefit followed etherisation. I refer you to this work for other interesting statements.

The *Cannabis Indica* was given with the same view as the chloroform. I shall not strongly assume the "post hoc ergo propter hoc," because we know that the patient recovered spontaneously from a former attack, which, however, was less severe, and lasted longer; but I may safely aver that the influence of the hemp was beneficial, for no increase of spasm took place after its administration; indeed, the treatment evidently arrested the threatened spread to the muscles of the trunk. None of the attributed inconvenient effects of the drug were induced.

### FRACTURED RIBS, WITH EMPHYSEMA— TYMPANITIS — GALVANISM — CONVALESCENCE.

(Case under the care of Mr. MAUNDER.)

J. P., aged 60, an omnibus-driver, of sober habits, stout, and of lax fibre, was admitted into the Hospital on January 17, for fracture of one or two ribs on the right side, attended by slight emphysema. Strips of plaister were applied to keep the right side of the chest at rest, and with great comfort to the patient. Six ounces of wine.

18th, afternoon.—He complained of nausea and distension of the abdomen. To take, by order of the House-Surgeon, a dose of house-medicine.

19th, 2 p.m.—Has retained two doses of salts and senna on the stomach, and took, at 10 a.m., one drop of croton-oil, but vomited, on taking some beef-tea, about half an hour afterwards. Bowels inactive, not even flatus having been passed per anum; eructations and vomiting persist, and the distension troubles him. At 2.30 p.m., galvanism was applied to the abdomen, one pole of the battery being placed upon the lumbar spines, the other being moved about over the anterior abdominal wall. The abdominal muscles contracted strongly under the influence of this agent, and, after the lapse of a quarter of an hour, voluminous discharges of flatus took place per anum, to the great relief of the patient. Brandy, six ounces. The application was continued during twenty minutes. 3 p.m.—The galvanism to be repeated at 7 p.m. if the bowels have not acted; and, after the lapse of an hour, to commence taking two grains of watery extract of aloes and one-twentieth gr. of strychnine, every two hours.

20th, 1 p.m.—Bowels were relieved at six o'clock last evening, three hours after the employment of the battery. The vomiting did not recur, and the patient expressed himself as being very much better.

21st.—The bowels have been freely moved, six pills having been taken.

22nd.—The patient is convalescent.

Mr. Maunder regarded the tympanitis and vomiting as dangerous symptoms, and believed the former to be due to functional paralysis of the muscular coat of the intestines, consequent on the sudden withdrawal of the usual stimulus,—viz., walking exercise of from three to four miles daily.

### GALVANISM APPLIED, BY AID OF THE LARYNG- SCOPE, TO THE VOCAL CORDS.

The electric current has been brought to bear directly on the vocal cords by Dr. Morell Mackenzie, and two cases of functional aphonia have yielded to it immediately. One patient had completely lost her voice for two years, and had been in the London Hospital for some months, where every remedy had been used in vain by Dr. Mackenzie. Cauterisation of the larynx, blisters, and even the employment of galvanism externally, had all failed, but the application of galvanism directly to the vocal cords succeeded at once, and, after a week, the patient spoke as well as she had two years previously.

In the other case, where the loss of voice was of eighteen months' duration, and where every kind of treatment had been tried unsuccessfully in the London Hospital, the voice was immediately restored by galvanism directly applied to the vocal cords. Dr. Mackenzie has invented an instrument, by which the electric current can be set going, but does not pass beyond a certain distance till the point is introduced into the larynx, when a spring is touched, and the current reaches the vocal cords. Dr. Mackenzie recommends the remedy in the early stages of clergymen's sore-throat, before the perverted state of the nerves has led to follicular deposit.

### ST. MARY'S HOSPITAL.

#### SEVEN CASES ILLUSTRATING THE TREATMENT OF JAUNDICE—CLINICAL REMARKS.

(By Dr. HANDFIELD JONES.)

*Case 1.—Jaundice Occurring in a Spirit Drinker after "a Cold"—Treatment by Mercurial Purgatives and Benzoic Acid—Recovery under the Nitro-Muriatic Acid.*

JAMES M., aged 36, admitted January 16. He had been ill three weeks, having caught cold, followed by pain in the upper part of the sacral region. It afterwards shifted thence to front of the chest. Yesterday his skin became yellow, and his urine red. He had no appetite, felt very sick, but

could not bring anything up, and said, "It all lies across the middle of my chest." He had no pain in the right hypochondrium. The liver was four finger-breadths below the ribs, but this was chiefly from its being depressed by the lung. The heart also is overlapped by the lung. He used to drink spirits very freely till three or four months ago, but ate freely at the same time. Appetite has failed since then. An ipecacuanha emetic was ordered, and three grains of calomel for two nights, with an ounce of decoction of aloes twice a-day.

On the 19th he was very faint and sick. Tongue white; the jaundice continued; bowels not acted on. He was ordered five grains of benzoic acid four times a-day.

23rd.—State same; bowels open; ten grains of calomel for two nights at bed-time, to be followed by white mixture in the morning.

25th.—Bowels freely acted on; but the stools were still quite pale; the urine was high coloured, and the colour of the skin as deep as before. The liver was decidedly small; there was almost no dulness to be discovered in the hypochondrium, and below the right nipple the resonance of the lung extended to within about two finger-breadths of the edge of the ribs; there was no abdominal tenderness whatever. Intellect is quite clear.

℞ Acidi nitro-muriat., ℥viii.; aq., ℥j., ter. die. Nitro-muriatic acid lotion to the abdomen. The lotion caused cutaneous irritation in three days, and was then omitted. The acid was continued till February 11, when the motions had become of natural colour, and the jaundice had greatly diminished; the urine being, however, still high coloured, and the conjunctiva tinged. He complained of griping abdominal pain. He was ordered twelve grains of quinine daily, and was perfectly recovered of his disorder by March 1.

*Remarks.*—This was a rather severe case of jaundice, probably induced by catarrhal tumefaction of the mucous membrane of the duodenum, extending to and obstructing the gall duct. The previous spirit drinking, no doubt, had predisposed the stomach and intestines to be the seat of inflammatory congestion. Calomel, even in large doses, was of no avail, nor was benzoic acid, but nitro-muriatic appeared to be really serviceable. I think it, however, very likely that the calomel purgation was useful in preparing the way for the nitro-muriatic acid, which without it might have caused irritation.

*Case 2.—Jaundice of Eight Months' Duration—Treatment by Long-continued Doses of Podophyllin and Nitro-Muriatic Acid—Subsequently by Iodide of Potassium and Podophyllin—Recovery—Remarks—Nervous Origin of the Pain in the Right Arm and Right Hypochondrium.*

Jane B., married, aged 31, admitted August 7. She had been ill (jaundiced) eight months, but had been worse the last fortnight. Her skin was very yellow, stools pale, urine very high coloured. The liver was only two finger-breadths below the ribs, and there was no tumour to be felt in the abdomen. There was some tenderness in the right side. She had been blistered in that position three or four times. Immersion of the right hand in warm water caused pain in the right side beneath the ribs. She had not taken meat for some time.

℞ Podophyllin, gr.  $\frac{1}{2}$ ; extr. hyoseyami, gr. ijss. M. ft. pil., ter. die.

August 18.—Urine of much lighter colour, yellow, and turned to a deep green by any acid. It did not, when treated with sugar and sulphuric acid, give the reaction for biliary acids. The same was the case when tested on the 14th.

Cont. pil. ℞ Acidi nitro-muriat., ℥v.; aquæ, ℥j., ter. die.

23rd.—Two days ago she had a sudden attack of an influenzal character. There was hysterical agitation at first, which was followed by disturbance of the stomach and prostration.

Cont. pil. ℞ Mist. pot. citrat. efferv., ℥j.; tr. opii, ℥iv., 4tis hōris.

September 1.—On examining yesterday, Dr. Jones found that the liver extended from about two finger-breadths above the edge of the ribs to the level of the umbilicus. It was very perceptible to the hand, and was decidedly tender at the lower part. She had much pain in the right side and back, catching on inspiration. The breathing in the right lung was good. Tongue clean. She was much less yellow, and stools were of a good colour. Urine scanty, and very high coloured.

Cont. pil. ℞ Tinct. cinch., ℥ss.; potass. iod., gr. ij.; mist. pot. citr., ℥j., ter. die.

On the 4th five grains of the compound soap pill were ordered to be taken every night.

11th.—She continued to have great pain, chiefly under the right breast and in the right side, and about the lower angle of right scapula. Right side fully resonant everywhere. State of stools and urine improves. She had some sickness occasionally. Taking last seven days pil. saponis eo., gr. v., o. n.

15th.—On the 12th and 13th she was very sick, and rejected everything from the stomach. She had one very pale stool on the 12th, and on the 13th passed urine "like blood." The evacuations were as before.

℞ Podophyllin, gr.  $\frac{1}{2}$ ; extr. cannab. Indic., gr.  $\frac{1}{2}$ ; in pil., ter. die. ℞ Tinct. aconiti, ℥j.; aquæ, ℥ij. M. ft. lotio.

18th.—Much improved; much less pain.

29th.—Is doing very well. Urine pale, but contains films consisting of homogeneous stuff containing coarse granules and triple phosphate prisms. She had passed such films as these at various times during the last three years, and the urine had then been like blood. She complained of weakness in the right arm, and had pain down the outer part when she exerted herself. Appetite not good.

Cont. pil. ℞ Tinct. ferri ses. chloridi, ℥xv.; acidi muriatis, ℥ij.; spt. ætheris chlor., ℥vij.; aquæ, ℥j., ter. die.

October 23.—She has quite a good colour now, having just returned from the country, and is much stronger and better, but has still some pain in the right arm and side. Stools and urine natural.

℞ Ferri carb. sacch., ℥j., ter. die. Rep. pil. and lotio. aconiti.

November 11.—Calls to say she is well.

*Remarks.*—The cause of the long-continued jaundice in this case was most probably obstruction of the ducts by biliary concretions. The podophyllin was given with the view of increasing the secretion of bile, and, so to speak, washing out the ducts. This intention it seems gradually to have accomplished, not without the occurrence of severe pain in the right side and back. Calculi were looked for, but none found. That the remedies were efficacious seems probable, because the disorder had continued unchanged for eight months, and was cured, after treatment was commenced, in three. The extension of the pain down the right arm is clearly a phenomenon of the same kind as occurs in cardiac anginous affections. Both must originate in irritation of sympathetic nerves, which is conveyed probably to the part of the cord where the brachial nerves are implanted. How external applications to the skin of the parts to which the pain is referred can afford relief, as they unquestionably do, is a great enigma. The curious circumstance, that immersion of the right hand in warm water caused pain in the right side, must also be referred to a central nervous action. Probably the grey matter of the spinal centre had become so hyperæsthetic that a slight impression communicated to it gave rise to the sensation of pain. On this view some explanation may be offered of the above enigma, viz., that the anæsthetic action of the aconite was also propagated to the centre, and diminished the excited state of the part.

*Case 3.—Active Congestion of the Liver—Jaundice—Benefit from Leeching and Purgation—Cure completed by Quinine.*

Isabella H., aged 35, married, admitted December 8, 1859. She had been ill four weeks, and had all the time been jaundiced. The urine was very dark, and the motions had been very dark, but were lighter, but still darker than natural. She had no appetite, and her tongue was rather coated, and she felt very languid. The liver was enlarged, and extended downwards fully three finger-breadths below the ribs, and also upwards higher than usual. There was considerable tenderness over the region of the liver. The lung resonance and breathing behind were normal.

Eight leeches applied to the right side, over the lower ribs, quite removed the pain. ℞ Hyd. chloridi, gr. ij.; ext. taraxaci, gr. vi.; ft. pil. duo omne nocte. ℞ Magnes. sulph., ℥j.; mist. pot tart., ℥j., ter. die. s.

This treatment was continued till January 2, when the jaundice was much diminished, the stools nearly of natural colour, and the urine still dark at times. The catamenia had appeared after twelve weeks' interval. There was still some degree of obscure pain and tenderness in the liver, as tested by deep and firm pressure on the right hypochondrium; the viscus still extended three finger-breadths below the ribs. Pulse quick. ℞ Quinæ disulph., gr. ij., ter. die.

6th.—She was very much better. The liver projected but little

beyond the ribs, and there was no uneasiness at all on pressing on the hypochondrium. The urine varied much, being sometimes quite thick with lithates and high-coloured, and at others clean; the day's urine is generally clearer than the night's. More appetite.

12th.—Feels quite well; eyes clear; urine quite clear and rather pale; she can bear pressure on the right hypochondrium quite well.

*Remarks.*—The foregoing was evidently an instance of a congested and semi-inflammatory state of the liver, which gave rise to the jaundice. It is to be remarked that there was apparently no obstruction, the stools being abnormally dark. Bile, or biliary colouring matter must have been produced in excess. The *quasi* inflammatory congestive state was first relieved and lessened by leeching, calomel and saline aperients; then, when it had become asthenic, was put an end to by quinine in small doses acting as a tonic to the vasomotor nerves and blood-vessels. It is worth remarking that in such cases as the above, and in the allied state of polyeholia or bilious flux, which is also attended with jaundice, the liver-tissue must be in an opposite condition to that which prevails in many common cases of icterus. Instead of being torpid, it is fully or over active, and the chief indication is to diminish the afflux of blood.

*Case 4.—Jaundice—Cure apparently by Nitro-Muriatic Acid Lotion alone.*

G. P., aged 25, merchant service, admitted March 3. He had been ill fourteen days, and markedly jaundiced all the time. He felt low and weak three weeks before the jaundice appeared. His stools were pale coloured, and the urine very dark. The appetite was very fair, but had not been for the first week or two of his illness. The liver extended about two finger-breadths below the ribs. Tongue coated. Bowels open three times a-day without medicine. He was ordered only a nitro-muriatic lotion to apply to the right side of the abdomen. Improvement commenced speedily, and he was quite well in a fortnight. At the end of the first week the urine deposited a copious sediment.

*Remarks.*—The nitro-muriatic acid appears to have acted very beneficially in this case.

*Case 5.—Jaundice—Treatment by Colchicum—Recovery—Colchicum a Cholagogue.*

James B., aged 22, admitted December 11. He had been ill two days, and, when seen by Dr. Jones, was jaundiced. Urine thick and high-coloured. Motions slaty. Tongue clean. Very little pain about the epigastrium; some tenderness about the region of the duodenum. Bowels open. Hydrargyri chloridi, gr. v., h. n. s.

13th.—Same state as before. Pulv. ipecacuan., gr. v., ter. die.

17th.—Since the 15th has had—℞ Acidi nitro-muriat., ℥v.; aquæ, ℥j., ter. die. Bowels relaxed two days. Urine to-day is yellow with bile, as tested by nitric acid. Motions still paler. Appetite good. ℞ Extr. colchici acet., gr. ij., in pil., ter. die.

20th.—His skin is much clearer, and the motions and urine are of a much better colour. No purging from the pills. Pulse good. Capiat pil. colchici, bis die.

31st.—He is quite well. There is scarcely a trace of yellowness of the conjunctivæ; motions natural; urine a little red in the morning.

℞ Acidi nitro-muriat., ℥v.; liq. taraxaci, ℥j.; infus. casearillæ, ℥j., ter. die.

January 14.—Discharged.

*Remarks.*—There can be no question that the colchicum exerted virtue in this instance as a cholagogue. In my belief it is one of the most potent. I have seen it succeed satisfactorily when mercury entirely failed.

*Case 6.—Simple Hepatic Torpor—Jaundice—Failure of Podophyllin—Good Effect of Nitro-Muriatic Acid.*

Charlotte S., aged 32, admitted August 30, 1862. She has been ill eleven weeks, and jaundiced all the time; the urine has been very high coloured, and stools pale, and they are so still; there is no pain in the abdomen, and no tumour is discoverable; the liver extends about two finger-breadths below the ribs; she has had pain after taking food, and her bowels have been relaxed; tongue clean; appetite indifferent. ℞ Podophyllin, gr. ½; extr. hyoseyami, gr. ij., ter. die.

September 4.—Some appearance of bile in the stools;

bowels much acted on; urine deep red, and when treated with nitric acid it is changed to a deep, dull green—when boiled it becomes almost black.

11th.—There is some, but not marked improvement; bowels relaxed; omit pill. ℞ Acidi nitro-muriat., ℥v.; aquæ, ℥j., ter. die. s. ℞ Acidi nitro-muriat. dilut., pro manuluvio.

26th.—Her health better, and the jaundice is declining slowly; the acid has produced some eruption on the arms from its local irritation; there is no bilious diarrhœa; tongue remarkably large, clean, and smooth, not a papilla to be seen in the mid part.

October 11.—The jaundice has now almost disappeared; the motions and urine are much more natural; the appetite is good; the manuluvium has been omitted.

She was discharged well soon after.

*Remarks.*—The pathological state giving rise to the jaundice in this case is far from being clear. There does not appear to have been any notable congestion, or any impaction of concretions in the ducts. The disorder was essentially chronic, and not very markedly influenced by remedies. Podophyllin had very little effect. Nitro-muriatic acid was more serviceable, at least taken internally; as a lotion it showed no virtue. The failure of podophyllin is, to my mind, tolerably conclusive that there was no vascular engorgement of the liver; and the absence of any abdominal tenderness also is against the view of catarrhal duodenitis causing tumefaction of the mucous lining and obstruction of the ductus communis choledochus. The action of mineral acids appears mostly to consist in a toning and astringing of the homogeneous capillary walls and liminary membranes, so that they allow less fluid exudation to take place. They diminish the alkalinity of the blood, and render it more exciting to the tissues. While the general effect of these acids is thus decidedly restrictive of morbid or excessive secretion of eutaneous or mucous flux, the nitric and nitro-muriatic have, evidently, in a high degree, an opposite influence in regard to the liver. The bile-secreting apparatus is by them powerfully stimulated, especially when they are applied in the form of bath. How they affect the sugar-secreting part of the organ we are quite ignorant; but it may, perhaps, be inferred that its saccharine product is not augmented like the biliary, as there appears to be no indication of an excess of sugar passing off by the kidneys. In the above case the acids appear to have acted as a general tonic and hepatic stimulant.

*Case 7.—Jaundice, at First Simple, afterwards assuming the "Pernicious" Character—Death—Autopsy.*

Laura P., aged 6, admitted January 6, 1862. She had been ill seven days, and was very yellow. The motions were very pale, and the urine high-coloured. She had not much appetite, but did not appear to ail much. Bowels open daily; thirsty; tongue whitish. A grain and a-half of calomel every night,

9th.—State the same. ℞ Extract colchici acet., gr. j., bis die.

13th.—The colchicum caused gastric disorder and vomiting, but did not alter the state of the urine or stools. The sickness had been quieted by an effervescing saline and hydrocyanic acid, and a blister had been applied to the right hypochondrium. Three grains of calomel also were given last night. She had slept well, but was drowsy to-day, though quite conscious. Tongue white. Some pain in the head. To continue to take three grains of calomel every night.

17th.—The liver did not extend beyond the ribs, and the spleen was not enlarged. The urine was clear and yellow, the stools solid and clayey. Tongue coated. She had five grains of calomel last night. Nitro-muriatic acid internally and as a foot bath.

18th.—She began to be delirious yesterday, and continued very much so during the night, screaming a great deal. She continued to-day in nearly the same state, moaning and screaming, and in a state of stupor. She had passed no stools or urine. Pulse not frequent, but weak; pupils large. A jalap purge was given, and a turpentine enema, and also some quinine, but she died in the following night comatose.

At the autopsy, no other change was found except shrinking of the liver. Its surface and interior were yellow in patches. The cells were deeply yellow stained, and tending to break up into granules and fatty detritus. The gall passages were free.

*Remarks.*—The most remarkable feature in this case was

the length of time which the disease continued without showing any indication of "perniciousness." The child had been ill twelve or thirteen days before any trace of serious disorder appeared, and it was not till the seventeenth day that head symptoms were clearly marked. Wunderlich thinks that cases of this kind have, in common with many others, where the disease has a different seat, the element of "perniciousness," by which he implies an inevitable, or almost inevitable, destructive tendency. Pernicious jaundice, one may conceive, may be similar to malignant scarlatina, which originates from the same influence that affects but slightly one member of a family, while, to another, it is most virulent. The difference of effect is not in the influence, but in the recipient system. So it may be with pernicious jaundice—the effective cause may be the same obscure influence which causes, in other cases, an innocuous paresis of the liver, such as seems to have existed in Cases 4, 5, and 6.

SATURDAY, FEBRUARY 7.

### CARDINAL WISEMAN ON "POINTS OF CONTACT BETWEEN SCIENCE AND ART."

"POINTS of contact between science and art! Would that they were multiplied so far as the healing art is concerned!" Such were our thoughts as we went, on Friday evening last, to hear the discourse on this subject by Cardinal Wiseman at the Royal Institution. It was evident enough that the curiosity of this great town had been thoroughly aroused. Never within our own recollection was the theatre more crowded, not even on Faraday nights, nor yet when Du Chaillu narrated his exploits amongst apes and cannibals. One veteran philosopher amongst the auditory declared that he had never seen such a throng there since the days of Humphrey Davy, in 1808. Well-shaven priests of the Roman Church, and well-bearded philosophers, Anglican clergymen, and many of the most conspicuous members of our own Profession, with Sir Henry Holland in the chair, were amongst the listeners to a discourse of nearly two hours' duration, of which we will attempt to give a rapid sketch, with such a commentary as may illustrate the relative position of science and art in Medicine.

The Cardinal, in treating of "science" and "art," on this occasion, used the term "science" in its widest application, as embracing all human knowledge which has the stamp of exactitude and precision; whilst, under the term "art," he dealt solely with those branches of "the fine arts" which appeal to the eye;—that is to say, the "arts of design," including painting, sculpture, and architecture, and not to the other branches of the fine arts, whence we derive solace and ornament, as poetry and music, nor yet to the practical arts, as agriculture, Medicine, and metallurgy, whence we derive the necessaries and luxuries of our lives.

First, he treated of science and art as they came in contact in painting. As an art, painting has been known from very early times, but it is only of very recent date that it has been

aided by science; for perspective, the science which treats of the representation of objects on flat surfaces, and of the method of representing distance by proportion, is of quite modern origin,—whether it be scientific perspective, strictly so-called, which gives correctness of form, or artistic or aerial perspective, which teaches the nicer gradations of tone. Herein we may gather the existence of three stages:—The first, in which paintings and other representations on flat surfaces were effected, not only absolutely without perspective, but in defiance of it, and, probably, with an utter unconsciousness, on the part of the painter, that such a science could exist, or would ever be developed. This stage may be exemplified by the Assyrian marbles, in which scenes are represented in low relief—sieges, battles, towns, and rivers;—but men are represented in the clouds as they are in a willow pattern tea-cup, and boats at the bottom of the river, amongst the fishes. In Egyptian paintings, too, kings and magnates are represented as of huge size, and common people like the pigmies; and this utter absence, not only of knowledge of perspective, but of consciousness of ignorance, prevailed amongst nations who were no mean proficient in many of the practical arts, and who could build royal palaces and mighty temples. This stage may typify that of the healing art in its lowest stage, as amongst the Greeks at the Trojan war, or the savages of the South Sea in our own day. But, reader, it does not the less typify the present state of Medicine so far as regards the nervous system, respecting which even yet we are dimly groping our way, and too often meddling with matters of which we know the facts most imperfectly, and the laws not at all.

The second stage is that of great Artists—men whose genius and industry, and powers of observation enable them to work out practical results—to do things before the invention of scientific rules, and to hand down methods of practice derived from experience. So when painting rose above Byzantine mannerism, the great pre-Raphaelites, Giotto, Van Eyck, and Pietro della Francesca, a friend of Raffaele's father, made themselves, practically, masters of perspective; that is to say, they did paint pictures, in which objects and distances were rightly represented on flat surfaces, although the scientific rules of perspective did not then exist. This stage represents that out of which actual Medicine is struggling. Our practice is not deduced from scientific data, but is empirical, that is to say, is based upon the experience of Great Masters, who have, from time to time, taught their disciples and successors to see things with their eyes, and work according to their rules. We who devoutly believe in the unity of Medicine hold that all great Physicians in all ages treat disease as much alike each other as the difference of circumstances permits—that the sagacity, and penetration, and practical tact of Hippocrates in one age, and of Galen in another, would, had they been born in these times, have ranked them with Sydenham, or Huxham, or Fothergill, or Baillie, or Halford, or Pennington, or Hooper, or Chambers, or Tegart—men who may be taken as types of the best Practitioners of their day. Modern times, with increased light for the collateral sciences, bring improvements in details—individual character causes difference in any age; but in all ages the great artists shine out as men who do things well, even in the absence of scientific laws, and who leave practical rules to a school of disciples and imitators.

But then followed, in painting, a third stage, in which science came thoroughly into contact with art. Leonardo da Vinci and Albert Durer perfected the art. Then arose the science of perspective: the first treatise published in 1608; Brooke Taylor's standard book in 1731. But now the representation of objects no longer depends on arbitrary conventions, as did those of the Egyptians; nor on the genius of individual artists, whose sagacity enabled them to work without rule, but on a body of scientific principles, which are everlastingly true, and admit of no possible deviation.

In some details, a scientific basis can be predicated in Medicine. Science, too, supplies infinite modes of exploration, diagnosis, and remedy; but we have not yet solved some of the most elementary problems of life. There are doubts yet as to the source of animal heat, the production of sugar, carbonic acid, and urea; and till these are solved, to say nothing of the higher phenomena of the nervous system, and till the natural history of health, and growth, and decay is more minutely known, a scientific, as distinguished from a practical or empirical, treatment of disease is an idle dream. Medical practice may be sagacious, may be the effort of genius or imagination, may be successful, may be a boon to humanity—still it is *art*, not *science*.

A fourth stage was indicated by the Cardinal in the history of the effects of science upon art; and that is, that a knowledge of scientific principles shall be so diffused, that a deviation from them would be scouted by the population, as certainly as would the notion that two and two could make aught else than four. The vulgar would not tolerate even a sign-board out of perspective now. So the day may come, though it has not come yet, when the vulgar may see the imbecility of quackery—the contrariety of the doctrines of quacks to each other and to truth; and it may be repeated as a joke, that, in some barbarous and conceited nineteenth century, an Irish archbishop could write on behalf of homœopathy and mesmerism!

We must pass over much that the Cardinal said showing how general progress in art of all kinds facilitates the operations of every individual branch; how the Crystal Palace, the product of the iron and glass trades, enables Handel's music to be performed with a grandeur which even the composer could scarcely have realised; and how the railway indoctrinates the masses with love of the natural landscape,—a love which the Cardinal, with other great scholars, denies to the ancients, though we venture to think on scarcely sufficient grounds. So we see how largely the manufacture of glass, India-rubber, gutta-percha, and aluminium, and improvements in chemistry, add to the means of relieving sickness and suffering. But the Cardinal's remarks on colour have a useful moral.

Poor as they were in perspective, the ancients were grand in colour. The frescoes in the tombs of ancient Egypt and in the monumental churches of mediæval Italy seem as if their colours would stand till the day of judgment. This was a good empirical result. Modern chemical science has not come to the aid of art here. The composition of these colours is unknown, and science prefers to enslave herself to dyers and other manufacturers than to assist fine art. We do not yet know, either experimentally or scientifically, the conditions under which colour will resist a London atmosphere.

The Cardinal might have added a weighty moral, but did not. Some modern painters, beguiled by imperfect chemical knowledge, have departed from old practical rules, and used colours which do not stand. Reynolds, for example. Here is exemplified that ridicule of our Profession,—the habit of altering old remedies and modes of treatment, on imperfect scientific data, false analogies, visionary theories, and experiments which prove nothing. Instances crowd upon us like leaves in autumn; space compels us to mention one only. Wine is or is not beneficial as an article of diet in health, and in certain cases of disease. If beneficial—a thing to be known only by experiment—it should be given; if hurtful, should be forbidden. What are we to think of the *quasi*-scientific Practitioners who forbid wine because the dubious experiments of Lallemand, Perrin, and Duroy seem to show that it is “not food”? Why, that patients treated on such visionary notions are very likely to show the ghostly, bluish colours of the decaying beauties on Sir Joshua's canvass.

The remarks on sculpture, on the proportions of the human figure, and their identity with the subdivisions of a musically vibrating string, and with that curve which bounds

the orbs in space, so as to make man, even by his outward configuration, a type of the power, and beauty, and harmony of all creation, must be passed over; but there followed some remarks on the relations of anatomy to art, which deserve notice and comment.

In Greek sculpture (said the Cardinal) two singularly contrasted features strike every observer:—the magnificent, placid, intellectual heads; and the exaggerated, brute-like development of the muscles. Whence the grand serenity of those heads of poets and philosophers culminating in Plato? Clearly the sculptor had before him men of thought—not always right thought, perhaps—but still men in whom the intellectual powers were developed beyond example before or since. But whence the muscular development? Was it a result of training and the gymnasium? The Cardinal thought not; but that it—exaggerated and untrue, as it seems to us—was the result of the witnessing by the sculptor of muscular actions, the physiological expression of intense brutal emotion of a kind which to us are, happily, unknown. He illustrated this point thus:—Amongst the most interesting by-sources of knowledge of the habits and life of the ancients are the *Graffiti*, or rough sketches and inscriptions which the slaves and vulgar of old time scratched on the walls, just as the vulgar now scribble whenever they can get access to any flat surface in public that they can deface. As cads and jockeys now would sketch prize-fights and horse-races, so, as a matter of course, slaves of old sketched gladiatorial combats. For example, amongst these *Graffiti* has been copied and published a sketch of a fight between two men—one, Spiculus, a tyro whose sword was unflashed; the other, Adtimetus, whom the numerals xvi. showed to have been the victor in that number of murderous conflicts. Spiculus was now the victor—Adtimetus lay at his feet. Now, imagine these men, inspired with no moral or noble feeling—not even with what the lowest of us call honour and good feeling—no preliminary shaking of hands—standing forth naked, under the eyes of 80,000 spectators, in the deepest silence, glaring at each other with murderous eyes, approaching each other with the stealth and ferocity of tigers, and animated alone with the lust of blood—how those hearts *bet*! (we thank the Cardinal for using the *strong* Saxon-English form of this preterite)—how those lungs dilated!—how every outward muscle would swell and knot itself with the intensest energy! And so the sculptor's keen eyes noted and represented *living* muscular forms, such as we see and wonder at (for, be it remembered that he could not dissect.)

And here, our readers will pardon us for recalling what we said, in our late *éloge* of Robert Knox, of that great anatomist's idea of the true functions of anatomy in the study of art. Anatomy is a means to an end; it is like the dictionary which explains the living forms of speech. An anatomist knows where muscular, and sinewy, and bony elevations *can* be shown, and where they *cannot*; but that is no reason why they *should* be shown, as in the grotesque figures of Fuseli and others, who fancy that a man is an artist because he is an anatomist. There is here the same distinction as between a scholar and a pedant; between the manners of a gentleman and the grimaces of a dancing-master. Beauty is the thing to represent—that which speaks of life: sinews, as shown by modern artists, reek of death and the dissecting-room.

We can only record the Cardinal's emphatic approbation of the study of ethnography—of the form, costume, and mode of life, and intellectual expression of various races; his whole remarks on architecture; his condemnation of the neglect of scientific insight into the nature of the stone with which the Houses of Parliament are built, and his account of the manner in which pure science was employed to detect and remedy the tottering cupola of St. Peter's. We must conclude this hasty notice of a long and eloquent discourse with one of the anecdotes by which the speaker gave it the

relish of geniality and humour. When saying how necessary it was for artists to *know* the objects which they undertook to delineate, so as to preserve truth in details, he told us that a friend once overheard a couple of Yorkshire grooms criticising a picture of the death of Absalom, represented, as usual, hanging by his hair, with his mule close by: "Sarve him right," was the exclamation of one of these hippologists. "But why?" "For riding such a vicious brute as that with only a snaffle."

### THE WEEK.

#### INCREASED DUTIES OF POOR-LAW MEDICAL OFFICERS AT OLDHAM.

ALTHOUGH we have shown that epidemic typhus is not prevailing in the manufacturing districts as the result of the prevailing distress, yet it is admitted on all hands, that the claims made upon the administrators of the Poor-law, and, consequently, upon the Poor-law Medical officers in Lancashire, have very largely increased during the last twelve months. Persons who have hitherto been able to pay for Medical attendance have latterly become incapable of doing so, and it has, therefore, followed, that the Poor-law Surgeons have had their duties enormously augmented—sometimes to double, and sometimes even to five times their former extent. A deputation of the Medical officers of the Oldham Union waited upon the Board of Guardians at Oldham on the 24th January, and, representing the circumstances to which we have just alluded, claimed an increase of salary as a just recompense for the extra labour which they were now called upon to perform. The board have not at present come to any definite resolution on the subject, the guardians seeming to be in doubt whether the difficulty should be met by an increase of the salaries, or by the appointment of additional Medical officers; but it appears that the complaints of the deputation were admitted to be founded in justice.

#### RECENT APPOINTMENT OF A CERTIFYING SURGEON AT OLDHAM.

FROM a letter, which appeared in our last Number, from a correspondent under the signature of "Beta," it will be perceived that very considerable dissatisfaction prevails in the town of Oldham in consequence of the recent appointment of a Certifying Surgeon to the Factories. The appointment in question is a rather valuable one, considering the usual rate of Medical remuneration at the present day, as it amounts to about £250 or £300 per annum, and the duties are by no means laborious or incompatible with the ordinary avocations of a Medical Practitioner. A vacancy has lately occurred in the district, in consequence of the death of Mr. Earnshaw, one of the Certifying Surgeons, and it was expected by the inhabitants of Oldham that the choice of a successor would fall upon one of the Medical gentlemen resident in the town; but, to the great surprise and disappointment of all parties, it appears that a young gentleman, who has just completed his Medical education, and who is not resident in the district, has been appointed to the post. The patronage rests with the local Inspector of Factories, and the gentleman whom he has appointed is said to be the son of a sub-inspector in a neighbouring district. The affair thus bears something like the aspect of official jobbery, and we, therefore, are inclined to applaud the Profession in Oldham for the steps which we find they have taken. At a numerously attended meeting of the local Practitioners, held at the Angel Hotel on the 29th of January, the following resolutions were unanimously adopted:—

"That this meeting views with the greatest dissatisfaction Mr. Redgrave's appointment of a non-resident junior member of the Profession to the office of Certifying Surgeon to the Factories, lately held by Mr. Earnshaw, thereby entirely disregarding the claims of Medical gentlemen of standing and experience, many years resident in the town, and possessing

the confidence of the public; and as this appointment is calculated not only to discourage rising local merit but to reflect discredit upon the whole body of the Profession in this locality, we, therefore, unhesitatingly record our protest against the disposal of public appointments, conferred, as this has been, without regard either to the age, the *status*, or the claims of the person appointed.—That the claims of the resident members of the Profession having been entirely overlooked in the appointment just made, J. M. Cobbett, Esq., and J. T. Hibbert, Esq., members of parliament for this borough, be respectfully requested to accompany a deputation from this meeting to the Right Hon. Sir George Grey, Bart., her Majesty's Secretary of State for the Home Department, to lay before him the circumstances of the injustice done to the resident Medical Practitioners, with the view of having the appointment reconsidered and revoked, and of inducing the Home Secretary to give such directions and instructions to the inspectors of factories as shall secure, in future, the appointment of Certifying Surgeon being conferred only on some duly qualified Medical Practitioner resident in the district.—That Messrs. Leach (chairman), Thomson, and Dr. Armitage, be requested to accompany the members of the borough as a deputation to submit the foregoing resolutions to the Home Secretary."

#### NON-INFLAMMABLE CLOTHING.

THE inquiry into the circumstances attending the late dreadful accident at the Princess's Theatre, besides its use in bringing to light a culpable omission of the usual provisions for extinguishing fire on the part of the theatrical management, was turned to good account by the coroner in a sensible and practical summing-up. It is of no use reviling the fashion of crinoline. It is only to be hoped that the epidemic of bad taste has reached its height, and that a decline may be expected:

"Dr. Lankester thought it quite impossible by any amount of reason or warning to produce any effect on fashion, and persons who had given much consideration to the subject had arrived at a similar conclusion. He did not know how many women would be required to be burnt to death before any of the fair sex would give up wearing an article of fashion—such a thing was not to be thought of; but if there was no chance of getting rid of the dress itself there were means of rendering it unflammable; yet, strange to say, such an obvious precaution was little thought of, while the danger of ignition had constantly been increased from the time of the ancients till now, when, by the extensive use of gas and the style of our grates, it was very imminent. In reference to the use of sulphate of ammonia, tungstate of soda, or other chemical preparation, by laundresses, it had been stated, in a letter to the *Times*, that the light dresses worn on the stage and in ball-rooms were never washed. If that was so, the question in respect to such dresses became one of manufacture; and from a letter published in the *Times* of that morning by a firm in Oxford-street, it appeared that if there was a demand for unflammable materials for ladies' dresses there would be an ample supply of such articles. This remark applied not only to tarletans and muslins, but to linens, and to all articles of cotton manufacture. There seemed no reason why an inflammable nightdress should be put on any child in the kingdom. Since his appointment as coroner for Central Middlesex he had held 601 inquests, of which 23 were in cases of burning, 18 of these having been caused by clothes catching fire. At least two-thirds of these might have been prevented by the wearing of unflammable clothing. From these figures they might form some idea of the annual loss of life throughout the kingdom from clothes catching fire; and as the attention of the public had recently been called to the subject by several very melancholy accidents and by writings in the press, it was to be hoped that a subject in which we were all so deeply interested might at length be dealt with in a satisfactory manner."

#### FEVER AND FAMINE IN LANCASHIRE.

THE remarks we made in our leading article of last week, in reference to the alleged connexion between fever and famine in the cotton districts, have received an ample confirmation by the publication of the quarterly return of the marriages,

births, and deaths, by the Registrar-General. This return is dated January 30, and our article on the fever-panic was in type on the 29th, and we mention these dates only to prove that, although our language and that employed by the Registrar-General are almost identical, the views at which we arrived were altogether independent of the official publication. The return, after alluding to Dr. Buchanan's report, refers also to the Report of the Manchester Central Executive Committee for the Relief of Distress, dated January 19, the latter document, as we stated, being at variance with the conclusions arrived at by Dr. Buchanan. We quote the following passages, *verbatim*, from the Registrar-General's return, in order to prove the close similarity of the language and of the sentiments which we ourselves expressed :

"The Registrar of Preston sub-district reports that typhus became prevalent there in the early part of October ; it excited the most serious apprehensions, and, notwithstanding the greatest efforts to check its progress, 48 cases proved fatal. Dr. Buchanan in his report pronounced it to be of the Irish type, 'the steady follower on famine ;' he found a decline from the normal standard of health among the unemployed operatives of the cotton towns, and that scurvy and other symptoms of a hæmorrhagic tendency had been manifested. On the other hand, the report of the Central Executive Committee (for the relief of distress), dated January 19, states that the middle of winter had been gained without the outbreak of any serious epidemic, or the appearance of scurvy, diarrhœa, or dysentery, forms of disease that follow prolonged low diet, and the use of coarse food without much variety. The Registrar of Chorlton-upon-Medlock writes that, notwithstanding the great number of persons unemployed, no epidemic has prevailed, nor any disease resulting from privation ; that the poor are provided for liberally and with 'wise economy.' Scarletina and diphtheria, and also diarrhœa, prevailed to a considerable extent in Manchester. An increase of deaths in Ashton-under-Lyne is attributed to scarlatina and measles. Scarletina caused eighty deaths, being a third part of the total number, in Oldham-above-town ; these occurred not only in the working class, but in the general population. In Blackburn and in Witton, which is also in the Blackburn district, the mortality was increased by measles and bronchitis ; and at the latter place there was 'much sickness in consequence of the damp weather.' The mortality in the Chorley sub-district was nearly doubled, chiefly by measles ; and the weather, 'mild and damp,' was considered unfavourable to health.

"It will tend to strengthen the conclusion, that the increase of mortality in Lancashire in the last quarter was not caused directly by famine, nor indirectly by diseases induced or aggravated by it, if it be stated, in addition to facts that have been mentioned above, that of the twenty-six districts of which that county is composed, while a certain number exhibited an increase of deaths over those of the corresponding quarter in 1861, there was in an equal number of districts an actual decrease. The districts of Bolton, Manchester, Salford, Burnley, and Preston are amongst those that stand in the latter more favourable category. The munificence of the nation, aided by its kinsfolk in other lands who 'have brought their food from afar,' has hitherto averted the last, direst extremity, the death of a people by famine. Amongst elements of the situation that have been conducive to health, are the cheapness of provisions, a winter in great part unusually mild, increase of maternal care, recreation out of doors, and, perhaps, for many men and women who were not robust, a season of needful rest. The future of 'the cotton-famine' is still undetermined,—in the language of the Central Executive Committee it may be even 'full of gloom and uncertainty,' and 'to chill the sympathy or arrest the efforts' that have been evoked would be rash,—but that which is passed may be subject of congratulation ; and it is now known that the history of the distress is not written in the death-registers of the year that has closed."

**CONSUMPTION OF HORSE-FLESH IN BERLIN.**—A Berlin newspaper makes the statement, that there are at the present time seven markets for horse-flesh in that city, in which, during the first ten months of 1862, there were 750 horses slaughtered. No horse is allowed to be slaughtered and sold without the certificate of a Veterinary Surgeon.

## REVIEWS.

*Clinical Lectures on Pulmonary Consumption.* By the late THEOPHILUS THOMPSON, M.D., F.R.S. With Additional Lectures by his Son, E. SYMES THOMPSON, M.D., M.R.C.P., etc. London : Churchill and Sons.

WERE the book before us merely a re-issue of the late Dr. Thompson's well-known lectures on Consumption, it would demand nothing more than a line of friendly recognition from the reviewer. But, as its title-page states, it is more than this. It contains two really valuable lectures by the son of the author, embodying, as he tells us, some observations which illustrate and some which modify the original lectures, together with remarks on new but correlative topics. The author's Lettsomian lectures, a paper read by him before the Royal Society on the "Influence of Different Oils in Phthisis," and an unpublished essay on "Venous Murmurs," have furnished the editor with part of the material of the additional lectures.

The manner in which Dr. Symes Thompson has performed his task is alike creditable to him as a son zealous for his father's Professional reputation, and as a young author desirous of securing a like reward for himself. To two or three points only in the added portion of the work we can now draw attention.

Dr. Thompson defines tubercle as morbid secretion taking the place of healthy product : the material thus imperfectly formed, failing to pass through the usual changes, is left as a foreign body in the organ in which it originated. It may be an accumulation of morbid lymph in the lymphatic glands ; or a collection of inspissated pus ; or a material differing from inflammatory exudation only in being prone to degeneration and disintegration ; or a modified form of epithelium. The last variety he regards as *the* tubercle of phthisis, except in those cases which are preceded by pneumonia, or in which tubercle is formed by the drying up of an encysted abscess. It will hence be seen that Dr. S. Thompson accepts the modern opinion, that the pulmonary vesicles are lined by an epithelium. He adds in a note :—

"In deference to the opinion of my esteemed teachers, Messrs. Todd and Bowman, I was long disposed to question the existence of epithelium in the air-cells of the lung, but was first shaken in this opinion by observing, some years since, a distinct epithelial lining in the pulmonary vesicles of the cat ; and, shortly afterwards, my friend, Dr. Andrew Clark, showed me a similar layer in the human air-cell. Recent observations with an ammoniacal solution of carmine, as employed by my colleague, Dr. Beale, in his minute researches on the 'Structure and Growth of Tissues,' have enabled me to exhibit these cells, the nucleus being coloured by the carmine and rendered perfectly distinct."

Those who have had the advantage of attending Dr. Andrew Clark's demonstrations of the pulmonary air-cells will entertain no doubt as to the existence of the epithelial layer. Dr. Thompson believes that the relation between epithelium and tubercle may be demonstrated by a frequent examination of the expectoration with the aid of a carmine solution, and by comparing it with the post-mortem appearances. He adds :—

"In phthisis, the expectoration may be simply frothy, as in catarrh ; sometimes it is quite gelatinous, and contains granules, molecules, and a few scattered mucous corpuscles. If examined in water, the edge of this gelatinous matter looks like the margin of an epithelial cell ; indeed, the structureless or molecular matrix seems to correspond with the scale of epithelium ; the contained granular mucus corpuscle to its nucleus. Regarded in this light, epithelium differs only from mucus in being apt to break up into distinct pavement-like portions ; whereas the mucus, which has not this propensity, forms a tenacious mass, resisting the pressure of the microscope glasses."

Phthisis, in its totality, Dr. Thompson describes as an error in the organism, exhibiting itself generally in defective blood and imperfect hurried action—locally in faulty cell formation. The first appreciable step in the disease he thinks to be changes in the mesenteric glands, as indicated by an imperfect performance of their part in the elaboration of the blood. Evidences of the hurried action are found not only in the quick pulse, but in the hastened respiration and over-rapid secretion. Cod-liver oil, whilst it relieves other symptoms,

seems to act last upon the pulse. It is for this reason that ozone has been combined with it by the author. The experiments, both of Dr. Thompson and his son, have led them to believe "that ozone exerts a remarkable influence on the pulse, lowering it, in many instances, ten, twenty, or even thirty beats per minute," without the depressing effects of digitalis.

The author has found neats-foot oil (*Oleum bubuli*) of great value in cases where irritability of the bowels forbade the employment of cod-liver oil. Its slight smell especially renders it useful for inunction. He recommends that two or three ounces, combined with a grain of iodine and a few drops of oil of lavender, be rubbed in warm at bedtime, the body having been previously sponged with tepid water containing a little soda.

We have only touched cursorily on a small portion of the subjects of the additional lectures, but we cannot extend our notice. We would only say, in conclusion, that they contain much that is of interest—much that is suggestive in theory, and several hints that may be useful in practice.

*The Climate of the South of Devon, and its Influence upon Health; with Short Accounts of Exeter, Torquay, Babbicombe, Teignmouth, Dawlish, Exmouth, Budleigh-Salterton, Sidmouth, etc.* By THOMAS SHAPPELTON, M.D., F.R.C.P., Senior-Physician to the Devon and Exeter Hospital, etc. Second Edition. London: John Churchill and Sons. 1862. Pp. 282.

THE first edition of this work appeared twenty years ago: its plan has been preserved in the present; but the book has been re-written and improved in accordance with the increased experience and extended observations of the author. The work constitutes, in its amended form, an excellent introduction and guide to all that concerns the topography, climate, geology, natural productions, and industry of South Devon. The seventh chapter is devoted to a consideration of diseases as they occur there, arranged in the order now adopted by the Registrar General. The eighth chapter relates to the climate of South Devon considered with reference to its general effects on health and disease. The book is one of those few Medical works, the perusal of which may be usefully recommended to the general public as well as to the Profession. It is evidently designed for the reading of both classes.

*Life in Nature.* By JAMES HINTON, Author of "Man and his Dwelling-place." London: Smith, Elder, and Co. 1862. Pp. 258.

MR. HINTON is a speculative philosopher—some would call him a pseudo-philosopher—who would persuade us that we all live literally in a vain show, and would resolve the material, about which we even now know little, into the spiritual, about which we know infinitely less. Well, what then—suppose it were true that all physical existence were a myth and a dream, we are ourselves a portion of the deception, and we and our surroundings constitute a harmonious whole, in which everything proceeds so regularly that the relations of the one to the other may be studied, and its so-called laws deduced, as if all were a reality. Until, therefore, Mr. Hinton proves to us a little more satisfactorily that we are wrong, and that our wrong notions lead to practical errors, we prefer the old to the new light. Still, there are minds which, at any rate, may find a beneficial exercise in the perusal of Mr. Hinton's book, and to such as possess them we commend it. It is readable and interesting, if not always clear. We should be sorry to crush or even to discourage inquiries into the relations between the material and immaterial. The ground, however, on which the inquirer must tread is dangerous as well as difficult.

*Health in the Tropics; or, Sanitary Art Applied to Europeans in India.* By W. J. MOORE, L.R.C.P. Edin., M.R.C.S. Eng., Bombay Medical Service. London: John Churchill and Sons. 1862. Pp. 318.

SOME little time ago we had occasion to notice favourably a "Manual of the Diseases of India" by this author. We are glad to meet with him again in print, and writing upon a subject so vitally important as the application of sanitary art to the residents in tropical climates. Nothing can be more practical than this volume, which should be read not only by

our Medical officers in India, but by combatant officers also, and by civilians, for its truths concern all. Well does the author say that "the principles of sanitary science should form part of the educational course of every military officer. Having been made aware of the truth of those principles, there would be little danger of any superior officer questioning their practical application in matters of detail, the due observance of which must always be initiated by the professional knowledge of the Medical officer."—P. 9. Besides, the book before us is not by any means devoid of interest to ourselves, though living in a temperate climate. The principles involved are of world-wide application; and the special suggestions of the author have often that in them which may furnish a wrinkle to sanitarians here. Mr. Moore is a clear, concise, and agreeable writer. The book is enhanced in value, too, by a copious index.

*Illustrations of Dissections in a Series of Original Coloured Plates the Size of Life, representing the Dissection of the Human Body.* By GEORGE VINER ELLIS, Professor of Anatomy in University College, London, and G. H. FORD.

THIS work is original in design and original in its execution; that is to say, the plan and object are new, and the plates, which form the basis of the whole, are new—copied from nature only. In the anatomical plates in common use the various systems are, for the most part, represented separately, the muscles connected only with the bones, the blood-vessels apart from the nerves, and so on. But in this new work all structures are shown together, as they are in nature, or rather as they occur in a good dissection. The old plates had their uses, and they still have their uses. To the student they were useful, especially when the examinations in anatomy consisted in questions about "the origin and insertion" of muscles, "the course" of an artery, or "the distribution of the branches" of a nerve. But now that the quality of examinations has been much altered—that the candidate for a degree of the University, or a diploma of the College of Surgeons, is required either to make a dissection, displaying the various parts in their natural combination, or to point out the details of a dissection already prepared, the old plates are of but little assistance to the student. A new kind of anatomical plates was wanted in the new circumstances; and the want will be supplied by the work of which the first part is before us.

But how far are plates really of value? It is most important that there should be no misunderstanding as to the reply to be given to that question, and, therefore, we answer it thus:—

1. They are useful to the student as helps to his dissection.
2. They are useful, also, to recal the impression made by the careful examination of parts previously seen and learnt in dissection; and so they serve the purposes of the Surgeon as well as the young learner. Such are their real uses, and those are important. And in order to guard against a baneful mistake, we would add that plates of any kind are not to be regarded in any degree as substitutes for dissection. No error would be more injurious than to consider any imitation of nature in that light, wherever, as in the case before us, accurate knowledge is required.

The part of the work now published is quite successful. The plan of the dissection in each case, and the manner in which it has been rendered by drawing and colouring, are all that could be looked for. With these plates, and such as these, by his side, the learner will be well guided in his dissection; and under their guidance he may safely continue his study when out of the dissecting room. With such plates as these the Surgeon will be fully reminded of all that is needful in anatomy when engaged in planning an operation.

A word respecting the authors. The work is published in the joint names of Professor Ellis and Mr. Ford,—the anatomist and the artist. Mr. Ellis is well known as a teacher of anatomy, and the author of a most accurate anatomical treatise, "The Demonstrations of Anatomy," which has reached a fifth edition. Though there had been books named "Dissectors" long in use, that was really the first treatise in any language in which the student was completely guided in his course of practical study. It was remarkable also in this, that the various details of description were written, not from other books, but from the objects themselves; and hence the accuracy which characterises it. The intimate knowledge of so-called "descriptive anatomy" possessed by the author of that book, and his long experience as a teacher, are the best

guarantees for the accuracy and the judgment which ought to be expected in the new work. Mr. Ford is well known as an anatomical artist. The admirable expression and finish of his drawings for the work of Dr. Falconer on Fossil Bones, and of those for the illustrations of the Museum of Fort Pitt, were among the first proofs of the excellence that entitled Mr. Ford to the high position in his art which he has held for many years, as well as to the post of artist to the Royal Medical and Chirurgical Society, to which he was appointed after enquiry and report by a committee of that body. In securing such a fellow-labourer Mr. Ellis has been fortunate.

Considering, then, the usefulness of the work, its originality and truthfulness, as well as the care and finish of the part before us—considering also the reliance which may be placed on the authors as anatomist and artist, we give a hearty welcome to the "Illustrations of Dissections." Hereafter, when the publication is further advanced, we shall resume our notice of the book, and shall then review the commentaries which Professor Ellis connects with the explanation of the plates.

## FOREIGN AND PROVINCIAL CORRESPONDENCE.

### AMERICA.

CAMP, NEAR FALMOUTH, VIRGINIA, December 31, 1862.

#### THE BATTLE OF FREDERICKSBURG.

SINCE I wrote you last (a), many circumstances have occurred that, if chronicled by a pen more expert than mine, would, I believe, prove interesting to the Profession in peaceful England. My last, dated from Warrenton, told how the Surgeon's morning report was almost a blank; how robust was the health of the army; how high its spirits, and its hopes of success. This, written opposite Fredericksburg, has a different story to record: low spirits, from defeat, tell heavily on the health of the soldier, even though he is well sheltered, fed, and clothed,—though fuel is abundant, and the weather mild. Home-sickness, too, among the old regiments, impairs their energies, and renders them more susceptible to the operation of the many exciting causes of disease by which they are surrounded. During the early part of this month we were exposed to very severe weather, in consequence of which five deaths were recorded, and many cases of bronchitis and some of pleurisy found origin. A few days before active operations against the enemy behind Fredericksburg were commenced, the weather, fortunately, became quite mild, and continued so during the four days we spent on the south bank of the river. Had it been otherwise, we would have suffered much, as the men had to lie on their arms in the streets, without fires in many instances, lest, in the darkness of night, they should afford a tempting mark to the enemy's artillery. Many of the wounded, who, unable to crawl from the spot where they had fallen, had to remain for twenty or thirty hours before assistance was permitted by the enemy to reach them, would have been lost if the intense frost of the previous week had still continued.

The mass of our army crossed the Rappahannock on the 12th inst., and, entering Fredericksburg, found it ruined—deserted, save by a few negroes. The only sign of habitation to be seen was, depending from the windows of one or two houses, the red flag, indicating the regimental hospitals of those troops who had the dangerous honour of laying the pontoons, and being the first to cross.

On the morning of the 13th, when the heavy guns on our left told us the battle had already begun, we in the town were drawn up anxiously awaiting the next order. Presently the noise of artillery is heard immediately in our front, and the shells, with their fearful whirr, skim over the housetops. Now, we march slowly along the streets to the front, keeping as much under shelter of the houses as we can. Nothing is heard, save the ceaseless booming of the great guns, and the harsh sound of the death-bearing shells that fly overhead.

Scarcely does a man speak to his comrade; each knows that something must happen shortly, and each in fearful expectation awaits death's arrival in the ranks. He has come! See how suddenly that circle is cleared by the men falling back!—no, not cleared, for in it lie three motionless forms, one dead, and two severely wounded. The Surgeon and his assistant are immediately on the spot, and the wounded are carried into the nearest house. A little whisky is given, and some encouraging words spoken, and they feel much more comfortable while their accoutrements are being cut off, and their clothes ripped up, so as to expose the wounds. One, whose leg is found to be shattered, is placed upon a table that chances to be in the room, chloroform administered, the tourniquet applied, and the leg is speedily amputated. The other, whose scapula and upper part of humerus have been laid bare and shattered, has had some loose splinters gently removed, and lint applied as a dressing, so that he may be satisfied the Surgeons are not unmindful of him, and with a slight opiate he is left for after consideration. The house is searched for beds, but, as none are found, blankets are spread upon the floor, the red flag is suspended from the window, and a regimental Hospital is established. By this time the battle is raging fiercely without, and the wounded now come seeking assistance from the Surgeon's hands; severe cases carried in from the field by the men detailed for that purpose, slightly assisted by stragglers—others without any assistance at all—some of these last having barely an excuse for leaving the field. The Surgeons have now a busy time—cheering every one, probing this wound, extracting this bullet, bandaging one limb, supporting that other in a sling, placing a ligature on this little branch severed by a splinter from a shell, and that *will* persist in bleeding, sending those able to walk across the river for safety, and making those unable to do so as comfortable as they can, until orders concerning them shall arrive from the Medical Director of the corps d'armée to which they belong; and all the while the boom of the heavy guns, the sharp and ceaseless rattle of the musketry, and the noise of the travelling shot and shell, as they curve through the air, or crash through the houses, ring in their ears unheard and unheeded.

By the way, I may here tell you of a very useful application of a very useful instrument, which I had great pleasure in observing in one of the Hospitals, and which, I believe, is not yet generally known. I refer to the extraction of superficially-lodged bullets by means of the aneurismal needle; *e.g.*, a bullet struck a soldier on the left side of the chest, pierced the skin, and ran over the ribs and intercostal spaces, lodging a little above and to the right side of the umbilicus. The ball was steadied with the left forefinger and thumb, a puncture made through the skin with a scalpel, and the aneurismal needle hooked round the intruder, which was rendered prominent by slight traction on the handle of the instrument. This traction being continued, a cut through the integuments an inch in length was made, and the lead rolled upon the floor. Several bullets I saw very cleverly extracted after this fashion.

On Tuesday morning, the 16th inst., an order was issued that the wounded be immediately conveyed across the river to the Division Hospital; and until dusk the town presented a busy but sorrowful appearance—ambulances at every door, and wounded men being transported to them on stretchers, blankets, or in the arms of kind-hearted comrades.

On Wednesday, your correspondent paid a visit to one of these Division Hospitals, constituted on the plan originated by Dr. Letterman, the Medical Director of the army, and now, for the first time, on trial, to judge for himself of the success of the new organisation.

In my last, I sent you a circular in which the constitution of a Division Hospital is detailed: permit me here, however, shortly to state that there are—1. One Surgeon in charge and two assistants, one of whom keeps the records, the other providing food, shelter, etc., for the wounded. 2. Three operative Surgeons, each of which is provided with three assistants to aid him in his operations. 3. Additional Medical officers—that is, all the other Surgeons that can be spared from their regiments—to act as assistants, dressers, etc.

The Hospital to which I paid a visit consisted of a long street of handsome walled tents, falling perpendicularly on the centre of a shorter horizontal one: the former was occupied by the wounded and the operating theatres of the three Surgeons; the latter accommodated the Medical staff, their stores and supplies, and afforded shelter to the cooks while employed in preparing the food.

(a) The letter referred to by our correspondent has not come to hand.

Almost the first thing worthy of record that I observed after entering the street was—shall I tell it?—a Medical officer—a full Surgeon, as indicated by the oak leaves on his shoulder-straps—reeling complacently along with an as yet unopened bottle of brandy in his hand. This was, however, I am happy to state, the only instance of the kind I observed, and I fully expect that ere now this officer will have received the award his conduct at such a time so richly merits—a disgraceful dismissal from the service. Hearing piteous cries proceeding from one of the tents, I entered, and found ten poor fellows, ranged five on either side, shivering, dreary, and comfortless, on wet hay, with a damp blanket thrown over each.

It was bitterly cold; during the night it had rained, and towards morning a hard frost had set in, and the ten men with whom I then spoke, and many more, had been exposed, wounded as they were, to such weather for eight hours. They had arrived at the *dépôt* before the means to shelter them, and, what was nearly as bad, the officer whose duty it was to provide food, shelter, etc., being so much occupied in endeavouring to procure the latter, had but little time to look after the former, so that many of them owed the cup of warm coffee that so comforted them to slightly wounded companions, instead of to those under the orders of the "one assistant to provide food, shelter," etc. Of course, since tents were not on the ground when required, it would be out of the question to expect that stoves would be. Four days afterwards, indeed, every tent was furnished with a capital stove; bed-ticks were filled with *dry* hay; food, varied according to the case, was regularly supplied; bed pans, basins, &c., there were in abundance, and all glided smoothly in this department; but then four days were required to get things into working order. Now, though some of the essentials of a good military Hospital were not to be found when required, yet skilful operative Surgery was not one of them. The operative Surgeons, chosen, as the circular required, for their ability without reference to rank, were busily employed. Amputations rapidly followed each other, the circular operation being the favourite, on the ground that flaps were more apt to get shaken asunder by the jolting while being transported to the General Hospitals at Washington, Philadelphia, etc. I observed some cases of gunshot fracture of the femur in its upper third, in which the Surgeons had declined operating, but had splinted as skilfully as their meagre supply of appliances would permit. In one case I saw an incision, nine inches long, made along the outer aspect of the thigh, and five inches of the bone removed by the forceps and chain saw; the patient died twelve hours afterwards. One case of excision of the knee-joint I came across: the operation had been performed in Fredericksburg. In my opinion, the operator was too much of a conservative. It is useless, however, to attempt to mention in a letter one tithe of the interesting cases to be met with after such a battle as that of Fredericksburg.

With respect to the additional Medical officers detailed to act as assistants, dressers, etc., I found that they had had some difficulty in portioning out the labour. All desired to assist at operations; none to act as dressers. The wounded thus were neglected until about the third day, when the officer in charge remedied this by appointing one Surgeon to dress so many men. Now we have seen that the wounded were fed, sheltered, operated upon, and dressed, yet one thing is wanting. Enter a tent, and listen:—One man complains of a cough; another's bowels have not been opened for so long; a third is so weak, and requires something to strengthen him; and a fourth has been shot in the loins,—motion is lost, and sensation impaired, in his lower extremities,—his *feces* are passed involuntarily, and his abdomen is swollen and tense, yet no catheter is, or has been, lodged in his bladder. Since none of the supernumeraries had made it their business to attend to wants such as these, much good would have been effected, and many complaints suppressed, if an officer had been expressly detailed for this purpose.

To conclude, for I find that my letter is assuming a magnitude that I had not intended, I would recall to your memory a remark that I made in my last, to the effect that a process of weeding was going on among the Medical staff of this army, and would state, that since the last battle many Surgeons have resigned their positions. Important private concerns, they said, called them home; but it is known, among a select party, that an order requesting their presence in Washington before a board of examiners was the true cause.

## LEEDS.

(From a Correspondent.)

January 28.

A CASE has been made public in Leeds this week, though it has not found its way into the local papers yet, in which a gross piece of injustice was attempted on a Medical Practitioner; and, as it may prove interesting to the Profession, I write to furnish you some particulars.

In May last year, a workman, in the service of one of the extensive forges in Leeds, was driven, by the shaft of a wherry, through a plate-glass window of a shop, smashing the window-frame, and forcing him completely through the window into the interior of the room. The man sustained serious injury to his chest, and from the evidence it appeared, also, there was considerable concussion of the spine. He was most assiduously attended by two Medical gentlemen—Dr. Bishop and his assistant, Dr. Moss—for fifteen or sixteen days, and afterwards for five or six weeks occasionally, and the bill for such services amounted to the not very large sum of £9 7s. 6d. But now come the interesting particulars. The patient is in a club, of which Dr. Bishop is the Medical attendant; but on the day following the accident he requests to be attended privately, expresses a wish to have most assiduous care bestowed upon him, that he would be responsible for the bill, and should sue the owner of the wherry for damages, and should include the Medical bill in his damages. On his recovery, he called for and obtained his bill, expressed no dissatisfaction with it, and placed it in the hands of his solicitors, who commenced the proper legal proceedings. In a few weeks' time, after several consultations between the respective lawyers, in every one of which the Medical bill was duly set forth as part of the claim for damages, the action was settled for £50 to cover all expenses. To those who have met with the ingratitude of which some people are capable, it will not be surprising that the patient did not only delay discharging his Doctor's bill, but repudiated it altogether, saying he was not liable to pay anything, because he was a club patient; and, on coming into court, this was the plea he set up, and on which he relied chiefly for a verdict, and, what would have been so very surprising to a stranger, the same attorneys who, on the strength of the Medical bill, obtained £50 damages, were the parties who appeared in court with this defence. The judge, in a few very judicious observations, soon upset this plea, remarking that a portion of the original sum obtained for damages should be returned before such a plea could be allowed. The next question raised was as to the unreasonableness of the charges. On a suggestion from the court, this was referred to a highly respectable Medical Practitioner, whose opinion would be respected by all parties.

A point of great importance to Medical Practitioners was raised by the plaintiff during the trial, viz., whether the Medical officers of clubs were liable to attend accidents of any kind, there being no special agreement—the by-laws of each club being the only appeal as to the duties of the Medical officers; and he produced in court the by-laws of the club in which defendant was a member, and proved that these by-laws only provide Medical attendance in cases of sickness. The judge evidently took the same view, though he declined giving his opinion, as the issue was not raised on this point.

There are two other particulars in which this trial was interesting, showing the way in which the lawyers protect each other, and explaining, also, the reason why Medical men are often compelled to suffer indignities and injustice at the hands of the public, in consequence of their taking every opportunity of injuring each other. One of the attorneys, who had been chiefly instrumental in obtaining the damages, was placed in the witness-box, to state what he knew of the transaction, but was speedily removed by the judge, on the ground of "privileged communications." The other point is, that there were two Medical men found who would come into court to state that, as a club patient, he ought not to be required to pay anything, even after hearing the by-law read, and were prepared, also, further to say that the charges were most unreasonable.

The Profession may well receive the snubbings it does, when such things as these occur. It is only right to state, there were several Medical men in court who occupy a respectable position in the town ready to speak to the reasonableness of the charges.

The first part of the lesson has been taught by the judge of

the court—viz., the “liability” of the person after making such an agreement (both he and his wife, however, denied this agreement on oath, notwithstanding his subsequent conduct in calling for his bill, and presenting it to his attorneys); and it is to be hoped that the gentleman to whom it is left to decide as to the amount, will be able to find for the whole sum claimed, and thereby show the world that the services of the Medical Practitioner are not to be so lightly esteemed as is usually the case by this class of people.

## GENERAL CORRESPONDENCE.

### A CASE OF STRANGULATED OMENTAL HERNIA.

LETTER FROM MR. JOHN ADAMS.

[To the Editor of the Medical Times and Gazette.]

SIR,—I beg to record, in the pages of your valuable Journal, the account of an interesting case of strangulated omental hernia, in which the symptoms were unusually severe.

A young woman, about thirty years old, was admitted into the London Hospital on Thursday, January 22. Her account of her condition was, that on the preceding Saturday a swelling had suddenly taken place in the left groin, after which she complained of great pain in the belly, and became excessively sick. She continued to vomit at intervals from that time until I saw her. Her bowels had never acted since the appearance of the swelling, although she had taken numerous aperient medicines. She said, also, that she had once observed a swelling in the same situation, but it disappeared. Her symptoms were now somewhat intense, that is, she vomited more frequently; the pain in the abdomen had increased in intensity; there was much distress in her countenance; and her constipation was confirmed: her abdomen was tense; there was a small swelling in the region of the crural opening, but this was by no means tense, although painful on pressure; and the impression I received from my examination was, that there was a hernia with a small lymphatic gland over the sac.

The House-Surgeon, Mr. Appleyard, had prudently abstained from all but the gentlest manipulation, in consequence of the urgency and lengthened duration of the symptoms, and I was quite willing to pursue a similar line of practice, and I, therefore, resorted to the operation immediately. A small hernial sac was exposed by the ordinary incision; this was much thickened and divided edgeways after I pinched it up with my left finger and thumb. I could feel no gliding of intestine beneath my finger, nor was there any fluid in the sac. There was, however, to be seen a small, dark, thickened mass, which gave me the idea at once that it was a piece of omentum; I cut upon it, and carefully peeled it out layer by layer, until I came to a small cavity containing a drop or two of bloody serum. It was quite shut up, and I could not pass the smallest probe into the abdomen; there was no intestine whatever to be seen; the omentum was thickened and congested, but by no means spoiled. I passed my finger round the neck of the omentum, and divided the stricture, which was situated at the femoral ring, downwards and inwards, by passing a bistoury along a deep-grooved director; for, from the excessive tightness of the stricture, I could not get my nail within it. The entire removal of all constriction was at once indicated by the escape of at least an ounce of clear serum from the peritoneal cavity.

I ordered one grain of calomel and half a grain of opium to be taken every four hours. The operation was performed at 10.30 p.m., and on the following morning, at 10, I found that her vomiting had wholly ceased, and that she had passed five free evacuations. Her gums were touched by the mercury.

All medicine was discontinued, and she is now completely convalescent.

Such cases are not very numerous; I do not remember to have met with more than three in which the operation has been required to liberate the stricture of a strangulated omental hernia. I witnessed one instance of an analogous character, but the hernia was umbilical, and I operated under the impression that strangulated intestine coexisted, but I found nothing but a piece of constricted omentum: I divided a tight stricture, and the case succeeded. It is very curious that a stricture of the omentum should occasionally be

attended with precisely similar symptoms as characterise strangulated intestine, and it can only be explained from the sympathy existing between the varied contents of the cavity of the abdomen. In the case now under consideration, the vomiting was severe and the constipation decided, yet the intestinal canal was free. There could be no mechanical obstruction arising from the gut passing under the omentum, for the latter was left *in situ*, and yet the symptoms were relieved by the simple division of the stricture. In former days it was nothing unusual for a Surgeon, if, in operating for hernia, he chose to remove a piece of omentum, to tie the omentum in a single tight ligature to obviate the necessity of securing the blood-vessels separately; but what was the consequence? Why, the symptoms continued until the patient died, because the Surgeon, after removing one stricture, at once placed another ten times as tight on the delicate omentum. I did not attempt to return the omentum, as it was thickened and congested, and the femoral opening was too small to admit it. I am, &c.

4, St. Helen's-place.

JOHN ADAMS.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JANUARY 27.

SAMUEL SOLLY, Esq., F.R.S., in the Chair.

DR. E. H. SIEVEKING communicated a paper by Dr. A. B. Buchanan on a

CASE OF WHITE FIBRO-SEROUS DISCHARGE FROM THE THIGH.

The author recorded the history of a remarkable case of discharge of white fibro-serous fluid from the posterior cutaneous surface of the thigh, at present under his care in Glasgow. The patient was a woman, in other respects in fair health, aged 46, and mother of six healthy children. The discharge was white, like milk, and flowed from excoriations produced by the rupture of small vesicles scattered over the back of the thigh, and particularly from an infiltrated patch, of the size of the palm of the hand, on which the vesicles and excoriations were most abundant. The milky fluid coagulated a few minutes after being passed. It contained a fatty molecular base, similar to that of chyle, and a few nucleated cells. The results of a chemical analysis closely corresponded with those yielded by “chylous urine.” The patient dated the commencement of her malady from a shivering-fit twenty-one years ago, shortly after which she noticed a “lump” in the situation of the affected surface. Fifteen years ago vesicles appeared, from which a brownish fluid exuded on scratching. For the last six years the discharge has been milk-white, and is always worse in wet weather, and while the patient is walking about, when its amount may be half a pint per hour. At night it ceases to run, recommencing about an hour after the patient rises in the morning; but in dry or frosty weather it may occasionally be absent for a week or two. The veins of the affected limb are varicose, but no enlargement of the lymphatic glands can be detected. The author succeeded in controlling the discharge for two months by a long elastic stocking, the use of which, however, had to be discontinued, owing to severe lancinating pains in the thigh. Immediately on ceasing to use the stocking the uneasy sensations subsided, and the discharge commenced anew. After remarking that cases of this affection were extremely rare in temperate latitudes, Dr. Buchanan pointed out, by referring to several recent examples, that they were probably more frequent in warm climates. He cited, however, and gave an account of two unequivocal cases of the same affection, both dating from the seventeenth century, one of which, in a male subject, occurred in Germany, and the other, in a female, in France. While referring to various pathological theories, the author fully recognised the identity of the above disease with “chylous urine,” or, as he would prefer to call it, “white fibro-serous urine.” He objected particularly to the theory which identified white fibro-serous discharges in general with chyle. He gave his reasons for believing that it was more natural to consider them as equivalent to the white liquor sanguinis—to transudations of the serum of the blood during its periodical milkiness after meals,

but with certain modifications inseparable from the mode of its secretion. Thus, while the water, albumen, and salts, and possibly also the fibrin, would come from the blood directly, he showed that the cells present in the discharge must be derived from the secretory layer of the skin, or from the epithelium of cutaneous glands. He contended that the molecular base was unquestionably derived from the blood; but that the molecules could not be conceived to filter directly through the walls of the vessels without pre-supposing the existence of a uniformly and intensely milky serum while the discharge was flowing, even at long intervals after meals. To avoid this difficulty, it might be supposed that the epithelial cells of the glands of the skin had the power of separating, by a perverted function, fatty matter from the blood, much as the epithelial cells of the intestine are concerned in filtering it into the lacteals. The cells would then become gorged with fatty molecules, and the uniformly white colour of the discharge would be accounted for without its being necessary to suppose that the liquor sanguinis was ever milky except, as usual, after meals. On this view, white fibro-serous discharges would depend immediately on deranged glandular action, and the foregoing case might be defined as a rare functional affection of the glandular apparatus of the skin. The paper was illustrated by specimens of the milky discharge, and by a drawing of the diseased surface.

After the reading of Dr. Buchanan's paper, on which there was no discussion,

A portion only of Mr. MARSTON'S

REPORT ON SYPHILIS AS A CONSTITUTIONAL DISEASE

was read, and its further reading was adjourned to Feb. 10.

Mr. CURLING rose, and said he thought it was scarcely judicious to commence the reading of Mr. Marston's paper at so late a period of the evening. It was a communication which was likely to be discussed, and the whole of it should be read the same evening, and in time for discussion. He made these remarks with deference to those who had thought differently.

Mr. SOLLY said he was not responsible for the paper being read in part. It was thought the evening would have been occupied by a discussion on the first paper.

Mr. MOORE was responsible for the division of the paper into two readings. It embraced so many topics, that it would have been impossible to abridge it, and he, therefore, thought it advisable that it should be read in two parts, there appearing to be a natural division in the paper at the point at which he had stopped. There were precedents for this course of proceeding in the early history of the Society.

Mr. HENRY THOMPSON exhibited some

LITHOTRITES OF A NEW CONSTRUCTION,

on behalf of Messrs. Weiss and Son, who wished to show them to the Fellows of the Society before making them generally public. As the alteration appeared to him to be a real improvement, he readily assented to do so. He premised that this related entirely to the mode of applying and disengaging the power, and not at all to the part concerned in crushing the stone. In order to demonstrate the qualities of these instruments, it was necessary to call to mind what are the main points to be achieved in constructing the movement of a first-rate lithotrite. 1st. Economy of time in its action: anything which shortened the period necessary to a proper performance of the operation in the bladder was so much clear gain to the patient. 2nd. To reduce to a minimum vibration or concussion in its action. 3rd. To permit the utmost delicacy of perception, especially valuable in dealing with small fragments. He showed the deficiency of the old screw instrument in all these respects, and the inferiority of this latter to the instrument known as Charrière's, which was now so commonly substituted for it. He showed the improvement made by Mr. Coxeter, and placed in the International Exhibition; and finally demonstrated the action of Weiss's new instrument as uniting all the characters given above with the greatest strength, comparing it also with the rack and pinion instrument, to the advantage of the former. The power in Weiss's instrument is that of the screw; it is disengaged and converted into sliding action with the most perfect ease, and without moving the hand, while the entire instrument can be changed in direction, or even entirely rotated, by a light application of the finger and thumb. The apparatus for accomplishing this is exceedingly simple, at the same time very strong, and not liable to get out of order.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JANUARY 7.

Dr. TYLER SMITH, President, in the Chair.

A PREPARATION of concentrated beef-tea was exhibited to the Society by Mr. BUCKLE, Culinary Chemist, of North-place, Gray's-inn-lane, convenient for administration in cases where expeditious employment of nutritive material is required.

A paper was read by Dr. AVELING, of Sheffield, on

VAGINAL LITHOTOMY.

The paper commenced by reciting the particulars of thirty-five cases in which this operation had been performed—twelve British, and twenty-two foreign. The author also gave another case, in which he divided the vesico-vaginal septum, and extracted a small rough stone. The wound was brought together with silver wire sutures. Gilt beads were passed over the ends of these, and run down to the lips of the wound. These were kept in position by a perforated shot, also passed over the ends of the sutures, and tightened upon them by a pair of forceps. He proposes in future to use a coil, made by winding a piece of the suture wire round a pin, instead of the beads. The wound healed in a week, and the patient returned to her home in a fortnight.

Mr. SPENCER WELLS congratulated Dr. Aveling upon the successful result of his interesting case, and heartily concurred in the tribute he had paid to the services of Dr. Marion Sims. But he (Mr. Wells) had begun to doubt whether the success which had followed the operation for the cure of vesico-vaginal fistula of late years was so much due to the use of wire sutures as to the improvements which Dr. Sims had originated in the mode of bringing the fistula into view, accurately paring the edges, and bringing them into perfect apposition. Provided the edges of a fistula were thoroughly pared, and kept in close apposition, it was probably of little importance how this was done. A year ago he (Mr. Wells) was as strongly in favour of metallic sutures as anybody; but latterly a wider experience had taught him that it is only after five or six days that wires show any advantage over silk, and before that time the sutures ought to be removed. Then silk offers the great advantages over wire of being more easily applied, of not requiring so large a needle to pass it, of the ends being much less irritating, and of being more easily removed. After many comparative trials on different parts of the same wound with wires of silver, iron, lead, platinum, and aluminium, and with fine catgut, horsehair, telegraph wire, India-rubber thread, and the fine strong silk known as "Chinese twist," he had become convinced that wires offered no advantage over silk, while silk offered many advantages over every other material used for sutures. In a recent case he had closed a vesico-vaginal fistula by five silk sutures, and perfect union resulted, although no catheter was used. The supposed necessity for the use of the catheter after closing vaginal fistulae, was another error which time was correcting. The urine is by no means so irritating a fluid as some believe. The lower orders use it as a lotion to the eyes and to sore legs; and it certainly cannot differ much from the dilute saline solutions constantly prescribed as astringents or stimulants. The use of the catheter is the most troublesome part of the after treatment, and often most distressing to the patient. One of his patients really could not bear it, yet she did perfectly well; and lately he had not used it at all, union taking place quite as well as when it was used, and the patient being much more comfortable. With regard to stone in the bladder during labour being a cause of vesico-vaginal fistula, he had once removed in the Samaritan Hospital a large stone through a fistula before closing it; but it was very questionable whether it could often be necessary to remove a calculus through the vagina when no fistula existed, or to run the risk of making a fistula to remove a stone. Lithotripsy was very easily performed in women; and large fragments of stone passed readily through the short female urethra, so that no form of lithotomy could often be called for. Simple dilatation of the urethra was not likely to answer in any case not suitable for lithotripsy, and its effects are very uncertain: a large stone might be removed and no incontinence follow; but incontinence might follow removal of a very small calculus. The usual aid to dilatation by incising the urethra was still worse. A Surgeon of very large experience had told him

that he had done it for two adults and seven children, and "they were all dribblers." Where, from some exceptional condition of bladder or stone, lithotomy was inappropriate, vaginal lithotomy might, therefore, become a valuable operation; but experience was still wanting to show that it was better than, or as good as, the lateral operation so successfully practised by Dr. Buchanan, of Glasgow. The subject was a comparatively new one, and Dr. Aveling deserved the thanks of the Profession for the light he had thrown upon it.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS, EDINBURGH.**—The following gentlemen passed their First Professional Examinations during the January sittings of the Examiners:—

William Thomson Crawford, Midlothian; William Chambers, Banbridge; James Johnstone Hyslop Hope, Lanarkshire.

The following gentlemen passed their Final Examinations, and were admitted Licentiates of the College:—

John Rogerson Diekson, Dumfriesshire; Alexander Doig, Forfarshire; William Fettes Murray, Forfar; Thomas Francis O'Dwyer, County Tipperary; David Ross, Edinburgh.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, January 29, 1863:—

Joseph Handley, King-street, Oldham; James Mercer Johnson, Everton, Liverpool; Samuel Alexander Patrick, Tipping-street, Manchester; John Dixon Mann, West View, Kendal; Frederick John Gray, March, Isle of Ely; Heber Dowling Ellis, St. Bartholomew's Hospital; Thomas Lewis Brittain, Chester; John Nicholas Miller, The Square, Hampstead; John Lyman, Guy's Hospital; James Matthews, Cowes, Isle of Wight.

The following gentlemen passed the Preliminary Examination in Arts on January 30 and 31, 1863:—

Frederick John Burge, Hammersmith; Henry Trensham Butlin, Cambridge; Nathaniel Edward Davies, Billesdon; Thomas Bradford Donahoo, London; Alfred Stanbank Drew, Stow-on-the-Wold; James W. G. Farwell, St. George's Hospital; Thomas Flower, Middlesex Hospital; Richard Murhall Hickman, Shrewsbury; J. B. Hughes, Congleton; George Askew Hull, Kensington; Stanley Peacock, London; Charles Richardson, Gomersal; Julius Ottaway Sankey, Witney; John H. Waters, Nottingham; James C. Worthington, Lowestoft.

## APPOINTMENTS.

**BALFOUR, DR. JOHN HUTTON**, has been elected Honorary Member of the Edinburgh Geological Society.

**FOLEY, JAMES J.**, M.R.C.S. Eng., has been appointed Surgeon to the Constabulary, Killeagin, County Cork.

**HELPS, DR. WILLIAM**, has been appointed Resident Physician and Medical Superintendent to the Royal Bethlehem Hospital, Lambeth.

**MACKENZIE, MORELL, M.D.** Lond., has been appointed Physician to the Metropolitan Free Dispensary for Diseases of the Throat and Loss of Voice.

**MATTHEWS, MR. CHARLES S.**, F.R.C.S., late House-Surgeon to King's College Hospital, has been elected Surgeon to the Farringdon General Dispensary.

**M'DONNELL, DR. ROBERT**, has been elected one of the Medical Visitors of the Jervis-street Hospital, Dublin.

**MURRAY, J. JARDINE, F.R.C.S. Ed.**, has been appointed Surgeon to the Brighton and Sussex Infirmary for Diseases of the Eye.

**OFFOR, MR. CHARLES**, has been appointed Resident Dispenser to the Clapham General Dispensary.

**WHYTE, MR. WILLIAM DUDLEY**, has been appointed Resident Apothecary to the Jervis-street Hospital, Dublin.

**WILLIAMS, DR. WILLIAM RHYS**, has been appointed Resident Apothecary to the Royal Bethlehem Hospital, Lambeth.

## DEATHS.

**AUBANEL, DR. HONORE**, Physician-in-Chief of the Lunatic Asylum at Marseilles, Chevalier of the Legion of Honour, well known for his enlightened treatment of the insane, has just died of apoplexy, age 53.

**BEALE, MILES, M.R.C.S. Eng.**, at 31, Finsbury-square, E.C., on February 2, aged 65.

**BEVAN, WILLIAM, M.D.**, at Sydney Avenue, Blackrock, co. Dublin, on January 26.

**BUCKNILL, SAMUEL, F.R.C.S. Eng.**, at Rugby, Warwickshire, on February 1, aged 78.

**CEJKA, DR. JOSEPH**, Extraordinary Professor in the University of Prague, and Dean of the College of Physicians, of phthisis, on December 26, 1862, aged 51. He bequeathed 15,000 florins to the widows' fund of his College.

**CHALMERS, WILLIAM**, Staff Assistant-Surgeon, at Union-street, Aberdeen, on January 22, aged 28.

**DAVIS, THOMAS**, at Upton-on-Severn, on January 16, aged 73.

**DOYLE, ANDREW JOSEPH, M.R.C.S. Eng.**, at St. Michael's, Lewes, Sussex, on January 31, aged 55.

**HALLAM, WILLIAM, M.D.** Aberd., at Newcastle, Staffordshire, on January 30, aged 49.

**HARRIOTT, WILLIAM**, at Rainford, on January 30, aged 38.

**HARWOOD, THOMAS, jun.**, M.R.C.S. Eng., at Boston, Lincolnshire, formerly of Kuton, on January 28, aged 51.

**HEMING, GEORGE OAKLEY, M.D.**, at Kensington, Bath, on January 28, late of Manchester-square, London.

**LEHMANN, DR.**, the celebrated Professor of Chemistry at the University of Jena, whose works are so familiarly known in England, on January 6, in the prime of life.

**SHIRREF, JAMES, M.D.**, at Demilliquin, New South Wales, on October 6.

**ROYAL COLLEGE OF SURGEONS.**—The readers of the *Medical Times and Gazette* will, no doubt, be glad to be reminded that the Hunterian oration will be delivered on Saturday next, in the theatre of the College, at three o'clock, by our esteemed contributor, Professor Gulliver, F.R.S.; and on the following Tuesday, Professor Huxley will commence his course of lectures.

ALL old genuine English surnames, derived from nicknames and occupations, are now threatened with extinction. Bug becomes Norfolk Howard, and Stubbs is transmogrified into De Montmorency; and it is said that a Medical student of Guy's, named Caudle, has announced his intention of assuming a surname which will render him less of a mark for witticisms when he practises Midwifery.

**ROYAL RECOGNITION OF MEDICAL SERVICES.**—On the occasion of the christening of the infant son of Dr. William Jenner, yesterday morning, her most gracious Majesty was pleased to stand sponsor, being represented on the occasion by Lady Augusta Bruce, who, in obedience to the wishes of the Queen, gave the boy the name of Albert Victor, accompanied with the present of a magnificent tankard, bearing a suitable inscription, and as a royal recognition of the great Professional attention paid by Dr. Jenner to his Royal Highness the Prince Consort.—*Times*, January 31.

WE are glad to hear that a Cottage Hospital is proposed for East Grinstead and surrounding parishes. A cottage on East Grinstead Common, enlarged and adapted for the reception of seven patients, is offered by the proprietor rent free, on condition that a sufficient amount is contributed to pay for the beds, bedding, furniture, and other requisites for the accommodation of the patients. About 120*l.* will be required for this purpose.

**DEATH BY DROWNING IN SIX INCHES OF WATER.**—The *Freeman* states that a man, named Macabe, aged about fifty years, was found on Friday lying in a ditch in Bishop's Field, near Stillorgan. Deceased had been in a weak and almost helpless state for some time previously. It appears that he fell into the ditch head-foremost, and his foot being entangled in a brier he could not extricate himself, and was drowned, although the water was but six inches in depth.

**THE MEDICAL DEPARTMENT OF THE ITALIAN ARMY.**—The military Surgeons of the Italian Army, who, in 1858, numbered 155, now, in consequence of the various annexions, amount to 755. The following is the distribution, according to grade:—President of Council, 1; Inspectors, who are also members of Council, 6; Surgeons of the Military Department, 6; Surgeons of Division, 44; Surgeons of Regiments, 227; Surgeons of Battalions, 334; Assistant-Surgeons, 137; total, 755.

**A VETERAN MEDICAL JURIST.**—Casper, the renowned Professor of Legal Medicine at Berlin, a few weeks since celebrated a remarkable day in his long and laborious scientific career, viz., the day on which he executed his thousandth Medico-legal autopsy. He certainly was justified in placing on the title-page of his "Manual of Legal Medicine," the epigraph, "*Quod vidi scripsi.*"

**PROPORTION OF VIOLENT DEATHS IN AUSTRIA.**—Taking the entire Austrian monarchy, the proportion of deaths from diseases is 987 per 1000, and of deaths from violent causes, 13 per 1000. This proportion varies, however, considerably in different parts of the empire; thus, in the mountainous regions, as well as on the coast, the violent deaths rise as high as 19 per 1000. A vast majority of the violent deaths arose from accidents, as in 1000 deaths there were only, on an average, 1 from murder or manslaughter, and only 2 or 3 from suicide.

**AMATEUR THEATRICALS.**—On Monday night, the students of the University of Aberdeen gave a dramatic and musical entertainment in the Music Hall Buildings, in aid of the Lancashire Distress Fund. The hall was crammed to suffocation by a very fashionable audience, and numbers were

turned from the door. So great was the crush, that the Lord Provost, the patron of the performance, finding an entrance impracticable by the ordinary way, had to procure admission for his party by crossing the stage. The dramatic portion of the entertainment consisted of Townley's "High Life below Stairs," and Rhodes' "Bombastes Furioso." The students who took part in this entertainment were chiefly Medical, although not exclusively. The amount realised, after deducting all expenses, was £46 14s.

ROYAL INSTITUTION OF GREAT BRITAIN.—General Monthly Meeting, Monday, February 2, 1863; William Pole, Esq., M.A., F.R.S., Treasurer and Vice-President, in the Chair. The Earl of Clanwilliam, Edward W. Cox, Esq., Sir William Augustus Fraser, Bart., General Charles H. Hamilton, C.B., and Peter Vanderbyl, Esq., were elected members of the Royal Institution. The secretary reported, that the executors of the late James Walker, Esq., F.R.S., M.R.I., had bequeathed to the Institution a marble bust of Professor Faraday, by Mr. Matthew Noble, M.R.I. The thanks of the members were returned to Professor Tyndall, and to his Eminence Cardinal Wiseman, for their discourses on the evening meetings on Fridays, January 23 and 30. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

ILLEGAL PRACTICE OF PHARMACY BY THE SISTERHOODS IN FRANCE.—Although we have in this country charlatanism enough to contend with, we are not subjected, like our neighbours across the Channel, to the invasions of bands of religious sisterhoods. The complaints are incessantly occurring in the provincial districts of France of this nuisance, and its abatement (supported as the Sisters are by the local authorities) seems a matter of great difficulty. The most recent instance is stated on the authority of Dr. Fouquet, Vice-president of the Medical Society of Morbihan. It seems that the religious sisterhoods of that department not only give away but sell medicines, while their pharmacies, or rather shops, are conducted with gross negligence. Bottles of laudanum or of Pearson's arsenical solution were found in the kitchen drawers, while illegal weights are employed, even grains of wheat being used for weighing active substances. The Medical Society represented these facts to the authorities, and received the reply that the Sisters must be prohibited selling medicines, but may distribute them, and give gratuitous Medical advice to the poor.

ST. THOMAS'S AND BETHLEHEM HOSPITALS.—Mr. W. J. Nixon, secretary to the London Hospital, in a letter to the *Times* of the 4th inst, announces that a Surrey magistrate, an old supporter of this charity, makes the following munificent offer:—"Convinced that the best site for the future St. Thomas's Hospital is the present site of Bethlehem Hospital, and agreeing with the general verdict, that lunatics should be located in the country, he is prepared to give a freehold site of seventy-three acres for the new Hospital of Bethlehem on condition—first, that St. Thomas's Hospital be built on the site of Bethlehem; and secondly, that the sum of 21,000*l.* (20,000 guineas) be added to the capital stock of the London Hospital in the Whitechapel-road." "The estate (which is freehold and land tax redeemed) occupies the southern slope of one of the finest hills in Surrey, has a frontage of nearly a quarter of a mile to the high (Croydon) road, is close to an intended station on the Brighton railway, is eight miles from the city, and seven from the West-end, and is worth at least 300*l.* per acre, less eligible neighbouring land having sold at half as much more."

METROPOLITAN FREE HOSPITAL, DEVONSHIRE-SQUARE, BISHOPSGATE-STREET, CITY, N.E.—A most interesting ceremony took place in this establishment on Thursday week, in the presence of a large and influential assembly. The occasion was the opening of two new wards which have been prepared for the reception of Jewish patients. At three o'clock the Rev. the Chief Rabbi, attended by several of his colleagues, proceeded to inspect the several apartments, including the wards (male and female), the kitchen, and receptacle for the dead, with all of which all present expressed their entire satisfaction and approval. Some appropriate psalms were then intoned by the Rev. A. Barnett, of the Great Synagogue, and the responses by the choir of the same place; after which the Rev. the Chief Rabbi offered up a most beautiful and impressive prayer for the prosperity of the institution, and for the blessing of God upon all connected with it; and after partaking of some slight refreshment in

the board-room the company separated. Amongst the gentlemen present we noticed the Revs. A. Levy, A. L. Barnett, Myers, and Asher; Drs. Ramskill, Jones, and Warner; John Gurney Fry, Joseph Fry, S. B. Power, H. E. Murrell, Coleman Defries, R. L. Ogilby, E. J. Chance, G. Borlase Childs, and Henry Defries, Esquires.

LONDON INSTITUTION.—On Wednesday last, Mr. Carter Blake, F.A.S.L., commenced a course of lectures on the "Zoology of Warm-blooded Vertebrates." After offering a few definitions of the prevailing distinctions between the animal and vegetable kingdoms, in the main consonant with those of Mr. Hogg, the lecturer called attention to the characters of the kingdom *Acruta*, or *Protozoa*, composed of the most simple organic beings, retaining the primitive form of the nucleated cell, and intermediate between the plant and the animal. The latter great kingdom of nature was divided into four distinct sub-kingdoms, the *Vertebrata*, *Articulata*, *Mollusca*, and *Radiata*. Amongst the latter Mr. Blake preferred to retain the *Bryozoa*, admitting, however, their affinities to the *Mollusca*. The *Echinodermata* were likewise doubtfully retained in the radiate sub-kingdom. The proposal made by some authors to institute a sub-kingdom, *Cœlenterata*, was commented upon at length. Discussing the primary principles of biological classification, examples were adduced of the operation of such laws as those of subordination of character, as exemplified by the usual modes of scientific notation. The relations of the osseous, tegumentary, respirative, digestive, circulatory, and nervous systems in *Vertebrata* were briefly discussed; and the demonstration of the existence of ideal patterns of construction, as proved by the laws of morphological osteology, was prominently insisted on. The next lecture will be devoted to a detailed exposition of the classification of *Aves Præcoces*.

SUFFOCATION OF FIRST-BORN CHILDREN.—On Saturday afternoon an inquiry was held by Mr. H. Raffles Walthew, the deputy coroner, at the Pitt's Head, Tyson-street, Bethnal-green, respecting the death of Eliza Short, aged three months, who was suffocated under the following circumstances:—Deceased was a healthy child, and on Wednesday evening last was placed in bed as usual, and at half-past twelve the parents went to bed. The mother pressed the child close to her to keep it warm, and in two hours afterwards it was found dead from suffocation. The mother was only 20 years of age, and deceased was her first child. The coroner said that the number of children destroyed by suffocation annually was much to be deplored. One great source of the distressing extent of infant mortality from this cause was the inconsiderate and over-eager fondness of young mothers, who clasped their first-born close in their arms, and believed they were doing their infants a kindness, when they deprived them of all access to the air, in order to "keep off the cold." By such means, children, even when healthy, but especially when delicate, were killed as effectually as if they were strangled. Even where death did not immediately result from asphyxia, there was no doubt that in numberless instances the constitutions of children were undermined, and death eventuated from consumption or other diseases, which the most ordinary attention to common-place hygienic rules might have obviated. The jury returned a verdict that deceased died from suffocation—how caused there was no evidence to show.

THE SECOND FRENCH EXPEDITION TO MEXICO.—The small amount of sickness and few deaths which have attended the transport of an army across the Atlantic are regarded, with reason, by the French Medical officers, as a triumph of naval hygiene. Great advantage is considered to have accrued from each detachment, as it arrived, remaining a week at Martinique. The men, beasts of burden, and cavalry horses were all landed while the vessels were cleansed and re-victualled. By some, this was thought to be a risk, on account of the frequent prevalence of yellow fever in the Antilles, and which, in fact, did then prevail in the English possessions there. However, the men were landed, and placed in barracks or in improvised camps. This agglomeration of Europeans, and the fact that, at the same time, there were going on extensive alterations in the harbour, giving rise to severe intermittents, justified alarm, which fortunately proved groundless. It might have been different had a chance case of yellow fever been imported, seeing the destructive effects upon the first expedition caused by such an incident. Thus, 20,000 troops of all arms were landed there, in the course of three months, for the space of one week; and, of this number, only 218

entered the Hospital, of which number 2 died, and 155 re-joined the expedition, 61 remaining in the Hospital on October 1. This immunity from disease is the more remarkable, as the soldiers gave way to great excesses on landing, especially as regards drink, exposure to the sun, etc.; and the weather, at this time of the year (the expedition arriving at Martinique between the beginning of September and October 10), was characterised by torrential rains, intense heats, and great atmospheric vicissitudes.—*Gazette Hebdomadaire*, January 23.

**SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN IN LONDON AND ITS VICINITY.**—A half-yearly general meeting of the members of this Society was held on January 28; T. A. Stone, Esq., President, in the chair. It appeared that, during the past year, £1933 had been distributed in half-yearly grants amongst 43 widows and 26 orphans of former members; £10 10s. in immediate relief to a family; £45 towards the self-maintenance of two older orphans; £15 for extra relief to a widow; and £20 as a special grant to an adult son in great distress and illness abroad. We are happy to state that a much larger number than usual of new members had been elected by the Society, and we hope that this increased ratio will continue,—so lamentable, and often so unexpectedly, is the condition of families of deceased Medical men. The following officers and directors for the ensuing year were elected on January 26. The names with the asterisks prefixed are fresh elections:—*President*.—Thomas Arthur Stone, Esq. *Vice-Presidents*.—Martin Ware, Esq., Everard A. Brande, Esq., Peter M. Latham, M.D., John Bacot, Esq., Thomas Turner, M.D., D. Henry Walne, Esq., A. J. Sutherland, M.D., F.R.S., Edward Tegart, Esq., Geo. Burrows, M.D., F.R.S., \*John Miles, Esq., \*Sir John W. Fisher, and \*Cæsar H. Hawkins, Esq., F.R.S. *Treasurers*.—James T. Ware, Esq., G. Hamilton Roe, M.D. (Atg.), \*Richard S. Eyles, Esq. *Directors*.—B. G. Babington, M.D., J. Wetherfield, Esq., John J. Sawyer, Esq., Thomas Brown, Esq., C. J. B. Aldis, M.D., Wm. Dickinson, Esq., J. C. Salisbury, Esq., Henry Blenkarne, Esq., T. King Chambers, M.D., John Clarke, M.D., Daniel Seannell, Esq., Prescott J. Hewett, Esq., \*William Cathron, Esq., W. J. Little, M.D., J. Gregory Forbes, Esq., Wm. Munk, M.D., Barnard W. Holt, Esq., Charles Miles, Esq., \*Henry Sterry, Esq., \*Alder Fisher, Esq., \*Henry Jeaffreson, M.D., \*James Paget, Esq., \*H. S. Illingworth, Esq., and \*Francis Hawkins, M.D. The seventy-fifth anniversary dinner of the Society is appointed to be held on May 20, at the Albion Tavern. Stewards' names are requested.

## NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon*.

We think *J. T. B.* is a little too severe.

*Dr. C. Kidd*.—We are delighted to receive the communications of *Dr. Kidd*, but, probably, a history of misunderstandings with other journals would possess no interest for our readers.

*Dr. J. P. O'B.*—We are sorry that our arrangements do not permit our inserting any notices of deaths but those of Medical men.

Papers by Professor Laycock, Dr. Ramsbotbam, Dr. Althaus, Dr. Venables, Mr. R. Ellis, Mr. F. Bainbridge, Dr. J. Robertson, and Mr. E. L. Hussey, are in the printer's hands, and will shortly appear.

*Consultations with Homœopaths*.—The man who consults with these slippery personages, of *malice prepense*, who cultivates their acquaintance, and thirsts for the fees that they bring to his consulting-room, deserves all reprobation. But we do not think that it is fair or honourable to drag a respectable Physician before his brethren, because he has been entrapped into consultation with such a person, or has met him under peculiar and exceptional circumstances, of which every man of honour is judge for himself. How is a man to know who is a homœopath? or, why should a sick person be refused advice because he is a fool? The practice of homœopathy in a country town is a regular imposture. Country people will have their bowels moved, and the so-called homœopath uses the ordinary powerful remedies in secret, whilst he hangs out his homœopathy to delude the vulgar with something supposed to be German and mysterious—patronised by some clergymen, and many courtiers, people of fashion, loose women, and old *roués*. By all means do not let respectable Physicians give to an adventurer the sanction of a consultation. But we must take care equally to avoid flunkeyism, *espionage*, and the idea of dogging the steps of gentlemen, and showing them up if they are supposed to call at houses where a homœopath attends. Homœopaths are bad; but no man of honour will consent to lose his freedom of action, and live under a system of *espionage* and tale-bearing.

## MEDICAL CHARGES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg the favour of your informing me what I ought to charge for attending a lady, suffering from phthisis, for seven months. She resided in my house, with the consent of her trustees, and I had the entire Medical charge of her. She required me to visit her morning and evening, which I invariably did, and, on any emergency, at all times gave her my advice. She was a young lady, with £400 to £500 a-year. I charged for her board £100 a-year. Would £75 be a proper fee? I paid 432 visits.

I am, &c.

Hertford-street, Coventry, February 2. A REGULAR SUBSCRIBER.  
[£100 per annum is little enough for the board of a person who lives as a consumptive patient should live. The sum of £75 for Medical attendance is also very moderate.—Ed.]

ON THE WIRE COMPRESS, A SUBSTITUTE FOR THE LIGATURE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the *Medical Times and Gazette* of January 24 is a report of the meeting of the Royal Medical and Chirurgical Society on January 13, from which I learn that a paper was read by Mr. Dix, Surgeon to the Hull Dispensary, on "the Wire Compress, a Substitute for the Ligature." In describing the compress, Mr. Dix states, that it is a modification of the method of arresting hæmorrhage devised by Professor Simpson, which is believed will obviate all the disadvantages inherent to that method, and that "the idea was promulgated in a paper on Acupressure, June 2, 1860," and put to proof in a case of amputation of the finger in September, 1860, and afterwards in more important cases, which Mr. Dix details, and he affirms the superiority of the compress over the ligature both in amputations and aneurisms.

Having read the report of the paper with the carefulness of an interested party, it appears to me that Mr. Dix has led his audience to infer that he was the originator of the compress he described and eulogised, and that his hearers understood him to be so. If correct in these suppositions, Mr. Dix has done me some little injustice, though I trust not intentionally. In strict right, and by written promise, Mr. Dix was under obligation to state that I originated the compress, and presented it to him with explanations how to apply it, and that he had applied it as instructed. I devised the compress in January, 1860, in the hope that it might prove more simple of application than Acupressure, and I took the liberty of submitting it to Professor Simpson about the 18th of that month. In June following I saw Mr. Dix's letter on "Acupressure," which enumerated "certain disadvantages" attending that method. I, therefore, forwarded to that gentleman the compress which I had planned five months before, believing that it would obviate the disadvantages he mentioned as belonging to acupressure. The receipt of the compress was, I thought, somewhat unkindly acknowledged, and the plan ridiculed. I heard no more of the matter for eighteen months, when, in November, 1861, Mr. Dix favoured me with a letter, informing me that he had found the value of my suggestions, and had fully tested the compress in three cases of amputation—that the subject would soon probably be brought forward in the Medical societies and periodicals, "when," he says, "I shall take care to mention your name, as is just and due." Mr. Dix has now brought the subject before the Royal Medical and Chirurgical Society, and ably defended the compress in the discussion which arose; but he altogether omitted to state what was "just and due," that, if the simple method of arresting hæmorrhage which he was advocating possessed any merit, it belonged in all fairness to me.

I am, &c.

WILLIAM B. HILLIARD,  
Instrument Maker to the Glasgow Royal Infirmary.

IS PODOPHYLLIN A CHOLAGOGUE?

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A clever, though somewhat over-sanguine, friend has frequently vaunted to me the powers of podophyllin in producing a flow of bile. Having learnt to distrust the evidence offered in favour of this power in other remedies, I listened, but waited. After waiting some time, there came before me a young soldier, aged 23, well made, well fed, and healthy in constitution, but as yellow as a bottle of the best Durham,—an appearance which had been gradually coming on for about a week, and the result, apparently, of continued exposure to cold during rifle practice. Otherwise, he looked well, spoke cheerfully, slept well, and had a good appetite, and no dyspeptic symptoms, though his bowels were "rather bound." On examination, there was no enlargement of the liver, nor tenderness, but the stools were formed and white, and the urine over copious, very turbid, and so loaded with biliary matter as to look like a thick muddy decoction of—as I should say—cinchona, oak bark, and log-wood.

After the usual warm bath, he had, on the 2nd, a purgative of comp. jalap, ʒj., and podophyllin, gr. j., and was ordered podophyllin, gr. ʒ, James' p., gr. ij., and ex. of conium, gr. iij., in pill, thrice a-day. On the 3rd, the purgative proving ineffective, he had a two-pint injection, containing turpentine, ʒiv., sulph. magnes., ʒiiss., and ex. of henbane, gr. iv. On the 6th, the podophyllin was increased to gr. ʒ, in a pill thrice a day, without admixture, and this, on the 7th, purged him seven or eight times with pain, his expression, on the 9th, after the omission of the medicine, being, that he had been much better, and felt no pain,—an expression which, as I had been absent on the previous day, puzzled me until he explained himself. His diet during this period was—tea and eight ounces of bread on the 2nd; the same, with two ounces of sago, on the 3rd; tea, twelve ounces of bread, and the beef-tea of eight ounces of meat, from the 4th to the 6th, inclusive; and tea, fourteen ounces of bread, bulter, beef-tea as before, and a pudding of two ounces of rice and one egg, from the 7th onwards.

On the 9th, the complexion remaining unchanged, and as I considered him not quite as a *corpus vile*, but as a favourable case for continuing an experiment, he was ordered fluid extract of tarax., ʒj., in two ounces of an infusion of chiretta or gentian thrice daily; and, on the 13th, the stools, for the first time, showed a tinge of the ordinary colour, and, the next day, the legs were less coloured; the urine, however, continued as copious, and much loaded with bile for three or four days, and then showed a good deal of white sandy sediment, after which it became clear. His diet was changed to half on the 17th, and to "entire" on the 24th; and on the 27th he was discharged, still somewhat coloured, but well.

*Remarks*.—There is nothing in this case to show decisively that the return of function was due to anything more than time and Hospital residence, and there is certainly nothing to show that podophyllin had

any effect beyond uncomfortably purging the patient. My personal experience of this medicine as a purge is, that it produces watery stools, and may gripe, even when combined with henbane. It has been said that this is an evidence of the flow of bile over the intestinal surfaces; and, again, it has been told me that podophyllin gripes until one is used to it. I cannot see the advantage of a purge that requires a course of acclimatization on the part of the intestines; and I believe the "flow of bile" theory to be a pleasing *placebo* for the mind of the griped patient. Lastly, I forward this case in the hope of producing a flow of facts, of a non-acrid character, as to the observed effects of this new medicine.

I am, &amp;c.

STAFF-SURGEON.

## DIABETES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I suppose your two correspondents of last week, who have made use of my case for the purpose of castigating me, would expect a groan of thankfulness. To neither of these gentlemen should I have replied, were there not two accusations therein made, one reflecting on myself, the other touching the fair fame of Dr. Pavy. I do not yield to your correspondent in my respect and admiration for that gentleman, although he is personally unknown to me, nor do I think any disrespect can be fairly implied from the supposition that certain things ought to follow if so-and-so is true; but it is quite another thing to affirm that, in the absence of such a sequence, A. or B.'s statement is false. I cannot refer to the exact words of my case, as all my notes are packed away, and I am at this present time a bird of passage. With regard to myself the accusation comes double-tongued—an inclination to homeo-quackery, because, forsooth, I mention the use of sugar in connexion with diabetes, or give minute doses of strychnia. Dr. Budd, in his paper on this subject, had some misgivings that this "jaw-bone of an ass" would be raised to strike him; and surely I, as a poor honest workman in the ranks, must be content to be "written down an ass" if by means of it I can in any way subscribe the advancement of the "great commonwealth of Medicine." I utterly detest and disown any approach, even in thought or otherwise, to a craft which I know to be untrue, and believe to be dishonest; but had the "Four Years Old" been a little more modest before he (unaccredited as yet to the Profession of Medicine) began to pick holes in my prescriptions, he would have seen that this one drachm of my liquor strychniæ was increased to three, and I relinquished it when the man's muscles were twitching violently, an indication to a practical man of more moment than the subdivision of his doses. Strychnia with some is a very violent remedy, with others not so. It can hardly be a mortal sin to stand on the side of caution; but with regard to my other prescriptions I have this to say, that I am quite aware of their unchemical nature, but having once proved the worthiness of a friend, I do not pass him by because he has faults, and so with my medicine: the result in this case, as well as many others, is, I trow, worth a head full of chemical ideas.

Will my young friend undertake to say how far the chemical relations of any given mixture remain unaltered after their entrance into the stomach? Chemistry is but the handmaid, not the parent, of experience. Country Doctors do not study nicety for pauper patients; they do not sit down to escritaires, and, with diamond-laden finger, pen equipped, write on perfumed paper elegant prescriptions in irreproachable Latin, but to bring about good even by the veriest "hotch-potch" that ever was concocted is always their aim. Why, with the tea and coffee and mixtures of all kinds that enter into our stomachs, a perpetual metamorphosis must be going on between food and physic, and several unchemical mixtures are of utility, perhaps, from the very decomposition which takes place. I will mention one very common example—the mixture of acetate of lead and opium, commonly used as an astringent in diarrhoea: here we have learned in the lecture-room, that there is a decomposition into a meconate of lead; is it now disused?—I opine not. Chemistry is a very fine exercise for the minds of young gentlemen, but it will not cure our patients; nor do we see its professors always Physicians *par excellence*. No. 1 correspondent, I presume, is also a student, otherwise he would gladly have put down his degree or diploma instead of signing himself "Hyperboræan." In common courtesy, he might have given me the benefit of *my* degree, which I obtained at great labour, and no small expense. If I have unwittingly fallen into an error, in considering glycerine to be allied to grape sugar, I crave pardon, on the grounds that I carried such an impression from the lecture-room; but years make a wonderful difference in chemistry, and in the exigencies of country practice; I have had neither time nor inclination to indulge in the beatitudes of that study. If glycerine has no relation whatever to sugar, then the case simply resolves itself into the treatment of diabetes by remedies, the most prominent of which are glycerine, strychnine, and iron. Simply saccharine food could not produce such a result as this case furnishes, inasmuch as the other cardinal requisites, oleaginous, saline, and albuminous, must be somewhere forthcoming. Is it, then, too presuming to say that other constituents exist, as yet, perhaps, undetermined by chemists?—and it may be that glycerine will yet hold a very important place as a therapeutic agent. This, however, can only be determined by practical Physicians. In the diet of my patient I may remark, that an abundance of sugar was allowed, and those vegetables said to be rich in it; whilst he was also advised to carry candied sugar in his pocket. The condition of the patient when first seen was the result of nine months' constant illness, and he had sojourned meanwhile in Hospital. When I first visited him his condition was precisely as I have stated it. The printer's trivial omission need not afflict No. 1.

I believe that a communication between the liver and the skin is established by nerves passing through the ligaments of the former, and that the action of these nerves become exalted at times by the congestion of that organ stretching the inflamed capsule, just as the nerves of the tense and inflamed pleura become exquisitely sensitive under similar circumstances.

Having stated thus much for their mutual edification, I think the "Four Years Old" ought to be able to illustrate my meaning for himself, if he has spent his time to any purpose. For them, as well as myself, I would, in the words of old Dr. Alvary, of school memory, express this hope—"Experientia te plura docebit." May I also hope that they will have the courage, when they again raise the pen of the critic, to affix their names, and not adopt the concealment of anonymous writers?

I am, &amp;c.

Late of Canterbury, February 3. HENRY USSHER, M.B., Surgeon.

## APPOINTMENTS FOR THE WEEK.

February 7. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.

## 9. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.

MEDICAL SOCIETY OF LONDON, 8½ p.m. Lettsomian Lectures on Surgery—Lecture I.—Thomas Bryant, F.R.C.S., "On the Differences Between the Physiological and Pathological Processes in Children and Adults, and on some Congenital Deformities, as Hare-lip and Malformations of the Rectum."

## 10. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Mechanics." ROYAL MEDICAL AND CHIRURGICAL SOCIETY (Ballot at 8), 8½ p.m. Continuation of Dr. Marston's Paper on "Constitutional Syphilis." Mr. T. Longmore, "On Two Cases of Kelis."

## 11. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.

HUNTERIAN SOCIETY, 7 p.m. Annual Election.

## 12. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopaedic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m. ROYAL INSTITUTION, 3 p.m. Dr. E. Frankland, "On Chemical Affinity."

## 13. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

HUNTERIAN SOCIETY. Annual Dinner.

ROYAL INSTITUTION, 8 p.m. Dr. E. Frankland, "On Artificial Illumination."

ORIGINAL LECTURES.

LECTURES ON THE  
BLOOD OF VERTEBRATA.

DELIVERED AT THE

Royal College of Surgeons of England,  
DURING THE SESSION 1861-62.

By GEORGE GULLIVER, F.R.S.

Professor of Comparative Anatomy and Physiology to the College.

LECTURE XI.—*View of the Corpuscles as Animalcules—The Cell Doctrine and Endocystics—The Fibrin—Its Diagnostics and Diffusion in Animals and Plants—Its Structure—Its Viscidity—False Membranes and the Cell-Doctrine.*

*View of the Corpuscles as Animalcules.*—After the history of the coagulation of the blood, and the description of the corpuscles, we come to the consideration of that fluid in which they are moved, and live, and have their being. Live? Certainly. We have amply proved this by their power of reproduction and self-preservation; in short, by their vital endowments. And so, before finally quitting the corpuscles, and proceeding to treat of the fibrin, let us take a parting look at them in the further point of view as zoological entities; and this in company with and under the guidance of a very eminent zoologist, happily still spared to adorn that science the bounds and prospects of which he has so greatly extended. Numberless observers, such as Treviranus, Doellinger, Pander, Prevort and Dumas, Schultz, and Dr. Alison, and more especially Wolff, have described a power of self-motion in the red corpuscles of the blood. But Professor Grant maintains that not only all the different kinds of blood corpuscles which we have been describing, but the globules of chyle, of milk, and of the secretions and excretions, are really so many distinct animals. He arranges them accordingly in his class *Cystodia* and order *Endocystica*. Should his views be confirmed, it follows that the different solids of the body, —among which he specially indicates the genera of bone, muscle, cartilage, nerve, etc., — nay, even the entire frames of the highest animals, originate from or are composed of a congeries of the lowest; in short, that each portion of the soft and hard textures, as a bit of fat or cartilage, of the highest animals, and, indeed, throughout the animal kingdom, is originated or formed by these animalcules. It would follow that the highest Phanerogams of vegetables are but a congeries of the lowest Cryptogams, just as a fragment of animal fat would be a mere collection of *Endocystica*. The starch-cells and pollen grains, and, indeed, the cells of plants, high or low in the scale of organisation, would be only so many masses of different and lower plants. So the phenomenon of rotation, with which we are so familiar as a beautiful microscopic object, might be regarded as a number of smaller vegetables confined, but yet circulating, within a larger and different cell or vegetable. Indeed, it seems possible that we may even be called upon to raise these imprisoned globules, of starch, chlorophyll, or mucus, to the dignity of animals, since their movements have been repeatedly described as “evidently spontaneous”; not by Dr. Grant, but by certain French physiologists, as M. Donné. In starch granules, as well as in the particles of the fovilla of pollen, we are familiar with motions, which have also been regarded on the Continent in a more or less similar point of view. It is fortunate for science that the discovery of the so-called “molecular motions” was made in this country by such a profound observer as Robert Brown, who at once placed them in their proper position, and for ever deprived this phenomenon of any necessary relation to animality, since he proved that these motions might be excellently seen in the minutest particles of mineral matter. Fortunate; for had this fallen into the hands of a second Bywater, that ingenious speculator on the composition of vegetables by animalcules, we might have missed the truth, and got into a maze of error. But it is to animals that Professor Grant’s views are confined and expressly applied. He maintains that these animals of his order *Endocystica*, by their multiplication and metamorphoses, originate all the soft and solid textures, healthy and morbid, throughout the animal kingdom; and, as we have said already, besides the solids, the fluids—as blood, chyle, lymph, milk—

the secretions and excretions are inhabited by these animalcules. And so, of course, all the corpuscles of which we have been discoursing in the preceding Lectures are regarded by him as so many different animals, and by no means as mere parts of this or that animal to which they belong.

To go into all the evidence which might be adduced either for or against this transcendental doctrine would far exceed our present purpose and limits; and so it may be briefly noticed what we should be prepared to admit, provided we accept it as completely valid. We might have to regard the regular corpuscles of certain vegetable fluids as animals; to conclude that fibre or membrane *must* be formed by a multiplication or metamorphosis of animals; and that the two leading subdivisions of the vertebrates have red corpuscles entitled to rank at least as two or three different genera of these animals. Species merely would hardly be sufficient for the two kinds; for, as we have already shown, the distinction is not merely one of form and size, but an essential and fundamental difference of structure, which in this point of view constitutes the most extensive and certain single diagnostic ever yet recognised between the two great and leading divisions of the vertebrata—to wit, Pyrenæmata and Apyrenæmata, as more particularly described in Lectures III. and VII. And then we should have one genus of these *Endocystica* inhabiting the blood of the early embryo of Apyrenæmata, when the temporary red corpuscle with its nucleus is the equivalent of the permanent red corpuscle of Pyrenæmata, and another genus afterwards inhabiting this blood of these same Apyrenæmata when this corpuscle is devoid of a nucleus.

As to vegetables, we have just mentioned the globules in cells exhibiting the phenomenon of rotation; and, independently of caoutchouc, in the latex there are certainly, at least, two different kinds of particles to which the opacity of this milky juice is owing. Of one set these particles are remarkable for their extreme minuteness and equality of size, like those forming the molecular base of the chyle in the higher vertebrates, and to which, also, the opacity in that chyle is owing. Of the other variety of vegetable latex, the particles, on the contrary, are remarkable for their inequality of size, and their definite spherical or spheroidal form, and, in short, for their resemblance to the globules of milk; nor is there the slightest evidence that these vegetable globules contain any cellulose or sclerogen. If, then, the globules of milk are to be considered as distinct animals, how soon may we be called on to accord the same dignity to these vegetable globules?

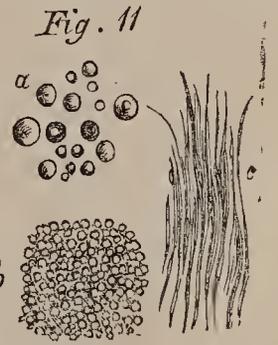

FIG. 11.—Latex of vegetables: a, Molecules in Urticaceæ, Convolvulaceæ, Cynaraceæ, &c.; b, Molecular Base in Papaveraceæ, Campanulaceæ, Cichoriaceæ, etc.; c, Fibrin of some Cichoriaceæ coagulated into fibrils.

*The Cell Doctrine and Endocystics.*—Next, as to all the soft textures, throughout the animal kingdom, being formed by a multiplication or metamorphosis of cells—these *Endocystica*—as stated by Professor Grant. My excellent predecessor here, Professor Savory, in a lecture delivered last season at the Royal Institution, truly asserts of the higher animals that they have many parts not proved to be formed from cells; for example, the clear, transparent, structureless and homogeneous basement membrane; and, to descend to insects, the equally structureless membrane of the Malpighian tubes. Again, to revert to the vertebrates, the common simple white fibrous tissue may be formed by fibrils produced directly in the previously homogeneous plasma; while even the warmest advocates of the cell-docrine have recently admitted that the fibrous matrix of fibro-cartilage is really thus formed. Further, as a result of his own observations, he questions whether cells have the share commonly assigned to them, if, indeed, any share, in the development even of such complex tissue as muscle. I have been for upwards of twenty years asking how this doctrine of Schleiden and Schwann—this fundamental part of Professor Grant’s system—can be reconciled with the undoubted fact of the formation of fibres or membranes by the simple act of coagulation in the blood; and the question has never been satisfactorily answered to this day. My figures on the subject were published in the appendix to the English version of “Gerber’s Anatomy,” and in the *Philosophical Magazine*, at a time when this objection to the universal doctrine was either neglected or despised. The

diagrams represent these fibrils thus formed, independently of any cells whatever, by the mere act of coagulation in fibrin of the blood of vertebrate animals (Fig 12); and similar fibrils will form in like manner in vegetable juices (Fig 11, c). Further, in another diagram (Fig. 13), is shown a membranous sac, to be more particularly explained presently, the intimate structure of which is made up of fibrils, with a sprinkling of minute molecules, and which was formed by the simple act of coagulation in pure animal serum, and certainly without "the development or metamorphosis of cells." Well, then, here is a bulky closed sac, surely as much entitled to the rank of an independent animal as many of Dr. Grant's Cystodia; and yet produced utterly independent of cells or of any principle involved in that doctrine which is assumed as the very key-stone of his system. Nor, considering the potency of such forces as isomerism, which render the metamorphosis of one substance to another merely dependant on contact, can we doubt but that that mysterious agency, under which this curious and really typical structure was created in dead serum, may be in operation within the living body for similar formations?

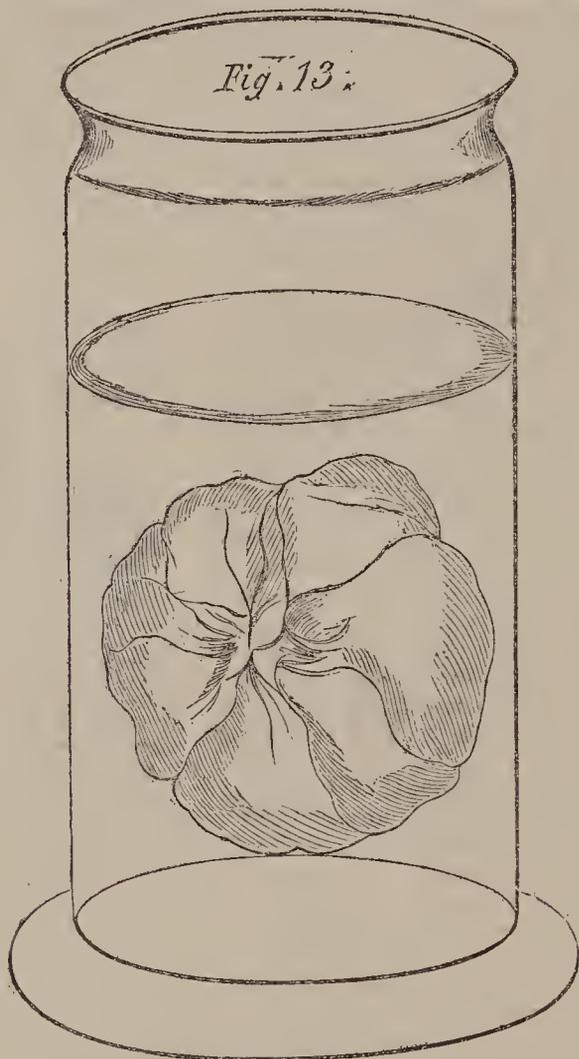

FIG. 13.—Closed sac with internal processes formed simply by coagulation in a mixture of serum. Half the size of the preparation.

Dr. Grant's doctrine, including the whole question of equivocal generation, will have to be tried by a far wider evidence than has been now adduced. On a mere question of zoological entities, it would not become me to offer opinions against the high authority of that respected and venerable professor. We have simply attempted to try how far that doctrine may be reconcilable with the truths of our limited subject, and especially whether all the corpuscles we have been describing are to be elevated to the dignity of independent animals to swell the domain of zoology, already so oppressed by its number of species. His views are not presented to us as minor or subordinate, but as central or fundamental phenomena, ruling the whole system of animated nature; as if a pyramid, of which his Endocystica would form the base, becoming modified or more select, yet always predominating, in their ascent, till man himself, still composed of, or originating from them, stand alone on the apex. Nor even here in undisputed pre-eminence, for that, or any material system, would be disputed by the monkeys; though he is surely not a mere aggregation of brute matter,

and differs from all beasts by his mental endowments, not so much by that understanding which they share with him, as by his reason, to which in its essence they have no claim—that faculty by which he comprehends religion and acknowledges a God, discerning his laws to be "holy, just, and good;" that elevation of man by "the divinity that stirs within;—those thoughts that wander through eternity;" and which comprise something far beyond and above this troublous world and all its systems.

*The Fibrin.*—Before its coagulation, the fibrin exists in a fluid or liquid state with the serum, a mixture which was happily called "liquor sanguinis" by Dr. Babington, in 1830; but when the blood is drawn from its living vessels, it coagulates in the course of a few minutes. A pellicle first appears on the surface of the blood; next, the whole of it forms a homogeneous red clot, of the consistency of soft jelly; and, lastly, the clot contracts, becomes firmer, and squeezes out the serum, which then surrounds the clot. Some of the serum always remains in the clot, and the relative quantity of clear serum will appear more or less, according to the degree of contraction in the clot. It is the fibrin only that thus coagulates spontaneously, and forms the framework of the clot, which contains, in its interstices, the red corpuscles and the other solid particles, and that portion of the serum which has not been pressed out by the contraction of the clot. Thus, this clot will be soft and diffuent, or consistent and firm, in proportion to its contraction. All the serum and corpuscles which it may include will only make it softer than it would be without them; so that a portion of fibrin coagulated, free from red corpuscles, and containing but little serum, may be as tough almost as the coats of an artery, as opaque, too, and somewhat elastic; while another portion of fibrin, equally free from red corpuscles, but retaining in its meshes a large quantity of serum, may be like a soft, trembling, and transparent jelly. Bearing in mind the three phases just described in the coagulation of the blood, to wit: 1. The film or pellicle on the top. 2. The formation of the whole into a clot; and 3. The separation of the serum by the contraction of the fibrin; we shall be better able to understand the details of some of the best experimentors, and to perceive how useless it may be to attempt to get reliable information from others. The clot is as well known under the term "crassamentum;" and a soft mixture of serum and red corpuscles, whether containing fibrin or not, is mentioned by our best older writers under the name of "cruur." Thus you may often find a cruor in the heart after death, quite red and without any distinct separation of fibrin or serum, but with soft, pulpy clots, as if the ventricles had been acting after the commencement of a feeble coagulation, as Dr. Davy has noticed. The largest part of the serum commonly exudes from the clot; the red corpuscles may be obtained by breaking it up in the serum, and the fibrin in various ways. You may procure it by washing away all the other parts, by whipping fresh blood with twigs, also by shaking shreds or strips of heavy things, as metal or glass, with the fluid blood in a bottle. The last is the best way when it is desired to get the fibrin as free as may be from the contact of atmospheric air, which will be done by receiving the blood to overflowing in a bottle previously charged with the metallic or other strips, quickly closing it, and then passing the heavy foreign bodies backwards and forwards through the blood until the fibrin coagulate around and on them. I have commonly used for this purpose cuttings of glass or lead, nails or bits of iron wire. Whatever method be adopted, the agitation should be continued until all the fibrin be separated, or nearly so, for some portion of it may remain for hours and more, either fluid or in the state of minute flakes or particles. But, after all, we know not how to get rid of the pale globules, molecules, and a large proportion of the membranous frames of the red corpuscles, as more or less of these will remain entangled in the washed coagulated fibrin. Still, fibrin often occurs quite free from these last, for, as it is specifically lighter than the red corpuscles, it may form a pale yellowish coloured layer on the top of the clot, and is then well-known as the buffy coat of the blood, which is so often and properly looked for as a pathological sign in certain cases. Yet, though a manifestation of disease in man, the buffy coat is really the healthy or regular condition of the blood clot of some lower mammalia, as well as in women at a certain period of utero gestation.

*Diagnostics of Fibrin; its Diffusion in Animals and Plants.*  
—The most obvious and peculiar character of the fibrin is

its power of coagulating spontaneously, and its disposition thus to assume a fibrous texture. And if we accept these as its diagnostics, the wide distribution of fibrin through the animal and vegetable kingdoms must immediately prove to us its immense importance in organised beings. As already described, the red corpuscles are characteristic only of the vertebrata, though it will be recollected that some invertebrata have coloured corpuscles. But the fibrin may be traced more or less through the animal kingdom, and even through part of different orders of phænogamous vegetables (Fig. 11, c). Though very little mention, much less description, of this interesting and important subject occurs in books of botany—this limpid fluid, endowed with the property of self-coagulation and the formation of fibrils—I have found it abundantly in many parts of flowering plants of different orders and in species too numerous for detail at present. Softened fibrin in man and animals used to be mistaken for pus; but the truth is that a clot of dead fibrin is reduced to a pultaceous matter when kept for awhile at a heat of about 100°; and this is another property in which a clot of fibrin differs from a clot of albumen, as particularly described in the *Medico-Chirurgical Transactions* for 1839.

*Structure of Fibrin.*—Animal fibrin often occurs in membranous expansions or in shapeless clots, and indeed it is seldom that pale clots of fibrin are not found either in the heart or great vessels after death, for coagulation is then so slow, and the corpuscles often run so much together, that they are very apt to sink and leave the upper parts of the clots more or less pale. Hence, as Mr. Paget has well observed, in conformity with the old observations of Petit, evidence might be obtained in medico-legal inquiries as to the position of the body in the first hours after death. Now what is the structure of these clots? Their proximate structure may or may not be laminated: it often is so, and is always fibrous. You may frequently pull off membraniform layers, and can easily tear them or the whole clot in one direction, generally lengthwise, but not at all, or with difficulty, in another. In short, these clots are easily torn in a line with their fibres, but not across those fibres. The diagrams represent clots thus treated from the heart. The ultimate or intimate structure is also fibrous, made up of fibrils of extreme tenuity, “fibrillated,” as it is commonly termed; but you will probably not much like this bastard word any more than many others of its tribe, without legitimate paternity, which have crept into our scientific descriptions. There are also molecules, about  $\frac{1}{30000}$ th of an inch in diameter, which are mostly of a fatty or oleo-albuminous nature, in these clots, besides a finely granular matrix. It is not till the fibrin has completely coagulated

Fig. 12.

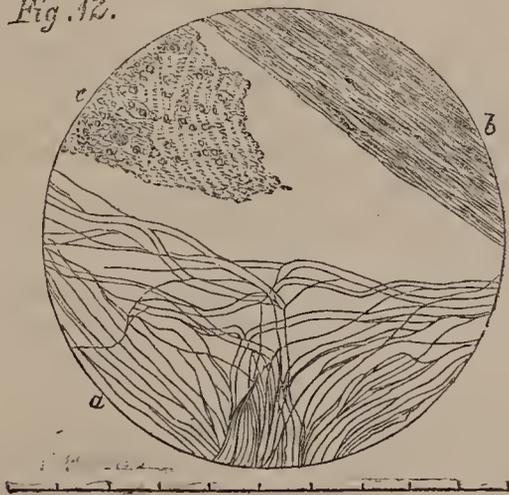

FIG. 12.—Fibrils, minute molecules, and granular base of fibrin. a, the fibrils teased out; b, parallel arrangement of the fibrils; c, granular base.

that the contraction takes place and the fibrils become plainly visible. Previously, they are more or less indistinct, though coagulation is demonstrable, and you only perceive a hyaline, homogeneous matrix, with a very few pale globules and some molecules, or merely a minutely granular matter. But, in whatever way the fibrin may have coagulated and contracted, its intimate structure is mainly composed of the fibrils. They are of extreme tenuity, about  $\frac{1}{30000}$ th to  $\frac{1}{20000}$ th of an inch in diameter, with an indefinite length; and it is probable that they would appear to be composed of still finer fibrils under a still greater magnifying power than we are yet able to use, for by microscopic analysis, from a lower to a higher enlarge-

ment, every fibre seems to be resolved into fibrils to the utmost verge of distinct vision with the best object glasses.

*Visciduity of Fibrin: False Membranes and the Cell Doctrine.*—We have treated of the fibrin in those states—the fluid and the solid—in which it is commonly observed and described. But there is an intermediate condition, little or not at all noticed in the books of physiology, though very interesting and important for us. This is the visciduity which the fibrin acquires in passing from a fluid to a solid, and which visciduity, with a slight degree of elasticity, you may easily witness in fibrin at that period. So remarkable is this visciduity, that you may smear your fingers with the fibrin in this state, slowly separate them, and draw it out into strings or membranes. And then microscopic analysis, after final coagulation, will show the fibres arranged always in the direction of the extension. Nor can you fail to recollect, when making such trials, numberless instances of similar forms in the false membranes of serous sacs, and how this visciduity of fibrin will most readily account for those false membranes or strings. The true nature of these was well known to Hewson and Mr. Hunter, though Dr. Hunter held less accurate views on the subject. Hewson mentions that, when the inflammatory crusts appear on membranes, the effused lymph composing the crusts is “more viscid and coagulable.” But, I believe, Dr. Davy first described this visciduity as a regular property of fibrin between its fluidity and solidity, and this so as to explain the appearance of false membranes. Now, we are familiar with the frequency and extent of these morbid products as part and parcel of the living body, and must perceive how they are formed by a simple coagulation of the fibrin into the shape of membranes and strings, made up of an intimate texture of fibrils. And the question must again occur to us whether this structure, so common and abundant, has any origin explicable by the cell theory? For, though it is true that these adhesions, in the recent state, abound in free cells or pus-like globules, there is not a tittle of evidence that these either give shape or frame to, much less originate the texture of, these false membranes. In short, it must be asked again, what is the proof that these fibrils of fibrin, both in health and disease, may not be the primordal fibres of animal or even of some vegetable textures, thus formed at once by the coagulated lymph, and ready for further organisation, according to the simple, beautiful, and original doctrine of Mr. Hunter?

We owe to Dr. Buchanan the important discovery, about the year 1844, that serum may be made to coagulate, at the atmospheric temperature, by putting into it bits of fresh muscle or blood-clot. On repeating some of his experiments soon afterwards with simple mixtures of different varieties of clear serum, I unexpectedly observed these further interesting facts: the transparent coagulum would sometimes assume the form of a closed membranous sac, with delicate processes forming lacunæ within it, while the outer membrane, also very fine, might become so puckered at one part as to form an opaque white spot there (Fig. 13). As already stated, cells had nothing whatever to do either with the production or intimate structure of this typical form. In short, it belongs to the class generated by the mere coagulation of fibrin; and this is as perfectly in accordance with the simple doctrine of Hunter as it is at variance with the more complex tenets of Schwann. As to the cause of such coagulation of serum on the addition of the solids just mentioned, Dr. Carpenter supposes it may be similar to that by which we get a further crystallisation of a salt by putting a hard or insoluble substance into the mother liquor. But this explanation is not applicable to the prompt coagulation of mere mixtures of serum, and which, when kept separately in glasses for some days, had remained perfectly liquid, as was the case with the preparation depicted in Fig. 13. Indeed, the phenomenon seems rather consistent with isomerism; and thus may agree with the observations of Dr. Brown-Séguard concerning the immense quantity of fibrin which must be daily formed in the body, as inferred from the regular disappearance of all the fibrin from the renal and hepatic blood each time after it has traversed the kidneys and liver.

PRESIDENCY OF THE LEOPOLDINO-CAROLINA ACADEMY.

—This, the oldest and most renowned Academy of German Naturalists, has just elected to its Presidency, in the room of Professor Kieser, deceased (in his 87th year), Privy-Councillor Dr. Carl Gustav Carus, of Dresden, by a majority of 11 voices out of 15 of its Council.

## ORIGINAL COMMUNICATIONS.

## CLINICAL OBSERVATIONS

ON THE

## EFFECTS OF DIET AND DRUGS

IN THE TREATMENT OF

## TWO CASES OF DIABETES MELLITUS,

Conducted at the Royal Infirmary, Edinburgh, under Dr. LAYCOCK,

By DR. ANDREW SMART,  
Clinical Clerk.

THE two diabetic cases here referred to have been under observation for a period of six months, but the following results do not include more than ten weeks.

First series of observations were instituted with the object of determining the sugar-producing agency of certain articles of diet. They were conducted simultaneously on the two patients, both of whom, during the course of the researches, were placed in as nearly as possible similar conditions, and all sources of fallacy were carefully avoided. The substance to be tested was given to both patients in like amount at the same periods of the day; and the analyses of both urines were made repeatedly during the course of each trial. No trial was considered complete which was not confirmed in both cases; and the time allowed to conclude any observation was seldom under forty-eight hours, but it more generally extended over a period of several days.

In all cases, it was considered necessary, for the sake of accuracy, to note other characters of the urine besides its merely saccharine condition; and the amount of the urea with that of the sugar was in nearly every instance carefully determined. Besides these precautions, the amount of urine was accurately measured. The exact quantity of solid aliment (exclusive of its water) partaken by the patients was ascertained by weight—the proportion of water contained in the solid as well as fluid articles of food being previously estimated, deducted, and added to the fluid column. The total quantity of fluids taken was, in like manner, exactly ascertained. The weights of the alvine excretions were known, and the patients were weighed from time to time.

The following articles are arranged in the order in which they were found to act as sugar-producers. The exact ratio of saccharine elimination produced by each has been ascertained and recorded, but general results only are here indicated.

1. *Sugar* (cane), whether used as an article of diet or medication, besides undergoing transformation into grape sugar, acted as a powerful diuretic and stimulant to the morbid production of sugar. It also greatly increased thirst.

2. *Rice*, contrary to general belief, was next to sugar in its influence on the production of diabetic sugar and increase of urine. Its action in these respects was much greater than can be explained by reference to the proportion of starch and sugar which it contains.

3. *Potatoes* were inferior to rice in their sugar and urine-producing powers, but exerted a markedly greater influence than the ordinary sorts of wheaten bread.

4. *Gluten Bread*.—We have not succeeded in ascertaining the exact composition of the bread usually sold under this name. It is decidedly sweet to the taste (but this saccharine quality does not depend on admixture with sugar). It is also very palatable, and preferred by diabetic patients to ordinary bread. It has been much recommended in diabetes, under the belief that, as an article of food, it operated more mildly in exciting and maintaining morbid action. This opinion was contra-indicated by repeated and careful trials, the results of which demonstrate that its influence as a sugar eliminator exceeds that of ordinary white and bran bread.

5. *White Bread*.—The trials with this bread, as with the others, were extremely varied, but invariably with like results. It undoubtedly produced less sugar than gluten bread, but was superior in that respect to brown bread and oatmeal. It is interesting to know that the amount of sugar found in the urine invariably maintained a fixed relation to the combined proportions of sugar and starch contained in the bread, the proportion of diabetic sugar always exceeding that of the starch and sugar elements as two to one. Thus,

for example, if the amount of bread taken in twenty-four hours contained, say 500 grains of combined sugar and starch, and no other substance interfered with the experiment, a careful analysis of the urine during the same period yielded, with remarkable uniformity, nearly double that amount, *i.e.*, somewhere about 1000 grains.

6. *Bran Bread*.—This bread differed in no important particular except in its milder action in the production of sugar. But this difference was trivial.

7. *Oatmeal*.—The influence of this cereal, when given weight for weight with the others, was so decidedly less than there can be no doubt in placing it last in the list now given. It diminished the amount of urine while rather heightening its density, but, as an article of diet, it was not relished by the patients.

8. *Eggs*.—When the patients were put on an exclusively egg diet, the amount of urine and sugar progressively diminished, and the latter would probably have entirely disappeared from the urine had it been possible so to restrict the diet for a sufficiently lengthened period.

9. *New Milk*.—Contains sugar as sugar of milk; but, judging from all the trials which were made with it, we were led to infer that this constituent does not undergo glucose transformation. Under this, as in egg diet, the sugar progressively disappeared from the urine. But the great difficulty always experienced was, to confine the patients for some time to one or two kinds of food.

10. *Animal Diet*.—When eggs, milk, fish, beef, mutton, and all other kinds of animal diet, were given either alone or in combination, the following results invariably followed:—1. Marked decrease in the elimination of sugar and secretion of urine, which was progressive with the continuance of the diet. 2. Sense of hunger and thirst greatly lessened. 3. Increased density of urine.

11. *Vegetables*.—Such as cabbages and turnips, sensibly augmented the production of sugar, but to a much smaller amount than is generally supposed. They were also apt to derange the digestive system. Cabbage invariably produced diarrhoea in one of the patients, and in the other indigestion and flatulency.

12. *Cod-liver Oil and Fats*.—Their use was followed by the same results as were found in the animal diet trials; but they could not be taken by the patients for some time, or in considerable quantity, without inducing nausea.

13. *Mixed Diet*.—The production of sugar under this diet, of whatever substances it may be composed, was found to be invariably proportional to the amount of sugar and starch contained in the articles which were used (a).

II. *Second Series of Trials to Determine the Influence of Remedies on the Elimination of Diabetic Sugar.*

1. *Permanganate of Potash*.—Allayed thirst, lowered the density, but increased the amount of the urine and also of the sugar.

2. *Sesquinitrate of Iron*.—Stimulated appetite for food; did not allay thirst; did not materially influence the amount of urine, but increased that of the sugar.

3. *Glycerine*.—Markedly increased thirst and the amount of urine; lowered density of urine, but total amount of sugar greatly increased.

4. *Chloroform*.—This was exhibited by inhalation, which was repeated every two hours during the experiment. Quantity of urine greatly increased; its density lowered, but total amount of sugar in twenty-four hours increased. Chloroform increases sugar simply by acting as a diuretic.

5. *Sulphuric and Chloric Ethers*.—Both these agents operate as chloroform, but in a much less marked degree.

6. *Strychnia*.—The experiments with this powerful agent were begun by administering  $\frac{1}{40}$ th of a grain thrice daily, and the dose progressively increased until its physiological action on the nervous system became incipiently apparent.

The result was a progressive and commensurate decrease in the amount of urine and sugar. The patients' diet during the course of this and the other trials of remedies was uniform. The patients' general health was good, and they gained weight. Edinburgh.

(a) *Porter and Ale*.—It is generally supposed that all malt liquors very powerfully stimulate to the morbid production of sugar in diabetes mellitus; but the experiments made with ale and porter do not support that opinion. Their use, to the extent of twelve or twenty-four ounces daily, is attended with little more than an appreciable increase in the amount of sugar. The rate of increase, as in the other articles, was ascertained and recorded.

SUGGESTIONS FOR FACILITATING THE USE OF THE LARYNGOSCOPE.

By GEORGE JOHNSON, M.D.

Professor of Medicine in King's College; Physician to King's College Hospital.

THE use of the laryngoscope being unquestionably of great practical value in the investigation and treatment of diseases of the throat and larynx, every suggestion tending to facilitate the application of the instrument, and so to render its use more general and more successful, must be deemed worthy of attention. With this view I venture to make the following observations:—

1. *On the Position of the Concave Reflector.*—Hitherto, in whatever way the reflector has been supported, whether between the teeth, or in a spectacle frame, or on a band passing round the head, the practice, so far as I know, has always been to retain the reflector in front of one eye—usually the right eye—and the observer has looked into the throat, either with the one eye applied to the central opening in the reflector, or he has used only the uncovered eye; or he may, perhaps, have succeeded in using both eyes. Every manipulator, however, must have experienced a degree of discomfort and inconvenience, resulting from one eye being kept behind the reflector, and from the effort required to keep the eye adjusted to the aperture; more especially is this found to be inconvenient and troublesome when both hands have to be used in the performance of any operation on the throat. The discomfort and inconvenience here referred to are completely obviated by the plan, which I have recently adopted, of having the reflector so attached to the frontal band, that it shall come to the middle of the forehead, and leave both eyes uncovered, as in the accompanying diagram. I am not aware

that there is the least advantage to be gained by peering through a hole in the reflector. On the other hand, the advantages resulting from having the reflector in the position here indicated are that the manipulator, having the free and unrestrained use of both eyes, finds it much easier to direct the light into the patient's throat, to keep the faucial mirror in the required position; and, in short, to do everything for the performance of which two eyes are more helpful than one. The reflector can be fixed in the position represented in the diagram, by shortening the hook which attaches it to the frontal band. This can be done with the greatest ease. I made the alteration in my own instrument with a file and a pair of pincers in about five minutes. With the reflector on the forehead there is no need for the central hole. The manufacture of the instrument, therefore, may be more simple, and in the same degree less costly.

2. *A Darkened Room is not Necessary for Satisfactory Laryngoscopic Examinations.*—I am in the habit of examining

patients in the wards of the Hospital, with only such a moderate exclusion of light as is to be obtained by drawing down the blinds of one or two of the nearest windows. The illumination of the throat certainly is easier and better with a good light in a dark room, but, since a darkened room is not always to be had, it is important to be able to make a satisfactory examination of the larynx in a room which is not completely darkened. All observers agree that the light of the sun, when it can be obtained, is the best means of illuminating the throat.

3. I have found, as others must have done, that the concave reflector is invaluable as a means of illuminating the throat, for the purpose of examining the tonsils, palate, and pharynx, Placing a candle or a lamp on a table by the side of the patient, the operator, with the reflector on his forehead, throws the light into the throat, and has both his hands free to do whatever requires to be done—to depress the tongue, to apply caustic or other local remedies, etc.

4. *Since the preceding was written, I have devised a simple and very satisfactory method of autolaryngoscopy.*

Sitting at a table of a convenient height, I place a common dressing-table looking-glass at a distance of about eighteen inches in front of me, and a moderator or gas lamp at one side of the glass, but three or four inches further back, so that no light may pass directly from the lamp to the mirror. Now, with the concave reflector on my forehead, as before described and represented, I throw the light from the lamp, as it were, into the open mouth of my own image in the looking-glass; then introducing the faucial mirror, I at once see the reflection of my larynx in the glass before me, and any one looking over either of my shoulders can see the image at the same time. This method, therefore, serves for autolaryngoscopy and for demonstration: in plain English, the experimenter can thus see his own larynx and show it to others; and the method here described possesses some advantages over that employed with such wonderful success by my friend, Professor Czermak.

I find that, while holding the faucial mirror with my right hand, and changing the position of my head and neck so as to obtain different views of the larynx, I can keep the light directed where it is required by adjusting the frontal reflector with my left hand. This cannot readily be done with Professor Czermak's apparatus, on account of the distance at which the reflector is fixed.

It is no small advantage that this method requires no special and costly apparatus. The concave reflector and the faucial mirrors used for the examination of patients, with a common looking-glass, suffice for the purpose.

For beginners in the art of laryngoscopy this method will afford a very useful means of training. One of the chief difficulties at first is to reflect a steady light into a patient's throat. Now, the student, after arranging his looking-glass and his lamp, may direct the light from the frontal mirror into his own open mouth as reflected in the glass. This process scarcely differs from that which he will have to practise on his patients. Then, having learnt to keep the light steady, he may practise the introduction of the faucial mirror, and he will soon see the interior of his own larynx.

This method of autolaryngoscopy requires a greater angular movement of the frontal reflector downwards than is needed in the ordinary examination of a patient. In order to give this free movement, and to prevent the lower margin of the reflector from coming in contact with the nose, I have found it convenient to throw the reflector forwards from the forehead, by placing a small movable pad or cushion, about half an inch thick, between the forehead and the frontal band to which the reflector is fixed.

CLINICAL MIDWIFERY.

By FRANCIS H. RAMSBOTHAM, M.D.

Physician-Accoucheur to the London Hospital, etc.

(Continued from page 106.)

THE following three cases of puerperal convulsions occurred in my practice during the last four months of the year 1840:—

*Convulsions after Delivery.*

Case 175.—On September 27, 1840, at 7.30 p.m., I was requested, by one of the district Surgeons to the Royal Maternity Charity, to see Mrs. P., in the Kingsland-road, after her first labour. The membranes broke on the previous

morning at three o'clock, before any painful sensations, and the os uteri did not begin to dilate till 3 p.m., twelve hours after. From that time the pains were frequent, and she was delivered naturally of a live child at 10 p.m. During the whole of the labour she was harassed with incessant sickness, and, though she appeared quite sensible to everything around her, there was great drowsiness and much snoring between the pains. She did not complain of headache, nor, indeed, of any unusual sensation within the skull. After the birth of the child, the stertor ceased, and she appeared progressing favourably, when, at 3.30 a.m. of the 27th, five hours and a-half after delivery, she was attacked by a convulsion, a second soon followed, and they continued to recur every thirty or forty minutes. The district Surgeon saw her at 6 a.m., bled her to the amount of twenty ounces, and applied twelve leeches to the head. For a time she seemed relieved, but soon gradually became quite insensible, the fits continuing as frequent and severe as before the bleeding. When I saw her, sixteen hours after the seizure, there had been about twenty-four. She was perfectly insensible, constantly rolling about the bed, and moaning. From twenty to twenty-five ounces more blood were abstracted from the arm, with considerable difficulty. Ten grains of calomel mixed with sugar were put upon the tongue, and one tablespoonful of a strong purgative mixture was ordered to be given frequently. From the time of the last bleeding, the convulsions ceased, and there was no return of them; she fell into a quiet sleep, and was, by degrees, perfectly restored to consciousness by ten o'clock on the following morning. She then would not believe she was delivered, as she had felt no pain; and she declared the child could not be hers. She recollects the membranes breaking early on the morning of the 26th, and also remembers the midwife being fetched to her in the course of the afternoon, but nothing that occurred in her labour, although she appeared perfectly conscious during the whole of it. She recovered perfectly, and nursed her child satisfactorily.

*Convulsions before Delivery, at Seven Months.*

*Case 176.*—On November 11, 1840, at 3.30 p.m., a Medical friend sent for me to Mrs. G., at the "Duke of Kent," Lower John-street, Commercial-road East, in labour of her first child, at seven months. She had suffered from severe headaches for a week, and, about eight o'clock that morning, was seized with a convulsion fit, without any indications of labour. Her Medical attendant was called to her, and he applied sixteen or eighteen leeches to the temples, without any good effect. When I saw her, she had had ten or twelve fits, and was perfectly comatose. I directed twenty-four ounces of blood to be taken from the arm. Ten grains of calomel were administered, as in the last case, and a strong purgative mixture was written for, of which a tablespoonful was to be got down as often as possible. From that time there was no return of convulsions, but she remained quite insensible. The os uteri was not at all dilated, and I left her. It would seem that labour soon commenced after my departure, though the people about her knew nothing of it; and the first intimation they had that labour had been progressing was their finding the child born, of course, dead, and in the absence of the Medical Practitioner, at 7 p.m. She speedily recovered her senses after delivery, and when I visited her the next day she was perfectly herself and rational; but we could not without great difficulty persuade her that she had been delivered, as she had not the slightest knowledge of her labour. Her recovery was better and quicker than might have been expected.

*Convulsions before the Commencement of Labour at Seven Months.*

*Case 177.*—On December 8, 1840, at 12 noon, a Medical friend requested me to see Mrs. D., Liverpool-street, Bishopsgate, seven months pregnant with her first child. She had been out walking on the previous evening, and on her return home complained of a sudden and violent pain in the head; for a time she lost her sight. She went to bed, and at 1 o'clock in the night she had a convulsion fit. On her Medical attendant being summoned, he took, at two bleedings, fully three pints of blood. This moderated the violence of, though it did not stop the fits, and when I visited her there had been fourteen or fifteen, more than one an hour from the commencement. She was perfectly insensible, rolling about the bed and moaning. The os uteri was quite close. I directed her to lose another pint of blood, and ordered her calomel and a purgative mixture as in the cases just detailed. She had no more fits after that bleeding, though she continued insensible.

The purgative medicine acted freely at 7 p.m.; and at 10 o'clock the next morning she had by degrees perfectly recovered her senses. Labour did not come on until the morning of the 13th, and she was delivered naturally of a dead child in the course of the day, and made a favourable recovery.

N.B.—We should be prepared to expect that a patient, after having suffered a convulsive seizure, would have no remembrance of anything that occurred between the commencement of the attack and the time when she regained her sensibility; but this *obliviscence* of occurrences that had taken place frequently extends much further back, for the disease seems to wipe away all recollection of events that had happened some time before the accession of the fits, while the patient was to all appearance perfectly conscious. Thus, I have attended many women who were apparently well and perfectly conscious when delivered, but who, having been attacked by convulsions some hours after, have (like the subject of the 175th case just related) had no recollection of their labour, and were only convinced they were delivered by their infants being brought to them. My father mentions a case in which, "although the lady at the time of her delivery appeared in perfect health, she had no recollection whatever, after her recovery, of the occurrences during her labour, or indeed of those of some days preceding that event; they appeared a blank in her existence." A case in point occurred to me on August 8, 1845, in which the lady, after her recovery from a succession of convulsions, recollected nothing that had occurred for three days before the attack, although she seemed quite well all that time, and was going about as usual. But the strongest instance of this forgetfulness of foregone events that ever came under my notice was in the last case which I have just related. It was on a Tuesday morning that this patient was first attacked, and when she came to herself she had not the least consciousness of anything that had happened since the previous Wednesday, nor did she ever after recollect any one of them. Her sister came from the country to spend a few days with her on the Saturday before; she welcomed her with pleasure, and yet she had not the least remembrance of her arrival. On the Monday before her attack she had visited another sister, a patient in St. Thomas's Hospital; in the evening she had walked from the neighbourhood of Bishopsgate Church to Temple Bar with her husband and sister: having been only a few days here, her husband wished to show her some of the sights of London. On her return, she called on a Medical man, whom she had never seen before, to engage his attendance in her approaching confinement. She remembered nothing of her visit to the Hospital, nor of her subsequent walk, nor of seeing her Medical attendant, which latter circumstance, as he was a stranger, might be supposed to have made an impression. She was equally unconscious of all that had passed during those six days. The same phenomena have been observed after other accidents in which the brain has suffered. For instance, in vol. iii. of the *Academie Royale de Médecine*, there is a case given by M. Köempfen, of a cavalry officer who fell from his horse and pitched on the right parietal bone. He had vomiting and syncope; and a total want of recollection came over him of everything that had occurred on the day before the accident as well as for some hours after it. He never regained his recollection of those periods. A Medical friend of my own, having visited a patient, also a friend of mine, in the neighbourhood of London, on June 11, 1849, was thrown from his horse while returning at 10 a.m. Although, after being brought home, he ordered appropriate medicine for his patient, when he had quite recovered from the shock he remembered nothing that had happened since seven in the morning, not having the slightest recollection of having visited my friend, or of his accident. Nor did he recollect anything that had occurred for twenty-four hours after his fall, although he was conversing quite rationally during the day, not only with his family, but also with his Medical friend, who was sent for in the emergency. The last thing that dwelt in his memory was the death of a child, who expired in his arms at seven o'clock of the morning when his horse fell with him.

Sir Benjamin Brodie, in his "Psychological Enquiries," gives two cases of this kind. A groom, in the service of the Prince Regent, was cleaning a vicious horse, which kicked him on the head. He did not fall, nor was he stunned or rendered insensible, but he entirely forgot what he was doing at the moment the blow was inflicted. There was an interval of time, as it were, blotted out of his recollection. A young man was thrown from his horse while hunting. He

was stunned, but only for a few minutes, and rode home, twelve or thirteen miles, in company with his friends, chatting with them as usual. On the following day he had not only forgotten the accident, but all that happened afterwards. Such an effect has been noticed also in other instances of cerebral injury; and persons who have been restored after hanging have been in the same manner deprived of the recollection of events that occurred some hours before suspension. In the *Penzance Gazette*, February 14, 1844, there is the account of a servant who hung herself, but was cut down before life was extinct. After her restoration she had no recollection that her illness proceeded from an attempt at self-destruction, but thought it was occasioned by a fall down stairs; she did not remember anything that happened on the previous day. In the *Times* of July 4, 1845, there is the notice of a youth who was charged at the Thames police-office with attempting to commit suicide by hanging himself, about eleven o'clock on the night of Sunday. When taken into custody on Wednesday night, he professed total forgetfulness of having perpetrated the act; and I have no doubt the forgetfulness was not feigned. He had remained insensible from the time he was cut down until nine o'clock on the next morning. In Sir Walter Scott's "Fair Maid of Perth," it is stated (a) that a woman was hung at Oxford for child murder within this century, who was restored, and remembered but little of her trial and sentence, nothing of her confession, nor of the particulars of her execution. Scott says a Professor of the University has published an account of his conversation with the girl after her recovery, but I have not been able to trace this. One woman whom I attended under a very severe attack of puerperal convulsions, and saw a month after her labour, had completely forgotten how to write, though she wrote very well before. She could not make a letter without having a copy before her; and when she tried she looked exactly like a child beginning to learn. Such instances as the foregoing are worth being recorded, not only as physiological and pathological facts, but because they may influence our opinions in some Medico-legal questions.

8, Portman-square.

ON THE  
PUBLIC HEALTH OF THE COTTON  
DISTRICTS.

By JOHN BEDDOE, B.A., M.D.

Physician to the Bristol Royal Infirmary.

THE publication of the Registrar-General's report for the last, or autumn, quarter of 1862, may tend to re-assure those who, by undervaluing the efforts made to relieve the Lancashire distress, had led themselves to expect a frightful increase of mortality among the unemployed cotton-workers. So accurate an observer as Dr. Buchanan was probably in the right, when he remarked the prevalence of an anæmic and depressed aspect in the people of the distressed districts; but the sallow and unhealthy aspect of many of the operatives in the cotton towns had often been a subject of comment in more prosperous times. It would appear, that the unemployed in Lancashire—thanks to the admirable mode of administering the relief funds—are at present supplied with means of subsistence equal to those of the labouring classes in some less favoured districts of our country. Accordingly, the mortality returns continue to exhibit no overt sign of the presence of famine. The quarter has been an unhealthy one, owing, doubtless, to its meteorological character; and the mortality in England generally, when compared with that of the corresponding quarter last year, shows a large increase; but Lancashire contributes in but a small proportion to this increase. In a recent paper, quoted in the *Medical Times and Gazette*, I showed that a considerable decline which had occurred in the mortality of Lancashire in the summer quarter had been confined to the suffering cotton districts, and that, roughly speaking, where the distress was deepest, there had the improvement in the death-rate been greatest; or, in other words, the mortality had been in inverse ratio to the distress. This somewhat paradoxical aspect of affairs still continues to exhibit itself in the returns. There is, indeed, a certain

(a) Vol. ii., chap. 7 (original edition).

increase in the death-rate of Lancashire; but if we divide the county into two groups of districts, of which the eastern one contains all those (a) in which a large per-centage of the population finds employment in the cotton trade, we shall find that the whole of the increase is to be found in the other or no-cotton region, and almost the whole of it in the town and suburbs of Liverpool, which are so far from suffering any great amount of distress, that they have contributed with open hands to the relief of their unfortunate neighbours.

There are, moreover, six registration districts beyond the bounds of Lancashire (viz., Stockport, Hayfield, Bakewell, Todmorden, Saddleworth, and Carlisle), in which the cotton trade is extensively carried on; and these, grouped together, exhibit the same rate of mortality, to a fraction, which they did twelve months ago, whereas the counties to which they respectively belong, taken similarly *en masse*, yield a considerable increase.

These figures appear to me to testify, with trumpet tongue, in favour of the modes of administering relief which have been adopted, and of the energy and thoroughness with which they have been carried out. Perhaps we may, in part, ascribe the fact (which one of the subjoined tables exhibits) of the excess in the death-rate of the autumn of 1861, when the cotton-dearth was beginning to tell, in a slight degree, over that of 1860, when all was prosperous, to the early exhaustion of the means of the more improvident workmen, while the system of relief had not yet been organised. In reference to the question of amount of relief, I may remark that an increase of the money dole, except in special cases, might, probably, tell rather unfavourably than otherwise on the returns. It is a melancholy consideration that the amount of strong drink consumed in the districts in question is reported to be almost as large as ever.

The "prudential check" had not, at least up to September, where the returns leave us, operated so strongly on the number of marriages in the cotton districts, as might have been expected, and, indeed, desired. Though the ratio of unions to population had declined to a certain extent, it still amounted to 8.02 in 1000, whereas in the remainder of England it was but 7.63.

MEDICINE AND SURGERY.

KING'S COLLEGE HOSPITAL.

EXTENSIVE TUMOUR OF THE ANTRUM, INVOLVING THE FLOOR OF THE ORBIT AND THE SOFT PALATE—EXCISION OF SUPERIOR MAXILLA—RECOVERY.

(Under the care of Mr. FERGUSON.)

[Reported by Mr. SMITH, House-Surgeon.]

DAVID P., aged 48, a pale, weak-looking Welshman, was admitted into Albert ward on December 3, for a malignant tumour of the left upper jaw.

*History.*—He is married, but has had no children. He is

(a) Viz.: Manchester, Chorlton, Salford, Ashton, Oldham, Rochdale, Bury, Burnley, Blackburn, Haslingden, Clitheroe, Preston, Chorley, Bolton, Wigan, Barton, and Leigh. I have taken as my principal guide the occupation returns of the census of 1851, those of 1862 not being accessible.

a tradesman of temperate habits, and has always had good health. His relations on both sides seem to have been very healthy, his father being still alive, in his 89th year. He has been subject to great mental and physical exertion.

About two years ago he had a set of false teeth made, which were kept steady in the mouth by a piece of silver wire fastened round one of the sound teeth on the left side. There was also a thin piece of silver added afterwards to the gold plate. This, he says, caused great irritation, but he still continued to wear it, when, about twelve months ago, he noticed a red and thickened state of the gum of the upper jaw on the left side, particularly in front. At the same time he noticed, on the inside of the gum, a distinct tumour about the size of a bean. A fungous growth gradually sprung up from the thickened gum on the front of the jaw, and involved part of the hard palate. Three teeth about this growth were removed last August by his Medical attendant, and were found to be perfectly sound. The cavities left were soon filled up with the fungous growth, and the tumour rapidly increased in size. Some caustic was then applied to the gum, which caused a large slough to come away, and the tumour diminished a little, but soon afterwards grew and increased with great rapidity, involving the skin of the cheek, and extending up to the left temple. The lower eyelid also began to swell, and he had a severe pain, which, he says, was of a sharp, shooting character. At the beginning of October, he was admitted into a London Hospital, and the Surgeon in charge of the case proposed an operation. When the patient was put under chloroform, an incision was made from a little below the external canthus of left eye to the corner of the mouth, and the flaps turned back. Then the skin was thought to be so extensively involved, and the disease spreading so far in all directions, that no further steps in the operation were taken, and none of the tumour was removed. Three weeks after the operation, the patient returned to Wales, where he suffered from a severe attack of erysipelas in the face, after which he noticed both eyelids on the left side to be very much swollen, and the left nostril to be closed up.

*State on Admission.*—Very much exhausted and out of health. There was a considerable enlargement on left side of face. The eye was very much protruded; both lids much swollen; the lower one everted, and the mucous membrane thickened and granular; the sight of the eye was gone. The left nostril was swollen, and there was a thick discharge constantly coming from it. Running across the cheek was the cicatrix of the exploratory incision made in October. The skin was thickened and unhealthy-looking, and there could be felt under the buccinator a large, well-defined, hard tumour. Upon examining the inside of the mouth, there could be seen a large fungous mass involving the left side of the hard palate, nearly all the soft palate, and the uvula. The disease seemed to have involved the base of the orbit, and extended up under the zygoma. The glands in the neck were not enlarged. The patient suffered most excruciating pain, which was intermittent, and of a neuralgic character.

*Operation, December 20, 1862.*—The patient having been put under the influence of chloroform, Mr. Fergusson first made an incision through the mesial line of the upper lip, then along the left ala of the nose, and another incision at right angles to this, under the lower margin of orbit, as far as the middle of the zygomatic process. After dissecting back the flap of skin, he divided the maxillary bone a little to the right of the mesial line with a small stiff-backed saw; he then, with a strong pair of bone-pliers, cut away the tumour from the floor of the orbit, and cut through the pterygoid as high up as possible. After the remaining bony attachments had been cut by the bone-pliers, the tumour was forcibly dragged away from the base of the cranium by a pair of very strong clawed forceps. Most of the soft palate was then cut away with the knife, and several pieces of suspicious-looking tissue at the bottom of the wound were dissected out. One ligature was applied, the edges of the skin brought together, and fastened in the upper lip by harelip needles, and in the cheek by ordinary sutures. The whole operation did not last more than fifteen minutes, and not more than three ounces of blood were lost.

January 17, 1863.—The patient since the operation has got well with scarcely a single bad symptom. He has had a little swelling of the eyelids of both sides, which, in the right, has extended to ulceration, but from this he has now quite recovered. The whole of the wound united by the first intention. Has had no difficulty in swallowing liquids, and can now eat meat. There was, for a fortnight after the operation,

a copious, fetid discharge from the inside of the mouth, but this has now ceased, and the mucous membrane and surrounding tissues look perfectly healthy. His appetite is very good, and he takes a fair amount of exercise in the day. The left eye has not receded at all into the orbit since the operation. Discharged well.

## ST. BARTHOLOMEW'S HOSPITAL.

### CASE OF GLANDERS—DEATH ON TWENTY-SEVENTH DAY—AUTOPSY.

(Under the care of Mr. SKEY.)

[Reported by Mr. HOWARD MARSH.]

J. H., aged 24, after being out of work for three months, engaged himself to a horse-slaughterer on June 14. On the following day he thrust a rusty nail into the tip of the left forefinger, and, thinking the accident of no consequence, continued his employment. By the next day the finger had become inflamed and very painful, and he observed red streaks running up the forearm. At the end of a fortnight, having in the interval suffered a very severe attack of inflammation of the finger, accompanied by much general fever, he was advised by the Surgeon under whose care he had placed himself to come to the Hospital. He was at once admitted on June 29. On examination, it was found that his health was in a very bad state, and his expression indicated severe suffering and distress. Almost all the soft tissues of the finger had sloughed, and the whole hand was much inflamed and swollen. The lymphatics on the radial side of the forearm had suppurated, but the axillary glands were scarcely at all enlarged. He stated that he was a butcher, but did not mention anything which pointed to his real condition till several days later. Incisions were made for the escape of matter, and he was ordered good diet and quinine, and a charcoal poultice to the fingers. From this date he appeared steadily to improve, both as to the local mischief and the general health, till July 4, when symptoms of severe constitutional disturbance occurred, and a patch of dusky-looking erysipelatous inflammation appeared on the forehead, involving the right eyelid.

On the 5th, the forehead was sprinkled with small bullæ, containing a dirty-looking, dark-coloured fluid, and the scalp and face were œdematous. He had slept little during the night, on account of severe pain in the head; the skin was clammy and relaxed; the pulse 120, and very feeble. He was ordered three grains of quinine every three hours, and ten ounces of brandy daily, with sufficient opium to procure sleep.

On the 6th, he was decidedly worse. The erysipelas had extended over the greater part of the scalp, and the face and throat were much swollen. A free incision was made into the integuments of the forehead, and a small quantity of ill-formed, fetid pus drained out from the subcutaneous tissue in which it was infiltrated.

On the 7th, the whole of the integuments over the frontal bone were beginning to slough, and he was very weak and exhausted.

On the 8th, the anterior half of the scalp was sloughing rapidly. Several pustules, about as big as those met with in small-pox, had appeared on the chest and right arm. They were seated on a dusky, inflamed base, and contained an opaque, brownish-coloured fluid.

On the 9th, the anterior half of the scalp was converted into one large slough. The chest and extremities were covered with a crop of pustules similar to those described above, and there was an inflamed, cord-like condition of the lymphatics of the left foot and leg. From this date he grew rapidly worse, and died in a comatose condition on the 12th—that is, on the twenty-seventh day after the reception of the poison into the system; the erysipelas having commenced on the twentieth day, and the pustular eruption three days later. There was no discharge from the nose during his illness.

*Examination of the Body Fifteen Hours after Death, from the Notes of Dr. Andrew.*—Post-mortem rigidity slight. Over the left tibia inferiorly a small, firm, subcutaneous swelling, over which the integument was ulcerated. Numerous shot-like pustules, none of them presenting any central depression, scattered over the neck, trunk, and extremities; most abundant on the upper arms. Integuments of forehead and anterior half of scalp sloughing; bones not exposed; great œdema of eyelids; conjunctivæ seemingly natural. No

change detected in any of the salivary glands. Lymphatic glands in neck slightly enlarged. Submucous glands at base of tongue slightly enlarged, but not unusually so. Pharynx and œsophagus natural. Larynx: two small pustules, the size of peas, one at the level of the cricoid cartilage, the other immediately below the right vocal cord. Pericardium contained about an ounce of serous fluid; no ecchymoses on any part of the membrane. Heart: right cavities contained two small fibrinous clots; one or two smaller ones on the left side. Blood in large veins fluid; valves normal; muscular substance pale and soft; no petechiæ on the endocardium, but it was slightly blood-stained. Lungs: on the surface were one or two small petechial spots. In the substance of the lung were numerous small, firm, dark red masses, seemingly consisting of coagulated blood, with yellow points in their centres. One or two small purulent deposits were also detected generally near the surface. Lungs emphysematous throughout; contained no tubercle. Supra-renal capsules seemingly natural. Liver: 5 lbs. avoirdupois; on section, pale and very soft, its consistence being scarcely greater than that of a lung in a state of grey hepatisation. Gall-bladder contained a very little yellow bile. Kidneys large and congested. Lumbar, axillary, and inguinal glands seemingly unaffected. The nasal fossæ were not laid open, but no evidence of any discharge having taken place, or of any change in the mucous membrane, could be detected by an external examination; and the upper surface of the soft palate, which was removed together with the tonsils, uvula, etc., was perfectly natural.

#### CASE OF FARCY—TREATMENT BY LARGE DOSES OF THE IODIDE OF POTASSIUM—RECOVERY.

(Under the care of Mr. SAVORY.)

[Reported by Mr. HOWARD MARSH.]

C. H., aged 52, came to the Surgeon's consulting-room on August 28, 1862, giving the following history of himself:—He had been in easy circumstances, as a gentleman's servant, till January, when, being out of employment, he took to the care of a stable and to driving a cab. The stable was known to have been infected with glanders poison for a twelvemonth previously, and six or seven horses had suffered from the disease. He remained well till the end of May, at which time, after feeling very languid and depressed for some few days, he noticed that the left side of his nose was red, swollen, and painful; and on the mucous membrane of the nostril he found six or seven small, red, and very sensitive pimples. A copious, thick, yellow, and very fetid discharge began to flow from the nose, and a quantity was spat from the back and upper part of the pharynx. The glands under the jaw were enlarged, and he had "kernels along his jugular"; the throat was sore, and deglutition was painful. About a fortnight later, seven or eight "buds" as big as a fourpenny-bit, and about twelve smaller ones, appeared on the left side of the neck and the left arm. These suppurated, and, after a time, healed, being succeeded by others which, in their turn, also healed, and gave place to fresh eruptions of similar pustules. The glands in the axilla were enlarged, but the lymphatic trunks seemed unaffected. He now became much emaciated, and so feeble that he could scarcely walk, and, not being able to obtain proper food and good lodgings, fell into the deepest distress.

When he came to the Hospital, the "buds" had ceased to break out; the discharge from both the eye and nose was very abundant, thick, yellow, and fetid. The eye was considerably protruded, and the conjunctiva slightly chemosed. The glands under the jaw and along the side of the neck were still enlarged. He was much emaciated and exceedingly weak. He was ordered to be kept in a room by himself; to take two grains of quinine three times a-day, and two pints of porter, with good meat diet.

August 30.—Seemed more feeble than when admitted. To take a teaspoonful of bark with the quinine, and four ounces of brandy.

31st.—To take two teaspoonfuls of bark, instead of one, with the quinine.

September 8.—Appeared getting worse: the discharge was very copious, and the eye was more prominent than when he was taken in. Ordered two teaspoonfuls of bark with seven grains of iodide of potassium three times a-day.

26th.—Was certainly improving under the iodide. Had gained strength and was more cheerful, and could take his food better. Discharge about as before. To take ten grains of the iodide instead of seven.

October 12.—Was very much better. The eye was less prominent, and the discharge both from it and the nose was decreasing. He was gaining flesh, and was able to sit up. To take twelve grains of the iodide three times a-day.

20th.—Was now able to walk about, and expressed himself as nearly well again; general condition good; the discharge though much decreased had not ceased, and the eye was still more prominent than natural. To take fifteen grains of the iodide three times a-day.

He was discharged on November 17, at which date, although the secretion from the nose was excessive, it had ceased to be fetid, and the eye had receded into its natural position.

When seen on February 7 he was in good health, and considered that he had entirely got rid of the disease.

#### DISLOCATION OF THE TIBIA AND FIBULA, BACKWARDS AND INWARDS, WITH DISPLACEMENT OF THE PATELLA BY ROTATION ON ITS AXIS.

(Under the care of Mr. CALLENDER.)

[Reported by Mr. EDLIN.]

Henry F., aged 30, admitted April 24, 1862, a carman, strong, healthy, and of temperate habits. Whilst walking across a yard, shortly before his admission, a heavy packing case fell against him, so that he was thrown violently to the ground on his face and hands, and beneath the case; at the same time his left foot was wedged between two large stones, and the left leg was further fixed by the right being crossed in front of it. When freed from the packing case he found that he could not rise from the ground, owing to his being unable to use the left knee, which was the seat of intense pain.

On examination of the injured limb, it was at once evident that the tibia and fibula were dislocated backwards and inwards from the femur. The head of the tibia projected on the inner side, whilst on the outer the external condyle of the femur was sharply prominent, owing chiefly to the backward displacement of the bones of the leg, so that fully one inch and a-half of the inferior surface of the femur as well as the depression between the two condyles could be distinctly felt with the finger, being covered only by superficial structures. In front the ligamentum patellæ was lax; behind, the tendons inserted into the tibia and fibula were tense, and the muscles connected with them were rigid and contracted. The inner edge of the patella was prominent, projecting sharply beneath the skin. The leg was semiflexed on the thigh, and the foot was slightly everted, the space between the two inner toes corresponding with the outer edge of the patella, which, however, could be but indistinctly traced.

The patient having been placed under the influence of chloroform, the tibia and fibula were readily brought into their natural situation by means of simple extension; and it then became more evident that the patella (over the inner margin of which the skin was now tightly stretched) was so displaced that its outer edge rested upon the space between the condyles, whilst its inner projected forward, the articular surface of the bone being also turned slightly forward towards the integument. The ligamentum patellæ still remained lax until, on making sudden and forcible flexion of the leg upon the thigh, it tightened, and at the same moment the patella twisted round and regained its natural position. The limb, slightly flexed, was placed on a back splint, bandaged, and swung, tincture of arnica being applied to the knee. Beyond slight effusion into the joint, which occasioned neither pain nor inconvenience, the patient progressed without an unfavourable symptom.

On November 12, 1862, the movements of the knee-joint were completely regained.

#### THE LONDON HOSPITAL.

##### CASE ILLUSTRATING THE EFFECTS OF NERVE-SECTION UPON NUTRITION AND ANIMAL HEAT.

(Under the care of Mr. HUTCHINSON.)

THE following case is of interest as a contribution to our knowledge of the remote effects of division of nerves. It very closely resembles, in most points, one which I published a few months ago. In both, a great loss of temperature was the most marked feature. In both, the influence of the nervous force in preserving a normal state of nutrition was illustrated by the occurrence of whitlows at the ends of the fingers from which it had been cut off. In the former case, three fingers were so affected; in the latter, only one. In all, the position

of the inflamed part was precisely the same—the very end of the finger. It is an interesting fact, in the present case, that there was very decided loss of temperature in the integument, even above the position of the wound. The details given will, however, tell their own story.

*Analysis.*—Section of the Ulnar Nerve, with probably Wound of the Median also—State of the Hand Three Months afterwards—Loss of Temperature in the whole Hand, and also in the Fore-arm above the Scar—Dilated and Atonic Condition of Capillaries—Whitlow at the end of the Ring Finger—Atrophy of the Muscles supplied by the Ulnar Nerve—Recovery of a Slight Degree of Sensation in the Parts.

Emma R., aged 15, on October 19, thrust her right hand through a pane of glass, and received a deep cut on the inner part of her fore-arm, about an inch above the wrist joint. The radial end of the incision passed as far as the middle line of the fore-arm, but possibly it passed deeply still further. It crossed the ulnar vessels and nerve. There was very free bleeding, which was stopped by compress and tight bandage. She was taken to the London Hospital an hour afterwards. No further bleeding occurred. The wound healed slowly and with suppuration. She was discharged five weeks after her admission.

*Examination.*—February 1, 1863, rather more than three months after the accident. She is in good health, but has not been able to make any use of her hand. The hand is chilly and bluish red, like that of a person suffering from chilblains; the capillaries fill slowly when emptied by pressure; all the finger nails are somewhat clubbed, and decidedly more curved than those of the other hand. The scar has been quite sound for six weeks, and is free from tenderness. It moves when the fingers are straightened, the tendons being adherent to it. Sensation good above the scar, and exceedingly imperfect below it, over the ulnar side of the hand, the little and ring fingers. No discoverable difference between the two sides of the ring finger. The middle and forefinger have only imperfect sensation; in the thumb it is tolerably good. It appears to improve gradually as we go from the little finger to the thumb. Even over the little finger she has a slight degree of sensation, and can tell sometimes when lightly pricked. All the fingers are bent forward to the palm, but do not touch it. To straighten them causes pain at the scar.

The muscles clothing the metacarpal bone of the thumb are much wasted. The carpo-metacarpal joint is too visible, and the outline of the metacarpal bone is exposed. On the back there is a remarkable hollow between the thumb and forefinger, and the metacarpal bone of the latter is immediately under the skin, the abductor indicis being quite wasted.

When told to draw her thumb across the palm to make it and the little finger meet, she bends the thumb by the long flexor, and is quite unable to adduct it whilst extended. She cannot bring the thumb and little finger together by any effort, partly because she cannot move the little finger at all. The structures in the palm are a little thickened, and she has slight tenderness on pressure there. She says that she has not had much annoyance from sensation of cold or aching in the hand, but she is quite aware that it is colder than the other; she has also noticed that when the hand is put into hot water she does not feel the heat well.

At the very end of her ring finger (injured hand) is a small whitlow; it looks as if a few drops of pus had been effused beneath the skin, and were now nearly absorbed. The skin over it is dry and horny; there is a little red areola around it. She has had no pain in it, and it is not tender. It began to form nine days ago.

The following is a statement of the temperature as determined by the thermometer, applied to different parts. The experiments were made after the girl had sat in a warm room for half-an-hour, with the two hands equally exposed:—

	Left. Degrees.	Right. Degrees.	Difference. Degrees.
Ulnar borders of the two hands	66	61	5
Between little and ring fingers (in the cleft)	65	59	6
Between thumb and fore-finger (in the cleft)	66½	62	4½
Between fore and middle fingers (in cleft)	65	60	5
Pulp of thumb end	62½	60½	2
Ball of thumb (palmar aspect)	65	61	4
Front of fore-arm four inches above wrist (three above the scar)	78	74	4

CARCINOMA OF TONGUE AND SUBMAXILLARY GLANDS—RAPID PROGRESS.

(Under the care of Mr. HUTCHINSON.)

The following case affords a good instance of the rapid course which epithelial cancer occasionally runs. Often it is difficult to assign a correct date to the commencement of the disease, but, in this instance, it is tolerably certain that it followed the extraction of a tooth only two months before the man's admission. Nor is this wild-fire rapidity of progress by any means unprecedented in the history of this form of cancer. Epithelial carcinoma, when once fairly developed, is one of the most rapidly fatal forms of malignant disease with which the Surgeon has to deal. It is impossible to exaggerate the importance of a correct diagnosis very early, and of very early measures for its extirpation.

The following are the notes taken at the time of the man's admission:—

“Joseph H., a carpenter, aged 46, always healthy. He does not know that any of his relatives have ever had cancer. He has smoked largely. Two months ago he applied at the London Hospital, and had a broken lower molar of the left side extracted. At that time there was no sore on the tongue; the tooth ached, and that was his motive for wishing it out. Shortly afterwards a sore formed on the tongue, just where the tooth had scratched; the sore spread rapidly. It now extends from near the tip to the very posterior edge, and also involves somewhat the structures in the floor of the mouth; it has a sloughy base, an overhanging border, and very hard edges. Last night it bled freely. Under the jaw are numerous very hard glands. He has not as yet had much pain, but has lost flesh greatly, and has felt very weak. He still does not display any appreciable degree of cancerous cachexia. He has never before seen a Surgeon about it. Although of only eight weeks' duration, the case is clearly hopeless as regards operation.”

The case ended in death between two and three months after the above notes were taken. The glands had ulcerated, and opened through into the mouth.

SATURDAY, FEBRUARY 14.

RUSSELL v. ADAMS.

WHY should we not have a grand jury in civil as well as in criminal cases? If a man's character is as dear to him as his life, why should he not have it protected from public contempt and ignominy whenever the verdict of a grand jury could throw out of court a cause based on evidence that is worthless, or worse than worthless? We ask this question, as bearing with peculiar force at the present moment, in relation to the trial of Russell v. Adams. It is as clear as crystal, that if the rule we have suggested had been in force, this scandal would never have seen the light of day. Mr. Adams would have stood, as he stands now, acquitted of the charge brought against him; while all the annoyances and all the expenses to which he has been so unjustly subjected, would have been wisely and entirely prevented.

It is hardly necessary for us to say a word of explanation in

respect to the trial of the past week, in which one of our Surgical celebrities has been so prominent a figure. That which is proclaimed on the omnibus tops, if not on the house-tops, and on which our daily contemporaries have written so fully, requires, necessarily, but little exposition here.

Still, as matter of current Medical history, the facts of the trial may be briefly stated. They are to the effect that a woman named Russell, and her daughter, persons claiming family connection with Earl Russell, the Bedfords in general, a dean or two, several rectors, and at least one admiral, accused Mr. Adams of a breach of promise of marriage with Miss Russell, the daughter. The circumstances under which the promise said to have been made was effected are peculiar. The promise was certainly not made in writing, no document containing such promise having been ever produced; and, if it were made verbally, the terms of it, together with the date and situation, were also forgotten.

Of what was really shown in evidence the main facts were, that Mrs. Russell took a child, named Crompton, having a deformed foot, to the Orthopædic Hospital, in 1860. There the fascinating old lady, like Mr. Simon Tappertit, presumed on her powers of persuasion so far as to talk Mr. Adams out of himself, and into her confidence. It is not suggested that between Mr. Adams and the old lady any kind or tender feeling arose, nor that any offer was ever made to her; but it appears that Mr. Adams, under the impression that she was the widow of a Medical man, invited her to go to his house with the child for morning consultation. After a time, Miss Russell took her mother's place, and, being a highly susceptible young woman, though not quite so lovely as her counsel depicted her, she informed her mamma—so said her mamma—in October, 1860, that Mr. Adams had made her an offer of marriage. On the receipt of this startling intelligence, Mrs. Russell, according to her own statement, wrote a letter to Mr. Adams, the terms of which she repeated *verbatim et literatim* to the Court, the copy having been lost. Unfortunately for her, she again had no correct idea of dates. After a time the two left Hornsey, the place where they had been living, and in March, 1861, moved to Osnaburgh-street, Regent's-park. Here they lived in the house of a Mrs. Lama, establishing themselves on Mr. Adams' name. They now sent constantly for Mr. Adams to visit them, on pretences of illness; he did visit them, and on one occasion called in the evening, stayed some two hours, heard Miss Russell play, heard Miss Russell sing, stood at the back of Miss Russell's chair, and even sang a song himself. Atrocious man! For months, under the impression that the engagement was a fact, Mrs. Lama lodged, boarded, and, to use an American phrase, not very elegant but true, *liquored* these two ladies. They had their gin, their brandy, their soda-water; they feasted well. Though one of them complained that in the morning she had thirst, dryness of the mouth, and pain in the head, otherwise all was propitious. Mrs. Russell was quiet, Miss Russell was quiet, both were quiet, except when they were asked for money—then there was a sharp breeze in Osnaburgh-street, which did not come from over Primrose-hill.

The Russells remained with the Lamas until a bill of extraordinary length became an accomplished addition to the manuscript literature of this country. By various little pieces of by-play they kept the idea of the marriage always on the *tapis*; they were skilled at the work; and, it would seem, had previously learned many practical lessons. But there came at last a time when Mrs. Lama's patience would bear no more: she pounced on Mr. Adams as he was entering her house, and had it out with him. She asked him point-blank whether he was not going to marry Miss Russell; and when she received an indignant negative, coupled with the information from himself that he was a married man with a family, she was not less astounded than he. She had kept them on the faith of this engagement, and now her expecta-

tions were suddenly and definitely thrown aside. Imagine the scene!

There remains, in the general statement, but little more to add: Mr. Adams, accompanied by Mr. Blaise, visited the Russells, and received from them a flat contradiction of the statement made by Mrs. Lama. Ultimately they retracted this contradiction, and, after making many ineffectual attempts, at last brought forward the action which has ended in a verdict to their exposure and grief.

We have looked at every line of the evidence supplied on both sides; we have read it critically, heard it discussed critically, and for the life of us we can discover nothing in it that were beyond actual comedy, if the results that depended on it had not been so serious. The evidence brought by Mrs. Bardell against her deceiver, in the celebrated cause which some years ago occupied the public mind, was conclusive and irrefragable compared with that of Miss Russell. It was admitted by the prosecution that not one affectionate sign or token had ever passed between the assumed lovers: to the young lady, not so much as one poor three-cornered note had even been sent. Letters written by herself to her betrothed were read; they were couched in terms so hard and business-like that one could have traced them, without any stretch of imagination, had the authorship been unknown, to the immortal Sarah Brass, or at least to a pupil of that illustrious lady. To be brief, look into whatever part of the evidence we may, not a tittle of fact can be detected bearing even an approach to the indication of a real or false attachment. If it were for a moment admitted that, on such half-cunning, half-maniacal statements and protestations as those of Mrs. Russell, Medical men could be prosecuted successfully for breach of promise, the Colleges of Physicians and Surgeons might close their doors in a twelvemonth, and leave Professor Holloway and the British College of Health masters of the Medical field, to take alike all risks and all rewards.

Happily, the verdict, although couched in most absurd terms, demonstrates that English juries, stupid as they may be, are not quite prepared to back any unsupported assertions affecting a man of unblemished character that may be offered them; and we congratulate the Profession on the fact, that, after a severe and rigorous trial, its honour has been sustained in the complete and demonstrative vindication of one of its representatives.

## THE WEEK.

### DR. BROWN-SEQUARD'S LECTURES.

A COURSE of six lectures on "Diseases of the Nervous System" was begun on Thursday, the 5th inst., by Dr. Brown-Séquard, at the National Hospital for the Paralysed and Epileptic. The Board-room, in which the lectures are given, was nearly filled by an audience consisting almost wholly, we imagine, of Medical men engaged in practice. The first lecture was upon "Wasting Palsy," and was prefaced by some remarks on the difficulty of the subject, and by a modest reference to a special difficulty which the lecturer has to contend with—viz., that, we presume, of expressing himself in the English language. But, indeed, this allusion was scarcely needed: since we last had the pleasure of hearing Dr. Brown-Séquard address an audience, his progress in the language has been so rapid, that, though no one would suppose him, when lecturing, to be speaking his mother-tongue, each of his hearers must be struck by the copious and idiomatic knowledge of English which he displays, as well as by the facility and effectiveness with which he uses it. In fact, the piercing insight and rigorous scientific method which characterise this distinguished physiological discoverer and original thinker impress their own qualities on his language, thus rendering it at once clear, compact, and logical. Wasting palsy, the lecturer said, was first described

as a distinct disease by Sir Charles Bell, his description being completed by Cloquet. This form of paralysis is often restricted to certain muscles, and does not necessarily involve all the muscles of a limb: generally, those acting in concert, though supplied by different arteries, and controlled by different nerves, are affected at the same time. During the process of atrophy the muscles implicated usually present a wavy or corrugated aspect, and, though powerless, their reflex sensibility is such as to cause them to quiver more or less when touched. A considerable part of the lecture was occupied in stating and discussing the post-mortem phenomena, and the hypotheses founded thereon, which have been from time to time adduced in explanation of the cause of the disease. Morbid alterations of the spinal cord have often been found in persons who have died afflicted with wasting palsy; but these alterations, instead of being constantly of the same nature, have differed from each other so essentially in the different cases as to preclude the possibility of establishing a causal relation between any one of them and the disease in question. On the other hand, cases of wasting palsy occur in which post-mortem examinations reveal no structural change in any part of the cerebro-spinal axis. In presence of these facts, the lecturer confessed his inability to divine the source of the malady. He showed a remarkable illustrative case, that of a labouring man, who had evidently been very healthy and strong, and who, a few months ago, got wet, and afterwards lost the use of his arms. The whole of the muscles of both upper extremities are wasted; those of the back, and especially those of the back of the neck, are also involved to such a degree that the man cannot maintain himself erect; his head falls forward; the spine of the seventh cervical vertebra projects greatly; and in order to balance himself he counteracts the hanging of the head forward by throwing the shoulders backward. There is a sub-inflammatory condition of the muscles of the shoulders and back of the neck, as evinced by the general tenderness on pressure of those parts; but concerning the relation of this affection to the disease in question, Dr. Brown-Séguard did not hazard an opinion. Treatment has been of no avail in this case; and as the cause of wasting palsy remains a mystery, of course no rational method of cure was indicated. Unfortunately, in this instance, empiricism offers, we believe, no help to supplement the defect of science.

#### SIR CHARLES LYELL ON THE ANTIQUITY OF MAN.

THE work of the accomplished geologist, which has just appeared, has two aspects—one of fact, the other of theory. The first is most valuable, embracing as it does the whole evidence, direct and collateral, as to pre-historic man; the other affords a curious example of mutability of opinion. Sir Charles, who, in the earlier editions of his "Principles of Geology," dedicates a chapter to the refutation of Lamarck, has now become the open supporter of transmutation, and is looking forward to the "missing links," which an examination of the pliocene and post-pliocene beds of Western Equatorial Africa, and the islands of the East Indian Archipelago, may bring to light. One of the most acceptable features of his book is the very careful and full account of the geological evidence as to the antiquity of the principal discoveries both of bones and instruments. The diagrams of sections of the post-pliocene alluvium in the valley of the Somme, together with the accompanying description, carry conviction as certainly as if the reader had visited the excavations. The evidence of the disputed antiquity of the Engis cranium is, as Sir Charles states it, most forcible. Here is his description of the difficulties under which Schmerling's discovery was made:—"To have undertaken, in 1832, with a view of testing its truth, to follow the Belgian philosopher through every stage of his observations and proofs, would have been no easy task even for one well-

skilled in geology and osteology. To be let down, as Schmerling was, day after day, by a rope tied to a tree, so as to slide to the foot of the first opening of the Engis cave, where the best-preserved human skulls were found, and, after thus gaining access to the first subterranean gallery, to creep on all fours through a contracted passage leading to larger chambers, there to suppcntend by torch-light, week after week, and year after year, the workmen who were breaking through the stalagmitic crust as hard as marble, in order to remove, piece by piece, the underlying bone-breccia nearly as hard; to stand for hours with one's feet in the mud, and with water dripping from the roof on one's head, in order to mark the position and guard against the loss of each single bone of a skeleton; and at length, after finding leisure, strength, and courage for all these operations, to look forward, as the fruits of one's labour, to the publication of unwelcome intelligence, opposed to the prepossessions of the scientific as well as of the unscientific public;—when these circumstances are taken into account, we need scarcely wonder, not only that a passing traveller failed to stop and scrutinise the evidence, but that a quarter of a century should have elapsed before even the neighbouring professors of the University of Liege came forward to vindicate the truthfulness of their indefatigable and clear-sighted countryman." The anatomical characteristics of the Engis and Neanderthal crania have been furnished for Sir Charles by Professor Huxley, and the same authority is constantly quoted on the questions of the position of man and his relations to, and differences from, the other *Primates*. Sir Charles Lyell considers the remote antiquity of the Neanderthal cranium doubtful; but he is evidently disposed to allow it considerable weight as evidence of transmutation, whether it be very ancient or comparatively recent. "The direct bearing of the ape-like character of the Neanderthal skull on Lamarck's doctrine of progressive development and transmutation, or on that modification of it which has been of late so ably advocated by Mr. Darwin, consists in this, that the newly-observed deviation from a normal standard of human structure is not in a casual or random direction, but just what might have been anticipated if the laws of variation were such as the transmutationists require. For if we conceive the cranium to be very ancient, it exemplifies a less advanced stage of progressive development and improvement. If it be a comparatively modern race, owing its peculiarities of conformation to degeneracy, it is an illustration of what the botanists have called 'atavism,' or the tendency of varieties to revert to an ancestral type, which type, in proportion to its antiquity, would be of lower grade." We hope on a future occasion to furnish our readers with an extended review of this the most important, because the most comprehensive, work which has yet appeared on the "mysterious past" of humanity.

#### HEALTH OF THE ARMY AT NEW ORLEANS.

WHEN the history of the great American Civil War shall be written, sentences such as these from Surgeon Browne's Quarterly Report of the Army at New Orleans, will be quoted in explanation of the results of the war. They are found in the *American Medical Times*:

"The troops are uniformly destitute of all notion of cleanliness of body or clothing, and have never observed any condition of health in their habits. They were utterly unmindful of all care for the hygiene of the body, and *without animal spirit in anything but one notion, that of being discharged from the service*. Their subordinate officers, some of them quite illiterate and ignorant, were wholly unqualified in education or character to enforce any observance of the rules of health. Their Medical Officers were, as a rule, alike incompetent to deal with the diseases or the men—being equally defective in scientific insight and professional force of character and discretion, or wisdom. The Hospital was sought by the men as

a refuge from camp duty, even when the want of energy or a shifting pain was the only infirmity of the body."

Gangrene of the throat—not an acute inflammatory affection, but a low, insidious rotting of the tissues—has been observed:—

"It has been found in cases not under treatment, which have presented themselves complaining of sore mouth or gums. In two cases of the guard it was found to invade the line of the mucous membrane of the cheek, pressing against the teeth. Here it was accompanied with slight tumefaction of the lower part of the cheek, and soreness. The left tonsil was invaded also; surrounding the base of the teeth of this side was presented an abundant collection of epithelial and mucous matter, closely resembling the light-coloured *débris* of masticated and pulverised food. The irregularities of the grinding surface of the teeth were also covered as with plaster. The left tonsillar space was invaded, and the gland nearly destroyed. Again, it was found in the mucous membrane of the lower lip, where it adjoined the lower teeth; it was curious that the continuity of the membrane affected seemed entire until the probang saturated with nitrate of silver swept it, in doing which it all came away. The denuded surface now presented the same appearance as the others. It had previously presented a mottled bluish look. It is an example of the *fatuous* moral condition of the invalids here, that in this instance the patient would not clean his teeth and gums, though he was most imperiously enjoined to do so. For three succeeding days he presented himself, without this having been perceptibly done, but said he had done it. I was obliged myself (as it was my duty) to force him to be cleaned by my own hands. He shrank from it, and closed his mouth—a puling babe."

Speaking of the causes of disease in the soldiers, he traces them to—

"The unutterable foulness of their persons and apparel, and in the places, camp, field, or Hospitals they had previously occupied. A *nimbus* of foul, organic matter, from the skin and breathing surface of the lungs, as a focus, the exhalations of effete and desquamated organic particles from their bodies, their clothes, bedding, and personal utensils, were the conditions supposed to account for its presence. I have never known a clean invalid, in the ordinary civil sense, to enter this Hospital, nor one in whom evidences of uncleanliness were not perceptible to more than one sense. I do not here allude to 'clean dirt,' such as earth, or mud, or earth-dust, but to skins cadaverically foul with effete substance, to fetid mouths and nauseating breath, to reeking feet, to hairs and beards matted with sebaceous and sweaty excretions, and to gums whence arose a stench no putrescence could exceed, evident through the nares even when the jaws were closed."

## REVIEWS.

*A Treatise on the Continued Fevers of Great Britain.* By CHARLES MURCHISON, M.D., Fellow of the Royal College of Physicians; Senior Physician to the London Fever Hospital; Assistant-Physician and Lecturer on Pathology, Middlesex Hospital, etc., etc. London: Parker. 1862. Pp. 638. Demy 8vo, price 18s. Illustrated with Coloured Plates, Diagrams, and Wood Engravings.

*Lectures on the Distinctive Characters, Pathology, and Treatment of Continued Fevers, delivered at the Royal College of Physicians, London.* By ALEXANDER TWEEDIE, M.D., F.R.S., Fellow of the Royal College of Physicians, London; Consulting Physician to the London Fever Hospital; Physician to the Foundling Hospital, etc., etc. London: Churchill and Sons. 1862. Pp. 301. Demy 8vo, price 12s. Illustrated with Coloured Plates.

As Hospitals afford unusual opportunities and facilities for studying diseases, their Medical Officers incur a two-fold responsibility. While they owe the patients much of their time and all their skill, they likewise owe their professional brethren a share of whatever superior knowledge such exceptional advantages may have enabled them to acquire. This two-fold responsibility has ever been duly appreciated by the Medical Officers of the London Fever Hospital. In behalf of its inmates, they have lavishly expended both time and skill; they have risked, sometimes even sacrificed, their lives. In behalf of their Profession they have not failed to record from time to time the precious results of their observation and

experience of continued fevers. Our periodical literature, for the last fifteen years or so, has abounded with their contributions; but, until the present winter session, we have had no systematic account of continued fevers, such as is presented in the two volumes which head this review.

We have not space for anything like a summary of their contents. It must suffice if we lay before our readers a few of the more difficult points which they elucidate in the subject of continued fevers. Both authors, strongly advocating the non-identity of their different forms, adopt the same classification. Besides febricula (*i. e.*, simple fever depending on a non-specific cause, such as nervous exhaustion, exposure to heat, errors in diet, etc.) they recognise and describe three different kinds, viz., typhus, typhoid or enteric, and relapsing or famine fever. These three fevers they hold to be, not mere modifications of one disease, but three distinct species, in all respects as distinct from each other as are measles, scarlatina, and small-pox. In support of this view they urge the differences observable in their respective modes of origin and propagation, in their respective courses, symptoms, complications and sequelæ, and in the treatment they respectively require. The non-identity of two of them (typhus and enteric fever) is still further confirmed by well-defined differences in their respective eruptions. We are aware that many members of our Profession still hesitate to recognise the plurality of these two commonest forms of fever. To such we would strongly recommend a perusal of either of the volumes before us, or at least of so much of them as bears upon this question. If they are still open to conviction, we think they will find, especially in Dr. Murchison's work, evidence amply sufficient to satisfy their doubts. Again, both authors, taking into consideration the obvious differences in the mode of origin of the different forms of fever, hold them to be generated by different poisons. But while Dr. Murchison's researches satisfy him of the exact source of the poison in each case, Dr. Tweedie admits that for himself he is not yet in possession of sufficient data to determine this point with exactness.

Dr. Tweedie's book is a re-publication of his Lumleian lectures, delivered in 1860. He confines himself therein as much as possible to practical details, dwelling but little on obscure unsettled points in the etiology or pathology of fever. It would be unfair to disparage his work on this account; such points would not have admitted of satisfactory handling within the limits of his course. Dr. Murchison's book, on the other hand, is a professed "Treatise" on fever; and well it deserves so comprehensive a title. While eminently practical, it deals fully with all those vexed questions concerning fevers, which yearn for more exact adjustment. For instance, the causes of fevers, *i. e.*, their respective modes of origin and propagation; the extent to which these causes are under human control; the reasons of the varying prevalence of the different kinds of fever; the possibility of their co-existence with other acute, specific diseases: all these and many other kindred questions are investigated by Dr. Murchison with exhaustive, but never tedious, minuteness. We are also bound to add that there are few upon which he has failed to throw more or less light. Evidence for and against is, in all cases, impartially weighed, and, where the balance is even, he is generally ready with facts and arguments of his own sufficient to turn the scale. We would draw special attention to his views about the preventibility of fevers, and the grounds upon which these views are based. He believes the spread, and, in most cases, the origin of fevers to be due to disregard of various sanitary precautions which he fully details. He is strongly in favour of isolating the contagious fevers, and not distributing them in the wards of a General Hospital.

A point so important, and so much cleared up, as the distinctive pathology of the different forms of fever is, of course, dwelt upon at length by both writers. Dr. Murchison enters, also, into the obscurer questions of the fundamental pathology of fevers in general—*i. e.*, the causes of symptoms as well as symptoms themselves; in other words, the *modus operandi* of fever poisons. This is a question of the deepest interest; for, in proportion to the fullness and correctness of our knowledge regarding it, shall we attain to a more rational and, probably, successful treatment of fevers. It receives full attention from Dr. Murchison, and we must do him the justice to observe, that his observations and researches have advanced a deal of more or less probable conjecture, if not of legitimate conclusion, on a point hitherto involved in the greatest uncertainty. His explanation of the *cerebral symptoms* (convulsions, delirium, stupor, coma, etc.), so often super-

vening in the course of fevers, especially of typhus, seems to us to have strong clinical evidence in its favour. He argues, that these symptoms depend, not on any lesions of the brain or its membranes, nor yet primarily, or to any considerable extent, on the immediate action of the fever poison, but mainly on its secondary effects. These are:—Increased waste of tissue, non-elimination by the kidneys of the products of such waste (urea, etc.), their accumulation in the blood, circulation in the brain, and consequent perverted nutrition of the brain itself. "Hence it is," he thinks, "that the symptoms in the advanced stages of many fevers are closely assimilated, although the primary poisons have been perfectly distinct." Thus, too, he accounts for the striking resemblance between the cerebral symptoms in fevers (especially typhus) and those in uræmia from Bright's disease; the probability being, that the symptoms in both sets of cases "are due to the circulation of the same morbid materials in the blood." Why the urea is excreted in some cases and more or less retained in others, it is hard to say; but his own observation inclines him to believe that its elimination is generally prevented "by some morbid condition of the secreting tissue of the kidney, either of old standing, or consequent upon the febrile attack." He also gives some reasons for supposing that "a sudden check to the excretion of urea and of other products of tissue metamorphosis, is one cause of the development of local inflammations in the course of fever."—P. 13.

In connexion with the treatment of fevers comes the great change-of-type question. Many members of our Profession advocate the notion that, within the last thirty years or so, fevers—and, indeed, acute diseases of all kinds—have assumed a less sthenic character; that at present they neither tolerate nor require those depleting, lowering measures which were formerly employed in their treatment. Both our authors, after closely examining the grounds upon which this opinion is supposed to rest, are convinced that it has no solid foundation. The change, they urge, has taken place not in the diseases, but in our views of their nature and our estimate of the powers of remedies. In respect of fevers, the notion of a change of type has mainly arisen from non-recognition of their different forms.

The portions of the volumes before us which concern the treatment of fevers will not disappoint the expectations of the Medical Practitioner. Keeping in view the non-identity of the different forms, they consider, not merely their general therapeutics, but likewise those minor, though still essential differences which regulate the treatment of each form. Disbelievers in the plurality of continued fevers will be inclined to think that these volumes contain more refining in the matter of treatment than holds good in actual practice. Many cases of fever will, no doubt, get well with any treatment, or even with none at all; but in critical cases, when life trembles in the balance, it is often just the recognition of these points of nicety which turns the scale in the patient's favour.

Both writers, fully acknowledging the beneficial effects of alcohol, advocate a most guarded use of it in fevers, and lay down, as far as possible, rules for its administration. They insist much on a point which was urged years ago by Dr. Stokes, of Dublin, viz., that the cardiac sounds, not the radial pulse, furnish the true criterion for the administration of stimulants. Dr. Murchison, further, considers the much-controverted question, *how* alcohol acts—whether as a mere medicinal stimulant, or as food, contributing (as Todd held) to the nutrition of nerve-tissue and maintenance of animal heat. "After a careful study of all that has been written on the subject, and observations of many hundreds of cases," he is led, briefly, to the following conclusions:—That alcohol may help to support combustion and animal heat, and perhaps check destructive waste of tissue; that beyond this its action is purely that of a medicine, its effect being to stimulate the nervous and vascular systems; that as such it is invaluable, but it can never prevent emaciation and failure of strength. Plastic food alone will do this.—Pp. 257-259.

Dr. Murchison's view of the causes of certain symptoms in fevers suggests a modification of the old routine, according to which these symptoms are usually treated. We allude to the cerebral symptoms (stupor, delirium, etc.) which so commonly arise in the progress of fevers, especially of typhus, and are usually treated by stimulants, sedatives, and derivatives. If, as seems highly probable, these symptoms are generally due to uræmic poison, then our main object should be, while supporting the patient's strength, to neutralise the

effects of this poison, and promote its elimination by the kidneys, skin, and (where there is no intestinal complication) by the bowels also. The best means of accomplishing each of these objects will be found under the head of "Treatment" (p. 265 and 570). He dwells much on the importance of maintaining the action of the kidneys. The supervention of head symptoms should at once lead to examination of the urine; and if it give evidence of obstructed renal excretion—such as diminution of urea, presence of blood, albumen, etc.—prompt measures (p. 279) should be adopted to remedy the cause of the obstruction, which will, probably, be either congestion of the kidneys, or old-standing organic disease. In typhus he has found renal mischief, either antecedent to or consequent on the fever, to be one of its commonest and, likewise, most fatal complications.

Dr. Murchison's is a work which will stand, and stand high on its own merits. It is independent of the critic's praise. We venture to predict that for very many years to come it will be the standard authority on every question connected with fevers, and the fountain-head from which succeeding writers on that subject will draw largely for their materials. In clearness of arrangement, in the multiplied conveniences it affords for reference, his book is a model. It has a complete index. It teems with references to the present and past fever literature of all countries. In order not to encumber the text, these references are thrown into foot notes, and, to save repetition, are restricted to the author's name, with the date and page of his work. The full title of each work is given in a bibliography, which brings together in chronological order all the more important contributions to fever literature from A.D. 1500 down to the present time.

Dr. Tweedie's work has much solid merit to recommend it, embodying, as it does, the results of a life's observation and experience of fevers. But its usefulness is most seriously crippled by the literary trim in which it comes before the Profession. Its author should have remembered that Medical books are used infinitely more for casual reference than for continuous reading. The busy Practitioner who wants to get at Dr. Tweedie's views on any given point will rarely have patience to rummage them out from the chaos of matter in which they lie buried. His book has no index, no table of contents, no running titles at the page-heads, and nothing worthy of the name of preface. The only sign-posts to direct the inquirer where to find what he wants are certain epitomes at the commencement of the different lectures; but these, again, are too vague and incomplete to be of much service. For instance, the epitome at p. 97 wholly ignores two very important sections of the lecture it is supposed to summarise, viz., the sections treating of the lesions of the organs of respiration and circulation. These defects simply do injustice to himself; they do not give a good book a fair chance. There are, however, further defects, and these do injustice to others. To wit, he rarely gives references to the works of those whom he has occasion to cite. Here and there he transcribes whole sentences from an author without acknowledging the same in inverted commas, and so leaves the reader in uncertainty as to whose the words are. A comparison of pp. 107-110 of Dr. Tweedie's work with Rokitansky's "Pathological Anatomy," vol. ii., pp. 68-73 (Old Syd. Soc. Transl.), will afford an instance in point. It is the same absence of full, free, and precise acknowledgment of borrowed language which has lately involved him in a misunderstanding with Dr. Murchison. That such absence of acknowledgment is to be regretted, we readily admit; that it was intentional, we will never believe. The explanation of the whole thing lies in the palpably careless manner in which Dr. Tweedie has allowed his lectures to appear in print. No charge more serious can fairly be brought against him than inadvertent omission, or than a misapprehension of the extent to which he was at liberty to avail himself of Dr. Murchison's labours. The fact, that a portion of Dr. Murchison's work, quoted by Dr. Tweedie, was ascribed by a Cork Physician to Dr. Tweedie himself, is a significant proof that a careless reader might not see to whom the passage really belonged, though a careful reader would not have made the mistake. We only wonder that Dr. Murchison did not feel himself too strong to mind such a trifle.

W. COULSON, Esq., has been appointed Sheriff of Cornwall for the ensuing year. We are always glad to hear of Medical men taking a high social position. It helps to raise the general estimation of our body.

## PROGRESS OF MEDICAL SCIENCE.

## Selections from Foreign Journals.

## CASE OF EMBOLISM.

AN interesting case of embolia of the infundibulum of the right ventricle and pulmonary artery communicated to the Société Anatomique, of Paris, by M. Gouraud, has been made the subject of a report by M. Lancereaux. The following is M. Gouraud's *résumé*:—"A healthy woman, aged 46 years, entered La Charité, for a fracture of the right leg, accompanied by considerable extravasation of blood. Scutter's apparatus was applied, and all went on well, the size of the limb lessening. After three weeks the apparatus was replaced by a starch bandage. On the following morning the patient was quite well, but, some hours later, violent palpitations of the heart occurred, the patient cried out, became livid, and was dead in a few minutes. On post-mortem examination, the right tibia presented two solutions of continuity, the fibula being fractured in only one place; there was an extravasation of blood infiltrating the whole thickness of the soft parts in this region. The veins of the right leg presented small coagula, which became more distinct and large in the femoral vein, the external and common iliac, and even in the lower part of the vena cava. The fibrinous coagulum was firm, elastic, of a deep red or rose colour, and was adherent at several points to the internal surface of the vessel. On the left side the limb and veins were healthy. From the lower part of the vena cava to the heart the blood was liquid. There existed in the infundibulum of the right ventricle and in the pulmonary artery a clot drawn out into the form of a leech, thirty-six centimetres in length, of a diameter much less than the vessel where it was found, of a rose or deep red colour, and not homogeneous. The lungs were engorged, but crepitant." M. Gouraud explains the obliteration of the passage by the arrest of the long clot, on arriving at a branch of the pulmonary artery, such as would not allow it to proceed further, and then by the ventricular contractions causing the other extremity to be folded back in the infundibulum, so as to lie opposite the sigmoid valves. It is necessary that we should abridge considerably M. Lancereaux's observations. The first question to which he applies himself is the cause of the coagulation which took place in the veins. He explains it thus:—"The blood coagulated at the seat of the fracture necessarily compressed the mouths of the ruptured vessels; but, at the same time, coagula would form at the extremities of these vessels, and mount up, as is the rule for them to do, as high as the nearest valves. From the withdrawal of the *vis a tergo*, there would be stasis of the blood proceeding from the collateral veins, a new coagulum, commencing this time at the valves, and these latter coagula would lengthen gradually, and become, in their turn, the cause of new coagula, until the principal venous trunk becomes completely obstructed. In this view the cause is a local one, namely, the diminution of the current of blood, and the influence exercised by the fibrinous clot upon the blood which surrounds it. Admitting the sufficiency of this cause to produce venous coagulation, other causes may be added, such as diminution or loss of contractile power in the veins, tumours compressing them, and whatever retards the venous circulation. General causes would also operate, on the one hand, by lowering the force of the heart and the contractility of the vessels, and, on the other, by causing modifications in the blood itself such as are even now little understood. It is important to point out that, under the influence even of general causes, it is always where the circulation tends to be slow that coagulation commences.

The clot, which begins to be formed at the situation of a valve, presents a form and characters which must first be treated of. At one extremity it presents the mould of one or two of the valves; its other end is rounded or conical, and upon its length may be perceived the smooth and clean impressions of valves. One of its surfaces, that in contact with the wall, is slightly striated, yellowish or marbled; the other surface, free and bathed in the blood, is brownish and granular. The length varies from some millimètres to several centimètres; its bulk may become considerable, since it generally forms in the largest vessels, and is thus the most frequent cause of sudden deaths. Besides, by reason of its characters, it constitutes the

most positive evidence of embolia of the pulmonary artery when it is met with in this entirely valveless vessel. Observation teaches us that, where there is but one clot, and the death has been sudden, it is always the trunk of the pulmonary artery or the infundibulum which is found obstructed. The blood in the heart is ordinarily black and fluid, as in death by asphyxia. I do not, for my own part, think that a single embolus, arrested in one of the divisions of the artery, can bring about this fatal accident. For the most part the embolic clots are multiple, and always, I say again, if death has been rapid, they are found either in the trunk of the pulmonary artery or in its principal branches. As respects the smallest clots, they are rarely found in divisions of the fifth order, but mostly in those of the third or fourth. In some special cases known as capillary emboli, very small clots have been found in the smallest branches. The form of the migratory clots is generally cylindrical, their extremities at one time regular, smooth, and conical; at another, rough and torn; at another, only one end is torn, while the other is polished and conical. It is in cases where both extremities are smooth and untorn that valvular impressions are found upon the body of the clot, and one or two moulds of valves at one extremity. The clots which are torn at their extremities are generally devoid of impression and moulds, but they are now and then channelled. When one extremity only is torn, the other is generally conical. The same difference which we have established in the characters of venous clots is, consequently, found in the clots of the pulmonary artery; and there exists between the venous coagula and those of the pulmonary artery such a resemblance, that we are compelled to admit that the clots have been transported from the veins into this artery.

Besides these characters, embolic clots differ from coagula formed just prior to or immediately after death in their elasticity, brownish or marbled colour, and the condition of the fibrin which is always in progress of retrogression. The clots formed at death are soft, œdematous, flattened, branched, and only close incompletely the containing vessel. The clots which, during life, form primarily in the branches of the pulmonary artery (autochthones), differ from emboli in their form and seat, and in the absence of the characters which have been described. In certain circumstances, however, they are readily confounded with embolic clots, namely, where fibrinous coagula have become added to the latter, but it is always easy, by means of a section and examination with the microscope, to recognise the central embolus. If the bulk of embolic clots is very variable, their length especially presents great variety: thus, whilst some may only measure a few millimètres, others are several centimètres in length; such as I have seen produce sudden death, have been five centimètres long; that which M. Gouraud has described in his observation presented the extraordinary length of thirty-six centimètres. I am disposed to believe that some error has slipped into this measurement, especially seeing that the femoral and part of the iliac veins were filled with a fibrinous coagulum. Under these circumstances it is necessary to suppose that the embolic clot occupied primarily the greater extent of the vena cava, a hypothesis of little probability, since no symptom of such an obstruction was apparent during life. I am, consequently, driven to believe that some secondary coagulations have been comprised in the measurement. But be this as it may, it is certain that very long clots may be carried by the torrent of the circulation, and an important and peculiar character of them is, that they are curved and wound round, at one time in the trunk of the pulmonary artery, and in the infundibulum, as in M. Gouraud's case—at another, in one of the principal divisions of the pulmonary artery. But after a certain lapse of time these distinctive characters become wanting, and it is then very difficult to tell whether a coagulum, met with in the pulmonary artery, has been formed there, or has arrived there by migration. The only circumstance which we may thus be able to call up in favour of embolus, is the existence of a venous thrombus. The phenomenon which renders the embolus unrecognisable is important and really remarkable. The continued contact of the clot with the arterial wall determines a slight irritation, in virtue of which a blastema, exuded between the wall of the vessel, and the clot, soon becomes organised; by degrees, this substance extends on the circumference of the plug, and soon forms a sort of cupule, in which the latter is contained. At last it envelopes it completely, and encysts it, so that, after a time, often not very long, the fibrinous

coagulum of the pulmonary artery is found to be everywhere surrounded by a perfectly organised membrane. Within this membrane, microscopic examination discovers an amorphous substance, more or less granular, embryo-plastic nuclei, elongated cells, and, above all, fibres of connective tissue. In the midst of these elements we sometimes find capillaries, free granules, the *débris* of red globules, and amorphous and crystalline hæmatin. After describing further changes in the condition of these encysted clots, M. Lancereaux proceeds to the subject of the condition of the lungs in cases of pulmonary embolia. It is evident (he continues) that an embolus which closes up the trunk of the pulmonary artery, and gives rise to sudden death, cannot cause any important disorder in the pulmonary parenchyma. Supposing such alteration possible, time would be wanting. But it is different when a coagulum comes to be situated in an important division of the artery, closing its canal completely. In this respect, M. Lancereaux expresses his agreement with Virchow, who states that, however complete the obstruction, it produces no alteration in the parenchyma, and, above all, no gangrene of the lungs. At the most, Lancereaux has observed slight diminution of volume, anæmia, or some œdema; and he explains this, physiologically, by the fact, that the pulmonary artery is an organ engaged in hæmatosis, and that the nutrition of the lung is effected, not by this, but by the bronchial arteries. Still (he proceeds to say) pulmonary coagula are sometimes accompanied by a lesion of the parenchyma of the lungs, whether they be the cause of it or not. Pulmonary apoplexy is frequently conjoined with obstruction of the branches of the artery; but it is to be remembered, that this generally occurs in the course of affections of the heart, especially in fatty degeneration; and it is also to be observed, that, under these circumstances, the clot is always situated behind the apoplectic spot, has none of the characters of an embolic clot, and is evidently autochthonic—not the cause, but an effect, of the apoplexy. The same thing may happen in certain cases of tubercular disease, of pneumonia, or even of gangrene. It is, however, important to notice, that there are certain special conditions of the embolic clot which are capable of giving rise to two of the alterations just alluded to—namely, pneumonia and gangrene. These conditions pertain to a special state of alteration of the tissues, in the midst of which the thrombus has been formed: if the coagulation has taken place in the midst of a purulent or gangrenous focus, the coagulum, formed in part of fibrin, and in part of other elements, possesses qualities in virtue of which it may alter the tissues with which it subsequently comes in contact; thus it is that metastatic abscesses often appear in the lungs of individuals, with suppurative thrombus of the cerebral sinuses, and in women suffering from metritis or suppurative phlebitis. Thus, too, gangrenous spots in the brain are found in persons who have primarily a gangrene of the lung; and gangrene of the lungs is met with frequently in paralytic individuals, in whom a sphacelus has formed over the region of the sacrum. Particles of fibrin or fragments of tissue, impregnated with pus or septic matters, become the points of origin of secondary foci, purulent or gangrenous, as the case may be.

Certain practical conclusions flowing from this fact related by M. Gouraud deserve attention. We find here a condition which has already been mentioned in other cases, one of which is related by Klinger. In three different cases sudden death has followed shortly upon compression exercised by a bandage upon the limb, which is the subject of the thrombus. It was, as we know, formerly customary to apply a compressing bandage upon a limb affected with œdema, or even with phlebitis, as soon as the acute stage of the inflammation had ceased. The practice is far from being free from danger, and it must necessarily be proscribed. But, besides, when, consecutively to a traumatic condition, fracture, amputation, etc., we have reason to suspect the existence of a venous thrombus, it will surely be prudent in the Surgeon to abstain as much as possible from strong compression, if he would not expose his patient to more or less serious accidents. It is especially some time after the commencement of the coagulation, when the fibrin begins to disintegrate, that we must avoid this practice. And, for the same reason, every kind of handling of the injured limb should be avoided, and the most complete state of rest maintained. Indeed, in a certain number of cases, a slightly exaggerated effort, as I have seen on two different occasions, may suffice to bring about the separation of the clot, and sudden death. Occa-

sional causes of this kind are marked, in the greater number of cases of sudden death, by embolia, and it is thus pointed out how necessary it is to be cautious when we have to do with patients suffering from venous thrombus.

## FOREIGN CORRESPONDENCE.

### FRANCE.

PARIS, January 13.

#### ON THE DISEASES PRODUCED BY UNWHOLESOME DRINKING-WATER.

M. BOUCHARDAT's communications to the Academy on the above subject have now come to a close, and I shall give you to-day the more salient facts and conclusions at which this distinguished and persevering observer has arrived. Endemic cretinism is principally due to two causes acting simultaneously, viz., the connexion of cretinism with endemic bronchocele and consanguinity of marriages. In all localities where endemic cretinism has been observed, endemic bronchocele is, likewise, met with; thus, in the Himalaya mountains, in the Andes, the Pyrenees, and the Alps,—in these parts people affected with goitre have cretinous children, and the progeny of these latter are cretins. The intermediate degree of "cretinous" may be wanting, but only in exceptional cases. In order that endemic bronchocele may be developed, a few years' nay, even a few months' use of bad drinking-water may suffice, but that cretins may be produced, it is necessary that insalubrious conditions should extend over several generations. Amongst these influences marriages of consanguinity between people who have been subject to the action of bad drinking-water are the most powerful. This hypothesis explains the considerable influence exercised by the configuration of the soil. We observe cretins in closed valleys, which have little communication with the world without: the inhabitants of such localities intermarry; and even if all the marriages should not be decidedly consanguineous, they, nevertheless, take place most frequently amongst people who have been subject to the same influences. For such degenerate races consanguinity is full of danger. M. Bouchardat was formerly of opinion that consanguinity was not noxious to persons otherwise well developed; and believed that, although certain inconveniences might be connected with it, these were compensated by the increase of beauty and purity of race. This opinion was founded on certain facts in zoology, and on the circumstance that, in ancient Greece, the most perfect types of humanity had, under the influence of consanguineous alliances, become rather improved than deteriorated. His convictions, however, have been shaken by M. Boudin's researches on the influence of such marriages in producing deaf-and-dumbness; and he will, probably, give up this idea altogether if he should become acquainted with M. Liebreich's investigations on "retinitis pigmentosa," as caused by the same influence, and which seem to have hitherto escaped M. Bouchardat's attention.

In order to prevent cretinism, public and private hygienic measures should be taken. As regards the individuals affected, they should be removed from the localities where endemic goitre and cretinism are found to exist, and transferred to a moral, intelligent, and humane household, where they should be under continued *surveillance*. They ought not to be left to a degrading inaction, but those faculties which are given them should be brought into play. With respect to public hygiene, we must keep in mind the fact, that cretinism has been diminished, or even altogether disappeared, as soon as a broad high road has intersected the places in question, and they have been animated by commerce. They should, therefore, be cut through, not by railways, but by roads, leading a healthy population into the localities, and thereby diminishing the chance of marriages of consanguinity. The church should only give licences for such marriages with the very greatest caution. Gin-shops should be placed under strict *surveillance*; and all should be rigorously punished who would sell alcoholic liquors to children, or to beings devoid of reason.

In France, and on the Continent generally, persons affected with goitre, and having a disposition to cretinism, are exempt from military service; but M. Bouchardat is inclined to think that, by recruiting amongst such persons for the army, we

should render them the most essential services. The change of place, the attention that would be given them by the army Surgeons, etc., would soon free them from their infirmity; while military discipline would raise the level of their intelligence, and, in subjecting them to the "reign of rule," would make useful men of them. Another consideration here would be, the amelioration of race. If bronchocele is the first step leading to cretinism, it is obvious that, if the *élite* of the population is taken away by conscription, persons with bronchocele, who are exempt, will, as it were, monopolise the country, and condense the focus of the evil. Thus conscription, which for these localities might be a condition of progress, if it removed those affected in order to bring them back cured, becomes, on the contrary, one of the most active causes of degeneration. Persons of the kind mentioned might do good duty in military infirmaries and other branches of the army and navy. If transferred to this latter, the mere circumstance of living in a port or on the sea would effect a speedy and definite cure. The last word of advice, however, to the authorities is—give these localities wholesome water. Everywhere you may collect rain-water in sufficient quantity for the wants of man. Distribute, moreover, to the populations of such districts salines, with a small proportion of iodine, so that each person may take a few milligrammes of iodine every day, proper medical attention being at the same time necessary. Drinking-water, the continued use of which causes the formation of endemic goitre and cretinism, contains organic substances in solution which come from the decomposition of certain vegetable parts in dolomitic soil. Such water generally comes from ponds, marshes, fens, and swamps, and should never be taken unless previously filtered or boiled.

The "bouton" of Aleppo, and the "bouton" of Biskra, two endemic diseases of the skin which are still enveloped in much obscurity, are in all probability produced by the use of unwholesome drinking-water. All those who drink of the water of Coïck for a certain time become affected with the "bouton" of Aleppo, while those who do not partake of it are spared. The country people who come to the town of Aleppo and drink of the bad water soon begin to suffer; while those peasants who stop at home remain free. The water of Coïck is slightly alkaline, and contains the salines usually found in drinking-water, as well as organic matter, which latter is no doubt the cause of the evil. The "bouton" of Biskra, which very much resembles that of Aleppo, is to be ascribed to the use of the water of a torrent coming from a plain where the remains of more than a hundred thousand palm-trees are accumulated. It is highly probable that the organic substances coming from the decomposition of these remains, under the influence of salines in solution, impart this remarkable property to the water.

The following are the chief hygienic characters of the different species of drinking-water:—

1. *Spring-water* has the advantage of being generally limpid, so that there is no occasion for filtration, and of being fresh and agreeable to drink; springs come, moreover, frequently from a higher elevation than the towns where they are used, so that we do not want mechanical contrivances for raising the water. Spring-water is mostly richer in salines than river-water. If it is pleasant to drink, and if the fixed constituents consist of bicarbonate of lime without organic matters, and with oxygen, the water is extremely salubrious; but if it contains organic substances, if it comes from marshy soil, and is devoid of oxygen, it must be looked upon with distrust, in spite of the good appearance it may present. Water of this kind should only be used, if the experience of several generations has fully proved its innocuity. This is of much more importance than any chemical analysis, however well made.

2. *Water of rivers and rivulets* is generally wholesome, but its composition may slightly vary according to high or low-water, and this is not the smallest disadvantage it offers. It requires to be filtered, and in summer to be cooled; and the poor man has no filter for purifying, and no cellar for cooling the water.

3. *Water of canals* usually contains more fixed constituents than river-water, and also organic matter.

4. *Water of wells* in old towns is almost always saturated with sulphate of lime; it contains, moreover, the last products of decomposition of organic substances, amongst which we find nitrates and compounds of ammonia, which arise from putrid fermentation of bodies interred in cemeteries, and other impurities.

5. *Water of cisterns*, accumulated by rain, is generally pure, unless collected from roofs soiled by dust or soot. This water is almost too pure, and the absence of lime is prejudicial in certain conditions, as, for instance, for wet-nurses, young children, etc. This water should, therefore, be filled up. Rain-water combines with lead, and we should, on no account, collect it in cisterns of lead, or raise it by pumps in the construction of which lead has been employed.

6. *Water of marshes, ponds, swamps, fens, etc.*, is generally bad, because it contains a considerable proportion of organic substances in suspension and solution. If one is obliged to drink water of this kind, it is preferable to choose such only as has undergone the influence of the sun, and which contains red or green monads. If possible, it should be filtered through carbon, and only be employed after having been boiled. As boiled water, by itself, is unpleasant to drink, tea or coffee should be added, or, if these substances cannot be procured, roots of the strawberry plant, leaves of holly, oak, soap-wort, sage, mint, thyme, etc.

## GENERAL CORRESPONDENCE.

### ACUPRESSURE.

LETTER FROM MR. A. M. EDWARDS.

[To the Editor of the Medical Times and Gazette.]

SIR,—As acupressure has been again brought before the notice of the Profession, I may be allowed to contribute some further evidence on the subject. But I would preface my remarks by an expression of my attachment to the ligature. Surely, a practical Surgeon may test the worth of any addition to Surgical appliances without any disparagement of those already established, though this may be thought presumptuous, as opposition to innovations appears to be often mere obedience to an universal law.

Those who first made coffee in London were prosecuted for annoying the neighbours "with evil smells;" it was described as "syrop of soot and essence of old shoes;" and Patin called tea "l'impertinente nouveauté du siècle." Numberless instances of this curious trait in human nature must occur to every one. In the present case it would have been more satisfactory had some of those Surgeons who have discussed acupressure taken some pains to test its value rather than rise self-elected champions of the ligature, which was quite independent of their support. Being curious in the matter I have tried acupressure very frequently; and to secure myself against misunderstanding the published directions, I requested Professor Simpson and Dr. Alexander Simpson to apply it in several cases.

The long pins which were used at first, passed from without, did their work so far that they arrested the bleeding, but they had several drawbacks. They left suppurating tracks on some occasions, perhaps from being left in too long; they were unwieldy; their length and rigidity interfered with the dressings in unaccustomed hands; they seemed also liable to shift, but for all that they stopped the bleeding from arteries, and could be removed at pleasure. In one case, that of an old man, I tried in vain to arrest bleeding from the superficial femoral after amputation, and being unwilling to run any risk I applied a ligature: this was probably rather owing to want of skill on my part, than inefficiency of the instrument.

Soon after this, Professor Simpson substituted sewing needles for the long pins, threading them with wire, and applying them on the raw surface of the wound. He thus arrested the bleeding in a case where I removed a man's arm above its middle third, and after a similar operation on an infant. The adult stump healed by first intention entirely; the other almost entirely. I applied sewing needles in three amputations through the leg, four excisions of mammae, one case of Pirogoff's amputation at the ankle-joint, and in an excision of the knee where the parts were more vascular than usual. I have used them in several other cases—for instance, on one occasion, when I was removing, unassisted, a glandular tumour from under the lower jaw, and as the patient was tossing his head about, I cut the facial artery, also in several tumours and smaller cases. However, I still very frequently use the ligature, perhaps oftener than the needles. One of the breast cases in which I used the latter, a stout, elderly woman from the Highlands, died of rapid effusion into the chest when apparently convalescent. A very similar case

died the same week, and her arteries had been tied. Since Dr. Simpson has further modified the method of application by adding a wire-loop to the needle, the latter can be adjusted with very great ease and rapidity. I would thus contrast the advantages and disadvantages:

- |   |                                     |
|---|-------------------------------------|
| 1. Metallic.  | 1. Rigid.                           |
| 2. Moderate compression on vessels.   | 2. Sometimes difficult to apply.    |
| 3. Inflict no new injury to arterial tunics, and leave the cut end of the vessel undisturbed to the natural hæmodynamic processes.                                | 3. Inapplicable in some situations. |
| 4. Prevent flow of blood efficiently, and may be applied in any number, and to the most insignificant arteries, as they can be removed at the Surgeon's pleasure. |                                     |
| 5. Unless left in for a long time they set up no morbid processes.  |                                     |

As to the other advantages theoretically claimed for acupressure over ligature, it seems to me we have not yet sufficient evidence: such must come from Hospitals. And one cannot help being struck by the significant fact, that our great Hospital Surgeons, who have for many years been engaged in operating—in weighing the relative value of Surgical proceedings, and have always shown themselves anxious to seize upon any real improvement, have not expressed themselves as yet in favour of acupressure. However, that is no reason why private Practitioners should not, with all due deference, bring forward what evidence their more limited opportunities enable them to obtain.

Edinburgh, February 5.

I am, &c.

A. M. EDWARDS.

## REPORTS OF SOCIETIES.

### THE PATHOLOGICAL SOCIETY.

TUESDAY, JANUARY 20.

Mr. PRESCOTT HEWETT, President, in the Chair.

THE PRESIDENT, in taking the chair, for the first time after his election, expressed his heartfelt thanks to the Society for the honour they had conferred upon him. It was, however (he said) an honour due mainly to the fact that he had been one of the first half-dozen who, some years ago, met to consider how they might best further the cultivation of Pathology. It was to the part he took in laying the foundation of this Society, that he owed his election. At that time, there were (he continued) great difficulties in the way, and they were nearly shipwrecked; but, thanks to the great exertions of the members, they weathered the storm. Year by year the Society had progressed, and had now attained a position second to that of no other society in London. The volumes of *Transactions* were highly considered, not only in England, but abroad. Yet, although they contained so great an amount of information, that information, to working men, was not available for want of an index. He (Mr. Hewett) had felt this want, and hoped soon to see it supplied. It was believed (he said) that a good index could be supplied without trenching on the funds of the Society. He felt confident that it would be undertaken by one well capable of executing it, and that as good an index would be published as any working man could wish for. In concluding his address, Mr. Hewett said that he should endeavour in every way to further the interests of the Society.

Mr. HULME showed a specimen of

#### BLACK CATARACT.

It was removed by operation from the eye of an old woman. Its colour was due, probably (Mr. Hulme said) to the pigment of the blood, and it doubtless contained iron.

Mr. POLLOCK asked if there were any marked symptoms, *i.e.*, if Mr. Hulme had been able to diagnose the exact nature of the cataract, by ordinary examination, before operation? He had seen a case, under the care of Mr. Dalrymple, in which that gentleman was led to operate, without being able to diagnose cataract by ocular examination. He depressed it,

as the operation of extraction was inadmissible, because the patient had paralysis agitans. Some years after, he (Mr. Pollock) was sent for to see the patient, and found that the cataract had escaped into the anterior chamber.

Mr. HULME said that he had not been able to diagnose the nature of the cataract before operation.

Dr. OGLE showed a series of eight preparations of

#### FIBRINOUS COAGULA IN THE HEART,

illustrating the spontaneous formation of fibrinous coagula, at a long period before death, in the cavities of the heart, most of which had undergone considerable softening, and some of which were quite fluid in their centre. In several of these specimens the *central puriform fluid* was limited by a firm, smoothish surface, reminding one of the wall of an abscess, and it welled out on section of the coagulum being made. The firm character of these coagula, their colour, their adherence to the wall of the heart, and the various changes which had occurred within them, proved, conclusively, that their formation had taken place some time previously to death. Out of the eight cases, this old-standing and degenerating coagulum was found in the *right auricle* in five cases; in the *right ventricle* in three cases; in the *left ventricle* in one case only. In almost all cases, the diseases under which the patients laboured had involved much retardation of the blood's circulation through the lungs, and for the most part death had been lingering, the patients being also chiefly subjects of intemperance and previous ill-health. In addition to the interest connected with the formation of fibrinous coagulum previous to death, within the heart's cavities, Dr. Ogle suggested that these specimens raised the question as to what would be the probable effects of a rupture of them during life, and the escape of the contained puriform fluid, and its admixture with the general stream of the blood. Would they not, most likely, be more or less those which are associated with pyæmia? May it not frequently have happened before now that such anomalous symptoms may have been due to an escape from the middle of coagula of the puriform fluid? Would not experiment in this direction render the question capable of solution?

Dr. OGLE also showed a case of

#### EMBOLISM OF BOTH MIDDLE CEREBRAL ARTERIES, WITH SOFTENING OF THE BRAIN, IN CONNEXION WITH FIBRINOUS DEPOSITS ON THE SURFACE OF THE LEFT AURICLE, FOLLOWING RHEUMATIC FEVER AND SCARLET FEVER.

The patient was a young woman who died shortly after an attack of hemiplegia had occurred. Some years previously she had had rheumatic fever, which was followed by symptoms which were in all probability those of cardiac mischief; and also, shortly after that, scarlet fever, which was followed by dropsy. After death there was also found slight ulceration of the lining of the left auricle, with bony deposit around, and also masses of fibrinous deposit within the substance of the kidney.

Dr. OGLE also mentioned an interesting case, of which there was a specimen in the museum of St. George's Hospital, showing, without much doubt, the occurrence of embolism in a case which was recorded by Mr. Cæsar Hawkins, in the year 1829. The case was that of a woman, aged 56, who was thought to have been hysterical for some time. Only a few days before death she had complained of great pain at the region of her heart, which was followed by œdema and gangrene of the lower limbs. On post-mortem examination, fibrinous masses, some of which were undergoing softening, were found between the columnæ carneæ of the right ventricle, and a few of the same nature also adherent to the inner surface of the left ventricle. But, in addition, one of the coronary arteries was found plugged up with a coagulum of fibrin, and the carotid artery within the cranium, on the left of the sella turcica, was also found to contain a quantity of fibrin, coagulum, and clotted blood, apparently of long standing. This case was of much interest, as showing the co-existence of fibrinous plugging of the coronary and carotid arteries, with fibrinous deposition on the surface of the endocardium, at a time when the doctrine of embolism did not exist to give any rational explanation of such a coincidence.

Dr. CRISP exhibited the following series of

#### SPECIMENS FROM THE LOWER ANIMALS.

1. A nodulated bony concretion taken from the stifle joint (knee) of a horse: it weighed 318 grains, measured  $2\frac{1}{2}$  inches in length, and  $1\frac{1}{2}$  in breadth. The animal, when six months of age, was injured by slipping down when playing with

another colt, and was lame from this period; but it continued to plough and do slow agricultural work for six or seven years, when it was killed. The concretion was found in the cavity of the joint. Dr. Crisp thought it probable that a portion of cartilage was partly detached by the injury—that ossific matter was gradually deposited, the substance afterwards becoming free.

2. The crop of a turkey, enormously distended from an accumulation of dry, tough grass, which the bird was unable to get rid of. The contents of the crop weighed twenty ounces, and the cavity held fifty ounces of fluid. The bird was very thin, but in other respects all the organs of the body were in a normal condition. The muscular parietes of the crop were much thickened. Dr. Crisp said that the contents of the crop might have been readily removed by incision during life. Some years since he saw a number of hens that were poisoned by arsenic; one only was alive, but she was unable to stand, in consequence of the distension of the crop from barley. He made a large incision, removed the contents, washed out the crop, and sewed up the wound; the hen ate directly, and quickly recovered.

3. The tuberculated spleens of two pigs. The tubercles varied in size from that of a hazelnut to that of a walnut. The lungs and liver were also diseased, but the animals, notwithstanding, were in a tolerable condition, and were killed for food. The tubercular matter formed the greater part of the bulk of the spleen. The person who slaughtered the pigs, and who had killed many hundred pigs during eighteen years, had only met with three similar instances.

4. Fungoid disease from the orbit of a sheep, which weighed about two ounces, and projected two inches from the orbit. It had much the appearance of the same lesion in the human subject. The disease was of rapid growth, and commenced four months before the animal was killed.

5. A large oblong scrofulous gland of an ox, situated at the bifurcation of the trachea. It weighed about seventeen ounces, and so pressed upon the air tube as to occasion approaching suffocation. This was always relieved by introducing a hollow probang into the stomach and evacuating the gas.

6. A large cyst (*echinococcus*) from the abdomen of *Ælian's* wart hog (*P. Æliani*). The cyst held five pints of fluid, and was in a state of chalky degeneration. Also three small *echinococi* from the peritoneal coat of the Java masked hog (*Sus pliciceps*). Dr. Crisp said that he had found these parasites in all the foreign hogs that he had examined, including the other species of wart hog (*P. Æthiopicus*), the Red River hog (*P. penicillatus*), and the African and European wild hogs.

7 and 8. Pericarditis in a young emu, the pericardium being covered with recently formed lymph. The liver of a Stanley crane (*A. paradisea*), in which the hard, semi-cartilaginous tubercles formed nineteen-twentieths of the bulk of the organ. Dr. Crisp believed that one form of tubercle in some quadrupeds and in many birds was of parasitic origin.

Mr. HILTON, in reference to the specimen of bony mass in the knee, said that it would be interesting to ascertain if any part of the articular cartilage were wanting. If so, it would help to sustain the opinion, that "loose cartilages" are pieces struck off.

In reply, Dr. CRISP said that he had had no opportunity of examining the joint.

Mr. NUNN showed a specimen of

#### TUMOUR OF THE UTERUS.

The specimen was, so far as the Society was concerned, unique. During life the tumour filled the abdomen, and it was supposed to have been ovarian disease, and an operation for its removal was attempted by Mr. Baker Brown. A large cyst was discovered and emptied. The patient did well, but at the end of three weeks the wound re-opened, and a large quantity of fluid escaped. She still went on well for a short time, but soon suffered from vomiting, dyspnoea, etc., and died twenty-six days after the operation. The uterus was much elongated, and at its upper part were several large cysts, one of which was strangulated in the umbilicus, so that it was impossible to remove it without dividing the ring. There were several cysts adherent to the pelvis, but not firmly. The whole of the omentum was adherent to the tumour.

In reply to Dr. Bristowe, Mr. Nunn said that there were no other growths in the body.

Dr. BRISTOWE said that the specimen was very like malignant disease of the peritoneum in its general appearance.

Mr. Nunn and Mr. Holmes were requested to make a further examination of the specimen, and to report on it to the Society.

The PRESIDENT said that he had seen a similar case when he was curator of St. George's Hospital Museum. Sir Benjamin Brodie sent him a tub, labelled "Extensive disease of the ovary on the left side." It turned out, however, that the ovaries were healthy. The mass, which weighed 54 lb., was a fibro-cellular tumour, and was attached to the uterus by a pedicle. In St. George's Hospital Museum there was also a similar specimen. In this case, too, during life the diagnosis was that of ovarian disease. It was tapped, and four pints of fluid were drawn off. It was found at the autopsy to be a fibro-cystic tumour of the uterus.

Mr. HOLMES exhibited for Dr. Carter, of Bombay,

#### PARTS OF THE MEDIAN AND ULNAR NERVES FROM A CASE OF ANÆSTHETIC LEPROSY.

An account of Dr. Carter's examination of the nerves in this case will be found in this Journal, April 19, 1862. Dr. Carter adds now that he finds on some occasions that the fluid is characterised by the presence of numerous delicate corpuscles, not larger than the  $\frac{1}{4000}$ th to  $\frac{1}{5000}$ th of an inch in diameter, which takes the place of the granular masses and nuclei described in his previous communication.

Mr. HOLMES also exhibited a specimen of

#### ACUTE NECROSIS OF THE TIBIA.

The patient was a male child under his care in the Children's Hospital. The disease began fourteen days before admission. The whole of the tibia was exposed. As the child was suffering greatly in health, Mr. Holmes removed the limb. He amputated at the knee-joint in order to avoid exposing a cut surface of bone. The patient was rapidly recovering, when, three weeks later, bronchitis, passing into pneumonia, set in, and death followed. Tubercle was found in the lungs. The specimen showed that the amount of periosteum removed corresponded to the new bone. Mr. Holmes also brought the stump in order to show that, in this case, after amputation at the knee-joint, the patella was movable. The stump was quite healed at death.

Mr. MAUNDER raised the question whether such cases should be called cases of "acute necrosis" or "acute periostitis."

Mr. HOLMES said that the whole of the shaft of the bone was dead, and the surface exposed, and was quite white and dead. There was a large cavity at the lower end of the bone, due to death of the nucleus of the epiphysis. He considered that the term "acute necrosis" was preferable to "acute periostitis."

Mr. MAUNDER showed a specimen of

#### ACUTE PERIOSTITIS OF THE TIBIA OF A CHILD, INVOLVING THE ANKLE-JOINT.

About two-thirds of the whole surface of the shaft of the tibia had been bared of periosteum, the denudation being also prolonged over the anterior surface of the epiphysis, detaching the anterior ligament, and thus opening the ankle-joint, which contained pus. The disease had run its course very rapidly, occupying only ten days, and the patient was so thoroughly exhausted that amputation was performed with a slender hope of saving life. The child is convalescent. The term "acute periostitis" appeared applicable to this case (in which the inflammatory action had involved the periosteum covering the epiphysis by continuity of its texture with the membrane covering the shaft), in contradistinction to the term "acute necrosis" given to a case where the shaft of a bone dies independently of its epiphyses and adjacent joints, and in which new bone is developed in and about the periosteum to replace the original shaft.

Mr. FERGUSSON said that, from what he had just heard, he thought the specimens were of great interest, and verging on a subject of great moment. He would hardly venture to give an opinion as to the propriety of amputation in these cases, as it requires personal observation to be certain as to the treatment of any case. He would say, however, that he did not meet with cases of necrosis requiring amputation. He had not gathered from Mr. Holmes that there was any absolute necessity for the operation, although he had not seen the exhausted condition of the patient. He had, however, seen cases reduced to the last degree, but the exhaustion had ultimately passed off, and he had subsequently removed the necrosed bone. In cases in which the whole bone was involved, new bone would be formed. He had not had an opportunity of

carefully examining Mr. Maunder's specimen, but he saw that the foot and the calf were not emaciated. There was, evidently, great separation of periosteum, and yet there was no proof that there was no development of new bone. He had been taught that, in cases of necrosis of large bones, there was no hope of recovery of the limb, that it would be sure to exhaust the patient, and that amputation would have to be had recourse to. His experience had convinced him that this was erroneous. He thought, too, that in cases of early amputation the suppuration was suddenly checked. He had already expressed his opinion that the process of suppuration was often a salvation to the patient, and hence that, when stopped, it might cause mischief in some other part of the body.

Mr. HOLMES said that the child was under observation three weeks, and was gradually getting worse. His surgical colleague agreed with him, that there was no prospect of saving the limb. The ankle-joint was disorganised, and there was an abscess in the calf. He did not believe that it was possible to save the child without amputation; and that, as to checking suppuration, he considered that she would have sunk more quickly with it than without it.

Mr. MAUNDER said that in his case the disease was acute, having, at the time of amputation, only lasted ten days. The child had lost appetite; the tongue was like a toast. His colleague, Mr. Curling, agreed with him, that amputation should be performed immediately. The rapid progress of the disease was, he considered, an indication that they ought not to wait, especially as the ankle-joint was exposed.

Dr. GIBB exhibited a series of diagrams, illustrating

#### DEFORMITIES OF THE LARYNX IN FOUR INSTANCES.

Two were congenital and two acquired. 1. *Congenital Deformity of the Larynx in an Adult Deaf-Mute.*—Man, aged 54. The epiglottis was half its usual length; it lay low down in the larynx, concealed or exposed according to the action of the right aryteno-epiglottic fold, which projected across the glottis towards the left side. The left fold was wanting, as also were the vocal cords. The epiglottis was useless for all practical purposes. This man's wife, also deaf and dumb, had no vocal cords. 2. *Congenital Deformity of the Larynx in a Deaf and Dumb Boy, aged 14½.*—The epiglottis was shortened, as in the first case, and originated low down, close to the vocal cords, and was, therefore, practically useless in deglutition. The glottis was covered by the two usual folds, but originating from the back of the tongue. The vowels were well articulated. 3. *Deformity of the Larynx with a Double Voice, the result of a Wound of the Left Vocal Cord.*—The subject of this was a young man, who fell upon the point of his pen-knife some three years before, the blade entering the neck, close to the larynx, upwards of an inch. Dysphagia and aphonia followed. He recovered his voice, but it was ever afterwards double, being a mixture of tenor and bass. The structures of the larynx were oblique in direction; the left vocal cord was narrowed and contracted near its attachment to the arytenoid cartilage, and did not meet its fellow at this situation. A very distinct, oblique cicatrix could be seen, showing where the cord had been at one time divided. His sentences were very short. 4. *Deformity of the Larynx and Alteration of Speech from Small-pox.*—Woman, of 43, who had small-pox at 4 years old, with a fit and subsequent aphonia for a short time. Speech was ever after indistinct. Mr. Ure operated upon her for strabismus at 21. Never could sing. The right vocal cord was destroyed, and her language has remained that of a child in pronunciation ever since, *e. g.*, calling good, dood; silly, chilly; and so on.

Dr. MURCHISON showed a specimen of

#### PERFORATION OF THE STOMACH BY PRIMARY CANCER.

There were several excrescences at the lesser curvature. One of them had become gangrenous, and hence perforation occurred. Peritonitis followed.

Dr. MURCHISON also showed specimens from a

#### CASE OF SEVERE PURPURA.

The patient had been sent to the Fever Hospital for scarlet fever, but when he saw her it was impossible to say what disease she was labouring under. The whole surface of the abdomen was one mass of lividness. She passed blood from the bladder. After death, nearly every tissue was found to be infiltrated by blood. The pelvis of the kidneys, the ureters, and the bladder were filled with it.

## EPIDEMIOLOGICAL SOCIETY.

MONDAY, DECEMBER 1, 1862.

DR. MURCHISON in the Chair.

Mr. J. N. RADCLIFFE read a detailed report on the

#### STATE OF EPIDEMIC DISEASE IN GREAT BRITAIN IN 1861-62.

The report referred to the twelve months ending September 30, 1862. The following is a recapitulation of some of the principal facts recorded:—The health *status* of the English population, as estimated from the unusually low rate of mortality throughout the year, was generally good, notwithstanding dearth of provisions and an excessive amount of pauperism. The health *status* of the Scottish population was markedly below the average, as shown by the large amount of sickness prevalent in the last quarter of 1861, and the high rate of mortality since the commencement of 1862. The average death-rate of Scotland, it is well to remark, is below that of England. Thus, during the six years 1855-60, the annual proportion of deaths in England was 219 per 10,000 population: during the same period in Scotland the proportion was 208. The high range of temperature in the winter months, and low range during the summer, in England, exercised a favourable influence over the health, notwithstanding much wet and variability of weather. In Scotland similar conditions of temperature and weather existed, but to an exaggerated extent; and the great changes which were experienced, and especially the undue humidity of the atmosphere, were apparently the fostering causes of the influenza and throat affections, which appear to have been more common there than in England. The epidemic diseases most prevalent in England were continued fever, scarlatina, measles, diphtheria, whooping-cough, and small-pox. In Scotland the same diseases, with the exception of small-pox; also, and more particularly, sore-throat, often assuming a diphtheritic character, and accompanied by diphtheria, played the chief part in the epidemiology of the twelve months. In both parts of the kingdom continued fever prevailed most commonly in the autumn quarter of 1861; and in England the affection would appear to have been more general in the northern than in the southern portion of the kingdom. In both countries scarlatina was widely prevalent in the northern districts in the last quarter of 1861; but the disease became more active in the southern district in the third quarter of 1862. Measles prevailed extensively, and in some instances very fatally, in the winter quarter in England. In Scotland the disease appears to have been most prevalent in the spring and summer quarters. Diphtheria was, in England, principally fatal in the autumn quarter, but the disease prevailed, more or less, in every registration district during the year. In Scotland, the disease, together with sore throat, appears to have been epidemic throughout the year. Whooping-cough was widely prevalent in England during the winter quarter; in Scotland, during the winter and spring quarters. Influenza was epidemic in Scotland in the autumn and winter quarters. Finally, small-pox broke out in many districts of England, but more particularly in the eastern, south-western, and northern counties, and in Yorkshire. In no instance did an outbreak of any of the different diseases referred to as occurring in England, assume what may be termed "general proportions." The outbreaks were essentially local; but the dispersion of the various maladies, or of their centres of manifestation, over the kingdom,—the cropping out of exaggeration of these diseases in different localities, and the effects they apparently exercised upon the sickness and mortality of certain districts, without heightening the death-rate of the whole kingdom,—present a study of great interest. From this study it is reasonable to conclude that, in dealing with these local outbreaks of epidemic disease in ordinary periods, the best chance is afforded of warding off the widespread and more deadly outbreaks of extraordinary periods. The detailed mortality returns for Scotland extend, as yet, only to the year 1857; but the returns for England are brought down to 1860. From the latter, then, may be obtained information as to the *status* of the several epidemic diseases most prevalent in the twelve months discussed, immediately prior to that period. Since 1857 the mortality from continued fever has slowly declined; in that year the deaths from this cause amounted to 19,016; in 1860 they were 13,012. In 1855 the mortality from scarlatina was 17,314; in 1856 and 1857, the number of

deaths from this disease fell considerably, the mortality in the latter year being 12,646. The year following the mortality increased enormously, becoming well nigh doubled, the number of deaths from the malady being 23,711. In 1859 the number fell to 19,310; and in 1860 it became as low as 9305. Prior to 1855 deaths from scarlatina, cynanche maligna, and diphtheria were not separated in the Registrar-General's report. Whether the detailed reports of the Registrar-General will show an increase of the mortality in the whole of England from scarlatina, during 1861 and 1862, as great as occurred in London cannot be predicted. It is certain, however, that the activity of scarlet fever was great in several parts of the kingdom. The deaths from cynanche maligna in 1855 amounted to 199; in 1858, to 1770; in 1860, the mortality from the disease had decreased to 376. The mortality from measles was largely augmented in 1858, and there was a steady increase in the number of deaths from the disease in the two subsequent years. The deaths registered from diphtheria in 1855 numbered 186; in 1859, 9587; in 1860, the mortality from this disease had decreased to 5212. The mortality from whooping-cough, in 1860, was the lowest since 1852; and the mortality from small-pox had declined from 6460 in 1858, to 2749 in 1860. The reduced rate of mortality throughout England which occurred in 1860, was chiefly due, Dr. Farr states, to the decline of the number of deaths from scarlatina, diphtheria, and diarrhoea. A decrease also in the mortality from small-pox, erysipelas, and cholera contributed to the favourable results. The most noteworthy fact in the epidemiology of the metropolis during the twelve months was the remarkable outbreak of typhus. In 1858, 1859, and 1860, typhus had become so rare a disease in London, that the question of converting the Fever Hospital to other uses was seriously entertained. In 1861 typhus again became epidemic; and since January, 1862, the number of admissions to the Fever Hospital for typhus has exceeded that at any period of the history of the Hospital. Dr. Murchison attributes this epidemic to the artificial scarcity produced by the system of strikes, which had for some time previously disorganised the labour market, and the condensation of population caused by the arrival of labourers in the metropolis from the country in search of work (a). The mortality from continued fever in London, doubtless owing to the outbreaks of typhus, was in excess of that of any like period since 1848. Indeed, the total mortality of the winter, spring, and summer quarters of 1862 (2839) from this disease was alone in excess of that of any year since 1848. The true source of this excess of mortality would not have been rightly understood except by the careful nosological and etiological distinction of the forms of continued fever insisted upon by Dr. Murchison. The mortality from scarlatina was but a little below that from continued fever during the twelve months,—the total mortality from the former malady being 3437; from the latter, 3463. Next in order of mortality was whooping-cough. Continued fever, scarlatina, and whooping-cough were the chief epidemic affections of the period under observation in the metropolis. The mortality from continued fever increased to a maximum in the second quarter of 1862. The mortality from scarlatina was at its maximum in the last quarter of 1861, then decreased throughout the two succeeding quarters, but largely increased again in the summer quarter of 1862. The mortality from whooping-cough was greatest in the first quarter of 1862. Diphtheria was still largely fatal, having occasioned 625 deaths. Mr. Radcliffe detailed the history of the outbreak of typhus at Preston, in Lancashire, to the date of reading the report: he dwelt also at some length on epizootic diseases, brought together the chief accessible information on epiphytics, and terminated his report by a brief analysis of the principal contributions to epidemiological literature in Great Britain during 1861-62. The chief diseases prevalent among domesticated animals were epizootic pleuro-pneumonia, and the vesicular disease of the mouth and feet. Scores of sheep suffered and were lost from *filario* in the bronchial tubes and abomasum; there were several local but very fatal outbreaks of influenza among horses; and an outbreak of *variola ovina* occurred in Wiltshire. The history of the latter outbreak, which occasioned great alarm at the time, will be imperfect until the official reports are published. There was no special disease among plants during the year.

Dr. MURCHISON complimented the author on the valuable report which had been read to the society, and observed that a continuation of such reports would be of great service to future writers on epidemics. With regard to continued fevers, he pointed out the necessity of distinguishing the different forms before drawing conclusions as to their causes. The terms "typhus" and "continued fever" were commonly employed to designate different idiopathic fevers arising from totally different causes, as well as many febrile affections symptomatic of local inflammation, which might put on typhoid symptoms. Consequently, all official returns from which these sources of error were not excluded were of no value for drawing any inferences as to the probable causes of an increased or diminished prevalence of the diseases in question. He proceeded to allude to certain instances where great misunderstanding had arisen from confounding the different forms of continued fever. Twenty years ago, a memorable discussion took place between the late Dr. Alison, of Edinburgh, and the London Poor-Law Commissioners respecting the causes of fever, the latter maintaining that it was often due to putrid emanations from decaying organic matter, and was independent of destitution, whereas Dr. Alison asserted that its main cause was destitution, and that putrid emanations had nothing to do with it. Both observers were right; but they referred to different diseases. Dr. Alison's observations were made upon typhus and relapsing fever; those of the London observers on enteric fever. Again, the year 1858, in which the filthy condition of the Thames attracted so much notice, had often been referred to, as proving that enteric fever was independent of putrid emanations, because fever was less prevalent in London than it had been for many years before. Dr. Murchison did not believe that the condition of the Thames in that year was sufficient to give rise to enteric fever; but he insisted that there was no diminution in the prevalence of enteric fever in London in 1858: the diminished prevalence of fever was due to the almost complete disappearance of typhus, which was acknowledged to be independent of putrid emanations. Dr. Murchison then proceeded to allude to the present condition of Lancashire, in reference to the appearance of fever. Typhus had broken out at Preston early in October, and from the reports, published in the *Times*, as well as from private information, he believed it to be due to overcrowding, consequent on destitution. The unparalleled relief which had been afforded to the distressed operatives, and the great ability with which this relief had been distributed, had alone prevented the outbreak of an epidemic like that which devastated Ireland in 1847, after the failure of the potato crop. It had been repeatedly stated that throughout Lancashire there had not as yet been a single death from starvation. In London, on the other hand, the daily papers reported numerous deaths from starvation, and the poor population had been condensed by the arrival of numerous labourers from the country in search of employment. Consequently, London had been suffering, from the commencement of 1862, from an epidemic of typhus greater than any which had visited it for many years. Since January 1, nearly 2000 cases of true typhus had been admitted into the London Fever Hospital, a far larger number than in any previous year of its existence; and there had also been numerous cases in the other metropolitan Hospitals.

Dr. LAWSON, Inspector-General of Army Hospitals, directed attention to the probable existence of a certain epidemic influence which, for want of a better term, he designated *epidemic force*. His own observations, systematically conducted in several parts of the globe, had shown that, the ordinary, local, predisposing causes of epidemics being present, epidemic outbreaks recurred with curious regularity. This periodical recurrence indicated, he thought, a law of epidemic action, independent of, although acting concurrently with, the recognised fostering causes of epidemics, which was deserving of wide and attentive examination. The epidemic force, as he characterised the phenomenon, became, at times, pandemic. He suggested the propriety of keeping this probable epidemic influence in view in examining the mortality records of this kingdom. They would, doubtless, throw much light on the subject.

Dr. RICHARDSON remarked that he had been much struck, whilst listening to Mr. Radcliffe's report, with the tacit assumption by the author of the spontaneous development of certain epidemic contagious affections. He thought that the question of the spontaneous development of contagious maladies of an epidemic character was open to much doubt.

(a) See Dr. Murchison's recently published treatise on the "Continued Fevers of Great Britain" (page 52), for an account of this epidemic.

He believed that it was a question which might, with much advantage, be submitted to discussion by the society. He would, therefore, with the permission of the members, take an early opportunity of asking the society to express an opinion upon the debated point.

## WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, JANUARY 16.

Dr. BAINES, Vice-President, in the Chair.

A PAPER was read by Mr. JONES on

SOME POINTS IN CONNEXION WITH CEREBRAL HÆMORRHAGE.

The author's opinions were based upon 40 fatal cases which had occurred at St. George's Hospital. These were taken indiscriminately; but after a careful scrutiny, selecting only those cases in which a perfect post-mortem examination of all the organs of the body took place, and in which a visible hæmorrhage could be demonstrated from the cerebral arteries, 36 cases were found perfectly reliable for his remarks. Of the predisposing causes, the influence of age was first discussed, and, contrary to what had been often advanced, he showed that the greater number of cases occurred between the ages of 40 and 50; for in 38 cases he had found 3 had occurred between 30 and 40 years, 13 between 40 and 50, 10 between 50 and 60, 9 between 60 and 70, and 3 between 70 and 80. But a further examination showed that, by comparing the numbers of cases with the respective numbers of population at similar ages, the period of life at which the disease was most prone to occur relatively was between 60 and 70; for between 30 and 40 years, 3 cases occurred in a population of 2500; between 40 and 50, 13 cases in a population of 1800; between 50 and 60, 10 cases in 1300; between 60 and 70, 9 cases in 1000; and between 70 and 80, 3 cases in a population of 500. With regard to sex, males were shown to be more liable to the disease than females; for of 40 cases 11 only were females. Mr. Jones next described the efficient causes of cerebral hæmorrhage, and the intimate connexion between the latter and disease of the kidneys, heart, and arteries. This being one of the principal objects of the paper, he entered minutely into details of the 36 fatal cases in which disease of the kidneys, the heart, or arteries was found conjointly or singly with cerebral hæmorrhage. The analysis of these 36 cases was then examined, the result being that disease of the cerebral vessels, other vessels, of the heart, of the kidneys, was found in conjunction 10 times; disease of the cerebral vessels, of the heart, of the kidneys, 22 times; disease of the heart and kidneys, 29 times; of the cerebral vessels and kidneys, 22 times; of the cerebral vessels and heart, 24 times; of the cerebral vessels and heart (hypertrophy), 10 times; of vessels not cerebral and kidneys, 13 times; of vessels not cerebral and heart, 13 times. The further result of the analysis showed that in more than one-half the cases the kidneys, heart, and cerebral vessels were simultaneously affected; and in almost all those cases in which there was absence of disease in one or other of these organs there was the history of an accident to which the attack was attributed. The various morbid appearances found in the kidneys, heart, and arteries, under the foregoing circumstances, were fully and minutely explained, the author being strongly of opinion that the diseased condition of the kidneys first led to that of the arteries, and subsequently to the heart. In support of this opinion, Mr. Jones offered an hypothesis to the effect that the kidneys, from their disorganised state, being unable to deplete the blood on the one hand, but allowing the albumen to unduly pass away on the other, this fluid was rendered unfit to carry on the nutrition of the tissues, and that the arteries suffered early from this defective nutrition. The conclusions the author drew from his elaborate examination of the subject was, first, that cerebral hæmorrhage, when associated with renal disease, is almost always found to be dependant upon rupture of one or more of the cerebral arteries, in consequence of certain morbid changes having taken place in their walls; secondly, that these changes in the walls of the vessels are induced by the altered state of the blood, the effect of advanced disease of the kidneys; and, lastly, that the enlargement of the heart is the immediate effect of the renal disease, conjointly, perhaps,

with the alterations in the coats of the vessels. The paper concluded with some remarks upon the treatment of these cases, in which a tonic and stimulating plan, rather than a lowering one, was advocated, and two cases were given which seemed to justify it.

## PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS, FEBRUARY 9.

BIRTHS, ETC., REGISTRATION (IRELAND).

SIR R. PEEL, in moving for leave to introduce a Bill on this subject, said—It is undoubtedly a great deficiency that in a country like Ireland, having a population amounting to nearly six millions, there should be no systematic collection of the statistics of human life. A system of registration would be of immense utility in many respects. It would be very beneficial, for instance, in promoting sanitary reforms. In Ireland there is at present a great want of information as to any increase of sickness or disease, especially in remote country places. If correct data could be obtained as to the health of the people, measures would be more promptly and effectually taken to mitigate disease. (Hear, hear.) This is a subject which has excited considerable interest in Ireland. In December last, a resolution declaring the necessity for, and the probable benefits of, a system of registration was carried on the motion of the President of the Royal College of Physicians of Ireland, at a meeting in Limerick. I have also had the honour of receiving deputations who urged the importance of legislation on the matter. I received deputations from the Royal College of Surgeons, the Royal Medical Council, the Statistical Society, and the Social Science Association. I asked them to put their views in writing, in order that the Government, in framing a Bill, might meet their wishes as far as possible. They complied with my request, and in the document which they forwarded to me they expressed the hope that the registration of births and deaths should be made compulsory. Last year I proposed a plan, which had been originally submitted by the noble lord, the member for Cocker mouth. Its object was to make the constabulary the registrars and superintendent-registrars. If that plan had been adopted, the districts would have coincided with the areas in which the constabulary act. I think, however, the noble lord, the member for Cocker mouth, will agree with me that, whatever might be the plan adopted, the general feeling in this House was not in favour of using the constabulary for that purpose. (Hear, hear.) I have considered the matter carefully during the recess, and my firm conviction now is, that it would be impossible, with the concurrence of this House or of the country, to work a system of registration by the action of the constabulary. (Hear, hear.) The constabulary are fully occupied with the duties which they now perform, and which, I am bound to say, they discharge most efficiently; and I think it would be injudicious to burden them with the work which would devolve upon them as registrars and superintendent-registrars. (Hear, hear.) In the present Bill, therefore, I have adopted a system in conformity with that in operation in England—that is to say, I have adopted what I may call the Poor-law system, so that the areas or districts will be the areas of the unions, the dispensing Medical officers of the unions will be the registrars, and the clerks of the unions will be the superintendent-registrars. I believe that is the scheme which, on the whole, will meet with the greatest amount of support from the Irish members, and I believe it is the scheme which is likely to work best for the social and sanitary improvement of the people of Ireland. (Hear, hear.) The Poor-law districts are well known, whereas, considerable inconvenience would have resulted in that respect from the employment of the constabulary. We have, therefore, followed the Poor-law system, and I think the districts will be found very suitable for the purposes of the registration. The area of Scotland and Ireland is very nearly the same; but in Ireland we propose to have the system much better arranged. The districts will be very much of one size, the average population of each being 7400. Besides 163 unions we have 718 dispensary districts with 777 dispensary Medical officers—thus forming an admirable machinery ready to our hand. These dispensary Medical officers are superior to the village doctors in England; many of them have professional connexions extending over large tracts of country, and I believe they will be able to furnish most valuable returns. We next come to

the question of expense. The deputations I had the honour to receive at Dublin from the College of Surgeons, the Statistical Society, and the Social Science Association, all recommended that the remuneration of the registrars should be defrayed from the local rates, but that the superintendent-registrars should be paid out of the Consolidated Fund. I gave the best attention I could to these suggestions, and the proposal I have now to make is, that the registrars should be paid, as in England, out of the rates, but that the superintendent-registrars should receive their fees out of the Consolidated Fund. Considering the advantage that will be derived by all classes from this measure, the total burden that will be thrown upon the public will be comparatively very trifling—namely, £16,000 a-year, or just upon five-sixteenths of a penny in the pound on the whole rateable valuation of Ireland. We propose, then, to pay the registrars 1s. for each entry, and the superintendent-registrars 2d. There will be no other outlay attending the scheme except the salary of the Registrar-General, which we propose to increase to £1000 a-year, in consideration of the additional duties to be devolved upon him. The Registrar-General of England formerly received £1000 a-year, and now receives £1200; but it must be recollected that he has charge of three times the population of Ireland, and has three times the amount of registration to attend to. The only other point on which I need trespass on the time of the House is a very important one—namely, the Medical certificates. We wish to make our scheme as complete as possible, in order to obtain, not a mere registration of births and deaths, but a scientific record of vital statistics, and with that view we have introduced into our Bill a provision which we think will meet the approval of the Medical officers. We have not desired, as is done in Scotland, to make it binding on them penally to give the return. From the opportunities I have had of conversing with the President of the Royal College of Surgeons, and judging also from other sources of information, I believe that the Medical officers generally will be prepared to co-operate with the State, and to furnish it with the requisite particulars as to the deaths of persons whom they may have attended Professionally, with greater readiness if it is left to them to do it freely, instead of its being made compulsory on them by the insertion of a penal clause.

Lord NAAS was glad that his right hon. friend had thus early called the attention of the House to this important subject. In his opinion, Doctors, of all others, were the most unsuitable for the performance of these duties in Ireland. It was a great mistake that Boards of Guardians were not to have an uncontrolled discretion. There was an omission in the Bill which he very much regretted. It made no provision for the registration of marriages, on which questions of legitimacy and succession to property still more largely depended than on the registration of births and deaths.

Dr. BRADY regarded a system of registration of births and deaths as most important, not only in a statistical and social, but also in a moral point of view. But to make it effective there must be a proper staff; and, apart from his Professional predilections, he maintained that Medical men were of all classes the best qualified to act as registrars. In this country butchers and bakers were appointed registrars, who, in copying the cause of death from the Medical certificate, were often totally at a loss, being ignorant of the Professional meaning of the terms employed. It was true, no doubt, that Dispensary Doctors in Ireland were in full employment, but there was on that very account no difficulty in handing to them the particulars for registration, as they were almost always engaged in the houses where either deaths or births took place.

After some further discussion, leave was given to introduce the bill.

#### INFECTION IN CABS.

Dr. BRADY asked the right hon. baronet the Home Secretary if his attention had been directed to the evils resulting from persons labouring under infectious diseases being carried to hospitals in public conveyances; and, if so, if it was his intention to introduce any measure this session with a view to remedy the same?

Sir G. GREY said that no representations had been made to him upon this subject, but he had read in the newspapers letters referring to it. When the last Hackney Carriages Act was before Parliament a clause was proposed having for its object the prevention of the evil to which the hon. gentleman's question referred, but after a good deal of discussion

it was withdrawn. There was no difficulty in enabling parochial authorities or hospitals to provide carriages for the transport of persons suffering from infectious diseases; the difficulty was as to empowering the drivers of hackney carriages to refuse fares on the ground that they believed that the persons about to enter their carriages were afflicted with such diseases.

Dr. BRADY asked whether the right hon. baronet would object to his introducing a Bill to deal with the question?

Sir G. GREY said that, on the contrary, he should feel much obliged to the hon. gentleman if he would embody his views upon the subject in the form of a Bill.

## MEDICAL NEWS.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—The following gentlemen passed the First Part of the Professional Examination for the Licence of the College on February 9, 1863:—

Sidney Hyde, King's College; John Morgan Bryan, St. Mary's Hospital; Edwin Burrell, Guy's Hospital; Alexander James Low, St. Bartholomew's Hospital; Washington Lovegrove, 34, Dowgate hill; George Edward Pyle, Middlesex Hospital; Charles Edward Squarey, University College.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.**—The following gentlemen passed their First Professional Examinations for the Double Qualification during the February Sittings of the Examiners:—

William Wright Milligan, Dumfriesshire, and Miles Walker, Hexham.

The following gentlemen passed their Final Examinations, and were admitted L.R.C.P. Edin., and L.R.C.S. Edin.:—

William Bentley Ford, Waterford; Daniel O'Sullivan, Cork; Forbes Dick, Edinburgh; Thomas Cairns, Fife; and Andrew Ross Miller, Edinburgh.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following Members of the College having undergone the necessary examinations, were admitted Licentiates in Midwifery at a meeting of the Board on the 11th inst.:—

Richard Luscombe Elliot, Kingsbridge, Devon, diploma of membership dated May 7, 1862; John Cook, M.D. St. Andrews, Fitzroy-place, Kentish Town, November 5, 1859; William Taylor Morgan, M.D. Edinburgh, Dreadnought Hospital Ship, Deptford, January 14, 1859; Thomas Sheldon, Stratford-on-Avon, December 5, 1859; George Granville Bothwell, Rathmullan, County Donegal, July 31, 1861; Edward Charles Anderson, Birmingham, November 18, 1862; Matthew Bloxam, Duke-street, Grosvenor-square, November 20, 1862; Thos. Baker, Birmingham, November 18, 1862; Samuel Lloyd, Smithwick, near Birmingham, November 15, 1860; William Patterner Hollis, Burton-crescent, March 8, 1861; Henry Charles Wine, Bristol, June 4, 1861; Stephen Winter Fisher, Bristol, August 1, 1861; William Henry Emmett, Bolton-le-Moors, Lancashire, January 30, 1862; John Holt, Bolton, Lancashire, May 8, 1862; Samuel Smith Crosland Richards, Bedford-square, July 29, 1862; and Albert McDiarmid, Rochester, June 10, 1862.

#### APPOINTMENTS.

CONSTABLE, JOHN, M.D. Univ. Glasg., and C.M. Univ. Glasg., has been appointed Parochial Medical Officer for Leuchars, Fifeshire, *vice* Robert T. Scott, M.D., deceased.

FRASER, J., M.D., has been appointed a Director of the Glasgow Lock Hospital.

FREEMAN, R. G., M.D., has been appointed Surgeon for the District of Greenwich, Royal Kent Dispensary.

FULLER, Dr. WILLIAM HENRY, has been elected President and Treasurer of the Harveian Society.

GIBNEY, WILLIAM, M.D., has been appointed Vice-President of the Cheltenham General Hospital and Dispensary.

KAVANAGH, P., M.D., has been appointed Surgeon for the District of Deptford, Royal Kent Dispensary.

M'GEEVY, Dr. NEIL, K.Q.C.P.I., has been elected Resident Apothecary to the Workhouse of Lurgan Union, County Armagh.

OLDHAM, JAMES, M.R.C.S. Eng., has been appointed Consulting Surgeon to the Brighton and Hove Lying-in Institution.

RIVINGTON, WALTER, M.R.C.S. Eng., has been appointed Resident Medical Officer to the Tower Hamlets Dispensary.

SAVERY, JOHN, M.D., has become Surgeon-Extraordinary to the East Sussex, Hastings, and St. Leonard's Infirmary.

STONE, THOMAS ARTHUR, F.R.C.S. Eng., has been elected President of the Society for the Relief of Widows and Orphans of Medical Men.

WILSON, J. GILMONT, M.D., has been appointed a Director of the Glasgow Lock Hospital.

WOLLASTON, ROBERT, M.R.C.P. Lond., has been elected Physician to the Stafford County Infirmary, also Visiting Physician to the Coton-hill Lunatic Institution, Stafford.

#### DEATHS.

BARTLETT, THOS., Assistant-Surgeon 41th Regiment, on half-pay, recently.  
BENTLEY, J. M., of Turton, recently.

BLACKMAN, MATTHEW, at Whitstable, Kent, on February 4.  
 BROOKS, RICHARD BIRKETT, M.R.C.S. Eng., at Madeira, on January 12, formerly of Chelmsford, Essex, aged 27.  
 CLARK, ESAU, M.D. Edin., at Twyford, Buckinghamshire, on January 20, aged 56.  
 DOAK, WILLIAM, in practice prior to 1815, at St. Giles-street, Oxford, on February 5, aged 68.  
 FRAZER, WYNNE PEYTON, M.R.C.S. Eng., Staff Assistant-Surgeon, late of 2nd West India Regiment, at Toronto, Canada, on January 1.  
 GRIERSON, D., M.D., Deputy-Inspector-General of Hospitals, Poona Division, Bombay Army, at Poona, on January 6.  
 HOLMES, ARTHUR NEWSTEAD, M.D. St. And., at Bradford, Yorkshire, on January 22, aged 38.  
 JONES, WILLIAM, M.D., Army Surgeon on half-pay, at Burton-on-Trent, recently.  
 KINAHAN, JOHN ROBERT, M.D. Dub., at Dawson-street, Dublin, on February 2, Professor of Zoology in the Department of Science and Art Museum of Industry, Dublin.  
 MARLES, WILLIAM, at the "Sear," Woolhope, Ledbury, Herefordshire, recently, aged 65.  
 PACKMAN, FREDERICK WILLIAM SMITH, M.D. Edin., at Alexandria, on January 24, of Tupton-hall, Derbyshire, and Clarges-street, London, aged 46.  
 PRENTICE, J., at North Walsham, Norfolk, on January 26, aged 74.  
 SMITH, JOSIAH, at the Royal Medical Benevolent College, on February 3, aged 74.  
 WINSTON, DAVID, M.R.C.S. Eng., late of Carlton Lodge, Haverstock-hill, on February 1, aged 30.  
 WHITE, PETER, at 4<sup>2</sup>, Grove-place, Brompton, London, on February 5, late Surgeon of the 72nd Regiment, aged 82.

**NOBLE ACT OF CHARITY.**—Mr. A. Ryland announced at the weekly meeting of the Governors of the Birmingham General Hospital, the following extraordinary act of munificence on the part of a lady, viz., to provide a large house for a convalescent institution in connexion with the Hospital, and to defray all the expenses of an efficient staff to the amount not exceeding £230 per annum. It is to be regretted that the name of this gentlewoman is withheld, as she prefers to do good by stealth.

**SCHOLARSHIPS IN NATURAL SCIENCE AT SIDNEY-SUSSEX COLLEGE, CAMBRIDGE.**—This college has just issued a notice that two scholarships, of the value of £40 per annum each, will be given this year for Natural Science; the examination to commence October 13; the subjects being electricity, chemistry, geology, and anatomy (human osteology and general anatomy). The scholarships are perfectly open. The successful candidates will be required to enter at the college. Further information may be obtained by application to the Rev. J. C. W. Ellis, tutor of the college. Other scholarships, ranging in value from £32 to £80 per annum, for Classics and Mathematics, are to be competed for at the same time.

ON Saturday last, Mr. Glaisher, F.R.S., delivered a lecture at the Army Medical School, at Chatham, on the "Accidents and Derangements to which Meteorological Instruments are most Subject, and the Best Means of Correcting those when the Skilled Labour of an Instrument-maker cannot be procured." The lecturer showed practically the steps to be taken when the thread of mercury or of spirit in a thermometer becomes broken, and when air has gained admission into the tube of a barometer. He then took to pieces a barometer, and explained the mode of cleaning mercury, refilling the tube, and putting the instrument in good working order. The lecture was very clear and practical, and was listened to with the greatest attention by the gentlemen who have just concluded the course of special instruction there, preparatory to joining the army as Medical officers. At its close, Dr. Anderson, the Inspector-General, returned thanks to Mr. Glaisher, on behalf of himself and the other gentlemen present, for the very interesting and practical lecture which he had so kindly delivered to them.

**POPULATION OF BERLIN.**—From the census taken December, 1861, it results that this amounted to 524,945 civilians (261,385 males, 263,560 females), and 22,345 military—total, 547,290. The ages were—under 16, 323 per 1000; from 16 to 60, 628 per 1000; and above 60, 48 per 1000. The unmarried amounted to 179,767 males, and 160,541 females (together 648 per 1090); the married to 78,698 males, 79,577 females (301 per 1000); the widowed to 2906 males and 22,521 females (48 per 1000); the divorced to 14 males and 921 females (1 per 1000). The number of families amounted to 107,916. The Protestants numbered 480,407; the Catholics 25,121; and the Jews 18,847. There were 283 (172 males, 111 females) deaf and dumb, and 191 (110 males and 81

females) blind. The entire population of Prussia amounted to 18,491,220; the military constituting 268,372 of this.

**ENUMERATION OF MEDICAL PROFESSORS AND STUDENTS IN GERMANY IN 1862:**—Vienna, 28 professors and 579 students; Prague, 22 professors, number of students not returned; Berlin, 21 professors, 323 students; Leipzig, 20 professors, 230 students; Munich, 18 professors, 244 students; Tübingen, 14 professors, 105 students; Göttingen, 13 professors, 166 students; Bonn, 12 professors, 119 students; Heidelberg, 11 professors, 96 students; Königsberg, 10 professors, 104 students; Jena, 10 professors, 51 students; Greisswold, 10 professors, 167 students; Freiburg, 10 professors, 44 students; Giessen, 9 professors, 152 students; Würzburg, 14 professors, 289 students; Erlangen, 8 professors, 83 students; Halle, 7 professors, 45 students; Marburg, 8 professors, 61 students; Rostock, 7 professors, 32 students; Breslau, 6 professors, 119 students; Kiel, 6 professors, 38 students. Total, 21 universities, having 264 Medical professors (181 of these being ordinary professors, and 83 extraordinary professors), and 3047 Medical students; those of Prague not being enumerated.

**HARVEIAN SOCIETY OF LONDON.—ANNIVERSARY MEETING, JANUARY 15.**—Mr. Weeden Cooke, President, in the Chair. The Honorary Secretary read the report of the Council. It was proposed by Mr. Henry Thompson, and seconded by Dr. Ballard, that the report be received and adopted, and that the thanks of the Society be given to the Council. The Treasurer laid before the meeting a statement of the expenditure and income of the Society for the past year, showing a balance in hand of £79 8s. At the close of the ballot, the following gentlemen were declared elected officers for the ensuing year:—*President*—Henry W. Fuller, M.D. *Vice-Presidents*—William Adams, Esq., J. Burdon Sanderson, M.D., W. Sedgwick, Esq., Wm. Wadham, M.D. *Treasurer*—Henry Wm. Fuller, M.D. *Honorary Secretaries*—J. Brendon Curgenvin, Esq., Charles R. Drysdale, M.D. *Council*—Patrick Burke, Esq., Frederick Cock, M.D., J. K. Hornidge, M.B., Ernest Hart, Esq., T. H. Hill, Esq., J. C. Langmore, M.B., W. Boyd Mushet, M.B., W. O. Priestly, M.D., O. A. Field, Esq., Edwin Sercombe, Esq., H. G. Times, Esq., J. B. Walker, Esq.

**ODONTOLOGICAL SOCIETY.**—At the monthly meeting, on Monday, February 2, a paper was read by W. A. N. Catlin, F.R.C.S. Eng., Licentiate in Dental Surgery, etc.; Samuel Cartwright, jun., F.R.C.S., President, in the chair. The author of this paper commenced by a comparison of morbid conditions of the teeth which have, in his experience, given rise to neuralgia, with analogous pathological conditions in other organs, as well as with conditions not strictly analogous, but in which local disease had been shown to have had an etiological relation with neuralgia. He discussed briefly the probable causes of the variety which every one knows to occur in the degree of pain suffered by different individuals under circumstances of local disease apparently very similar, referring it to variety in temperament, size of nerves, &c., and then passed on to the main topic, namely, an inquiry as to how far neuralgia, due to a morbid condition of the teeth, may be distinguished in practice from that dependant upon constitutional causes or local mischief elsewhere. The conclusion arrived at is, that, as in all other questions of difficult diagnosis, the Surgeon must carefully examine not only the local conditions of those organs and parts of the body most likely to originate the neuralgia, but into the general constitutional condition of his patient, and, weighing carefully the facts he ascertains, exercise his judgment in determining the proper conclusions to be arrived at. Before condemning a tooth as the cause of a local neuralgia, it is thus often proper to strive after the removal of other causes of reflex irritation and the improvement of the general health. At the same time, the author strongly deprecates the prevalent practice of retaining diseased teeth in the mouth, to the sacrifice of health and comfort, after they have become useless for mastication or appearance. The paper was illustrated by a large number of interesting cases which have occurred in the practice of the author, some of them being cited to show that the symptoms of intermittent or regular paroxysms mainly relied upon by some authors in their diagnosis of constitutional neuralgia, frequently attend local neuralgia in patients of shattered health. He recommends stimulants in full doses as an antidote to nervous shock, and as the best remedy for the neuralgia which sometimes succeeds dental

operations. An interesting case is recorded in which deafness was cured one hour after the extraction of a tooth.

**JUNIOR MEDICAL SOCIETY.**—The last meeting of this Society was held at the Whittington Club, Arundel-street, on Tuesday, January 20; Dr. Edward Harvey, of St. George's Hospital, Vice-President, in the chair. The following pathological specimens were then exhibited:—Dr. Deck, President, showed an interesting specimen of cancer of the omentum; the patient from whom it was taken had been under the care of Dr. Bristowe, in St. Thomas's Hospital, for ovarian disease. Mr. Foxon, of St. George's Hospital, showed a nut-shell which had been impacted in a bronchial tube for some time. Mr. Kempthorne, of King's College Hospital, showed a phosphatic concretion removed from a tonsil. Mr. H. Cooper, of St. George's Hospital, then proceeded to read a paper on the "Treatment of Typhus and Typhoid." Mr. Cooper remarked that the great distinction, drawn by Jenner, between these two diseases has been well marked at St. George's during the last three years, and more especially within the last twelve months—the rose-spots co-existent with restlessness, but no delirium, as indicative of typhoid; and the mulberry-rash, with delirium or stupor, as seen in typhus. No specific has yet been found to cut short the ordinary duration of this disease, and thus contradict the saying of Pitcairn, that you may guide a fever, but cannot cure it. Emetics have been very useful in Dr. Chalmers' hands. Out of 60 cases of fever which have occurred at St. George's within the last three years, 40 have been treated by stimulants and 20 by cinchonising doses of quinine. The quinine was exhibited in  $\mathcal{O}$ j. doses every hour for three successive hours, preceded by an emetic, or, if the patient were greatly prostrated, by a good dose of wine. This large dose of quinine was followed by gr. ij., every four hours, until the patient was convalescent. If the pulse was not reduced by the first dose, another  $\mathcal{O}$ j. would be given on the second or third following day. In some, the cinchonism produced was of a much severer nature than in others, and, in 2 cases, the extreme depression that followed proved fatal. The pulse was generally reduced, on an average, 19 beats, and, in some cases, even from 120 to 80. In 4 out of 7 cases in which  $\mathcal{O}$ j. was given on the day after the larger dose of quinine, the effect produced on the pulse was that of increasing rather than decreasing it. In the cases of typhoid treated by cinchonism, the diarrhoea seemed to be kept in check by it. In concluding, Mr. Cooper expressed his belief that alcohol is the only remedy upon which we can rely, and that we have in it one which will restore to the nervous system its power over the animal functions; but, as there are many difficulties connected with its administration, it ought to be carefully handled,—experience alone teaching us when to give it and when it had better be omitted. In nearly all the cases treated at St. George's, wine was given on the first day, the amount being from  $\mathfrak{z}$ vj. to  $\mathfrak{z}$ xij., according to the state of the patient. An interesting discussion then ensued, in which Messrs. Dickson, Freeman, Hatherly, Gedge, Sheers, Gervis, Deck, and Stephens took part. The author of the paper having replied, the meeting adjourned.

**ETHNOLOGICAL SOCIETY, FEBRUARY 3.**—J. Crawford, Esq., President, in the chair. On the "Psychological Differences which Exist amongst the Typical Races of Man," by Robert Dunn, Esq., F.R.C.S. Eng. As papers of a psychological character have so rarely been read at the meetings of the Society, the author offered no apology for asking the attention of the meeting to this subject, being satisfied that if there were any branch of the science more interesting than another, it was that which related to the psychological differences which characterise the different varieties of the human species. Thus, the genus *Homo* was one, the author believed and maintained, on the ground that in man's moral and religious attributes the inferior animals do not participate, and it was this, he considered, that constituted the difference between him and them. The barrier was thus, he considered, impassable between man and the chimpanzee and gorilla; and that wherever two-handed and two-footed man, in his erect attitude, and with his articulate voice, is found, his claims to our common humanity must be immediately acknowledged, however debased the type may be, or mean the garb in which that humanity is clothed. His conviction was, that there was proof of a general unity exhibited in all the races of the great family of man, inasmuch as they were all endowed with the same instinctive, sensational, perceptive, and intellectual faculties—the same mental activities, however much they may

vary in degree. It had, he thought, been fairly argued that all the races of the human family form but one species, from the physiological fact, that they are all capable of fruitful union, which would not be the case with the hybrids of two species of even the same genus. Believing the brain to be the material organ of the mind, where the ultimate molecular changes take place, and whence the mandates of the will issue, the author considered the study of the cerebral organisation and development in the various typical races, as one of the most effectual means of better understanding and elucidating the psychological differences which characterise them. This subject, however, was one that yet required to be worked out; and ethnic psychology was still a desideratum. The difficulties which formerly beset it no longer exist; and it was, he thought, to our shame that, notwithstanding our extensive and daily spreading intercourse with all the nations and races on the face of the earth, so little had been done. The author then reviewed at length what had been done by anatomists and ethnologists, including Spurzheim, Tiedemann, Gratiolet, Herbert Spencer, Huxley, Owen, and others. In conclusion, he pointed out that the lower savage races, such as the Sandwich Islanders, made progress in the early part of their education, and were so far as apt and quick as the children of civilised Europeans; but at this point they stopped, and seemed incapable of acquiring the higher branches. The Sandwich Islanders have excellent memories, and learn by rote with wonderful rapidity, but will not exercise the thinking faculties; they receive simple ideas but not complex ones. In like manner it was found practically that negro children could not be educated with white children. In all these cases, as well as in the minor cases continually occurring amongst ourselves of inability to understand subjects and reasonings of a certain order of abstruseness, the true explanation is, that the cognate faculties have not reached a complexity equal to the complexity of the relations to be perceived; and, moreover, it is not only so with purely intellectual cognitions, but it is the same with moral cognitions. In the Australian language there are no words answering to justice, sin, guilt. Amongst many of the lower races of man, acts of generosity or mercy are utterly incomprehensible—that is to say, the more complex relations of human action in its social bearings are not cognisable. This, the author thought, was in accordance with what *a priori* might have been expected to have resulted from organic differences in the instruments of the higher psychical activities, or, in other words, in the nervous apparatus of perceptive and intellectual consciousness. The leading characters of the various races of mankind were simply representatives of particular stages in the development of the highest Caucasian type. The negro exhibits permanently the imperfect brow, projecting lower jaw, and slender bent limbs of a Caucasian child, some considerable time before the period of its birth. The aboriginal American represents the same child nearer birth. The Mongolian the same child newly born. In the discussion, the President, Dr. Copland, Mr. Luke Burke, and Dr. Donnelly took part.

## NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

**Caution to Authors.**—Mr. Churchill finds it a duty again to publish the fact, that certain swindlers make it a practice to address authors for a copy of their work, to be sent per book-post, stating the cost shall be remitted by post-office order. The books so sent are sold at some book-stall, and, of course, no payment is contemplated. An old offender is repeating his applications, dating his letters from Manchester.

A series of Clinical Reports of Difficult, Preternatural, and Complicated Cases of Labour, which occurred from 1857 to 1863, by Dr. Robert Lee, will shortly be commenced.

X. O.—Consult your own family attendant, or the Physician of best reputation in your neighbourhood.

**Death in a Brothel.**—An unhappy woman, married too, entered a low house in the New Kent-road, with a companion, one evening last week, and had scarcely entered a room when she complained of illness, begged to be taken out of the house, then soon became unconscious and died. An inquest was held, and a verdict returned that she had died a natural death from excitement. Instances of death under these appalling circumstances are not uncommon, though far more frequent in men, especially if advanced in life, than in the other sex. The struggle between passion and conscience seems too great for a full heart to hear.

**Dr. MacLoughlin and the College of Physicians.**—The venerable Dr. MacLoughlin has published a correspondence between himself and the authorities of the Royal College of Physicians, in which he urges upon the College the necessity of throwing open that Institution for discussions on scientific and Medical subjects. Spite of the existence of the College documents on the cholera, the worthy Doctor asserts that the English Medical Profession knows nothing of that disease scientifically. We consider that the acuteness and energy of the venerable Doctor, and the practical import of the question, whether cholera be ever, be usually, or be invariably preceded by diarrhoea, will give him and his opinions a marked place in the history and literature of that remarkable disease.

**Remedies for Burns.**—Writers in the *Times* are busily descanting on the treatment of burns. As is usual, amateur discoverers find that all that is valuable in their discoveries has been known long before. The *sine qua non* in all remedies is, that they keep out air and cold. Common paint (used by Sir C. Bell), chalk ointment, copaiba, treacle, lime-water and milk, lime-water and linseed-oil, scraped potato, cotton-wool, flour, and basilicon ointment, all have these properties. Many remedies, too, of great vogue, have something of turpentine in their composition, e.g., Kentish's liniment of resin ointment and turpentine. Whiting, with water, or with oil, may certainly be included amongst promising remedies.

**Removal of St. Thomas's Hospital.**—A clash of interests may prevent the removal of St. Thomas's, but it was felt that the whole question was settled by Mr. Paget, when he delivered the following emphatic remarks (or something like them) in his address at the College of Physicians before the British Medical Association last summer:—"Of all the remedies for pyæmia," he said, "the best I know of is *fresh air*. I have seen patients who were hopelessly ill recover by being kept in the freshest air night and day." When Mr. Paget uttered these words, a friend near us said, "That settles St. Thomas's." It is of no use to go on boring our readers, for there is no more to be said. Country air is better than town air: so it is, say the obstructionists, but the air of our wards is so much better than that of the vile courts and alleys that it is good enough. Dr. James Turle has written warmly and ably on this subject; but if men who sleep out of town for their own health will make their poor patients sleep in town on the plea that it is good enough for them, of what use is argument?

A REQUEST.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you kindly notice the fact, that Dr. Yearsley's work, entitled "Deafness Practically Illustrated," a new edition of which has just appeared, was translated into German, a few years ago, by Dr. Claudius Ulmann, of Weimar.

15, Savile-row, W., February 4.

JAS. YEARSLEY.

ADVICE GRATIS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I was sent for to a patient this evening, and was told candidly enough that she had been ill for some days, but that she had been tempted to go to an M.D. who gave advice gratis. The M.D. gave her a prescription, with the remark, "You had better let my man make it up;" for this ornament of a university keeps a chemist's shop with red bottles round the corner of his house. On looking at the prescription I saw that nobody but "his man" could have made it up, for it ran thus—"℞ An. G. c., ʒvi.; am. c., ʒiii.; aq. ad., ʒvi.; capt. cochl., ij., t. d.; ʒs. 6d." The only intelligible part of it were the figures wherewith the M.D. had assessed the value of his man's drugs. After seeing him at home twice, my patient was told by the M.D. that he had better call on her, as her case "wanted watching." Whereupon she sent for me and told me this artless tale. I mused to myself, "Gammon! thy name is *advice gratis*."

I am, &c.

A GENERAL PRACTITIONER,

(who does not keep a shop, nor give advice gratis, but loves to live like a gentleman, and let live).

## COMMON RESIN IN WHOOPING-COUGH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your Journal of January 31 is a paragraph stating that the common resin is recommended, and has been used by a Practitioner in Australia, as a specific in whooping-cough. In some parts of Devonshire, amongst the labouring classes, it is administered as a specific for this complaint, but in larger doses—for instance, five or six grains, three times a day, for a child. I tried it in one case for about a week, but I did not observe any marked improvement in that time; the only effect that I noticed was its purgative action, and I had to reduce the dose to twice a day. I, nevertheless, think that the remedy deserves a fair trial.

I am, &c.

J. BRENDON CURGENVEN.

11, Craven-hill-gardens, Hyde-park, W., February 9.

THE LATE GRADUATION AT ST. ANDREWS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—An article having appeared in your Journal of January 31, on the Graduation Week of St. Andrews, by a "Secound who was there," it gives me no pleasure to state that I can bear your correspondent out in his assertion, that students of only two years' standing were admitted to examination for the M.D. degree in December last. Surely, the Senatus Academicus will at once take measures to prevent the further onslaught on the British public of men so dangerously armed, and so imperfectly drilled, by cancelling their degrees, and recommending them to return to their Medical studies;—in which case I would kindly advise those premature Doctors to keep company with the midnight lamp, and to pass through that course of study which most Medical students consider it necessary to go through before presuming to offer themselves for any diploma.

I am, &c.

A MATURE GRADUATE.

[Our correspondent's letter is duly authenticated, and, we think, should receive the explanation it seems to demand.—Ed.]

## THE RECENT ACTION AT LEEDS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your Leeds correspondent would wish to impress upon the Medical public that the parties alluded to were called to disparage and cut down the charges of their Medical brethren. Far otherwise; they were both subpoenaed on the occasion. On the other hand, they could not acquiesce in the charges of three guineas for three visits, exclusive of medicines charged 2s. 6d. for each mixture, two of which visits were paid, not only on the same day, but within two hours of each other, at a distance at least within three-quarters of a mile. As regards the statement of Medical men being in court to confirm the plaintiff's charges, it is incorrect, as there only was one on his side of the question. The charge could not be considered reasonable when such a high authority as Mr. Teale reduces a bill from £9 7s. 6d. to £5 10s.

In conclusion, I think most Medical men will agree with me, that it was bad policy to take a case into the County Court, the defendant at the very time being a club patient of the plaintiff's. The defendant, at the time of the accident, no doubt considered his life in danger. Under such impression, he made a promise of reward as a means of insuring extra attention; and, as a working man of only 22s. per week, he did not show himself altogether devoid of gratitude for any extra services, for he voluntarily made an offer of £5—such a gift as few Medical men ever have the opportunity of refusing. Only wishing that such occurrences might frequently befall some of our ill-paid Poor-law Medical Officers,

I am, &c.

AMICUS JUSTITIE.

## THE TREATMENT OF PSORIASIS INVETERATA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The details which accompany the relation of a valuable case of psoriasis inveterata, by Dr. Moriarty, in a late Number of the Journal, render its perusal both interesting and instructive. There is no doubt that, in the treatment of that particular case, quinine was highly useful. It has occurred to me, however, to have found psoriasis accompanying more than one kind of defective constitutional condition. It occurs, I think, very frequently in families of a gouty or asthmatic tendency; generally, it seems connected with diminished performance of the normal functions of the skin; sometimes it occurs in youth; often in extreme age. I believe it will be found that arsenic will fail to make any impression on many cases of psoriasis inveterata until a considerable loss of liquor sanguinis has taken place, which may be thoroughly effected through purging. I am by no means disposed to lower Dr. Moriarty's estimation of quinine as an adjuvant, however I may fear that it will not prove uniformly or constantly useful, or that the famous Fowler's drops will supersede other forms of arsenical preparations. While venturing to intrude these remarks upon your space, I may say that I felt surprised to see that, in a recent communication, the introduction of the liquor arsenici chloridi should have been attributed to any modern hand. When I was a young pupil, its valuable properties were pointed out to me by my predecessors, who had it from their predecessors, and so on. It had suffered much, no doubt, from fashionable neglect, but the best of remedies are subject to that. Like most of the chlorides, especially of the metals, it is a powerful agent; it used to be considered, too, an efficient remedy in the treatment of neurosis, especially chorea, and even sciatica.

I am, &c.

GEO. GASKOIN.

## CASE OF HERNIA OF THE OMENTUM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A case of "Hernia of the Omentum, with 'Unusually Acute Symptoms of Strangulation,'" was inserted in the last Number of your Journal. It was written by me, as the case in question was under my care. I sent it to a gentleman for inspection, and requested him to forward it for publication. The case afterwards took an unfavourable turn, and the patient died. As there were some peculiarities displayed on post-mortem examination, somewhat at variance with the account given, I requested my friend to get the paper cancelled at once. He forgot to do this, and the case has been published.

It clearly remains for me to explain the case, otherwise a false impression would remain, which I should be sorry for. The patient was attacked with vomiting and other symptoms of peritonitis, and died exactly a fortnight after the first commencement of symptoms of strangulation, and rather more than eight days after the operation. It was found, on examination, that a portion of small intestine, which appeared to have been strictured at some period or other, had formed an adhesion to the peritoneum above the bladder, and that another portion of small intestine adhered firmly to this, and to this, also, a piece of the colon was adherent: at this latter point of adhesion, which was easily separable, ulceration into

the peritoneal cavity was beginning, and this led to fatal peritonitis. There was nothing in the sac.

The case is interesting, but there is considerable doubt upon my mind whether the intestine had not become the seat of disease, as the result of stricture at some period prior to the recent symptoms.

I am sorry to trouble you, but I must request, for the sake of truth, an early insertion of this letter.

I am, &c.

4, St. Helen's-place, February 9.

JOHN ADAMS.

THE SOUTH HANTS MEDICO-CHIRURGICAL SOCIETY.

The largest provincial Medical society in the kingdom—now numbering ninety-one members—held its annual meeting, for the election of office-bearers for the current year, at the house of Dr. Wibliu, on Saturday last, the 7th inst.

The following gentlemen were elected:—President—Dr. J. S. Bushnan, of Laverstock House, Salisbury; Vice-President—Dr. Wibliu, Southampton; Secretary—Dr. Palk, Southampton; Council—Dr. Orsborn, Bitterne; Dr. Dyer, Ringwood; Dr. Welch and Mr. Bencroft, Southampton. On assuming the chair, Dr. Bushnan delivered the following humorous "speech from the throne":—

"My Lords and Gentlemen,  
"In commencing the speech from the throne to which your voices have elected me, I feel compelled to use the customary beginning of other potentates, although, unfortunately, there is small chance of any of our Profession ever being raised to the dignity of a *peerage*. A stray baronetcy here and there is the utmost of which we can boast. One or two knight-hoods, perhaps, are occasionally bestowed upon us; although as a learned body we are not generally a *be-knighted* race; while as for any higher title our glorious profession is not only an unequalled, but, in the strictest sense of the word, a *peer-less* one.

"I regret to announce that our relations with foreign powers continue in a most unsatisfactory condition. I have in vain endeavoured to effect a reconciliation with a neighbouring society. They still persist in their heretical condemnation of good cheer, and their devotion to the cup and saucer—forgetful of the words of Horace:—

'Nulla placere diu nec vivere carmina possunt,  
Quæ scribuntur aquæ potoribus.'

which I would freely translate—

No paper worth writing or reading can be

Produced by the man who drinks nothing but tea.

"My Chancellor of the Exchequer will call upon you for the taxes—or subscriptions—for the current year's expenditure; and he has announced his intention of being very strict indeed in making you pay up.

"A project of an increase in the taxation will be submitted for your discussion, the object of such increase being the purchase of a library and scientific instruments.

"My government has been for some time in correspondence with that of the Hartley Institute, with a view to obtaining a room for the purposes of this Society in the Institution building, which room, if granted, will be eminently serviceable as a library and reading room, and a receptacle for scientific instruments and museum; but will, I trust, never be the means of putting an end to our present agreeable mode of social meeting at each other's houses—than which I can conceive nothing better calculated to foster friendly feelings among the members.

"Gentlemen of the Finance Committee,  
"The account for the year will be laid before you in due course. The estimates have, I have no doubt, been framed with a due regard to economy, as usual.

"My Lords (that is, you who ought to be Lords) and Gentlemen,  
"During the past year our society has been blessed with a most plenteous harvest of excellently-written papers, agreeable meetings, and interchange of kindly courtesies. These, doubtless, will be continued during the present year. My views in relation to the advantages of this society, to the effects of good papers on the audience, and of good audiences on the papers, and to other matters, will be now laid before you.

"In bringing my introductory remarks to a close, I beg most sincerely to thank you for the honour you have conferred upon me, and to assure you that I feel highly flattered by the position in which you have placed me.

"It is no little honour to be chosen to fill the part of President of a large and influential Medical society; to preside over and direct the councils and debates of men, among whom are those who have attained a high position in the world's esteem; to sanction their acts; and to set a seal upon their proceedings. I will not—as is frequently done upon occasions like the present—speak of myself as utterly unworthy of, and unfitted for, the post to which you have appointed me; for, in the first place, I do not believe any man sincere when he thus decries himself; and secondly, if I did suppose you had so terribly stultified yourselves as to elect a totally incompetent President, it would be the height of rudeness in me to tell you so. Still I cannot help saying that you might have found to fill the office one who was not like myself a specialist; one who, residing upon the spot, could more frequently attend your meetings and contribute more largely to your transactions than can I. But since you would, I cannot say you nay; nor will I further occupy your time by preliminary remarks, but will at once proceed to the ordinary business of the evening; again thanking you for the honour you have conferred upon me, and assuring you, in all sincerity, that I will, to the utmost of my power, strive to carry out the objects of the society, which I conceive to be—to assist the progress of science, to support the honour and dignity of the Profession, and to promote good and kindly feelings among ourselves."

The paper of the evening, an elaborate and highly scientific discourse on the "Advantages of Medical Associations for the Discussion of Professional Topics," was also read by Dr. Bushnan; and this the Doctor pre-faced by stating that, descending from his high estate, casting aside his regal mask, doffing his mimic crown, and laying down his player-king's sceptre, he addressed his numerous audience in his proper person, and as one of themselves placed by their kindness and good-will in the enviable and honourable position of their President.

APPOINTMENTS FOR THE WEEK.

February 14. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.

ROYAL INSTITUTION, 3 p.m. W. S. Savory, Esq., F.R.S., "On Life and Death."

16. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.

MEDICAL SOCIETY OF LONDON, 8½ p.m. Lettsomian Lectures on Surgery—Lecture II.—Thomas Bryant, F.R.C.S., "On the Differences Between the Diseases of the Nervous, Respiratory, Circulatory, Digestive, and Urino-genital Systems of the Child and Adult."

17. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.  
ETHNOLOGICAL SOCIETY, 8 p.m. Mr. Crawford, "On the History of the Gipsies." Dr. Shortt, "A Brief Account of the Yenadies of the Chingleput District."

PATHOLOGICAL SOCIETY, 7½ p.m. Meeting of Council.  
ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Mechanics."

18. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.

19. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.

HARVEIAN SOCIETY, 8 p.m. Mr. H. W. Lobb, "On the Uses and Value of Electricity in General Practice, Practically Illustrated."  
ROYAL INSTITUTION, 3 p.m. Dr. E. Frankland, "On Chemical Affinity."

20. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.  
ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 p.m. Gulstonian Lectures—Dr. Pavy, "On the Amyloid (so-called) and Fatty Degenerations."

ROYAL INSTITUTION, 8 p.m. Rev. G. Williams, "On Recent Discoveries at Jerusalem."

WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON, 8 p.m. Dr. Anstie, "On the Therapeutical Value of Cod-liver Oil in Convulsive Diseases."

EXPECTED OPERATIONS.

King's College Hospital.—The following Operations will be performed on Saturday (to-day) at 2 p.m.:

By Mr. Fergusson—Tapping an Ovarian Cyst; Removal of Tumour from the Back.

By Mr. Henry Smith—Removal of Warty Growths from the Perinæum.

# NEPENTHE, OR ANODYNE TINCTURE.

OBTAINED EXCLUSIVELY FROM OPIUM.

Prepared only by FERRIS, TOWNSEND, LAMOTTE, & BOORNE, Manufacturing Chemists and Wholesale Druggists, Bristol.

Messrs. FERRIS AND COMPANY take leave to direct the attention of the Medical Profession to a selection from various reports upon the use of this most valuable form of Opium. NEPENTHE may be used with perfect safety in every case where an opiate is indicated; and, from the peculiar process by which it is prepared, it is deprived of all constituents which render the Tinctura Opii, and most other forms of opium, in numerous instances, wholly inadmissible. NEPENTHE is always of uniform strength, and, in this respect, possesses high advantages. It may be procured direct from the Manufacturers, Messrs. FERRIS and COMPANY, Bristol, or through the leading Wholesale Druggists in London, and from most respectable Dispensing Chemists in Great Britain and Ireland. Every bottle has a fac-simile of Messrs. FERRIS and COMPANY'S Signature pasted over the Cork, to imitate which is forgery.

The price of NEPENTHE to the Profession is 8s. per lb., and the dose the same as the Tinctura Opii.

## Report from F. PORTER SMITH, Esq.

I have pleasure in bearing testimony to the decided advantages possessed by Messrs. Ferris and Company's preparation of Opium called "Nepenthe" over other preparations of that important drug. I have used it for several years in Cancer of the Uterus, continuing it, with scarcely abated advantage, as a sedative, in one such case, for the long period of eighteen months, in doses of, at the utmost, half a drachm, which served the purpose to the end. I have used it in "Subcutaneous Injection" for Neuralgia, without producing any local irritation, such as abscess, &c. In the cases of unusually

severe "after-pains" in connexion with labour, I can strongly recommend and endorse its successful and satisfactory employment. I have never met with any unpleasant symptoms, such as sometimes occur in some constitutions after the administration of morphia, &c., during an extensive use of this valuable addition to that "Practical Pharmacopœia" which waits for no "imprimatur" from College or Council.

F. PORTER SMITH, M.B. Lond.,  
Everreech, March, 1862. Associate of King's College, London, &c.

\* \* \* Fresh Reports will be published in the Medical Journals from time to time.—Bristol, 1862.

## Pulvis Jacobi ver, Newbery

is the ORIGINAL & GENUINE, was ESTABLISHED A.D. 1746,

And is Prescribed, with the greatest success, "by the highest authorities," for Fevers, Ague, Cerebral Congestion, Rheumatism, Chills, Influenza, &c. &c.

FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.

Prices for Dispensing—1 oz., 9s.;  $\frac{1}{4}$  oz., 3s. 4d.

## WALTERS' INDIA-RUBBER URINALS.

F. WALTERS having originally invented these Urinals, begs to warn the Profession of the many bad and useless imitations which are now sold, and he would advise them, before purchasing, to look that they are stamped with his name; as, unless that be the case, he cannot guarantee them.

These conveniences are made for those who require them only occasionally, during a long journey, as well as for those invalids who use them always. Mr. WALTERS has much improved them by making them of *Etherised India-Rubber*, which adds very greatly to the strength of the India-Rubber, at the same time that it prevents its sticking together; by this means he is enabled to make them less stiff and harsh than hitherto, and yet to retain all the advantages of that stiffness. There is a patent valve which prevents the return of the fluid; and they may be worn either sitting, walking, or lying, without the slightest inconvenience, and without being perceived by any one.

WALTERS' CONVENIENCES FOR LADIES will be found particularly useful during pregnancy. They are perfectly soft and flexible, and may be worn with perfect comfort.

All Orders must be accompanied by a Post-office order or reference.—Entrance for Ladies at the private door, where a Female attends.

MANUFACTURER OF ELASTIC STOCKINGS, BELTS, &c.

16, MOORGATE STREET, NEAR THE BANK, LONDON, E.C.

TRADE MARK

# CHLORODYNE

WAS DISCOVERED AND INVENTED IN THE YEAR 1848 BY  
DR. J. COLLIS BROWNE M.R.C.S.L. EX. ARMY-MED. STAFF.

AND IN 1856 HE CONFIDED  
THE ORIGINAL AND ONLY FORMULA  
FOR ITS MANUFACTURE  
SOLELY TO J. T. DAVENPORT, PHARMACEUTIST,  
33, GREAT RUSSELL ST. BLOOMSBURY SQUARE, LONDON.  
REGISTERED, 1856.

## NOTIFICATION.

The attention of Medical Men is directed to the Piratical application, by some parties in the Trade, of the term "Chlorodyne" to various mixtures compounded of Chloric Ether, Opium, Indian Hemp, and Peppermint, in Imitation of the ONLY Genuine preparation of this name.

The dangerous expedient of encouraging or advocating the assumption of a name specifically indicating a particular property or remedy—such as *Chlorodyne* is to spurious imitations and substitutions—ON THE GROUND OF CHEAPNESS, is a subject of surprise and grave reproach, supremely so, when the adulteration, sophistication, and tampering with Drugs, becomes so serious and important a consideration in the successful practice of Medicine.

The fact of these Piracies must fully convince the Profession of the extraordinary efficacy of the Genuine Chlorodyne; whereas the sad results and disappointment arising from the use of spurious compounds cannot be expressed.

Each Genuine Bottle bears a Red Stamp, with the words, "Dr. J. COLLIS BROWNE'S CHLORODYNE," in White Letters.

To be obtained from all Wholesale Druggists in 1oz., 2oz., 4oz., and 8oz. Bottles.

## ORIGINAL LECTURES.

## LECTURES

ON

## DISEASES OF THE EYE.

DELIVERED AT

The Middlesex Hospital,

BY

SOELBERG WELLS, M.R.C.S. Eng., M.D. Edin.

Ophthalmic Surgeon to, and Lecturer on Ophthalmic Surgery at, the Hospital.

## STRABISMUS.

## LECTURE IV.

GENTLEMEN,—In my last lecture I described the manner in which the operation for strabismus is to be performed, and how its extent is to be regulated by the amount of the squint. I must now call your attention to various other forms of strabismus and affections of the muscles of the eye which may demand operative treatment. They present numerous and important peculiarities, but my time will not permit me to enter fully into these, and I shall, therefore, only point out to you the leading principles by which you should be guided in their treatment. We may arrange these affections under the following heads:—I. Periodic squint. II. Insufficiency of the internal recti muscles. III. Diplopia. IV. Secondary strabismus, following paralysis of the opponent muscle. V. Secondary strabismus, following tenotomy of the opponent.

I. *Periodic Squint*.—The most frequent causes of this are:—1. Hypermetropia. 2. Myopia. 3. Difference in the refraction of the two eyes.

1. *Hypermetropia*.—I have already mentioned that this is by far the most frequent cause of convergent strabismus, and that these hypermetropic patients squint, in order to increase their power of accommodation, for an increased convergence of the optic axes is accompanied by an increased power of accommodation. At first this squint is only periodic, not appearing, except when the patient is looking intently at some object, so that on a casual examination we may fail to detect it; but as soon as the patient's attention is directed to some near object, as in reading, the one eye moves inwards, this squint, however, disappearing again when the object is removed, or, perhaps, also when suitable convex glasses are placed before the eyes. In some cases the squint only shows itself when the person is looking at near objects; in others it appears whenever any object, near or distant, is regarded. If it is not operated, or the hypermetropia neutralised by the constant use of the proper convex glasses, it generally soon becomes permanent. Even after an operation the squint may recur if convex glasses are not worn.

The question now arises whether this form of periodic squint should be operated or not. I think the answer should be in the affirmative; for by dividing the internal rectus we diminish its power, and a greater exertion of this muscle will, consequently, be demanded, in order to bring the optic axis to bear again upon the object.

This extra exertion will be accompanied by an increased power of accommodation, as was the case before when the eye squinted. We shall, therefore, have combined an increased power of accommodation with a normal position of the optic axes. On examining such cases of periodic squint with prisms, we generally find that the internal recti muscles are abnormally strong, this preponderance in strength extending throughout the whole field of vision, so that the correct position of the optic axes, which may occur when convex glasses are interposed, is frequently forced. A carefully performed tenotomy of the internal rectus muscle is, consequently, productive of very favourable results. By advising an operation for this form of periodic squint, I do not propose to set aside the use of convex glasses for the treatment of the hypermetropia; I only think it beneficial to balance the strength of the muscles of the eyeball, and to restore their normal equilibrium, for this will be accompanied by increased facility and comfort in the use of the eyes, particularly for prolonged work at near objects. Whether or not both eyes will require to be operated on, will depend upon the amount of the squint, and the relative strength of the internal recti muscles.

I believe that the best treatment for this form of periodic squint consists in a careful tenotomy of the internal rectus, with subsequent neutralization of the hypermetropia by means of convex glasses. In some cases the question may, however, arise whether, by operating upon the periodic squint, we may not only free the patient from the deformity, but also obviate the necessity for spectacles; for, after the operation, the increased exertion of the accommodation in reading, etc., will be unaccompanied by a squint. This question arises chiefly with ladies, who desire not only to be freed from the squint, but also from the perhaps even worse evil, the necessity of wearing spectacles.

2. The periodic squint which occurs in the short-sighted generally only shows itself when the object is removed beyond the range of accommodation. As this squint disappears as soon as the myopia is neutralised by the proper concave glasses, it might appear unnecessary to have recourse to an operation, but yet we find that this greatly facilitates the continued use of the eyes for near objects. On excluding the affected eye from the act of vision by shading it with our hand, we find that it then moves inwards, even although the object is held within its range of accommodation; its fixation was, therefore, forced. On testing such cases with prismatic glasses, the internal rectus muscle is generally found to be abnormally strong. It is, therefore, necessary to weaken it, and thus restore the equilibrium, so that the strength of the different muscles of the eyeball may be evenly balanced.

3. Periodic squint may also be caused by a difference in the refraction of the two eyes: in such cases there is a constant endeavour to diminish the annoyance produced by the difference in the retinal images, by increasing the distance between the latter by a voluntary squint. Our purpose in operating is to render the deviation more difficult, and thus to urge the act of vision,—rather to endeavour to unite the images than to separate them still further. The strength of the muscles should, however, be previously tested with prisms, so that we may ascertain to what extent the tendon may be divided.

II. *Insufficiency of the Internal Recti Muscles*.—As this affection is far from uncommon, and is frequently most troublesome and harassing to the patient, perhaps even quite incapacitating him from following his avocation, it is of consequence that you should pay particular attention to its symptoms and treatment. Although I have already explained the former to you, I would just recapitulate the leading features of the affection. Such patients complain that, after they have been working or reading for a certain length of time, the eyes become hot and uncomfortable, the print grows dim, the letters become confused, and run into each other. This is generally preceded by a feeling of tension in the eyes, and some patients distinctly feel how the one eye becomes unsteady and wavering, and then gradually moves outwards. They, consequently, often anticipate these symptoms by closing one eye. You will observe that these symptoms of asthenopia are somewhat similar in character to those produced by hypermetropia; and it is an interesting fact, that these two causes of asthenopia (hypermetropia and insufficiency of the internal recti) occasionally co-exist. In such cases, it is found that, although the use of convex glasses certainly diminishes the asthenopia, it does not cure it, and that, in order to perfect the cure, we must have recourse to a tenotomy of the external rectus. In the treatment of insufficiency of the internal recti, it is of the greatest consequence accurately to ascertain the relative strength of the external and internal recti muscles. In order to test the strength of the abductor, we must proceed in the following manner:—The patient being directed to look at a candle placed at a distance of from six to eight feet, prisms of various strengths are to be placed, with their base inwards, before one eye, until we find the strongest with which he can still see the object single—*i. e.*, which he is able to overcome by a voluntary divergent squint,—a voluntary exertion of the external rectus muscle. When a prism is placed with its base inwards before one eye, the rays from the object will be deflected towards the base of the prism; they will, consequently, not fall, as in the other eye, on the yellow spot, but on a portion of the retina internal to the latter. Homonymous diplopia will, therefore, be produced; and, in order to escape from this, the eye will be moved outwards by the action of the abductor, so that the macula lutea is brought to the spot to which the rays are deflected by the prism. In this way the diplopia will disappear, but there will now be a divergent squint. We may easily ascertain the strength of the external

rectus by increasing the strength of the prism until the diplopia can no longer be overcome by a voluntary squint. To ascertain the strength of the internal rectus, the prism should be turned with its base outwards, for the rays will then be reflected towards the outer side of the yellow spot, and crossed diplopia will be produced. In order to remedy this, the internal rectus muscle will contract and move the eye inwards, giving rise, of course, to a convergent squint. In healthy eyes the internal recti muscles are far stronger than the abductors, and can overcome much stronger prisms by a voluntary squint. The internal recti can overcome prisms varying in strength from  $14^\circ$  to  $30^\circ$ , whereas the abductors cannot generally overcome stronger prisms than of  $5^\circ$  or  $6^\circ$ . In insufficiency of the internal recti this is completely reversed, for then the abductors may greatly exceed the adductors in strength.

This affection may be alleviated by the use of concave spectacles for reading, or by the use of prisms with the base turned inwards. But we can only cure it permanently by strengthening the internal recti muscles, either by constant exercises with prisms, or by a division of the external recti. The prismatic exercises only answer in very slight cases, and even then their use is generally so wearisome to the patient, that it is far better to have recourse to an operation. By dividing the abductor, we indirectly strengthen the internal rectus, for the latter will now have only a diminished resistance to overcome. Our chief aim must be to enable the patient to maintain, without difficulty and exertion, the convergence of the optic axes during reading, etc.

The distance at which he will require to maintain this convergence will, of course, depend upon the state of refraction of the eyes; if he is so short-sighted as to hold the book at six inches from the eyes, he should be able to maintain a steady convergence at five inches. To attain this must be our primary object, even although there may be after the operation a slight convergent squint for distance; for this will be remedied by the patient by a voluntary exertion of the abductor, in order to escape from the diplopia. The amount of convergent squint which may be left with impunity after the operation, must depend upon the relative strength of the internal and external recti muscles. The extent of the operation must vary with the strength of the internal recti; if they are exceedingly weak, and if the covered eye moves outwards to the extent of from  $\frac{1}{2}$  to 1 line, we may have to operate upon both eyes. But both should never be operated upon at one sitting: it is wiser first to operate upon the worst eye, and then, after a few days have elapsed, thoroughly to examine the position of the eyes during convergence, and to ascertain the strength of the muscles, and then, should it be necessary, to repeat the operation upon the other eye. Should the effect be too considerable you can then always limit it by a conjunctival suture.

III. *Operation for Diplopia.*—We are sometimes called upon to operate for the cure of diplopia, the deviation of the optic axis being, at the same time, perhaps, hardly perceptible. These form the most difficult and intricate cases, for here less depends upon mere manual dexterity than upon a complete mastery of the theoretical portion of the subject, and a thorough knowledge of the actions of the muscles of the eyeball and their effect upon the position of the vertical meridian. My space will not allow me to do more than mention the chief points to be considered in the treatment. We must, in the first place, ascertain in what directions prisms have to be turned in order to fuse the double images, and whether any active tendency exists to unite the images if they are closely approximated. We find that certain kinds of double images are far more difficult to unite than others. It is quite impossible to fuse images which are of a different height, except, indeed, this difference be of the very slightest, equalling a prism of  $1^\circ$ . Crossed double images again are far more difficult to unite than homonymous. If the double images show a difference in height, we must first endeavour to remedy this by an operation, and then, when this is cured, the patient may be able to fuse them if they are sufficiently close to each other. Should they be crossed, we must change them into homonymous, and approximate them closely to each other, so that they may be easily united.

IV. *Secondary Strabismus after Paralysis of the Opponent Muscle.*—Our treatment must vary with the amount of immobility in the direction of the paralysed muscle. Let us assume that, after a paralysis of the abductor, the immobility outwards amounts to from 1 to  $1\frac{1}{2}$  line, but that there is no

deviation inwards, so that the diplopia only extends up to the middle line, or but slightly into the opposite half of the field of vision. In such cases, a simple tenotomy of the internal rectus will generally suffice. If the immobility exceeds 1 to  $1\frac{1}{2}$  line, ranging between this and 2 to  $2\frac{1}{2}$  lines, a simple tenotomy will not suffice, and we must then bring forward the insertion of the paralysed muscle, and combine with this a partial tenotomy of the opponent. If the want of mobility in the direction of the paralysed muscle exceeds  $2\frac{1}{2}$  lines, we must bring forward the paralysed muscle, and, at the same time, divide its opponent completely. Our object in bringing forward the insertion of the paralysed muscle is to afford it an increased amount of power over the eyeball; for, the more anterior its insertion, the greater its power (a).

I will now shortly describe the manner in which Von Graefe's double operation of bringing forward the insertion of the paralysed muscle and of dividing its opponent, is to be performed. Let us assume that the internal rectus of the left eye is paralysed, and that we purpose bringing its insertion forward, and dividing the external rectus. As the operation is painful and tedious, the patient should always be placed under the influence of chloroform. The lids being kept well apart by the wire speculum, the insertion of the paralysed muscle is to be divided just as in the operation for squint, but its connexion with the sclerotic is to be more freely severed, and the connective tissue on each side of the muscle more freely incised. The conjunctival wound, though larger than in an ordinary tenotomy, should not be too considerable. We must carefully sever the conjunctiva from the superficial portion of the muscle. Although the latter will still adhere to the lateral expansions of the capsule of Tenon, it will be freely movable upon the sclerotic, so that the free end of the tendon can be brought up to, or even beyond, the edge of the cornea. In order to retain it in this position, the eye must be turned inwards as far as possible, and be immovably kept in this position until the tendon has reunited with the sclerotic at the desired point. We need not fear any ill-effect to the cornea, for its epithelial layer prevents any union between it and the tendon. We must next pass on to the tenotomy of the abductor. A large squint hook having been passed beneath the tendon, we take a silk thread, carrying a curved needle at each end, and thrust one needle from without inwards through the lower third of the tendon, so as to bring it out below the lower edge; the other needle is then to be passed in the same way through the upper third of the tendon. The free ends of the thread are then to be tied, so that the suture, which is situated between the insertion of the muscle and the hook, will include the two external thirds of the tendon. The tendon is then to be completely divided behind the suture, so that the latter is left firmly attached to the stump. The eye is then to be rolled inwards as far as possible, and is to be maintained in this position by the threads, which should be fastened firmly to the bridge of the nose by strips of plaister. In order to maintain perfect immobility of the eyes I generally bandage up the healthy eye. Cold water dressings are to be constantly applied so as to subdue any inflammatory symptoms. The threads should be left in for from twenty to thirty hours.

V. *Secondary Strabismus following Tenotomy of the Opponent.*—In bringing the insertion of the formerly divided muscle forward, we must dissect the conjunctiva somewhat more freely off from the surface of the muscle, and also divide the adhesion between the latter and the sclerotic more freely; in other respects the different steps of the operation are the same as in the last. The prognosis is, however, more favourable.

I have seen also some very successful results from Mr. Critchett's operation. This consists in dissecting off from the sclerotic all the parts covering the inner side of the globe (in cases in which a former operation for convergent squint has been followed by secondary divergent strabismus), including conjunctiva, subconjunctival fascia, old cicatrix and muscle, with condensed tissue around it. He next divides the external rectus, and finally passes sutures through the flap which has been raised at the inner side of the eye, and stitches this to the small portion of conjunctiva left standing at the inner edge of the cornea. In this way the whole muscular layer of the internal rectus is brought forward. My space will not, unfortunately, permit me to describe Mr.

(a) I must refer the reader for further information upon these points to Von Graefe's article on "Strabismus."—*Archiv.*, vol. iii.

Critchett's operation at length, and I would, therefore, refer you to his papers on "Strabismus," published in the *Lancet*, vol. i., 1855.

Von Graefe has lately performed a somewhat similar operation with great success. He dissects the conjunctiva carefully off the upper surface of the muscle, and then freely divides the latter from its sclerotic attachments, so as to make it quite movable upon the sclerotic. A suture is then passed through the free end of the tendon, which is brought forward and fastened to the slip of conjunctiva which has been left standing at the edge of the cornea. The opponent muscle may then be divided. I think that this mode of operating would prove particularly advantageous in cases in which we wish to bring forward the tendon of the external rectus; for, if the suture is passed through the tendon of the internal rectus, the latter would have to be divided rather far back, the conjunctiva and subconjunctival tissue would be too freely incised, and considerable sinking of the earuncle might ensue.

## ORIGINAL COMMUNICATIONS.

### CASE OF POISONING BY SULPHURIC ACID.

By EDMUND HEGINBOTHOM, M.D.

ON Wednesday, November 19, at 5.30 p.m., I was called to attend Geo. B., an itinerant draper or packman, lodging within fifty yards of my house, who was said to have taken vitriol for the purpose of committing suicide. On my arrival I found a druggist present, who recognised the man as having bought three ounces of spirit of vitriol at half-past three o'clock that afternoon.

The patient was dressed, with the exception of his coat and boots, was laying on his right side, with the knees drawn up and body bent forward, breathing slowly, and moaning as from pain; there was dark-brown froth issuing from the nostrils, and a discharge of stringy, copper-coloured mucus and froth was issuing from the dependant corner of the mouth and there were patches of the same about the bed-clothes; the mucous membrane of the mouth was white and ragged, and the tongue presented a dead white appearance; there were no stains of acid on the face, lips, or body clothes; there was neither vomiting nor purging. Tested with litmus the discharge from the mouth proved intensely acid, that from the nose almost neutral.

The surface of the body was cold and clammy; pulse small and quick; he was roused with difficulty, and when roused, resisted fiercely, saying, in a hoarse, muffled voice, "Let me alone—let me die."

Owing to his violence, it was extremely difficult to gag him, but we succeeded at last, and then, by holding his nose and using a funnel, he was drenched with a fair quantity of magnesia and water; he was then put to bed, covered with blankets, and heat applied to the extremities; but reaction never took place; he had two or three rigors, and died collapsed at half-past six, just two hours and a-half after taking the dose.

*Post-mortem Examination Fourteen Hours after Death.*—Rigor mortis present; the body that of a well-developed, exceedingly muscular man of about fifty; cadaveric lividity of the dependant parts of body. On opening the abdomen, the stomach was visible, of a bluish black colour, distended with gas, and the vessels on the surface black and prominent. No stains on any of the adjoining viscera; no fluid in the peritoneal cavity. The tongue, larynx, œsophagus, stomach, and duodenum were removed entire, and presented the following appearance:—The apex of the tongue had almost escaped injury, but the sides and body were white and leathery; papillæ prominent; fauces white; mucous membrane easily detached; epiglottis swollen. Œsophagus: mucous membrane brown, thrown into folds, and having a tessellated or worm-eaten appearance; no breach of surface or perforation. The stomach contained about a pint of thick, black, tenacious acid-fluid, and was lined throughout with a firmly-adherent black gelatinous coat, which could be scraped off with the finger-nail, but was not detached by washing or rubbing. This was darkest at the cardiac extremity, and gradually shaded off towards the pylorus, where it became brownish-black, and continued getting

lighter though the duodenum and commencement of the jejunum, where it terminated in apparently healthy intestine. The action of the acid was most perceptible at the cardiac end, where the coats were extremely thin, but there was no perforation. The glands at the pyloric extremity shone through the adventitious coat, and had the appearance and feel of small tubercle; no perceptible contraction of the pylorus. Lungs, heart, liver, and kidneys healthy. Brain not examined.

The quantity of acid taken in this case was six drachms, of specific gravity 1.848, diluted with eighteen drachms of water, and there was positive proof that it was taken at four o'clock or a few minutes after, and the unusually rapid termination of the case may, I think, be attributed to two causes—1. The acid being taken on an empty stomach; 2. The deceased having been constantly drunk for the last week or more, the system was in a depressed condition, and not able to rally from the shock necessarily caused by such extensive injuries as the post-mortem revealed.

Bruton, Somerset.

### TWO CASES OF ENLARGEMENT OF OVARY.

Reported by Mr. E. L. HUSSEY.

#### OVARIAN DROPSY—ABSORPTION OF THE FLUID—RETURN OF THE DISEASE.

A WOMAN, aged 35 years, was admitted on December 14, 1846, into St. Bartholomew's Hospital, under the care of the late Dr. Hue, with encysted dropsy of the abdomen, which, from the account she gave, had existed for about five years. She had been in the Hospital in December, 1845, under the care of the late Dr. Roupell, with the same complaint; she had been tapped at that time, and Dr. Roupell's opinion was that she was the subject of ovarian disease.

She was in a low and very weak state, with aphthæ on the inside of the lips and cheeks; she complained of severe pain in the abdomen,—and, indeed, she seemed to be sinking from exhaustion.

Nutritious diet was ordered, with wine; and opium was prescribed freely, to allay the pain.

Under this treatment, with rest in bed, the swelling of the abdomen disappeared completely; no tumour of any kind could be detected in the abdomen or pelvis, by external examination. She left the Hospital, in comparatively good health, on February 1, 1847.

She was re-admitted on April 22 following, with a return of the dropsy, and discharged on July 12. She was again admitted on August 14 (under the care of Dr. Burrows, I think). After being tapped, she died, with symptoms of peritonitis, on November 28, 1847.

The abdomen was examined by Dr. Ormerod (now of Brighton) and myself. The usual appearances of acute peritonitis were present. A single ovarian cyst, with thick walls, contained several ounces of purulent matter, with the mark of recent puncture through the walls of the abdomen.

#### ENLARGEMENT OF OVARY: THE CONTENTS DISCHARGED THROUGH THE RECTUM.

A woman, 40 years of age, mother of several children, the wife of the President's gardener in Kent, was admitted into St. Bartholomew's Hospital on December 31, 1845, under the care of the late Dr. Hue, complaining of occasional attacks of obstruction of the bowels, with great pain in passing solid fæces. Before admission she had been under the care of Mr. Gould, of Watlington, who considered that she was suffering from disease of the uterus or ovary. The left ovary, much enlarged, and very tender on pressure, could be felt in the iliac region as she lay in bed. Pills of calomel and colocynth, and afterwards calomel and jalap, were prescribed. These caused great pain in action, as did also an enema of warm water administered by the sister of the ward.

On January 26 she was seen by the late Dr. Rigby, in consultation with Dr. Hue. Upon examination per rectum and per vaginam, the left ovary was felt, enlarged and inflamed, pressing on the rectum, and pushing the fundus uteri into the right iliac fossa. Small doses of sulphate of magnesia, with dilute sulphuric acid, were prescribed, to be taken twice a-day, and some leeches were applied to the groin. Dr. Rigby wished the leeches to be applied within the rectum, by means of a tube; but from the difficulty in keeping the tube steadily pressed against the tumour this could not be done effec-

tually. The motions, being liquid, now passed without pain. A common enema was also occasionally given without causing any pain. She improved much in health, the pain ceased, and she thought herself well enough to return to her home in the country on February 14. The tumour of the ovary, though no longer tender on pressure, was little, if anything, less in size.

She continued in good health till the end of April, when Mr. Gould was summoned to attend her under a fresh and more severe attack of pain and constipation, attended with acute fever. This continued without relief for about a fortnight, when, after passing, per anum, what she described as some "thick and stringy stuff," she suddenly felt complete relief.

As soon as she was able to bear the journey, she was brought to London, and re-admitted into the Hospital, under Dr. Hue's care, on May 26, 1846.

The next day she was seen by Dr. Rigby, in consultation with Dr. Hue. Upon examination per vaginam and per rectum, the uterus was found to be slightly displaced, but free from disease. The left ovary could be felt, but neither so large nor so painful as formerly; it could also be felt, through the abdominal parietes, smaller in size, knotty, and rather tender on pressure. Small doses of sulphate of magnesia, with dilute sulphuric acid, were ordered to be taken freely, and five grains of extract of conium night and morning. An enema of warm water brought away much thick mucus and purulent matter. Six leeches were applied to the groin. Meat diet, with wine, was ordered. A slight attack of menorrhagia followed the examination.

She recovered her health rapidly. The pain in the rectum was seldom felt, unless when in the erect position, and after taking much exercise; and she became able to pass a solid motion without pain. She was discharged from the Hospital on June 21. The remains of the enlarged ovary could scarcely be felt by external examination.

She continued for some years in good health, without making any complaint, and without any return of the disease. Having removed to a distant part of the county, she passed from Mr. Gould's observation, and she died at Gravesend in the last winter. Dr. Sanders, under whose care she was in her last illness, tells me that she died under an attack of fever, with congestion of the brain. She never complained of any pain upon making pressure over the abdomen or pelvis, and he did not find any appearance of a tumour.

*Remarks.*—These short notes of the cases were taken at the time the patients were under treatment. In one case, the disappearance of the fluid for a time threw some doubt around the diagnosis; the return of the disease and the examination of the body showed the real nature of it. In the other case, in the absence of the proof which might, perhaps, have been obtained by a careful examination of the contents of the pelvis, the correctness of the diagnosis must rest mainly on the opinion held by Dr. Hue and Dr. Rigby, both of whom considered, throughout their attendance on the patient, that it was the ovary which was the subject of morbid enlargement.

Oxford.

ON

## FUNCTIONAL APHONIA.

By MORELL MACKENZIE, M.D. Lond.

Physician to the Metropolitan Free Dispensary for Diseases of the Throat and Loss of Voice.

THIS disease, which is generally supposed to be of an hysterical character, and, indeed, often goes by the name of "hysterical aphonia," is not usually attended with any considerable alteration in the character of the laryngeal mucous membrane. In some cases, the membrane, as seen in the laryngeal mirror, appears perfectly healthy and of normal colour, whilst in others there is slight general congestion or limited follicular disease. The same degree of congestion is often met with, however, where there is no impairment of function, and where there are no subjective symptoms of disease. The hyperæmia, therefore, which is sometimes present, is regarded merely as an occasional accessory, due, perhaps, to the same cause which produced the aphonia, or, perhaps, the slight local congestion may be secondary to the loss of function in the part. The vocal cords are seen to

approach one another, and, in many cases, become approximated in apparently the same way as when sounds are emitted.

There is another class of cases in which aphonia is present, namely, where there is profound anæmia, with great muscular debility. In these cases the mucous membrane is extremely pale, and the immediate physical cause of the aphonia is imperfect approximation and insufficient tension of the vocal cords. This form of aphonia differs from that under consideration, both as regards its nature and the treatment it requires, and it is only mentioned here for the sake of discriminative diagnosis.

Pure functional aphonia, for the most part, affects girls or young women under thirty. The general health is almost always good, the patients are well nourished, and the muscles firm; there is usually no irregularity in the menstrual function. The local condition of the larynx has already been described.

Though this disease is often considered to be a form or symptom of hysteria, none of the patients who have come under my observation have been of the hysterical temperament. In none of them have there been any of the common and acknowledged phenomena of that disease. On the other hand, during eight years' daily attendance on Hospital practice, of the numerous cases of hysteria that have been seen, none have been affected with aphonia. If all those diseases in which there is functional derangement, without any palpable organic disease, are to be called hysterical, with an equal regard to scientific truth, the term might be applied to many cases of dyspepsia, tetanus, and other diseases where the ætiology is at fault.

The disease probably depends on an irregular or perverted distribution of the "nerve force," but it is better to be guided by the principles of positive philosophy, and merely recognise phenomena, than, carried away by an ambitious desire to penetrate the essence of things, to assume the operation of causes which cannot be shown to have had any actual existence (a). The want of success often met with in treating these cases must have annoyed every Practitioner who has had to deal with them; and in recommending the application of galvanism to the vocal cords, in cases of simple functional aphonia, as a remedy at once rational, safe, and certain, it is believed that another item has been added to the category of positive therapeutics.

The two cases reported below have been selected from among others, where the treatment was not less successful, because the patients were both for a long time in the London Hospital, and are well known to several of the Physicians and Medical pupils. In neither case was there a single symptom of hysteria. It is to be observed, though no particular importance is attached to the fact, that magneto-electricity has always been used in applying galvanism to the vocal cords.

In employing galvanism, one sponge was placed externally over the thyroid cartilage, and the other introduced into the larynx with the aid of the laryngoscope, and applied to the vocal cords (first to one and then to the other); this sponge was also carefully placed in the posterior surface of the arytenoid cartilages, where, in consequence of the connexion between the superior and inferior laryngeal nerves, it is easy to stimulate both branches.

*Case 1.*—Sarah S., a healthy, fresh-coloured young woman, aged 25, living at High Wycombe. She first lost her voice in March, 1861, "after inflammation in the throat," as she states. In September, 1861, she became an in-patient in the London Hospital, and, though a laryngoscopic examination did not detect any local disease, every kind of treatment—topical and general—was industriously tried. Blisters were applied to the throat, and galvanism was used externally—the current being passed right through the neck. The anti-hysterical *regimè* was strictly enforced, cold shower baths were used daily, and a generous diet allowed. After persevering for three months in this plan, no benefit having resulted, the patient was discharged.

In January, 1862, she was again admitted into the London Hospital, and, though the same severe system was not pursued, the larynx was swabbed every other day with strong solutions (ʒj. ad ʒj.) of nitrate of silver, the laryngoscope being

(a) In one of the cases related by Rühle, in his comprehensive work on "Kehlkopfkrankheiten," the so-called hysterical aphonia, which had resisted every kind of treatment, disappeared after an epileptic seizure. Does not the termination of the disease point to a different ætiology than its nomenclature indicates?

used to ensure its proper application. Though, perhaps, not strictly in accordance with the rational requirements of the case, this method of treatment seems to have proved useful (in the so-called hysterical aphonia) in the hands of M. Trousseau. In this case, however, it was abandoned after a month's unsuccessful trial, and the patient left the Hospital unrelieved.

At the end of September, 1862, my connexion with the London Hospital having ceased, the patient again came under my care, and this time I resolved to try the diffusive method of cauterising the larynx. My friend, Mr. Thompson, the inventor of the hydro-pneumatic injecting apparatus, was kind enough to use his highly ingenious instrument on my patient. I was induced to try this plan of treatment from the apparent success which has attended its use by Mr. Thompson in similar cases. It must be stated, though, that in the cases in which that gentleman was successful, the exact diagnosis was not verified with the laryngoscope. This method of injection was employed every other day for some weeks, and, whilst the patient was under treatment, her friends thought that she once spoke a word out loud. She, however, was not aware of it. The injections were industriously continued, but, as the patient did not regain her voice, she returned to the country.

In the beginning of January, 1863, she again came under treatment, and this time I determined to apply galvanism to the vocal cords. After internal galvanism (which was used daily) had been repeated twice, the patient spoke for half-an-hour. After galvanism was applied on the fourth day, she recovered her vocal powers for some hours, though the voice became feeble in the evening.

At the end of a week she completely regained her voice, and since that time it has remained as perfect as it was before she lost it two years previously.

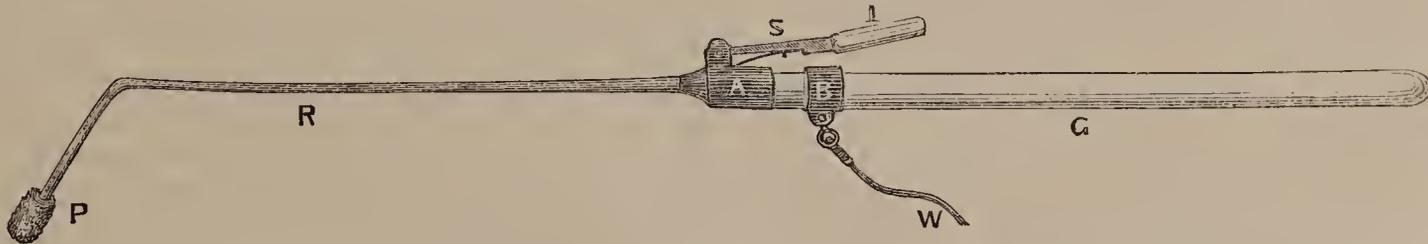

*Case 2.*—Emily M., aged 18, a tolerably robust, healthy-looking girl, living in Shoreditch. She lost her voice suddenly in September, 1861. On getting up one morning she found that she was unable to speak out loud, though the night before her voice was as good as usual. She had no pain in the throat at the time, nor has she ever suffered from

any irritation of the larynx since she was first affected. This young woman was in the London Hospital for some months, and every kind of treatment (including external galvanism and local cauterisation) was tried in vain.

On January 6, after this patient had suffered from complete loss of voice for sixteen months, galvanism was applied to the vocal cords. Whilst galvanism was being applied for the second time, the voice returned during the operation; within an hour, however, the voice was again lost. After the third application of electricity, the voice was recovered altogether. The galvanism has been applied once or twice since, but the patient is now completely cured.

In the application of galvanism to the vocal cords, considerable difficulties had to be contended with. The irritability of the larynx is such, that it does not allow sufficient time to set the current going after the sponge has been passed below the epiglottis. Again, if the current is passing along to the sponge, before the latter is introduced into the larynx, however carefully the rod is covered with a non-conducting substance, in introducing the instrument, it is very difficult to avoid touching some spot above the larynx. This causes the patient to start and withdraw, and afterwards it is almost impossible to reach the larynx. The woodcut shows the instrument (b) which will be found to obviate these difficulties. The instrument is twice the size of the cut. The current is set going, but does not pass beyond a certain distance (the metal ring B), until the operator has introduced the point (P) into the larynx, when he touches the ivory handle (I), and the spring (S) connects A and B, so that the current then passes on to the vocal cords.

As a corollary to this communication, it is suggested that galvanism might be advantageously applied to the vocal cords in the early stages of clergyman's sore throat. There is no doubt that, in this disease, the nerves are affected primarily before any deposit takes place in the follicles; and though the disease has been hitherto supposed to commence in the fauces and proceed downwards into the larynx, the laryngoscope shows that, though organic change sometimes commences coevally in the larynx and pharynx, it more often originates in the vocal cords, and is at first a purely nervous affection.

A and B, two rings of metal, separated by an intervening portion of glass rod. There is a permanent metallic connexion between A and B, the metal spring which connects A and B, when I, the ivory handle, is pressed upon. R, conducting rod, covered with gutta-percha. G, glass handle. P, point covered with sponge. W, wire, which connects the instrument with galvanic machine.

## REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

### ST. BARTHOLOMEW'S HOSPITAL.

#### CASE OF FRACTURE OF BASE OF THE SKULL— DEATH—AUTOPSY.

(Under the care of Mr. PAGET.)

FOR the notes of this case we are indebted to Mr. Best:—

W. R., aged 35, a powerfully-built man, a carpenter, and of intemperate habits, was admitted into St. Bartholomew's Hospital, on Monday, November 3.

About two hours previous to his admission, and while at work, he is said to have fallen from the height of about ten feet upon some timber. He was not actually seen to fall, so it is uncertain upon what part of his body he was struck; he was found, however, lying on his stomach, in an unconscious state. He gradually recovered consciousness, and, as he was bleeding from the left ear and complaining of pain in the back, was brought to the Hospital.

At the time of his admission he was able to answer questions rationally, though slowly and somewhat confusedly; was very restless, and complained of great pain in the dorsal and lumbar regions. There were no external marks of violence on the head, with the exception of a slight bruise over the

occipital and right parietal bones; there was, however, a continuous and tolerably free discharge of blood from the left ear. There was no loss of motion or sensation in any of his limbs. Pills of calomel and jalap were given, and a black draught next morning.

November 3, 10 o'clock p.m.—He was very sick after the pills, and about 6 o'clock p.m. became delirious and very restless, complaining of more pain in his back. Shortly afterwards, he was seized with a convulsion of a distinctly epileptiform character, preceded by a scream, and this was followed by three others of a similar character, at intervals of ten to fifteen minutes. His head was shaved about 7 p.m.

At the present time he is very violent, and endeavours to get out of bed, so that it is necessary to confine his limbs with straps. He lies scarcely sensible; both pupils are dilated and inactive; and the bleeding from the ear still continues. Breathing natural. Pulse small and quick. Skin hot and perspiring. It was found on inquiry that he had never before suffered from epileptic fits.

4th.—Passed a restless night, and this morning he still lies in a drowsy, barely sensible, state. Lips, teeth, and tongue dry; eyes closed; breathing heavily and rather noisily, but not stertorously. He can be roused by speaking to him, touching his conjunctivæ, etc.; and when roused he stares anxiously about him, but almost immediately closes his eyes again, moaning. The hæmorrhage from the ear is now suc-

(b) This instrument has been made in a very neat manner by Mr. Krohne, of the Whitechapel-road.

ceeded by the continuous flow of a clear, pinkish fluid, not coagulable by heat. There is no loss of power in the limbs, but the sensation seems somewhat impaired, but very slightly. Skin natural; pulse 60, of good volume, and steady. He has taken a moderate amount of food. No more sickness has occurred. Bowels not open.

7th.—Since the date of the last note there has been a gradual but very slight improvement. Though lying for the most part in a semi-conscious state, yet he can be roused more readily, and takes more notice of those about him. He has passed tolerably quiet nights, with the exception of last night, when his bowels were opened three times (after five grains of calomel), and each of these times he got out of bed of his own accord. The discharge from the ear still continues, but less freely. Skin, pulse, and breathing almost or quite natural. Tongue clean and moist. Takes his food (beef-tea, milk, etc.) better, and seems to express a desire for it by making signs. He has not spoken since the evening after the accident. He has made signs, also, of feeling pain between the shoulders.

10th.—During the last three days there has been a change for the worse. The discharge from the ear had quite ceased on the 8th, and in the latter part of that day he again began to suffer from convulsions, differing only from the first in not being preceded by a scream, and in being, on one or two occasions, confined to the right side of the body. These have continued up to the present time, occurring frequently, but at irregular intervals. Yesterday, in the intervals of the fits, he seemed rather more sensible, looking as if he understood what was said to him, but either could not or would not speak. He would put out his tongue and move any limb when told to do so. This morning, however, he looks pale, anxious, and unsteady, rolling his eyes about, and seeming but half-conscious when spoken to: he is constantly working his fingers and turning over uneasily in his bed. Sensation is not so good. Skin natural; pulse 96 and jerking. Bowels open last night; urine passed involuntarily, as it has been almost since the accident, though he has occasionally got out of bed to pass it. He has taken but a moderate quantity of beef-tea and milk.  $\mathcal{R}$  Hydrarg. chlor., gr.  $\frac{1}{2}$ ; ext. belladonnæ, gr.  $\frac{1}{6}$ , to be taken every two hours.

12th.—His bowels were freely opened by the pills, which were discontinued after he had taken them twelve times. The fits were much less frequent and severe yesterday. To-day he has had but one. He spoke a few words on the evening of the 10th, which was the first time since the day after the accident, and this morning he speaks well and rationally, but hurriedly, when addressed. He seems much better, not, however, looking composed, but lying with a flushed and unquiet aspect and unsteady eye. Slept well last night, and says that he is "all right;" has taken beef-tea and arrowroot in fair quantity, and one egg. Bowels opened again freely yesterday, and urine passed naturally.

14th.—He has had no more convulsions, but yesterday afternoon he again changed for the worse. He has been very restless, getting out of bed and walking about the ward, so that it was necessary again to confine his arms. He is now lying with his head thrown back on the pillow; his face paler and duller, and is incessantly muttering, talking, or singing. He comprehends less, apparently, of what is said to him—putting out his tongue, however, if asked to do so, and occasionally answering questions. He did not sleep at all last night. Pulse of fair volume and strength, but variable, being 112 in the morning and 90 in the afternoon. Skin cool and relaxed, temperature being 100 in the axilla. Tongue drier, but not much furred. Has taken some beef-tea and arrowroot. Bowels freely opened after repeating the pill of calomel and belladonna six times. Fæces and urine passed involuntarily. Six ounces of wine were ordered.

16th.—He has not slept now for three days, and, in other respects, has steadily become worse, being less conscious, more restless, and constantly delirious. He has had no fit since the last note. His face is flushed, dull, and sweating; eyes restless and wandering; lips dry and sore from herpes; sordes on the teeth; is constantly moving his fingers about in a fidgety manner; speaking occasionally, but thickly and indistinctly. A clear, colourless fluid again began to flow from the left ear yesterday (this fluid, on analysis, was found to contain albumen in large quantities, alkaline phosphates, and a little chloride of sodium; no fibrin, gelatine, urea, or sugar were detected). There is no paralysis of the face, arms, or legs. Pulse 120, feeble and small; breathing 36; tem-

perature in the axilla 101; tongue brown and dry; bowels opened freely last night; urine and fæces passed unconsciously. Has taken beef-tea and milk, with wine  $\mathfrak{z}x.$ , in the twenty-four hours. Ordered to take fifteen drops of tincture of opium every two hours until he sleeps.

18th.—The only change observable yesterday seemed due to the opium, the influence of which became very marked after the third dose; and after he had received the fourth dose its exhibition was discontinued. He lay dozing and sleeping during the greater part of the day, with a flushed but quiet face, and no restlessness. Pulse 126, and soft. Temperature in axilla 101 $\frac{1}{2}$ . This morning the effect of the opium has gone off, and he has had three fits, preceded by gaping, but not by a scream. He lies now quite quietly, and without any of the restless movements either of the head, eyes, or limbs, which had been so evident up to yesterday. His face is flushed, slightly sweating, and very heavy and dull; eyes closed; the only sign of intelligence being an attempt to put out his tongue when told to do so in a loud voice, and an occasional semi-conscious look. Discharge from the ear continues. He has dozed or slept during the night. Skin relaxed and perspiring. Temperature 101 $\frac{3}{4}$ . Pulse 132, feeble. Breathing 36, and very shallow. Tongue dry. Takes nourishment with some difficulty and in small quantities. Bowels opened freely. Urine passed unconsciously.

19th.—This morning he lies quietly with his head on its side and thrown back; face flushed; eyes half open, and giving no indication of consciousness, his only movements being those of respiration, which are quick, regular, and shallow, over 50 in the minute. Pulse 144, small, soft, weak, and tremulous. He has taken a small quantity of wine and beef-tea in the night, but has now been unable to swallow for several hours. Bowels quiet. Urine passed unconsciously. Skin hot and sweating. Temperature in axilla 105. The discharge continues to flow slightly from the ear, and he has had several fits since yesterday—the last occurred at twelve o'clock to-day. Died at 6.30 p.m.

*Post-mortem Examination Seventeen Hours after Death.*—In cutting through the skull cap in the usual manner nothing unusual was to be observed, unless that the bones were thin, and particularly that part of the occipital bone which is included between the superior and inferior curved lines—the bone in this situation being quite translucent. The surface of the brain was much congested, and smeared over, especially at its posterior lobe, with a quantity of extravasated blood, mixed with puriform lymph, both on the free surface of the arachnoid, and between the arachnoid and pia mater. On removing the brain a considerable quantity of blood was found extravasated in two places at the base of the skull, on the inner surface of the dura mater, one of which covered the space occupied by the posterior and lower part of the left cerebral hemisphere, and extended forwards to the anterior edge of the "tentorium cerebelli" on this side; the other, and, apparently, distinct extravasation, was also on the inner surface of the dura mater, and covered the left orbital plate of the frontal bone. In the latter spot the blood was broken down, soft, and grumous-looking, as if it had been effused for some time; and the portion of the anterior lobe of the brain in contact with this extravasated blood was found to be cracked and ecchymosed. (For further account of the appearance of the brain see next page.) On taking off the dura mater and carefully examining the base of the skull two discontinuous cracks were discovered. The first began at the posterior part of the occipital bone, about an inch to the right of, and somewhat below the torcular Herophili, and passed almost straight downwards towards the foramen magnum, where it finished by dividing into two, as it were, and thus making the bone comminuted. The other crack began with some comminution on the left margin of the foramen magnum, and, after first passing outwards as a single crack, took a more straight direction forwards, and passed almost transversely over the petrous portion of the temporal bone, and, after passing down the anterior surface of the petrous bone, finished at its anterior border in the upper wall of the tympanum in a slightly starved manner. Between the dura mater and the petrous bone, in and near this spot, a small quantity of clotted blood was found, but no opening in the dura mater could be found in any part. In order to examine the bones more carefully, the whole of this part of the base of the skull was removed by including the petrous bone between two cuts, one transversely across and in front of it, to the

sella turcica, the other obliquely behind it into the foramen magnum, the two being joined by sawing straight forwards through the basilar process of the occipital and sphenoid bones, from the foramen to the sella turcica. After the removal of the bones, the upper wall of the meatus auditorius internus was removed by bone-nippers, and the cut extended up to the point at which the fracture crossed the bone. It was then found that the latter had not cracked the meatus, but had extended quite through the bone immediately in front of the cribriform plate, through which the auditory nerve enters the internal ear, and thus had cracked the vestibule, and laid open the orifice of one of the semicircular canals. The nerves in the meatus (the facial and auditory) were apparently quite uninjured. On the inferior surface of the bone the crack was found to run from the foramen magnum, behind the condyle of the occiput, then transversely outwards at about mid-distance between the mastoid process and the jugular foramen, and so on through the vaginal process up to the wall of the tympanum and membrana tympani. This lower crack was but the lower part of a fissure through the whole thickness of the bones, of which the upper part has been previously described with the base of the skull. The membrana tympani was found ruptured in two places; and from the upper surface of the base of the skull a fine probe could be passed from the anterior end of the crack downwards through the cavity of the tympanum, and out again through the hole in the membrana tympani.

*Appearance of the Brain.*—There was a quantity of lymph effused between the layers of the arachnoid, especially about the fissures at the base, and in chief between the cerebrum and cerebellum over the crus. Also beneath the visceral arachnoid, and chiefly in the valley of the cerebellum. The vessels of the pia mater were congested, with numerous ecchymosed spots. The substance of the cerebrum was generally soft, pulpy, and over-vascular, with extravasation of blood over the anterior and posterior extremities of the left hemisphere, and also at an isolated spot corresponding with the upper surface of the left petrous bone. The substance of the cerebellum was tolerably firm. That of the medulla and of the pons was greatly congested. As regards the contusions of the cerebrum, the posterior and middle were superficial; the anterior one, however, reached to the extreme depth of one inch, irrespective of the convolutions, and measured superficially two and a-half by one and a-half inches. The brain-substance was here much softened and rust-coloured on the outer half inch; less softened, and mottled with ecchymosed spots, on the inner half. The ventricles contain some puriform fluid, and flakes of softening lymph; their capacity was enlarged, and their walls, towards the posterior horns, were somewhat congested. The septum was broken down and softened, as also was the formix. There was some soft lymph effused about the Pineal gland, and on the under surface of the velum interpositum. The lining membrane of the fourth ventricle was congested, and particularly about the situation of the hypoglossal, glossopharyngeal, and pneumogastric nerves of the left side.

#### NOTES OF A CLINICAL LECTURE ON THE ABOVE CASE.

(By Mr. PAGET.)

This patient was admitted into the Hospital stunned. In a little time he recovered his consciousness, but shortly afterwards again became unconscious. The first stage is from the shock of the injury. It may be followed by complete recovery, and is generally followed by consciousness for a time, which is the second stage. When the patient passes into unconsciousness for the second time, this corresponds to the filling of the vessels in the brain, and probably to effusion of serum. This is the third stage. These stages may be illustrated by simpler forms of injury, as, for instance, a blow on a muscle. The muscle is for a time stunned by the blow, but after a while regains power, but when it becomes inflamed from the after effects of the blow the patient either cannot or will not use it.

In this case, the subject of these remarks, when the patient had recovered from the stun, he answered so rationally and seemed so well that there appeared nothing further to fear. Six hours later he became restless, then delirious and convulsed. There had been no remission of symptoms since.

There was bleeding from the ear for two days, and then a pinkish fluid drained away. It was not the serum of the blood (as it did not coagulate by heat), but probably cerebro-spinal fluid. The symptoms were those of fracture of the

base of the skull, but there was no convincing and certain sign of this.

Mr. Prescott Hewett, in Holmes' "System of Surgery," has (Mr. Paget said) treated the subject of injuries to the head in an exhaustive manner, and has cleared up many obscurities.

Bleeding from the ear is a sign of fracture of the base, which is of great value, and is generally to be relied on. Yet Mr. Prescott Hewett has brought forward two cases in which there was this symptom, and no injury through into the cranial cavity. The fluid in these cases must have flowed from the mastoid cells or from the tympanum.

What is the treatment of fracture of the base of the skull? As regards the fracture, all we can do is to leave it alone. Occasionally, recovery will take place. As regards the damaged brain, do nothing but shut out all possible sources of mischief. For instance, keep away all possible causes of excitement. Just as we would keep a hurt joint quiet, so we ought to keep a hurt brain quiet. When the patient even looks or thinks, or is roused up, it is like moving the injured brain. In private practice it is difficult to keep the patient quiet, but in hospitals this can be more easily managed. The friends of such patients almost insist on something being done. This question of treatment may be illustrated by the way in which we treat an injury elsewhere, as, for instance, a bruised muscle. There is nothing to do but to keep it at rest. Would it occur to any one to bleed here? And yet it occurs to men of sense to bleed because a man has hurt his brain. What good would it do in injury to a muscle to give mercury? And yet it seems not unusual to give mercury in injuries to the head. Of course there are cases in which there are distinct indications for this kind of treatment. Its adoption as a matter of routine in injuries to the head was to be deprecated. If (Mr. Paget said) the Surgeon is not prepared to give mercury in bruised muscle, he has no ground whatever for giving it in injury to the brain. If, however (he continued), his patient had had symptoms of inflammation, he would proceed to treat it, but as yet he had had no symptoms of the kind. Delirium, convulsion, or other symptoms of cerebral disturbance, are not sufficient alone to establish the diagnosis of inflammation of the brain. The signs to be relied on are those that would indicate inflammation elsewhere—the pulse full and rapid, breathing rapid, skin hot, and the organs of sense acute, and the pupils acting more rapidly. If these symptoms are not present, we ought not to bleed or give mercury, on account of delirium or convulsions, or other symptoms of cerebral disturbance.

What we ought to do is, as before mentioned, to keep away from the patient all possible sources of excitement. We ought also most carefully to attend to the bowels and to the digestive organs. We should keep in mind that the patient can digest little, and, therefore, give but little, and that generally fluid. If the general health should flag, then we should give wine.

In another clinical lecture, Mr. Paget again alluded to this case. He again said that there were no certain signs of fracture of the base, and, as pointed out before, the escape of serous fluid from the ear was not a certain one. Even if there were paralysis of the portio dura, it did not follow that there was fracture through the petrous bone. He had (he said) seen a case of paralysis of this nerve and of bleeding from the ear, following an injury, and yet the patient recovered quickly, and had no head symptoms at all. Another case, lately in the Hospital, also showed this. A man came in with paralysis of the portio dura, with bleeding from the ear, following an injury to the head. The bleeding soon ceased, but the paralysis of the face was permanent. Otherwise he was well.

Again, no amount of cerebral disturbance showed that there was inflammation, and that, therefore, special treatment was required. In this case, for ten or eleven days, the man's breathing and pulse were not quickened, and there was no paralysis except of the bladder. There was no general indications for treatment, and nothing, therefore, was done but to shut out all excitement. On the eleventh day after the injury, along with increased cerebral disturbance, the pulse, which had never been frequent, became rapid, and at 10 a.m. was 112, and at 3 sank to 90. The pupils were dilated and the skin natural. Although the pulse was quicker, it was feebler. This showed that some important changes were taking place in the brain. Six ounces of wine were ordered, and next day, his

pulse having risen to 140, ten ounces. He had not slept for three nights, and, therefore, fifteen drops of tincture of opium were ordered. Having taken this three times he slept for twenty-four hours. This appeared hopeful, but he awoke in the same state as before, and died soon after.

It was found, at the *Autopsy*, that the anterior lobes of the left hemisphere had been bruised (the blow was on the *right* side of the occiput). The brain in the neighbourhood of the bruise was softened, and there were spots of ecchymosis in various parts. There were tracks of purulent lymph along the course of the veins of the pia mater. In the ventricle there was an increased amount of fluid, which also contained some pus. These changes, no doubt, began on the eleventh day, when the man's condition changed, when his pulse quickened.

In reference to treatment of inflammation following injuries, Mr. Paget said, that if the symptoms set in soon after—*e. g.*, within the first two or three days of an injury, or of an operation—we might bleed or depress the patient, or at least refrain from stimulating him. But, when the symptoms set in later—*e. g.*, as in this case, on the eleventh day—then clearly the inflammation was an asthenic one. It was analogous to erysipelas setting in some days after an operation. If, after an amputation, we find tenderness and swelling of the stump within two days, we may treat it with depressing means, apply leeches, or cold lotions, or, perhaps, rather, merely keep the patient quiet, and refrain from stimulants and full diet. But if on the eleventh day the stump were to inflame we should treat the patient with good diet and stimulants. Just so in injuries to parts we cannot see. If after ten days signs of inflammation set in we ought to give wine, just as we ought in erysipelas of the scalp setting in at that time. In fact, we ought to be guided by the time when the symptoms set in, as well as by the symptoms themselves. The man's breathing was more frequent, but it was more shallow; his pulse was quicker, but it was more feeble, so that everything indicated stimulants. That the treatment was unsuccessful does not necessarily show that it is wrong. In fractures of the base of the skull, if we save one in twenty, we should do very well indeed.

It was found that on the right side the bone had been broken. The fissures passed through the expanded part of the bone into the foramen magnum; but on this side it did not reach the petrous bone. Then, beginning at the left of the foramen magnum, a fissure extended outwards and forwards to a point just external to the jugular foramen. It then passed across the middle of the petrous bone, just external to the meatus auditorius internus. It passed through the vestibule, and broke into one of the semicircular canals. Both divisions of the seventh (facial and auditory) had escaped injury. On cutting away the upper wall of the external auditory meatus, two rents were found in the membrana tympani, or rather, as seen, they were oval holes. Just as an aperture from a slit in an artery becomes round, so also in this muscular membrane rents become round.

Several ounces of clear fluid had flowed from the ear during life. As to the source of this, it was in a great majority of cases cerebro-spinal, but it might be from the vestibule, or from the mastoid cells. In this case, the dura mater was intact, so that cerebro-spinal fluid could not have passed through the fissure. The fracture had not torn into the sheaths of the nerve, so that the fluid contained in the pia mater, accompanying these into the meatus internus, did not from this point pass along the fissure into the tympani, and then through the hole in the membrana tympani. In this case, then, the fluid, no doubt, came from the vestibule.

### GUY'S HOSPITAL.

#### INJURY TO THE HEAD—BLEEDING FROM THE NOSE — DEATH — AUTOPSY — FRACTURE THROUGH THE ETHMOID.

(Under the care of Mr. POLAND.)

In this case the cause of the accident was rather an unusual one:—

A man was brought to Guy's Hospital; he had put his head out of a railway-carriage window whilst the train was in motion, and his head came in contact with some stationary object. He lived twenty-four hours. He did not show any signs of compression. Blood flowed into his nose and pharynx.

At the autopsy, a fracture was found on the left side of the frontal bone. It traversed its orbital plate, the posterior part of the ethmoid, and sella turcica of the sphenoid. There was a fissure here one-fifth of an inch wide, and the dura mater in this position was separated from the bone, to a limited extent, by clotted blood. There was much blood between the pia mater and the arachnoid. The anterior and middle lobes of the cerebrum were much crushed and bloody.

#### INJURY TO THE HEAD—APPARENT RECOVERY IN A FEW DAYS—SUPERVENTION OF HEAD SYMPTOMS SEVERAL WEEKS LATER—DEATH IN TEN DAYS—AUTOPSY.

(Case under the care of Mr. POLAND.)

This case shows that, after apparent recovery from injuries to the head, the patient is still in danger. He may appear perfectly well, and be suddenly seized with cerebral symptoms and die. Sometimes, however, as in a case under the care of Mr. Laurence, in St. Bartholomew's Hospital, the patient may be liable to repeated attacks of delirium, attended with violent pain in the head. In this case there was deafness on one side and discharge from the ear. It followed an injury to the head received some months before. Numerous cases are on record, and we have reported several in point.

Sometimes, as in the second of a series of cases of abscess in the brain, related in this Journal, February 23, 1861, the symptoms may begin some months after the accident. In others, as in the first of that series, the abscess may form soon after the injury. Still, in that instance, the man was reported as progressing favourably until ten days before his death, which occurred just a month after the accident. In Mr. Poland's case, which we give below, the man died six weeks after the injury, but had apparently recovered from the accident, and had returned to work. The symptoms of the morbid processes, the immediate cause of death, were not noticed by him until eight days before death. The position of the injury is also interesting.

E. J. C., aged 20, was admitted on October 29, and died November 2. This patient was admitted about six weeks ago into Luke's ward, under the care of Mr. Hilton, for concussion of the brain after a fall on the head. He went out tolerably well after some days, and resumed his work. About four days before admission, cerebral symptoms came on, and he again entered the Hospital. He was in a drowsy and semi-comatose state. He died November 2.

*Autopsy, by Dr. Wilks.*—There was no mark of external injury, nor was any found on removing the scalp, and the dura mater under the skull-cap was sound. The surface of the brain was healthy; but on attempting to remove the brain the anterior lobe was found to be adherent over the cribriform plate and the orbit, and was consequently torn. The brain was of an ochry colour and very soft; the cineritious matter being most affected, the medullary but little. On taking out the brain, a quantity of tenacious green lymph was seen at the base covering the optic commissures, pons, etc.; it extended beneath the arachnoid to the cord. The medulla spinalis was found thickly covered with lymph throughout its whole length. The ventricles contained opaque fluid, and their surface was covered with a thick inflammatory exudation which could be scraped off with the knife. The fornix was much softened. At the spot where the brain was adherent, near the inner angle of the orbit, there was a depression, a hollow space about a quarter of an inch in diameter. At one edge of this was an opening which passed into the orbit. There was no appearance of caries, its edge being smooth and firm, and at its lower part it was hard and smooth, like new bone. Near it, on the outer side, was a slight furrow, which might have been a fracture of the internal table. Dr. Wilks adds to the above:—If the appearance here seen had resulted from injury, repair had taken place very quickly. The opening passed into the frontal sinuses and down to the nose, and on examining these they were all found filled with purulent mucus; so that the appearances were quite compatible with a chronic disease of the ethmoid bone.

We shall next week give a further series of cases of injuries to the head.

THE *Times* of February 19 publishes the following telegram:—"Naples, February 18.—The *St. George* left last night for Malta, with Prince Alfred on board. The Prince is suffering from fever."

PROFESSOR HUXLEY'S LECTURES.

THE Engravings to illustrate the Course are in the hands of the artist, under the direction of Professor HUXLEY. The First Lecture will appear in our next week's Number.

Medical Times and Gazette.

SATURDAY, FEBRUARY 21.

THE COMPOSITION OF THE SKULL—NASAL SEGMENT.

ALTHOUGH the vertebral composition of the skull was discovered by Oken in 1807, and although various works, published immediately afterwards, recognised more or less the doctrines of philosophical anatomy, we believe that the honour of the first practical impetus which was given to the science in Europe is due to Spix, the author of the magnificent work, "Cephalogenesis," published at Munich, in 1815. It was the first collection of the skulls of animals, which, accurately drawn, exhibiting the outside and inside views of the skull, and, in many cases, the cranial bones disarticulated separately, had been offered to anatomists. In spite of its cumbrous shape, and its absurd and obsolete nomenclature, it still remains the "handybook" of the philosophical student. Such a work, comprehensive, succinct, erring neither on the side of prolixity nor brevity, ought to be placed beside every anthropotomist whilst he pursues his inquiries into the composition of the human skull. As many of our readers, however, will not enjoy the advantages of this work, we do not hesitate to recommence the study of the composition of the skull *ab initio*.

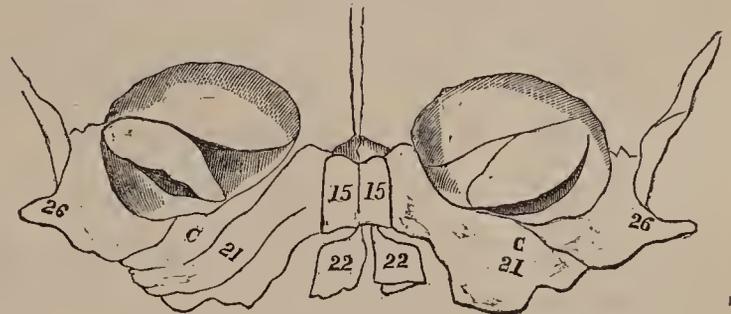

The organ which our readers exercise in the task—*i.e.*, the brain—is comprised within four distinct segments of the body. Commencing peripherally, the nasal, frontal, parietal, and occipital vertebræ are each composed, like those of the trunk, of an upper and an under arch. Thus, the nasal vertebra is composed of the rhinencephalic and maxillary arches; the frontal vertebra is composed of the prosencephalic and mandibular arches; the parietal vertebra is composed of the mesencephalic and hyoidean arches; whilst the occipital vertebra is composed of the epencephalic and scapular arches. We propose to commence the consideration of these several segments in detail, and, although the most complex, we prefer to commence with the ultimate segment of the trunk—the nasal.

The centrum of the nasal vertebra is the vomer. This structure in few other animals but man is composed of the ploughshare-like piece, from which its name has been derived. In the fish it is formed like the other centra of the skull, of a long bony rod, perfectly straight, and in the median line. In the crocodile, it is bifid, being composed of two symmetrical elongated plates of bone, each of which has a distinct centre of ossification. A third ossific centre, symmetrical and azygos, is wedged in, and is connate with the expanded pterygoid plates. We shall have to consider these plates more in detail when treating of the diverging appendages of the skull.

The neurapophyses of the nasal vertebra are the "prefrontal" plates, the "*pars media ossis ethmoidei*" of the old anthropotomists. In man and in mammalia they are perforated by a large number of minute foramina, which transmit the olfactory nerves. The prefrontal supports the olfactory ganglia. The median vertical plate, or "*lamina perpendicularis*," has, however, by many anatomists—amongst whom we must reckon Professor Huxley—been considered not to represent the neurapophyses, but the centrum of the nasal vertebra, thus having the same morphological value as the presphenoid.

The prefrontal in man, mammalia, and birds, is symmetrical and single; in the reptile and in the fish the ethmoid is double, situated above the vomer, to which it is connected. The neural spine of the nasal vertebra, composed of the two nasal bones in the bird, is bifid, its two long, slender portions sending forth processes to join the premaxillaries and maxillaries.

The pleurapophyses, or "ribs" of the nasal vertebra, are the palatine bones. These, in all vertebrata with the exception of fishes, form an osseous platform, which separates the buccal and nasal cavities. They are united posteriorly to the frontal vertebra by their diverging appendages, the pterygoids. In man and mammals these are slender vertical plates; in birds they are distally dilated, and articulate to the tympanic on one side, and to the palatines and presphenoid on the other side; in crocodiles, they are developed in the form of two large wings, continued on the same line as the horizontal palatines; in fishes; they extend from the palatine to the pedicle of the tympano-mandibular arch. The palatines, or pleurapophyses, are continued anteriorly by their hæmapophyses (the maxillaries), of which the peripheral extremities unite to each other by means of a true hæmal spine, the much-discussed *os intermaxillare* of old, or premaxillary of modern anthropotomists. The primitive distinction of this latter bone is, so far as our experience goes, best illustrated in a preparation made by Dr. Déramond, of Toulouse, of which we give a sketch below:

15. Nasal bone. 22. Premaxillary bone.  
21. Maxillary bone. 26. Malar bone.

The nasal segment in its entirety has now been explained; in man, however, its vertebral nature is, we confess, not easily recognisable. The slender bifid neural spine; the neurapophyses, divergent above, and nearly confluent beneath, the olfactory capsules being on either side of them; the vomer, or centrum, essentially consisting of two slender plates, also divergent above; the enormously developed palatine and maxillary bones forming the hæmal arch,—all form instances which tend materially to obscure our correct perception of the vertebral signification of the nasal segment. When, however, we turn to the homologous structure in the fish, we recognise in the upper, or neural, arch of this segment (rhinencephalic arch—*Owen*) an undoubted ring of bone, composed of the nasal, prefrontal, and vomeral elements. And the composition of the maxillary arch is equally demonstrable, although the tendency to "vegetative repetition" has, by the development of such bones as those which complicate the hæmal arch of the fish, somewhat obscured their vertebral signification. Special homology, into which we shall not at present enter, has, however, demonstrated the correspondence, bone for bone, of every essential element in the ichthyic and in the human segments.

THE WEEK.

REPORTED OUTBREAK OF FEVER AT HASTINGS AND ST. LEONARD'S.

A RUMOUR of an outbreak of continued fever in Hastings and St. Leonard's has been so prevalent lately, that "the Lords of her Majesty's Council" have directed an inquiry into the matter, which inquiry proves that rumour has, as usual,

exaggerated to a degree closely bordering on falsehood. There has, apparently, been nothing approaching to an "outbreak" of continued fever; but there have been a few isolated cases of fever, of the typhoid or enteric type, and, at least, two deaths from it—a Medical man and a clergyman having died; the latter from intestinal hæmorrhage, on the eighteenth day of the fever. We understand that no new cases have occurred for some weeks, so that it may be concluded that the salubrity of these pleasant health-resorts is, in reality, not deteriorated; but we would remark that the occurrence of these cases ought to impress upon the local authorities the necessity of constant watchfulness over the drainage and sewerage, lest the rapid development of these watering-places, in the hands of building speculators, should outrun the provisions made for the perfect and immediate removal of decomposing organic matters; and so our sea-side health-gardens should be converted into pest-nests and *foci* of fever. We are led to suspect that some danger of this sort has threatened St. Leonard's, not only from the type of the few cases of fever which have occurred, but also from noticing that complaints of nuisances have been laid before the local Board of Health. We are bound to add that such complaints appear to have been promptly attended to.

MEDICAL APPOINTMENTS IN THE HOUSEHOLD OF THE  
PRINCE OF WALES.

The *London Gazette* makes the following announcements, which will be received with universal satisfaction by the Profession:—

To be Physicians in Ordinary to H.R.H. the Prince of Wales.—William Jenner, Esq., M.D., and Edward Sieveking, Esq., M.D.

To be Surgeons in Ordinary.—James Paget, Esq., and George Pollock, Esq.

To be Surgeon Extraordinary.—John Minter, Esq., R.N., M.D., F.R.C.S.

To be Hon. Physicians.—Thomas King Chambers, Esq., M.D., William Henry Acland, Esq., M.D., and Alexander Armstrong, Esq., M.D., R.N.

The Royal Family of England set a good example to the country at large of sound and discriminating appreciation of Medical services.

RUSSELL v. ADAMS.

THE interest excited by this case amongst our Professional brethren is by no means abated, although it is gratifying to find that it is taking a practical and general turn, and not a personal one. It is generally felt that it is luckily quite unnecessary to consider the case in the interests of Mr. Adams. His Professional friends have rallied round him, and it is quite certain that he will suffer neither in his personal nor his Professional relations. Luckily, he does not need the offer of pecuniary help; and the whole thing, so far as he is concerned, will resolve itself into a somewhat ridiculous and costly misadventure. In reviewing the case in its Professional aspect, the question naturally arises,—Why did Mr. Adams suffer Hospital patients to come to his house; why did he visit them at their apartments; and why did he lay himself open to this abominable and ridiculous charge? To this we reply, that the private history of the whole case, when it shall be ripe for publication, will exonerate Mr. Adams by showing that he is but one of a series of Professors of Law, Physic, and Divinity, in Wales or London, in St. Marylebone, in St. Barnabas, who have, in turns, been captivated by the artless eloquence of these injured and unfortunate ladies, and who, in turns, have supplied them with sympathy and cash. If Mr. Adams was, as may be admitted, foolishly goodnatured—too chivalrously kind towards the widow and daughter of a Professional brother—too ready to admit them to the *status* of friends, and not of paupers,—all we can say is, that (unless rumour is unusually false) he erred in goodly company; and that, if the protector *par excellence* of Medical widows and orphans—the man who, *ex officio*, has had the

largest experience of Medical charity—had not been similarly beguiled, it is most improbable that we should never have had the case of "Russell and Adams" before a jury. But, leaving Mr. Adams and his ill luck to the consolations of time, we feel that the whole question of Professional conduct and responsibility deserves to be well discussed. Actions for *malopraaxis*, and for neglect, are on the increase; and if our Profession is open to such attacks, the least that we can do is to organise some scheme for mutual protection. Some limitation of gratuitous advice is clearly demanded, not only for the pecuniary interests, or the etiquette, but for the safety of Medical Practitioners. It is worth noticing, that the late Dr. Thomas Elliotson, when Physician to the Surrey Dispensary, found, to his horror, on his desk, one morning, a notice of action for breach of promise of marriage from one of the patients.

DISCREPANCY IN MEDICAL EVIDENCE.

A CASE of alleged ill-treatment of a servant by a mistress has lately been decided at the Surrey Sessions. The jury returned a verdict of Guilty, notwithstanding the glaring contradiction of the Medical men. We reprint the depositions of the Medical witnesses, only remarking that it is from such opposed statements the public draw the damaging inferences we constantly meet as to the value and reliability of professional evidence:—

"Mr. James Broad, Surgeon, practising at Mitcham: On December 20 I was called in to examine the girl Jarvis. I found her emaciated in appearance. Her cheeks were sunken, her eyes hollow, and one was black and cut. There were two large swellings on the back of the hands. There were bruises on both elbows and on her back, and she was in an extremely weak condition. My opinion is that her emaciated condition was caused by insufficient and improper food. The hands now show the effects of the injury. These wounds could have been caused by a fishing-rod. The state of the body was not caused by constitutional defect.

"Cross-examined by Mr. Robinson: There was nothing in her appearance to denote a scrofulous disease.

"Mr. Thomas Evans, Surgeon, Trinity-square: I agree entirely with Mr. Broad."

The following gentlemen were called on the part of the defendant:—

"Mr. Arthur Sergeant, F.R.C.S., twenty years in practice at Queen's-road, Peckham, had examined the girl. She was apparently in fair health, but rather scrofulous. He had seen her hands and fingers, and should think the swellings were caused by scrofula, and not by violence. He thought it was brought on by anxiety, and on that being removed she would in a few days recover her health.

"By Mr. Sleight: I don't say that the marks on the hands, etc., were not caused by violence.

"Dr. Richard Stokoe, of Peckham Rye: I have examined Sophia Jarvis, and I perfectly agree with the last witness. Had there been starvation during four months she could not have recovered in a week.

"Mr. John Davis, Surgeon, Great George-street, Westminster, fully concurred in the evidence of the other Medical witnesses for the defence."

THE DUTIES OF MEDICAL MEN TO RAILWAY COMPANIES.

A CASE in which two Medical men were severely censured by Mr. Baron Martin for negotiating compensation in a case of railway accident, has brought the subject of the propriety of Medical men acting as agents for Companies in such cases again prominently into notice. The case was one of injury caused by a collision on the London, Brighton, and South Coast Railway. Dr. Hall, the Medical adviser of the Company, and Mr. Taff, the patient's Medical attendant, offered, on the part of the Company, £10, which was refused, and afterwards £15, which was accepted; and the patient's father signed a document renouncing further claim. However, the patient's condition did not improve, and an action for com-

pensation was brought. The result was an award of £500 damages against the Company. The Judge, on this occasion, said, "that the conduct of the Company was such as he hoped not to see repeated. If Medical men, in the position of Dr. Hall and Mr. Taff, chose, in addition to their Professional duties, to act as a Company's agent in settling claims against the Company, and obtaining receipts for the same, they must expect to hear some unpleasant comments made on their conduct; and he hoped he should hear of no more such cases in future. He would be sorry, however, to impute actual fraud to Dr. Hall." We may regret the strong terms of this censure; but we decidedly hold, that a Physician or Surgeon who lends himself to such a proceeding quits his true Professional status, and places himself on the level of an attorney's agent. We think it incompatible with his Professional duty to his patient. The question of damages always before him, it would be more than human not to be biassed, both in diagnosing the seat and cause of symptoms, and in prognosticating the time of recovery. It may be said that, to avoid litigation, it is expedient that slight cases should be settled in this manner. We do not think so. Railway Companies have plenty of channels through which they can make fair offers to the persons they have injured, without employing a Profession whose calling it is to minister to the sick and maimed, and not to weigh human suffering in the balance against pounds, shillings, and pence.

PROFESSOR FRANKLAND ON ARTIFICIAL ILLUMINATION.

PROFESSOR FRANKLAND'S lecture on Friday last, at the Royal Institution, was a remarkably happy specimen of its class. It was an attempt to give, in a nutshell, an account of the practical improvements in this most important social art, and it did give it with such clearness and simplicity that there could have been no educated person present who failed to understand, and carry it away with him. The sanitary and economical bearings of the lecture were manifold. After referring to the electric and magneto-electric lights, and to the very clever mercurial electric light, whose disadvantage is its flickering propensity, and the feebleness which attends all luminosity derived from incandescent vapour, he went on to consider gas lighting, in which not much improvement was palpable in the last ten years; for all coal gas still contains sulphur (by law it may contain twenty grains per 100 feet), but it often contains more, and hence most of the offensive and unwholesome vapours given off during combustion. A process had been devised which effected this admirably on a small scale, the inventor of which, as readers of the *Medical Times and Gazette* well know, is the Rev. Mr. Bowditch, of Wakefield. Be it remembered that coal-gas, as supplied to us, does not contain sulphur in the form of sulphuretted hydrogen—for it is purified from that by means of lime or oxide of iron—but in the form of volatile sulphide of carbon and organic sulphur compounds, which these re-agents will not touch. Mr. Bowditch's process consists in passing the gas over slacked lime heated to 400° F., which converts the refractory sulphur compounds into HS, which then can be nearly or altogether abstracted in the ordinary way. A new illuminating constituent in coal-gas, acetylene, unlike other hydrocarbons, is the product of great heat. It may be made by heating carbon in hydrogen or light carburetted hydrogen with carbonic oxide. By passing coal-gas through a solution of oxide of copper in ammonia, a reddish acetylide of copper is thrown down, which, heated with hydrochloric acid, promptly gives off a gas of great illuminating power. The acetylide of copper explodes with great violence on application of heat or friction; hence many mysterious explosions, which have injured workmen employed upon copper gas-pipes and old meters. Oils, vegetable and animal, have long been common sources of artificial light, and to these is now added oil from the bowels of the earth; whether produced

by the artificial distillation of bituminous coal at a low temperature, as is the mode in which the now famous paraffine oil is prepared by Mr. Young, of Bathgate, near Edinburgh, or whether it is distilled by the subterranean forces of nature herself. It is necessary that this oil should be burned in lamps which do not heat it—of glass, for example; and it is requisite, too, that the manufacture should be conducted without much heat, else a light naphtha will be generated, which will volatilise readily, and explode when a match is applied. A sample of Young's and of two American kinds of paraffine oil were heated to 120°, when it was seen that the first did not, but the last two did, volatilise and form an explosive mixture. The 20,000 gallons obtained from the Canadian oil wells are reckoned to give light equal to that of 180,000,000 lbs. of sperm candles. The following is a list of

*Illuminating Equivalents.*

Young's paraffine oil	. 1 gallon	gives light equal to that of
American rock oil, No. 1,	1.26 "	" "
" " No. 2,	1.30 "	" "
Paraffine candles	. 18.6 lbs.	" "
Sperm candles	. 22.9 "	" "
Wax	. 26.4 "	" "
Stearic	. 27.6 "	" "
Composite	. 29.5 "	" "
Tallow	. 39 "	" "

*Comparative Cost of Light equal to that of Twenty Sperm Candles, each burning for Ten Hours, at the rate of 120 Grains per Hour.*

	s.	d.
Wax	7	2½
Spermaceti	6	8
Tallow	2	8
Sperm oil	1	10
Coal gas	0	4¼
Cannel gas	0	3
Paraffine candles	3	10
Paraffine oil	0	6
Rock oil	0	7⅔

The speaker then gave some general observations on flame, whose excellency consists in the number of solid incandescent particles which it contains, and in the temperature to which it is brought. The richness of flame depends, of course, on the nature of the substance burned. It is also greatly intensified by high atmospheric pressure, for it is found that a fall in the barometer of one inch causes a reduction of 5 per cent. in the luminosity of gas. The effect of a heightened temperature is produced by the device of putting a glass cylinder outside that of the Argand burner, so that all the air which feeds the flame shall pass downwards first of all between the two surfaces of heated glass.

	Rate of consumption per hour.	Illuminating power.
	Cubic ft.	Sperm candles.
Argand burner supplied with cold air	{ 3.3	13
	{ 3.7	15.5
	{ 4.2	17
Same burner supplied with hot air	{ 2.2	13
	{ 2.6	15.5
	{ 2.7	16.7
	{ 3	19.7
	{ 3.3	21.7

For an equal amount of light the saving of gas = 33 per cent. For an equal consumption of gas the gain in light = 62 per cent.

A light, to be perfect, should be capable of showing all colours, and of being refracted into a spectrum which can show them; for, of course, no light can show colours which it does not contain. Light emanating from incandescent solids, as the carbon in flame and in the electric light, has this property. Not so the light of incandescent vapours, which show but one colour on the spectrum, and which absorb the corresponding ray emitted from a solid body if it pass through them. Thus the heated vapour of sodium, produced by burning common salt with alcohol, shows only a yellow ray on the spectrum, and shows a dark band if the electric light be passed through it.

Solar light does not show some yellows, in consequence of the presence of sodium in the solar atmosphere. Experiments were shown which demonstrated how entirely the colour of every object depended on those in the light thrown upon it. The excellency of sunlight is, that it contains proportionately less heat than any other; for it had been rendered highly probable that the uneasiness of the eyes following the use of artificial light, depends on the absorption by the eye of the heating rays given off by the luminous body. The following table shows the

*Amount of Carbonic Acid and Heat generated per Hour by Various Illuminating Agents, each giving the Light of Twenty Sperm Candles.*

	Carbonic acid. Cubic feet.	Heat.
Tallow . . . . .	10.1	100
Wax	8.3	82

„ „ „ vitreous humour . . . . .	2.5	—	1.0
„ which penetrate to the retina . . . . .	7.7	8.4	9.1

We repeat, that a lecture such as this is pregnant with facts of interest for the Medical Practitioner.

#### DR. BROWN-SÉQUARD'S LECTURES.—LECTURE II.

DR. BROWN-SÉQUARD delivered the second lecture of his course at the National Hospital for the Paralysed and Epileptic, on the 12th inst. He began by some remarks on the treatment of Paralysis in general, and on Wasting Palsy in particular. He insisted strongly that the main object to be kept in view should be to increase by all means possible the amount of blood in the part affected. Hot baths applied locally during three-quarters of an hour twice a-day, unless swelling supervenes, are amongst the most potent remedies. Whether baths are used or not, the heat should be retained in the limb affected, by surrounding it with non-conductors—thick flannel, for instance. The cupping-boot, invented by Dr. Junod, will often prove of great service. It consists of a metal vessel which, when used for the leg, has something the shape of a large boot coming above the knee, and from which the air is exhausted, the result being a large determination of blood to the limb operated upon. There is sometimes a drawback to the use of this effective instrument: it not infrequently induces œdema, by disturbance of the venous circulation. These means may be often useful, at least, preventing the extension of wasting palsy; but this “terrible disease,” as the lecturer justly designated it, is itself all but, if not absolutely, incurable. In the treatment of paralysis, galvanism is also frequently of great value. In the first instance it contracts the blood-vessels, and, therefore, lessens the amount of blood in the part submitted to its action; but the dilatation which follows results in great additional warmth. The lecturer spoke of acupuncture, as a curative agency, in terms of strong commendation. He exhibited the needles which he employs, and which were between two and three inches long; he ascribed the benefits arising from them to one of two causes: they either promote reflex action, or, by the slight wounds which they inflict on the capillary vessels, cause effusions, resulting in a renewal of vitality. Especially in the treatment of paralysis due to poisoning by lead, they are of great use. Shampooing, pounding of the flesh, and friction in the direction of

the venous current, may often prove advantageous. The lecturer was very emphatic in insisting on the importance of using friction only in the direction named. He said that if the friction be made in the direction of the arterial current, the acceleration of the circulation will be incomparably less than that which may be induced by the opposite method. Of internal remedies, the only one of which he spoke with confidence was strychnine: in other medicines having any beneficial influence he remarked, “we are very poor.” Strychnine can only be used with advantage if the paralysed muscles have not yet wholly lost their contractile power: the medicine must cause them to contract even if it should first induce great movement in the healthy muscles, or it will fail to be of use. Having thus adverted to the general treatment of paralysis, the lecturer directed the attention of his audience to a very interesting case of a woman who had been stabbed with a knife in the back of the neck by a sailor in a fit of jealousy. She was in the London Hospital, under the surgical care of Mr. Maunder, by whom Dr. Brown-Séquard was requested to see her. He found that one lateral half of the spinal cord was all but severed, and that the remarkable group of symptoms which he has artificially produced in dogs, by division of one lateral half of the spinal cord in the cervical region, presented themselves. On the side of the lesion there was complete paralysis of the motor nerves; and that part of the sympathetic nerve going to the brain, to the blood-vessels of the face, to the dilator of the iris, to the muscle of Müller, and to the ear, being also divided, there was, on the same side, increased heat, hyperæsthesia, contraction of the pupil, incapacity of advancing the eye forwards, and slight approximation of the eyelids towards each other. The hyperæsthesia was of all kinds: ordinary sensibility, the sense of pain, of heat and cold, and of touch being each intensified. On the opposite, or, so-called, healthy side there was total loss of these four kinds of sensibility, but the “muscular sense” was perfect. (Of course, it was impossible to determine whether or not this sense persisted on the wounded side.) This case proves that the decussation of the conducting fibres of the muscular sense does not take place in the spinal cord. There were symptoms of some inflammation of the cord, and Dr. Brown-Séquard remarked that this inflammation probably conduced to the healing of the wound. Reunion of the cord has taken place, and will often occur, as it does in animals, when its division has been effected, as in this case, by some cutting instrument, or cause not of the nature of disease. The treatment consisted in giving iodide of potassium in small doses, together with belladonna and ergot of rye. The patient can already use her limbs, the only remnants of her paralysis being a contraction of the forefinger, and of the foot inwards, on the wounded side. She can walk with the help of a stick, and says she has “only a little weakness of the knee.” A second case, similar in character, but of twenty-two years' standing, was also exhibited. As the accident causing the symptoms in this instance occurred so long ago, and as no accurate record of them has been kept, this case is, of course, less clear and instructive than the one just described. The next case referred to by the lecturer was one of myelitis, in which a complete cure has been effected. The patient had got wet through on a warm day; he soon afterwards experienced pricking and tingling; the feeling as if a cord were tied round his belly; jerking of, and complete loss of sensibility in, the lower limbs. The sphincters of the bladder and rectum were not affected; therefore, it is probable that in this instance the disease did not extend upwards beyond the middle of the lumbar swelling, thus allowing the nerves controlling those muscles to escape. He had all the other usual symptoms of myelitis. He was treated with iodide of potassium, sulphate of quinine, and sesquicarbonate of ammonia, as well as belladonna and the ergot of rye. Dr. Brown-Séquard remarked that he had never seen a complete cure of

a case with symptoms like this before. A case of inflammation of the membranes of the spinal cord, and of the sheaths of the nerves at their exit from it, was also shown: a coachman had pain and tenderness along the spine, from the sixth dorsal vertebra downwards; his sexual power is lost; and for some time he had pain in and jactitation of the legs. He now says that his feeling in them is normal, but, as indicated by the compasses, great anæsthesia exists. Referring to this case, Dr. Brown-Séquard remarked that the only reliable test of the degree of the tactile sense is the compasses, and that the best test of the sense of heat and cold is water of two temperatures. This patient has not as yet made much progress towards recovery. In conclusion, the lecturer mentioned a case occurring in his private practice of complete paralysis from caries of the bodies of two vertebræ: there was entire loss both of sensibility and of motive power, as well as of all control over the sphincters of the bladder and rectum. A cure was effected by causing the patient to lie on his belly, and by placing, at the same time, a pillow beneath him. His body having been supported by a suitable apparatus, he began immediately to move about in society, and is now quite well.

#### EPPING FOREST.

THE people of London have to thank Mr. Peacocke and the House of Commons for a vote on the 13th inst., which, although it may be only a temporary measure, and may be rescinded to make way for some more carefully considered means of attaining the same object, is really a substantial interference on the part of the Legislature to preserve, for the metropolitan population, not only a privilege which they have held for centuries, but a provision for health, recreation, and physical and mental enjoyment, which every year's numerical increase renders more indispensable. Mr. Peacocke's motion, carried by a large majority, proposed an address to the Crown, praying that no sales be made to facilitate the enclosure of Crown lands within fifteen miles of the metropolis. It is quite true that the only power which the Crown possesses over such tracts as Epping-forest is derived from the old Norman forest laws, giving the monarch the right to use them for hunting purposes,—to run stags, roebucks, and wild boars over them. It is equally true that there are no deer now in Epping-forest, and that in England *Sus aper* has followed *Bos primigenius* into the regions of palæontology. But, whilst the Crown maintains its right, it is impossible to enclose these lands, and to shut out from them the Queen's subjects. No royal hunt now sweeps over Epping and Hainault, and for many a long year their glades have not echoed a horn; but artisans of the Tower Hamlets, and school children of St. Giles's and Bethnal-green, have to thank the old Norman love of the "gentle craft" for an acquaintance with bush and brake, dingle and haunted dell, and leafy summer, as nature gave them to their forefathers. Take a London compositor or seamstress, and put him or her in Epping-forest on a fine Easter Monday, and mark the effect on mind and body, on respiration and pulse, on temper and muscular tone. Parks for the people under a sky of London smoke, gravel walks and smooth grass-plots, stunted trees and dusty flowers, are all very well, but they are not, and never can be, substitutes for *country*. The Medical Profession, therefore, as conservators of the public health, will hail this effort on the part of Parliament as a piece of legislation practically wise, whatever objection may be brought against it on the ground of its being a revival of an obsolete claim. Epping-forest must not be enclosed; and although, as we have hinted, this proceeding in Parliament may only serve a temporary purpose, it will, at least, prevent present encroachment, and must be the forerunner of a measure, which, on the broad basis of public good, will secure for the people of London a most salutary and necessary boon.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE Hunterian Oration, now *biennially* given in the theatre of the above institution, was delivered, on Saturday last, the 14th inst. (the anniversary of the birth of John Hunter), by Professor Gulliver, F.R.S., before the President, Vice-Presidents, and Council of the College, and a great number of distinguished visitors.

The ORATOR commenced by observing, that it had been often said or implied that the matter for these orations was so far exhausted as to make it quite hopeless to look for anything new or interesting so often on such a limited subject. But he dissented from the general tenor of this view, and expressed some surprise at such a sorry representation of the Profession as unable or unwilling to find in the great book of Hunter an appropriate text "to point a moral or adorn a tale" in the rich chapters of physiological history; as if we, to whom his fame had descended as an honourable heirloom, were becoming indifferent to the sacred trust, which, indeed, it is our duty to perform, and in which it is to be hoped that we shall never fail to feel a just pride, and to take every fitting opportunity of rejoicing. As to "such a limited subject," the genius of Hunter so far embraced the whole domain of organised nature, that he became its very Evangelist since the revival of letters, and left such records of it as never human hand and mind had done before. And, whatever difficulty there would always be in finding absolute newness, surely there might, and ought to be, a relative novelty, and, at least, perennial interest and instruction, in reviewing the works of a man of genius, both in the steady and fitful lights and shades of advancing science; nor could a more grateful homage than this be paid to the memory of a great man, as it is to view his reputation in the very glass he himself would like to see it, were he to re-appear among us, and, though dead, to show him yet speaking. By "the book of Hunter" was meant the grand exposition of the works of nature to be found in his magnificent Museum, as well as in his writings: these last contain some parts since supplanted by better matter, and others, even, not equal to the knowledge of his time; though we cannot fail to admire the vast amount of truths displayed in them, and so formed into a consistent whole, with the illustrations of his Museum, as to afford a beautiful example of what poor things mere facts are, compared to what they may become when touched by the magic wand of genius, and seen in the light of comprehensive truth. And so Hunter had established the most important era in modern times in physiological science, and the foundation of philosophical Surgery. Nay, he had done still more, for in his time physiology and zoology were so oppressed by mere facts, as to be in danger of sinking under their number, confusion, and weight, until he so surveyed and arranged them as to show their affinities and contrasts. Thus he transformed the old dead order into a living method; and this legitimately from relation and difference, progression or development—proofs of which abound in his Museum and writings.

A somewhat familiar acquaintance with them had taught the orator to look up to Hunter as the foreteller of many principles or central phenomena, only recently become well known by new and improved means of research, and claimed accordingly as late discoveries in utter ignorance of his earlier observations. His description of the leading fact in the formation of the buffy coat of the blood was selected for explanation as an example, not only for its importance, but because Hunter's observation was so long unknown or disregarded, that it was left to the orator to show how it had anticipated the excellent results of Schroeder Van der Kolk, Nasse, Henle, Wagner, and Wharton Jones: "The increased disposition of the blood to separate into its component parts," and "the mottled appearance and spots of red," described by Hunter in the lateral separation, not mere downward sinking, in thin layers of blood. This was only an instance of disregard of his priority; but, while careful that this is not unfairly ignored, we should be equally solicitous not to give him the merit of discoveries to which he has no just claim; a caution the more needful, as such mistakes have been too often committed, as shown in the introduction to the Sydenham Society's edition of Hewson's works.

While it is hopeless to attempt in a single oration anything like a view of Mr. Hunter's labours, it seemed that this might be done in an interesting and instructive manner in a number of successive orations, especially as the subject had received so much illustration from the present orator's predecessors. To this end, we have only to choose some remarkable truth in which the genius of Hunter shone; to note the state of our knowledge when he found that truth; and, finally, to survey it and his labours in connection therewith by the lights of modern science. This was the course adopted on the present occasion; and so far from feeling any want of matter, it so abundantly crowded before the mind that the chief difficulty was one of selection. No time could fade the infinite variety of Hunter's labours, so long as proper care was taken of them. And this had involved a great amount of labour and expense, accruing with the growth of the Museum, which the Council had met, and was prepared still to meet, if not always most judiciously, certainly with becoming zeal and liberality, and, it is hoped, with a due sense of the importance of this great and pure fountain of Hunterian biology. Of such care was cited, as evidence, the example of the twenty-nine quarto volumes (besides the octavo Synopsis) of the "Descriptive Catalogues and Memoirs of the Museum," which were characterised by the orator as a magnificent series, of which the College might be justly proud, not only as a fitting tribute to the memory of Hunter, but as a particular and comprehensive account of the design and contents of that Museum, and the most valuable work of the kind in Europe.

The subject chosen for illustration of the genius of Hunter was the life of the blood, and the special anatomy and physiology of the fibrin; and, more especially, as great errors still prevail as to his merits on these points. The history of the subject given, as far as it relates to his labours, was such as is included in our report of the orator's tenth and eleventh College Lectures. Nothing could be more unfair to Hunter's view of the life of the blood than to say, as was too often said, that "he only discovered what the ancients, as well as Harvey, had described aforetime;" for the fact was, that Hunter specially described the vital endowments of the fibrin, which was as much a discovery as similar properties would have been in any other proteic matter, and not to be confounded with the properties of the compound blood. Both on the Continent and in England, the membraniform appearance of clots of fibrin, as well as the true nature of the so-called polypi of the heart and of the buffy coat of the blood, had been well described long before Hunter's time; but those excellent observations were hid, and the fibrin ignored, during the strange reign of fancy in physics and poverty of imagination in poetry, which prevailed about the period of Davies and Hewson, both of whom preceded Hunter in accurate observations on the three chief parts of the blood. But Hunter's idea of the vital endowments of the fibrin was a step far in advance of anything done by the fine old observers, such as Harvey, Malpighi, Borelli, and Collins. The first had an exalted and just doctrine of the life of the compound blood; and the three latter, as well as Ruysch, distinguished the fibrin as the spontaneously coagulable matter, and its form and texture when coagulated; but that was all, and it was left to the genius of Hunter alone to invest the fibrin specially with a dignity never dreamt of in their philosophy, just as one touch of nature's own poet may give an enduring value and interest to the most common-place objects. He observed not only that "a clot of fibrin may be as tough and elastic as the coats of an artery, becoming fibrous, and even forming laminæ . . . which gives us a clear idea how a membrane may be formed, and probably can be varied, according to the impression made on it by the surrounding parts," but that it "can be organised by forming in and by itself blood-vessels, like the membranes of the chick," as related more particularly in the orator's eleventh Lecture, appearing by the merest accident in our impression of last week. He was old enough to remember when the charm of the novelty of this doctrine had not quite passed away; and when, to the minds of Hunter's contemporaries or immediate successors, it was a sort of spell. The venerable and respected Clift, in his proud sanctuary of the Museum, might have his enthusiasm ever and anon lit up most delightfully on this subject by the student-visitor; and when some of our great teachers, as Mr. Abernethy, had well wound-up the soft melody of their eloquence on the vital endowments of the coagulated lymph

of Hunter, the warmth of their admiration and reverence was like—

"An Orphic tale of high and passionate thoughts  
To their own music chanted!"

But this was an old tale; and the original view of Hunter, supposed to be gone the way of all the Capulets, since the advent among us of the cell-doctrine of Schleiden and Schwann, which had eclipsed, or supplanted, this leading tenet of Hunter, and was believed to have put it out evermore. The orator then submitted that this verdict required re-consideration, and that its validity would be disproved on a new trial. And, certainly, when he showed such a typical form as a membranous closed sac, produced by simple coagulation of fibrin, or in a mere mixture of varieties of serum—and this, as was proved, utterly independent of any cells whatever, or of any principle involved in the cell-doctrine—it must remain with the advocates of this view to reconcile such a fact with their doctrine, before it can be fairly regarded as having supplanted that of Hunter. Fibres as well as organic molecules are often, as in the coagulation of fibrin of the blood, and in the chyle and other fluids of animals and latex of vegetables, prior in formation to cells, contrary to the leading tenet of the cell-hypothesis. But the whole of this part of the argument, which was gone into at some length, need not be repeated here, as it was generally to the same effect as reported in the orator's eleventh and twelfth College Lectures. He concluded this part of the oration by asking whether the results of these experiments were not as confirmatory of the old, simple, and beautiful doctrine of Hunter as they were adverse to those more novel, complex, and meretricious theories by which it was supposed to be extinguished; inquiring, also, what is the new plasma, blastema, or cyto-blastema, and the matter of some such other hard words, of the Germans but the old coagulable or coagulated lymph of Hunter? Finally, expressing the hope that he had adduced sufficient proof that even this single scene in the great drama—this little episode in the grand epic of Hunter's labours, would be alone sufficient to show the depth of his genius, to entitle him to the gratitude of posterity, and to the place of honour in philosophical Surgery. Alluding to the marble statue to his memory, amid the deeds he loved so well, it was remarked that all the shows of art, pictured pomp or sculpture, speak in feeble imagery their own cold powers, frail and vain for his renown. His best eulogy, as of other great men, was to be found in his works, and especially in his Museum. There, verily,—

"He, in our wonder and astonishment,  
Hath built himself a live-long monument;  
And so sepulchred in such pomp doth lie,  
That kings for such a tomb might wish to die."

And here (observed Professor Gulliver) we might have concluded, but that, since the last oration, death had been so busy as to number among his victims such worthy disciples of Hunter—*haud passibus æquis*—as Quekett, Norman, Stanley, and Brodie, to whom a passing tribute must be paid. The three latter died full of years, and in the enjoyment of that which the greatest secular judge of human nature tells us "should accompany old age, as honour, love, obedience, troops of friends." But Professor Quekett was early lost to science, and not without leaving beautiful marks of his course behind him; indeed, he was one of the first, if not the very first, gone in this country, of those eminent men who devoted their talents exclusively to the abstract and higher branches of our Profession, quite regardless, in this noble pursuit, of the meaner considerations of practice and profit. His researches, small or insignificant as they might appear to superficial minds, are really large and important; and the remark that has been often repeated of late, to the effect that his observations were only of a fragmentary or isolated character, deficient in connexion, the orator believed to be unjust to his memory. Mr. Quekett explored the field of histology in its widest sense. His inquiries not only extended through the animal and vegetable kingdoms, but also to mineral substances; and his collected specimens of intimate structure of organic nature surpassed in number and value anything of the kind before displayed in this country. And those which he had, indeed, found and collected as a mere heap of isolated facts, with little more affinity than the order of words in a dictionary, he soon reduced by their relations to arrangement and method, of which only a mind diligent and comprehensive could have been capable, as was well attested by his published lectures and by several volumes of the Descriptive

Catalogue of the Museum, more especially by the histological series. Such a mind could not be thus employed without discovering central or comprehensive phenomena—could not be confined to mere fragmentary, subordinate, or minor facts. Accordingly, among other fundamental or leading truths, his early observations on the nature and arrangement of capillaries led him soon to exhibit in the blood-vessels alone, rational evidence, proof of function from structure, of the significance and use of the air-bladder in fishes. His original researches, two or three years afterwards, on the intimate structure of bone, were of still higher import, for they at once and for ever demonstrated the analogies and contrasts of this structure, and with such admirable precision and clearness as not only to establish the essential characters in this respect of the vertebrate sub-kingdom, but also the means of determining the affinities of minute fragments of the organic remains of a former world. (The orator, with distinguished modesty, omitted all mention of his own valuable discovery of the relative sizes of the blood corpuscles, which so singularly confirmed Quekett's views, more especially with regard to the piscine or batrachian character of that rare animal, the *Lepidosiren*, some time since exhibited at the Crystal Palace.) So no wonder (added the learned Professor) that results of such importance should have been conveyed, as ancient Pistol would say, by certain Germans pretending to give the literature of the subject, but carefully excluding the mere mention of Mr. Quekett's name, though we cannot but feel something stronger than surprise to find this frequent practice, this sorry violation of truth and of the just claims of British science, silently acquiesced in, if not approved, adopted, and patronised by our societies, translators, or commentators, and too many of our eminent teachers. But, as Mr. Quekett more than once emphatically remarked to the orator, he suffered this indignity in very worthy company; and (added Mr. Gulliver) the fair fame of our illustrious countrymen should be accepted by us as a sacred trust, a precious heirloom, to be cherished while our science lasts, in the hope, too, that generous hearts would not be wanting to defend Hewson and Quekett on the proud pedestals which they had so honourably gained. Though Mr. Quekett, like Pope, might truly have complained of "that long disease, his life," he retained to the last his wonted serenity and affability, kindness, and humility. Neither was his constitutional sweetness of temper affected by the plagiarism of his labours abroad, nor even by the pitiful attempts of anonymous detraction at home. In truth, it was Mr. Quekett's happiness to have his mind so full of the importance of those pursuits which he loved so well and truly, as to leave no room in it for the nurture of lower feelings. His gentle nature could not entertain what our great epic poet calls "the troubled sea of noises and hoarse disputes," but preferred, in a calm and pleasant retirement, to enjoy the still air of his delightful studies. He was not, like honest Isaak Walton's poor rich man, condemned to riches, and then to a busy discontent, but enjoyed, in his meekness, as foretold by the Psalmist and St. Matthew, a far richer and better possession, and thus had truly found the ways of pleasantness and the paths of peace. And if thus, in the happiness of the common routine of his life, "in populous city pent," how would his heart leap up when he left it for a short country recreation, such as angling, which he loved, and did then behold with joy and gratitude the outward forms and shows of rural nature! Such were some of the ruling traits of this meek and good disciple of Hunter.

Mr. Norman was a man of a different stamp. He early marked out the goal for which he panted, and won it in a manner alike honourable to himself and to the Profession, having been twice elected chief magistrate of the city of Bath and deputy-lieutenant of the county. In 1825, he successfully tied the external iliac artery, and also the *arteria innominata*, and some years earlier had tied the common carotid. But his chief operation was that of taking up both the lingual arteries. He was the author of some valuable contributions to the advancement of Surgical science.

Mr. Stanley was chiefly distinguished in Surgical anatomy and pathology, and was one of the best and most successful teachers of his time, and a great master of what he loved to call "practical anatomy." He was the author of numerous papers in the *Transactions* of the Medico-Chirurgical Society, and of several independent works.

Of Sir Benjamin Brodie, the last survivor of a great race, the orator paid a well-deserved eulogium, and for which we regret we cannot find space. After alluding, in eloquent terms,

to the discoveries or merits of those young and illustrious physiologists, Hewson and Falconer, the orator expressed a hope that if he had rather forcibly submitted to his audience some of the just claims of the British school of physiology in the labours of John Hunter and his disciples, it had been done conscientiously and in the defence of Truth, and, he hoped, temperately, and not lightly or inconsiderately, and yet with sufficient decision and accuracy to assert, if not maintain, her sacred cause. "Let us never forget," said Professor Gulliver, "that we belong to the country of Harvey and the Hunters; nor, when we deplore the loss of such of their followers as Brodie, Norman, Quekett, and Stanley, cease to feel that excellent consolation which is afforded by the character of their lives, and the example they also have left to us and to our posterity, for 'these were honourable men in their generations.'"

An interesting occurrence took place immediately before the oration. When Mr. William Adams, F.R.C.S., of the Orthopædic Hospital, the defendant in a recent action in one of our law courts, entered the theatre, he received quite an ovation from his Professional brethren: this mark of sympathy considerably affected him. In the evening the President and Council entertained a large and distinguished number of visitors to a banquet at the Albion Tavern.

## REVIEWS.

*A Treatise on the Physiological Anatomy of the Lungs.* By JAMES NEWTON HEALE, M.D. London: Churchill and Sons.

MANY original works on anatomy have not of late years issued from the English press, and it is on this account that we are disposed to look with more critical eyes on any new book professing to be an addition to English anatomical science, than on others treating of lighter subjects. If we can show but little, that little should be of the best quality. In human descriptive anatomy not much is left to be done. To use an often quoted simile, the great workers of the last century have, like a band of lusty reapers, cleared the harvest; their successors, like humble gleaners, must be content to pick up here and there an ear which may have escaped the notice of their more fortunate predecessors. But our own and the last generation have been instrumental in building up the splendid fabric of tissue anatomy, and have witnessed the greatest amount of light yet thrown on the structure of the special organs. It is to this latter department that the work before us professes to be a contribution, and it puts forward claims to originality in discovery, which, if supported by fact, would at once place it in the same rank with the most valuable monographs that have issued from the German press. We shall endeavour to lay before the reader an account of the discoveries to which Dr. Heale lays claim, and, as far as opportunity may permit, shall try to test their validity. We would *in limine*, however, express our opinion that great credit is due to Dr. Heale for the conscientious labour with which he has pursued his researches.

Passing over the introduction which reiterates the author's peculiar notion, "that every organ of the body is galvanised into its vital activity, through the instrumentality of the atmospheric oxygen, acting upon the blood in the lungs," in a tone of confidence and positiveness, which, we think, is not only precipitate and unwarrantable, but will, we suspect, prejudice most readers against the ready reception of the conclusions in the after part of the work, we at once proceed to examine the points of novelty which Dr. Heale advances, with regard to the anatomy of the pleura. The first is the assertion, that the blood-vessels which are actually distributed to the tissue of the pleura are exclusively derived from the pulmonary arteries. On this assertion he establishes a theory, that the function which the pleura is called upon to discharge is wholly and exclusively connected with the process of "respiration;" since he considers that he has proved conclusively that the pulmonary vessels are engaged solely in the respiratory process, and that the bronchial vessels are entirely subservient to nutrition, and have no anastomosis with the pulmonary vessels. He includes the costal pleura in this description, asserting that "eight or ten arteries (pulmonary) of considerable size, and about twelve or sixteen corresponding veins of some magnitude, cross behind that fold of the pleura which is sometimes called the broad ligament,

to reach the thoracic pleura, and to become distributed upon it, imparting, therefore, to that structure also properties auxiliary to the process of respiration." It is admitted by most anatomists that the pleura receives branches from the pulmonary system of vessels. On this point Kölliker observes "Vessels are seen in the pleura, most abundantly in that covering the lung, where they are furnished to the subserous tissue from the bronchial and pulmonary arteries; the parietal lamellæ (costal pleura) are supplied more scantily by the intercostal and mammary vessels." On the other hand, that the pleura is *exclusively* supplied by the pulmonary arteries, is an assertion which is contrary to the positive observations of preceding writers. We might quote testimony on this point from Cowper and Haller downwards, but we will only refer to Kölliker's description, that the last distribution of the bronchial arteries is to the pulmonary pleura, "the twigs for which go off, partly at the hilus, and in the fissures between the main lobes, partly arise between the secondary lobules from the vessels accompanying the bronchia." We may also observe that, if it be shown that pulmonary arteries are supplied to the pleura costalis, we cannot admit that that membrane is a respiratory structure, for we have no notion of respiration without the access of air, and we have yet to learn that air comes in contact with the costal pleura. In our opinion, therefore, if Dr. Heale's account of the distribution of pulmonary branches to the pleura costalis be correct, it is insufficient to support his corollary. We, however estimating the anatomical testimony in opposition to the observation of Dr. Heale as to the exclusive supply of the pleura from the pulmonary system, must withhold our assent until his views have received further confirmation. The next point of novelty advanced is a description of certain longitudinal channels of a remarkable character which are said by the author to exist in the pleura. The largest of these channels are, he tells us, "to be found at the reflections of the pleura over the acute margins of the lobes." These channels, he further asserts, are in connexion by means of certain tubular passages running through the sub-pleural cellular tissue with the open extremities of minute bronchial tubes. Again, we would say that this observation requires confirmation. Excellent anatomists, who have studied with most painful scrutiny the structure of the lung have never observed these passages. The mode in which Dr. Heale demonstrates the channels is by inflation, and the open extremities of the minute bronchial tubes are made evident by stripping off the pleura and sub-pleural cellular tissue from the surface of the lungs. Both these methods of examination are open to the objection, that they are the very means by which channels and open extremities of tubes might be artificially manufactured. Dr. Heale's description of these "longitudinal channels" is also very vague: he nowhere tells us whether they possess a lining membrane. He at first compares them with the sinuses of the dura mater, observing, however, that they are colourless and transparent, and certainly do not transmit a coloured fluid; he afterwards asserts that, "without doubt, these longitudinal channels are rudimental representatives of the air channels which exist in the long bones of birds!" We commend this observation to the consideration of transcendental anatomists.

For our part, we are unable to conceive either homology or analogy between the problematical pleural channels of Dr. Heale, and the means by which the diverging appendages of the vertebral column in birds are rendered light and adapted for flight.

We must pass on, however, to the author's observations on the anatomy of the lung itself. The first point on which Dr. Heale believes he is correcting previous anatomists is, as to the mode of division of the bronchial tubes. He remarks that this is not dichotomous or trichotomous, as has been asserted, but that it is strictly that of a panicle. "In every part a straight diminishing tube may be observed, which closely resembles the midrib of a leaf; and from this, branches are given off, alternately on each side of it, throughout its whole length." There can be no doubt that Dr. Heale is right in asserting that there is no regular binary or ternary division of the bronchial tubes; but he is wrong if he is under an impression that this is a discovery. Alternation of branches from the bronchial tube is most clearly figured in the first plate of Reisseisen's work on the "Anatomy of the Lung." Dr. Heale's own plate (p. 32) shows that the branches (like those of a tree) are not given off with any great regularity; but the same figure shows also that, besides branches given off alter-

nately, there is occasionally a close approach to exact binary division of the main trunk. The author proceeds to say, that "the bronchial tubes thus given off form no sort of anastomosis nor junction among themselves, and they are divided into sets or groups which remain distinct from each other, and do not become mingled or intermixed." Here he only confirms the descriptions given by most competent observers. He then proceeds to remark that the distribution of the pulmonary artery follows closely that of the bronchial tube:—

"Each group of lobules, then, is distinct and separate, as regards the distribution of its bronchial tubes; and as the peculiarities of the pulmonary artery also strictly coincide in those particulars with those of the bronchial tube (with the course and distribution of which it closely corresponds), and as its branches, like those of the bronchial tube, do not at all inosculate with one another until they finally split up into their capillary subdivisions, it follows that, as regards the pulmonary artery likewise, each group of lobules is quite distinct from those which surround it. The same prevails also with respect to each lobule, and, in a modified degree, with respect to each leaflet. Each lobule receives its own special bronchial tube and pulmonary artery."—Pp. 29, 30.

Again,—

"The pulmonary artery is always seen accompanying the bronchial tube, dividing as it divides, and maintaining an exact correspondence with its subdivisions down to the point at which the terminal bronchial tubes give off their pedicels." . . . "Throughout the lung the pulmonary artery always runs on the upper side of the bronchial tube, and whenever the bronchial tube is of sufficient size to have an accompanying pulmonary vein, this is placed as universally underneath the bronchial tube."—Pp. 65, 66.

We have no doubt that this, in the main, is an accurate description of the distribution of the pulmonary artery in connexion with the bronchial tubes, as in it Dr. Heale has confirmed the observations of previous writers. Thus, Reisseisen—"Etenim arteria pulmonalis, bronchia ad extremos fines secuta, singulos ad extremas vesiculas ramos emittit." Bourgerie, also—"Ainsi, en rappelant ce qui a été dit plus haut des gros troncs, il est évident que les artères, quel que soit leur volume, sont toujours satellites des canaux aériens." Addison says—"The pulmonary artery accompanies the bronchi, branch for branch, to the minutest divisions of the latter;" and Kölliker observes, that "the branches of the pulmonary artery generally follow the bronchia, and lie above and in front of these tubes." Dr. Heale's description of the origin of the pulmonary veins also confirms that given by Bourgerie and Addison. He writes:—

"These do not, like the former, penetrate, as it were, into the substance of the lobules, and thus become identified with a particular lobule, but they are invariably placed between contiguous lobules, and between contiguous groups of lobules, and collect their venous radicles (conveying, of course, arterial blood) indiscriminately from the lobules between which they are situated. The only pulmonary veins, therefore, which are found in connexion with the minute bronchial tubes and their accompanying arteries are the ramusculi, which collect the blood from the mucous membrane which lines those tubes: the true pulmonary veins, on the contrary, are placed in the interlobular spaces which separate contiguous lobules and contiguous groups of lobules, and, as respects the smaller bronchial tubes and their accompanying pulmonary arteries, are placed at a distance from them. The smaller veins issue out from each lobule, and partially cross the interlobular space to join the trunk of the vein."

Bourgerie speaks of the pulmonary venules as being found at the periphery of the lobules; and Addison says:—"The pulmonary vein may be distinctly traced from larger to smaller trunks towards its source, until we reach the common cellular membrane between the ultimate lobules, from the exterior of which the vein appears to originate." Kölliker also asserts of the pulmonary venous radicles, that they run between the smallest lobules. In these particulars, therefore, Dr. Heale's description is of value, as confirming those of previous observers. With regard to the ultimate distribution of the pulmonary artery, the author writes:—

"When each bronchial tube spreads out into its final pedicels, the corresponding twig of the pulmonary artery expands into a very remarkable reticulation. This reticulation is a mesh-work of minute capillaries, which anastomose in the most intimate manner; and this anastomosis is not con-

fined to the meshes of each terminal twig of pulmonary artery; but there is likewise a close intercommunication between the capillary networks of adjoining leaflets; so that, like the bronchial tubes, the trunks of every subdivision of the pulmonary artery are kept wholly asunder and distinct until they arrive at their final distribution, and then the most equal and free intercourse is established between all the capillaries."

The fine anastomosis of the capillary network formed by the pulmonary artery on the air cells has been described and represented by various writers, amongst whom we may name Rossignol, Rainey, Adriani, and Kölliker. Mr. Rainey speaks of the smaller ramifications of the pulmonary artery anastomosing very freely with the ultimate ramifications of neighbouring pulmonary arteries; and Kölliker, after describing the excessively close capillary network into which the lobular branches of the pulmonary artery break, states that the network "extends continuously over all the alveoli of an ultimate lobule, and is partially connected also, at least in the adult, with the plexus on neighbouring lobules."

One of the chief points on which Dr. Heale insists is, that an extensive plexus formed by the pulmonary veins is distributed over the bronchial mucous membrane. He speaks of this plexus as constituting a diverticulum, whereby a portion of the blood returning from the lobules undergoes a second exposure to the air previous to reaching the larger trunks of the veins. We have no doubt that such a network exists, but here again Dr. Heale has been anticipated by other anatomists. In Weber's edition of "Hildebrandt's Anatomy," it is asserted that the pulmonary veins originate not merely from the capillary network covering the terminations of the air tubes, but also from a capillary network lining the inner surface of the bronchi. It is true that the author quoted believed this network received its blood from the bronchial arteries, and Dr. Heale denies all communication between the two systems of vessels, but the former ascribes the oxygenation of the blood in part to this plexus. Adriani again states that the pulmonary arteries and the pulmonary veins are the vessels chiefly concerned in the formation of the capillary network on the surface of the bronchia. According to Beau, the pulmonary arteries supply the mucous membrane of all the bronchial tubes, even up to the trachea. The difference between Dr. Heale and these two latter observers amounts to this, that the former asserts that the plexus in question is formed by the small pulmonary veins returning from the lobules, the latter that the pulmonary arteries assist in forming or form the plexus; but Dr. Heale allows that the plexus can be injected through the pulmonary arteries. All the statements made refer this plexus to the pulmonary as distinguished from the bronchial system of vessels.

The bronchial or "sustinent" arteries, as Dr. Heale, in reference to their function, prefers to call them, supply the fibrous and cartilaginous structures of the bronchial tubes, and by means of a very fine network, which he asserts is entirely distinct from the pulmonary plexus above referred to, the mucous membrane lining the bronchial tubes. Adriani, however, asserts that in this situation there is a connexion between the two systems of vessels. The bronchial arteries, besides, supply, by means of a fine plexus, into which they ultimately subdivide, the whole of the pulmonary tissue; they also send branches to the subpleural tissue. In these observations Dr. Heale confirms the statements of Reisseisen.

The assertion, which, if it be true, is, we think, the most important in the work before us, is that of the entire absence of communication between the bronchial and pulmonary systems. Dr. Heale's statement is certainly supported by his own injections; but even he allows that, unless the experiment of injection be conducted very carefully, it is easy to force fluid from the "sustinent" arteries into the pulmonary vessels.

"It may occasionally happen, when an injection is made through the sustinent arteries, that, in consequence of some violence being used, the capillaries in connexion with the arteries are made to burst into one or more of the vessels belonging to the pulmonary system, and then the pulmonary vessels of one or more of the lobules may become injected from the sustinent arteries; but, whenever that happens, it is always in consequence of a clumsy amount of force having been employed."

We are by no means convinced that this is a true explanation. That an anastomosis between the two systems of vessels exists, has been maintained by Ruysch, Haller, Scemmering,

Reisseisen, Rossignol, Adriani, Williams, Waters, and many other observers. Guillot's observations first threw doubt on the existence of any communication between the bronchial artery and the pulmonary artery; and Rossignol also showed that fluid thrown into the bronchial artery did not find its way into the pulmonary artery, although it did find its way in large quantity into the pulmonary veins, and in smaller quantity into the bronchial veins.

Adriani and Rossignol both assert that the bronchial vessels can be injected from the pulmonary veins, and *vice versa* the pulmonary veins from the bronchial arteries.

Dr. Waters fully confirms their observation, as far as the pulmonary veins and bronchial arteries are concerned. But, apart from experiment, there are pathological facts which, in our opinion, are not consistent with a belief in the entire separation of the two systems. Where the circulation through the pulmonary arteries has been interfered with, the bronchial have been found enlarged, the extent of their distribution increased, and they have taken on the function of true respiratory vessels.

Lastly, we may remark that a belief in the entire separation of the two systems of vessels is not for the first time promulgated by Dr. Heale. It had previously found a supporter in Hasse.

We have left ourselves no space for noticing several other points in Dr. Heale's work. We regret that he has not entered more fully into the minute structure of the lung itself. For instance, we should have been glad to have seen his opinion on the question of the epithelial lining of the air-cells. Although we have not hesitated to criticise his book, and although we doubt the truth of some of his observations, and conceive that others have been anticipated, we yet allow no small degree of merit to the author. Right or wrong, he has evidently worked hard and worked honestly. There are not many provincial Physicians in considerable practice who would devote leisure, and labour, and expense to the elucidation of points of abstruse science as Dr. Heale has done. If he has done nothing more, he has at least confirmed some observations that needed confirmation, inasmuch as they had been denied. His errors, if they be errors, would have been excusable if his subject of investigation had presented far fewer difficulties.

In conclusion, we would say that the exquisite woodcuts, from preparations made by Dr. Heale, are, in themselves, a valuable contribution to anatomical science. We differ from Dr. Heale in many things, but we concede to him the merit due to an honest and a diligent investigator.

---

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### CASE OF HYDROPHOBIA.

As our readers are aware, hydrophobia has been of late prevalent at Vienna. The following are some of the particulars of a case recently treated in the General Hospital:—On October 11, a boy, aged 6, was bitten in the left cheek by a mad dog. A Surgeon, called at once, merely approximated the edges of the wound, which was partly healed when he was brought to the Hospital. It was then re-opened and cauterised, and the child remained in the house without any bad symptom until the night of November 5 (twenty-five days after the bite), when the signs of hydrophobia began to manifest themselves, and rapidly became highly characteristic of the disease. Belladonna was given internally, while externally mercurial friction and subcutaneous injection of opium were resorted to. The boy died forty-eight hours after the outbreak of the disease, and three hours prior to his death erections existed. At the autopsy, the wounds were found cicatrised and covered with scabs. The dura mater was tense, and the sinus contained not only dark fluid blood, but also soft fibrinous coagula. The membranes and substance of the brain were considerably injected, and about a drachm of serum was found in the ventricles. The pons Varolii and the medulla oblongata were soft and humid, but to this in so young a subject Professor Rokitansky attached little importance. A few fibrinous coagula were found in the sinus at the base of the skull. The mucous membrane of the mouth and throat was pale, as was that covering the tonsils, although these last

were swollen, and discharged a discoloured purulent matter. The par vagum and sympathetic nerves were red and swollen, appearing also thicker on the right side. The sympathetic was remarkably softened. The left ventricle of the heart was contracted, and contained some soft fibrinous coagula, as did the left ventricle, which was in a relaxed condition. The stomach was contracted, and at its fundus a portion of the mucous membrane, the size of a thaler, had disappeared. The rest of the membrane was very pale, although there were also numerous ecchymoses, the size of pins' heads, scattered over it. The intestines were much distended and pale, the follicles being also enlarged. The kidneys were firm and the bladder contracted. The urine in this case was examined very carefully by Professor Haller. Its specific gravity was 1036, and it contained a most surprising quantity of uric acid. The proportion of urea was also greatly augmented, but only mere traces of any abnormal bodies were discoverable. The chlorides were only moderately diminished, while the sulphates were increased to an extent seldom met with, except in sulphuric acid poisoning. The earthy phosphates were also greatly increased.—*Wien Spitals-Zeitung*, No. 46, 1862.

[Professor Sohuh, in a clinical lecture on this disease, states that our only reliance is in prophylactics, and that the best of these is the caustic potass. He adds, that seeing the great number of persons who are bitten by mad dogs in Vienna, and who neglect applying at the Hospital for treatment until the day after the accident, and the very few cases of hydrophobia that occur, it follows either that man is very little susceptible to the contagion of this disease, or that the caustic may be applied with tolerable certainty of success twenty-four hours after the occurrence of the accident.—*Ibid.*, No. 48.]

#### EXCERPTA MINORA.

*Ointment in Decubitus.*—The following ointment, contrived by M. Brandes, an apothecary of Salzuffen, has been found by several German Practitioners a most efficacious application for bed-sores:—Armenian bole, prepared litharge, of each ʒ½; camphor, gr. v.; yellow wax, ʒiij.; lard, ʒvj.; M., to be spread on thick linen.—*Deutsche Klinik*, 1862, No. 32.

*Dislocation of the Great Toe.*—A workman, passing over a bridge on a dark night, fell into the river, and, in spite of the strong boot he wore, dislocated his right great toe. Compared with the opposite side, the toe was directed somewhat outwards and upwards—an obliquity of the great toe often met with, as a consequence of wearing too narrow shoes. A projection was felt plainly over the posterior surface of the metatarsal bone, while on the plantar surface the cavity in front of the metatarsal could be completely traced. The skin was uninjured, and the swelling was only slight. There was considerable pain, and walking was impossible. Chloroform having been administered, reduction was effected without much difficulty by employing strong extension (no apparatus being, however, required), after having bent the toe backwards to a right angle. The sesamoid bones offered no obstacle to the reduction. Some swelling followed, which subsided under the use of a bandage, splints not being required. The difficulty which has often attended the reduction of this dislocation, and the ill-consequences which have sometimes ensued, render it desirable to place this case on record.—*Ibid.*, No. 29.

#### REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, FEBRUARY 10.

Dr. BABINGTON, President, in the Chair.

A REPORT, by Dr. JEFFERY A. MARSTON, Royal Artillery, upon

SYPHILIS, IN ITS MANIFESTATIONS AS A CONSTITUTIONAL DISEASE,

was communicated by Mr. Henry Lee.

After referring to a previous paper,\* the writer gave a short *resumé* of prevailing doctrines. Upon the subject of one attack

\* Syphilis, with Reference to the More Mixed and Unusual Forms of the Primary Symptoms.—*Medico-Chirurgical Transactions*, vol. xlv.

of true syphilis affording an immunity against a second, the writer made some remarks illustrative of its general truth, to which, however, there were a few rare exceptions. Under this category he gave a case in which a soldier had been treated twice during eighteen months for indurated chancre. The writer next briefly adverted to the comparatively modern reaction relative to the contagious character of secondary syphilis. He then passed to the subject of secondary sores upon the penis, commencing either by a recrudescence in the cicatrix of a former sore, or upon some part not previously diseased. These he described under three heads:—1st. Such secondary lesions may commence as a circumscribed patch of purple or bluish redness, very slightly raised, from which the epithelium is shed, the surface becoming abraded, cracked, or covered with ill-formed and degenerating epithelial products. 2nd. This purplish-red spot, after becoming raised, takes on a chronic ulceration, similar to that of the scooped-out ulcers seen upon the tonsils. The first variety corresponds with, and often accompanies, a squamous or erythematous exanthem; the latter appears allied to the syphilitic tubercle, the ulceration of which plays so important a part in the evolution of syphilis in some subjects. The third variety appears as a persistence of the ulceration, or an unhealed condition of the chancre, which becomes transformed into a mucous tubercle, as described by Ricord. Of these he gave illustrative cases. Upon syphilitic infection, contracted from some other source than contact with a virus obtained from a primary lesion, the following were cited as in all probability instances:—1. A wife and two children. The former had syphilitic nodes and an ulcerating tubercle upon the lower extremity. Of the latter (who slept with her), one was an infant, in whom the disease was probably hereditary, though not congenital in its outward manifestations; the other was a girl of five years, with anæmia, non-ulcerated sore-throat, engorged post-cervical glands, cutaneous syphilids of trunk, with psoriasis palmaris. All had very restless nights. The husband lived separately, and was healthy. 2. The subject of disease was a military servant, a married man, who suffered from secondary and tertiary symptoms after intercourse with a woman known to be constitutionally syphilitic. Attempts to trace any primary lesion in this man failed. 3. The infection of a female by labial contact with diseased secretions from secondary lesions upon the lips of a male. The disease so produced in the female commenced as an irritable and indolent fissure upon the mucous membrane of the lower lip. The writer next adverted to the evolution and succession of syphilitic symptoms as ordinarily witnessed among soldiers. Under the cutaneous affections, he particularly remarked upon the mixed character of these; the majority of cases partaking of more than one affection at the same time, and upon the same or different parts of the body. Although great modifications in the future health and efficiency of the soldier were, doubtless, the result of syphilitic infection, yet cases of the more severe and intractable forms of constitutional disease were not very common. With the view to prognosis, the writer said it was important to inquire, what relation, if any, has the severity of the primaries to those of the later symptoms? From a consideration of his own observations, he inferred that the following were as approximate expressions to the truth as the facts warranted:—1st. That the greater the induration, and the longer the period during which primaries remain unhealed, the more certain will it be that the constitutional infection will be severe. 2nd. That the amount of ulceration, etc., of the primary sore stands in some relation to the worse and more intractable forms of secondary lesions—*e.g.*, the pustular, erythematous, and rupitic eruptions—the unhealthy ulcerations, nodes, and gummatous tumours. The writer then passed to those cases in which there was an irregular evolution and succession of the stages and symptoms of syphilitic disease. Assuming that, when an indurated sore has been recognised, some specific treatment has been employed, and that soldiers are exposed to changes of climate, etc., we might infer, what is actually the case, that the constitutional symptoms would be irregular in their appearance and varied in their kind. As illustrative of his remarks, the author cited:—1. A case of Hunterian chancre unhealed at the end of three months, when syphilitic rheumatism and a node upon the left parietal bone appeared. 2. A case in which, three years after a sore upon the external integument of the penis, a soldier suffered from two attacks of jaundice, anæmia, nodes upon the tibiæ, synovitis of left knee-joint, and rheumatism, without any history of secondary

symptoms having been traced. 3. A case of repeated epileptic attacks, with violent pain in the head (upon which a node appeared), cured by specific treatment. The subject of the disease had suffered from repeated attacks of venereal disease, but not from any primary disease for two years and a-half previously. 4. A case of chronic dyspepsia, slight icterus, pseudo-epilepsy, and paralysis of the third nerve. History of syphilitic attack two years before. Treated then by mercury. No history of secondary symptoms elicited by close questioning. 5. A case of osteocopic pains, paralysis of seventh nerve, followed by lichen and iritis, in a man undischarged from Hospital for primary disease. 6. One of secondary syphilis, in which symptoms of intracranial inflammation appeared, followed by marked alteration of manner, loss of memory, dirty habits, etc. 7. Case in which there were—first, symptoms indicative of venous lymphatic absorption of pus, or some of the diseased products of secondary lesions; second, ocular disease, paralysis of third nerve, and other symptoms indicative of intracranial mischief. The writer adduced also other cases, and made some remarks upon the character and nature of these nerve lesions. As illustrative of the long interval which sometimes ensues between an attack of primary and secondary symptoms, he adduced the following:—8. Lepra, psoriasis, and syphilitic cachexia in a man who had not suffered from primary disease for nearly five years; he had been married for three, and his offspring were healthy. 9. Syphilitic cachexia, etc., in an infant, who died of the disease; the father not having had primary symptoms for four years, and having been subsequently the parent of one healthy child. The author then spoke of the occasional latency of the syphilitic element, until some other disease or impairment of health appeared, which seemed to act as an exciting cause to its manifestation. He also remarked upon the modifications of diseases, or convalescence from them, that are sometimes, apparently, the result of a prior syphilitic infection. In support of the foregoing he gave some cases. The paper concluded by stating the experience of the author to show that the effect of the Mediterranean climate upon the syphilitic diathesis was very inimical during the summer months.

Mr. SOLLY said that it appeared to him, after the reading of the paper, that the anti-mercurial treatment of syphilis was now bearing its fruits in the remarkably frequent occurrence of secondary symptoms. When he was a pupil at St. Thomas's it was thought a disgrace to a Surgeon that his patient should suffer from secondary symptoms. That was the period when mercury was mainly relied on in the treatment of the primary affection. Then the Army Surgeons said there was no necessity for the use of mercury, and the disease was treated without. He (Mr. Solly) might be wrong in attributing the present prevalence of secondary disease to the abandonment of mercury; but with respect to the facts there could be no doubt.

Mr. HOLMES COOTE said that there was difficulty in replying to an essay which embraced so many points as the paper which had just been read. He begged, however, to record his protest against the prevailing practice of including so very many diseases, without further and more stringent proof, in the category of constitutional syphilis. He had never met with cases of syphilitic pericarditis or peritonitis, nor did he understand syphilitic inflammation of the lungs. That persons who had suffered from syphilis might be the subjects of such affections there was no doubt, but he saw no relation between the two. Respecting the treatment of primary syphilitic sores, he entertained no doubt, in the first place, that mercury was unnecessary in by far the greater number of cases; in the second place, that when administered, even in the best selected cases, that mineral afforded no security against the occurrence of secondary symptoms. He thought that the use of mercury was to enable the Surgeon to expedite the healing of an indurated chancre. It mattered not at all whether it were administered by the mouth, or, as in the fashion of the past times, by inunction. The occurrence of secondary symptoms, or rather, he should say, of constitutional symptoms (for secondary and tertiary symptoms by no means invariably preserved their numerical relations), was greatly influenced by the habit and position of the patient. The immunity of the convicts at Gibraltar from such disease was only an instance of what temperance and healthy avocations would effect. Among the people of the Levant, who are certainly abstemious, syphilis in any form is uncommon. He

had taken some pains to ascertain at St. Bartholomew's Hospital the relative frequency of constitutional syphilis among those who had and those who had not taken mercury for the treatment of the primary sore, and he should say that, *ceteris paribus*, the returns were equal.

Mr. SPENCER WELLS defended his old associates in the Navy, and their brethren in the Medical Department of the Army, from the charge implied in the remarks made by Mr. Solly. It would be most unjust if a statement were to go forth from that Society without contradiction, that the prevalence of secondary syphilitic disease in the public service was the fruit of the disuse of mercury by Army and Navy Surgeons in the treatment of the primary sores. There was no foundation for any such charge. It is to the Army and Navy Surgeons that we are indebted for much of the knowledge we possess of the pathology and treatment of syphilis. Soldiers and sailors are under the observation of their Surgeons for many years, and the rules of the services require that records of all cases of illness must be preserved; so that Army and Navy Surgeons have far better opportunities of observing the final result of their treatment than can often be found in private practice or in civil Hospitals. Thus, as syphilis is so very common a disease in the services, a greater number of facts has been collected to determine the true influence of mercury upon syphilis than can be obtained with regard to any other Medical question, with the exception, perhaps, of vaccination. These facts, carefully observed and accurately recorded, and numbered by many thousands, prove not only that mercury is unnecessary for healing primary sores, but that it actually retards the cure of the common or non-indurated sore, although it hastens the healing of the indurated sore, or true Hunterian chancre. And they prove not only that mercury is no preservative from secondary symptoms, but that the frequency and severity of the secondary symptoms are increased in direct proportion to the quantity of mercury used, and that many of the more formidable varieties of tertiary disease are caused, not by syphilis, but by mercury. The true use of mercury in small quantities in the treatment of the primary indurated sore, and in some forms of secondary disease, is well understood in the Army and Navy,—its failure in preserving from secondary symptoms is better known than it is in civil practice; and it would be most unjust to blame gentlemen because they had ceased to follow a mode of treatment which ample experience has proved to be not only useless but injurious.

Mr. WYATT did not understand that Mr. Solly cast any reflection on Army Surgeons, but merely stated the fact, that when primary sores were not treated with mercury, secondary disease was more common. He (Mr. Wyatt) differed from Mr. Coote in respect to the influence of syphilis on pulmonary disease; he had seen it modified by syphilis on many occasions. This influence he had observed in several other diseases.

Dr. O'CONNOR said it was a delusion to suppose that a blood disease like syphilis was purely Surgical, and he had no hesitation in stating that nearly all the mischief resulting to patients who were the subjects of primary syphilis was owing to their being supposed to be cases requiring only Surgical interference. This would account for the errors in treatment which Mr. Coote seemed to labour under. Notwithstanding the large field for observation at St. Bartholomew's Hospital, he (Dr. O'Connor) had quite as extensive opportunities at the Royal Free Hospital, where he had seen a vast number of patients, the subjects of syphilitic diseases of the nervous centres and internal organs. Mr. Coote doubted the existence of such forms of constitutional syphilis, although they had been for years written on by many truthful authors, including Drs. Graves, Stokes, Todd, and Read. He had himself placed on record many interesting cases of paralysis and epilepsy depending on syphilitic origin. Dr. O'Connor related the particulars of cases of syphilitic disease of the liver, lungs, ovaries, and cases of syphilitic menorrhagia, which had come under his care, and all of which he treated successfully. He was of opinion that there was no blood poison that so extensively influenced the true nature of disease at the present day as the existence of constitutional syphilis. That condition he believed to be due either to non-mercurial or imperfect mercurial treatment. He contended that what was good in the treatment of syphilis was mercury, and what was not good was not mercury; when to use and when to discontinue it was the great desideratum in the treatment of syphilis. The insoluble preparations of mercury he believed to be the most efficient,

used externally by inunction, internally, or in the form of suppositories. Iodide of potassium he believed to be valueless as an anti-syphilitic remedy, but much benefit was derived from its use after a proper mercurial treatment, in promoting the elimination from the tissues of the insoluble preparations of mercury already partially acted on by the juices of the body. Besides, iodide of potassium was a prophylactic to tertiary symptoms. It was supposed by some that syphilis was communicable from a wet nurse to her nursing without the presence of an eruption. He was of a contrary opinion; many cases had been under his care where the disease was communicated by the milk and saliva, and he related the particulars of one case, a patient at the Royal Free Hospital during the last year.

Mr. SOLLY had no wish to cast a slur on either navy or army Surgeons. The matter before them was one of opinion, and was open to discussion.

Mr. COOTE did not dispute the statements made by the author; but he contended that we required more stringent evidence than he had given as to what was or was not syphilitic. The effects of mercury, as spoken of, were not sufficient tests. He was not prepared to admit the occurrence of the internal syphilitic diseases enumerated by the author.

Mr. HILTON regarded the paper as an able one; but there were so many complications in the treatment of the cases, and so much depended on change of climate and other causes, that it was difficult to deduce any direct opinion from the facts presented. What did Mr. Solly mean by the non-mercurial treatment now bearing its fruits? Did he refer to the general treatment of syphilis thirty years ago in the army by nitric acid? He thought that it had been proved by that practice, that there were fewer cases of secondary affection than when mercury was indiscriminately employed. He (Mr. Hilton) thought the great error in the treatment of the disease at the present time was the complication of remedies employed; so that it was really difficult to determine what symptoms were the results of the disease and of the remedies respectively. Mercury, properly administered, was the best treatment in syphilis; but, when given internally, it must not be allowed to interfere with digestion, or it would do harm by setting up irritation—a very common effect when mercury was given in a routine way. He preferred the treatment by inunction. Small quantities of mercurial ointment, such as five or ten grains, rubbed in night and morning, were sufficient to produce the specific effect of the remedy, and cure the disease in almost every case. His (Mr. Hilton's) Hospital experience of the disease differed from that mentioned by Mr. Coote. He found that most of the cases admitted presented complications, the result of improper treatment, the administration of mercury by the mouth, variety of remedies, and carelessness in regard to diet. When mercury was administered by the skin, it was not necessary that the same great care as to changes of temperature, etc., should be observed. Complications arose from improper treatment, which served to confuse that which in reality was a simple disease.

Dr. WEBSTER said, although Physicians were sometimes considered as no great authorities in reference to syphilis, he would nevertheless remark that this disease was occasionally assigned in asylum reports as a cause of mental alienation. Indeed, one of the cases described in the paper read formed a good illustration. Some observers believed such a sequence was by no means uncommon, especially among persons hereditarily predisposed. On that point he would appeal to Dr. Wood, then present, who, having had much experience in mania, was in a position to answer the inquiry. Respecting another question—namely, whether climate ever exercised any influence—he (Dr. Webster) did not wholly agree with the author; nor in the deduction implied, that hot summer weather aggravated syphilis and rendered it more common compared with a cold temperature. In support of an opposite opinion, Mr. Coote had just mentioned its rarity at Smyrna; while he (Dr. Webster) would assert, after lately visiting Spain and Portugal, notwithstanding the malady was rife in those countries, it did not appear either more severe or more general than throughout northern regions. For example, at St. Petersburg and Moscow syphilis prevailed quite as inveterately as the author had noticed in warm, moist, Mediterranean climates. To Stockholm similar remarks applied, as, likewise, to other large towns in the north of Europe, where the disease seemed both as prevalent and marked in symptoms as elsewhere. Regarding this fact, a recent report presented to the Norwegian government might be quoted,

which stated that in Christiania 3560 individuals—all being from the lower ranks—were admitted into the Hospital appropriated for syphilitic patients during the last thirty years. But as the above number did not include persons analogously affected who belonged to other classes of society, nor those treated at their domiciles, that official statement proved the frequency of syphilis in that northern city, which contains only about 35,000 inhabitants. Thinking the circumstance might be interesting to British practitioners, Dr. Webster added that at the Venereal Hospital of Moscow the non-mercurial treatment was not much in favour with the Medical officers, who chiefly relied upon mercury for effectually curing true chancre and its consequences.

Dr. Wood said that, during the time he was at Bethlehem, cases, he believed, were occasionally admitted which were stated to have been caused by syphilis; but he could not be quite positive on the matter. Since he had been Physician to St. Luke's no case had been admitted in which alienation was attributed to syphilis. It was very rare indeed to find insanity produced by that disease. It might tend to the production of insanity, no doubt, by its exhaustive influence on the system, as did other exhaustive diseases; but it did not, he thought, act as a direct cause.

Mr. SOLLY regarded the most successful treatment of syphilis as that by inunction. He believed that the greater success of treatment at St. Thomas's over St. Bartholomew's was to be explained by the fact, that in the former the mercury was administered by the skin, and in the latter by the mouth. It was difficult to say what was the real amount of secondary symptoms in his Hospital patients; but in his private practice it was certainly very small.

Mr. COOTE said that the inunction system was only the old fumigation revived. The results were equally good in whatever way mercury was administered, provided proper care and discrimination in its employment were exercised.

## LEGAL INTELLIGENCE.

### LIVERPOOL COUNTY COURT.

(Before Mr. Serjeant WHEELER, Judge.)

ACTION BY A SURGEON TO RECOVER HIS FEES.

PARKER v. CHILTON.

THIS was an action brought to recover £8 8s., the balance of an account for Medical attendance. The plaintiff, Mr. E. Parker, is a Surgeon, residing at Kirkdale; and the defendant, Mr. J. Chilton, is a solicitor, of Liverpool, but residing at Walton. £2 15s. was paid into court.

Mr. Dodd appeared for the plaintiff, and Mr. M'Oubrey for the defendant.

It appeared from the evidence of the plaintiff that he had been in practice for twenty-four years. During 1861 he visited Mr. Chilton's family professionally. Mr. Chilton resided at Orchard Hey, near Preston-road station, about two miles from the plaintiff's residence. His attendance began in March, 1861, and was continued until July of the same year. Mrs. Chilton was confined in June, 1861, but the plaintiff's visits prior to her confinement were to the children and Mrs. Chilton, and not in connexion with the confinement of the latter. Mrs. Chilton presented the plaintiff with three guineas on the day of her confinement. The three guineas paid him up to that time. On the 26th of June Mrs. Chilton asked the plaintiff to send in his bill, and he did so. He charged 10s. 6d. for a night visit, and 7s. 6d. for the other visits, which he considered to be a reasonable and the usual charge. The bill amounted to £6 10s. 6d. He made five visits subsequently, and charged 7s. 6d. a visit; and he sent in a second bill for £1 7s. 6d. He had called to get his bill paid, but was ultimately informed by Mrs. Chilton that her husband was not sure that all the visits charged had been made, and the plaintiff said he would send a bill of particulars to Mr. Chilton.

In cross-examination, the plaintiff said that he had been sent to Mrs. Chilton by Mr. Banner, Surgeon, of Rodney-street, who had previously attended the family. He (plaintiff) had prescribed for her with reference to her general health.

His Honour asked if Mrs. Chilton was to be called as a witness, and Mr. M'Oubrey said that she would not be called. His Honour said it appeared to him the only question that could be disputed was, whether the charges made by the plaintiff were proper. It was a serious imputation upon a

Medical Practitioner in Liverpool, who had undoubtedly, as far as he (his Honour) had seen him in the box, given his evidence with the greatest possible regard to truth, to turn round upon him in this way. This case had been adjourned to allow Mrs. Chilton to be in attendance, but he had so good an opinion of the sex that he should have been very sorry to see her go into the box to disparage the Medical gentleman who had attended her.

Mr. R. J. P. Harris, Surgeon, of Rodney-street, deposed that the charges made by the plaintiff were, in his opinion, reasonable. In cross-examination, he said the charges of a Practitioner were influenced by distance and the respectability of the patient.

Mr. Brown, of London-road, was called for the defence, and in answer to his Honour said he was a Physician.

His Honour: How can a Physician tell a Surgeon's charges? It was intimated that Mr. Brown was also a Surgeon. He was a Doctor of St. Andrew's.

His Honour: Just what I expected. This is done away with now, is it not?

Mr. Brown: No; residence is now required.

His Honour: Formerly a person could go there one day and get a degree, and walk away dubbed "Doctor" the next. I have a great objection to this, and prefer degrees got by hard work.

It was stated that Mr. Brown was a member of the College of Surgeons, Edinburgh, and his Honour expressed his satisfaction.

Mr. Brown said he had attended Mrs. Chilton. If witness's patients were of the ordinary class, and if he called upon them in his round, he should charge 5s. 6d. a visit and for expenses—that was 6d. for the toll-bar.

His Honour gave a verdict for the plaintiff for the amount claimed.

## MEDICAL NEWS.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—At a General Meeting of the Fellows, held on Monday, February 16, the following gentlemen, having undergone the necessary Examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—

John James Barrett, 29, Merrick-square; Joseph James Henry Bartlett, Ladbroke-lodge, Notting-hill; Hermann Beigel, M.D., 19, Woburn-place, Russell-square; Charles Blatherwick, Highgate; Richard Luscombe Elliot, Kingsbridge, Devon; Anastasius Joannides, M.D., 43, Chepstow-place, Bayswater; William Jones, Ruabon; Washington Lovegrove, 34, Dowgate-hill; and George Padley, Swansea.

**ROYAL COLLEGE OF SURGEONS.**—The following gentlemen, having undergone the necessary Examinations at a meeting of the Board on the 18th inst., received the Diploma to Practise the Art and Science of Dental Surgery:—

James Gabriel Surene, M.D. Edin., Heriot-row, Edinburgh; Edwin Holboro Green King, Portsmouth; William Vanderkemp Moore, Plymouth; John Hewitt Hatfield, Lloyd-square, Pentonville; Geo. Frederic Fox, Gloucester; Edwin Cox, Chapel-street, Preston; Samuel Amos Kirby, Huntingdon; John Henry Brown, Brighton; Henry Robt. Rowe, Preston, Lancashire; and John James Holford, Princes-street, Cavendish-square.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, February 12, 1863:—

Francis James Ryder, Royal Kent Dispensary; Thomas Osmond, Thorpe-le-Soken, Essex; Isidore Bernadotte Lyon, 20, Euston-square; Arthur Beadles, Broadway, Worcestershire; George Granville Bothwell, Rathmullan, Ireland; and Thomas Edward Williams, St. Bartholomew's Hospital.

The following gentleman also on the same day passed his First Examination:—

Alexander James Low, St. Bartholomew's Hospital.

## APPOINTMENTS.

BRADLEY, SAMUEL M., M.R.C.S. Eng., has been appointed Physician's Assistant at the Manchester Royal Infirmary and Dispensary.

BRITAIN, THOMAS LEWIS, M.D. Edin., has been elected Assistant House-Surgeon to the Chester General Infirmary.

COULSON, WILLIAM, F.R.C.S. Eng., appointed, by his Royal Highness the Prince of Wales, Sheriff of Cornwall.

COWELL, GEORGE, M.R.C.S. Eng., has been appointed Surgeon to the St. George's and St. James' Dispensary.

DUNN, ANDREW, M.D. Edin., has been appointed Ordinary Medical Officer to the Public Hospital, Jamaica.

FIDDES, ALEXANDER, F.R.C.S. Edin., has been appointed Ordinary Medical Officer to the Public Hospital, Jamaica.

FORBES, D., M.D., has been appointed Surgeon to the Glasgow Lock Hospital.

GERVIS, HENRY, M.D. Lond., has been appointed Assistant-Physician to the Surrey Dispensary.

GRIFFIN, F. C. G., Weymouth, B.A. Lincoln College, has been elected to the Radcliffe Travelling Fellowship, Oxford University.

MCDONALD, KEITH N., L.R.C.S. Edin., has been appointed Resident Medical Officer to the Eastern Dispensary, Bath.

MASON, FREDERICK, L.R.C.P. Edin., has been appointed Surgeon to the Bath Eye Infirmary.

NUNN, THOMAS WILLIAM, F.R.C.S. Eng., has been appointed Surgeon to the Middlesex Hospital.

SCHOLLICK, T. J., M.R.C.S. Eng., has been appointed Resident Medical Officer to the Guildford and West Surrey Dispensary.

STERN, MORITZ, M.R.C.S. Eng., has been appointed Resident Medical Officer and Medical Registrar of the Public Hospital, Jamaica.

TEEVAN, WILLIAM FREDERIC, F.R.C.S. Eng., has been appointed Third Surgeon to the West London Hospital.

WATSON, WILLIAM, M.R.C.S. Eng., has been appointed Honorary Surgeon to the Lancaster General Dispensary and House of Recovery.

## DEATHS.

CHALDECOTT, FREDERICK JAMES, M.D., at Sydney, Australia, on December 22, 1862, aged 37.

COLLYNS, WILLIAM, M.R.C.S. Eng., at Chudleigh, Devon, on January 15.

FREMONT, C. J., M.D., of Quebec, Dean of the Faculty of the Diocese of Laval University, at sea, on board the Canadian mail steamship *Bohemian*.

HENDERSON, P., M.A., M.D., of Ottawa, at Buritts Rapids, on December 26, aged 45.

HUMPHREYS, W. H. J., M.B., only son of G. Humphreys, M.D., of Harcourt-street, Dublin, on February 2.

THOMAS, JOHN, M.R.C.S. Eng., at Ladbroke-place West, Notting hill, on February 15, formerly Resident Medical Officer of Bethlem Hospital.

WILLIAMS, RICHARD PARRY, L.F.P.S. Glasg., at Bron Offa, Adwyr-Clawdd, Wrexham, lately.

**ANTHROPOLOGICAL SOCIETY OF LONDON.**—We hear that the above young society is already so far in a flourishing condition as to be able to hold its first meeting on Tuesday next, the 24th inst., at 4, St. Martin's-place (7.30 p.m.), when an introductory address will be delivered by Dr. James Hunt, F.S.A., President.

**LONDON INSTITUTION.**—In Mr. C. Carter Blake's second lecture on *Aves Præcoces*, after briefly describing the general characters of the class of Birds, he discussed in detail the order *Natatores*, divided into *Brevipennatæ*, *Longipennatæ*, *Totipolmatæ*, and *Lamellirostratæ*; the order *Grallatores*, divided into the *Macroactyles*, *Cultirostres*, *Longirostres*, and *Pressirostres*; the order *Cursores*, exemplified by the *Apteryx*, *Dodo*, *Ostrich*, *Cassowary*, *Notornis*, and *Dinornis*; and the order *Rasores* divided into the *Clamatores* and the *Gemitores*. The next lecture will be devoted to the *Aves Allrices*.

**NOBLE MUNIFICENCE.**—Miss Rosa Frances Lewis, of Cadogan-place, the only daughter of the late Mr. W. T. Lewis, the celebrated comedian, and past proprietor of Covent Garden Theatre, has left nearly 15,000*l.* to charitable institutions, and has not forgotten some of our Medical institutions, having bequeathed to St. George's Hospital, 200*l.*; the Hospital for Consumption at Brompton, 200*l.*; the Asylum for Idiots, 100*l.*; the Lying-in Charity, Liverpool, 200*l.*; the Infirmary, Brownlow-hill, Liverpool, 200*l.*; and the Dispensary, Vauxhall-road, Liverpool, 200*l.* By the death of this estimable lady a sum of 10,000*l.* and the portrait of her father by Sir Martin Shee reverts to the National Gallery.

**THE Metropolitan Association of Medical Officers of Health** will hold their next meeting this (Saturday) evening at half-past seven o'clock, at 8, Richmond-terrace, Whitehall. A communication will be read from the Secretary of the Epidemiological Society, respecting the "Proper Registration of Sickness among Paupers." Mr. Chadwick will make a proposal in reference to an application to Parliament on the "Sanitary Requirements of Public Schools." At eight o'clock, Dr. Murchison, Physician to the London Fever Hospital, will read a paper on "Continued Fever." A communication will be read by Dr. Boycott, Physician to the Canterbury Hospital, on the "Fever of Canterbury." Visitors may be introduced as usual.

**DISCOVERY OF HUMAN REMAINS.**—Five skeletons have been found in a field on the right of the road leading from Guildford to Merrow. They were buried in excavations cut

in the solid chalk, at a depth of between two and three feet from the surface. The skeletons lay due east and west, the head to the west and the feet to the east. Mr. F. D. Ross, Surgeon, who examined the bones, pronounced them to have belonged to individuals of different ages. The pelvic bones of one skeleton indicated that it had belonged to a female. A blade of iron much corroded, about four inches in length, was found in one of the excavations. There have been various theories started with regard to the remains, but none assign to them a very high antiquity.

**RUSSELL v. ADAMS.**—The case of *Russell v. Adams* is creating considerable attention in Professional and general circles, owing to the equivocal character of the verdict for the defendant. On Wednesday afternoon an influential preliminary meeting was held at No. 5, Cavendish-square, John Brady, Esq., M.P., in the chair, at which a resolution was unanimously passed, calling a public meeting, and inviting members of the learned professions and the public to take into consideration the best means to suppress the increasing practice of attempting to extort money by false charges. A resolution was also passed, electing a general and executive committee. The following gentlemen were present:—W. Coulson, Esq., Borlase Childs, Esq., J. B. Brown, Esq., J. F. Clarke, Esq., Haynes Walton, Esq., Dr. Markham, Spencer Wells, Esq., W. Harvey, Esq., G. Lawson, Esq., Dr. Leared, Dr. Wynn Williams, Dr. Dick, H. Thompson, Esq., W. L. Leaf, Esq., H. H. Cannan, Esq., John Churehill, Esq., Ernest Hart, Esq., J. Tomes, Esq., S. S. Scriven, Esq., Dr. Brown-Séguard, John Chapman, Esq., W. F. Low, Esq., Dr. A. L. Fisher, Erasmus Wilson, Esq., Dr. Bloxam, John Gay, Esq., John Erichsen, Esq., Dr. Cape, Dr. Ross, etc., etc. The following executive committee was also elected:—The chairman, John Brady, Esq., M.P., M.D.; John B. Walker, Esq., 17, Clifton-gardens, W., hon. secretary; W. L. Leaf, Esq.; Benjamin W. Richardson, Esq., M.A., M.D.; J. Dangerfield, Esq.; Mr. Sheriff Jones; T. Spencer Wells, Esq., F.R.C.S.; H. H. Cannan, Esq. The proceedings of the meeting were enthusiastically received, and terminated with a vote of thanks to the chairman.

It is now definitely stated that the principal officers of the staff at Fort Pitt Hospital, Chatham, together with the professors and heads of departments connected with the Army Medical School at that establishment, will leave the garrison and enter on their duties at Netley Hospital during the first week in the ensuing month, immediately after which the entire invalid depôt at St. Mary's Barracks will also move to the same establishment. As soon as the new arrangements are completed Chatham will cease to be the station to which troops will be forwarded from all parts of the world for the purpose of being discharged. Under the new system the vessels arriving from abroad with troops will lie in Southampton Water, near Netley, where the time-expired men and invalids will be landed, when those not requiring Medical or Surgical treatment will be at once sent inland to their depôts or forwarded to their homes, while the sick and wounded only will be detained in the hospital, the plan of keeping up what is termed an invalid depôt, as at Chatham, being discontinued. The intention to convert Fort Pitt into barracks for the reception of officers and troops has, it is understood, been abandoned, and the building will still be retained for a hospital, for which its excellent site eminently fits it. According to present arrangements, it is intended to make Fort Pitt the central hospital for the whole garrison, thus doing away with the necessity of separate hospitals for the Royal Artillery, Royal Engineers, and the Line, as is the case under existing arrangements. The officers of the staff already named as selected for the new hospital at Netley are Col. R. Wilbraham, C.B., Governor; Major J. M. Kennedy, Paymaster; and Capt. W. Hawtree, Captain of Orderlies.—*Times*, Feb. 19.

**UNIVERSITY OF DUBLIN.**—The Spring Commencements were, according to custom, held on Shrove Tuesday, in the Examination Hall of Trinity College. More than ordinary interest attached to the proceedings this year, in consequence of the installation of the Earl of Rosse, as Chancellor of the University, having been fixed for the same time. The auspicious occasion was chosen also to confer on three distinguished members of the Surgical Profession the well-merited and high compliment of the honorary degree of M.D. Mr. Mackesy, of Waterford, whose distinguished Professional reputation led to his being the first provincial Surgeon ever chosen to fill the office of President of the Royal College of

Surgeons in Ireland; Dr. Arthur Jacob, the discoverer of the membrane in the eye, which has received his name; and Mr. Butcher, well known by his numerous and valuable contributions to Surgical science, were the gentlemen thus honoured. With respect to the selection by the Senate of the Earl of Rosse to fill the highest office in the University, we copy the following just remarks from one of the oldest of the Dublin newspapers, *Saunders's News-letter and Daily Advertiser*:—"Lord Rosse is an Irish nobleman of ancient and distinguished family, the owner of large estates, and, better still, a resident on the land he owns. He possesses not only the advantages of rank and fortune, but, apart from his distinguished position as a peer, is known to the world as one of the first of living men in point of scientific attainments. An acute and persevering observer, it has been his lot to throw new light upon the study of astronomy, to discover unknown worlds, to explode chimeras, and to establish just and well-founded theories. His magnificent telescope is one of the world-wonders of the present age; and although the cloudy skies of our climate have, no doubt, much impeded his course of observation, his discoveries have raised him to a European fame. Lastly, he is an *alumnus* of the University,—a fact which, in itself, constitutes no mean qualification, and which, taken in connexion with the other circumstances that rendered him so well fitted for the office to which he has been elected, leaves no room for wonder at the unanimity displayed in the recent vote of the Senate. No other candidate could, by any possibility, have been preferred to one who so fully satisfies all the conditions required in the Chancellor of the Irish University—Irish birth, distinguished position, an honourable name, high talents, extensive scholarship, and popular esteem. The College authorities have acted wisely, not only in electing Lord Rosse, but in making his installation an event of the first importance. No fact which has been chronicled in their calendar ever awakened as deep interest, or, in all probability, accomplished such permanent good. They have chosen to draw still closer the bond which links the University to patriotism, genius, and public service; and there is little doubt that they will have their reward in the growing strength of the affection with which intelligent Irishmen of all creeds and classes, who possess one spark of national pride, shall henceforward regard the institution of which the Earl of Rosse is the head." The following degrees in Medicine and Surgery were conferred by the newly-installed Chancellor:—*Baccalauri in Medicina*—Matthæus Steele, Christopher John Weir, Johannes E. Purdon, Gulielmus West Quinton, Gulielmus Stokes, Carolus Cameron, Gulielmus H. Symes. *Magistri in Chirurgia*—Carolus Cameron, Johannes E. Purdon, Gulielmus Stokes, Gulielmus H. Symes. *Doctores in Medicina*—Thomas L. Mackesy, Præses Coll. Chir. (*honoris causâ*); Arturus Jacob (*honoris causâ*); Ricardus G. H. Butcher (*honoris causâ*); Gilbertus De Poulton Nicholson, Philippus Crampton Smyly, Johannes B. Hamilton, Johannes Barker, Gulielmus Stokes. Among those on whom non-Medical degrees were conferred were:—William, Earl of Rosse, LL.D. (*honoris causâ*); Benjamin Lee Guinness, the munificent restorer, at a cost to himself of about £100,000, of St. Patriek's Cathedral, LL.D. (*honoris causâ*); Sir James South, LL.D. (*honoris causâ*); the Right Hon. and Hon. John Prendergast Vereker, *filius nobilis*, Lord Mayor of Dublin, LL.D., etc., etc. The proceedings were honoured with the presence of his Excellency the Lord Lieutenant, who, in the evening, entertained at dinner, at Dublin Castle, the Chancellor, Provost, Fellows, and Professors of the University, and a distinguished company.

**MEDICAL STATISTICS OF BERLIN IN 1861.**—At the end of 1861 there were 522 Physicians; 44 Surgeons of first class; 29 Surgeons of second class; 36 Dentists; 42 Apothecaries; 62 Veterinary Surgeons; and 154 Midwives.—Total, 889. In the Charité Hospital there were treated during the year, 11,188 patients, viz., 6432 men, 4089 women, 370 boys, and 297 girls: of this number 8791 are returned as cured or improved, 162 as incurable, 7 as sent away, 1104 as dead, and 1124 as still under treatment. Among the deaths were 71 children born dead. The proportion of deaths to the entire number treated was 9.8 per cent. The days of treatment amounted to 413,639. Returns are given of the patients treated at various other establishments, belonging to the different religious bodies and private persons; but the numbers of each are insignificant. Still, in the aggregate, they are considerable, making 22,444 patients treated at all the Berlin Hospitals, the days of treatment being 976,734.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

To Correspondents.—The present arrangements of the *Medical Times and Gazette* only allow the insertion of deaths of members of the Medical Profession.

*Veritas Vincit.*—Certainly not.

Dr. Kidd.—We regret that the space at our disposal does not permit us to insert Dr. Kidd's letter, nor to enter on the controversy to which it refers.

Dr. Morell Mackenzie's communication, on the "Dispensary for Diseases of the Throat," has been received.

M. D., 100.—The paper shall be inserted, but the great press of matter in our columns will necessitate some delay.

West Haddon.—Our correspondent will see, on referring to the report alluded to, that it was sent us by a correspondent, and referred only to the *Medical* details of the case. Our comments are reserved until the whole facts have been investigated before a legal tribunal.

The College of Dentists has found it expedient quietly to give up the principle of independence, and to seek amalgamation with the Odontological Society. We are well content that the body of Dentists should be one and indivisible, but we think that they would have better consulted their own dignity and professional standing by remaining a separate profession than by obtaining a doubtful standing within the walls of the College of Surgeons. We hear that a strong effort is to be made to induce the Medical Council to allow the enrolment of the certificated Dentists of the College of Surgeons on the Medical Register. We are certain that any such concession on the part of the governing body of our Profession will be received with marked disapproval by the legitimate Practitioners of Medicine and Surgery.

The Dwellings of the Working-Classes at Belfast.—Dr. Henry M'Cormac has addressed a letter to the mill-owners, house-proprietors, and employers of Belfast, calling attention to the condition of the working-classes in that city, and especially to their house accommodation. He says that, for many years, he has been labouring to bring about an amelioration in their condition, but hitherto in vain. We hope, however, that his very able remonstrance and appeal (from which we append an extract) will not be unproductive of good result:—

"It is not, I suppose, too much to say—is it?—that the municipality, that house proprietors and employers generally should inquire efficiently, see with their own eyes, into the state of the habitations of the poor. There is a very great—there is, in fact, an incredible—deficiency in house conveniences and propriety. If anything I could say would but lead to a periodical personal inspection on the part of mill-owners, employers, and others, I should rejoice indeed. Kindlier sympathies would awaken at the aspect of human suffering, and lead to commensurate efforts at relief; for, indeed, the houses of the Belfast poor are ill-constructed and worse supplied in respect of appliances for insuring human comfort and human decency. Few widows are made to pull down, and the vicinage of the dwellings is not kept adequately clean.

"Religion needs to be carried into action. A spoken religion merely is not sufficient. The verbal must become a living creed. This, I believe, is the great want at once of Christendom and the world. Religion should be a practice, and not a profession simply. I see abundant tracts here and there in the houses of the poor—tracts proclaiming that man is a wretch, and that a proximate hell yawns open for him. But I want to see distributed broadcast tracts that tell him that God and heaven are also nigh, and that man may be a very angel if he will but follow the path of right and duty. I would have tracts to tell that pure air must be breathed, day by day and night by night, to cleanse the blood, to keep the inner system clean. I would have tracts to urge outward purity—tracts declaring that the living frame, if not daily, at least weekly, should be bathed from head to heel. I would have tracts to urge the preparation of wheatmeal bread; for white bread, with weak tea, used three times each day, is not azotised enough, is quite unfitted for exclusive sustenance, and impairs in this town yearly the health of thousands. I would have tracts to point out the confection of wholesome stews and other cheap and wholesome nutriment. For how are working people to know these things unless through printed tracts or spoken words? The art of cooking and of keeping garments clean and comfortable should be taught in every school. I would have practical lessons in temperance—I do not mean abstinence simply—with the names and rational uses of wines and fermented drinks. Everywhere there should be free lending libraries, free public baths, concerts, lectures, museums, and gardens. Everything, in short, ought to be done, not to degrade, but to elevate; not to confine the aspirations to this life, but to lead them to the reasonable hope and expectancy of a yet more elevated life to come."

THE LATE GRADUATION AT THE UNIVERSITY OF ST. ANDREWS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—I was so staggered by the statements made in your Journal of January 31, with reference to the candidates admitted to examination in December last at the University of St. Andrews, that I at once wrote to Professor Day, calling his attention to the subject. I send you a copy of his letter in reply.

I have waited for this day's issue of your Journal, expecting that the Senatus Academicus would have thought the subject "deserving of notice." I am surprised that no communication has been forwarded to you relative thereto. If it be true that persons were admitted who possessed no legal qualification, such a proceeding was not in good faith with the published regulations, a believed adherence to which on the part of the Senatus Academicus may have kept many a third-year-man from presenting himself for examination. Of the character of the examination as a whole, for Practitioners, I have written you in an October number of your Journal, up to which time I have reason to believe the regulations were strictly followed out.

I am, &c.  
JOHN ROBERT KEALY, M.D. St. Andrews,  
Gosport, February 14. L.S.A. 1854, M.R.C.S. 1855, etc., etc.

"St. Andrews, February 3, 1863.

"Dear Sir,—My attention has already been directed to the mis-statements contained in the article you refer to. I shall direct the attention of the Senatus to the subject, but do not know whether they will think the subject deserving of notice.

Faithfully yours,

"G. G. DAY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—As I happen to be one of the individuals concerning whom a letter from "A Mature Graduate" appeared in your impression of February 14, it is but right that I should disabuse his perturbed mind and allay its excitement. His letter states that students of only two years' standing were admitted to examination at St. Andrews for the M.D. degree in December last. If the Senatus Academicus have, through force of circumstances, rather deviated from the usual track, and admitted a select number of gentlemen to examination before the completion of their entire curriculum, I could show your correspondent that such a procedure is by no means without precedent with other examining boards; and that, in this case, the Senatus have been especially careful in withholding the parchment until such curriculum in its entirety is fulfilled.

I cannot but coudemn the language of my fellow graduate, and congratulate him upon his good fortune if he is not severely censured by the Senatus for such a depreciation of the performance of their duty.

Perhaps the time is not far distant when, in medicine as in kindred sciences, a man's attainments will gain the meed of honour, even though the prescribed onerous formula of classes should remain unfulfilled. I may say it is my opinion the junior candidates were by no means the most leniently dealt with.

I am, &c.

ALBY.

[We have received private information that certain students, who would have been eligible under the old regulations for examination for the M.D. in April of this year, and who had commenced their studies with the intention of graduating at St. Andrews, petitioned the Senatus for leave to be admitted, when they had completed their curricula, under the old regulations. A strong memorial on the subject was sent to the Scottish Universities' commissioners, who, however, refused to relax the ordinance in favour of these candidates. Under these circumstances, and with the approbation of high legal authority, it was resolved that they should be admitted to examination in December last, provided they gave written pledges to complete their course of study. Five or six candidates presented themselves on these conditions, of whom three or four passed.—Ed.]

THE LARGEST PROVINCIAL MEDICAL SOCIETY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In your account of the annual meeting of the South Hants Medical Society, it is stated that, having ninety-one members, it is the largest provincial Medical Society in the kingdom. This is an error, as the Liverpool Institution Medico-Chirurgical Society numbers over 100 members. The Liverpool Medical Institution was built about twenty-five years ago by the Profession at great cost, and is, probably, the handsomest non-corporate Medical building in the kingdom; and is considered one of the ornaments of this great town. It has, in addition to its extensive library and reading room, a large theatre, a smaller lecture room, a museum, council chamber, and other minor apartments. In this building the British Medical Association held their meetings a year or two ago, and found ample accommodation. There is also a residence attached for the Librarian. The meetings of the members take place every alternate Thursday during the session. At these meetings specimens are shown, cases related, and papers read, and then follows a discussion on the various subjects brought before the meeting.

I am, &c.

ALEX. STOKES, M.D.,

Hon. Sec. Liverpool Medical Institution.

Liverpool Medical Institution, Mount-pleasant, Liverpool, Feb. 16.

ON THE THERAPEUTICAL ACTION OF QUININE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Having seen Dr. Laycock's paper and some letters signed "M.D." in your late Number, I think this a favourable opportunity of advancing my opinion on a subject which has occupied my attention for some time.

I believe that quinine is held to be a direct tonic on insufficient grounds, and that its real action is that of a sedative to the efferent nerves of the sympathetic, a conclusion at which I have arrived from the observation of the following facts:—

- a. It requires very much larger doses of quinine to produce its physiological effects in robust persons than in the debilitated; and in extreme asthenia even small doses are poisonous.
- b. It decreases the force and frequency of the pulse.
- c. When given in inflammatory fever, it restores the activity of the secretions, according to the following laws:—
  1. In sthenic cases, it requires large doses (from five to ten grains) to produce any appreciable effect, but then it invariably establishes profuse diaphoresis, and frequently diarrhoea, and diuresis, too.
  2. In asthenic cases, these results follow the use of much smaller doses, but in the extremely debilitated it fails to act so altogether.
  3. Stimulants very much increase its action in all asthenic cases.
- d. When administered to apparently healthy persons, it produces diaphoresis, diuresis, diarrhoea, or all, or none of them, in such an extreme capricious manner as to leave its claim to be a special stimulant to any organ concerned, out of the question.
- e. When administered along with stimulants which act specially on any secretory organ, it very much increases their efficacy.

These facts, which I have verified over and over again, I think point rather to the subduing of some antagonistic force than to the stimulation of that by which the secretions are induced; and I deduce from them, along with the foregoing hypothesis, the following practical point, which will also be found true:—

Quinine is only useful in dyspepsia which results from suppression of the digestive secretions from febrile irritation. It should be used rather in sthenic than asthenic cases of inflammation. It is not suitable in disease of the heart. I may also mention here that in erysipelas, and the exanthemata generally, the pulse cannot be modified by quinine, so that it becomes a useful diagnostic agent in Surgery; for, in the fever which follows injury, should its administration fail to affect the pulse, erysipelas may be certainly predicted.

I am, &c.

ROBERT WALKER, F.R.C.P. Edin., F.R.C.S. Edin.

Longtown, February 13.

THE WIRE COMPRESS, A SUBSTITUTE FOR THE LIGATURE.  
TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As you have thought Mr. Hilliard's plaint worthy of a place in your columns, I suppose it demands a reply from me.

If, instead of coming to a hasty conclusion from reading a mere abstract of my paper, he had waited until the said paper is published *in extenso*, he might have saved himself from the folly of rushing into print with an altogether imaginary grievance, for he would then have found that I have given him full credit for his share of the matter; which, if any of your readers care to know, may be thus briefly stated:—

In my paper on "Acupressure," published in the *Medical Times and Gazette* of June 2, 1860, having pointed out certain disadvantages of the needling process, I suggested, "as a crude hint," the use of a fine suture wire instead of the needles, which, I believe, was the first promulgation of this idea. Next post brought me a communication from Mr. Field, of Brighton, stating, his experience of the defects of the needles had "made him resolve that on a future occasion he would adopt the very method which I then proposed." At the same time came a letter from Mr. Hilliard, of Glasgow, till then utterly unknown to me, in which he says, "I am much pleased to see the modification which you suggest on Simpson's method. He goes on to state that the same idea had occurred to him, and points out a way of applying the wire differing somewhat from my crude plan, which, says he, "I think embraces fully your suggestion, and in addition is, perhaps, more simple and expeditious."

And so, indeed, sir, it has turned out; and accordingly my paper, read before the Medical and Chirurgical Society, contains the following passage:—"Here I ought to mention it was from Mr. Hilliard I first learnt that the abrupt bending of the wire is not an impediment to its removal; he also suggested to me the use of two needles in the way just described, by which the wire is applied much more expeditiously and exactly than by using a single needle." I also showed his needles and wire, and spoke of them as the best I had seen for the purpose.

Now, Mr. Hilliard ignores the fact that my paper on "Acupressure" not only referred to the defects of the needles, but also "promulgated the idea that the wire would be free from all these disadvantages, and would eventually supersede the needles," and claims to have first suggested to me the use of the wire, and taught me its application.

But, sir, I think you will agree with me that all discussion as to originality in this matter is perfectly preposterous. In my paper, I have, for myself, expressly disclaimed it, and am free to confess that I got the idea of compressing arteries by a metallic substance, instead of strangulating them by an organic ligature, from Dr. Simpson, of Edinburgh, to whom I am happy to repeat publicly my own sense of obligation for his happy invention.

Hull, February 11.

I am, &c.

JOHN DIX.

THE RECENT TRIAL IN LEEDS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Having been present in court during the trial, I can bear testimony to the accuracy of your correspondent's report.

There were two highly respectable Practitioners ready to give evidence in favour of the reasonableness of the plaintiff's charges, and a third, who did not remain on account of an important engagement, and also because of the arrangement made at the opening of the case—to refer the charges to Medical arbitration.

I have carefully examined the "bill," and can assure "Amicus Justitiæ" he is in error as to three guineas being charged for three visits: and these two charged one guinea each on the day of the accident, which this "friend of justice" says were paid within two hours of each other, were each of about two hours' duration, at a time, I find, when the patient's life was in imminent danger.

"Amicus Justitiæ," in his attempt to patch up the defendant's conduct, omitted to state that he did not offer £5 until legal pressure had been put upon him; he also omitted to inform you that he offered it in terms such as no gentleman could accept. The feeble attempt of "Amicus Justitiæ" to damage your correspondent's report would not have been worthy of the least notice, did it not afford an opportunity of saying a word about the Medical award.

It has hitherto been an acknowledged rule, that the station in life—in other words, the ability to pay—should, to some extent, regulate Medical and Surgical charges in all cases, but particularly in cases of accident. Now, it could not, in common fairness, be argued, that this working man (who, by-the-by, is a skilled workman at the head of an important department) was the person really called upon to pay this bill, because he had already received the money from the wealthy firm who were responsible for the accident, and then, impudently buttoning up his breeches' pocket, denied his obligation; and on the plaintiff asking him to hand over what he had received, he coolly told him "to go the devil," which the judge jocularly suggested had been done by going to the county court." Perhaps the judge was right. The Medical award was here made, upon the ground that the defendant was called upon to pay the money out of his own pocket. Had such been the case, no one could find much fault with the cutting down of the charges; but as no notice whatever is taken in the award of the collateral circumstances, particularly of the clenching fact, that the defendant had received the full amount. No doubt this case will, in the Leeds court, be taken as a precedent for the payment of the very smallest fees in cases where railway companies or rich firms are, by their carelessness, the cause of serious injury to her Majesty's subjects.

I must add, that the plaintiff deserves the best thanks of his Professional brethren for bringing the defendant before the court; for, if tamely submitted to, such flagrant injustice as that contemplated would have been derogatory to his own character, and a direct injury to the Medical Profession.

I am, &c.

APPOINTMENTS FOR THE WEEK.

February 21. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m.; Charing-cross, 1 p.m.  
ROYAL INSTITUTION, 3 p.m. Professor Max Müller, "On the Science of Language."

23. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Deau-street, Soho, 1 p.m.  
MEDICAL SOCIETY OF LONDON, 8½ p.m. Lettsomian Lectures on Surgery—Lecture III.—Thomas Bryant, F.R.C.S., "On the Diseases of the Osseous System, and on Tumours, &c."

24. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.  
ROYAL INSTITUTION, 3 p.m. Professor Marshall, "On Animal Mechanics."  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m. Meeting.

25. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.  
HUNTERIAN SOCIETY, 8 p.m. Mr. Hutchinson, "On Herpes-Zoster, a Pathological Riddle."  
ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 p.m. Gulstonian Lectures—Dr. Pavy, "On the Amyloid (so-called) and Fatty Degenerations."

26. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopaedic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.  
ROYAL INSTITUTION, 3 p.m. Dr. Frankland, "On Chemical Affinity."

27. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.  
ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 p.m. Gulstonian Lectures—Dr. Pavy, "On the Amyloid (so-called) and Fatty Degenerations."  
ROYAL INSTITUTION, 3 p.m. Mr. J. Lubbock, F.R.S., "On Swiss Lake Habitations."

EXPECTED OPERATIONS.

King's College Hospital.—The following Operations will be performed on Saturday (to-day) at 2 p.m. :—

By Mr. Fergusson—Ovariectomy; Excision of Breast; Lithotrity; Amputation of Penis; Prolapsus Uteri.

By Mr. J. Wood—Radical Cure of Heruia.

INAUGURAL LECTURE  
ON THE  
SKELETON OF A GLYPTODON,  
RECENTLY PRESENTED  
TO THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS.  
DELIVERED AT  
The Royal College of Surgeons,  
By PROFESSOR HUXLEY.

—

MR. PRESIDENT AND GENTLEMEN,—All those branches of human knowledge which, because they are pursued by definite and precise methods, and lead to definable and verifiable results, are called SCIENCES, have, I apprehend, two principal objects in view, and two great goals after which those who follow them strive. The one aim is to increase man's knowledge and to develop those faculties by which he alone, among the whole of the living creation, is capable of becoming a conscious mirror of the order and method of the universe. The other great object is to increase man's welfare, to diminish the number of those causes which tend to produce pain and evil, and to remove, as far as possible, the results of those causes when they have been in operation. There is nothing new in this view; there is nothing in it but a commentary at large upon the noble words of Bacon, that all knowledge tends to the advancement of God's honour and the bettering of man's estate; and I know of no more concise or more weighty statement of the objects of science than those words of the great chancellor.

That duality of aim of which I have spoken is nowhere better exemplified than by those biological sciences which we all here follow. That duality of aim is illustrated by your museum, containing, as it does, a magnificent series of objects illustrating the whole range of animal structure, and, at the same time, comprising a no less elaborate series of preparations intended more particularly to illustrate the physical evils to which man is liable, and to serve as beacons and warnings, and as instructions to the practical Surgeon. Nowhere is it more clearly shown than in the assemblage in this theatre at the present moment, where you, sir, so worthily represent that great Profession which more than any other tends to assuage the ills of human life; and where I, for the hour that you favour me with your attention, am the feeble representative of that other great branch of biological science, which deals with broad and abstract principles, following truth for its own sake, but trusting that, in the end, its fruits will more and more become available for practical ends.

But it will be obvious to you, that the objects for which we both work, although not really separated, are yet, from the convenience of the division of labour, practically distinct. For the practical Surgeon—for the man in pursuit of the healing art, all knowledge as it comes to him is questioned, whether it will eventually bear upon the curing of the patient, or the healing of the sick—and its value is justly estimated in its exact proportion to the aid it will yield in that direction. But, to those who deal with life from what I might call its speculative side, were it not for the unsatisfactory meaning that has been attached to that word—but, if using the word "speculative" in its proper sense, I look upon myself for the nonce as representing the workers at the speculative or purely scientific side of biological science—then I say that our standard of value for every particular fact, and for every acquisition, is not this, but is another. The object we have in view, in the long run, is to attain to a knowledge of that chain of causation which has led to the present condition of organic nature, to unravel it, and trace the connexion of its links; and every fact is specially and particularly valuable, as it tends to show us that chain of causation and unravel its coil one from the other. And, inasmuch as that particular division of biological science which is called "palæontology," but which is, in truth, hardly deserving of any special name, seeing that it is simply the application of all the other biological sciences to the explanation of the past course of life upon the globe—seeing that palæontology includes all these, it is,

perhaps, that science which has for us, at present, the highest and most profound interest; indeed, to sum up shortly my own view of the case, I may say that Palæontology and Pathology—using pathology in the broadest sense of the word—that those are the two summits and out-comes of all biological knowledge; that they are the twin summits of the tree of life, to which the streams of knowledge, pouring to its roots, are constantly adding. And, holding these opinions, you will understand why it was that, when I had the honour of being appointed to a Chair of Comparative Anatomy and Physiology in this College, I gladly seized upon the opportunity which offered itself in the occurrence and gradual growth, under my own eyes, of this remarkable specimen of an extinct animal, to illustrate this favourite notion of mine—certainly with pleasure to myself, and, I hope, not without some profit to my hearers. I propose, in fact, to take it as a text, and to endeavour to show how, in the elucidation of a fossil of this kind—in order to build it up, to understand its place in nature, and to comprehend the lesson it teaches us, many different branches of biological knowledge must be brought to bear upon it, so that, as an example of palæontological study, it should exemplify what I have said—that that science is the ultimate out-come of all the rest of our biological studies.

In attempting this task, I do not propose to go into the complicated business of analysing and putting before you precisely the share which many observers in succession have had in bringing our knowledge of this particular fossil form to the condition in which it now is. The discussion of that point must be gone over for the sake of justice and right; but, having been once dealt with, the sooner it is forgotten the better. It will take its place in that formal memoir which it will be my duty to draw up on the subject. Nor do I purpose to enter, to any great extent, into anatomical details; for, if I were to attempt anything of that kind, the time at my disposal would not be one twentieth of that which would be necessary. On the contrary, what I suggest is, that we should consider this skeleton as a problem presented to us for the first time,—to be solved, approximately, by the help of that anatomical knowledge with which we are all, more or less, familiar; and I ask you not so much to follow me as to go with me, in tracing out the steps by which it is necessary to proceed in attempting to solve the problem. Before commencing our task, however, there is one pleasant duty to be performed, which is the expression of our great obligation to Señor Don Juan N. Terrero, the gentleman upon whose property this most valuable specimen was discovered, and by whose exertions it was forwarded to this country, and was presented to the Museum at the time Mr. South filled the presidential chair. It is impossible to overpraise the zeal, and, at the same time, the discretion with which this present was made—so large was the number of bones collected, so complete the freedom of admixture from foreign elements; while it is exactly those parts which have been made known by this particular skeleton of *Glyptodon*, which have revealed peculiarities of structure which are not known to exist throughout the mammalian series, or, rather, which were not known before these valuable fragments were put together.

The specimen was found in an exceedingly shattered condition upon the banks of the Rio Salado, about eighty miles to the southward of Buenos Ayres, in South America, in that wide-spread alluvial deposit which has yielded the remains of a great number of extinct mammalia, some of which are among the ornaments of our museum. That deposit, whatever its precise age may be, belongs to the latest of the geological epochs which preceded the present—that "post pliocene" deposit which has lately been so thoroughly described in this and other countries by Sir Charles Lyell, and in which the oldest known remains of men have been found. So that, speaking geologically, the age of the specimen is not worth talking about; but, speaking historically, it is immense, and historical epochs furnish us with no term by which it may be measured. And there remains yet another word to be said respecting the exertions of the skilful artist by whose care these broken fragments have been put together. Mr. Waterhouse Hawkins, who has been employed upon this task by the wise liberality of the Council, by the skill and perseverance he has devoted to these fragments, and by the infinite pains he has taken in their arrangement, until at length he brought the specimen to the condition in which you now see it, has, I think, earned our warmest thanks.

I will now ask you to follow me in a brief sketch of the

characters of the skeleton, during which I will point out those parts which are made known to us for the first time by this specimen, or made known to us better by this specimen than by any other. I will indicate, first, the skull. Here, the

parts which have been added to what was already known, are the fore part of the skull, and the whole of the palate, with eight deeply grooved teeth on each side, whence the name of the animal. And then we have an exceedingly valuable addition

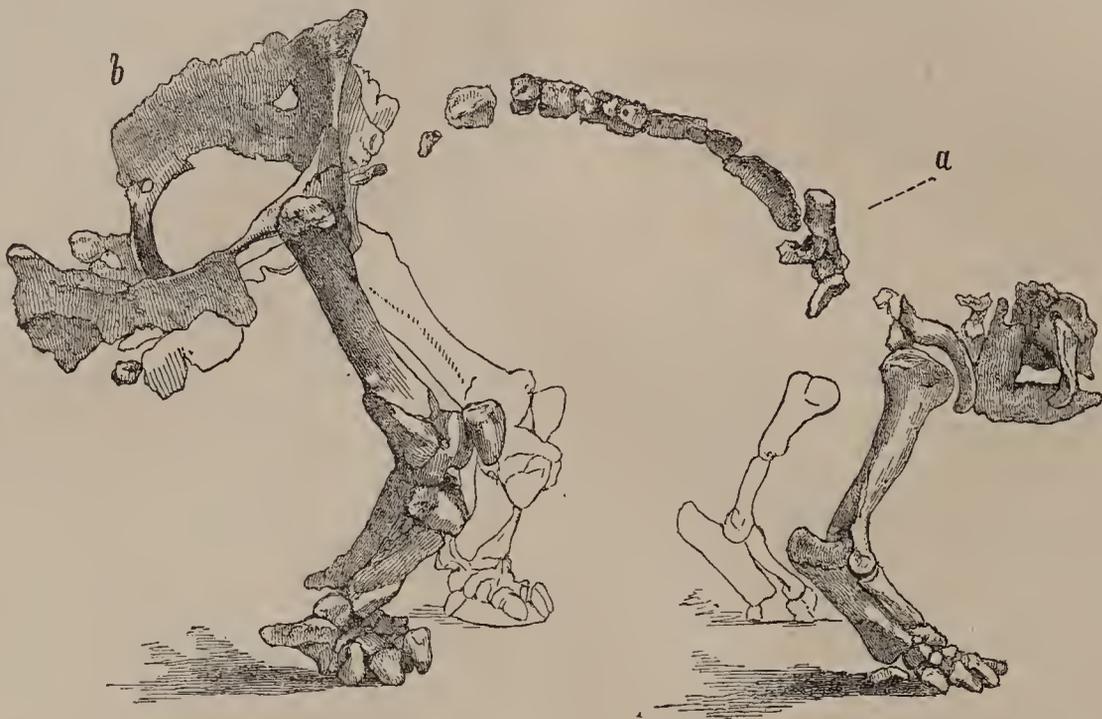

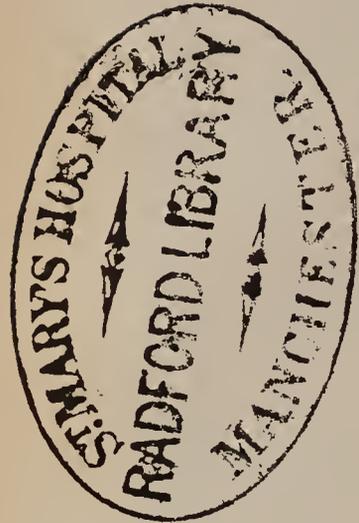

FIG. 1.—Side view of the skeleton of *Glyptodon*. *a*. trivertebral bone; *b*. sacrum.

in the complete lower jaw. In Professor Owen's well known paper on the specimen of *Glyptodon* already in the possession of the College, the lower jaw is represented in outline, and, as it happens, not correctly. That arises not from any fault of the describer, but from the fact, that a drawing of the jaw only was sent with the original osseous fragments, and this drawing turns out not to have been correct. M. Nodot has, indeed, proved that his *Schistopleuron* had a mandible of the same character as this, but it is not yet proven that *Schistopleuron* and *Glyptodon* are synonymous, so that we may fairly look upon this as the first complete example of the lower jaw of the *Glyptodon*.

It is to be noted that the teeth are not only grooved in the way I have described, but grow constantly from below, and consist of dentine and cement, with no external coating of hard enamel. The grinding surfaces of the teeth are broad and flattened by wear, and they indicate clearly that the food of the animal was of a kind requiring crushing and grinding. Next, there are two very interesting fragments of the cervical region of the vertebral column—there is a piece of the atlas, and a fragment of the axis, anchylosed with at least one other vertebra; then follows the remainder of the cervical and the dorso-lumbar portion of the vertebral column, consisting of two very definite portions. The first is this wonderful flat bone (*a*, Fig. 1), composed of three vertebrae anchylosed into a solid mass, and produced into a sort of handle, which represents, in fact, the spinous process of this great "trivertebral bone." Anteriorly and posteriorly the trivertebral bone exhibits very peculiar articular surfaces in addition to those on the ordinary articular or oblique processes; and these enable it to move in a vertical plane on the vertebra which follows it, allowing the vertebra (sixth cervical) which precedes it to move in a vertical plane on it. The anterior pair of these additional facets are convex—the posterior concave. There is nothing like this in ordinary Mammalia, but remarkable joints, constructed upon quite the same principle, are found in the armadillos. Next comes the great series of dorso-lumbar vertebrae, all anchylosed together, so that there could be no motion whatever in this vertebral column. It constituted, in short, a kind of solid tubular bridge, the bodies of the vertebrae being converted into segments of cylinders, while their arches are exceedingly flattened, and rise in the middle into spinous processes, which have all been broken off, but were, for the most part, anchylosed into one continuous high crest, so that we have a vertebral column, consisting of anchylosed vertebrae, arched from before backwards, and with a peculiar tunnel running through the whole, which lodged the spinal marrow.

The sacrum exhibits a similar structure. The sacral

vertebrae are anchylosed together with a considerable number of anterior caudal or coccygeal vertebrae, and, as you will see, the hindmost of these send out large, broad, transverse processes. The spinous processes of the sacral vertebrae are anchylosed and form a high crest, which unites with the expanded haunch bones, so that there was a kind of T-shaped support formed, with very broad and rough expanded edges; and then the iliac bones were united at the acetabulum with the ischia in the ordinary way, while these are tied to the coccygeal vertebrae by the great transverse processes already mentioned; so that, in fine, from the hinder extremity of the trivertebral bone to the commencement of the tail, there was one solid double arch of bones, consisting of all the vertebrae of the back save two, and of the lumbar, sacral, and anterior caudal regions, fused together into one mass. It is this structure which I referred to just now as being, so far as I am aware, without any parallel whatsoever in the mammalian series.

Unfortunately, the vertebrae of the tail are entirely absent. This is particularly to be regretted, for, in most other respects, this specimen enables us to reconstruct the animal. If we have not a bone of one side, we have that of the other side; or, if a part is absent anywhere, we have sufficient to make it up from other portions; but of the tail, all that is known is represented by this exceedingly precious fragment. It is one portion of a single ring of that great osseous case, which included, at any rate, the anterior part of the tail, just as other parts of the same vast shield protected the trunk and the head. You will see here that the top of the head was covered over with large bony plates, with serrated edges, all anchylosed together, and composed of so tough a bony material, coated externally, no doubt, with plates of horn, that it may be doubted whether even our modern bullets could very well have pierced it. The covering of the body is not yet complete, but you must imagine that multitudinous polygonal ossicles were united together to form a shell or carapace for the whole trunk, similar to that already in the Museum. The margins of this great shield were formed by special pieces, and it rested on the fulcra furnished by the ischia, by the sacral and iliac crests, and by the ridge furnished by the spines of the fixed dorso-lumbar vertebrae.

Even this brief description of the principal parts of the skeleton will bear out what I started by saying, that this is one of the most valuable and remarkable presents ever made to this great collection.

Having thus briefly sketched the character of the skeleton, I will now ask you to follow me through these enquiries—What was the place of this animal in the scale of animal life? What was there peculiar about it physiologically?

With what existing forms or fossil forms of life was it most closely allied? That it possesses a vertebral column is, I need hardly say, sufficient evidence of its belonging to the vertebrate division of the animal kingdom. But, furthermore, if we look at the articular surface of the atlas which is articulated with that occipital bone in the skull, which is absent in this skeleton,—this fragment of the atlas is sufficient to prove that this first bone of the vertebral column articulated with the occipital region of the skull by means of two facets; in other words, there were two occipital condyles. Again, if you look at this angular part of the ramus of the lower jaw, you will see that it goes straight down and is not bent in at all. Moreover, it is quite certain from other specimens that the mandible articulated with the squamosal element of the skull.

In these three characteristics the anatomist at once recognises full evidence that the fossil before us had, when alive, certain other characters. He does not hesitate to deduce from the existence of these three peculiarities four other very important concomitant structural features. He feels certain that the young of this animal was connected with the mother by means of that structure which is known as a placenta. He is also certain that the young, when born, were suckled with milk, and that the mother, therefore, had mammary glands. He is further certain that the animal had a four chambered heart, two auricles, and two ventricles. And he is no less certain that its blood was of a red colour; that it was warm; that it contained corpuscles which were of a red colour, and were, in truth, free nuclei.

In other words, to translate these propositions into ordinary zoological language, the anatomist is quite certain that this animal was one of the Mammalia, and, furthermore, that it belonged to one of the placental divisions of the Mammalia. I think you will agree with me that it is a remarkable circumstance that we should be able to speak with certainty and confidence on such points as these from such evidence, and to reason, in this definite manner, from such propositions as those which I first laid down to you; and it may be worth while to consider what is the basis of this certainty—what constitutes the logical validity of our conclusions. I doubt not that there are many persons here far more capable than I am of working out an argument from purely physiological data; but I think that, if I were to give to them the first three facts, and ask them to point out to me, by reasoning from the known laws of physiology, the necessary connexion between the first three conditions and the last four, I should have to wait long for an answer. In truth, the problem is an insoluble one. No person, however large his physiological knowledge, can show the slightest necessary connexion between a mandible with an incurved angle, and the absence of a placenta, or between the articulation of the mandible with the squamosal, and warm blood with free red nuclei. Doubtless, there is some good reason for the co-existence of these phenomena; but it is a reason which we have not discovered, and which, therefore, for practical, working purposes, does not exist. So, you see that the conditions of certainty in this case have nothing whatsoever to do with physiology, or with that description of the adaptation of parts to the performance of functions or purposes, which has been known by the name of the doctrine of adaptation to purpose. However excellent in many ways such considerations may be, they have most assuredly nothing to do with the basis of the argument, by which the place of an animal in the zoological scale is determined from more or less of its skeleton.

It is a very simple matter to state what the basis of that argument really is. It so happens that the studies of zoologists have led them to a knowledge of a great number of empirical laws, of which we have the same certainty as we possess of a great number of the empirical laws with which we work in daily life, the great mass of our actions being guided by such laws of experience, of which we can give no further account than that they are always verified by experience. And, at the present time, experience has led us to believe in the perfect validity of this law, among many others, namely, that any animal which has two occipital condyles, a mandible articulating with the squamosal bone, and a straight angle to the mandible, suckles its young, develops a placenta, and has hot blood with free red nuclei. I say we do not know why these correlations should exist, but it is a universal law of experience that they do—a law which has been universally verified hitherto, and, therefore, we work with it as confidently as we do with any other kind of empirical law. I think this conclusion must be obvious

to any one who will take pains to analyse the methods of palaeontological reasoning. Many years ago it was so obvious to me that I ventured to differ (though I always do so with the utmost hesitation from that great man) from Cuvier, and even to say that, in giving another account of the matter, he had “mistaken his own mental processes.” Reflection has not led me to alter a conviction which I hope the case I have put before you will lead you to share with me.

(To be continued.)

LECTURES ON THE  
BLOOD OF VERTEBRATA.

DELIVERED AT THE

Royal College of Surgeons of England,

DURING THE SESSION 1861-62.

By GEORGE GULLIVER, F.R.S.

Professor of Comparative Anatomy and Physiology to the College.

LECTURE XII.—*Fibrin Cells—Softening of Fibrin—Cause of Coagulation of Fibrin unknown—Doctrines of Mr. Hunter and Dr. Richardson—Review of the Vital and Chemical Doctrines—Adhesion between two Parts not a Proof of Life in both those Parts—Coagulation after Death by Lightning or Electricity; and after Death by Hunting and Fighting—Coagulation in dead Serum—Coagulation after Pickling and Freezing—Coagulation without Emission of Ammonia—Fluidity of Fibrin—Life of the Blood, and Doctrines of Harvey, Hunter, and Schwann—Conclusion of the Session.*

*Fibrin-Cells.*—Having said so much of the fibrils of fibrin, we come now to the corpuscles or cells which are often found in its clots. These cells are generally so faint or indistinct, that I know not that they had been shown before the publication, in the Appendix to Gerber's Anatomy, of the drawings and descriptions in 1842; and, afterwards, the existence of any such corpuscles in fibrin, save a few of the common pale globules of the blood, was either doubted or denied. But they have since been discovered again, and distinguished by hard names which need not be repeated, because they were and are needless, and no better than the original ones. The corpuscles may occur either in the form of cells or of naked nuclei, and, as

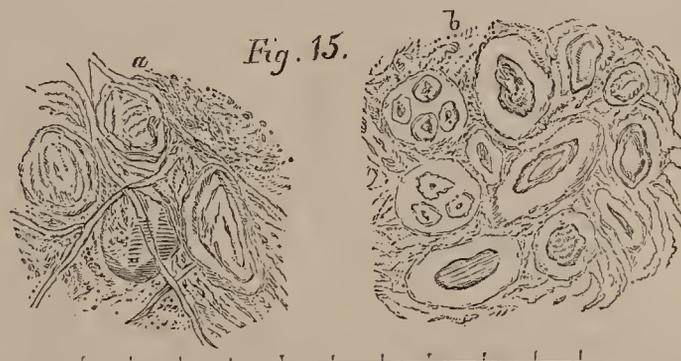

FIG. 15.—Cells of fibrin: *a*, the cells in a granular matrix with a few fibrils; *b*, the same, after having been many hours soaked in acetic acid; one cell with a triple, another with a quadruple, nucleus, and the rest with single, undivided, oblong nuclei.

from the very first described, may be quite independent of inflammation. But that they are often the result of disease of another kind is very probable, though it is difficult to conclude that they are always so; for then the morbid condition must be of great frequency, and we should be precluded from considering the corpuscles as ever forming a part of an early and healthy organisation of fibrin, destined for such further development as may be determined by the conditions, or, as Hunter would say, the “stimulus of necessity.” And in this point of view they were often mentioned as “organic germs” at the time of their discovery. You may find them, often abundantly and as often scantily, in clots of blood of healthy animals, provided the coagulation have taken place within the body, when the fibrin remains so long fluid that the red corpuscles sink so far through it as to leave more or less of its surface pale. I have seen the fibrin-corpuscles in two dogs two days after they had both been shot for disturbing the deer in Windsor-park; in many horses killed on account of chronic lameness; and seldom failed to find the corpuscles whenever they were carefully looked for in pale clots from the heart of the human subject, at all ages, as well as in abortions from

the fifth to the seventh month of utero-gestation. Still, the verification of this point is not quite so easy as might be supposed; for the common floating white globules are, comparatively to the red corpuscles, so light as to remain entangled in the clot after the latter have sunk through it. But the fibrin-corpuscles generally differ from the common pale globules of the blood, not only in form, as you may see by comparing the

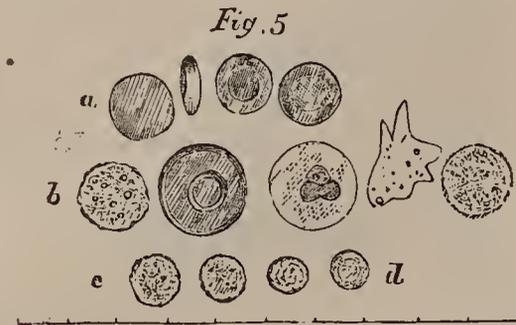

FIG. 5.—Red corpuscles and pale globules of blood, and lymph-globules. At *a*, four red corpuscles; *b*, five pale globules; *c*—*d*, four lymph-globules. The first pale globule, at *b*, contains spherical granules, the last is only minutely granular, and the fourth is collapsed and sending off processes; these three globules are in the natural state; but the second shows its circular nucleus exposed by the action of weak acetic acid, and the third the nucleus divided after treatment by stronger acid. Of the lymph-globules, which are from an inguinal gland, at *c*, the first two are in their natural state; and at *d*, the last two, after having been long steeped in strong acetic acid. From a child, aged 3, accidentally killed.

diagrams, but by the action of acetic acid, which is much less energetic on the cell-wall of the fibrin-corpuscle than on the cell-wall of the pale globule of the blood.

*Softening of Fibrin.*—A knowledge of this structure is important, because a clot of fibrin is liable to become softened, so as to produce a matter somewhat resembling, but truly differing from, pus; and they were always so confounded formerly, thus leading to a false inference in physiology and bad practice in Surgery. This softened fibrin, so common in the heart and veins, is truly a pathological element, distinct from pus, and a peculiar disease, essentially different from suppuration or phlebitis, and “independent of inflammation,” though so long and erroneously confused therewith; that is to say, up to the year 1839, when these facts were proved by experiments and observations (*Med. Chir. Trans.*, vol. xxii.; *Edin. Med. and Surg. Journ.*, vol. lx., p. 163), as well as the interest belonging to inquiries concerning the morbid effects of a mixture of this softened fibrin with the circulating blood. These observations comprehend the Thrombosis, many years afterwards so ingeniously announced by Professor Virchow, and were the forerunner of the Leucocythemia, so well and originally treated by Professor Bennett. Nor should the early labours of Dr. Davy (“Diseases of the Army,” chap. viii.) be forgotten on a subject of so much interest as the softening of fibrin, more especially when the Berlin Professor seems to claim for himself also Hewson’s discovery of an office of the lymphatic glands and spleen. But the history of disease forms no part of our present Lectures; if it did, this would be one of the most curious episodes of an important chapter in our pathological annals; and it would not have been alluded to on this occasion but for the admirable evidence afforded by the researches of the Edinburgh Professor of the validity of Hewson’s doctrine concerning the so-called “blood glands”; while also it is difficult to avoid resenting the unworthy treatment by the Würzburg and Berlin Professors of Hewson’s physiological labours. Besides, the subject has an independent physiological interest: thus, we all know how Mr. Hunter, or his disciples, considered this softened fibrin as pus in the centre of clots in the heart, and, consequently, as proof of the secreting power and vitality of such clots; whereas the fact is, that a coagulum of dead fibrin, kept for a while at a temperature of about 100°, becomes so softened as to assume that semblance of pus which had so long deceived pathologists; and this is a character of fibrin not even yet recognised in our current physiological treatises.

*Cause of the Coagulation of Fibrin.*—The interesting question of the cause of the coagulation of the fibrin still remains so problematical that it would be little profitable to employ our time in a review of the numberless speculations which have been entertained concerning this phenomenon. But in our fondness for anything of Hunter’s, we cannot dismiss his opinions without notice; nor can we withhold a due respect to the arbiters of the Astley Cooper prize essay, and Dr. Richardson’s valuable work for which that prize was awarded.

*Doctrines of Mr. Hunter and Dr. Richardson.*—The language of Hunter’s great book on the Blood is, perhaps, more vague than it would have been had he lived to see its publication completed. He says that blood is an inorganised substance, though ready to become organised according to the stimulus of the surrounding parts (iii., 36, 113, 119). In his Surgical Lectures he observes that coagulation of the blood appears to be that process which may be compared with life in the solids, and that this disposition to coagulate, when out of the vessels, or retained in them without motion, is one of the effects of the life of the blood (i., 236). And, in short, that the coagulation arises from the living principle of the blood, for if that be destroyed it does not coagulate at all; coagulation being that process which may be compared to life in the solids (iii., 113). Accordingly, he endeavours to prove (iii., 113) that the coagulation of the blood is analogous to the action of muscles, which we know depends on life, and that certain causes of sudden death will at once kill the blood and body together, and so prevent both the post-mortem contraction of muscles and coagulation of the blood. Hence, as far as we can gather from his writings, his opinion was, that the cause of the coagulation is an act of life. As facts in support of this view, he states, that in animals killed by lightning and by hunting, there is neither coagulation of the blood nor contraction of the muscles after death; and adduces instances in two deer which had been run till they dropped down and died (iii., 14). He mentions other forms of sudden death as having the same effect. To the student of his works—which we all ought to be—the firm conviction which these facts, and his leading opinion connected therewith, so long had on Hunter’s mind must be remarkable. They form the warp and woof of his theory, always more or less displayed whenever he discourses on the principles of the blood, and were as distinctly announced in his Surgical Lectures as in his last great book. He appears, also, to have had an opinion that adhesion between parts of an animal is a proof of the life of both those parts. Thus, the blood coagulates for the union: the simple act of coagulation, apart from its causes, is an operation of life proceeding upon the same principle as union by the first intention (iii., 34). It is well known how he transplanted teeth and cocks’ spurs, and saw them become fixed to their new seats, and his inference accordingly. Dr. Richardson, on the contrary, concludes, from many ingenious experiments and observations, that the cause of the coagulation of the blood is simply a chemical one—an escape from the fluid blood of the volatile alkali. Hence, we have the vital hypothesis of Mr. Hunter and his disciples, and the chemical one of Dr. Richardson and others; and it is remarkable that Mr. (now Sir Benjamin) Brodie noticed the coagulation of the blood as a “chemical change.”

*Review of the Vital and Chemical Doctrines.*—Before attempting a judgment of the value of these two very different opinions, let us examine them by the light of such evidence as we can fairly bring to bear on the questions at issue. First, then, as to *Adhesion*.—Dead parts will sometimes unite with living parts, and even increase by external addition, like a mineral. In the course of some experiments at Chatham, many years ago, I introduced splints of dead bone into the medullary canals of the tibiae of living rabbits, and occasionally found that the dead portion had become firmly united to the living bone; while there might be also a deposit of new osseous matter on the surface of the dead bone, and this even when union had altogether failed. In those cases, where the dead and living bone had become united, the adhesion was by new osseous matter, so that the two were thus simply cemented together without the aid of any kind of case or clasp formed by the living part. The preparations of these parts are in the Museum of the Army Medical Department at Fort Pitt; and, as I gave a specimen to the late Mr. Liston, it should be at University College. One of the specimens is depicted in the 3rd fasciculus of drawings from the Army Medical Museum at Chatham, plate x., fig 13, and the experiments are detailed in the *Medico-Chirurgical Transactions*, 1838. Thus, it may be inferred that union between two parts in the living body is by no means conclusive proof of the life severally of those parts.

*Lightning and Electricity.*—In my notes to the Sydenham Society’s edition of “Hewson’s Works,” cases are cited in which coagulation of blood and rigidity of muscles occurred in man and other animals after death by lightning and by electricity. Subsequently, a very eminent Teacher, having exhorted his pupils to lose no opportunity of making observa-

tions on the subject, received a communication from one of them (Mr. Henry Thompson), which Professor Sharpey kindly placed at my disposal, and nothing can be more conclusive of the fact, that the blood is regularly coagulated in sheep killed by lightning. More recently, Dr. Davy ("Diseases of the Army," p. 408-9) examined the body of a man who had met with instantaneous death from lightning at Malta, and, though putrefaction was very far advanced, there was rigidity of the muscles, and the heart contained some frothy blood, and a little soft coagulum.

*Hunting and Fighting.*—In all my examinations (*Edin. Med. and Surg. Journal*, Oct., 1848) of the state of the blood and muscles in animals either hunted to death or killed by fighting, not only was the blood found coagulated afterwards, but the rigidity of the muscles often increased and hastened. In stags, foxes, and hares hunted to death, the blood coagulated, and the muscles quickly stiffened. Such, too, was the case in game-cocks worried to death by fighting. In some of these birds the blood was found coagulated within the body in less than thirty minutes after death, nor did it fail to coagulate in any one of them; and in every instance the muscles were firmly contracted within four hours from the time of death. These are facts, to be taken for what they may be worth, which you are as well able to estimate as I can be. If you further inquire of old and observant sportsmen as to the state of foxes run very hard or until they drop down dead, you will most probably be told in such cases, as I have often been, that the animal quickly becomes "as stiff as a brick-bat," so that he may be held out horizontally by the hind legs.

It would seem hopeless to attempt to reconcile these with Mr. Hunter's facts and opinions. Perhaps he had seen animals after the post-mortem rigidity had ceased, as it occurs so quickly in these cases, that any one not familiar with them might be thus deceived. And, as to the blood, there might have been delayed coagulability, as in the examples given by Dr. Polli; or in hot weather it might have clotted soon, and become soft and pulpy, or even fluid again, from commencing putrefaction. Or a diffuent gore or cruor might be found in one part, while fibrinous clots were hid and escaped notice in some rather distant situation. And this last I have found to be the fact in more than one case, in which the blood was shown to me as having never coagulated after death in the human body. After all, Mr. Hunter's cases were probably true and exceptional, for it is difficult to suppose that such an acute observer could have been deceived in such a plain set of observations. Still, as we have seen, his remarks on the state of the blood in animals killed by lightning are equally unsatisfactory.

*Coagulation in dead Serum.*—As we cannot, therefore, admit the certainty or validity of the facts which he adduces in support of his view, let us see how far it may accord with any other facts available for us in this inquiry. If we admit that coagulation is an act of life, we must also admit that the serum is alive, that it may retain its life for days out of the body, and coagulate afterwards at the temperature of the air, under certain circumstances, as mentioned in the last Lecture. I have seen two varieties of serum, which had been kept separately in open glasses for upwards of three days, produce, when mixed together, a soft, trembling clot within six hours, the air at the time being from 49° to 60°; and the fibrin thus coagulated was not destitute of fibrils.

*Coagulation after Pickling and Freezing.*—Further, if coagulation be an act of life—if we adopt this doctrine, how can we refuse to admit also that we are able to preserve that life for an indefinite time by pickling with salt and by congelation by cold? As noted in the 12th and 21st pages of Hewson's Works, I have kept blood fluid with saline matter for more than twelve months, after which that blood coagulated when diluted with water; and since the experiments of Hewson have been confirmed and extended by Mr. Hunter and Dr. Davy, it is well-known that blood may be repeatedly frozen and thawed, and yet retain the power of coagulating spontaneously. These observations are not, and never were, given as dogmatically conclusive against Mr. Hunter's opinion; but merely to suggest what we must be prepared to accept if we adopt that opinion. They are more favourable to it than to the more modern hypothesis, that coagulation is the death of the blood. Nor do they give any support to Dr. Richardson's tenet.

*Coagulation without Emission of Ammonia.*—What probability is there that ammonia was retained by the specimens of serum as long as they were kept separate, and given out to cause

coagulation after they were mixed together? No evolution or discharge of ammonia would make them coagulate while unmixed, nor, indeed, will they coagulate at all, while separate, under any circumstances, at the temperature of the air, as I proved by numberless comparative trials. Again, after the blood has been kept fluid by salt for months, what likelihood is there that the addition of a little pure water produces coagulation by driving out ammonia or indeed any other volatile matter? This alkali was not thought of in those experiments, which were made for a very different purpose many years since. But in some blood which had been kept fluid by salt in an open jar for thirteen days no emission of ammonia could be detected by the most careful examination from the time of commencing coagulation to its completion; and repeated trials of the like kind gave the same negative results. Dr. Davy, too, before I had experimented with a special view to this subject, had come to the conclusion that the escape of ammonia is not the cause of the coagulation of the blood, and, indeed, that it is not caused by the escape of any volatile matter at all. His first experiments were made on the blood of fowls, and repeated since with the same result on the blood of the pig. Some observations which I made last summer (*Ann. Nat. Hist.*, March, 1862) on the spontaneously coagulable juices of plants were to the same effect. No trace of ammonia could be detected even when the coagulation took place at a temperature of 80°, nor under any circumstances whatever in the fresh coagulating juices, and much less evaporating from them. These are examples of the obstructions which lie in the way of this chemical view, and which will have to be removed before Dr. Richardson can expect it to be unconditionally admitted.

*Fluidity of Fibrin.*—After all, we might as well inquire the cause of the fluidity of the blood; or, with Mr. Hunter, ask, why it does not coagulate while circulating in the body? Probably, it never is regularly very long fluid. The wants of the economy may appropriate the fibrin not long after its production; and thus the constant formation and assimilation of fibrin may keep up the balance so nicely as to preserve the fluidity of the blood, and so this fluidity would necessarily be lost when removed from the conditions by which it was maintained. The blood never can be the same in distant, or even in comparatively near parts of its course. We know that successive small portions of blood from the very same orifice of one vein may possess different qualities. And how wonderfully must the blood be incessantly changing as it gives out the multitudinous materials for growth or nutrition, and receives additions by absorption, either from the chyle, lymph, air, or effete parts of the frame. And with what wonderful rapidity and abundance fibrin is incessantly being produced in the living blood, and used in the animal economy, may be inferred from the observation in the preceding Lecture, that all the fibrin disappears from the hepatic and renal blood after every passage of that blood through the liver and kidneys.

*Life of the Blood: Harvey, Hunter, and Schwann.*—Thus the life of this marvellous fluid, its power of self-preservation, amid quick and unceasing mutations, again presses on our attention. Professor Milne Edwards most erroneously represents me as arguing against that life; whereas I was only stating the objections, already detailed, to Mr. Hunter's view of the cause of coagulation. As to the life of the blood, it always seemed most strange to me that any physiologist could have doubted this great truth, from the inspired writer of the Pentateuch to Aristotle, from Aristotle to Harvey, from Harvey to Hunter, and from Hunter to our day: so manifold and plain are the proofs we have so often adduced, that any questioning of them so far always seemed mere trifling, to my apprehension. The corpuscles have already been seen in this point of view; and that the matrix or bed in which they exist, the fibrin, is also alive, as Mr. Hunter was so fond of asserting and proving, is not likely to be doubted by any one who has attended to his experiments and reasoning, so beautifully conclusive are they on this important point. This, indeed, was his great merit, in which he far transcended all his predecessors. However truly they had proved the general life of the compound blood, it was left for him alone to demonstrate the special vital endowments of the fibrin. Hence, it is most unjust to his memory not to resent the prevailing error, so often repeated of late years, that he only discovered that life which was so well known both to his modern and ancient predecessors. Further, it has been suggested in the preceding Lecture, that

his simple views on those endowments of the fibrin are still more exact than the recent, and, as far as regards this subject, more meretricious doctrine of the Germans. In short, Hunter began where Harvey ended, just as the cell-doctrine is rather the complement than the subversion of the Hunterian doctrine thus far; and, whoever would truly study Schwann's system, should not only so regard this part of it, but seek for further light by the aid of the later researches of such excellent British observers as Goodsir, Bennett, Huxley, Savory, Rainey, Nelson, and others. Then will the little defects be sifted from the vast excellencies of Schwann.

*Conclusion.*—If, in the course of these Lectures, we have sometimes insisted rather strongly on the just claims of the British school of Physiology—the school of Harvey and the Hunters—it has been simply in the cause of Truth, outraged by the strange indignity with which several of the best members of that school have, since the meridian of that truly ingenuous and eminent German, been treated by those very foreigners who have most profited by its fruits. Finally, we are led back to the grand declaration of our illustrious countryman, Harvey, that the blood is the primogenial part of the body, where the Lares and Penates of life are enshrined—the immediate and chief seat of the vegetative faculties of the animal; the first part to live and the last to die of this our wondrous microcosm. I may add, also, as the child is more worthy than the cradle, so is the blood more worthy than the parts which merely contain or defend it. And so, Mr. President and gentlemen, as we cannot part with a better impression of the dignity of our subject, I beg to take leave of you for the present, to thank you for your kind attention, and to express a hope that I may have the honour of meeting you again on the same ground.

## ORIGINAL COMMUNICATIONS.

A CASE OF

### ASTIGMATISM COMPLETELY REMEDIED BY CYLINDRICAL LENSES.

By J. ZACHARIAH LAURENCE.

In a late Number of this Journal I inserted an exposition of the *rationale*, diagnosis, and treatment of that peculiar optical malformation of the eye known as "Astigmatism." At that time my practical knowledge of this defect was rather limited, from my not possessing a complete set of cylindrical trial-lenses. These, however, I have since obtained from Messrs. Paetz and Flohr, of Berlin, and will, with your permission, lay before the Profession the following well-marked case of their beneficial application:—

Hannah M., aged 24, a tailoress, consulted me at the Surrey Ophthalmic Hospital in September, 1861, on account of asthenopia, from which she had suffered for the last ten years. The symptoms were dimness of vision, a sensation of "burning" in the eyeballs, congestion, and lachrymation, all of which came on after reading, etc., for a quarter of an hour, or after five minutes, if she had previously been hard at work at her business. I found that No. 22 was the highest type she could read at fifteen feet distance; and finding that no glasses, either convex or concave, enabled her to read any lower type, I, after a month's ineffectual treatment by tonics, eye-waters, rest, etc., gave her case up in despair.

On the 13th of the present month, I desired her to call on me with a view of seeing whether, perhaps, her symptoms depended on astigmatism?

Repeated examinations have yielded the following results with each eye:—

(1). On requesting her to regard a luminous point of two millimeters' diameter, and placing a twenty-inch convex lens before the eye, she, after a time (a), declared it appeared to her as a narrow vertical line.

(2). On her regarding a series of black, vertical and horizontal lines at about eight feet off, she saw the vertical ones perfectly distinctly—the horizontal ones very indistinctly: a

(a) In experimenting on my own eyes with cylindrical lenses, I have observed, the phenomena of astigmatism of a luminous point never appeared perfect, till a sufficient time was allowed for my accommodation to settle down into one constant condition.

sixteen-inch spherical concave glass reversed the order of things—the horizontal lines then became distinct, the vertical ones indistinct.

(3). With the naked eye, at twelve feet, she could read no lower than XX. of Snellen's types; but with a cylindrical concave lens of sixteen inches focus, she read XII. Thus, her "sharpness of definition" increased from  $\frac{1}{20}$  ( $= \frac{2}{3}$  nearly) to 1—became, in fact, absolutely perfect. This only occurred, however, when the axis of the cylindrical lens was transversely placed: if vertically, she could hardly see at all. In order to eliminate all source of error, I tried the crucial experiment of placing an ordinary (spherical) sixteen-inch concave glass before the eye: this only made her see worse than with the naked eye.

I then found that she, with her cylindrical glasses, could also read an ordinary printed book at a usual reading distance without feeling any fatigue in the eyes.

Both eyes, on careful examination, proved to be equally astigmatic.

From the above, it follows that this patient's eyes possess a normal refraction in their horizontal meridians, but are myopic ( $\frac{1}{16}$ th) in the vertical ones, her astigmatism equaling  $\frac{1}{16}$ th.

I intend exhibiting this case at the next meeting of the Harveian Society, on Thursday, March 5.

## DIGITALIS IN DELIRIUM TREMENS.

By W. B. KESTEVEN, F.R.C.S.

In a case of delirium tremens, which occurred to me a short time since, I administered three separate doses, one drachm each, of tincture of opium, without the least benefit, stimulants being freely given at the same time. Finding that no good result followed, I gave four doses, of half-a-drachm each, of tincture of digitalis. The patient continued still excited, not having closed his eyes for ninety hours. The relatives then requested a consultation.

Two hours after the last dose of tincture of digitalis had been given, Dr. Ballard met me at the patient's bedside, when we found that he had just fallen into a quiet sleep. This lasted more or less completely for thirty-six hours, and the patient was apparently safe. He was a man of middle age and an habitual toper. It was his first attack. He had, however, a relapse a few days afterwards. I at once gave him two drachms of tincture of digitalis, to be followed every two hours by half-drachm doses. In less than three hours he was soundly asleep. Several weeks have since passed, and there has been no return of the malady. I would add, that in the next case of delirium tremens that falls to my lot, I shall be disposed to begin with a larger dose than I gave in this case.

Upper Holloway.

## REPORTS OF HOSPITAL PRACTICE

IN

### MEDICINE AND SURGERY.

#### CASES OF DISEASE OF THE PONS VAROLII.

As the three following cases were the subject of a recent Clinical Lecture by Dr. Brown-Séguard, we take this opportunity of recording them along with other cases of disease of this part of the brain. Most of the remarks appended to them are such as we have gathered from the clinical observations of Dr. Brown-Séguard on these and similar cases, or from his published works. We shall allude, also, to cases already recorded elsewhere.

#### NATIONAL HOSPITAL FOR THE EPILEPTIC AND PARALYSED.

#### HEMIPLEGIA FROM DISEASE OF THE PONS VAROLII—PARALYSIS OF THE RIGHT ARM AND LEG, AND THE WHOLE OF THE LEFT SIDE OF THE FACE—PARTIAL ANÆSTHESIA OF BOTH SIDES OF THE FACE.

(Under the care of Dr. BROWN-SEQUARD.)

Charles R., aged 62, a farmer, was admitted on February 16, Eleven weeks ago, after dinner, he was seized with vomiting

and severe pain in the back of the head. There was, however, no paralysis observed until six hours later. He used to suffer from giddiness, but has in general had good health. He is a large, powerful-looking man. There is no arcus senilis, but there is some rigidity and tortuosity of the temporal arteries. His pulse is good, and there is no cardiac disease. The left side of the face and the right arm and leg are paralysed. There are, also, peculiarities as to the facial paralysis.

*The Face, Tongue, etc.*—The whole of the face on the left side is paralysed, as in disease of the trunk of the portio dura, so that the orbicularis and, in fact, all the facial muscles are affected. Yet, although he has lost voluntary control over this side of the face, there is evidently corrugation of the forehead on the paralysed side, and the face is rather drawn to this side. [At the next visit, three days later, this spasmodic condition of the paralysed side had disappeared.] The tears run over the cheek from paralysis of the tensor tarsi. The pupil on this side is slightly smaller than the other, and there is slight impairment of the external rectus. He has not now double vision, but he had soon after the attack. There is also loss of sensation of the face, not of the scalp, but this is equally affected on both sides. He contracts the temporal and masseter muscles equally. When his tongue is touched with salt or sugar, he fancies it is an acid, but the power of feeling the points of the compasses is normal. He can shout well, and his speech has never been affected. There is no defect of sight or hearing; in fact, his wife says that his hearing is better since the attack. He moves the muscles of the neck easily. He has no pain in the head now, but there is tenderness over the cervical vertebræ near the occiput.

*The Arm and Leg.*—The arm is considerably wasted, and the hand looks puffy and swollen. There is considerable œdema of the leg. There is tenderness in all the joints of the right side, on moving and on pressure. There is almost total loss of power in the arm, and considerable impairment in the leg. He can stand on the sound leg, which, in most cases of hemiplegia to this extent, is impossible. On examining the palm of the hand as to sensation, it is found that on the paralysed side he feels the point of the compasses at an inch and a-half. This was tried repeatedly. On the sound side, he feels sometimes two, and sometimes one, at four and a-half lines. Feeling is considerably impaired in the thigh. He very often gapes, and when he does so he has a sudden, involuntary throwing out of the arm and leg. The left side of the chest dilates very much more than the right. His memory is good, and his mind generally is as good as before.

He was ordered iodide of potassium, and blisters to the back of the neck. On account of the pain, he was to take a drachm of tincture of hyoscyamus every night.

#### HEMIPLEGIA FROM DISEASE OF THE PONS VAROLII—PARALYSIS OF THE RIGHT ARM AND LEG, AND OF THE LEFT SIDE OF THE FACE—SPASM OF THE AFFECTED SIDE OF THE FACE—PAINS IN THE PARALYSED PARTS.

(Under the care of Dr. BROWN-SEQUARD.)

Joseph B., aged 50. Except that he had been for several years subject to gout, he was quite well until 1859, when he was attacked with sickness, but not with vomiting. He had also giddiness and prostration for about a month, and was delirious at night two or three times during that month. One day he was suddenly attacked with a violent pain in the right shoulder-joint, which lasted two or three days, and went away suddenly. It was a sharp pain, suddenly ceasing and suddenly coming on again. It was increased or brought on by pressure. There was no swelling and no redness. He said that the pain in the shoulder was quite unlike the pain of gout. When this pain began, the other symptoms of giddiness, etc., had left him. For the month he felt quite well, but at the end of that time he was attacked with difficulty of breathing, and could hardly take a breath without effort for nearly three or four weeks. He was then admitted into St. Thomas's Hospital, under the care of Dr. Peacock. He recovered, though he remained weak. Soon after leaving the Hospital, he had an altercation with some one who annoyed him. He felt "queer, as if tipsy," and would have fallen if he had not been supported. His eyes were red, and he had a sensation as if something were actually burning the top of his head, and soon afterwards a very severe pain in the same place, and he felt almost powerless. After a few minutes the pain and the sensation ceased. He was carried to his bed, and was found to be hemiplegic.

He could not whistle at first, but could afterwards. There was no difficulty of breathing or of swallowing, no gaping or vomiting, no involuntary movement, no numbness, no feeling of pricking, and no tinnitus aurium. His sight was much affected: he saw double. The next day, at intervals, several times he lost consciousness, but had no convulsion and no biting of the tongue. After five days he again went to St. Thomas's Hospital, and was under the care of Dr. Peacock. He then had a severe pain in a small spot on the left side of the forehead, and the left eye was closed and suffused. He became stronger, and in five weeks could stand and walk by help. It was chiefly the pain in the head which at this time prevented his standing or walking. A few days after he went to the Hospital he had a burning sensation (which he compared to that of the actual cautery, afterwards applied by Dr. Brown-Séquard) all along the inside of the sole of the right foot. He went home, and for a day or two was better; but still, for five months, he remained in bed, unable, except with help, to get up. The face then began to be drawn on the left side, and this drawing was preceded by pain and numbness in the side drawn. There was, at the same time, slight difference of speech, but no difficulty of swallowing, nor in breathing, and no frequent gaping. The gaping was for a good while incomplete. His mind has never been affected.

He has now (January, 1863) pain in the left infra-orbital and frontal region, extending, however, to the right a little. The left side of the face is drawn. It is important to note that this drawing is from spasm of the left side, and not paralysis of the right. At first glance at this patient's face one would say that it was paralysed on the same side as the arm and leg, the right; but when the patient talks, it is seen that he moves the right side perfectly, and not the other; whereas, in ordinary hemiplegia, it is the side to which the face is drawn that moves. At a previous visit the spasm of the face could be increased by touching the cheek. The face on the affected side is also redder than the other. The tongue is straight. The feeling of the left side of the face and head is diminished. He feels cold and heat as well on one side of the face as the other. The face and head are often warm, but hardly more so on the left than on the right. The sense of taste is not affected. The pupil on this side is smaller than the other. There is no double vision, and the eyes move well. His hearing is good and equal on both sides.

The right arm and leg are weaker than the other, and he has constant pain, "tingling," "pricking," and aching in them. The fingers of the hand keep moving. This patient has improved very much since his admission. He has less pain, and can use his limbs much better. He has been treated by iodide of potassium, blisters, and the actual cautery.

This patient has, when he coughs, involuntary starting of the paralysed limbs.

These cases of hemiplegia from disease of the pons are in remarkable contrast to ordinary cases depending on disease higher up, as in the crus cerebri, or in the corpus striatum, or in the thalamus opticus. The two latter are the parts affected in the vast majority of cases of hemiplegia; but hemiplegia depending on disease of the pons is rare. The most obvious difference is, that the paralysis of the face is frequently on the opposite side to that of the limbs; but there are often also important differences as to the nature and extent of the paralysis of the face, which must be taken into consideration; for, as we shall see by the table at page 212, the paralysis may be on the same side when the lesion in the pons is above the decussation of the facial nerve.

It may be well to speak first of ordinary hemiplegia, in order that the difference may be seen more readily. In these cases, very little of the face is paralysed, and that nearly altogether as regards motion. The arm and leg on the same side are paralysed, also as regards motion. Dr. Watson ("Principles and Practice of Physic," vol. i., p. 503) writes:—"I have known many persons who have thought that the muscles of the face in hemiplegia, when they were affected at all, were affected on the opposite side of the body from that to which the palsied limbs belong. But they never could have examined actual cases of hemiplegia with any attention. How the error arose I cannot tell; but I have known professed anatomists make it." He says that he has only seen two cases of hemiplegia in which the paralysis of the face was on the side opposite to that of the paralysis of the arm and leg. The parts of the face affected are some

muscles about the angle of the mouth. Dr. Todd, in his "Clinical Lectures," stated that the muscles of the face paralysed in hemiplegia were those supplied by the motor branch of the fifth, chiefly the buccinator. He believed that the muscles supplied by the portio dura escaped altogether. He says, "The muscles of mastication, on the paralysed side, act with less power, although it seldom happens in hemiplegia that their power is completely destroyed. Doubtless, much of this action is reflex, and this explains the fact, that whilst the buccinator is very much paralysed, and even wasted, the masseter and other masticatory muscles retain a considerable amount of power." Dr. Todd, in a previous lecture, alluded to the paralysis of the buccinator muscle in disease of the portio dura. He said that this muscle received a branch from the portio dura, and one also from the motor root of the fifth. It is now stated, however, that the branch from the fifth is not a motor one. Dr. Brown-Séguard says that few fibres of the portio dura nerve pass higher than the pons, and hence there is little paralysis of the face in affection of the corpus striatum or thalamus opticus. What does exist, however, is due to the implication of these, and not to an affection of the motor branches of the fifth.

Romberg says:—"A peculiar feature in the central paralysis of the facial nerve in disorganisation of the brain, is, that, with few exceptions, the entire distribution is not affected, but those fibres only are implicated which supply the muscles of the alæ nasi and the upper lip, and are the agents of the respiratory functions of the facial."

The degree of paralysis of the face in hemiplegia depends on the part in which the lesion occurs. In the case of Chas. R., the whole of the nerve is affected, as the lesion is situated just at its entry into the pons. In the case of Joseph B. a considerable part of the face has escaped; the orbicularis has never been affected. In both these cases there is also anæsthesia. In ordinary hemiplegia, as above mentioned, there is rarely defect of sensation, and little paralysis of the face.

Dr. Brown-Séguard says that of the fifth nerve also but very few fibres go higher than the pons. It is clear, then, that it is only in disease of the pons that there can be any marked alteration of sensibility or great paralysis of the face. It has been long observed that the orbicularis has rarely been paralysed in cases of hemiplegia. It has, of course, been affected in cases of tumour when the tumour has pressed on the trunk of the nerve; excepting in such cases, the nerve can only be affected in all its extent by lesion in the pons Varolii.

This is well shown in the first case, Chas. R. The orbicularis and the whole of the muscle supplied by the portio dura are paralysed. The sensibility of the face also is diminished, but equally on both sides.

The fact that sensation is affected on both sides of the face is interesting.

The motor fibres coming from the limbs decussate just below the pyramids; the sensitive fibres, as Dr. Brown-Séguard was the first to demonstrate, decussate in the cord. So that both motor and sensory fibres from the *right* side of the body pass in the *left* side of the pons. But the fifth, sixth, the portio dura of the seventh, cranial nerves, enter and decussate in the pons itself. Hence, a lesion which damages the fibres which have come from the right side of the trunk, *i.e.*, after they have decussated, may injure one of these nerves before it has decussated, and thus produce paralysis on the side of the face opposite to that of the limbs, as is well shown in the first case (Chas. R.) It is clear, too, that if the lesion is extensive, and yet on the same side, it may also affect the other facial nerve after its decussation, and then both sides of the face may be paralysed. This has occurred, as regards sensation, in the first case (Chas. R.'s). Both fifth nerves have been somewhat injured, one before it has decussated, and the other after. The sixth nerve is not affected to any great extent in either of these cases, as it arises and crosses in another part of the pons; but if the lesion had extended, or if it should unfortunately extend, then this nerve will be affected on one or even on both sides, according to the extent of the lesion. Yet both of these patients had double vision at first; and even now, in Chas. R., there is slight defect in the left external rectus.

The following table, taken from one of Dr. Brown-Séguard's Lectures (*Lancet*, August 7, 1861) will enable the reader to see at a glance the relation of the various kinds of facial

paralysis in hemiplegia and disease of certain parts of the pons:

<i>Seat of Paralysis.</i>	<i>Seat of Disease in the Pons.</i>
1. Trunk and limbs, <i>left side</i> . Face, <i>right side</i> .	1. <i>Right side</i> : Pons, below decussation of the facial nerves.
2. Trunk and limbs, <i>left side</i> . Face, both <i>right and left sides</i> .	2. <i>Right side</i> : Pons, level of decussation of facial nerves.
3. Trunk and limbs, <i>left side</i> . Face, <i>left side</i> .	3. <i>Right side</i> : Pons, above decussation of facial nerves.

In this Journal for April 26, 1862, we reported a most remarkable case of extensive apoplexy of the pons Varolii. The lesion in that case affected both sides of the pons. Both sixth nerves and both sides of the face were paralysed, as regards sensation and motion. This, as we have shown, might have been produced by disease of one side of the pons, injuring the nerves before and after they had decussated. But both sides of the trunk also were paralysed, so that both sides of the pons must have been affected. A case of hæmorrhage into the spinal cord, in which, therefore, the cranial nerves were not affected, is reported in this Journal for January 10. It is an interesting contrast to the above.

In reference to pains in the limbs in these cases, and also in other cases of hemiplegia, Dr. Brown-Séguard remarked that care should be taken to distinguish them from true rheumatism. The joints are often chiefly affected and tender on movement, but are not swollen and reddened. They frequently (he said) simulate rheumatism so closely, that the history the patient gives might mislead us into thinking that he really had had rheumatic fever. Yet inquiry would often show that the pains were limited to the joints of one side, the side which afterwards was paralysed. In the second case (Joseph B.), the pains in the right shoulder preceded the paralysis for some time. It will be noticed that it began suddenly and left suddenly. We referred to this and several other points in connexion with rheumatism, in a report of a case of "Disease of the Cervical Region of the Spine after Rheumatic Fever," November 1, 1862. The following quotation from Dr. Copland will be read with interest:—

"Palsy is sometimes associated with rheumatism, but not so frequently as might appear on a superficial view of the matter. The pains, whether dull, gravative, or gnawing, sometimes complained of both before and during paralytic affections, are often mistaken for rheumatism, or for neuralgia, although they are not unfrequent attendants of that change of structure at the origins of the nerves supplying the pained parts that ultimately produce palsy."

One of our most eminent Hospital Physicians considers that rheumatic fever itself should be regarded as mainly an affection of the nervous system.

In the following case is an instance of paralysis succeeding to supposed rheumatic pains in the joints. Although both sides of the body are affected, it will be observed that the *left* side of the face and the *right* side of the body suffer most.

**"RHEUMATISM" FOLLOWED BY PARALYSIS OF ONE SIDE OF THE BODY, AND SUBSEQUENTLY OF THE OTHER—LOSS OF MOTION AND SENSATION ON BOTH SIDES; CHIEFLY OF THE LEFT SIDE OF THE FACE, AND OF THE RIGHT SIDE OF THE BODY.**

Richard G., aged 40, a tailor. He is a feeble-looking man, and has, having been unable to work, lived badly. Nine years ago he had what he fancied were rheumatic pains in his joints, but in a few days these were succeeded by paralysis of the left side of the body. This occurred in a fit, in which he lost consciousness. A few years later he lost power in the other side, but this time he had no loss of consciousness. Three years ago his hearing became impaired, and is now much affected, but chiefly on the left side. He has loss of sensation and motion on both sides, but especially on the right. He can walk with difficulty, and feeling is entirely lost in the right hand. On both sides of the face feeling is much diminished, but most on the left side, being just the reverse of what exists as regards the limbs. The loss of feeling in the tongue is so great that he does not feel two points of the compasses, however far they are apart. There is a want of parallelism in the eyes, but there is no apparent loss of power of eversion. He used to have double vision, but has not now. The left pupil is smaller than the right, and this eye

does not invert so well as the other. Dr. Brown-Séguard finds that there is great difference in his power of dilating the sides of the chest. He hardly dilates the right at all, and the left but little.

We next relate a few cases of apoplexy of the pons Varolii. In all these cases the patients died. Apoplexy of the pons Varolii is not necessarily fatal, even when very extensive, as is shown by the case to which we have already alluded at page 212.

For the following case the writer is indebted to his friend, Mr. Pritchett, of Huddersfield. Although it did not occur in Hospital practice, it illustrates the subject so well that we insert it here :—

**APOPLEXY-CONVULSIONS-DEATH FROM APNŒA  
—AUTOPSY—EFFUSION OF BLOOD IN THE  
PONS VAROLII AND INTO THE FOURTH  
VENTRICLE.**

John L., aged 75, eight years ago fell out of a barn window ten feet from the ground, pitching upon his head a little to the left of the sagittal suture. The scalp was cut to the bone for a length of four or five inches, and he remained in a state of coma for several hours. During the healing of the wound several pieces of bone came away, and he was unable to do anything for three months, after which time, however, he was able to follow any light occupation that did not require him to stoop much: he has, however, lately complained occasionally of much dizziness, and at times, also, of pain over the region of the heart, and did so especially the day before his fatal attack. On Saturday, at 10 a.m., he went up several steps to a workshop, chatted cheerfully with the workmen some minutes, and came down. When within two steps of the bottom of the ladder, his son, who was below, saw him stagger, and went to assist him, when the deceased said he was sick and giddy, and asked his son to help him to walk. After a step or two, however, his legs failed, and his son had to carry him into the house, when he could no longer speak; and, he becoming stupid, the family sent for me. I arrived in about fifteen minutes, and found him perfectly insensible, pale, the features shrunk, the mouth gaping, and the breathing was in inspiration a loud, laborious snore, and in expiration a rough, hurried sigh. Both pupils were immovably and completely contracted, and the eye itself and eyelids were totally insensible. His whole frame was powerfully convulsed, his knees drawn up, his hands clenched, and his cervical muscles rigidly contracted, till he seemed as though he would choke, his attempts to breathe being more like an inspiration in laryngismus stridulus than anything else. These convulsions continued at intervals for four hours and a-half, when he died at last from apnœa.

*Autopsy, Thirty-nine Hours after Death.*—*Head.*—On the scalp there was an old scar commencing about two inches above the left orbit, and proceeding backwards over the left parietal to the articulation with the occipital bone. The calvaria being removed, the external surface of the dura mater was found very rough; it was also firm and tough all over. A considerable quantity of blood and serum escaped at the time when the spinal cord was cut through. The arachnoid was lifted up everywhere by fluid, which oozed out on its being pricked. The large arteries at the base of the brain were tough, and cut gritty. The brain being removed, a piece of dura mater was found firmly attached to the sides of the middle third of the superior longitudinal fissure. In the falx cerebri, in this position, an irregular piece of bone was found about the size of a small almond. The hemispheres were not softer or more injected than usual. The lateral ventricles being laid open, the corpora striata and thalami optici were found soft, and the surface of the left corpus striatum was flocculent. The choroid plexuses contained gritty matter in larger quantity than usual. The septum lucidum was very transparent. The corpus callosum and fornix were very soft. A quantity of black blood was found in the pons Varolii, filling up the whole of the fourth ventricle, and extending into the crus cerebri of each side, especially on the right. A small old cavity was found at the middle of the line of junction of the right corpus striatum and thalamus opticus.

In Dr. Brown-Séguard's work on the "Physiology of the Nervous System," are some interesting observations on the parts of the nervous system having to do with respiration. He writes :—

"In man, hæmorrhage in the various parts of the base of

the encephalon, near the median line or upon it, produces trouble in respiration, which is more and more marked the greater the amount of effused blood and the nearer it is to the medulla oblongata. Certainly, in many cases, the trouble of respiration may be partly attributed to pressure on the medulla oblongata, but it is not always so; and, at any rate, in several cases of softening of the pons Varolii, in which it cannot be said that there was a pressure on the oblong medulla, there has been a trouble of respiration. From the examination of a great many cases, I have been led to the conclusion that the whole base of the encephalon is employed in respiration."

Hence we understand why the patients whose cases have just been related (Chas. R. and Joseph B.) should suffer from certain defects of respiration referred to in the narration of their cases—the gaping in one and the coughing in the other, attended by involuntary throwing out of the paralysed arm and leg, so that they became quite stiff on that side. The patient, Joseph B., said that ever since the attack he has suffered from what he calls asthma, and before the actual attack he had had considerable respiratory trouble.

A case is recorded by Dr. J. W. Ogle in the ninth volume of the Pathological Society's *Transactions*, in which there were similar symptoms. It was not, however, a case of disease of the pons, but hemiplegia from cancerous disease on the surface of the opposite hemispheres. The case altogether is full of interest, but the following quotation from Dr. Ogle's record bears most on our present subject :—

"A very remarkable phenomenon during life was the forcible clenching of the paralysed hand during yawning, which would immediately drop after the yawning; as also the involuntary muscular motion of the paralysed arm observed when the patient was about to come to the Hospital, and was thereby agitated in mind. The former of these facts is comparable to that first mentioned by Abercrombie, of a raising up of the paralytic arm in hemiplegia at each time of yawning. In a letter to the late Mr. Shaw, that Physician describes the case of a man who had not the least power of motion of the left side, except under the following circumstances :—

"He was very much affected by yawning, and every time he yawned the paralytic arm was raised up, with a firm, steady motion, until it was at right angles with his body, as he lay in bed. The arm was raised steadily during inspiration, and, when the expirations began, seemed to drop by its own weight, with considerable force. He continued liable to this affection for a considerable time, and it ceased gradually, and he began to recover the natural motion of the limb."

"This case," Dr. Ogle continues, "Bell adduces, as showing how independent the automatic respiratory acts are of volitional ones, and as coinciding with the movements of the muscles of the face, shoulders, sterno-mastoid, trapezius, etc., which occur in hemiplegia, through the agency of those nerves which control and combine the muscles in respiration. It is interesting to notice the coincidence of the arm movements in inspiration." Dr. Ogle adds in a note,—"Since the above was written, we have had, in St. George's Hospital, a man affected with incomplete hemiplegia, whose paralysed arm shook vehemently on any emotion being experienced, and whose flexed and paralysed fingers were extended involuntarily whenever he yawned."

Dr. Billing, in his work on the "Principles of Medicine," speaks of an affection of the respiration simulating spasmodic asthma, which he believes to depend on disease of the nervous centres.

In Mr. Pritchett's case there was, no doubt, pressure on the medulla oblongata, and hence the great trouble of respiration. As Mr. Pritchett said, the patient died of apnœa. There are cases, however, related, as one by Dr. Bristowe, in vol. ix. of the Pathological Society's *Transactions*, in which the breathing is described as being explosive, in which the effusion was quite limited to the pons.

**GUY'S HOSPITAL.**

**SYMPTOMS LIKE THOSE OF POISONING BY  
OPIUM—PUPILS CONTRACTED—DEATH—  
AUTOPSY: APOPLEXY OF THE PONS VAROLII.**

(Under the care of Dr. WILKS.)

Jane R. was admitted into Lydia ward, under the care of Dr. Wilks, on January 4; she died next day. She was a widow, but had never had any children. Whilst riding in an omnibus, about four o'clock on the afternoon of the 4th, she suddenly fell insensible, and was immediately brought to the

Hospital. She was perfectly insensible and quite motionless, except occasional twitchings, and appeared quite unconscious of everything. The pupils were much contracted. The breathing was stertorous, and irregular and catching. She died at eight o'clock on the following morning.

Body stout, with rather a mass of fat in the abdomen. The brain was healthy with the exception of the pons Varolii, which appeared rather bulky and soft on touching it. On cutting into it, a small effusion of blood was found in it. The blood-vessels at the base of the brain were hard and rigid. The pericardium was closely adherent. The walls of the left ventricle were more thick than usual.

**SYMPTOMS LIKE THOSE OF POISONING BY OPIUM—PUPILS CONTRACTED—AUTOPSY: APOPLEXY OF THE PONS VAROLII—BRIGHT'S DISEASE.**

(Under the care of Dr. WILKS.)

Margaret B., aged 44, was admitted into Guy's Hospital on May 3, at one o'clock in the afternoon: she died at ten o'clock the same evening. She had ridden to Newington Causeway in an omnibus with her daughter. Whilst on the road she complained of pain in the head, but alighted, and went into a shop, where she soon fell down in a state of insensibility. She was at once brought to the Hospital and put to bed; she was then in a perfectly helpless and unconscious condition—in fact, in deep coma. When the limbs were lifted they fell lifeless at the sides, and there was no rigidity. The pupils were minutely contracted. The breathing was deep, but not stertorous, and the number of respirations were more numerous than natural. The pulse, at first feeble, became, after two hours, throbbing and rather hard; but the artery itself was rigid. As at first the daughter was not present to relate the history, the exact nature of the case was not apparent. Poisoning by opium was negatived by the frequency of the respiration. The urine was drawn off, and found to be highly albuminous, which suggested uræmic intoxication; but when it was subsequently found that the symptoms had come on suddenly, it was clear that some lesion of the brain had taken place, the Bright's disease and accompanying disease of the arteries favouring this view. As it could not be positively ascertained that a part of the body had not been paralysed before the whole was affected, it was thought that the blood had been poured out in the most usual place, the corpus striatum or thalamus opticus, and had subsequently escaped into the ventricles, and diffused itself over the base of the brain.

*Autopsy.*—All the brain was healthy except the pons Varolii, which appeared soft and swollen; and on cutting it through it was found to contain a large clot of blood. The cerebral vessels were much diseased. The kidneys granular and atrophied.

In nearly all the cases of apoplexy of the pons Varolii recorded, the pupils were contracted. Dr. Brown-Séguard stated, in his lecture on the cases of Charles R. and Joseph B., that this occurred probably from lesion of the fifth nerve in the pons, as it was found that section of this nerve trunk produced contraction. Contraction of the pupils occurs also in poisoning by opium, and is one of the most important symptoms (a). It is not always easy to distinguish, when a patient is brought to a Hospital without a history, whether the case be one of poisoning by opium or apoplexy of the pons Varolii. At all events, errors of diagnosis have occurred in the hands of the most skilful. Dr. Taylor ("on Poison") writes:—"Dr. Birt Davies has published the two following cases:—'A person died in what was considered by the Physician and Surgeon attending to be a fit; but opium was found in the stomach. A person was attended by a Physician and Surgeon for some hours. The illness and death were ascribed to, and treated by them for, apoplexy, but it was proved beyond doubt that the deceased had died from laudanum. Such cases, I am convinced, are frequent.'" It is of great importance to make a correct diagnosis, as it is clear that if, ultimately, by examination or analysis, the case is cleared up, still, the mistaking apoplexy for poisoning by opium may be the cause of considerable annoyance and distress by giving rise to false charges of poisoning. Taylor, in the work referred to, writes:—"In apoplexy from disease, it is usually observed that coma (complete insensibility) is at once induced; but

(a) Dr. Taylor writes:—"The pupils [in poisoning by opium] are sometimes contracted, at others, dilated. From cases I have been able to collect, contraction of the pupils is much more frequent than dilatation. In a case referred to me in 1846, one pupil was contracted and the other dilated."

in poisoning, this symptom comes on slowly, and is generally preceded by giddiness and stupor." Still, persons may be found insensible and motionless with contracted pupils, or the Medical man may doubt the history given of the suddenness of the attack, and thus the diagnosis may present considerable difficulties. Besides, in fatal cases of apoplexy of the pons Varolii, there is, as in Mr. Prichett's case, sometimes an interval from the first symptom to the stage of unconsciousness, although a short one. In cases in which the patient recovers, as in the case of Charles R. (Case 1 of this series), the interval is sometimes considerable. Nor is the interval between taking the poison and the onset of symptoms from poisoning by opium always long. The symptoms usually commence (Dr. Taylor says) in from half an hour to an hour; but in "a case related by Dr. Skae, the person was found *totally insensible in fifteen minutes.*" If a patient falls down at once, and becomes immediately unconscious, his pupils being contracted, the diagnosis might be considered easy. Yet, in Medical practice we so often meet with exceptional cases, that it is difficult to rely on past experience in a case occurring suddenly.

In the following instance, a Surgeon of some experience was led to use the stomach-pump in a case of apoplexy of the pons Varolii, under the idea that, possibly, the symptoms might be due to opium.

A man, away from home, at an inn, called for a glass of ale. As soon as he had tasted it, he cried out, "I am poisoned," and fell down in a fit. He became quite insensible, and one pupil was contracted to a point; the other eye was lost by old disease. The Surgeon who was called thought it right to use the stomach-pump. The patient never rallied, and died a few hours later. A large clot was found in the pons, and it extended into the fourth ventricle. He had had an attack of paralysis some years before.

In the eighth volume of the Pathological Society's *Transactions* is a report of a case of apoplexy of the pons Varolii, in which this mistake was made. The patient, a woman, was under the care of Dr. Hare, at University College Hospital. He at once diagnosed apoplexy, but he adds, in remarks on the case: "The frequent twitchings of the muscles, almost equal in amount on the two sides, the extreme contraction of the pupils, the absence of distortion of the face, the character of the breathing [laborious, not stertorous], were such as to make three intelligent Medical men very strongly suspect that the case was one of poisoning by opium." The stomach pump was, therefore, used in Dr. Hare's absence, and the contents examined chemically for opium; none was found. There is (as Dr. Hare remarks) also a Medico-legal interest attached to this case. The patient was able to knock at a door and say she was dying before unconsciousness supervened. How long she had been confused and ill is of course not known. In the tenth volume of the Pathological Society's *Transactions* is recorded a case by Mr. Nunneley, of Leeds, in which symptoms very like those of poisoning by opium were found to be due to apoplexy of the pons Varolii.

Although the following case is not one of apoplexy of the pons Varolii, it will be read with interest as regards the difficulty of diagnosing between cerebral affections and poisoning by opium. The case was one of apoplexy, although the cause was not disease but violence. Blood from the cavernous sinus was effused at the base of the brain. There was fracture of the sphenoid, and no doubt the patient had had some injury to the head. It is of course possible that she may have taken opium, and may then have attempted suicide in some other way, as by throwing herself from a great height; or she may have been struck after attempts to poison her. We allude to this as being barely possible. Dr. Taylor relates an instance in which a man swallowed a large dose of laudanum, and then hanged himself.

**SYMPTOMS LIKE THOSE PRODUCED BY LARGE DOSES OF OPIUM—DEATH—FRACTURE OF THE BASE OF THE SKULL.**

The following case occurred in 1846, but has not yet been published. Unfortunately, the record cannot be found, but the following facts are supplied to us from memory by Dr. Braxton Hicks, who was dresser at the time:

A young woman was brought to the Hospital by two policemen, who said that she had taken opium. The pupils were contracted as in poisoning by opium. Her manner was sullen, and when asked questions she answered by swearing. There was torpor, drowsiness, and altogether everything seemed to favour the policemen's statement. The stomach-

pump was used ; but, after a time, having misgivings as to the diagnosis, inquiries were made as to the reasons for the suspicion of poisoning. The policeman replied that the Medical man had said it was so ; and it appeared that he had formed his opinion from the symptoms only. The patient was then put to bed. About six hours afterwards, the pupils began to dilate, and remained so until death. The extremities became livid and cold. She became perfectly comatose, and died about twelve hours after she was brought to the Hospital.

At the *autopsy*, a fracture of the base of the skull was found. It extended through the ala of the sphenoid on one side, and through the cavernous sinus, causing effusion to about three or four ounces.

A record of two interesting cases of injury to the head, in which the symptoms were such as to lead at first to the diagnosis of apoplexy, are recorded in this Journal for August 10, 1861. In both the mistake was corrected, and one of the patients was saved by trephining. In the other, there was an injury to the base of the skull.

Several interesting cases of disease of the pons Varolii will be found in this Journal for May 25, 1861. Many cases are recorded in the *Transactions of the Pathological Society*, one of which, by Dr. Broadbent, is of very great interest.

Medical Times and Gazette.

SATURDAY, FEBRUARY 28.

RUSSELL v. ADAMS.

It was our opinion, and that of many of our friends, that any further proceedings to vindicate Mr. Adams' character were simply unnecessary. Not only our Medical brethren, but the lawyers and the whole of the thinking part of society, felt that he had been the victim of an atrocious attempt at extortion, and that, beyond the unavoidable annoyance of the suit, and its expenses, he would suffer no damage. Some of the most active members of our Profession, however, thought that it would be a good plan to summon a public meeting, not only to show sympathy with Mr. Adams, but to call public attention to the frequency and facility with which infamous charges can be trumped up against Medical men, clergymen, and all other persons whose vocations bring them into private personal relations with women—charges which there is often no possibility of rebutting save by simple denial—which too often leave an undeserved stain on persons of unblemished rectitude—and to avoid which many a man of small moral courage is tempted to buy off the accuser, and so to encourage the crime by making it profitable. Accordingly, a public meeting has been held ; authentic copies have been circulated of Chief Baron Pollock's charge to the jury, of which a most garbled and unfair version had appeared in the *Times* ; and the whole history of the case has been freely ventilated, the result showing that Mr. Adams was even more free from the charge of indiscretion or incautiousness than many of his own friends at first were disposed to admit. We will set before our readers a few remarks on some of the critical points of the case ; and it gives us the sincerest pleasure to be able to say, that the fuller the scrutiny which we institute, the

more does Mr. Adams' case come under the category of simple misfortune, and not of misfortune provoked by misconduct of any kind.

In the first place, the question has been fairly asked, what right had Mr. Adams to receive a hospital out-patient at his own house ?—a thing clearly contrary to the etiquette and interests of the Profession.

The answer is, that when Mrs. Russell came to the Orthopædic Hospital in July, 1860, with the child Crump, it was not as a patient, but simply to inquire for the name of an Orthopædic Surgeon ; and when the list of Surgeons to that Hospital was shown her, she chose Mr. Adams by mere accident, saying that "Adam was the first man," and that she might as well take Surgeon Adams as any other.

In the next place, it has been stated in evidence that, although Mr. Adams' visits to the Russells were, with two exceptions, in the afternoon, and of short duration—about a quarter of an hour—yet that, on two occasions, he took coffee with them at half-past nine o'clock, and remained till between eleven and twelve o'clock ; on these occasions music was offered as the attraction.

It has, therefore, been asked, why did Mr. Adams admit *low* people to such familiarity as to visit them—to sing with them ? The answer is—and we request particular attention to this point—that they were not *low* people, but that they possessed the education, manners, and *status* of the professional circle to which they claimed to belong. Mrs. Russell claimed relationship with the noble family of that name, and likewise with the Dean of Down. She professed that "never in her life had she been in the habit of being in so public a conveyance" as an omnibus. All who have come in contact with her describe her as an educated, well-mannered woman—a musical professor, living on "the accomplishments of happier days," able to wheedle most men, pushing, artful, and capable of imposing upon the most wary. Mr. Probert describes her in nearly the same terms, and so do the clergy of Holyhead, with whom she attempted to enact the same farce, and so do half a dozen other persons who have met with her. Clearly, then, there is nothing wonderful or degrading in the idea, that Mr. Adams should show civility to such a woman, who represented herself as a Surgeon's widow in distress. But, on the other hand, it is most wonderful that such a woman should have acted as she did, if, as she pretends, her daughter informed her in October, 1860, that Mr. Adams had offered marriage. There is nothing that distinguishes the upper educated from the lower uneducated classes of society more than extreme sensitiveness on the subject of a daughter's honour. It is perfectly incredible—and we put it to the common sense of the whole community—that any *lady* should have let a proposal of marriage to her daughter pass unnoticed for a whole month—that she then should write a letter to the proposed husband, and so carelessly that she should not keep a copy—that she should not consult her brother about it, nor the Dean of Down—that she should make no inquiries about the suitor, nor ask to be introduced to his family, nor see his solicitor, nor know what his circumstances were, nor what provision he could make for his wife ! All such proceedings are characteristic of a she-adventurer, who would poke her daughter into matrimony anyhow if she could, but they are abhorrent to the character of a lady of birth, family, virtue, or even common sense or common respectability.

Again, whoever would desire to know the value of Mrs. Russell's testimony—on which alone her daughter's case rested—may consider in how many respects it was so directly contradicted by that of others, that it follows either that the Russells were perjured, or that, as the learned Baron put it, "Mr. Crump is perjured, Mr. Blaise is perjured, Mr. and Mrs. Lama, the girl Clamp, and three or four witnesses besides, are perjured." She said that she left Mr. Crump's house in order that her daughter might not ride in omnibuses.

He swore that he compelled her to leave because she got into debt. She detailed certain incidents during an interview with Mr. Adams and Mr. Blaise;—Mr. Blaise swore the direct contrary. But we do not think it worth while to revive the particulars of this wretched conspiracy.

Let us come to matters of rather more consequence to the public; let us scan the conduct of the legal advisers of this miserable woman, without whom she never could have made her appearance in a court of justice, nor could this grievous injury have been inflicted on Mr. Adams. It is a necessity for society that attorneys should exist, and that they should listen to the tale of every person who conceives that he has a wrong. They may often be compelled to institute proceedings of which they disapprove; still, every one who has had the good fortune to be concerned with attorneys who are gentlemen and men of honour will know, that even as antagonists they need not trespass the bounds of fairness or even of courtesy. Since, too, any attorney may bring any conceivable action against anybody, at the suit of anybody, life would be a nuisance, were it not that respectable attorneys will seldom bring actions unless their client be solvent, or unless he have a real grievance, and a reasonable chance of success. To bring a speculative action against a man at the suit of an adventurer, and harass him with anxiety and costs, is a thing which no sane man would do without inquiring into the facts beforehand, lest he might be inflicting a grievous injury on the defendant without the chance of benefiting himself or any one else. Will it be believed, then, not only that Mrs. Russell swore at the trial that she did not know and did not believe that Mr. Adams was a married man, but that her counsel and attorney affected ignorance of the same fact? Let us see what the learned judge says on this point:—

“Mrs. Russell said she did not believe he was married. She does not believe it now. Serjeant Shee said he had inquired for instructions, and he could not learn whether he was married or not. *I think great blame attaches somewhere*; for I must tell you, gentlemen, freely and plainly, I give my brother Shee no credit in point of fairness for the mode in which he opened this case. *It would have been far better, for the purpose of a truthful inquiry*, to have at once blurted out what the accusation was, and not to let you hear the whole case of the plaintiff without your understanding that the defendant really was a married man.”

So also with regard to Mrs. Russell's unsupported testimony as to her relatives:—

“It is not my office,” said Chief Baron Pollock, “to throw any doubt whatever on her statements; but I think Mr. Pike, if that is the name of her attorney, did not do his duty by her if he did not say to her, ‘It will be folly to bring this action if you are the only witness in the case whatever; their case may seem bad, but who will come forward and connect you with the people whom you say are your relatives?’”

“I own,” continued the judge, “I am astonished that the attorney did not before the trial of the case know he was a married man, and he ought to have known it at the earliest possible moment. I agree with the remark made by Mr. Lush, that it was not right to keep you in ignorance of that fact until all the circumstances came out. It may be part of the tact of the advocate, but it was not part of the duty of Mr. Pike—not that I say that my brother Shee was not ignorant of it, but it was impossible for the attorney not to know if he had made any inquiry. How came she not to be making inquiry? According to the evidence on the one side, she did not appear to have made a great secret of it; at least, how came Mr. Pike not to know that Mr. Adams was married, and let you know it, and let you know the whole extent, and infamy, and baseness of the charge that was made against him?”

Thus far, then, the learned judge gives his opinion as to the manner—the merciless and unfair manner—as we call it, in which the case against Mr. Adams was brought into Court. We do not condemn Mr. Pike, who is said to have a high character in his Profession, for we do not know what he has to say, nor by what instructions—what promises of pecuniary aid he was induced to bring this action. But now let us deal openly with a bit of scandal, which has caused

the greatest possible excitement and wonder in the Profession, and has, likewise, done Mr. Adams the most enormous injury. It is said that Mr. Pike, the plaintiff's attorney, is also the private attorney of Mr. Propert, the well known founder of the Epsom College, and it has further been said that the action has been carried on at Mr. Propert's instigation and cost; and the observation has followed, that there must have been “something” in the charges, else so benevolent and sagacious a man would never have sanctioned them. The facts that we have been able to ascertain are these:—

The Russells appealed to Mr. Propert in the latter part of the year 1861; for, in December of that year, he supported their application to the Medical Benevolent Fund. Hereupon ensued that remarkable correspondence which was read at the public meeting, and which will be found at pages 221 and 222. The only comment we will trust ourselves to make upon this correspondence is, how little of common justice, to say nothing of charity, or of regard for Professional honour, appears in Mr. Propert's conduct, who could thus not only assume the guilt of a friend, but coolly deny him all means of explanation; and how thoroughly his whole conduct shows him to have been beguiled by these sirens, and his better judgment and better feelings perverted, for a time, by their machinations! The first solicitor who threatened Mr. Adams was a Mr. Hill, in July, 1861. He let the matter drop. The next was a Mr. Johnson, of Doughty-street, who served a second notice of action in March, 1862. The trial was to have come off at Kingston, but Mrs. Russell was said to be taken ill, and the trial postponed in consequence of a certificate of her illness from Mr. Propert! Miss Russell was arrested for the costs of this abortive action on May 7, 1862. Again Mr. Propert appears on the scene; he is sent for, and tenders his cheque in payment. The cheque was refused, but the cash was shortly found by some one, and the young lady set free. The next move is, the serving a notice on Mr. Adams on January 29, 1863, by a clerk of Mr. Pike, who is well known to be the private solicitor to Mr. Propert.

Can it be wondered at, then, that Mr. Adams' friends should believe that Mr. Propert was the instigator of these proceedings?

Considering how serious this charge is, the writer of this article thought it his duty to ask Mr. Propert frankly what his share in the affair had been, and received from that gentleman, under the sanction of an oath, a most solemn affirmation that he never instigated these proceedings, nor paid, nor promised to pay, one farthing of the costs. It seems that the Russells applied to him, in distress, as hundreds of Medical widows do; and that hearing their case, which at that time was in the hands of another attorney, he gave them permission to consult his own attorney thereon; but that afterwards, so far from sanctioning the bringing of the action by Mr. Pike, he protested against it, and “split” with him in consequence.

Of course, we accept Mr. Propert's assurance, so far as the late action is concerned; but there is clearly a mystery somewhere. It is quite certain that the credit of Mr. Propert's encouragement and patronage procured for these ladies assistance from the Rev. W. Cadman and his curates. We cannot conceive how such a case could be taken up by a respectable solicitor, unless at the direction of some client more solid than the Russells; and, we repeat, if such an action can be brought by a respectable solicitor, who is safe? But we take the liberty of telling Mr. Propert that it would best be consistent with the character of the Founder of a Benevolent College if he were to extend to Mr. Adams a little of that charity and justice which he claims for the “hard working Welshman,” and if the Founder of that noble and perennial monument of benevolence on the Epsom Downs were to write Mr. Adams a handsome letter of retractation and apology for having fostered those base and groundless charges, and to enclose in it a cheque for Mr. Adams' costs.

THE WEEK.

THE ARMY MEDICAL SERVICE IN INDIA.

We reprint the following letter from the *Delhi Gazette* of December 30, 1862. At home and abroad the same deep-rooted feeling of discontent prevails amongst Army Medical officers. A different mood will never be in the ascendant until the department receives the full privileges and benefits granted to it by the royal warrant. Government will find sooner or later the necessity of yielding. It is a pity that the present opportunity is not seized, and the event of the royal marriage marked by concessions which might now be gracefully made, but can only be unjustly delayed at the risk of irreparable mischief to the service:—

“Statement of the Case of the Senior Assistant-Surgeons of her Majesty’s Home Army Quartered in India.

“1. Whereas the above officers have patiently waited four years for the Indian Government to comply with the royal warrant, that her Majesty was graciously pleased to issue for their benefit, and there being no certain sign of any inclination on the part of the Indian Government to carry out our Sovereign’s commands, the following statement of the case has been drawn up, so that the grievances so keenly felt by them may be more generally known.

“2. The following is an extract from her Majesty’s royal warrant regulating the rank, pay, promotion, and retirement of army Medical officers:—

“Victoria R.

“Whereas we have taken into our consideration the recommendations of the commissioners appointed by our authority to inquire into the regulations affecting the sanitary condition of our military forces, and the Medical treatment of the sick and wounded of our army, our will and pleasure is, that, from and after the date of this warrant, the following rules shall be established for the future admission, promotion, and retirement, and the pay, half-pay, relative rank, and allowances of the Medical officers of our army; and that by these rules our commander-in-chief shall govern himself in recommending officers for admission, promotion, and retirement.

“8. The rates of pay of the Medical officers of our army shall be in accordance with the following schedule:—

—	After 10 years’ Service on Full Pay.	After 5 years’ Service on Full Pay.	Under 5 years’ Service on Full Pay.
Assistant-Surgeon	13s.	11s. 6d.	10s.

“16. The relative rank of the Medical officers of our army shall be as follows:—

“Staff or regimental Assistant-Surgeon as a lieutenant, according to the date of his commission; and after six years’ full pay service as captain, according to the date of the completion of such service.

“17. Such relative rank shall carry with it all precedence and advantages attached to the rank with which it corresponds (except as regards the presidency of courts-martial, where our will and pleasure is, that the senior combatant officer be always president), and shall regulate the choice of quarters, rates of lodging money, servants, forage, fuel and lights, or allowances in their stead, detention and prize money.

“Given at our Court of St. James’, this 1st day of October, 1858, in the twenty-second year of our reign.

“By her Majesty’s command. J. Peel.

“3. The general order of the Indian Government annulling the Queen’s royal warrant:—

“General Order.

“Adjutant General’s Office, H.M.’s British Forces in India.

“Simla, April 16, 1860.

“The following Government general order is published for information:—

“Fort William, January 31, 1860.

“Pay of Medical Officers.

“No. 112 of 1860—With reference to such portion of her Majesty’s warrant, dated October 1, 1858, as relates to the pay and allowances of Medical officers of her Majesty’s army, it is notified that, in accordance with the instructions received from her Majesty’s Government, all claims to pay authorised by that warrant will be adjusted on the principle in-

variably observed under similar circumstances, viz., by increasing the amount of pay proper, and making a corresponding deduction from the amount of the allowances.

“2. The pay proper of Medical officers of her Majesty’s army, as payable in Indian currency, is—

—	Per mensem for any month.		
	Rs.	As.	Pic.
Assistant-Surgeon under 5 years . . . . .	149	1	4
” ” above 5 ” . . . . .	171	7	1
” ” „ 10 ” . . . . .	193	12	11

“4. An Assistant-Surgeon of seven years’ standing applied to the Pay Office for a detailed statement of his monthly pay. It is here placed, with another column by its side, showing what he ought to receive, according to his relative rank of captain:—

—	As an Assistant-Surgeon.		As a Captain.		Loss.	
	Rs.	As.	Rs.	As.	Rs.	As.
Pay and Indian Allowances	145	12	249	1	103	5
Extra Batta . . . . .	60	14	91	5	30	7
Tentage . . . . .	50	0	75	0	25	0
Palkee Allowance . . . . .	30	0	30(a)	0	0	0
Total . . . . .	286	10	445	6	158	12

“5. It will thus be seen that an Assistant-Surgeon loses 158 rupees 12 annas monthly; and the longer he serves in India the more he will lose.

“6. Medical officers in India are paid according to the appointments that they hold; and as these are given from interest rather than ability, the nomination being generally in the hands of an officer of the civil service, it naturally follows that the old Company’s Assistant-Surgeons obtain nearly all such emoluments, although home Medical officers senior to them may reside in the same stations.

“7. Notwithstanding the Government statement to the effect that—‘We will give you your English pay (because we are obliged to do so), but we will cut your Indian allowances, (which we can do if we like),’ the English pay intact is not given, the same English pay being reckoned at half-a-crown for a rupee, whereas it is only worth two shillings; so that an Assistant-Surgeon, who receives ten shillings a-day in England, is paid four rupees, as its equivalent, in this country.

“8. If words mean anything, and a royal warrant carries any authority, it cannot be denied that the Indian Government is committing the greatest injustice in not allowing home Assistant-Surgeons the pay and allowances of their rank. If the royal warrant states that an Assistant-Surgeon shall have the rank of captain after six years’ service, and that such rank shall give him choice of quarters, etc., how is it, then, that the Indian Government grants such a Medical officer only 50 rupees a-month for tentage, whilst it allows a captain 75 rupees? Surely the ‘tentage’ in India is a convertible term for ‘quarters’ in England.

“9. The injustice of charging an Assistant-Surgeon of six years’ service, a captain’s subscriptions when he is only receiving a lieutenant’s pay, is self-evident.

“10. The warrant was issued October 1, 1858, and it is in force everywhere but in India. The injustice of the present treatment of Assistant-Surgeons being once admitted—and, I think, I have clearly proved such to be the case—it necessarily follows that what is injustice now was injustice in 1858, 1859, 1860, 1861, and that the whole of the back pay which has been so unfairly withheld must be repaid to the sufferers. This is not a question whether the operation of payment will be pleasant to the Government or not; it is whether the charge be just or not; is the money really due to us? The Queen engaged us at a certain salary, signed the contract, and

(a) A captain saves about 30 rupees monthly out of his contingent, which is more than equivalent to the palkee allowance, as the Surgeon must keep a palkee, or horse, for his duties.

the Government must pay. Her Majesty drew a bill, and her servants must honour it. It is as dishonourable for the Indian Government to proceed in the way they are doing, as it would be to a private individual. What would be the opinion of counsel in such a case? Supposing a contractor had agreed to give a certain salary and position to an *employé*, and the conditions were not fulfilled by the agent, would not the advice be, 'Bring the case into court at once, and you may be sure of a verdict in your favour?' Is it to be thought that the defendant would be let off by pleading lapse of time without payment? Time makes no difference. Injustice is injustice, regardless of the hour or the man. What was unjust on October 1, 1858, has been unjust daily and hourly since. Restitution must come. Reimbursement must be made.

"11. It is strange it should be so, but it is nevertheless true, that it will be difficult to obtain this justice from the Indian Government. A corporate body will often perform acts mean and dishonourable, which any individual member would be ashamed of ordering on his own responsibility. The senior Assistant-Surgeons in this country, over six years' service, are very few, and their personal influence is not, therefore, great; so that they have but little more than the prosaic justice of their cause to attract attention to their grievances. Their juniors, ranking only with lieutenants, have nothing to gain by mooted the question, and Surgeons would probably lose by any alteration; so that the senior home Assistant-Surgeons are left to be unjustly treated without any holding out a hand to help them. 'God helps those that help themselves'; so we must each put our shoulder to the wheel, and, if we do not obtain redress, it shall not be from want of being heard.

"12. To the hundreds of Medical students now studying in the English colleges the present statement will be sent; and, perhaps, when the Government finds that the commissions are going a-begging—as was the case during the Crimean war—they will render us that justice for which we have waited so long.

"13. Members of Parliament will be communicated with, and it will be seen whether the House of Commons approve of the Indian Government breaking the promise made by her Majesty.

"14. The bitterness of feeling, and the disgust at the unfair treatment they receive, is making a valuable set of the Queen's servants loathe the service that they belong to, and such a feeling must be the source of much evil.

"15. It must be remembered, that for every year a European spends in this country, at least one year and a-half of his life has gone (an unpleasant fact for others besides doctors); and when it is considered that a senior Assistant-Surgeon receives about the same absolute pay at home, in a healthy climate, as he does in this unhealthy one, the injustice of the case will be more clearly seen. An Assistant-Surgeon in England receives 11s. 6d. a-day, or 172½ rupees a-month; in India he is paid 286 rupees, leaving him only 113½ rupees to pay for his bungalow, servants, horses, palkee, extra messing, extra subscriptions, etc., which sum barely covers his expenses, so that, in a pecuniary point of view, he is absolutely better off when he is serving in civilised England.

"16. That the Government of India may see the justice of our cause, and of their own accord grant what is not only morally but legally just, without placing us to the disagreeable necessity of 'fighting for our rights,' is the sincere wish of

"Yours truly,  
"UN PAUVRE DIABLE."

#### ARCHBISHOP WHATELY AND THE IRISH COLLEGE OF SURGEONS.

OUR readers are doubtless aware of the homœopathic tendencies of the Archbishop of Dublin. Every man has a right to his own opinion, but Dr. Whately has certainly displayed neither good sense nor good taste in allowing to be published in the Dublin papers a letter signed by himself, condemnatory of the conduct of the Irish College of Surgeons, in reference to homœopathy—a letter in which he stigmatises that conduct as "a detestable act of tyranny." In the *Freeman's Journal*, of February 19, appears a trenchant answer to his Grace, from which we extract the following:—

"With regard to the 'system of education' which he says the Medical student may 'keep clear of,' we must say a word.

There is no school, and no licensing body, professing homœopathic doctrines in these kingdoms. A man can acquire a license to practise only by his going through a certain curriculum. If found in an examination efficient, he signs the rules and regulations, takes in some instances a solemn oath, and then receives a diploma. Suppose he subsequently becomes convinced by 'reason and experience' of the fallacy of his teachers, or for any other good reason sees fit to turn atom doctor, a practice which his college denounces as a 'deception,' and 'derogatory and dishonourable,' the law does not in its present state enable the college to withdraw its license, and even if it did its action might not be attended with the wished-for result. But surely the college may with reason preclude its members from consulting with, &c., without being branded as tyrannous and detestable. Let us see how the Church, of which Archbishop Whately is a pillar, treats heterodoxy. An educational course is laid down for the aspirant for holy orders, in which he is instructed in divinity, church history, and certain doctrines supposed to be founded on Scripture. He gets a nomination, is strictly examined by the archbishop, or some one appointed by him, takes the oath of allegiance and supremacy, accepts the Thirty-nine Articles and the rubric, is ordained, and gets a license. Let him change his views, and alter his tone a note too high or too low, either from the generally accepted doctrines and practices of the Church, or the peculiar interpretation of his archbishop—let him but decorate the cloth, light candles in his church, wear a surplice in the pulpit, or read portions of the service with his back to the people, and we know what will follow. Let him even rise to be a dignitary, and have his faith shaken by a Zulu, and he must either throw up the Thirty-nine Articles, bishopric and all, or be dragged before the Court of Arches. The doctors look on, but they do not designate the proceeding an act of 'detestable tyranny.' The logic may not be so good as that of 'one of the best logicians of the day,' but I think analogy is reasonable."

#### EVIDENCE AS TO MAN'S PLACE IN NATURE.

UNDER this title, Professor Huxley has published a work, which will be read by thousands both in and outside the circles of science. Descriptions, for the most part admirable—zoological, physiological, and anatomical—and a style always transparently clear, at times rising to eloquence, make his book a most fascinating evening's reading. As a scientific work—using the word "science" to embrace all branches of knowledge, and not merely anatomy and physiology—it is eminently suggestive, but as eminently inconclusive. At present, it could not be otherwise, for the facts known are far too few to warrant conclusion. But, whilst acknowledging the high merits of Professor Huxley's book, it seems to us to fulfil only partially the promise of its title. Evidence as to man's place in nature we think it is not, although it is admirable evidence as to man's place in the animal kingdom deduced from his anatomical structure. Man's place in nature, we hold, is to be decided on psychical equally with physical grounds. Admitting that Professor Huxley has proved that, in many points of physical structure, the gorilla and other anthropoid apes make a nearer approach to man than the lemurs do to them, we still must wait for evidence that intellectual and moral faculties undergo the same ascensive development in the *Simia*, advance *pari passu*, and finally approximate as closely as do the plan of the cerebral lobes and cavities, and the mechanism of the limbs. Until this is proved, we may fairly withhold assent to the doctrine, that, "if man be separated by no greater structural barrier from the brutes than they are from one another—then it seems to follow, that if any process of physical causation can be discovered by which the genera and families of ordinary animals have been produced, that process of causation is amply sufficient to account for the origin of man." It is unfair, however, to criticise separate passages in a book which must be read as a whole to be justly appreciated. We commend it to individual study, but, at the same time, we feel bound to insist upon the gaps which occur in Mr. Huxley's chain of facts and argu-

ments, and which he himself most unreservedly admits. First, the anatomical differences between man and the gorilla are so great, that it is utterly impossible to suppose that man can have been derived from it or any other existing or known extinct ape. To speculate, therefore, on the probability of a discovery of some anthropoid ape or pithecoïd man which shall bridge over the chasm, may be a pleasant exercise of the imagination, but it certainly is not a scientific occupation. Science deals only with facts, and her conclusions are founded only on facts; but here the sole fact that can be of real importance, that of the past or present existence of an ape sufficiently like man to allow of the probability of any law of development from the lower to the higher being brought into play, is entirely wanting. To assume the fact, and then to argue on the assumption, is simply to quit the arena of scientific controversy. But even supposing that a future palæontologist, deep down in the miocene, or yet older formations, should find evidence of an ape which, in length of limb, structure of foot, pelvis, cranial capacity, and dental characters, approached far nearer to man than do the disgusting brutes of Borneo and the Gaboon, the proposition of a serial relationship must then wait until satisfactory evidence is produced in proof of the origin of species by natural selection, or by development. Mr. Huxley acknowledges that "the question of the relation of man to the lower animals resolves itself in the end into the larger question of the tenability or untenability of Mr. Darwin's view." But as the crucial evidence is wanting of any physiological species having been yet produced by selective breeding, we must again wait for facts. On this point we will quote Mr. Huxley:—"But, for all this, our acceptance of the Darwinian hypothesis must be provisional so long as one link in the chain of evidence is wanting; and so long as all the animals and plants certainly produced by selective breeding from a common stock are fertile with one another, that link will be wanting. For so long, selective breeding will not be proved to be competent to do all that is required of it to produce natural species." These two most necessary links in the chain of evidence being entirely missing, whilst we advise our readers to give themselves the pleasure they will surely derive from Mr. Huxley's book, we do not advise them to accept unreservedly what we may call the "Yahoo hypothesis,"—an hypothesis which at present is unsupported by observed facts, and, we may add, is at variance with the inmost convictions of the human mind.

#### SANITARY LAWS AND SEWAGE IRRIGATION AMONGST THE ANCIENT JEWS.

It is well known that most of the ceremonial laws of the Jews have a profound philosophical and sanitary import, apart from their religious significance. The rite of circumcision, which was adopted not only by the Jews, but by the Arabians, Egyptians, and many of the tribes which migrated along the eastern coast of Africa, is so important as a means of cleanliness, of preventing certain sexual impurities, and of averting disease, that many of us wish it had never been abolished amongst Christians; and though it may be said that it is unnecessary for a cleanly and moral people, yet, alas! Christians are far from being cleanly and moral yet. The prohibition of pork, and of the flesh of animals which had died of themselves, was well calculated to prevent the spread of disease arising from the parasitic animalcules with which filthily kept pigs are infested; but as it is possible to keep those useful creatures in a cleanly and wholesome manner, so we may claim the privilege of eating pork. The absolute prohibition of blood is a thing more difficult to understand. We can conceive of the expediency of a law against eating "flesh with the life,"—*i.e.*, the flesh of animals cut from them whilst living, after the disgustingly cruel fashion described by Bruce in his Abyssinian travels; but we feel that there is something yet to be learned of the

reasons for that primeval law against eating blood, which was given to Noah, confirmed by Moses, and singularly enough sanctioned by the council of the Apostles at Jerusalem. In the Eastern Church, this law is, we believe, observed to the present day; and neither blood, nor the flesh of animals which have died of disease or by strangulation, is permitted to be eaten. In the Western Church, it fell into disuse about the sixth century, and blood became not only a common but a popular article of food, and continued so over Western Europe until a more delicate style of eating was introduced in the present century. We have a cookery-book of the year 1780, by C. Carter, cook to George III., and amongst the bills of fare for a grand dinner, in October, we find—"a Beef-Pye in Blood;" and that "a Haunch of Venison, Roast in Blood," figured on his Majesty's table, on December 20, in some year not mentioned. The blood was that of sheep, calf, lamb, or deer, mixed with a little salt, stirred to hinder "clodding," and rendered savory by spices and herbs. The meat was immersed in this all night; and in the case of a pie, the dish was filled up with the blood, and in the case of a roast, the meat, blood, and all were done up in a veal caul, and so roasted altogether. There is evidently room for a revival of archæological cookery, if any one is tired of modern dinners. But to return to the sanitary customs of the Jews. We were not aware, until Mr. Williams gave his lecture on Jerusalem, last Friday, at the Royal Institution, that the practice of sewage irrigation was known to them. But so it was.

"Recent discoveries (said Mr. Williams) fix beyond all question the position of the temple of Solomon and its successors. No one could read the accounts of the sacrifices without being convinced that there must have been some great system of water-works for the purpose of clearing away the blood and other impurities resulting from them. There is a hole in the rock which Professor Willis was the first to identify with its real purpose; and underneath the 'dome of the rock' Signor Pierotti discovered a cave. The hole was the drain, and the cave in the rock the cesspool of the Jewish altar. This confirms the position of the altar of burnt offering.

"The water came from the Pools of Solomon, which exist to this day, and passing in an easterly direction turned northwards, and flowed under the dome of the rock. But, we are told in the Mishna that the place of slaughter was on the north; and, accordingly, we find two cisterns, one at the north, and the other on the west, from which aqueducts led eastwards and southwards to carry away the blood and offal from the altar. A further dilution was made by the accession of water from the Pool of Bethesda on the north, whence the mixture passed on to the valley of the Kedron, where it was sold to the gardeners, and the lands manured with it were remarkable for their fertility."

If we understand the subjoined notes from the Mishna aright, the sin offerings were held not to have been duly performed till the blood reached the brook Kedron—*i.e.*, the extremity of the outfall sewer, and was delivered to the gardeners. Our Metropolitan Board of Works may take a lesson in this matter from the wisdom of the ancient Jews.

"Super locum mundum altaris spargebat septies, reliquiasque sanguinis in lembum occidentalem altaris exterioris fundebat, reliquias vero sanguinis altaris exterioris fundebat in lembum ejus meridionalem. In fossa autem miscebantur, et currebant in torrentem Cedron, et stercorandis hortis olitoribus vendebantur, et oblationem transgressionis persolvere tenebantur in illis.

"*Note.*—Isti et isti in fossa miscebantur et currebant in torrentem Kedron. Isti et isti, id est, sanguines interiores et exteriores miscebantur. Duo enim foramina erant in basi altaris, instar duarum narium exilium, ut in 'Middoth' traditur, ex quibus utrinque sanguines in fossam subterraneam cadentes, simul in torrentem Kedron ferebantur.

"*Note.*—(Et Stercorandis—*in illis.*) Sanguis autem iste iâ Tribunis ærariis et rei quæstuariæ præpositis vendebatur, nec oblationem transgressionis persolvere tenebatur, antequam sanguis esset in torrentem Kedron devolutus."

THE following announcement appeared in the *London Gazette* of February 21:—His Royal Highness the Prince of Wales has been pleased to appoint Claudius F. Du Pasquier, Esq., F.R.C.S., M.S.A., to be Surgeon-Apothecary to his Household.

## RUSSELL v. ADAMS.

REPORT OF MEETING AT FREEMASONS' TAVERN,  
ON TUESDAY, FEBRUARY 24, 1863.

ON Tuesday last, a public meeting of members of the Medical Profession and others took place at the Freemasons' Tavern, Queen-street, Lincoln's-inn-fields.

The chair was taken by W. E. FOSTER, Esq., M.P., who said that the number of gentlemen then gathered together, the majority of whom were very busy men, showed how much they felt the object of the meeting. What were the facts the meeting had before it? A few days ago a charge was brought, in a civil court, against a man of eminence in his Profession, whose character stood to that time without stain. The charge which was brought in a civil court was, in fact, a criminal charge of the most serious character. If a Medical man made use of his position to gratify his passion, it was as much a criminal charge as was possible to be brought. That trial went on for three days, and he ventured to say that, of the vast number of persons who read the reports of the trial in the papers, almost every one, or ninety-nine out of a hundred, wondered that it had lasted so long, and felt certain as to the nature of the verdict. Well, the trial lasted this time, and the conclusion come to was a very extraordinary one. He did not mean to find fault with a British jury, but, though British jurymen sometimes protected our liberties, they sometimes gave rather eccentric verdicts. The verdict was a compromise. This was one of the results of the British jury system. This compromise legally acquitted Mr. Adams and gave him costs, but it did not clear him before the public as he and his friends thought he ought to have been cleared. Then there was a sifting of the case by public opinion, by the press, and especially by the Medical press, the result of which would be still more conclusive than that before a jury. They all agreed that this second trial of Mr. Adams before the press and public opinion had been a conclusive acquittal. Crime was, as they all knew, infectious, and there would be danger of this case being followed by similar cases.

Dr. LANKESTER moved the first resolution—"That all classes of society are interested in supporting those who incur great trouble, annoyance, and expense by resisting and exposing any attempt to injure their character by false charges,"—in an able and eloquent speech, in the course of which he said, that a similar attack might be made against any one of them by the distortion or falsification of facts. The clerical, legal, and artistic professions should equally sympathise in this movement. Perhaps the legal profession knew better how to take care of themselves. (Laughter.) Instances were constantly occurring where men who were ministering to spiritual wants had their confidence betrayed, and were brought before a court of law in this way. It was only the other day he was called upon to arbitrate in the case of an artist, who had a young lady sitting to him for her portrait. She went at first in company with her mamma and sister, but after some sittings she came alone. During one of these sittings she dropped a book, which was picked up, and, in answer to an observation of the young lady, that the book belonged to the artist, he gallantly replied, "Oh! every thing I have is yours," and this was construed into a declaration of marriage. (Laughter.)

Mr. Edward Parker, who had been named as the seconder of this resolution, not being present,

Dr. JOSEPH ROGERS rose and said that he had attended there that day with a view to sympathise with Mr. Adams. He advocated the establishment of some associations to uphold the humbler members of the Profession in defending themselves against charges of this nature. The magnates of the Profession might look upon even £1000 as nothing; but there were struggling members to whom the outlay even of a £5 note would be a serious inconvenience. He was ready to admit that, on two several occasions, patients who had contracted a debt to him threatened to prefer charges against him of immorality with their wives. (Loud laughter.) The first man charged him in his own surgery, so he took the man by his collar, and turned him into the street with considerable violence, then proceeded against him in the county court, and recovered the debt; and against the second man he took legal proceedings, and smashed him at once. It was rather singular two such occurrences should take place in the practice of one

individual. There was no doubt but that that gentleman (Mr. Adams) had fallen into the hands of a designing Irish woman. He (Dr. Rogers) had had to do with some in a large metropolitan union, and he believed that they were the most artful, cunning, and scheming people on this earth. There was also among them the spirit of clanship, so that wherever they were Irishmen would support each other. They had been told there were Irishmen on that jury—perhaps, purposely put there. (Here confusion ensued, for the meeting disapproved of Dr. Rogers' attack on the Irish, and the speaker was called to order by the chairman.) He referred to the case of Rich v. Pierpoint, in which the defendant had suffered heavily. His object was to have some central committee to which a charge of this nature could be referred.

Dr. O'CONNOR said he was there to support Mr. Adams, who, he thought, had vindicated his character; but he thought that, as it was currently reported that a Medical man belonging to a portion of the United Kingdom had been base enough to find means to prosecute this inquiry, and as he was sure that Mr. Adams would receive the hearty sympathy and support of the Medical Practitioners of Ireland, he deprecated the sneer against the people of this country thrown out by the foregoing speaker, and had yet to learn that they were so wanting in virtue, and sunk so low in social and moral degradation. He could not hear the people of his country aspersed in that room, in which had been heard the voice of O'Connell, Grattan, and Shiel. (Hear, hear, cheers, and great confusion, in the first interval of which the chairman informed Dr. O'Connor that the allusion had been repudiated by the meeting; had it been made with a personal application, he would at once have called the speaker to order.)

The resolution was then put to the meeting by the chairman, and carried unanimously.

H. H. CANNAN, Esq., in moving the next resolution on the list—"That a careful consideration of the charge of the judge, and of the evidence adduced in the case of Russell v. Adams, should have led to an unqualified verdict for the defendant,"—said that he was a relative of Mr. Adams, and had known him for twenty-five years, and during the whole of that period Mr. Adams' conduct had been that of an amiable and virtuous member of society, untiringly devoted to his studies and the duties of his Profession, most exemplary as a husband and father. He questioned the policy of the law which required that a jury should be unanimous.

Dr. RICHARDSON seconded the motion in a brilliant and effective speech. He had been in the court during the whole of this trial, and not only heard the evidence, but seen the way in which that evidence was given. The play of feature often expressed more than words. There was not in the evidence adduced against Mr. Adams one tittle that amounted to an iota of proof of the charge brought against him. A case might be supposed of a Medical man visiting people, and receiving from them modest little favours as the only return they could make for his services; but here there was not one such that could be brought against Mr. Adams. But, even supposing Mr. Adams had on any occasion assumed any other character than that of a Medical man, there was no acknowledgment on his part that could be construed into the act of a lover,—no attempt to misrepresent facts into what would constitute an assault. Therefore, he thought Mr. Adams had passed through the ordeal entirely unscathed. It should be borne in mind that the trial commenced on the assumption that Mr. Adams was a single man, and during the first few hours the decision of the jury was being formed on that. When the defence began, it was shown that he was a married man; so that the counsel for the plaintiff made two distinct charges against the defendant, who, in fact, went through two trials. It had also been stated that Mr. Adams saw Mrs. Russell at the Orthopædic Hospital. He never saw her there at all. She went there and asked for a list of Medical officers. She looked at the list, which Mr. Adams' name headed, and said, "Ah! Adam was the first man; let's go to Adams." (Loud laughter.) When Mr. Adams commenced his acquaintance with Mrs. Russell, he knew nothing of her daughter; her introduction was a long time after. He had treated Mrs. Russell most kindly before the daughter appeared upon the scene. There was also another fact which did not come out in evidence—namely, that there was a gentleman in court during the whole time who had been a "lover" of this young lady, and with whom matters had progressed so far, that the Russells got the wedding dress made up, to persuade the poor old woman they lodged with that the marriage

must come off, for the dress was made. (Laughter.) The charge of the judge, he thought, showed that he was strongly in favour of Mr. Adams; and he had pretty evident proof of that in the fact, that Mr. Lush had been so kind as to write a letter to himself, in which he stated his lordship's opinion, and, by inference, his direction:—

“60, Avenue-road, February 20.

“My dear Sir,—Pardon my delay in answering your kind favour, for which I thank you heartily. I can truly say that I never was engaged in a case which gave me more anxiety, because I felt convinced that you were the victim of a foul conspiracy. It is a great comfort to me to know that my client is satisfied that I did my best.

“There is, as far as I can learn, but one opinion, in and out of court, as to the injustice done to you. Notwithstanding the inaccuracy and elusiveness of the report in the *Times*, the case, as reported, has impressed every one whom I have heard express an opinion on the subject with the conviction that the verdict ought to have been entirely in your favour. I wished to know from the Chief Baron, before I advised you what to do, what his views were. I saw him yesterday; he complains, as I do, of the report of his summing up, and of the great injustice done to yourself by it; and when I told him that I meant to advise your publishing a short-hand authentic report of it *in extenso*, he at once said he hoped you would do so, and that he would revise it, if I wished, before going to press. This, I think, you should do at once; send it to me, and I will hand it to the Chief Baron. I am rejoiced to find that the Medical body are taking up the case; I have told more than one of that body they ought to do so. I hope you will not—I do not think you will—suffer permanently from this unaccountable verdict.

“Believe me, my dear sir, yours very truly,  
“R. M. LUSH.”

The resolution was passed by acclamation; and the Chairman then called upon W. W. LEAF, Esq., to move the following resolution:—“That this meeting offers to Mr. Adams a vote of thanks for his manly conduct in courting the fullest public investigation into his conduct, expressing deep regret at the annoyance to which he has been subjected, and firm conviction that there was nothing in his behaviour which gave the slightest ground for any charge against him.” Mr. Leaf's speech was a glowing eulogy on Mr. Adams.

SPENCER WELLS, Esq., said: In the first place there was a vote of thanks to Mr. Adams for his manly conduct. It would have been much easier for him to have put £100 down to have compromised the matter than to have exposed himself to the very heavy annoyance of a lawsuit, the uncertainty of a verdict, and the manner in which he was exposed to attacks from unscrupulous counsel. The case for the plaintiff was opened in a manner that well merited the severe censure passed upon it by the Chief Baron. When counsel, in representing a case to a jury, allowed them to draw unfair inferences, he exceeded the power he should have. The charge of the late Mr. Justice Coleridge—“never to do as an advocate that which he would be ashamed of as a gentleman”—should have been applied in this case to the counsel for the plaintiff. A low and mercenary tone of the bar of England would be a national misfortune, because the dangerous classes would then feel they could hire counsel to take up any vile action which a man would compromise sooner than let his character be blackened. With regard to the second part of the resolution, he would only say that there was not a Medical man who did not give as full, and perhaps fuller, opportunities of making a charge against him than Mr. Adams did.

Mr. WILLIAM JONES, a member of the legal profession, in reference to an observation made by Mr. Spencer Wells upon Mr. Serjeant Shee, said that there was no more honourable an advocate, and he would not have misled the jury and the judge, but he had been misled himself upon the point. In reference to the evidence, he could not understand how it was that a verdict was not unanimously returned in favour of the defendant: the evidence was all one-sided. He might say that Mrs. Russell had not only been practising at Holyhead, but also at Conway, and she had been making a similar charge, by trumping up a matrimonial alliance for her daughter. At that place her exigencies obliged her to have credit, which she procured by representing her daughter as about to be married to a D.D.

Dr. WOOD (of St. Luke's Hospital) said that a good many years ago, he supposed now nearly twenty, he knew Mrs. Russell, who at that time represented herself as the widow of a Medical man, and who had an only child, then about four years old. This child was a prodigy, and certainly he never knew a child so young play so well on the piano. Being a lover of music, and then a very young man, he took an interest in the widow, and he did what he could to relieve their present necessities; but, after a time, found Mrs. Russell was very well able to keep herself. He thought the Mrs. Russell

he referred to was the one Mr. Adams had unfortunately known.

Dr. O'CONNOR said it was a serious point as to how far these persons were independent of any encouragement. There was a general rumour which ought to be cleared up, that some person connected with the Medical Profession had lent himself to this dastardly attack upon Mr. Adams. No one doubted for an instant that it was a conspiracy, but, if it was one, the real root of the evil should be discovered. It was ridiculous to suppose these two adventurers could come forward and prosecute a respectable man like Mr. Adams, without some aid; and the Medical Profession generally would want to know what Medical man was at the bottom of this? Be he high or low, rich or poor, great or small, noble or ignoble, they should unearth him, and—

“Exalt his carcass  
Sublimely on a gibbet, that miles around  
It would be a sign and monument  
Of infamy.”

The CHAIRMAN said that he would be guided by the wishes of the meeting in reference to letters which had been put into his hands. He then put it to the vote if the letters should be read, and, there being but three dissentients, read the following communications:—

(1.)

“5, Henrietta-street, Cavendish-square, December 23, 1861.

“My dear Mr. Propert,—I have had a letter forwarded to me by Mr. Toynbee from a Mrs. Russell, who has for the third time applied to the Med. Benev. Fund for assistance, and your name is made use of as a referee.

“Fearing that, like myself, you may have been deceived by the plausible tales and touching appeals made up by these people, the Russells, I send you a few lines to say that beyond all doubt they are thorough impostors, and I enclose a copy of the letter to Mr. Toynbee in which your name is made use of, and also a copy of my reply to Mr. Toynbee's note to me requesting information respecting this case. When I believed in the tales told by Mrs. Russell and her daughter and heard of their distress I not only assisted them with money, but sent them to Mr. Toynbee who obtained one grant of £5 for them. Very judiciously, however, the Secretary of the Fund made independent inquiries—and if I had only known the result of these inquiries, it would have saved me both money and annoyance, but in the last report, recently issued, case 42, you will see the statement, ‘Visited, and believed to be a begging letter-writer and deemed unworthy of credit.’ This refers to Mrs. Russell, whose name is abbreviated.

“The Russells constantly speak of their friend Dr. Hawkins, whom they represented to me as Dr. F. Hawkins of London, and indeed it was very much through seeing a letter signed ‘Hawkins,’ that I was induced to place any confidence in Mrs. Russell. It now seems that this was Dr. J. V. Hawkins of Lynn, to whom I intend to write. I shall be happy to give you further information respecting these Russells if you require it.

“J. Propert, Esq.”

“Very faithfully yours,

“WM. ADAMS.

(2.)

“6, New Cavendish-street, December 24, 1861.

“Dear Sir,—I have perus'd your letter and enclosures, which have rather surpris'd me, more especially as a tale of a very different character has very recently been plac'd before me, which I cannot conceal from you made my hair stand on end; and as from a sort of common consent I am in some measure look'd upon as the friend and protector of Medical men's widows I was on the point of placing the whole of the case for investigation in the hands of my solicitor, but intended to-day (previous to calling upon him) to see you and learn something respecting your acquaintance with the widow Russell and her lovely daughter!—and I must confess that the unmeasur'd terms you have pour'd out your wrathful indignation against them, has (pardon me for saying so) rous'd my suspicion greatly. Glad indeed shall I feel to find that the tale is unfounded when it has been properly investigated.

“I remain, dear sir, very truly yours,

“Wm. Adams, Esq.”

“JOHN PROPERT.

(3.)

“34, Cannon-street West, December 30, 1861.

“Sir,—My client Mr. W. Adams has forwarded to me your letter to him and instructed me to afford you any information in my power which may assist you or your solicitor in the investigation which you state is to be your intention to make—I may perhaps be permitted to say that so far as I am acquainted with any charge advanced against him by either Mrs. or Miss Russell it is wholly without foundation and that I have no doubt of being able to substantiate what I say should the necessity arise.

“I am, your obedt. servt.

“John Propert, Esq.”

“JOHN MACKRELL.

(4.)

“6, New Cavendish-street, January 1, 1862.

“Sir,—In answer to your communication I beg to say, that I feel oblig'd to you and your client for your generous and disinterested offer!—I have every confidence in my solicitor that he will be able to conduct matters satisfactorily—Glad, indeed, shall I feel, for the honour of our noble Profession, should a jury coincide with you in opinion.

“I remain, sir, obedt. servt.

“J. Mackrell, Esq.”

“JOHN PROPERT.

(5.)

“34, Cannon-street West, January 18, 1862.

“Re Mrs. Emily Russell.

“Sir,—I shall be obliged by your giving me an appointment to see you to lay before you information which has been furnished me herein, and I shall be happy to meet your solicitor also if you wish it.

“I am, yours faithfully,

“Jno. Propert, Esq.”

“JNO. MACKRELL.

(6.)

"6, New Cavendish-street, January 18, 1862.

"Sir,—I hasten to acknowledge your letter this morning receiv'd, and to say, that I am compell'd reluctantly to decline the honour of a visit from you, as, whatever you may have to say against Miss Russell, will have better effect, in TRUTH, before a jury—and for the honor of our Profession I do earnestly hope your client will be able to clear himself, or more plainly speaking, *not guilty*—at the same time as a lover of my honor'd Profession, I should MUCH prefer that such an action were never allow'd to appear in the Court of Queen's Bench, against an honor'd member—but matters now must take their course!

"I remain, sir, your obedient servt.

"John Mackrell, Esq."

"JNO. PROPERT."

(7.)

"34, Cannon-street West, January 22, 1862.

"Sir,—I have no wish for an interview with you in opposition to the views expressed in your letter of the 18th inst.

"I consider however that you ought not to have made such use of my letter to you as to entail upon me the scurrilous communication I have received to day and of which I think it right to send you a copy.

"I am, your obedt. servt.

"John Propert, Esq."

"JNO. MACKRELL."

[\* \* \* This seems to refer to some communication from the Russells, of which we have no copy.—ED.]

(8.)

"6, New Cavendish-street, February 24, 1863.

"My dear Churchill,—I think after the many years of uninterrupted friendship that has existed between us—you might strain a point to defend the hard-working Welshman, that is, *provided* you should hear it said to-day at the meeting 'that I had brought the action Russell v. Adams'—when I say 'so help me God' I had nothing to do with it; proceedings had been begun MONTHS before I ever knew that such people existed in the world as Mrs. Russell and her beautiful daughter, and that I never contributed or ever promis'd to contribute one farthing towards the expense of the trial!!

Ever most truly yours,

"J. Churchill, Esq."

"JOHN PROPERT."

The CHAIRMAN said he would not make any comment upon the letters, but let them speak for themselves, and gentlemen could then form their own opinion upon them.

Dr. O'CONNOR asked the name of Mr. Propert's solicitor?

Mr. CANNAN said he believed it to be Pike. The gentleman who conducted the prosecution was not Mr. Propert's solicitor.

The CHAIRMAN: I understand that, before this case was brought forward, Mr. Adams entered into a correspondence with Mr. Propert. One or two solicitors had before taken the matter up, but had given it up. (Hear, hear.)

Mr. DANGERFIELD, in moving the last resolution—"That a petition be presented to Parliament, praying that a committee may be appointed to inquire into the reforms necessary in the present legal procedure, and praying especially that greater facilities may be given for prosecuting persons who make unfounded attacks upon character"—said, the meeting had not only a sympathetic but also a practical character. There were, at present, several anomalies in the law, some of which he could point out. It was a curious thing, that threatening to make a charge against any one, to extort money, or with the appearance of an intention to extort money, was criminal; but, if the charge itself was brought, that was not criminal. With regard to the law of conspiracy, however artful a person might be, yet, unless two persons combined, an indictment would not lie. In the law of perjury, when a witness was sworn to facts totally inconsistent with the truth, and capable of being contradicted, an indictment will not lie against that individual unless evidence can be contradicted by two witnesses. There was also another matter to which he would draw their attention. In this case of Mr. Adams, evidence could have been given, in favour of Mr. Adams, of charges of this nature having been previously made in Wales. The judge would not receive that evidence, because it was an immaterial issue, on which, too, an indictment for perjury cannot lie (?). A thing Lord Brougham had given various reasons in the House of Lords for was, that there should be a public prosecutor. He thought the law should be altered, for the purpose of giving persons attacked as Mr. Adams had been greater facilities for redress.

J. CHURCHILL, Esq., supported the resolution. It was felt that a great injustice had been perpetrated upon Mr. Adams, and it was to the law that this resolution addressed itself. Mr. Adams had been the victim in this action; in the next, perhaps, some gentleman in the room who least expected it. (Laughter.)

The resolution was then proposed, and carried unanimously; and a vote of thanks to the chairman concluded the proceedings.

MESSRS. SAVORY AND MOORE have been appointed chemists to H.R.H. the Prince of Wales.

## REVIEWS.

*Travels in Peru and India while Superintending the Collection of Chinchona Plants and Seeds in South America, and their Introduction into India.* By CLEMENTS R. MARKHAM, F.S.A., F.R.G.S., etc. With Maps and Illustrations. London: John Murray. 1862. Pp. 572.

WHY, it will be asked, is the word spelt "Chinchona," instead of the usual "Cinchona"? Be it remembered, that the nomenclature of a plant forms one of the most delicate of compliments and the most enduring of monuments. As Linnæus well observed, the name of the physician Euphorbus will be handed down to remotest posterity as the godfather of the genus *Euphorbia*, whilst a patent of nobility or a marble statue would long have been mouldering in dust and oblivion. In 1638, as Mr. Markham tells us, the wife of Luis Geronimo Fernandez de Cabrera Bobadilla y Mendoza, fourth Count of Chinchon, lay sick of intermittent fever in the palace at Lima. She was a remarkable woman, and had been wife to two viceroys of Peru—once at 16, and now, a second time, in her 63rd year. The Corregidor of Loxa, Don Juan Lopez de Canizares, sent a parcel of powdered quinquina bark to her Physician, Juan de Vego, who administered it, and effected a complete cure. She returned to Europe in 1640, bringing a quantity of the bark with her. Hence it was originally called Countess's bark, or *Pulvis Comitissæ*, and hence the great Linnæus named the genus *Chinchona*; and Mr. Markham, with Mr. Howard and the Spanish botanists, restores the correct spelling in honour of the Countess's memory. The noble family of Chinchon holds, besides, so conspicuous a place in Spanish history—in 1623, the Count of Chinchon received Prince Charles, of England, and gave him a supper of "trouts of extraordinary greatness"—that there is no more excuse for the mis-spelling than there would be if the Spaniards spelt Buckingham as Buckingham.

It seems that the Chinchona bark was very imperfectly known to the natives of Peru, many of whom are to this day prejudiced against it. Even now, in Guayaquil, according to Mr. Spruce, the prejudice against it is so great, that the Physicians who prescribe it are obliged to call it by another name. Yet its name, *quina quina*, or bark of barks, indicates some belief in its virtues. In what way and at what date the Spaniards first became acquainted with it seems uncertain; but after the conspicuous cure of the Countess, its popularity rapidly spread amongst Europeans, and parcels of the bark were widely distributed in Europe by the Jesuit missionaries. Hence its second name of "Jesuits' bark," or "Cardinals' bark;" and it was, says Mr. Markham, a ludicrous result of its patronage by the Jesuits that it was for a long time opposed by Protestants. It became the subject of as much controversy afterwards as the use of chloroform or ovariotomy at the present day. As the second Lord Shaftesbury, writing in the seventeenth century, observes, the "tribe of inferior Physicians" made a bugbear of it, and the world has not altered much in this respect.

Readers of the *Medical Times and Gazette* have been kept well posted up, as the Yankees say, in the history of that great and beneficent experiment, the transplantation of the Chinchona from Peru to India, in which Mr. Markham was the chief agent, and of which his book contains a detailed account. It is just the kind of book which our Medical friends should order in their book club, because it contains a vast amount of information about one of our most important remedies, and a very large mass besides of adventure and travel, which renders it as fit for the ladies in the drawing-room as it is for the professional man in his study. The first part of it contains a history of the Chinchona; of the gradual progress of knowledge and discovery; of the *habitat* of the different species and varieties, their chemical constituents; of the rapid destruction of Chinchona trees in their native forests; the increasing price and scarcity of their bark; and the attempts which had been made by the Dutch to introduce them into Java. It may be mentioned, as an unfortunate result of the Dutch experiment, that they have filled the forests of Java with a species, the *C. Pahudiana*, which appears most barren in febrifuge alkaloids. The second part of the work contains an account of Mr. Markham's journey from England to Peru, and of the adventures of himself and his agents in that country. He does full justice to the foresight of the East India Company,

and of the late Dr. Royle, who drew up two memoirs, ten years ago, urging the Government to undertake this great work. Mr. Markham had the good sense to arrange that the search for plants and seeds in the various Chinchona regions of South America should be conducted quickly and simultaneously, so that the deed might be done before the jealous and narrow-minded inhabitants of the South American Republics should be able to obstruct it. He employed Mr. Spruce, an excellent botanist and most intrepid explorer, to undertake the red-bark districts of Ecuador. Mr. Pritchett was employed for the grey-bark districts in the Peruvian forest of Huanooko; whilst Mr. Markham himself undertook to explore the forests of Bolivia. He left England on December 17, 1859, accompanied by gardeners, provided with thirty Wardian cases, and on June 23 following despatched fifteen of these cases from the port of Islay to England. As our readers know, many of the plants perished in the Red Sea, through the intense heat; for the Secretary of State, who had done so much to promote this great experiment, would not give that which was wanting for its completion,—viz., the means of direct transshipment from Peru to India; so that the plants which travelled from the slopes of the Andes to the Pacific were afterwards subjected to the risks of crossing the Isthmus of Panama, of changing steamers at the Island of St. Thomas, at Southampton, at Suez, and at Bombay, and of the journey through Egypt.

As a proof of the author's wisdom in executing his task rapidly, it may be mentioned, that on May 1, 1861, the Legislature of Ecuador passed a decree forbidding all persons from making collections of plants, cuttings, or seeds of the quina tree, and imposing a fine upon every person who should attempt to export them; but by May 1, 1861, the plants and seeds were safe on the Neilgherry Hills, in Southern India.

The third part of the book describes the author's travels in India, with a view to the fixing on sites which should combine conditions of temperature, of moisture, and elevation similar to those of the native Chinchona forests. How sagaciously these sites were chosen, and how well the culture has been attended to by Mr. M'Ivor, the Government gardener, may be gathered from the success which we have already chronicled: in March last, 25,000 Chinchona plants were flourishing on the Neilgherry Hills.

But our readers must not imagine that this work is of a dull Medical cast, or that it is suited to those persons only who care for the Chinchonaceæ. On the contrary, the writer, who seems the model of a scientific traveller, gives us not only his personal adventures, which are interesting in themselves, but a graphic account of the *mores multorum hominum*, the language, costume, social condition, and political history of the people amongst whom his wanderings led him. He seems to have good hope of the ultimate reconstruction of government and society in Peru, and records the history of the civil wars which have followed their independence. He gives a most painfully interesting account of the native inhabitants, or "Indians," as they are called; of their treatment by the Spaniards, and the fate of the last of the unhappy Incas. Here is a little ethnographical bit. Speaking of the Nairs, one of the tribes of Malabar, he says:—

"The Nairs live under the remarkable institution called *murroo-muka-tayum*. Sisters never leave their homes, but receive visits from male acquaintances, and the brothers go out to other houses to their lady loves, but live with their sisters. If a younger brother settles in a new house, he takes his favourite sister with him, and not the woman who, according to the custom in all other countries, should keep house for him. The man's mother manages the house, and after her death the eldest sister takes her place; but no man has any idea who his father is, and the children of his sister are his heirs. Movable property is divided amongst the children of the sisters of the deceased equally, and the land is managed by the eldest male of the family, but each individual has a right to a share in the income. This strange custom gives the women an important position; and as they are pretty, and take pains with their personal appearance, their influence is very great."

Our friends of the Ethnological and Anthropological Societies will find in Mr. Markham's pages many interesting notices of aboriginal tribes, and the order of their invasion of India. The geological formation, the flora, the plants cultivated, and the temperature of every place, are recorded. The account of the coca plant, derived from personal observation, fully bears out what is said of its soothing properties,

and power of enabling abstinence and fatigue to be borne with comfort. Here we may learn the different plants used as febrifuges in India, as well as those employed in the confection of a curry. The Medical Practitioner, if he take the hint that Mr. Markham gives, will not confine himself to the use of *quinine*, but will try the effects of cinchonine, quinidine, and the other cheaper alkaloids yielded by the Chinchonaceæ, which may serve all the purposes of quinine as a tonic and stomachic, though not so powerful as febrifuges. It seems that our author not only transplanted the Chinchona, but the Aji pepper, the Schinus molle, and the Chirimoya, of which last Dr. Seeman says that it is the finest fruit in creation. Lastly, considering that the valuable Chinchona trees were perishing in their native forests under the barbarous treatment to which they were subjected, it is a matter of gratulation for humanity that they have been rescued in good time, and that the New World, which has been supplied with wheat, barley, apples, peaches, sugarcane, wine, rice, olives, sheep, oxen, and horses, may fairly be called upon to contribute the tree which heals the malariious fevers of the Old World, and the alpacas, which we hope will furnish food and clothing for ages to come to Australia.

*Ueber die Behandlung der Lungenschwindsucht durch die Brusterweiterung und den Gebrauch der Scrophularia Nodosa.* Basel und Genf. 1862. •

*On the Treatment of Pulmonary Consumption by the Expansion of the Chest and the Use of the Scrophularia Nodosa.* By Dr. J. SEILER. Basle and Geneva.

IN the preface to this book, Dr. Seiler states that his observations are not intended for the Medical Profession alone, but also for the educated portion of the public, and he, therefore, writes in a somewhat popular style. He describes, in the early chapters, the causes of pulmonary consumption, with the nature and progress of the disease, and its principal symptoms; but his chief objects are to point out the necessity of expanding the chest as a remedy for phthisis, and, in the second place, to recommend the use of the *Scrophularia nodosa*, a common weed in Europe, both as an internal medicine and as an agent to be used in inhalation. In reference to the first subject, Dr. Seiler describes the flattening and compression of the chest, which are so characteristic of pulmonary consumption, and he argues that an expansion of the chest not only allows the diseased lungs a larger sphere for the performance of their functions, but actually cures the disease. In order to effect this object, Dr. Seiler has recourse to galvanism, and he has invented an apparatus, the application of which to the muscles of the chest causes their contraction, and thence induces a greater capacity of the thoracic cavity. He adduces a number of cases in proof of the position he assumes, and he gives results showing that, under the course of treatment which he recommends, the capacity of the chest is really increased to a perceptible degree; and he also relates that he has observed a corresponding diminution of the tubercular cachexia. Dr. Seiler appears to have been induced to employ the *Scrophularia nodosa* in the treatment of consumption, by the accidental circumstance of his being asked the name of the plant by a non-botanical friend; its application to scrofulous diseases occurred to his mind, and he, therefore, employed it in the treatment of pulmonary consumption, and, afterwards, of other diseases of the chest. He gives no chemical analysis of this plant, which, we believe, possesses no well-marked properties, and has hitherto been considered as a useless and innocuous weed. He employs it in the dose of five minims of the juice every two hours, and, according to his observations, with the most favourable results; but we fear that Dr. Seiler often mistakes the *post hoc* for the *propter hoc*. We are by no means convinced that the *Scrophularia* possesses the powers which Dr. Seiler assigns to it, and we rather incline to believe that it must belong to the class of expectant medicines, especially in the doses recommended.

*Eine Neue Milchprobe.* Von Dr. ALFRED VOGEL. (*A New Test for Milk.* By Dr. ALFRED VOGEL.) Erlangen. 1862.

DR. VOGEL, after alluding to the different methods which have hitherto been adopted for testing the purity of milk, describes an apparatus devised by himself, and which is founded upon optical principles. The chief adulteration of

milk is water, and the quality of pure milk depends upon the greater or less abundance of oil globules which it contains. The principle on which Dr. Vogel's test is founded is the impermeability of milk to the rays of light, and his first experiment was made with a flat bottle, such as is sometimes used for keeping scents. A taper was placed behind the bottle, and a certain quantity of water was poured into it, the flame of the taper being, of course, seen through the water and the glass sides of the bottle. Milk was now gradually added to the water, until the flame of the taper became invisible, and a repetition of the experiments proved, that invariably at the moment of the addition of the same drop of milk the last ray of the light from the taper disappeared. Hence it was shown, that a measured layer of water between two parallel glasses always becomes, by the addition of a measured quantity of milk, so opaque that a light can no longer be seen through it. The same milk was then diluted with water, and it was found that a greater quantity of this diluted milk must be added, in order to render the mixture opaque. Dr. Vogel's apparatus consists of the following materials, namely:—1. A glass for mixing the water and the milk, having a graduated scale marking exactly 100 centimètres; 2. A test-glass, with parallel glass sides separated exactly half a centimètre from each other; and, 3. A fine, graduated pipette. Dr. Vogel gives minute directions for using this apparatus; but the principal operations consist in first pouring water into the mixing-glass, and gradually adding milk from the pipette. The mixture is then shaken and poured into the test-glass, behind which a lighted taper is placed. If the light is still visible, the mixture of water and milk is poured back into the mixing-glass, and a measured quantity of milk is added, and then the mixture is again poured into the test-glass. By a little practice, the exact time is soon ascertained when the light is on the point of disappearing, and when it has quite disappeared the experiment is at an end. It is thus ascertained how much per cent. of milk is necessary to cause the complete opacity of a layer of water half a centimètre in thickness.

This very simple, and, at the same time, ingenious, contrivance of Dr. Vogel is well worthy of attention, considering the great importance of milk as an article of diet for all classes of the community, especially children, and considering, also, that the most common adulteration of milk, namely, water, is the most difficult of detection.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON THE CONTAGION OF SECONDARY SYPHILIS.

By Dr. AMÉDÉE PARIS.

THE contagion of secondary syphilitic accidents, demonstrated by numerous clinical observations, is now admitted by most writers on syphilis. But while the principle is thus generally acknowledged, a difference of opinion exists as to the mode of infection. Some believe that the initial occurrence resulting from the contagion of secondary syphilis is entirely distinct from true chancre—*i.e.*, from the primary and infecting chancre. The majority, however, agree with M. Langlebert, that constitutional syphilis has constantly a chancre, and especially an indurated chancre, as its point of departure, even when it has been communicated by the product of a secondary accident. It is the object of M. Paris to fortify this latter proposition by the relation of three cases, in showing the regeneration of indurated and infecting chancre by secondary syphilitic accidents of the most common and dangerous kind—condylomata (*plaques muqueuses*):—

1. F. applied to the author on August 3, having three hard chancres on the glans, and two large bubos. The chancres had appeared within a week. He had had frequent intercourse during a month with a female, who, upon examination, exhibited numerous vaginal condylomata, sympathetic glandular swellings, psoriasis of the hand and forehead, and impetiginous crusts on the scalp. We need not follow the detail of F.'s case, it sufficing to say, that he was treated with the proto-iodide of mercury, the bubos being opened by means of filiform sutures. By August 15 the chancres were entirely healed, some induration remaining awhile longer, and by September 5 the bubos had entirely ceased dis-

charging. No other symptom showed itself until October 20, when the hair began falling, and buccal and anal condylomata appeared. He continued the mercury until the end of December, all symptoms having for some time disappeared, forty-four drachms of the proto-iodide in all having been taken. 2. M. X. applied, with a soft, freely suppurating chancre, he not having touched the vagina of the woman, her mouth, probably affected with buccal condylomata, alone coming in contact with the penis, and that two months since. The sore was cauterised with the nitrate of silver, and soon completely healed, no consecutive symptoms appearing. 3. M. Z., after repeated connexion with the same woman, a subject of condylomata, applied to the author on account of two bubos which had appeared without any previous sore having existed. The most minute examination failed to detect any trace of such. The patient, not believing in the existence of syphilis, refused for more than a month to take any remedies. The bubos, however, were opened, and at the end of the time mentioned the hair began to rapidly fall, while condylomata of the anus, impetigo of the scalp, and psoriasis of the forehead were visible. He got well after prolonged mercurial treatment. The author believes that in this case a primary sore had existed, but was overlooked by the patient.—*Gazette des Hôp.*, No. 22.

#### EXCERPTA MINORA.

*Sesquichloride of Iron in Hæmoptysis.*—During a recent discussion at the Berlin Medical Society, the question of the utility of the inhalation of the *Liquor ferri sesquichlorali*, in the hæmoptysis of phthisis, was entered into. Dr. Lewin stated that he had employed it with good effect in thirteen cases; and he referred to a case occurring in Ferich's Clinic, in which the abundant sputa were rendered colourless by the inhalation, while, after death, free iron was discovered in the large cavity which existed. Dr. Zdekauer, of St. Petersburg, also found, in five cases, a larger proportion of iron in the blood than normally exists. Dr. Waldenburg stated that, in several cases, he had met with great success from the employment of a five-grain solution of alum; and Dr. Schlesinger also warmly advocated the inhalation of this substance. Dr. Lewin had derived similar benefit from a solution of tannin (one scruple to eight ounces). Dr. Tobold stated that he had employed alum inhalation, in ten-grain doses of alum (by means of Mathieu's apparatus), in twenty-one cases, within eight months, the hæmoptysis ceasing after from one to three inhalations.—*Deutsche Klinik*, No. 34.

*Fatal Stenosis of the Larynx.*—Dr. Lewin related the following case to the Berlin Medical Society, as a warning against delay in performing tracheotomy:—An officer, thirty-two years of age, acquired a syphilitic ulcer in 1856, which was followed by an obstinate cutaneous eruption. The disease of the throat, which brought him under Dr. Lewin's notice, commenced, only in 1860, with a slight hoarseness, which, however, gradually increased, and became accompanied by difficulty in swallowing, and cough. At a later period, severe and increasing dyspnoea set in. The partly snoring, partly saw-like inspiration could be heard at a considerable distance. The laryngoscope exhibited the cordæ of the larynx swollen, reddened, and superficially ulcerated, and only slightly separating from contact with each other during inspiration. Tracheotomy was proposed to be performed the next day, but a short time prior to the appointed time, the patient, soon after having drunk a glass of beer, suddenly expired. At the autopsy, the walls of the larynx were found so swollen as to leave a mere slit between them, which was further encroached upon by thickening of the mucous membrane. The cordæ were infiltrated and superficially ulcerated. The operation was here culpably delayed, especially when it is remembered that almost all cases of fatal stenosis of the larynx on record have terminated in a sudden and unexpected manner.—*Ibid.*, No. 34.

**ACTION BY AN APPRENTICE FOR BREACH OF COVENANT.**  
—A foolish youth, who did not know when he was well off, brought an action against a Practitioner, near Dublin, to whom he had been apprenticed, on the plea that the Practitioner had closed an open dispensing establishment and converted it into a private surgery, and thus had deprived him of the privilege of seeing a greater number of prescriptions. There evidently appeared to be some private causes of *pique* in the plaintiff's mind; and the jury very properly found for the defendant.

## FOREIGN CORRESPONDENCE.

## FRANCE.

PARIS, February 2.

THE psychologists of France are applying themselves with great industry to the statistics of insanity, and they are procuring, as far as they are able, information from all quarters. One of the great objects is to ascertain the truth of the idea that is generally prevalent of the increase of insanity within the last few years. It would appear that dæmonosophy, with its rappings, its mediums, its table-turnings, and its spiritualisms, has had a most pernicious influence on the understandings of the predisposed to insanity and the susceptible. M. Philibert Barlet has furnished the Medical world with an interesting memoir on this subject founded upon his experience at the Hôpital de l'Antiquaille at Lyons. He narrates the circumstances attendant upon six cases of mental alienation which were under his care, and shows the intimate connexion that existed in all of them with spiritualism in its different forms.

Dr. Carrier has, within a very short period, had under his care three females, whose insanity has been produced by similar causes. These have been cases of decided mental alienation; but, besides such instances, most Medical men in large practice have presented to them cases of hallucinations, of delusions, of illusions, of high mental excitement, produced by the machinations of pretenders to preternatural communications. In some of the departments an actual epidemic exists, which threatens to extend widely, and to be productive of much mischief.

Those who are thus rendered insane are generally incurable: they are fully impressed with the idea that they are in actual communication with supernatural beings, and treat the science that could relieve them with ineffable contempt. These victims to a deplorable hallucination will listen to no attempt at reasoning them out of their folly: the attention of their families, the advice of their friends, are totally disregarded by them, and they are so wrapt up in the information given to them by the spirit whom they fancy deigns to watch over them, that there is no folly, no crime even, of which they would not be guilty, if they believed that they were suggested by the demon in attendance. All sorts of moral means have been proposed for the cure of the malady in its various forms, but with little success.

The great object of those who have written on the subject of these aberrations is, to point out to parents and to friends the necessity of preventing the exhibitions which are made by charlatans, and which seem to have a marvellous seductive power over those of weak intellect, who are incapable of examining carefully into causes and effects, and drawing sound inferences from what they see and hear.

The endemic disease of the north of Italy, known under the name of "pellagra," which some Physicians have considered as the remains of the old leprosy of Asia and of Europe, has been the subject of much discussion amongst psychologists, from the observations of Dr. Baillearger, the Physician to the Salpêtrière, and to the Lunatic Asylum at Ivry. The striking feature of the mental alienation which accompanies the disease is the belief that the individual entertains, that he has become either enormously wealthy, or that he has obtained a high elevation amongst his fellow-men. This monomania is carried to its fullest extent, and most exaggerated ideas take possession of the mind that nothing can efface. Some persons have attributed the disease to the prevalent food of the country, consisting of Indian corn, grown there; but this idea does not seem to be borne out by anything approaching to observation or experience.

The difficulties attendant upon the study of the disease hydrophobia have lately been the subject of much discussion in the scientific world in France. The Académie des Sciences has had it under its consideration within the last month, but, notwithstanding the cautious investigations that have been pursued, little certainty has been arrived at. M. Renault has been exceedingly active in his inquiries into the length of time for which the disease may lay dormant in the dog without giving rise to the suspicion of its ulterior development. M. Renault has tried a series of experiments at the veterinary establishment of Alfort, and has arrived at the conclusion, that at least four months ought to elapse before a dog that

has once been bitten should be set at liberty. During twenty-four years' experience, he has had 131 dogs bitten before his eyes, and kept apart for the space of four months; sixty-three of these exhibited no symptoms of hydrophobia, thirty-one were seized after the fortieth day, seven after the seventieth, three after the eightieth, seven after the seventeenth, eighteen after the sixtieth, and one after the one hundred and eighteenth day.

The discussions have hitherto thrown little or no light upon the many interesting points which were investigated. It is, however, ascertained, beyond any doubt, that many of the horrors with which popular belief have invested hydrophobia are greatly exaggerated. The symptoms, though painful to the eye of the bystander, are by no means so distressing to the sufferer as might be imagined. It is muscular motion rather than nervous sensation that is excited by the virus. The tremors and the convulsions which are induced even by a breath of air, are unattended with pain. As for the barkings and howlings that have been said to have been heard, they are, for the most part, imaginary: the death occurring generally within three days after the development of the disease leaves little time for long or acute suffering; and as for the necessity, which has been said to exist, of terminating life for fear of other individuals becoming infected by the rabid bite of the sufferer, no such instances are upon record.

Nothing new has been elicited as to the length of time in which the virus may be incubating in the human frame before its full development; but the stories that are afloat of years having elapsed before any symptoms have appeared are without anything amounting to authenticity. Certain it is that no premonitory symptoms have given notice of the outburst of hydrophobia in its worst form; and there are instances in which there could be no apparent cause—no tracing of communication from a diseased animal. That hysteria in an aggravated form has assumed the appearance of the disease Medical records fully establish. Notwithstanding the varied accumulation of histories of hydrophobia, with the attempts made to arrest its progress, it is fairly acknowledged by those who have expressed their opinion, that still the field is to be explored, and, doubtless, some great truths will be arrived at. Excision and the actual cautery to the part that has been bitten are all that can be, in the present state of science, recommended.

The most prevalent disease throughout the Continent during the winter season has been that to which the School of Broussais attached the name of bronchitis, from the idea that an inflammatory action existed, confined to the membrane entering into the air-cells, but which was formerly called by the classic Physicians "peripneumonia," they believing that the membrane investing all the respiratory organs was more or less in a state of disease. This view still exists very largely, and many Medical men attribute the increased mortality to the discontinuance of the use of the lancet, in conformity with the opinions of some writers, who have loudly condemned, in all cases, blood-letting, notwithstanding the certainty that it is the most valuable remedial agent which the experienced Practitioner possesses to combat the progress of inflammation.

The sanitary state of the Medical Military School is most unsatisfactory. A fever of an alarming character has appeared amongst the students; three deaths have occurred, and there are seventeen individuals under treatment. The Minister of War has appointed a member of the Council of Health to inquire into the causes, and take such measures as may be required.

The wood of the campeche in form of extract has been employed in Mexico with very good effect by the military Surgeons accompanying the French army in the disinfection of gangrenous wounds.

Some operations have been performed here for the cure of hydrocele by means of electricity, with complete success. Two acupuncture needles are passed into the scrotum at its inferior part, taking care to avoid the testicle; a current of electricity from a battery is applied to the needles externally, the positive pole on one and the negative pole on the other; some pain is produced at the moment, but in about twenty-five minutes the swelling is evidently diminished. Sometimes in three days the liquid entirely disappears, in other instances the electricity has to be repeated.

The opinion that secondary syphilis is not contagious has been demonstrated to be incorrect by a curious circumstance that has occurred at a glass manufactory at Lyons. Glass-blowers are in the habit of blowing firmly into a tube of iron;

three workmen follow each other, and it is ascertained that if one of them has chancre or secondary symptoms about the mouth, he communicates the virus to his comrades.

*Nux vomica*, so much employed by the hydropathic Doctors, is avoided by the scientific Physician, generally from the knowledge of the bad effects which frequently accompany its use. Professor Brugnoti has lately employed it in small doses with considerable success in Bright's disease; but where there is organic disorder of the kidney it is to be avoided.

A singular controversy is now carrying on between two scientific men, MM. Baly and Bayard. The former of these disputants attributes to vaccination a diminution of the population. He thinks that many of the epidemics are owing to employment, and even supposes that it exerts an influence upon the production of cholera. The arguments on both sides are supported by quotations from learned authors; but the one essential point is by no means proved, that there has been a decrease in the population. M. Bayard denies that such is the case.

At length, Professor Sperino's system of evacuating the aqueous humour in diseases of the eye, may be fully investigated. M. Raymond, his clinical assistant, has published a memoir of his observations, which are evidently drawn from the best sources, and may be relied on as correct and truthful.

## REPORTS OF SOCIETIES.

### THE PATHOLOGICAL SOCIETY.

TUESDAY, FEBRUARY 3.

Mr. PRESCOTT HEWITT, President, in the Chair.

DR. BRISTOWE exhibited a specimen, in which was shown a COMMUNICATION BETWEEN A SMALL OVARIAN CYST AND THE RECTUM.

The case from which the specimen was taken, was that of a woman 40 years of age, who was suffering from phthisis, and also from extensive ulceration of the intestines, especially of the rectum. Around the rectum were numerous small faecal abscesses communicating with the rectum; and it was into one of the largest of these that the ovarian cyst opened. The cyst was a simple one, about as large as a chesnut; it had thick, dense walls, and contained faecal matter. A cyst of similar size existed in the opposite ovary (the left), but this was thin-walled, and contained the usual kind of contents. There was nothing in the history of the case to throw light on the point which the specimen was exhibited to illustrate.

Dr. MURCHISON exhibited specimens of

#### TYROSINE AND LEUCINE,

from the urine of a patient who had jaundice with typhus. Jaundice in typhus fever was so rare (he said) that some observers doubted whether it ever occurred. He had seen three cases in three months; in all, the urine was jaundiced, but there was no reaction on testing for the bile acids. In two of the cases he had found tyrosine and leucine. In one of these the urine was almost devoid of urea. At the autopsies of two of the cases there was no derangement of the biliary ducts. He (Dr. Murchison) considered that the pathology of the jaundice in these cases was similar to that of jaundice due to blood-poisoning, as pyæmia, snake-bites, etc.

A report, by Mr. NUNN and Mr. HOLMES, was then read on Mr. Nunn's specimen of

#### UTERINE TUMOUR.

The report concludes as follows:—"From a careful examination, we incline to the belief that the disease is a specimen of fibro-cystic tumour, attached to, and incorporated with, the fundus uteri, but probably originating in the sub-peritoneal tissue in its neighbourhood; and that the adhesions which it had formed to the parietes of the abdomen were a secondary effect of the pressure of the mass, by which it had been made to project into the peritoneal cavity. We do not feel prepared to give suggestions for the diagnosis of such a tumour from ovarian disease."

In reply to Dr. Graily Hewitt, Mr. HOLMES said that the cavities mentioned in the report were true cysts.

The PRESIDENT said that, at the last meeting of the Society, he had ventured the opinion that the disease was fibro-cystic.

He referred to two similar cases: one, of which the specimen is now in the College of Surgeons' museum, occurred in the practice of Sir Everard Home; the other was under the care of Mr. Cæsar Hawkins. In the latter case the patient was tapped, and sixteen pints of fluid were drawn off.

Dr. GRAILY HEWITT had been informed of a similar case, which occurred in the practice of Mr. Fletcher, of Liverpool. An abdominal tumour was diagnosed to be ovarian, and an operation for its removal was successfully performed. It turned out to be a fibro-cystic tumour of the uterus. As to the origin of such tumours, Dr. Hewitt suggested that they might be due to detachments from the ovary, as it were, transplanted to the external surface of the uterus. There were (he said) more facts in favour of this hypothesis than might be supposed. Dr. Turner, of Edinburgh, had pointed out that pedunculated tumours of the ovary might be detached and become fixed to the abdominal wall. It was well known (Dr. Hewitt said) that the tissue of the ovary consisted of a stroma, in which were the elements of cysts; hence, when transplanted, cysts might be developed.

Dr. DICKINSON then showed a piece of skin from, and a drawing of, a patient who had had
