their haunts of old in search of some excitement. We are told that the "facts" reported in this book "are certified by an immense number of persons who are here indicated by name or otherwise;" that the marvellous "manifestations" herein recorded have been "seen and investigated by persons of all ranks and classes from statesmen down to those in humble life," and that Mr. Home has "for years met, and meets every day with men of the highest attainments in art and science, who have carefully examined all these wonderful phenomena, and who have not rested satisfied with 'conjectures' either as to the table, or as to machinery alleged to be concealed" about his person. The testimony thus stated to be adduced in favour of the truth and reality of "spirit manifestations" sounds overwhelming both in quantity and quality; yet, if Mr. Home cherishes any hope that his book will silence or convince the unbelieving, mocking Hotspurs of the every-day world, he will be grievously disappointed, for when this promised mass of evidence is examined, it melts down into little more than Mr. Home's own "averments." We do not think that our mind is unusually closed against conviction, and we have carefully read the book, in the expectation of finding something like real proof of the pretensions of the "spiritualists," but we confess that we have utterly failed. Mr. Home's experiences as a "Medium" began in the nursery; his very cradle was kindly rocked by the "dear spirits" and in the same region of innocence he seems to have gained his idea of what constitutes evidence. In the nursery history of an apple-pie, all the witnesses as to its fate and the events of its career are letters of the alphabet: "B bit it," "C cut it," "D danced for it," and so on; and in like manner the vast majority of witnesses to the truth of "spirit manifestations" are letters of the alphabet: Count O., Count B., the Princess O., the Abbé de C., Miss E., the Princess de B., etc. It is true that nearly all Mr. Home's ladies and gentlemen of the alphabet bear titles, but we cannot allow that even that greatly increases the value of their evidence. We may be very narrow-minded and prejudiced, but we dare to confess that, though our dear old history of an apple-pie had stated that Baron B. bit it, Chancellor C. cut it, and Duchess D. danced for it, we should not think that the initials were any the more entitled to be considered as unexceptionable witnesses. All these alphabetical witnesses we must then utterly reject. Of the "statesmen" and the "men of the highest attainments in art and science," before mentioned, not one is named; and out of all Europe, only a short dozen of persons are brought forward by name as bearing testimony to the "facts" in the book. Of these few, "faithful among the faithless found," the majority are, like the Howitts, eager believers in any and every form of the supernatural, from the sweating statue of Hercules down through the Cock-lane ghost to Mesmerism, clairvoyance, spirit-rapping, and table-turning; and others bear a very meagre and modified testimony, the only evidence, indeed, of their belief in "spiritualism" being the fact of their presence at *séances*. Mr. Home considers this quite sufficient; but Mr. Adolphus Trollope has written to one of the journals a letter, which shows how very little such testimony may mean: he informs us that he "never saw anything of what, for brevity, may be termed professedly supernatural (so to speak) substances, such as 'hands,' or the like, but only professedly supernatural movements of natural substances." It must be regarded also as, at the least, a very suspicious circumstance, that it is only unquestioning, whole-hog believers who are deemed worthy to participate in the highest mysteries, and to witness the most wonderful "manifestations." Mr. Adolphus Trollope says: "I was requested by Mr. Home to absent myself for the future, in consequence of having expressed doubt and incredulity respecting a certain manifestation."

Mr. Home here again reminds us of the choleric Welshman—

" . . . . . of many men  
I do not bear these crossings."

While even in the presence of only out-and-out disciples the

most wonderful phenomena, as the "levitation" of Mr. Home, never occur save in dark rooms, so that it is chiefly by the sounds of his voice that it is judged that Mr. Home is floating about in different parts of the room, and at varying heights from the floor. Altogether, therefore, though with the fear before our eyes that we shall be considered as being as hardened and as truth-rejecting as Sir David Brewster, we must still exclaim, with Hotspur—

"But will they (the spirits) come,  
When you do call for them?"

We do not think it necessary to describe the means by which the spirits manifest themselves; everybody has read or heard of their rappings; their table-turnings, sofa-liftings, and chair-movings; their bell-rings and accordion-playings; their hand-claspings and knee-pressings underneath tables, and so on. The only remarkable points about them are their pettiness, uselessness, and monotony; the spirits display a most woful lack of invention—one good *séance* exhibits nearly all their powers. The utmost that we can allow to be made out in the book is that several people honestly believe that they have witnessed various material phenomena inexplicable by any of the known laws of physics; this truly is not much, as we by no means deny that "there are more things in heaven and earth than are dreamt of in our philosophy:" and we do not forget that the skill of the juggler in the West has hitherto fallen far short of that shown by his brethren in the East. But we entirely sympathise with Sir David Brewster when he declares, to Mr. Home's great anger and contempt, that, though things happen which he cannot at once explain, "spirit is the last thing he will give into" in connection with rappings and the pitching about of furniture. It will indeed require vastly more evidence, and evidence of a much higher character than Mr. Home's "Incidents in my Life" contains, to persuade us that the spirits of the departed, of those "who have entered into their rest," occupy themselves in any such way; or that, if they are permitted to watch over, and hold communion with, their loved ones still in the flesh, they adopt any such modes of communication.

We ought perhaps, however, to apologise to our subscribers for our boldness in thus stating our doubts and our disbeliefs, and to warn them that in so doing we are endangering their property, for at one of Mr. Home's London *séances* the spirits occupied themselves in worrying and tearing to pieces a number of "Once a Week," which contained an article called "Spirit-rapping Made Easy." Rather a useless proceeding, and rather *infra dig.* on the part of the "spirits" we think; but we have disburdened our consciences by giving this hint of the special danger to which this number may be exposed.

In one light, however, as is suggested in the preface to the book, Mr. Home's autobiography may be found by us interesting and instructive, viz., as a pathological, or psycho-pathological study. He was a frail, sickly, highly-sensitive child, and was trained and nurtured in an atmosphere of superstition and credulity; his mother "was a seer throughout her life;" her great-uncle and uncle were also "seers, and gifted with second sight." While a mere lad he left the Scotch Kirk for the Wesleyans, the Wesleyans for the Congregationalists, was prevented only by the "spirits" from joining the Swedenborgians, and finally became a Roman Catholic, or rather a sort of Roman Catholic unattached, for he could not get on with his confessors, as the Roman Catholic Church denounces "spiritualism;" and he must hold strange and most unorthodox opinions about purgatory. He grew up a feeble, sentimental, half-educated man, cultivating only, or at least chiefly, the powers of the imagination; living in perpetual excitement, in that nursery and hotbed of "sensation," America—run after, fostered, and flattered as a "medium" of unusual eminence even in that land, where for a table to float in the air with half-a-dozen adults seated on it is a not uncommon "experience." How

can we wonder then that he should fall into "trances," or that he should fancy he could see things we cannot see, and hear voices that we cannot hear? To what a morbid state of mind a man must have been brought when he could publish to the world that during his wife's pregnancy he was obliged to forbid her attending his spirit *séances*, because the child leaped in her womb in exact consonance with the rappings of the "spirits!"

## THE WEEK.

CONGRATULATORY ADDRESSES TO H.R.H. THE PRINCE OF WALES.  
ON Wednesday, April 29, addresses of congratulation were presented to the Prince of Wales upon His Royal Highness's marriage, from the Royal College of Physicians, London, by Dr. Watson (Physician Extraordinary to the Queen), President; Dr. Budd (Senior Censor); Dr. Alderson (Treasurer), and Dr. Pitman (Registrar). From the Royal College of Surgeons, Edinburgh, by Patrick Newbigging, M.D., F.R.S.E., President, Royal College of Surgeons, Edinburgh. From the President and Council of the Royal College of Surgeons in Ireland, by Dr. Mackesy, M.D., President; Dr. Adams, M.D., Surgeon-in-Ordinary to Her Majesty in Ireland; and Dr. Hutton, M.D., Secretary.

## A CAUTION TO OVIOTOMISTS.

THE *Dublin Medical Press*, of April 29, contains an account of a case in which pregnancy complicated an advanced state of ovarian disease. Dr. Donovan, of Skibbereen, who relates the case, states that the patient, a woman named Mary Fitzgerald, came under his care about four years ago. She was married, and the mother of two children. At that time he detected an ovarian tumour in the right iliac region, which he treated by pressure and iodine inunction. Twelve months after, the bulk of the tumour had so much increased that he determined on paracentesis, and drew off fifteen pints of a thickly gelatinous fluid. She made a good recovery, but five months after, the tumour having again filled, he again performed the operation of tapping, and drew off eighteen pints of a black, muddy-looking fluid, with a very offensive smell. A sharp attack of inflammation supervened; on its subsidence, the abdomen again enlarged, and he had again recourse to paracentesis, evacuating about sixteen pints of purulent fluid, probably the product of inflammation of the cyst. After this he lost sight of the patient for nearly a year. He was then summoned on a dispensary ticket to visit her, and was told by her husband to bring the instrument, as she was in great pain, and required to be tapped at once. He found her in great agony, but the pain recurred at intervals, and from its character he was induced to make an examination *per vaginam*. A child's head was at once discovered in the passage; labour went on regularly, and in a few hours she was delivered of a healthy full-grown infant. The woman died some months after from the ovarian disease.

## TURNER AND ANOTHER v. RAYNELL.

THIS case, which was heard at Westminster on April 28, before the Judges of the Court of Common Pleas, is of great importance to the Profession. One of the points at issue was, whether it be necessary that a Medical man, bringing an action to recover for attendance and medicines, should be registered at the time of the commencement of the action. Another was, whether, in the case of a partnership, the registration of one partner entitled the firm to recover.

"The original action was brought on a Surgeon's bill to recover £46, in which a verdict was found for the plaintiff. A rule, however, was obtained to set aside the verdict and enter it for the defendant, on the ground that one of the plaintiffs was not registered as a Surgeon when the action was commenced, and that therefore, being partners, neither of them could sue for the partnership account.

"For the plaintiffs it was contended that one of the plaintiffs, Mr. Turner, being registered as a Surgeon and Apothecary, that was sufficient under the statute to entitle both to sue as partners, and the other partner, Mr. Smith, was registered as a Surgeon before the trial came on, which he contended was sufficient, under the 31st section of the Medical Act (the 21st and 22nd Victoria, cap. 90), which only required it to be proved at the trial that the Medical man suing was registered. It was further contended that both partners ought to be registered as Apothecaries, otherwise, one being disabled from recovering for Medical attendance for want of being registered, the partnership could not sue for the Medical attendance; and the whole of this bill, with the exception of two items, one for syringing an ear and the other for galvanising Mrs. Raynell, which it was contended were Surgical operations, was for Medical attendance. The charge for these two items was £2 10s. It was contended that to give this construction of the statute would be unreasonable, as it would prevent two persons joining in partnership, one of whom was a Surgeon and the other an Apothecary, one devoting himself to the Surgical and the other to the Medical practice of the partnership, which could not be the intention of the statute.

"For the defendant it was contended that the object of the statute was to secure that persons practising in the Medical Profession should be well qualified persons, under the penalty of not being able to recover their bills if they were not registered as Surgeons and Apothecaries, and, further, that the mere registry of one of the partners before the trial was not sufficient; it ought to have been before the action was brought.

"The Chief Justice, in giving judgment, said this was an action for Medical attendance and medicines supplied, and there could be no doubt that the defendant had had the consideration for the bill, and he now claimed to defeat the action under the 32nd section of the Medical Act, which provided that no Medical man should recover for his services unless he proved at the trial that he was registered under the statute. But the plaintiffs had complied with the words of the statute; they were registered at the trial. There was a direct judgment of the Court of Exchequer in Ireland, that this was sufficient, and he entirely concurred with that authority. If one of the partners only was registered, he still thought they were entitled to recover. A Medical man might employ an assistant or other person not qualified. Here one of the partners was qualified from the beginning as a Surgeon and an Apothecary, and the defendant had the fullest security in employing a firm the head of which was qualified and registered. How could it matter to the patient, when a Medical man sent his assistant who was not qualified, whether that person called himself a partner or an assistant; or whether he was entitled to be paid for his services by a salary or by a proportion out of a partnership? So far as the patient was concerned, it seemed to him to be precisely the same thing. Here both partners were thoroughly qualified; but the head of the firm, thoroughly well qualified and registered, gave the valuable services for which the defendant was taking what he (the learned judge) might call a stamp objection to prevent his recovering, which he thought not tenable.

"The other learned judges concurred.—Rule discharged."

The ruling of the Chief Justice, if he be rightly reported, would seem to open a door to illegal practice, which we can hardly suppose the learned judge intended. It would appear to amount to this, that if in a firm one partner is qualified and registered, the other partners may practise legally without any qualification. We are heartily glad that Messrs. Turner and Smith obtained their verdict, to which they were clearly entitled; but we must dissent from the construction put on the law by Chief Justice Erle.

#### PARLIAMENTARY.

DURING the past week the Alkali Works Regulation Bill has passed the House of Lords. The chief alterations made in the bill have been the exemption of servants from responsibility, in the case of nuisances originating on their employers' premises; the imposition of an increased penalty, not exceeding £100 for a second or subsequent offence; and a provision that a party charged with occasioning a nuisance should not be allowed to appeal to a superior court, except when the

Court of Quarter Sessions certified that there was some point of law on which it was desirable to have the decision of a higher tribunal. Without such a provision the law would be inoperative; for, as Lord Derby remarked, "It was frequently well worth while for a wealthy manufacturer, convicted of occasioning a nuisance, to appeal to the superior courts, knowing full well that the informer could not bear the expense of such a proceeding."

In the House of Commons on Thursday, the 23rd ult., the Chancellor of the Exchequer's contemplated changes in the imposition of the Income-tax were discussed. The taxation of charities is, we think, as much a piece of vexatious meddling legislation as is Mr. Gladstone's proposal to make every club or association pay £17 1s. for a licence to sell beer and spirits to its members. Sir H. Willoughby instanced the case of some Hospitals whose incomes would be reduced by £1500 or £1600, drawing from the Chancellor the rejoinder that they were so much the better able to bear their share of the taxation of the country. Mr. Roebuck's motion "that in the opinion of the House the tax imposed on precarious incomes should be lower than that on permanent incomes," although deserving a better fate, was withdrawn. Mr. Gladstone ultimately passed his tea, sugar, and income-tax resolutions.

The adjourned debate on the Irish Vaccination Bill was resumed.

"Lord Naas contended that the introduction of compulsory vaccination would lead to a decrease of its use and encourage inoculation, and therefore the bill would not carry out the object it was intended to accomplish. There were also cases in which it would be dangerous to vaccinate children at a certain fixed time, and in such instances it would be most unfair to subject the parents to a penalty for not having their children vaccinated. The measure would also interfere with the Births Registration Bill, just passed, as persons would avoid registering the births of their children, because by so doing they would bring themselves under the operation of this bill.

"Mr. Whiteside showed from the report of the Royal Jennerian and Vaccine Institutions, that the system of compulsory vaccination now in force in England had not been successful. It would be better not to pass this bill, and, in order to test the question, he would move that it be read a second time that day six months.

"Sir R. Peel said nine of the most populous unions in Ireland had pronounced in favour of the bill. As to the expense, it was a very infinitesimal burden upon the resources of Ireland, especially when compared with the immense sanitary advantage that would be derived from the measure. One beneficial result of compulsory vaccination was that where it was in force the loss from small-pox had enormously diminished. He trusted his right hon. friend would allow this bill to be read a second time.

"Mr. Whiteside then withdrew his amendment, and the bill was read a second time.

"On Friday, April 24, Lord Naas asked the Secretary of State for the Home Department whether the attention of the Government had been drawn to the increase of small-pox in the metropolis; and whether it was his intention to propose during the present Session any measure for the promotion of vaccination.

"Mr. Lowe said the misfortune of the question of vaccination was, that in quiet times no trouble was taken about it, and it was only when disease appeared in all its horrors that applications were made to the Government for legislation, which, if ever so good in itself, must then be tardy and inefficient to meet the evil. This subject had engrossed the attention of the Government. The House was aware that there was already in existence a measure for compulsory vaccination. That measure was not in all respects satisfactory; but the fault connected with the present spread of small-pox was not so much attributable to the state of the law as to the neglect of the local authorities on whom devolved the working of it. The matter, however, was still under the consideration of the Government, but no decision had yet been come to."

On the same night Sir George Grey had to defend his course of action in the case of Jessie Maclachlan, the Glasgow convict. He admitted that the verdict of the jury was right,

but stated that facts subsequently came out, which, if they had been laid before the jury, might have led to a different result, and the impression made on his mind thereby was that the capital sentence ought not to be carried into effect. His statement, however, we believe failed to convince any of his hearers of the propriety of commuting the sentence, unless it were the party of northern "sympathisers." It is admitted on all hands that if not a principal, Jessie Maclachlan was at least an accomplice in the crime.

"On Tuesday, April 28, General Buckley asked the Secretary of State for the Home Department whether the building intended for criminal lunatics was ready, and whether those criminal lunatics now confined at the private asylum at Fisherton, near Salisbury, amounting to the number of 284, were likely shortly to be removed to the new Asylum.

"Sir G. Grey was informed that a large portion of the asylum was very nearly ready, so that very shortly about 100 patients would be removed to it. He did not know what number might ultimately be placed there, but the first patients received would be female patients.

"Mr. K. Seymour moved that the analysis of evidence appended to the Report of the Select Committee on Sewage of Towns, in Session 1862, be cancelled. He detailed the circumstances under which the Report was prepared, and complained of the manner in which the analysis of the evidence was drawn up, as irregular or informal.

"The motion was seconded by Mr. Paget.

"Dr. Brady, the Chairman of the Committee, defended the analysis, which he had drawn up, he said, with great labour.

"After some further discussion, the analysis was ordered to be cancelled on the ground of informality."

## REVIEWS.

*Illustrations of the Surgery of the Female Pelvic Organs, with Physiological and Pathological References.* By HENRY SAVAGE, M.D. Lond., F.R.C.S., Physician to the Samaritan Hospital for Women. Folio. London: John Churchill and Sons.

HAD this work been entitled "The Anatomy of the Female Pelvic Organs, with Surgical and Pathological References," its nature and extent would have been more correctly indicated. It consists of coloured plates displaying forty figures, twenty-nine of which illustrate the general anatomy and relation of the pelvic organs, seven others displacements of the uterus, and the remaining four plastic operations for the relief of prolapsus uteri.

The artistic part of the work is the production of the eminent anatomical artist M. Léveillé, and those persons who are acquainted with Hirschfeld's "Névrologie" will at once have an idea of the style of the illustrations; and we need only say that for clearness, and delicacy and beauty of execution, they quite equal his best delineations.

The plates are accompanied by descriptive text, in which reference is constantly made to the surgery of the part described. In his description of the superficial anatomy of the perineum, the author points out that the appropriate place for division of the pudic nerve is just aside of the clitoris, where it emerges from behind the crus clitoridis.

The erectile system of the generative organs is very fully illustrated and described, Kobelt's views being altogether adopted with regard to the analogy of the bulbi vestibuli to the bulb of the male urethra, and of the superior communicating plexus of veins beneath the clitoris to the corpus spongiosum urethra of the male. In conformity with the views of the same observer, the "Constrictor vaginæ muscle" is called "Musculus bulbo-clitoridis."

The author claims for Mr. James Traer, by whom the majority of the dissections represented in the plates were made, the merit of having discovered a new venous body situated immediately beneath the ovary, and named by Mr. Traer the "bulb of the ovary." We believe, however, that the existence of this plexiform mass of veins has been long recognised by anatomists under the name of ovarian or pampiniform plexus.

The fasciæ of the perineum are described as forming three distinct compartments—the two layers of superficial fascia form the "vulvo-scrotal or pudendal sac," lying in front of the other structures between the vestibular orifice and the pubic

ramus. The adipose contents of the sac are liable to labial abscess, and the pus, "making its way backwards, points anywhere at the surface of the ano-perineal triangle."

The next fascial compartment is called the "superficial fascial compartment," formed in front by the deeper layer of superficial fascia, and behind by the "middle perineal fascia" (the anterior layer of the triangular ligament). The tensor cruris clitoridis muscle, the superficial transverse muscle, the bulb of vestibule and its pubic (*sic.*) efferent vein, and the crus clitoridis are described as being contained in this compartment; but with respect to the bulb and its pudic efferent vein this statement is inconsistent with Fig. I., Plate 2, where these venous structures are represented in their proper situation beneath the middle perineal fascia. The vestibular bulb may be considered as ensheathed in the middle perineal fascia. The third fascial compartment is included between the "middle perineal fascia," and the "posterior perineal fascia," *i.e.*, between the two layers of the triangular ligament. In this compartment are found the deep transverse muscle, the pudic vessels, and, we may add, the vulvo-vaginal gland, (which is elsewhere stated to be placed beneath the middle perineal fascia) and the pudic nerve. As a result of their sub-fascial position, acute abscess of the bulb or of the vulvo-vaginal (a) gland form characteristic projections in the vulva.

The relation of the peritoneum is perhaps of all others the most important point in Surgical operations on the pelvic viscera, and it is therefore disappointing to meet with the following indefinite statements:—"The recto-vaginal peritoneal fold descends on the back of the vagina as far as the cervix uteri;" "the pelvic peritoneum covers the anterior and upper third of the bladder."

The following description is given of the connexion between the vagina and uterus:—"The external coats of the vagina lose themselves by degrees on the body of the uterus, the outermost being traceable half way towards the fundus. By this arrangement the entire cervix can be freed by dissection from the vagina without entering the pelvic cavity, wounding the bladder in front, the recto-vaginal fold of peritoneum behind, or interfering laterally with the uterine vessels." This we take to be a dangerous statement, and one that does not accord with anatomical facts, and we would prefer adhering to the safer and more correct determination that the vagina terminates "at the line of demarcation between the lower, or vaginal, and the upper, or supra-vaginal division of the cervix."—*Cyclop. Anat. and Physiology*, art. "Uterus," p. 625.

Dr. Savage states that the fundus of the uterus reaches a line drawn from the upper border of the symphysis pubis to the sacro-vertebral articulation. This is certainly too high. Dr. Farre, in the article just quoted, in common with other authors, makes the line to reach from the lower border of the symphysis pubis to the sacro-vertebral joint. It is a matter of regret that in Fig. 2, Plate 6 (which is intended to show the natural relation of the parts) the fundus of the uterus should be represented as projecting altogether out of the pelvic cavity.

The functions of the uterine ligaments are very clearly demonstrated in Plate 9, in downward and backward displacements of the uterus.

Plate 10 contains the only illustrations of the Surgery of the female pelvic organs, and appears to proclaim that it is the intention of the author to bring out another volume in continuation of the present one. The importance which Surgical operations for the relief of conditions incidental to women have attained, demands a further illustration of the subject, and from his connexion with the Samaritan Hospital no one perhaps has better opportunities for supplying the want than Dr. Savage.

The present work is a credit to those who have been engaged in its production, and will prove no less useful to the general Practitioner than to those who make the Surgical diseases of women their special study.

*On the Cure of Club-Foot without Cutting Tendons; and on Certain New Methods of Treating other Deformities.* By RICHARD BARWELL, F.R.C.S., Assistant-Surgeon Charing-cross Hospital, etc. London: John Churchill and Sons, New Burlington-street. 1863.

MR. BARWELL has come to the conclusion that the treatment of acquired and congenital deformities by tenotomy is proved

(a) We use the terms bulb of the vestibule (Kobelt) and vulvo-vaginal gland as being more appropriate than "bulb of vagina" and "ano-vulvar gland."

by the results of actual practice to be most frequently unsuccessful; that such deformities frequently recur; that in other cases a different or opposite distortion supervenes; and that in the large majority of instances power over the limb is injured or destroyed by the operation. We believe that this experience is at variance with that of many of our best Surgeons, but as the author has arrived at it honestly, we think that the Profession is indebted to him for avowing his conviction, and endeavouring, in accordance with that conviction, to substitute what he believes to be a more certain and successful mode of treatment. It is not, however, only to the operation of tenotomy that the author objects; he equally reprobates the after-treatment usually adopted. He holds that the different varieties of talipes all primarily affect the front half of the limb, and that the mechanical treatment of club-foot by shoes acting primarily and principally on the ankle-joint, is manifestly a mistake. He argues that to fasten the sole, which ought to be mobile and free, upon a stiff iron, and to force the contracted muscles *while at rest* into a new posture can only be a temporary remedy for the contraction, and will necessarily increase the paralysis which is "the head and front of the offending."

The plan of treatment he would substitute is founded on the principles of restoring the balance in muscular action lost by the paralysis of certain sets of muscles; of substituting a force for the weakened or paralysed muscles without depriving the still useful ones of their power; of applying the force as nearly as possible in the direction and position of the paralysed muscles, so that it shall act only on the parts on which the muscular force is nominally expended, and, at the same time, of maintaining movement in each part of the foot, which movement is gradually to be guided by the applied force from an abnormal into a normal direction. The means he adopts to carry out these principles are, "to substitute for the absent or diminished forces a spring or springs of india-rubber, stretched between the origin and insertion of the muscle, at a degree of tension that would supplement the weakened or supply the absent power of the organ."

We cannot here attempt to examine the manner in which Mr. Barwell has applied his method of treatment to the various distortions of the foot. It is sufficient to say that he has displayed a considerable amount of ingenuity, and that he has found his appliances, in his own hands, successful. On the whole, we think the book creditable to him as a practical Surgeon.

## PROVINCIAL CORRESPONDENCE.

### BIRMINGHAM.

APRIL 26.

THE most noteworthy fact in our recent Medical history is the establishment of a country house for convalescents in connexion with the General Hospital. Originally letters were addressed "The General Hospital, near Birmingham," but now the Institution is in the very centre of the most dense manufacturing district, with many peculiarly obnoxious factories in its immediate vicinity. The internal arrangements of the Hospital are as perfect as existing circumstances admit of; and it is beyond question that the Medical and Surgical staff fully sustains its high historical repute; but the growing hygienic difficulties of the situation have imperatively required the Sanatorium so opportunely provided.

A local pamphleteer has recently recalled public attention to the growing evils of prostitution, and the advisability of controlling it after the continental fashion. It is to be regretted that the author's statistical data are incomplete, and that he is imperfectly acquainted with many of the able papers which have been written on the subject, since it became the theme of the late Dr. Holland's elaborate contributions to the pages of the *British and Foreign Medico-Chirurgical Review*. It does not, however, admit of doubt that the evil is so rapidly extending that something must be attempted for its mitigation. The sanitary consequences are those which immediately concern us; and, seeing the apparently insurmountable nature of the difficulties in the way of legislative enactment, it becomes most important to ascertain if all be done that is possible for the treatment of venereal diseases.

A crowd of out-patients suffering from venereal affections

seek relief at our two great Hospitals, and a considerable number are admitted within the walls; but there is very good ground for believing that a large proportion of the infected, especially women, do not submit to treatment;—hence spread of the mischief and degeneracy of the race. A Lock Hospital would certainly be a great *desideratum*, but the multitudes of poor at the doors of the existing charities are so large, and so many draw upon the funds who are perfectly able to pay for professional attendance, that a debt of many thousand pounds burdens the Hospital exchequers, and, so long as it does so, it is quite out of the question to set on foot any other establishment for the gratuitous treatment of disease.

Under existing circumstances, the problem for solution is how to treat venereal patients, particularly those suffering from the constitutional disorder, with the greatest economy of expense and time, and with the utmost simplicity and efficiency. During the last few months, the treatment of secondary syphilis, by means of moist mercurial fumigations, has been extensively adopted at the Queen's Hospital by the Resident Surgeon, Mr. John Wilders, who inclines to the belief that no other curative method, either mercurial or non-mercurial, is so likely to eradicate the syphilitic poison from the constitution, and to restore the sufferers to their pristine health. It is highly interesting to see the improvement that takes place in the condition and appearance of the patient, even while taking the baths, a process which is necessarily rather debilitating. Persons who at the commencement of the treatment are wan, pale, and thin, rapidly regain flesh and ruddy colour. Many of the cases cured by this method had before been treated by iodide of potassium in large doses, by nitric acid, and all the usual anti-syphilitic remedies, with little or no result; in fact, instead of getting better, many of them had become considerably worse—to wit the two following:—

W. R., aged 48, a sailor, contracted syphilis, about twenty years since, at a town on the Spanish coast, and has since that period frequently suffered from sore-throat, nocturnal pains in the bones, and, in addition to this, his wife has had several miscarriages, and some of his children have died within a year after birth, from hereditary syphilis. He was treated with mercury for the primary disease. About two years ago he first noticed a small ulcer over the sacrum, which, rapidly increasing, burrowed under the skin, until the whole of the buttocks and the lower part of the back became affected; the appearance presented was as if the man had had a burn on the back, which had destroyed the cuticle without penetrating deeper. His countenance was wan and pale, and he had been treated by many Medical men, without any benefit, with mercury by the mouth, iodide of potassium, etc. When he applied at the Hospital he was in such a state that he could not sit down. He had nine baths (cinnabar being the mercurial preparation used), and was perfectly cured in three weeks from the commencement of the treatment by fumigation.

T. W., a labourer, aged 35, had contracted a chancre nine years since, for which he was treated with mercury. His wife had miscarried, and also brought forth syphilitic children. He had had nocturnal pains, and his countenance had an unhealthy, earthy look. His legs, thighs, and buttocks were covered with rupial patches. Iodide of potassium had been given in very large doses, but under that treatment the disease progressed rapidly. After ten mercurial vapour baths the rupial patches had all disappeared, and the man's countenance had resumed the hue of health. He expressed himself as feeling stronger than he had done for years.

Two cases of complete excision of the os calcis, and in one of these of a portion also of the astragalus, have occurred in the practice of Mr. Oliver Pemberton, at the General Hospital. An abundant period having elapsed since the operations, the usefulness of the limbs can be spoken of with confidence. In both cases the patients were women about 25 years of age. In the one instance, performed eighteen months since, the entire os calcis was removed for extensive necrosis arising from a sprain. The line of incision was carried along the outer side of the tendo-Achillis and margin of the foot in the view of not dividing the attachments and connections of the plantar fascia with the former. The incision was seven or eight inches long, and admitted of sufficient widening for the removal of the bone without any additional transverse cut. There was only limited cellular inflammation, and the wound healed in six weeks. The patient can now use her foot with confidence and power. The ankle-joint is perfect, and long

distances can be accomplished without fatigue. In the second case, Mr. Oliver Pemberton removed the posterior surface of the astragalus as well as the entire os calcis. A horse-shoe-shaped incision was adopted, the flap being turned down from the tendo-Achillis towards the toes, thus exposing at once the diseased bone and avoiding any division of the side of the foot. The recovery was rapid and complete, and now, at the end of six months from the date of the operation, the patient can walk about without any perceptible peculiarity in gait. Mr. Pemberton is of opinion that this operation will succeed in persons whose bones are fully developed and consolidated, and that it should be avoided in young subjects. The line of incision adopted in the second case will be found most desirable.

I have had an opportunity of seeing the man on whom Mr. Gamgee performed amputation at the hip-joint last September, for an enormous enchondroma of the femur, measuring upwards of four feet in circumference. Weighed immediately after removal, the limb was ascertained to be within a few ounces of 100 lbs. The man made a rapid and uninterrupted recovery, and is now residing in the neighbourhood of Lichfield in excellent health.

GENERAL CORRESPONDENCE.

MEDICAL PROVIDENT ASSOCIATION.

LETTER FROM MR. CARTER.

[To the Editor of the Medical Times and Gazette.]

SIR,—Will you kindly allow me space to say that the letters I have received leave no doubt on my mind that the Association will be sufficiently supported, while they seem to prove, also, that it can be very inexpensively maintained. A week in three years and a-half seems to be about the average of sickness among Practitioners.

The gentlemen who have favoured me with letters will receive private communications by-and-by, and I shall be glad to hear from any of those who have not yet written.

I am, &c.

ROBERT B. CARTER.

Stroud, Gloucestershire, April 28.

BROMWICH v. WATERS.

LETTER FROM MESSRS. KIMBER AND ELLIS.

[To the Editor of the Medical Times and Gazette.]

SIR,—We were much astonished at reading in your paper of the 18th instant a letter written by Dr. Ramsbotham in explanation of your remarks on his evidence at the recent trial. He says "the result has proved that we were grossly misled by the chief witness." We submit that the result has proved simply that the legal evidence was not sufficiently strong to obtain a verdict for the plaintiff.

The chief witness was contradicted, as was to be expected, but not in the slightest degree broken down in cross-examination. The Doctor bears unwilling testimony in her favour when he says, "She made her statement to us with a degree of simplicity and absence of exaggeration not often united to falsehood, and she never wavered in the minutest particular in the account she first gave, although she underwent many very severe examinations and cross-examinations as well by Medical men—myself being one—as by acute counsel and solicitors."

Now that her mistress has not obtained a verdict, and the Medical journals have commented in harsh terms on the conduct of the Professional gentlemen engaged in the case, we are for the first time surprised by his opinion, that she is "the most artful and thorough impostor that it has ever been his lot to hear of." If he has arrived at this conclusion, he certainly had not done so the day after the trial.

The part of his letter which we feel most bound to object to is the next paragraph, wherein he asserts that he had been consulted in the case some time "before he had an idea that it was to be brought into a court of justice." To that assertion we are compelled to give a distinct denial. No Medical gentleman has been consulted by us in this case without having been plainly told at the first interview the reason why his opinion was desired, and that an action for the seduction of the girl was about to be tried. Dr. Ramsbotham first saw

the girl in the presence of another Medical gentleman, whose name need not be mentioned, and knew perfectly well why they met in consultation. The mistress of the girl was present, and a gentleman from our office, and Dr. Ramsbotham was asked by his colleague to test the girl's story by putting any questions he liked to her, and he did so.

The Doctor goes on to say that it was "with great pain to himself that he became implicated in the case," and that he told us "his evidence would be of no use to us," and that he was "obliged" to appear to speak to the fact that there was no mark remaining of an ulcer ever having existed.

The Profession may infer what pain the Doctor felt in appearing at the trial from the following letter:—

"Bromwich v. Waters.

"Messrs. Kimber and Ellis.

"Gentlemen,—I presume by the series of questions which you transmitted to me respecting the above case a few days ago that you are desirous I should appear at Chester and give evidence at the trial. If so, you will oblige me much if you can inform me when my presence will be required. I understand it is expected that the trial will come off in April. Is that the case, and can you tell me what part of the month?

"I am, very faithfully yours,  
"8, Portman-square, "FRANCIS H. RAMSBOTHAM,"  
"March, 16.

In that letter there does not appear to be any expression of great disinclination to be "implicated" in the case, and it is only common justice to the girl to state, that Dr. Ramsbotham expressed a favourable opinion of the truth of her story after he had examined her himself, and also after he had heard her evidence given in open court, though he now suggests that he has been deceived.

We must also state that since the trial the girl has not lost the confidence of her friends; and such is the opinion her mistress entertains of her, and so great is that lady's desire to prove in every possible way the innocence of Dr. Waters, that she has offered the large sum of 100*l.* (notwithstanding the expense she has already incurred in her attempt to vindicate her servant's character), to anyone who will come forward and prove the paternity of the child in a satisfactory manner.

In justice to the plaintiff and to ourselves, we beg that you will be good enough to publish this letter in your next issue.

We are, &c.

KIMBER AND ELLIS,

1, Lancaster-place, Strand, Plaintiff's Attorneys.  
April 29.

P.S.—We take this opportunity of observing that the theory of some portion of the Medical press, and of certain Medical men, as propounded at recent meetings on this case—that a person who sincerely (if erroneously) feels herself aggrieved by a member of the Profession should not have the assistance of respectable members of the same Profession in her endeavours to elucidate the truth of the case—is one to which we cannot subscribe. That principle carried out would involve, as a consequence, that no Medical men should give evidence at all in a seduction case against one of their own Profession. Surely it is sufficient that there should be, as Dr. Ramsbotham virtually admits there was here, a *prima facie* case.

REPORTS OF SOCIETIES.

THE PATHOLOGICAL SOCIETY.

TUESDAY, MARCH 17.

Mr. PRESCOTT HEWETT, President, in the Chair.

Mr. LITTLE exhibited a specimen of

MYELOID TUMOUR OF THE LOWER END OF THE FEMUR.

This specimen, consisting of a tumour involving the lower end of the femur, was removed by Mr. Curling from a man aged 27. The patient had enlarged glands in the groin and ham. The tumour had been two years forming. After amputation, the patient rapidly convalesced; the glands in the groin subsided. The lower end of the femur was enlarged to twice its natural size; the vertical section showed a thin shell of bone, from which the cartilage had disappeared, filled with dark red masses, and much bloody fluid. Some of these masses consisted of blood-clot, others contained myeloid cells.

Dr. DICKINSON exhibited a specimen of

CRETACEOUS DEPOSIT IN THE PERITONEUM.

It was taken from a man who died of disease of the spine, in connection with which was an abscess in the pleura. The cretaceous matter was no doubt the result of drying up of tubercle.

Mr. HENRY THOMPSON showed for Mr. JEAFFRESON, of Framlingham, the

BLADDER, PROSTATE, URETER, AND KIDNEYS, AND DEBRIS OF CALCULI

From a man who died recently, aged 86. Mr. W. Jeaffreson crushed a uric acid stone for the patient in 1846, and again in 1856. Mr. George Jeaffreson removed three or four small calculi with a lithotrite in 1859. The patient died of bronchitis in 1863. At the autopsy, seven small stones, evidently uric acid, the size of pins' heads, were all the calculus matter that remained in the bladder. The kidneys were atrophied, the ureters and bladder tolerably healthy. The prostate gland was greatly enlarged, especially the left lobe, which presented a well-isolated fibrous tumour, the size of a large nut, projecting very prominently. There was no difficulty in introducing an ordinarily curved instrument at any time; there was never any retention, nor, when awake, any overflow, or involuntary passage of urine.

Mr. CANTON exhibited the parts removed in a case of

EXCISION OF THE ANKLE-JOINT.

The patient was a lad 15 years old, and had had the disease nine months. Rest and treatment were fairly tried; but as he was no better, Mr. Canton operated on February 21 last. The patient was doing well.

Mr. HOLMES said that it would be interesting to trace the progress of this case, to ascertain how long he was in recovering, and also what kind of a foot would be the result. There was, he said, a great difference of opinion as to the relative merits of this operation and amputation at the ankle-joint. Mr. Barwell, in his work on disease of the joints, has stated that excision of the ankle was a trifling operation, and that the patients recovered quickly. He (Mr. Holmes) had seen several cases, and could not say that they were so successful as Mr. Barwell would lead us to suppose. They were slow in recovering, and they were not yet safe from amputation. One of the cases to which he referred was that of a boy who was not able to put his foot to the ground until eight months after the operation. In another case, the patient could not do so ten months after the operation.

Mr. PARTRIDGE said that he had performed Pirogoff's operation twice in children, and in the adult had once performed Syme's operation. In the last instance the convalescence was long and tedious, but in the others recovery was rapid.

Mr. HENRY THOMPSON called attention to the difference in age between the cases compared. He could hardly imagine that it was to be expected that the retaining a portion of bone in the lower flap could contribute in any way to the rapid convalescence. As to experience, he had every reason to be well satisfied with the results of Syme's operation at the ankle-joint. He had done it five times; in four with excellent results; the fifth died of phthisis a few months after, before any opinion could be formed as to matured results. He believed that he could show three of them to the Society, and would do so.

As already announced in this Journal, it was resolved that members should be requested to bring cases of the various operations spoken of before the Society on the evening of Tuesday, April 21, in order to compare the results.

Mr. THOMAS SMITH then exhibited ureter and bladder, showing

PROLAPSE OF THE URETERS INTO THE BLADDER.

It was taken from a patient who had had stricture. The left ureter formed a swelling as large as a walnut, having a pin-hole aperture on one side for the escape of urine. The right was prolapsed to a less degree. In other respects the specimen presented the usual pathological changes found in cases of old stricture. Mr. Smith considered that when the ureters became so large as to be influenced by the pressure of the abdominal muscles, just as the intestines are ordinarily in defecation, the urine being unable to find a sufficiently easy exit from the ureter into the bladder during efforts of urination, the mucous membrane of the lower end of the ureters was forced into the bladder.

Dr. MARKHAM showed a specimen of

CYST OF A SEGMENT OF THE MITRAL VALVE.

The patient had had obscure symptoms eighteen months before death, and for five or six months had been worse. There was a distinct diastolic murmur. He died suddenly of angina pectoris.

Dr. Markham, Dr. Peacock, and Dr. Bristowe were requested to make a report on the specimen.

Dr. GIBB brought forward a patient before the Society afflicted with

ELEPHANTIASIS GRÆCORUM AND LEONTIASIS.

He was 44 years of age, and had been twenty-five years on the Malabar Coast. He returned to England about five years ago, and, shortly after, the disease commenced in the hands in the usual way; afterwards it appeared in the feet; then the mouth, throat, face, and ears became affected, giving to the face the peculiar characters and expressions of leontiasis. His voice was a sort of shrill squeak or false tenor, owing to the extension of the disease to the larynx, which had been examined by Dr. Gibb with the laryngoscope, and the peculiarities there noticed were described. Some of the phalanges of the fingers and toes had fallen off; the nails were in a state of ulceration; insensibility of the various parts was present; and here and there hard tuberculous lumps were felt beneath the skin of the wrists, hands, etc. Altogether, the case was shown as a tolerably well-marked example of this terrible disease, and the voice had that peculiar character which permitted of the immediate recognition of the disease in ancient times.

Dr. GIBB illustrated a case of

SPONTANEOUS EXPULSION OF AN ELONGATED POLYPUS GROWING FROM THE LEFT VOCAL CORD,

by means of a series of diagrams, showing its progress from the beginning. The patient was a young lady whose voice had been affected for some years, but not lost. Latterly a growth had formed two-thirds the length of the vocal cords, and running parallel to them from before backwards. When the glottis was closed it lay over the fissure, and did not hang downwards in the trachea. Its pedicle was small; it became strangulated one evening, and permitted of spontaneous expulsion, thus obviating the necessity of its removal by operation.

Dr. DICKINSON showed a specimen of

APOPLEXY OF ONE SUPRA-RENAL CAPSULE.

It was taken from a patient who died of phthisis. There was no discoloration of the skin. The capsule was soft, and infiltrated with blood.

Dr. WILKS said that he had recently received a pamphlet from an Italian Physician on "Apoplexy of the Supra-renal Capsules." He had found that several persons had died suddenly from—he believed—apoplexy of the organ. He (Dr. Wilks) had often seen this condition of the capsule, and had not regarded it as having been of any great moment.

Dr. Wilks was requested to make a report on the specimen.

Dr. MONTGOMERY then showed a specimen of

LARGE FATTY KIDNEY.

The structure was infiltrated with whitish matter, some of the tubes being filled with it. By careful examination he had found that the material was not fat, but cholesterine. He had found, too, that the so-called "nuclei" of inflammatory products consisted of cholesterine. He had suggested that some drug, which was known to have the property of dissolving cholesterine, should be used in treating these cases; and Dr. Bristowe had given copaiba in several cases, and with some improvement.

Dr. BRISTOWE remarked that he had given the copaiba in cases in which there was supposed to be the large fatty kidney as well as the granular one, with about equal results.

At a previous meeting, Dr. OGLE showed a case of

FIBRINOUS CONCRETION OF A GLOBULAR FORM, AND OF ABOUT ONE INCH IN DIAMETER, LYING LOOSE WITHIN THE LEFT AURICLE OF THE HEART.

The case was that of a woman, E. M. C., aged 43, who, having complained for six weeks of difficulty in breathing and swelled legs, was admitted into St. George's Hospital with anasarca of the legs, dyspnoea, and feeble but irregular action of the heart. On stethoscopic examination, "mucous râles" were heard all over the chest, and ægophony on the right side. Moreover, there was a loud *bruit* at the apex of the heart, heard distinctly with the systole, and doubtfully with the

diastole. The patient much improved after being cupped on the chest, and under the use of diuretics. No albumen was found in the urine. After a time, the breathing became more hurried, but no pain was felt. Dyspnœa increased until death occurred, about five weeks after admission. On post-mortem examination, the lungs were found to be œdematous, and their lower parts hepatised, and much fluid was found in the right pleural cavity. The heart was larger than ordinary, and its walls thinned. The mitral valve was reduced by thickening, and by calcareous deposit in its elements to a small buttonhole-shaped aperture. The inner surface of the left auricle had several patches of fibrin attached to it, and also lying "loose" within its cavity was a large spherical mass or concretion of fibrin, weighing rather more than four drachms, perfectly solid throughout, and uniformly granulated in a remarkable manner on its surface, excepting in two places, where marks, like indentations, existed. This globular mass had also attached to it at one spot a small amount of shreddy loose fibrin. Section through this singular body showed its interior to be mainly composed of friable fibrin; but at one part its circumference, and a certain amount also of its inner substance was formed of distinctly laminated and darker coloured fibrin. The kidneys were found to be large and very congested and to contain "fibrinous blocks." The supra-renal capsules were of ordinary size, but so firm in consistence as to be of almost cartilaginous hardness.

Dr. OGLE also exhibited a case of

LACERATION, WITHOUT EXTERNAL INJURY, OF THE WALL OF THE LEFT AURICLE OF THE HEART—FIBRINOUS CONCRETION UNDERGOING SOFTENING IN THE SAME AURICLE.

The subject of this was a child, aged 12, who had had scarlet fever, which was followed by suppression of urine and anasarca, and also by epileptiform attacks. When examined, it was found that there was a strong systolic *bruit* at the base of the heart, the action of which was very turbulent. There was also much dyspnœa. The child became collapsed and died, but before death the systolic *bruit* had disappeared. On post-mortem examination, the lungs were found to be œdematous; the heart was natural as to its walls and valves; several old-standing small masses of fibrinous coagulum, which in places were undergoing softening, were adherent to the endocardium of this cavity. In one part (only) the endocardium was slightly thickened and opaque, and just above the posterior edge of the mitral orifice it presented a horizontal laceration of about one inch in length, penetrating through the muscular walls of the auricle, but not the external serous (pericardial) covering thereof. The edges of this slit were sharp and rather uneven, and the muscular substance between them was darkly stained, and covered by coagulum and dark clotted blood. Excepting a slight thickening and yellowness of one part of the endocardium of the auricle, this structure was natural.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 14, 1863.

RICHARD PARTRIDGE, Esq., F.R.S., President, in the Chair.

A PAPER by Mr. Henry Thompson was read on  
THE SUCCESSFUL TREATMENT OF SEVERE STRICTURE OF THE URETHRA BY GRADUAL DISTENSION AT A SINGLE SITTING.

It is the author's object to illustrate and explain a new method of treating severe or obstinate strictures of the urethra. This term is intended to denote those which are little benefited by dilatation. The distinction which constitutes its novelty does not consist in the mere production of some alteration or improvement in existing mechanical contrivances, but in the adoption of a mode of action on the stricture itself, which is different from those which characterise any of the other systems of treatment pursued at the present day. The author shows in what it differs from dilatation, simple and continuous; from rupture, or "instantaneous treatment;" from cauterisation; and from incisions. He illustrates the proceeding, which he distinguishes by the term "gradual distension," and describes the instrument employed to accomplish it. By the process in question, the strictured part of the urethra only is acted upon, and this not to a degree short of, but up to or even beyond the natural calibre of the canal,

wherever the stricture may be situated. All this is accomplished at one sitting, but with gentleness and slowness, so as to avoid unnecessary rupture; the degree of distension being regulated with absolute certainty, and its extent indicated with extreme accuracy, by apparatus in the handle of the instrument employed. The object of the operator is not to rupture, but to over-distend the fibrous tissue which constitutes the stricture, so as to destroy, or, at all events, to impair, its natural tendency to contract. He aims at attaining that result which occurs from the practice of over-distending vital tissues elsewhere,—viz., to impair or destroy their contractility. This is known to happen after the application of over-distension to both healthy and morbid tissues, and is turned to account by the Surgeon for that purpose. The class of patients for which this proceeding appears to be best adapted is described, and illustrative cases are appended. The instrument consists of two long and narrow steel rods, accurately applied throughout their entire length by the single plane surface which each possesses. The external surface of each rod is convex, so that together they form a nearly cylindrical instrument, but tapering towards the lower extremity, where they are closely united. At the opposite or upper end they are also united, and are surmounted by a handle resembling that of an ordinary sound. This handle is attached to a screw with a very fine thread, which being turned causes the two rods to diverge very slowly and very gradually from each other at a given spot, about six inches from the handle. When the separation of the blades is effected, an index placed near the upper end, and connected with some numerals on a disc, shows the exact degree of extension made by pointing out that number of the catheter scale to which the distension existing at that moment is equivalent. The general form and contour of the instrument is that of a slightly curved catheter. When the screw handle is turned, the two rods separate, so as to form a long oval or spindle-shaped figure, the long diameter being about three inches and a-half or four inches in length, and the short diameter corresponding to the number of turns given to the screw, and varying between the slightest possible separation of the rods and an interval of about three-eighths of an inch, or even more. The stem of the instrument has marked on it a graduation in inches, which commences one-quarter of an inch below the point of maximum distension or centre of the spindle-shaped figure produced by the separated rods. It is that point which will correspond to the stricture when the instrument is placed in the urethra, so that the contracted portion of the canal undergoes the greatest amount of distension which it can be desired to produce, while the rest remains wholly unaffected. The mode of applying the instrument is as follows:—A medium or full-sized bougie or catheter is first passed as far as to the stricture, and the distance from it in inches to the external meatus carefully noted. Suppose it to be five inches, the operator, taking the distending instrument, places the little blue steel collar which slides on its shaft opposite to the figure 5, and passes the instrument through the stricture until the collar arrives at the meatus of the urethra, and prevents the instrument from entering further. The maximum point of distending power must therefore correspond with the narrowest part of the stricture. The act of distension is now commenced by making two or three turns of the screw-handle, and is continued by slowly turning it once every half minute, taking care at the same time to prevent the instrument from shifting its position, by observing that the collar remains opposite the external meatus. In a short time the index, gradually rising, shows that the calibre is reaching Nos. 10, 11, 12, and so on, until in a few minutes No. 14 or 16 has been reached, which latter limit is usually quite sufficient. The screw-handle is now slowly turned backwards, not the whole way, but until the index has retreated to about No. 8 or 9, when the instrument is withdrawn. The operator next passes a full-sized gum-catheter into the bladder, and fastens it there, leaving it in place for about twenty-four hours. It is then removed altogether. All that remains to be done is to pass a full-sized metallic instrument every second day for a week, and after that at increasing intervals for a week or two longer.

Mr. HOLT said that his mode of operating having been alluded to by Mr. Thompson, he was desirous of offering a few remarks upon the plan which that gentleman had proposed to the Society, as contrasted with that which he (Mr. Holt) had adopted for some years. Mr. Thompson's instrument differed materially from his, both in the method of its

application and its capability of enlarging the strictured portion of the urethra, and he claimed for his instrument the power of dilating the stricture to No. 14 or 16, while the meatus is not interfered with. For its application, however, it was necessary a gum-elastic catheter should be retained in the urethra for two or three days. It was then removed, and the seat of the stricture accurately ascertained by passing a large bougie. This is to be marked, and such measurement is to regulate the distance which his dilator should be introduced. The patient being now placed under the influence of chloroform, the dilator was passed, and the handle slowly and gradually turned, so that dilatation could be effected to any extent, the whole operation occupying from ten to twenty minutes, according to the character of the obstruction. The dilator was now removed, and a No. 12 gum-elastic catheter substituted, and retained in the bladder for two or three days, according to circumstances. A No. 12 bougie was afterwards passed at intervals of a day, and so the after-treatment was continued as in any other plan. Now his (Mr. Holt's) first objection to this method of treatment applied to a difficulty which might arise in the hands of a Surgeon less accustomed to the passing of bougies than the author of the paper. The penis during an examination alternates in its length, and is at one moment quiescent and at another semi-erect. When this occurred, it would so alter the relative measurements as to render them of little value; and this part of the treatment was of great practical importance, inasmuch as it was necessary that the centre of the dilating power should exactly correspond to the centre of the stricture, and without it the dilatation would be either in front or behind the obstruction, and so be perfectly ineffective. His next objection would apply to instances in which there was more than one obstruction; for in his experience there were frequently two, and sometimes three or even four obstacles to be overcome, and in these instances it would be necessary to materially prolong the operation, or repeat it upon three or four separate occasions. Mr. Thompson laid particular stress upon his capability of dilating the stricture to No. 14 or 16 or more, when the meatus will only admit a No. 12. In the first place, he (Mr. Holt) believed the author was in error in supposing that a dense obstruction would allow itself to be dilated to the size he mentioned; it must be ruptured, as was shown by the occurrence of hæmorrhage. But even granting that it was so, he (Mr. Holt) could not see the least advantage that could arise from dilating a stricture beyond that which could be maintained by the after-passage of a bougie. The part which was so dilated quickly contracted, otherwise there would not be any necessity for the after-passing of the bougie; but as this was necessary, and the bougie could only represent the size of the meatus, no advantage could accrue from distending the stricture beyond its natural limit. If any further proof were required that this was so, he might refer to the median operation of lithotomy, which he had frequently performed, and removed, without cutting the neck of the bladder and prostatic portion of the urethra, calculi varying from an inch to an inch and a quarter, the parts being dilated by the introduction of the finger, the subsequent passage of the forceps, and the extraction of the stone. In all these cases the patient had retained the power of expelling the urine at will, which specially showed how speedily any undue dilatation of the urethra contracts again. His (Mr. Holt's) third objection would apply to the necessity of retaining a catheter in the bladder both before and after the operation had been performed. In many instances the patients were quite incapable of bearing the retention of a catheter, from the pain and irritative fever it produced, and it confined them to the house or bed for an unnecessary period of time. Mr. Holt then related a remarkable case of irritable and intractable stricture, in which, after all the usual means employed for a long period had failed in the hands of an experienced surgeon, he had, in a few minutes, split up the stricture with his instrument, and the patient recovered without a bad symptom, and remained well to this time—a period of twelve months. Were he not afraid of occupying too much of the Society's time, he could relate several most interesting cases to prove that he had not made any selection for the purpose of enhancing the success of his operation; but that, on the contrary, he had operated upon the most severe and complicated examples that could be submitted to the surgeon. Two other cases he would briefly allude to. One was that of a gentleman from Liverpool, who consulted him for incontinence of urine, from which he had been suffering

for two years, during which he was compelled to wear a urinal, and his health was so damaged that he was recommended to go to Madeira for a change. Upon inquiry, Mr. Holt was satisfied that the bladder was full, and, having gained the patient's consent to introduce a catheter, he with great difficulty passed a half No. 1, and removed three pints of most offensive purulent urine. His bladder was paralysed, and there was every probability, from the length of time it had been distended, that the ureters and the pelvis of his kidneys were abnormally enlarged. For the purpose of keeping the bladder empty, the catheter was introduced three times during each of the first two days, and upon the third he passed the dilator and split the strictures, so that the urethra would admit a No. 10 catheter. In one month this gentleman returned to Liverpool, with his health almost entirely re-established, passing urine with the greatest facility, and the urethra admitting a No. 10 easily. During the last month, Mr. Cutler asked his (Mr. Holt's) opinion upon the case of a gentleman who had been operated upon by Mr. Syme. The patient had subsequently been subjected to internal division, and a second time Mr. Syme's operation was performed by Mr. Bickersteth, of Liverpool. When he consulted Mr. Cutler, he was obliged to pass the catheter five or six times in the twenty-four hours, and he was entirely prevented, by the escape of urine during the intermediate periods, from entering into society. Mr. Holt, having explained to him that in such a case he could not positively affirm what the result might be, consented to split the obstructions; but the patient, being exceedingly nervous from the recurrence of rigors after every attempt to enlarge the urethra, would not consent to the operation without the aid of chloroform. The dilator having been passed, it required all the force Mr. Holt could make use of, even with a towel placed over the large extremity of the tube, before the stricture could be split. Upon the dilator being removed, a No. 10 catheter was passed, and the bladder emptied. This gentleman never had a bad symptom of any kind or description; he never even went to bed, and in two days was able to visit some friends in the country. He declared that he could now pass urine better than he ever remembered; and in a fortnight he returned to Jersey, being capable of introducing an instrument himself without the least difficulty or pain. Mr. Holt stated that he had now operated, in Hospital and private practice, upon more than 250 cases, without any complication of either infiltration of urine, abscess, swelled testes, or inconvenience of any kind, further than the occasional supervention of a rigor or mild attack of stricture fever. He must therefore still retain his opinion in favour of his instrument, which had now been tested to the utmost. It was perfectly simple, and capable of being used by any Surgeon who was able to pass a catheter. The operation did not require either the previous or after retention of a catheter in the bladder; it was completed in one second, however many obstructions there might be; it did not, excepting in very severe cases, require the administration of chloroform, and the patients were not confined to the house longer than the afternoon in which the operation was performed; the pain was of the most trifling description, and the danger *nil*. He would only detain the Society another minute in describing the improvement he had lately made in the dilator, and which had been only completed that day. The objections raised to it by some Surgeons were, that in its present state you had no positive evidence when you were in the bladder, and that the tube might possibly slip from between the blades. He had now so improved upon this that it was quite impossible the tube could so escape, and the dilator acting as a catheter permitted the flow of urine. He had no hesitation in declaring that, as now manufactured by Messrs. Whicker and Blaise, of St. James's-street, the dilator was as perfect as any instrument could possibly be.

Mr. SOLLY was pleased at any proceeding which showed the advantage of dilatation over cutting in the treatment of stricture. He contended that if an instrument could once be passed into the bladder, cutting was unnecessary. There might be cases in which it would be impossible to succeed in such an effort, and then incision might become requisite. He had never had recourse to the plans recommended by Mr. Thompson and Mr. Holt, but had been in the habit of adopting a modification of Mr. Wakley's plan, previously resorted to by Hutton, of Dublin. He used a catgut bougie instead of the metallic guide, and elastic catheters instead of the silver ones. He had used this plan of gradually dilating the urethra with much success. In Hospital patients he allowed the

catheter to remain in the bladder for some time, but not more than half-an-hour in private practice.

Mr. FERGUSSON said it had been proved that dilatation of the urethra might be effected, even to the extent of a No. 12, 14, or 16 catheter in a few minutes, without risk, and effectually. The mode now adopted for this purpose differed entirely from what was called "forcing down a stricture" by the introduction of a full-sized catheter. This was not unattended with danger; for it was not always possible to tell where the point of the instrument would go, or to what extent the urethra might be damaged. By the mode employed by either Mr. Thompson or Mr. Holt, no such risk was incurred. He (Mr. Fergusson) thought the plan mentioned by Mr. Solly would not be found so effective as when the silver instruments were used. With regard to Mr. Thompson's instrument exhibited that evening, he questioned if it were strong enough to break up the stricture without breaking the instrument in some of the more severe cases. This could not occur when Mr. Holt's plan was resorted to; however great the force applied, the instrument could not give way. So much force was occasionally required, that he (Mr. Fergusson) should be fearful of trusting to Mr. Thompson's instrument. This instrument, as far as the plan of treatment itself was concerned, did not differ much from that of Mr. Holt. The plan of immediate dilatation would do much towards dispensing with internal and external urethrotomy.

Mr. ACTON was glad to hear that the advocates of the various plans for treating severe forms of stricture had not found cause for disparaging that by internal incision, a treatment he had found most successful. It was admitted on all hands that dilatation, consistently persevered in, was alone sufficient to remedy the greater portion of strictures. In Hospital practice (in order to save the time of the poor) it might be necessary to resort at once to other plans; but among the upper classes, where a rapid cure was not of such importance, the patient usually objected to have his stricture split, or any other similar heroic remedy employed, and which he (Mr. Acton) was glad to hear was unattended with any danger. The Fellows of the Society must, however, recollect—and the shelves of the surrounding library would support the statement—that the advocates of every novel treatment of stricture had ever lavished the same praises on their different systems as had been listened to that evening. Time could alone test the value of the rival schemes; but he was not inclined to think that any one system would be found applicable to all cases. It had been stated in the course of the discussion, that within a short period, and in the practice of one Surgeon, 250 cases of stricture had been split. Now, seeing the comparative rarity of cases requiring such treatment, we must believe that many strictures had been split which would have been treated (by other Surgeons) by more simple means. The author of the paper had spoken of the success of his treatment depending "upon over-distension of the fibrous tissue, so as to destroy, or at all events impair, its natural tendency to contract." He (Mr. Acton) was yet to be convinced that over-distension at one sitting would accomplish this very desirable end; for the more he treated stricture, and the more he studied the structure which composed the india-rubber-like mass we had to distend, the less disposed was he to believe in a rapid cure, or that a healthy structure would at once displace this elastic tissue. Stress had been laid during the discussion by more than one speaker on the advantages of his or their operation as succeeding after others had been tried and failed. Mr. Acton would appeal to the practical Fellows of the Society if cases were not brought under their notice of patients who had been condemned to these heroic operations, and who before submitting to them applied for a second opinion, and who were cured by dilatation alone, showing that the operation that had been recommended was at least unnecessary. When dilatation was unable to effect a cure, internal incision came in most opportunely, and the division of the elastic tissue by the knife enabled the Surgeon to pass his instrument, and cure the stricture. This, he maintained, was the more scientific treatment, and more in accordance with all the theoretical and practical principles of surgery, and one which had been gradually gaining ground since the instruments employed had been perfected.

Mr. MAUNDER remarked that, whilst Mr. Holt stated that by his instrument the stricture was ruptured, Mr. Thompson called his mode of proceeding "gradual distension." Had Mr. Thompson had an opportunity of examining the urethra after death in a case in which his operation had been per-

formed? If so, he (Mr. Maunder) thought he would have found the stricture to have been ruptured. Mr. Maunder related a case of retention of urine in which it was necessary to puncture the bladder through the rectum. Eventually retention again occurred, when Mr. Holt's operation was performed without difficulty, and the patient made a good recovery.

Mr. BROOKE did not believe that Mr. Thompson's instrument would have sufficient power in some cases such as he had seen Mr. Holt operate on. The strain upon the joint was very great in Mr. Thompson's instrument, and no joint could be made of sufficient strength to relieve the worst cases of stricture. In no case that he could conceive of was either internal or external incision preferable to sudden dilatation. In the one instance there was a decided limit to the extent of the ruptured portion, whilst the incision might extend much beyond the limit of safety.

Mr. HULKE had employed Mr. Holt's plan in thirty cases, many of which were out-patients at the Hospital. He had never seen any untoward result, though the patients went about as usual. He did not regard it as a serious operation.

The PRESIDENT had in many cases followed Mr. Holt's plan of proceeding. He had never seen any but good results from it.

Mr. THOMPSON replied *seriatim* to objections raised by Mr. Holt. First, that there was no difficulty in measuring the distance at which a stricture was situated from the meatus in order to adjust his instrument, and that no man who found that a difficulty was competent to use an instrument in the urethra at all. It was, indeed, an ill compliment to Surgeons to imagine want of ability to accomplish so easy a matter. Secondly, that it was not often necessary to apply the instrument for two strictures in the same urethra, but if there were two, no difficulty in applying it twice existed. Thirdly, that although it had been his practice to tie in a gum catheter twenty-four afterwards, he did not regard it as necessary; he had done so as a precaution, and if any objection to this existed, it would be as safe to dispense with it here as after Mr. Holt's operation. From the remark, that there was no advantage in distending to No. 16, if the bougies subsequently passed could not exceed No. 12, he differed very widely. It had long been admitted to be a desideratum to find some means of dilating the stricture to the size of the canal where it is situated, and it is notorious that the bulbous portion, where stricture most commonly exists, is little more than half dilated by a bougie which fills the external meatus. The subsequent dilatation by such a bougie sufficed, but if thought necessary it might be maintained by the distending instrument itself which formed an excellent dilator. He had a patient at this moment who preferred it to a bougie for ordinary use. Again, it had been assumed on theoretical grounds that its power was deficient. He could only say that in practice the instrument had resisted very severe tests, and was amply strong enough for its purpose; but he would say again, as he had said in the paper, that where the induration surrounding the urethra was very considerable, involving, possibly, the substance of the corpus spongiosum throughout, especially when anterior to the scrotum, incision was more likely to be permanent in its effects than either his own or Mr. Holt's method. He agreed with Mr. Acton that this was highly useful in some cases. An important distinction existed between forcible catheterism and distension, which had been well drawn by Mr. Fergusson; the dangers of that now happily exploded method resulted from tearing away the stricture from its connexions, and driving it down the urethra. Simple expansion from within outwards, provided it was thoroughly efficient, had now been proved to be unattended with danger. Finally, it was most satisfactory to him to hear from Mr. Holt and others the success which had attended his operation, because in some particulars it was closely allied to his own proceeding: thus, he contended that Mr. Holt's operation might be perfectly performed with his (Mr. Thompson's) instrument, but that the latter possessed in addition these two advantages—first, power to carry the distension to a much higher point; and, secondly, that it could be done gradually and slowly, so as to over-distend the tissues as much, and rupture them as little, as possible. It was on these two grounds of difference that he claimed for this proceeding an examination and a trial, since he conceived them to constitute an improvement of no mean value.

## HARVEIAN SOCIETY OF LONDON.

MARCH 5, 1863.

Dr. FULLER, President, in the Chair.

Mr. J. ZACHARIAH LAURENCE gave an exposition of the

## DIAGNOSIS AND TREATMENT OF ASTIGMATISM.

Astigmatism is an inequality of refraction in the meridians of the globe of the eye, the maximum refraction generally existing in the vertical, the minimum in the horizontal meridian. The heterogeneous image thus produced on the retina causes a diminution in the "acuity of vision," so that types of given dimensions can no longer be distinguished at their normal distances. In many instances asthenopia is a prominent symptom, induced by rapidly alternating changes in the accommodation (with a view of obtaining correspondingly successive distinct portions of the retinal image), inducing muscular and psychical fatigue. The various changes the image of a luminous point thrown on a screen by an astigmatic combination of lenses underwent were then shown. At the focus of the vertical rays the focal line was shown to be horizontal; at the focus of the horizontal rays vertical, the images comprised within this range (the "intervalle focale" of Sturm) were shown to be ellipses with horizontal major axes, a circle, and ellipses with vertical major axes. An astigmatic eye perceives the images of a luminous point precisely in this way, the "focal lines" being producible by auxiliary convex or concave spherical lenses, which have the effect either of bringing forward or throwing backward their entire focal interval. The inability of simultaneously seeing horizontal and vertical lines with equal distinctness was then shown to exist in nearly all eyes, proving that astigmatism in a low degree is an almost normal condition of the eye. A series of cylindrical lenses were then exhibited, and their application to the cure of astigmatism. A very striking instance of this was then shown in the person of a young lady, whom Mr. Laurence, after having ineffectually treated for acute asthenopia three years ago by all kinds of lenses, general treatment, etc., had now completely cured by a 16-inch concave cylindrical lens with its axis transverse, the eye in this case presenting a normal refraction in the horizontal meridian, but a myopia of  $\frac{1}{6}$  in the vertical one. Mr. Laurence drew attention to the scientific advantages the test-types of Drs. Snellen and Giraud-Teulon possessed over those of Professor Jäger,—the former being always viewed under one constant angle, and thus affording a gauge of the relative acuity of vision of different individuals. The cause of astigmatism was shown to be most commonly an inequality of curvature of the cornea, sometimes a congenital obliquity of the crystalline lens (as, probably, in the case of the discoverer of astigmatism, Dr. Thomas Young). The ophthalmoscopic signs of astigmatism were then enumerated,—an elliptical form of the optic nerve entrance, and an inability of observing in the direct image the horizontal and vertical branches of the retinal artery with equal distinctness at the same time. Finally, Mr. Laurence alluded to the important development this branch of ophthalmic surgery had received within the last two years by the late researches of Professor Donders, of Utrecht, and Dr. Knapp, of Heidelberg, who had demonstrated the comparative frequency of astigmatism, which, when recognised, led to the remedy of many otherwise perfectly enigmatical cases.

## MEDICAL NEWS.

UNIVERSITY OF ABERDEEN.—At the late Graduation Term, the following candidates, after the usual Examinations, received Degrees in Medicine and Surgery:—

*Degree of M.D.*—James Forbes Beattie, A.M., Aberdeenshire, and John Brown, A.M., Haddington,—honourably distinguished; John Ford Anderson, Old Aberdeen; David Dyce Brown, A.M., Aberdeen; Alexander Collie, Aberdeenshire; François Gabriel Fropier, Mauritius; John Balmain MacLeod, Kingussie; Andrew MacMillan, Perthshire; James Shand Stuart, Banff; Robert Walker, A.M., Aberdeenshire; John Wight, Aberdeenshire.

At the same time, the following gentlemen were promoted to the Degree of M.D.:—

Alexander Stormont MacLaggan, M.B., and Alexander Turner, M.B.

*Degree of M.B.*—Francis James Padfield, Bermudas, and James Ross, Inverness-shire,—highest honours; Robert Collins, Ayrshire, and Robert

Harvey, Aberdeen,—honourably distinguished; James Ashburner Lightbourne, Argyllshire; James Green Milne, A.M., Fife; John Shand, Cape of Good Hope; James Dear Smith, Mayo; Robert William Troup, A.M., Aberdeen.

*Degree of M.C.*—James Beattie, John Brown, Francis James Padfield, and James Ross,—highest honours; Robert Collins,—honourably distinguished; John Ford Anderson, David Dyce Brown, Alexander Collie, François G. Fropier, Robert Harvey, James Ashburner Lightbourne, John B. MacLeod, Andrew MacMillan, James Green Milne, John Shand, James Dear Smith, James Shand Stuart, Robert William Troup, Robert Walker, and John Wight.

Also at the same time, the following gentlemen were declared to have passed part of their Examinations:—

George Henry Anderson, Charles Buchan, John Burton, Alexander Campbell, Samuel Davidson, Alexander Duncan, William Duncan, George Findlay, John Fraser, John Fowler, James A. S. Grant, William Grant, Alexander Gray, Robert Keith, George King, Benjamin Knowles, David Law, James Ledingham, Frank Leigh, Alex. Littlejohn, Christopher Macrae, William MacLean, John G. MacKendrick, Robert Milne, Thomas Milne, Alex. Minty, Alex. G. Mitchell, John Murray, Alexander Ogston, William Robertson, Peter Shepherd, Alex. Silver, William J. Smith, William S. Smythe, William Sutherland, Alexander Thom, John C. O. Will, John Whyte, and James Yates.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 24th ult., viz.:—

Messrs. Edward Lloyd Harries Fox, Broughton, Hants; Thomas Brewer, Halifax; James Atkinson West Spence, L.R.C.P., and L.R.C.S. Edin., Bedale, Yorkshire; Thomas Britton, M.D. St. Andrew's, and L.S.A., Driffield, Yorkshire; Michael Drury Lavin, Bushy, Herts; Thomas Lyle, L.R.C.P., Stratton, Cornwall; John Morton, Halbeach, Lincolnshire; Joseph Jeffery, Northampton; Nathaniel Heckford, Forest Gate, Essex; George Septimus Thompson, Newcastle; Peter Kirkpatrick Picard, M.D. Edin., Edinburgh; Edward Harley, L.R.C.P., and L.S.A., Ludlow, Shropshire; John Brown Oliver, High Wycombe; Thomas King, Monks-Risborough, Bucks; Edward Shaw Grattan, Belfast; Adolphus Burnell Great Rex, M.D. St. Andrew's, and L.S.A., Eccleshall, Staffordshire; Thomas Blunt, L.R.C.P., Wigston Magna, Leicestershire; John Nicholas Miller, L.S.A., Hampstead; William Donald Dear, Demerara; Fitzherbert Dermott, Australia, and Thomas Pilkington, Enfield, near Accrington, Lancashire.

The following gentlemen passed their Primary Examinations in Anatomy and Physiology at meetings of the Court of Examiners on the 28th and 29th ult., and when eligible will be admitted to the Pass Examination:—

J. J. Watson, J. H. Martin, T. H. G. Harding, John Stuckey, E. B. Shuddham, G. H. C. Cooper, B. H. Allen, J. A. M. Evans, Charles Bradley, Herbert Davies, James Whitworth, and John Morison, students of University College; Frank Holmes, Henry Pearson, Robert Whipp, T. J. Webster, and G. T. Joynson, of Manchester; James Follitt, W. F. Knapp, E. R. Smith, W. A. S. Roysds, and G. C. Tayler, of St. Bartholomew's Hospital; R. M. Micklejohn, T. R. S. Nivison, E. A. Briggs, Thomas Rigg, E. O. Williams, Henry Barnes, John Wylie, Thomas Nimms, and William Walford, of Edinburgh; T. W. Jewison, J. G. Nevitt, Thomas Percival, and H. G. Jackson, of Leeds; H. B. Spurgin, J. C. Dwyer, Henry Couling, Henry Dawson, A. C. Jackson, T. R. Nason, E. L. Fyson, A. H. Wheldon, and C. J. Trenning, of Guy's Hospital; Joseph Langhorn and J. E. Collingwood, of St. George's Hospital; G. H. Madelcy, Woodforde Finden, and D. G. Tuckwell, of King's College; A. G. Snewin, Charing-cross Hospital; G. B. Baker, St. Mary's Hospital; L. W. Morgan, St. Thomas's Hospital; E. W. Forster, Thomas Creighton, George Longbotham, and Anthony Bell, of Newcastle; A. B. Adams, C. M. Tidy, and John Craigie, of the London Hospital; William Bullus, Edwin Wykes, and W. S. Mann, of Birmingham; Thomas Elmes, of Dublin.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.—DOUBLE QUALIFICATION.—The following gentlemen passed their First Professional Examinations during the April sittings of the Examiners:—

Henry Black Purves, Kelso; Malcolm Brodie, Argyllshire; Henry Robinson, Derbyshire; Donald Macgregor, Perthshire; John Thomson, Fifeshire; Evan Jenkins, Cardiganshire; John Liddle Crombie, Perthshire; Stephen Coull Mackenzie, Calcutta; Archibald George Robertson, Edinburgh; William Sinclair, Stirling; John Fothergill, Westmoreland.

The following gentlemen passed their Final Examinations, and were admitted L.R.C.P. Edin., and L.R.C.S. Edin.:—

Richard Locke Johnson, King's County; Richard Philip Lisle, Cardiff, Wales; John Counolly, County Cork; Alexander James Macgregor, Perthshire; John Stewart, Berwickshire; Dennis Turnbull, County Durham; Patrick Hogan, County Clare.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The following gentlemen have passed their First Professional Examinations during the April sittings of the Examiners:—

Alexander A. H. Knight, Berwickshire; Alexander G. Miller, Edinburgh; Andrew W. M'Andrew, Lasswade; David Gentle, Fossaway; George B. Mouat, Stirling; John Crerar, Perthshire; Edward Hoggan, India; J. Keith Anderson, Arbroath; James Smith Crichton, Arbroath; Andrew D. Ducat, London; Joseph Wood, Northumberland; John Moffat, Isle of Man; Colin C. Sewell, Quebec, Canada; John Knox, Tyrone; Douglas Glendinning, Langholm; Alexander K. Morsou, Newcastle-on-Tyne; Robert Skimming, Wigton; James Brims, Caithness; William M'Neil, Wigton; John R. Thomson, Slateford.

The following gentlemen have passed their Final Examinations, and obtained the Diploma of the College :—

James Robert Joseph Woodbury M'Almon, New Brunswick; John Young, Fenwick, Ayrshire; William L. Stuart, Glasgow; George Macdonald, Perth; Joseph Fleming, Inch, Co. Donegal; John Parkinson Atkinson, Derbyshire; Thomas Algernon Chapman, Glasgow; William Fraser, Nova Scotia; Mathew Hunter, Eaglesham; William Chambers, Banbridge; James Rutherford, Falkirk; James Wallis, Aberdeenshire; George Arthur Wellesley Wright, Perthshire; John Mackie, Brechin; Francis Metcalfe Duncan, Edinburgh; Alexander M'Donald, Dunkeld; Gordon Hammond, Brechin; Douglas William Eshelby, Edinburgh University; William Jobson, Dundee; Alexander James Main, Mid-Lothian; John Ferguson, Fifeshire; Robert Robertson, Mid-Lothian; James Cleg-horn, Caithness; Thomas Walker, New Brunswick; Christopher James Allan, Northumberland.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, April 23, 1863 :—

Thomas Carter Wigg, East Dereham, Norfolk; William Henry Hosking, Guildford-street, W.C.; Hugh Richard Duncan Mackintosh, Cheltenham; Septimus Swyer, Brick-lane, Whitechapel.

The following gentleman also on the same day passed his First Examination :—

Thomas Powdrell, St. Bartholomew's Hospital.

The following gentlemen also passed the Preliminary Examination in Arts at the Hall on April 24 and 25, 1863 :—

Edward S. Angove, Camborn, Cornwall; Thomas E. Bowkett, East India-road, Poplar; James F. Cadle, Usk, Monmouthshire; Josh. Henry Cattell, Birmingham; James Charlesworth, North Staffordshire Infirmary; Matthew Owen Coleman, Surbiton, Surrey; George A. Coombe, Burnham, Essex; R. Gorton Coombe, Burnham, Essex; James Parkinson Cunliffe, Gannow, near Burnley; John Glanvill, Wedmore House, Islington; Henry Walter Gostling, Oakley, near Bedford; Thomas B. Hay, 43, Caledonian-road; Thomas Lettis, Yarmouth, Norfolk; W. L. Roberts, Grimsby; William Spratt, Tottenham; John Tremearne, St. Ives, Cornwall; C. E. Wing, Bury St. Edmunds; James Bissell Withington, Oldbury.

#### APPOINTMENTS.

\* \* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BONE, DR. WILLIAM, M.D. St. And., has been appointed Assistant Medical Officer to the Female Department of the Middlesex County Lunatic Asylum, Colney Hatch.

BOOTH, LIONEL, M.D., has been appointed Resident Medical Officer to York Dispensary.

DAY, E. E., M.B. Lond., has been appointed Assistant-Physician for Diseases of Women and Children at King's College Hospital.

GIBSON, DR. JOHN HAYDOCK, M.D. Edin., has been appointed Physician to the York Dispensary.

MARSHALL, HENRY, M.D. Edin., has been appointed Lecturer on Medical Jurisprudence at the Bristol Medical School.

MORRISY, DR. TOBIAS JOSEPH, M.D. Glasg., has been elected Coroner for Tipperary.

PLAYFAIR, DR., has been appointed Assistant-Physician for Diseases of Women and Children at King's College Hospital.

TUTIN, JOHN HASLEDINE, M.R.C.S. Eng., has been appointed Coroner for the Liberty of Ripon, Yorkshire.

#### DEATHS.

BANNER, J. MAURICE, F.R.C.S. Eng., at 42, Rodney-street, Liverpool, on April 2.

BEELEY, BENJAMIN, M.R.C.S. Eng., of Holmfirth, Yorkshire, on April 10, aged 68.

BUTCHER, JOHN BREAY, M.R.C.S. Eng., at Truro, Cornwall, on April 14, aged 34.

CUPPAGE, J. GREER, M.R.C.S. Eng., Staff Assistant-Surgeon Army, half-pay, on February 10.

ELLIS, JAMES, M.R.C.S. Eng., Surgeon R.N., at 7, Belgrave-street South, Pimlico, on April 17.

GELSTON, JAS. P., L.F.P.S. Glasg., at Chester-street, Liverpool, on April 14.

HARDING, WM. WOODS, M.R.C.S. Eng., at North Kent-terrace, Woolwich, on April 11, aged 32, Surgeon 14th Kent Artillery Volunteers.

HOUSTON, WILLIAM, M.D., formerly of Ballymena, County Antrim, at Sydney, New South Wales, on December 27, aged 45.

JOHNSON, HENRY CHARLES, F.R.C.S. Eng., at 6, Savile-row, St. James's, W., on April 28, aged 54.

ZIEGLER, ALEXANDER, M.D. St. And., at George-square, Edinburgh, on April 10.

**MR. FARADAY.**—The French Academy of Medicine has just elected our eminent countryman one of its Corresponding Associates. The honour is indeed great to be selected from such a list of competitors (viz., Ehrenberg, Rose, Bunsen, Delarive, and Matteucci), and that almost unanimously, fifty-two out of fifty-three voters who were present giving their suffrages for Faraday. He has long been a member of the French Institute.

**ACADÉMIE DES SCIENCES.**—M. Schönbein has been elected as a Corresponding Member in the Chemical Section, by forty-three out of forty-four voters present.

**THE LOSS OF THE "ORPHEUS."**—Messrs. J. M. Trouson and M. Coates, the Surgeon and Assistant-Surgeon of the *Orpheus*, were, it is feared, amongst the officers who perished in the terrible shipwreck on the Manukau Bar.

**GEOGRAPHICAL FEAT.**—Captains Speke and Grant have completed their journey across eastern and central Africa, from Zanzibar to Khartum, by the White Nile, where they have arrived in safety.

**ETHNOLOGICAL SOCIETY.**—By the resignation of Mr. John Crawford, F.R.S., who has held the post of President of the above Society for the last three years, the Fellows of the Society will be called on next week to elect a President. The advantages which would accrue to science if the successful candidate were to be a member of the Medical Profession, or an Anatomist, we shall not now insist on. Several gentlemen highly qualified for this dignity, and one especially, a physiologist of European reputation, are stated to be likely to come forward, with every prospect of success.

**FORT PITT.**—The Army Sanitary Commissioners, on the occasion of their visit to the Hospitals, barracks, and other Government buildings at Chatham, a few days since, approved of the proposal for the conversion of the buildings at Fort Pitt into a Hospital for the whole of the troops of the garrison, including the Royal Artillery, the Royal Engineers, and the three depots battalions of infantry. The invalids from the Royal Marines will continue to occupy Melville Hospital, as at present. Fort Pitt Hospital will accommodate about 300 patients, which is probably in excess of the number who will occupy it at one time. This arrangement will place at the disposal of the authorities the present garrison Hospital, a commodious building at the back of Chatham barracks, which, according to present arrangements, will be converted into barrack rooms for the troops of the Line. — *Times*, April 27.

**THE SODEN COLLECTION.**—At the last meeting of the Medico-Chirurgical Society several volumes, containing 850 portraits of members of the Profession, were presented to the Society by Mr. Soden, of Bath. They had been collected by his father. Many of the portraits were very rare, and, as works of art, there were some of great value. There was also a volume of autographs, one of caricatures, and two indexes to the volumes of portraits. The conditions on which they were given were that they should form the nucleus for the collection of Medical portraits, and that it should be called "The Soden Collection." The Council had gratefully accepted the gift, and had already thanked the donor; but, on the motion of Dr. Webster, the meeting passed a second vote of thanks to Mr. Soden. The President hoped the members would contribute autographs and portraits to the collection.

**PATHOLOGICAL SOCIETY OF DUBLIN.**—The last meeting of the twenty-fourth annual session of the above Society was held on Saturday, the 25th ult., in the anatomical theatre of Trinity College, John Hamilton, Esq., President, in the chair. Interesting communications having been made by Drs. Adams, Mapother, and Duncan, the President proceeded to announce the decision of the Council in reference to the awarding of the Society's gold medal. The successful essay of this year was, he stated, one of extraordinary merit, and displayed the greatest possible research, combined with the most accurate original observation. The work, for it was much more than an essay, was, moreover, admirably illustrated. The author had assumed the name of "Neuraglia," and on opening the corresponding sealed envelope, it was ascertained that the medal had been won by Mr. John Purser, resident pupil of the Richmond Hospital. On the evening of Tuesday, the 14th ult., the President received the members of the Society, and a large number of literary and scientific visitors, at a brilliant and agreeable *conversazione*, at his residence in Merrion-square.

**WINDSOR ROYAL INFIRMARY.**—Her Majesty and the Princess of Wales honoured this Institution with a visit last week, when they were received and conducted over the establishment by Mr. Blair, the House-Surgeon, who explained some of the most interesting cases to the royal party, the Queen, especially, taking a great interest in some of the patients.

**DEATH FROM SWALLOWING BLUE PILLS.**—An inquest has lately been held at Rogate on a woman named Caroline Stevens, who died from mercurial poisoning brought on by taking blue pills. It appeared from the evidence that she had once been ordered by a Medical man to take a quarter of an ounce of blue pill in a month. She derived benefit from the prescription, and the next year she procured more in larger quantities, which she took till it affected her mouth. The following two years she obtained still larger quantities, and on both occasions it produced more or less salivation. She usually procured it in lumps of a chemist living at Petersfield. She thought the last time that she left it off too soon. On the present occasion she procured more, and had been taking it six weeks. Dr. Peskett, who attended her, found, by directions of the deceased, in an old wardrobe, done up in a quack medicine paper, ten rolls of pills, which he produced. Each roll was  $1\frac{1}{4}$  inch in length, and  $1\frac{1}{6}$  inch in circumference. Deceased told him that she usually took fifteen pills twice a-day; on one occasion she took fifteen three times in one day; for several weeks not less than twice a-day. The druggist who sold her the poison said she had been in the habit of buying three or four ounces at a time. He sold it under the impression that she and her husband had bought the pills for the purpose of retailing them in the country.

**THE IODINE TEST FOR DIABETIC URINE.**—The announcement of MM. Trousseau and Dumontpallier has, of course, excited great attention, and some of their conclusions have already begun to be challenged. M. Dechambre, editor of the *Gazette Hebdomadaire*, has made several experiments. From these it results that in some cases the action of diabetic urine on the iodine was as complete and as rapid as stated by M. Trousseau, in other cases normal urine decoloured the iodine as rapidly and as completely, and in two instances even more rapidly. His experiments also seem to show that the principal agents in the decoloration are sulphate of potass, uric acid, and the urates of potass, soda, and ammonia. It is in fact the relative proportions of these salts in the urine which regulates the decoloring of the fluid, with or without glucose. If this power belongs especially to glucosic urine, the amount of these salts in such urine will then have to be sought for. Professor Farge, of Angers, has also tried the test, and found that in two diabetic patients, whose urine was very glucosic, the decolorising power was at its minimum, the maximum belonging to febrile, or uric urine from other causes.

**THE PREVENTION OF PITTING IN SMALL-POX.**—Dr. Smart, House-Physician at the Royal Infirmary, Edinburgh, has found that a solution of india-rubber in chloroform painted over the face and neck, when the eruption of small-pox is fully out, prevents pitting. A paragraph in the *Scotsman* states that "when the chloroform has evaporated, which it very readily does, there is left a thin elastic film of india-rubber over the face. This the patient feels to be rather comfortable than otherwise, inasmuch as the disagreeable itchiness, so generally complained of, is almost entirely removed, and, what is more important, 'pitting' is thoroughly prevented wherever the solution has been applied. It may be as well to state that india-rubber is far from being very soluble in chloroform, so that, in making the solution, the india-rubber must be cut into small pieces, and chloroform added till it is dissolved. Dr. Smart has tried several other substances, but found none so generally useful. For instance, gutta-percha was tried. It has the advantage of being very soluble in chloroform, and would have been a very admirable application but for the tendency it has to tear into ribbons whenever the mouth is used, or even when the features play. India-rubber, on the other hand, is pliable and elastic, allowing free use of the mouth without any danger (as a rule) of its tearing off. If, however, from some cause or other, a portion is torn off, a fresh application of the solution by means of a large hair pencil remedies the defect, and the mask is once more complete. Several patients who have had this india-rubber mask applied concur in stating that they found it agreeable to wear, and their faces were perfectly free from 'pitting,' although other parts of the body, such as the arms, were covered."

**THE MEDICAL BENEVOLENT COLLEGE.**—The eleventh annual festival of this Institution was celebrated on Wednesday last, when about 300 gentlemen sat down to dinner at Willis's Rooms, the Right Hon. the Earl Manvers in the chair. Amongst the guests present were Lord Chelmsford, Colonel

Brownrigg, the Master of the Temple, Sir Charles Locock, the Rev. Dr. Thornton, Sir John Fisher, Sir Watkins Williams Wynn, M.P., the High Sheriff of Cornwall, Dr. Sibson, Mr. Probert, Mr. Travers, Mr. Dunn, Mr. Toynbec, and others. After the usual loyal toasts had been disposed of, the chairman proposed "the President of the College, and success to the Royal Medical Benevolent College," which was warmly received, and responded to by Lord Chelmsford, who in return proposed the health of the Chairman, commenting on the fact that the Manvers family had been among the earliest and most firm supporters of the charity. The health of "the Treasurer" was proposed by the chairman, and responded to by Mr. Probert, who returned thanks warmly for the cordial manner in which his name had been received, and expressed his continued interest in the welfare and supervision of the arrangements of the College. The toast of "the Head-Master" was proposed by Lord Chelmsford, and acknowledged by the Rev. Dr. Thornton, who said that he was confident that the methods of instruction practised in the school were those most calculated to promote the future welfare of the boys through life. The "Honorary Local Secretaries," "the Press," "the Stewards," "the Medical Charities of England," and "the Ladies," were all cordially responded to, and the guests separated at an early hour. We did not hear the total amount of the subscriptions received.

We desire to remind our readers that the Society for Relief of Widows and Orphans of Medical men in London and its vicinity holds its seventy-fifth anniversary dinner on the 20th inst., which we hope will be well attended. The Society gave away last year £1948 in half-yearly relief, amongst forty-three widows and twenty-six orphans of its deceased members, besides £75 10s. in other relief. How strange, then, that this Society should only number some 450 present members in all Middlesex, and the London postal district elsewhere, when membership of the husband or father during at least the two years preceding his decease, and distress in the widow or children are the only things necessary for obtaining relief forthwith, and to be continued half-yearly. Why do not all Medical men join the Society, the wealthy and unmarried to give assistance to the families of their less fortunate brethren, the married, that their own families may not find themselves in want,—a far too common occurrence we regret to say? We feel that the non-publication of the names of the recipients of the Society's relief is one strong reason why the Society is so lightly regarded, but in truth very great honour attaches to its doings from this very cause, for the widow has only to prove her case to receive relief without delay.

**THE FRENCH SCIENTIFIC CONGRESS FOR 1863.**—The meeting of this body is to be held this year at Chambéry, in Savoy, from the 10th to the 20th August. The following are the subjects which are to be brought before the Medical Section:—1. The nature of Cretinism, and the question of the utility of establishments (as the Abendberg) for its treatment. 2. The question of the law respecting Cemeteries, and how far experience has determined the influence of these on neighbouring populations with respect to epidemics, endemics, etc. 3. The Pathogenic Influence of the Marshes found in Savoy, and what other means of neutralising this is there besides draining. 4. Would it be an advantage for Medical Science in France that the centres of Medical Education should be multiplied in proportion to the clinical, personal, and material resources of the Empire; if so, should these centres undertake a partial or complete education, and should they have the power of conferring the Doctor's degree. 5. What is the influence which the present system of the inspectorate of Mineral Waters has on the material prosperity of the various stations, on the Professional level in the vicinity of the stations, and on the progress of Hydrology. 6. Are the physical and chemical characters of the sulphurous waters of Challes and other places such as to render them suitable for employment under the form of pulverisation? 7. To what extent are the mineral waters of Evian lithontriptic, as compared with those of Vichy, etc. 8. What is the true part played by intestinal worms in pathology? Are they cause or effect, or both the one and the other; and, as a general rule, should their elimination be left to nature or be artificially induced? 9. Is the remuneration paid to ordinary Medical witnesses sufficient, especially in districts in which communication is difficult?

**PREVALENCE OF CRIMINAL ABORTION IN THE UNITED STATES.**—The editor of the *American Medical Times* draws

attention to the increasing frequency with which criminal abortion is perpetrated in the United States, and the very callous state of public feeling in the matter. He assumes this increase not only from the number of abortionists accused, though inefficiently punished, but also from the augmented proportion of still-births. This proportion has in New York rapidly increased since the first registry in 1805. Then the ratio of fetal deaths to the population was 1 in 1633, but in 1849 it had risen to 1 in 340. In 1856, 1 child in every 11 was still-born—the proportion being 1 in 15 in Europe. Accurate records of private practitioners give us the ratio of premature births 1 to 78 of the entire births; while in New York the ratio is 1 to 40. The ratio of premature still-births to those at full time in New York was 1 in 10 in 1846, and 1 in 4 in 1856. From 1850 to 1857, the still-births doubled, and since that period the proportion has rapidly increased. The State of Massachusetts exhibits the comparative frequency of abortions thirteen times as great as in New York city. The instruments of this crime are not exclusively the wretches who perpetrate it in Europe. "There is a class of Medical men, standing on the boundary between legitimate medicine and quackery, who both advocate and practise abortion. They assume a sanctimonious and clerical dress, and, under this specious guise, practise the black art of the abortionist. They are found in the most respectable Medical circles, and make their Professional associations subservient to their base purposes. Judged by the moral code of a Christian civilization, they are the most abandoned criminals in the community, and should be thoroughly purged from the Profession. In this city, the Academy of Medicine, and in the country, the Medical Societies, should inquire 'Have we not abortionists among us?' We do not doubt that they will be found, and that, too, in startling numbers, especially in large cities."

- Statistical Tables of the Patients under Treatment in the Wards of St. Bartholomew's Hospital during 1862. By George N. Edwards, M.D. Cantab., Assistant-Physician and Registrar to the Hospital. Lond. 1863.
- Statistical Tables of the Patients Treated in Guy's Hospital during 1862.
- \* \* \* Out of 329 patients operated on at St. Bartholomew's during 1862, 32 died; out of 541 operated on at Guy's, 44 died; the mortality, therefore, after operation at the former has been somewhat the higher. The Guy's report notices the increase of typhus during the past year; the total number of fever cases having been 164, of which 24 died. Of the 164, 55 were typhus and 43 typhoid, the rest are entered under common continued fever, the exanthemata and ague. At St. Bartholomew's there were only 7 cases of typhus and 20 of typhoid during the year. The outbreak of typhus at Guy's took place in one of the large wards of Hunt's House, and necessitated the temporary closing of the ward. Of 13 nurses and assistants engaged in tending the sick, 4 died. During this time the Surgical wards were remarkably free from disease. We are glad to see that they have improved the patients' diet at Guy's by the issue of green vegetables alternately with potatoes during the summer months. No doubt such a change has "proved very acceptable to the patients, and has been much commended by the Medical Staff."

NOTES, QUERIES, AND REPLIES.

Do that questioneth much shall learn much.—*Bacon.*

We have every reason to believe that the report of a trial on which a correspondent founded an accusation against Dr. Robert Barnes is incorrect, so far as its version of Dr. Barnes's evidence is concerned. We believe that Dr. Barnes on the occasion referred to gave no testimony that was injurious to his brother Practitioner, and that it is his constant practice to act fairly and liberally, and that our correspondent was misled by a report which cannot be relied on.

*Broughams v. Hansoms.*—Mr. Rawlenson, C.E., and Sanitary Inspector, has written a sensible letter to the *Times* on the subject of sanitary appli-

ances for the public use. We commend the following extract to the attention of some of our pallid, ailing Professional brethren:—

"An invalid takes a carriage airing with closed windows; such a ride is, however, in truth a carriage poisoning. If an open carriage cannot be used on any day in the year with safety, the individual had better not use a carriage, and no room should be occupied which has not an unceasing flow of fresh air through it—not necessarily a draught, but motion."

*Locusts in India.*—A new pest has afflicted India—that of locusts. For some months past large swarms of locusts have done no little injury in Scinde and the Punjab, and the fear is that they may take up their permanent abode in the latter. To deal with the scourge has called forth all the energies of the local authorities. The locusts have been especially plentiful in the districts of Goojranuala, Sealkote, Goojerat, and Rawul Pindee, all near the foot of the Western Himalayas. They cling to the long spikes of the acacia, the Shittim tree of Scripture, and there they breed, each female laying nearly a hundred eggs, which adhere to each other like an ear of corn. The Financial Commissioner of the Punjab has accordingly addressed a circular to all the subordinate authorities. As is the practice in Persia and Turkey, the villagers are to be induced by money and sweetmeats to grapple with the scourge by, morning and evening, forcing the locusts into bags while still drowsy or numbed, and burying them in pits. Experience shows that every bagful withdrawn from the swarm represents a large amount of grain and fodder saved, and a persistent destruction of them during the four or five months of the cold season will secure the best results. The locusts made a mistake when they selected the Punjab, of all other provinces, as the scene of their operations. They might prove worse than a famine caused by drought, and seriously affect the Budget.—*Calcutta Correspondent of the Times, March 23.*

Mr. Probert has at last given in. He has intimated to Dr. Markham his willingness to submit the question between himself and Mr. Adams to a court of honour, composed of his Professional brethren. That "question," or "case," or "affair," or call it what you will, has been submitted to the Profession already by Mr. Adams, and it is for Mr. Probert to reply to it manfully. We have all along regretted that Mr. Probert should have been so ill-advised or so unadvised, and hence that the memory of the services which he has rendered to the Profession, in the foundation of the Medical Benevolent College, has been overcast by this present flagrant instance of what seems to be injustice and cruelty to one of its members. Mr. Adams' case against Mr. Probert is, —firstly, the harshness with which Mr. Probert treated him, a Professional friend, in December, 1861, and January, 1862, when he assumed Adams's guilt, and referred him to a jury; and, secondly, the conduct of Mr. Probert in aiding and countenancing the Russells, which was equivalent to a condemnation of Adams. Mr. Probert may now show his Professional brethren that he was justified in the course he took; or if he should be judged to have acted wrongly, he will, no doubt, put himself into their hands, and do, say, and pay anything which the court may decide that he ought to do, say, and pay. Of course, Mr. Adams would be a mere imbecile unless he stipulated that both parties should bind themselves by the decision of this Court of Honour, as though it were a court of law. Now that the affair is *sub judice*, we must be silent. We have spoken heretofore on the basis of an accusation which Mr. Probert did not coudescend to reply to. We will only add that a man of honour can wipe out almost any offensive conduct by a full and frank retraction and acknowledgment of error, and that we shall be most glad to see the veteran defendant taking this course, if it be so adjudged, and thus handsomely winding up a long and distressing controversy.

*Mortality of the City Police.*—The Lord Mayor's remark in the recent debate, that "for physique and intelligence the City police are far above the metropolitan police," may now be illustrated by the report of Mr. Borlase Childs, the Surgeon to the City police, on "the probable duration of life, and Medical history of the force." From this we learn that candidates for admission to the force have to produce testimonials of trustworthiness, and a twelve-month's good character, before being submitted to examination as to the state of their physical fitness for a policeman's duties. The Surgeon conducts this examination in precisely the same way as prevails in examinations for the army, and the consequence is that the policeman's is a "picked life," and, on entering the force, he may be considered as a man possessing a high standard of health and capable of undergoing more than an ordinary amount of physical exertion. During the years 1852 to 1856, as many as 1,345 candidates sought admission to the force. Of this number, 534 were rejected by the Commissioner, who considers character only, and 181 by the Surgeon. Surgically considered, the recruitment of the force is similar to that of the army, but morally it was much superior, for as the men are chosen for good character and intelligence, these are the least likely to injure their health by excesses. Comparing the physical status of the force with that of the army, it is found that while the mortality of the household cavalry is 11.1, dragoons, 13.5, infantry, 17.8, and foot-guards 20.4, in our police force it is only 8.9 per 1000. Yet we may suppose that in the time of peace the duties of the policeman tax the constitution more severely than those of the soldier, and we may conclude that the system of recruitment for the police contributes greatly to the value of life among the members of the force. Of deaths which occurred during the years 1852 to 1856, there was only 1 of cholera, and this was the only death from this cause since Mr. Child's appointment in 1844; 2 died from typhus, 2 from small-pox, 11 from chest diseases, and 8 from other diseases.—*City Press*

*The Reputed Fossil Man of Abbeville.*—Dr. Falconer, the eminent palæontologist, has written a letter to the *Times* which fully confirms the opinion we advanced last week as to the recent character of the jaw discovered by M. de Perthes. He accompanied Messrs. Evans and Prestwich to Abbeville, and examined the jaw and flint hatchets himself. He writes:—

“Now for the jaw itself. What complexion of intrinsic evidence did it yield? The craniological materials available at Abbeville for comparison were, of course, very limited; but the specimen presented a series of peculiarities which are rarely seen in conjunction in the jaws of European races, ancient or recent. Here I must be a little technical. 1. The posterior margin of the ascending ramus was extremely reclinate, so as to form a very obtuse angle with the ascending ramus. 2. The ascending ramus was unusually low and broad. 3. The sigmoid notch, instead of yielding an outline somewhat like a semicircle, was broad, shallow, and crescentiform. 4. The condyle was unusually globular; and, 5, what was most remarkable of all, the posterior angle presented what I may venture to call a marsupial amount of inversion. The first three characters suggested to M. Quatrefages—if I may venture to cite him for a preliminary impression and not a judgment—the recollection of something corresponding in the jaws of Esquimaux, while the fifth character suggested to me the recollection of what I had seen in the jaw of an Australian savage. Neither of us had at hand the materials requisite for a satisfactory comparison, but the combination of characters above alluded to struck us both as sufficiently remarkable to demand serious examination. M. Quatrefages departed for Paris, taking the jaw with him, while I returned to London, bringing drawings and a careful description with measurements of the principal specimen, and M. de Perthes confided to me the detached molar. I may add that the jaw specimen, although professing to have been yielded from below a heavy load of coarse flints, presented no appearance of having been crushed or rolled; and that, making allowance for the crust of matrix enveloping it, the bone was light, and not infiltrated with metallic matter. The condyle washed yielded a dirty white colour.

“As to the result, I have as yet no authentic information of the final conclusions which have been arrived at in Paris. My friends, Mr. Busk, F.R.S., and Mr. Tomes, F.R.S., both practised anthropologists, gave me their assistance in my part of the inquiry. The former, like M. Quatrefages and myself, was struck with the odd conjunction of unusual characters presented by the jaw, and speedily produced a lower jaw of the Australian type, brought by Professor Huxley from Darwin Island, which yielded the same kind of marsupial inversion, so to speak, with a nearly corresponding form in the reclinate posterior margin, ascending ramus, and sigmoid notch. But Mr. Tomes's abundant collection brought the matter speedily to a point. From the pick of a sackful of human lower jaws, yielded by an old London churchyard, he produced a certain number which severally furnished all the peculiarities of the Abbeville specimen, marsupial inversion inclusive, although not one of them showed them all in conjunction. We then proceeded to saw up the detached molar found at Monlin-Quignon. It proved to be quite recent; the section was white, glistening, full of gelatine, and fresh looking. There was an end to the case. First, the flint hatchets were pronounced by highly competent experts (Evans and Prestwich) to be spurious; secondly, the reputed fossil molar was proved to be recent; thirdly, the reputed fossil jaw showed no character different from those that may be met with in the contents of a London churchyard. The inference which I draw from these facts is, that a very clever imposition has been practised by the *terraciers* of the Abbeville gravel-pits—so cunningly clever, that it could not have been surpassed by a committee of anthropologists enacting a practical joke. The selection of the specimen was probably accidental; but it is not a little singular that a jaw combining so many peculiarities should have been hit upon by uninstructed workmen.

“The break-down in this spurious case in nowise affects the value of the real evidence, now well established, but it inculcates a grave lesson of caution.

“Sir, your obedient servant,  
“21, Park-crescent, N.W., April 23. “H. FALCONER, M.D., F.R.S.”

\* \* We hear from Paris that the leading members of the scientific world there have unanimously come to the same conclusion as M. Boncher de Perthes, and consider the jaw to be geologically ancient. Notwithstanding this, our opinion is unaltered, and accords with that of Dr. Falconer, Messrs. Prestwich, Evans, and Tylor.

#### EMPLOYMENT FOR A SWISS PHYSICIAN IN INDIA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—You will oblige me by informing me, through the Correspondent column of the *Medical Times and Gazette*, if a foreign Physician (Swiss), graduated at a University, wishing to proceed to India or one of the British colonies, would be able to find Government employment in his Profession; or if not, what chance of success would he stand for private practice?

London, April 28.

I am, &c.

A. G.

[Write to Sir C. Wood, at the India House.—Ed.]

#### MEDICAL HANDBILLS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I enclose two circulars which have been very freely distributed in this neighbourhood. As the parties evidently desire publicity, perhaps you will insert them in your widely-circulated Journal.

I am, &c.

April 26.

AN OLD SUBSCRIBER.

“Mr. Rhind, L.R.C.P., M.R.C.S., begs to state that he has amalgamated the Practice of Mr. Grabham, Surgeon (who has left the neighbourhood), with his own. To meet the requirements of the district, Mr. Rhind has taken the residence lately occupied by Mr. Grabham, in Commercial-street, next door to the Mechanics' Institute, Shipley, in addition to his own residence, Claremont-villa, Victoria-park, Shipley. Mr. Roberts (Member of the Royal College of Surgeons, London), resides at the residence in Commercial-street. Mr. Rhind calls daily at the house in Commercial-street for messages and consultations. Special messages for Mr. Rhind will be forwarded at once to his house in Victoria-park. Hours for consultation may be learned on application at either residence; but it is specially stated that either Mr. Rhind or Mr. Roberts remains every Saturday afternoon, from 3 to 5, at the house in Commercial-street, for consultation. Claremont-villa, Victoria-park, Shipley.”

“Mr. Rawson, Surgeon, Thornton.—In consequence of the many demands

upon his time, Mr. Rawson finds it necessary to have stated hours each day, when he can meet patients coming from a distance. The hours of consultation at the Surgery in future will be:—Forenoon, 9 until 10 o'clock; Afternoon, 2 until 3 o'clock; in the Evening, after 7 o'clock. Saturday is devoted chiefly to Diseases of the Chest.”

#### ASTIGMATISMUS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am again in need of help on a question of etymology. *Unde derivatur* “Astigmatismus” (?) a word lately introduced into ophthalmic nomenclature. I know what astigmatism means; it is defined, in a recent publication by Snellen, as a peculiar condition of vision, in which “horizontal and vertical lines cannot be seen with equal clearness at one and the same time, because the focal distances in the two meridian planes are unequal.” This peculiar condition of the eye is no new discovery, having been described more than sixty years ago by Dr. Young, and subsequently by Professor Airy. A new name, however, has been given to it, and I cannot understand on what principle the word has been compounded.

Stigma, we all know, means a punctured or dotted mark. Stigmatism would, I suppose, be the act of making such marks, or being the subject of them; and astigmatism the opposite condition. But on what etymological principle does “astigmatism” imply this disparity of refraction in the vertical and the horizontal diameters of the eye? To me the word does not etymologically suggest the thing intended. I am &c.

April 26.

QUERENS.

#### THE ARMY MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A movement is being set on foot by some injudicious members of the Army Medical Department to petition the Secretary of State for War for certain “benefits.” Among these are the following:—

1. To have the place of the names of the Medical Officers in the Army List changed from its present location, and mixed with those of the other officers, according to the date of commission and rank. In other words, to try and hide from public gaze the names of men of so odious a Profession by blending them with the military ranks!

2. To have the relative military ranks printed after the name of each Medical officer, viz., Doctor —, —, Regt., Lieutenant-Colonel!

3. To have a precedence at the dinner-table, *i.e.*, to be allowed to sit next to, or opposite to, a Major-General, Field Marshal, Lord or Earl, if such dined at the mess, and to help these “big wigs” to soup!

There are only two legitimate places at a mess table: those of the President and Vice-President; and, beyond these, there is no precedence at the table which would not also exist on parade; for mess is in its nature a parade, and a commanding officer can order any of his officers to be present on any date he wishes.

The absurdity of these must be apparent to every thinking man, and I hope, sir, that you will insert this letter, and otherwise use your influence (which has always been exercised for the benefit of the service) in crushing a movement likely to bring discredit on the good common-sense of the officers of the Department, many of whom, like myself, strongly censure such absurdities.

It is quite true that the “new Warrant” cannot be depended upon any more than its deceased fellow; that “forage,” which was granted in the old, has been omitted in the new; that there is no guarantee that the Indian authorities will acknowledge the new one any more than they did the old; that a purveyor or general officer may deprive a Medical officer of his coals or light, or any other allowance just as readily under the new Warrant as under the old Warrant. These are sterling advantages, and the point ought to be taken up by a man like General Peel in the House, but the other “advantages” are simply likely to do a vast injury to our Department. I am, &c.

A SURGEON.

#### EXAMINATIONS FOR A MEDICAL DEGREE IN EDINBURGH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The Medical press has always taken great interest in the education of students, and to its influence are we chiefly indebted for the recent changes in the character of the qualifying examinations. I trust therefore that the subject of this letter will receive your consideration, and the much-needed reform your advocacy.

The present high standard of the examinations at the Universities not having been accompanied by arrangements fixing suitable intervals of time between each, nor by a convenient division of the subjects, has, instead of promoting Medical education, had a contrary effect, and caused much disappointment and distress among students and their friends. Though the new system has had but a short trial, there are ample data to prove that it has hitherto failed to raise the character of Medical education, though in one division of the United Kingdom (England) it may have promoted the introduction into the Profession of youths of a higher social origin than formerly entered it.

The subjects of Medical study have made such gigantic strides of late years that the present generation of students has much more work to do than its predecessors. The prevailing rule among British universities at present is to hold two Medical examinations, one in Chemistry, Natural Philosophy, Natural History, Botany, *Materia Medica*, Anatomy, and Physiology, and the other in five or six purely Professional subjects. To minds of ordinary memorial power it is simply impossible to retain such a mass of knowledge as is necessary to pass a *bona fide* searching examination in so many subjects at one time. Very many make the attempt, neglecting every other duty. How many succeed? An answer to this question may be obtained by comparing the number of matriculated Medical students and of graduates at the Universities of Edinburgh and London. The latter attain the degree by an assiduous cultivation of the memory or by chance, frequently to the evident injury of the higher mental faculties. Numerous students who, from ill-health or other difficulty, have their course of study interrupted, leave the Profession in despair, or at length qualify after undergoing repeated labour at accumulated expense. The two Universities seem now to be emulating one another in the severity of their examinations, and at Edinburgh quite recently the exactions in that not very essential subject, Botany, were difficult beyond precedent in any other seat of learning in the world.

Of the severity of the examinations, however, the students do not complain; they only require that these should be held annually, and in those subjects which have been studied the previous year. How much better, for instance, would it not be if at the end of the first year examinations were held in Chemistry, Botany, Natural History, etc.; at the end of the

second, in Anatomy, Physiology, and Materia Medica; at that of the third, in Midwifery, Medical Jurisprudence, and Pathology; at the fourth, in Theoretical and Clinical Medicine and Surgery. An arrangement of this kind prevails in all the Continental Universities. It induces regular and continuous study, counteracts the tendencies of the naturally idle, enables the industrious to acquire a thorough knowledge of their subjects, and is found to be productive of great Professional and individual advantages.

In proof of the fact that the proficiency of young Medical men has not kept pace with the increased exactions of the examining boards, I may refer to the last examination for Commissions in the Army, when not more than fourteen out of forty-five candidates satisfied the Examiners.

It is reported that Sir William Hooker, Mr. Syme, and other eminent persons have expressed an opinion that Medical education as now conducted, under the influence of the present system of examinations, is radically wrong. I am sure that those who are practically acquainted with this subject will endorse the opinion of these gentlemen. Let us hope that the attention of the authorities will soon be directed to this matter, as it is yearly becoming more urgent. The reform required does not involve a wide departure from the existing routine, and in its results would prove in the highest degree beneficial to students, gratifying to Professors, and creditable to the schools.

Scotland, April 20.

I am, &c.  
PATERFAMILIAS.

DR. ABBOTTS SMITH ON HUMAN ENTOZOA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—After the encomium which the reviewer of "On Human Entozoa," etc., in the last impression of your periodical, has passed upon the "most careful" and "most able manner" in which such portions as are taken from M. Davaine's "Traité des Entozoaires" are translated, I ought to have little cause for complaint; nor, indeed, should I have troubled you upon this matter were it not for the circumstance that I feel compelled to protest against the insinuation of falsehood on my part which is conveyed by your reviewer's placing a note of interrogation after the word "permission."

With regard to literary pretensions, I should be one of the last (especially as having been myself a reviewer for several years) to contend against the right of criticism, but as such a charge as that which is brought against me is of an unusual character, I must, relying upon your well-known sense of fair play, request you to allow me to make the following statements in your columns, in refutation of it:—

1. That I am in a position to prove by letters from M. Davaine that that author kindly and readily gave me the permission which I have mentioned in the Preface.

2. That I can also prove, in a similar manner, the permission granted to me by Messrs. Baillière, of Paris, and the payment to them of the equivalent, as fixed by themselves, for the right of reproduction of any portions of the work, and for the privilege of using any of the wood engravings.

3. That I have never attempted in any way to disguise my obligations to M. Davaine, of whose work mine would have been styled a translation, had it not appeared probable that this statement would have misled English readers with respect to the size, etc., of M. Davaine's book, which extends over more than 900 pages (many of which are closely printed), and describes the entozoa found in animals as well as in man; whilst some portions of the book reviewed in your Journal had not formed part of M. Davaine's treatise—e. g., the article on Santonine (at pp. 233—238), which was really taken from a paper written by me in the *Medical Times and Gazette* of last year, giving an abstract of fifty cases of intestinal entozoa in which I administered that drug.

In support of my third assertion, I may here refer to the acknowledgment in my preface that "I have largely availed myself" of the permission kindly granted to me, "as will be seen upon a perusal of the following pages;" and also to the fact that one of your Medical contemporaries, putting the construction which I desired to convey upon this part of my Preface, actually comments upon my "great candour" in making this statement.

Those who know me will, I believe, exonerate me from any suspicion of literary dishonesty; but, in order to avoid the semblance even of a wish on my part to mislead any one by what may appear to some to be an ambiguous statement, I intend to give directions that the words "Partly translated, by permission, from M. Davaine's 'Traité des Entozoaires'" be inserted in all future announcements of the work, and also upon the title-page if M. Davaine, with the courtesy which has distinguished his correspondence with me throughout, should give me permission to do so.

I have to thank your reviewer for drawing my attention to the error made, doubtless in the correction of my manuscript, of not acknowledging the passage from M. Pinel's work. Having duly acknowledged Comperat, Tarneau, Gamgee, and others whose observations and consequently whose names, do not appear in M. Davaine's treatise, no reason can be adduced for my purposely ignoring M. Pinel.

April. I am, &c.  
WM. ABBOTTS SMITH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Since I took the liberty of addressing a letter to you in explanation of certain points which were commented upon by the reviewer of "Human Entozoa," in the notice contained in your Journal of Saturday last, I have received a letter from M. Davaine (dated "Palais des Tuileries, 28 Avril, 1863," M. Davaine being attached to the Imperial "Service de Santé,") from which I extract the following passage:—

"Je vous autorise parfaitement à dire que c'est avec mon consentement que votre ouvrage ne porte point le titre de traduction. Cet ouvrage, ne reproduisant pas le mien intégralement, ne pouvait en être considéré comme le traduction." I am, &c.

April 29. WM. ABBOTTS SMITH.

COMMUNICATIONS have been received from—

ROYAL MEDICAL BENEVOLENT COLLEGE; MR. HARRY LOBB; THE CRYSTAL PALACE COMPANY; MR. W. D. WILKES, Westminster Hospital; DR. C. R. DRYSDALE; AN OLD SUBSCRIBER; APOTHECARIES' HALL; PATERFAMILIAS; DR. STRUTHERS; DR. R. LAWRENCE; DR. W. S. KIRKES; MR. HAYNES WALTON; DR. RAMSBOTHAM; ROYAL INSTITUTION; QUERENS; MR. F. J. ROBINSON; ANOPHTHALMOS; HARVEIAN SOCIETY; MR. R. B. CARTER; DR. DEVENISH; OBSTETRICAL SOCIETY; MR. J. S. BRAZIER; A. G.; ETHNOLOGICAL SOCIETY; DR. W. ABBOTTS SMITH; DR. MERRIMAN; MR. JAMES HINTON; PROFESSOR HUXLEY; MESSRS. KIMBER AND ELLIS; MR. JOSEPH GODDEN; SPES; DR. LOWES; MR. S. CROMPTON; DR. POWELL, London Hospital; MR. WILKES, Salisbury.

VITAL STATISTICS OF LONDON.

Week ending Saturday, April 25, 1863.

BIRTHS.

Births of Boys, 958; Girls, 1005; Total, 1963.  
Average of 10 corresponding weeks, 1853-62, 1757.5.

DEATHS.

APPOINTMENTS FOR THE WEEK.

May 2. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m.; Charing-cross, 1 p.m.

4. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.

ODONTOLOGICAL SOCIETY OF LONDON, 8 p.m. Meeting.  
ROYAL INSTITUTION, 2 p.m. General Monthly Meeting.

5. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.  
ETHNOLOGICAL SOCIETY, 8 p.m. Dr. King and Professor Buck, "On the Natives of Vancouver's Island." The Père Bourien, "On the Wild Tribes of Interior of the Malay Peninsula."  
ROYAL INSTITUTION, 3 p.m. Professor Tyndall, "On Souud."

6. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.  
HUNTERIAN SOCIETY, 8 p.m. Mr. Thomas Bryant, "On a Case of Calculus Vesicæ in a Woman, and Extraction by Rapid Dilatation, and Recovery, with Remarks."  
OBSTETRICAL SOCIETY OF LONDON, 8 p.m. Dr. Kidd, "Further Observations on Use of Anæsthetics in Midwifery." Mr. Cooke, "On a Case of Simultaneous Uterine and Extra-uterine Pregnancy." Mr. Marshall and Dr. Graily Hewitt, "On a Case of Tubal Gestation."

7. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.  
HARVEIAN SOCIETY, 8 p.m. Dr. Camps, "On Some Remarks on certain Diseases attended with Impaired and Perverted Motion."  
ROYAL INSTITUTION, 3 p.m. Professor Ansted, "On Geology."

8. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.  
ROYAL INSTITUTION, 8 p.m. Prof. Voelcker, "On the Soils of England."

EXPECTED OPERATIONS.

King's College Hospital.—The following Operations will be performed on Saturday (to-day) at 2 p.m.:—  
By Mr. Fergusson—For Fistula in Ano; Vesico-Vaginal Fistula; Removal of Tumour from Leg.

TO STUDENTS, SURGEONS, DENTISTS, AND OTHERS.

The Best House for Second-hand Instruments,  
Where there is the Largest Stock in London, is Mr. WILLIAM LAWLEY'S, 78, FARRINGDON-STREET, CITY.  
Army and Navy Regulation Cases, Pocket Cases, from 14s. each; Dissecting Cases, at 8s. 6d. and 10s. 6d. each.

## Pulvis Jacobi ver, Newbery

is the ORIGINAL & GENUINE, was ESTABLISHED A.D. 1746,  
And is Prescribed, with the greatest success, "by the highest authorities," for  
Fevers, Ague, Cerebral Congestion, Rheumatism, Chills, Influenza, &c. &c.  
**FRAS. NEWBERY & SONS, 45, ST. PAUL'S CHURCHYARD.**

Prices for Dispensing—1 oz., 9s.;  $\frac{1}{4}$  oz., 3s. 4d.

## TOWLE'S CHLORODYNE.

Medicinal Properties:—  
Anodyne, Diaphoretic, Sedative, Astringent, and Anti-Spasmodic.

**CAUTION.**—For the convenience and safety of prescribing Chlorodyne, in combination with other ingredients, so as to avoid decomposition (a result known to have taken place) through the use of SECRET COMPOUNDS, Mr. TOWLE begs to call the attention of the Profession to the following component parts in his Preparation:—

CHLOROFORMYL.  
ETHER.

OL. MENTII. PIP.  
ACID. PERCHLOR.

TINCT. CANNABIS INDICÆ.  
ACID. HYDROCYAN.

TINCT. CAPSICI.  
MORPHIA & THERIACA.

The proportion of Morphia— $\frac{2}{3}$  gr. inf. 3j. Dose—Five to Twenty Drops.  
Letter from ALFRED ASPLAND, Esq., F.R.C.S. Eng., J.P. Chester and Lancaster, Surgeon 4th Cheshire Batt. V.R., Surgeon to the Ashton Infirmary.—"After an extensive trial of your Chlorodyne in Hospital, Infirmary, and Private Practice, I am able to state that it is a valuable medicine. I have found its action peculiarly serviceable in Bronchial, Spasmodic, and Neuralgic Affections. I have never found it produce headache or feverish disturbance, results which not unfrequently occur from other forms of Chlorodyne. As a sedative to allay excitement arising from the abuse of intoxicating drinks, so commonly witnessed in our Barrack Hospital, I have been perfectly satisfied with it. Its known composition will doubtless prove an additional recommendation to the Profession."

Sold by Wholesale Houses in bottles, 1 oz., 1s. 6d.; 2 oz., 2s. 6d.; and 4 oz. to 20 oz., 1s. per fluid oz.

Sole Manufacturer—A. P. TOWLE, CHEMIST, &c., 99, STOCKPORT-ROAD, MANCHESTER.

## CHLORODYNE.

"INVENTED AND DISCOVERED, IN 1844, BY RICHARD FREEMAN."  
(Extract from Affidavit made before S. C. WARD, Esq., Chancery Record Office, Chancery-lane, London, June 16th, 1862.)

The Inventor begs to thank the Medical Profession for the liberal support he receives from them, and to assure those who have not yet tried his Chlorodyne that it is superior to any other maker's, being more certain and more lasting in its effects; and the low price which he charges for it allows the poorest sufferer to enjoy its extraordinary beneficial influence. The immense demand for it by the Profession is a convincing proof that they find it a most valuable therapeutical agent. The following are a few out of many voluntary Medical Testimonials:—

From W. VESALIUS PETTIGREW, M.D., Hon. F.R.C.S. Eng., formerly Lecturer upon Anatomy and Physiology at the St. George's School of Medicine.

"I have had the opportunity of trying the effects of Mr. Freeman's Chlorodyne, and find it an excellent Anodyne and Antispasmodic medicine."

From H. J. O'DONNELL, M.R.C.S.E. and L.M., &c., &c.,  
Albert-terrace, London-road, S.

"I can with much confidence bear testimony to the efficacy of Mr. Freeman's Chlorodyne as a Sedative and Antispasmodic, having used it for some years in Colic, Neuralgia, Phthisis, and Asthma. I daily administer it in after-pains, and in all cases find it infallible. It is the most valuable medicine we have in Labour cases. I find, since I have used it, the pains

seldom or ever exceed the third day, while with the former remedies my patients suffered eight or nine days. In fact, I cannot speak too highly of it."

From F. W. HOOPER, M.D., M.R.C.S. Eng., &c., &c., Medical Officer,  
Christ Church District, Camberwell.

"I have much pleasure in stating that, after a sufficient trial of Mr. Freeman's Chlorodyne, I am fully persuaded that it is superior to any preparation of the kind, and, from its moderate price, is a great boon to the suffering poor, who daily acknowledge its salutary benefit."

From W. G. KING, M.D., M.R.C.S. Eng., Hackney.

"I have used your Chlorodyne for some time, and can bear testimony to its efficacy and value in all cases in which a Sedative has been indicated."

Manufactured by RICHARD FREEMAN, Pharmacist, Kennington-road, London, S.;  
And Sold by all Wholesale Houses, in bottles, 1 oz., 1s. 6d.; 4 oz., 5s.; and 8 oz., 10s. each.

TRADE MARK

# CHLORODYNE

WAS DISCOVERED AND INVENTED IN THE YEAR 1848 BY  
DR. J. COLLIS BROWNE, M.R.C.S.L. EX-ARMY-MED. STAFF.  
AND IN 1856 HE CONFIDED  
THE ORIGINAL AND ONLY FORMULA  
FOR ITS MANUFACTURE  
SOLELY TO J. T. DAVENPORT, PHARMACEUTIST,  
33, GREAT RUSSELL ST. BLOOMSBURY SQUARE, LONDON.  
REGISTERED 1856.

## NOTIFICATION.

The attention of Medical Men is directed to the Piratical application, by some parties in the Trade, of the term "Chlorodyne" to various mixtures compounded of Chloric Ether, Opium, Indian Hemp, and Peppermint, in Imitation of the ONLY Genuine preparation of this name.

The dangerous expedient of encouraging or advocating the assumption of a name specifically indicating a particular property or remedy—such as *Chlorodyne*—to spurious imitations and substitutions—ON THE GROUND OF CHEAPNESS, is a subject of surprise and grave reproach, supremely so, when the adulteration, sophistication, and tampering with Drugs, becomes so serious and important a consideration in the successful practice of Medicine.

The fact of these Piracies must fully convince the Profession of the extraordinary efficacy of the Genuine Chlorodyne; whereas the sad results and disappointment arising from the use of spurious compounds cannot be expressed.

Each Genuine Bottle bears a Red Stamp, with the words, "Dr. J. COLLIS BROWNE'S CHLORODYNE," in White Letters.

REDUCTION OF PRICE.—In Bottles, 1oz., 3s.; 2oz., 5s.; 4oz., 8s.; 10oz., 15s.

To Hospitals and Charities in large quantity, a Liberal Discount.

## LECTURE VI.

*(Being the Fifth of Six Lectures on Classification, and on the Characters of the Principal Groups of the Animal Kingdom.)*

MR. PRESIDENT AND GENTLEMEN,—Having now arrived at the end of the list of classes, and having endeavoured to furnish you with a statement of the structural features common to, and characteristic of, each class, it will be my next object to discuss the relations of these classes one to another, and to inquire how far they present such common characters as will enable us to group them into larger divisions.

And, to commence with the highest classes, it is clear that the *Mammalia*, *Aves*, and *Reptilia* are united together by certain very striking features of their development. All possess an amnion and an allantois, and all are devoid throughout life of any apparatus for breathing the air which is dissolved in water. In other words, they constitute what may be termed the "province" of *Abranchiate Vertebrata*, in contradistinction to *Pisces* and *Amphibia*, which possess no amnion, nor allantois (or at most a rudimentary one), and being always provided at a certain period, if not throughout life, with branchiæ, have been termed *Branchiate Vertebrata*.

The *Abranchiata*, however, form a far less homogeneous assemblage than the *Branchiata*—Mammals being so strongly separated from Reptiles and Birds that one might almost be tempted to regard them as constituting one of three primary divisions, or provinces, of the *Vertebrata*. The structure of the occipital condyles, the structure and mode of articulation of the mandibular rami, and the presence of mammary glands, appear to separate Mammals almost as widely from Birds and Reptiles as the latter are separated from Amphibia and Fishes.

These five classes, whether divided into two or three provinces, again, present so many characters, already enumerated, by which they resemble one another, and differ from all other animals, that by universal consent they are admitted to form the group of VERTEBRATA, which takes its place as one of the primary divisions or "sub-kingdoms" of the animal kingdom.

The next four classes—*Insecta*, *Myriapoda*, *Arachnida*, *Crustacea*—without doubt also present so many characters in common as to form a very natural assemblage. All are provided with articulated limbs attached to a segmented body-skeleton—the latter, like the skeleton of the limbs, being an "exoskeleton," or a hardening of that layer which corresponds with the outer part of the epidermis of vertebrates. In all, at any rate in the embryonic condition, the nervous system is composed of a double chain of ganglia, united by longitudinal commissures, and the gullet passes between two of these commissures. No one of the members of these four classes is known to possess vibratile cilia. The great majority of these animals have a distinct heart, provided with valvular apertures, which are in communication with a perivisceral cavity containing corpusculated blood. But the *Cirripedia* and the *Ostracoda* among Crustaceans, and many of the Mites among *Arachnida*, have as yet yielded no trace of distinct circulatory organs, so that the nature of these organs cannot be taken as a universal character of the larger group we are seeking; still less can such a character be found in the respiratory organs, which vary widely in character, and are often totally absent as distinct structures. Some years ago I endeavoured to show (a) that a striking uniformity of composition is to be found in the heads of, at any rate, the more highly organised members of these four classes, and that, typically, the head of a Crustacean, an Arachnid, a Myriapod, or an Insect is composed of six somites (or segments corresponding with those of the body) and their appendages, the latter being modified so as to serve the purpose of sensory and manducatory organs. I believe this doctrine to be

substantially correct; and that, leaving all hypothetical supposition aside, the head of any animal belonging to these classes may be demonstrated to contain never fewer than four, and never more than six somites with their appendages; but until this view has received confirmation from other workers, I shall not venture to put forward any statement based upon it as part of the definition of the large group containing the four classes above mentioned, which has received from some naturalists the name of *Articulata*, from others that of *Arthropoda*, the latter being perhaps the more distinctive and better appellation.

The members of the class *Annelida* present marked differences from all the *Arthropoda*, but resemble them in at least one important particular, and that is, the arrangement of the nervous system, which constitutes a ganglionated double chain, traversed at one point by the œsophagus. In almost all other respects, Annelids differ widely from Arthropods. It may be doubted whether any annelid is devoid of cilia in some part or other of its organisation, and cilia constitute the most important organs of locomotion in the embryos of many. No annelid possesses a heart communicating by valvular apertures with the perivisceral cavity, none have articulated limbs, and none possess a head composed of even four modified somites.

Most Annelids are provided with that peculiar system of vessels termed "pseudo-hæmal;" but, in some, that system has not yet been discovered.

In endeavouring to separate from among invertebrated animals a first large group, comparable to the *Vertebrata*, it appears to me that the resemblances between the *Annelida* and the *Arthropoda* outweigh the differences, and that the characters of the nervous system, and the frequently segmented body, with imperfect lateral appendages of the former, necessitate their assemblage with the *Arthropoda* into one great division or "sub-kingdom" of ANNULOSA.

But what of the *Echinodermata* and the *Scolecida*? Should both these great classes be also ranged under the *Annulosa*; or do they belong to different sub-kingdoms; or, if they belong to the same, should they constitute a sub-kingdom of their own?

I will endeavour to reply to these questions in succession. Whether these two groups belong to the *Annulosa* or not, must depend upon whether they possess any characters in common with the *Arthropoda* and *Annelida* other than those which they have in common with all animals. I can find none of any great moment. No Echinoderm or Scolecid has a definitely segmented body or bilaterally disposed successive pairs of appendages. None of these animals has a longitudinal chain of ganglia.

On the other hand, there is much resemblance between the ciliated larvæ of some Scolecids and Echinoderms and those of Annelids; and the form of the body of many Scolecids is so similar to that of one of the most familiar of Annelids, as to have earned for both them and the Annelids the common title of "worms." Nor must it be forgotten that in the Annelids there seem to be representatives of that singular system of vessels which attains so large a development as the "water vascular" apparatus in many Scolecids.

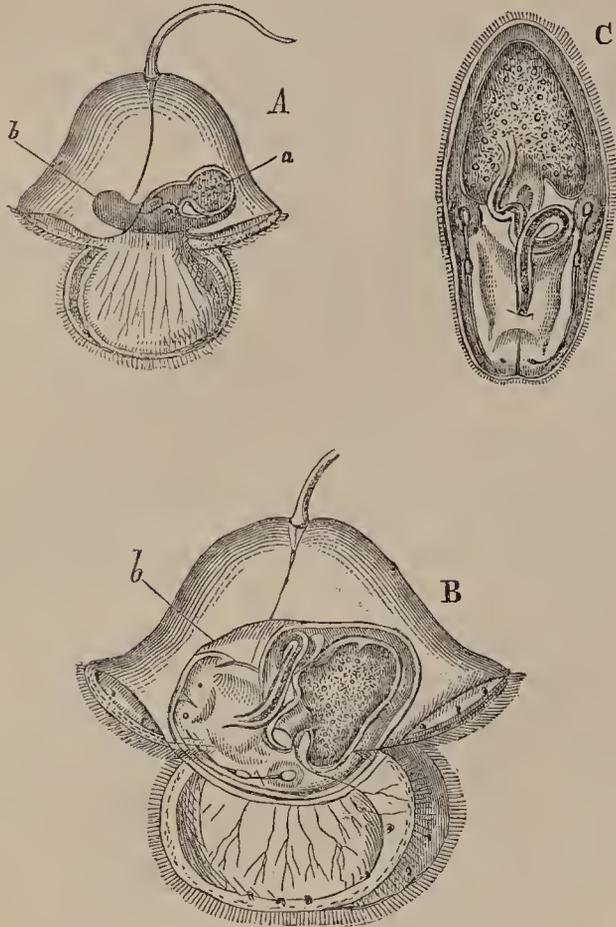

Whatever value may be attached to these resemblances, it must, I think, be admitted that, in the present state of our knowledge, it is impossible to affirm anything absolutely common to, and yet diagnostic of, all Annulosa and all Echinoderms and Scolecids. On the other hand, there can be no doubt as to the many and singular resemblances which unite the Scolecids and the Echinoderms together. The nervous system of the Echinoderm may present considerable differences from that of a Trematode Rotifer, yet, it must be recollected that the comparison is not altogether a fair one, seeing that the mouth and gullet of an Echinoderm, round which its nervous ganglia are arranged, are not, strictly speaking, the same as the parts so named in a Rotifer, but are new developments.

And it is exactly in that anomalous method of development of the Echinoderm within its larva, which is so characteristic of the whole group of *Echinodermata*, that this class exhibits its strong alliance with the *Scolecida*; the *Turbellaria*, and *Tentaculata*, exhibiting the only approach to the method of Echinoderm development known in the Animal Kingdom.

A singular larva studied by Johann Müller, in one of his many fruitful visits to the seashore, and termed by him *Pilidium*, in the hands of subsequent observers, more especially Krohn, Leuckart, and Pagenstecher, has furnished ample

(a) "On the Agamic Reproduction and Morphology of *Aphis*," *Transactions of the Linnean Society*, vol. xxii.

proof that a *Nemertes* (a genus of *Turbellaria*) may be developed in a manner altogether similar to that in which an Echinoderm takes its origin.

*Pilidium Gyraus* (after Leuckart and Pagenstecher.)

A, Young *Pilidium*; a, alimentary canal; b, rudiment of the Nemertid.  
B, *Pilidium* with a more advanced Nemertid.  
C, Newly-freed Nemertid.

The *Pilidium* is a small, helmet-shaped larva, with a long flagellum attached like a plume to the summit of the helmet, the edges and side lobes of which are richly ciliated. A simple alimentary sac opens upon the under surface of the body between the lobes.

In this condition, the larva swims about freely, but, after a while, a mass of formative matter appears upon one side of the alimentary canal, and, elongating gradually, takes on a worm-like figure. Eventually it grows round the alimentary canal, and, appropriating it, detaches itself from the *Pilidium* as a Nemertid—provided with the characteristic proboscis, and the other organs of that group of *Turbellaria*.

Many Trematode, and all Tænioid Scolecida, again, present an essentially similar process of internal gemmation by which either a separate offspring arises, or an adult is developed within an embryonic form; but in those cases that appropriation of the intestine of the primary by that of the secondary form, which renders the ordinary development of the Echinoderm so striking, does not occur.

In discussing the character of the *Echinodermata*, I have described at length the ambulacral system; and, in speaking of the *Scolecida*, I have no less insisted upon the peculiarities of the “water-vascular-system.” But it is impossible to compare these two systems of vessels without being struck by their similarity. Each is a system of canals, opening externally, and ciliated within; and the circumstance that the two apparatuses are turned to different purposes in two distinct groups of the animal kingdom, seems to me no more to militate against their homology, than the respiratory function of the limbs of Phyllopod *Crustacea* militates against the homology of these limbs with the purely locomotive appendages of other *Crustaceans*.

Thus it appears to me that the *Echinodermata* and the *Scolecida* are so closely connected that they can by no means be placed in separate sub-kingdoms, and in the course of studying the other sub-kingdoms it will be quite obvious that, unless they are to occupy an independent position, there is no place for them anywhere, save among the *Annulosa*. I have hitherto been accustomed to consider them, under the name of the *ANNULOIDA*, as a division of this sub-kingdom;

but until some structural character can be discovered by which all the *Annuloida* agree with the *Annulosa*, and differ from other animals, I am much inclined to think it would conduce to the formation of clear conceptions in zoology if the *Annuloida* were regarded as a distinct primary division of the Animal Kingdom.

## LECTURES

ON

## ECZEMA,

(INCLUDING ITS IMPETIGINOUS, LICHENOUS, AND PRURIGINOUS VARIETIES,)

DELIVERED AT THE

Dispensary for Skin Diseases, Glasgow.

By T. McCALL ANDERSON, M.D., F.F.P.S.

Physician to the Dispensary for Skin Diseases; Physician to the Deaf and Dumb Institution, etc., Glasgow.

### LECTURE I. (a)

GENTLEMEN,—It is my intention to enter at some length upon the consideration of eczema; seeing that, in one or other of its protean forms, it is one of those diseases which you will most frequently encounter in practice. It is, at all events, by far the most frequent of the diseases of the skin, of which ample evidence is afforded by the statistics of Devergie. For, of 1800 cases of skin disease, he noted 600 of eczema, or one-third of the whole number. And, as he gives a considerably more restricted application to the term eczema than it is my intention to do, this proportion may be within the mark.

Another reason for fixing your attention upon this disease is, that the views I am about to propound to you—though shared in, in many respects, by my colleague, Dr. Buchanan, and several continental dermatologists, especially by Hebra, of Vienna, who has certainly the credit of being the first to put us upon this track—differ, in many important respects, from those which are adopted and taught by the majority of the Profession in this country.

It has always appeared to me that much confusion exists in the descriptions given of eczema in most standard works upon dermatology, so that I trust you will compare my remarks, not so much with the views you may have already received with regard to it, as with what is observed in nature, for I am desirous that you should follow me without preconceived opinions.

The restricted meaning which is commonly given to the word eczema has arisen, no doubt, from the adoption of the classification of Willan and Bateman, in accordance with which the elementary lesion of eczema is, of necessity, a vesicle. Defective as any classification of skin diseases must be, there can be little doubt that the anatomical classification is the most objectionable of all; for in this way are many dissimilar diseases brought together under one group, and violence is done to the symptomatology of many of them, owing to the necessity of placing them under the head of one of the elementary lesions. Thus, scabies is ranked with eethyma and small-pox—diseases which have no connexion with one another whatever; and the first of these (scabies), though it often shows itself in the pustular form, is still more commonly met with as a vesicular or papular eruption, or as a mixture of all three.

There can be no doubt, in my mind, that the best classification of skin diseases is one founded, not upon the elementary lesion, but upon the nature of the affection. This is the basis of the classification of Hardy, and of that which is adopted, as you are aware, at this Institution. (b)

Now, to return to the subject of eczema, I feel pretty confident that those of you who study this disease carefully at the bedside without bias, will be forced to the following conclusions:—

1. That the elementary lesion of eczema is not of necessity a vesicle.
2. That it may be an erythematous state of the skin, a vesicle, a pustule, a papule, or a fissure.
3. That impetigo, lichen, and prurigo are merely varieties

(a) These Lectures have been carefully revised, and many alterations and additions made.

(b) For a very interesting paper on the “Classification of Diseases of the Skin,” from the pen of my colleague, Dr. A. B. Buchanan, see *Edinburgh Medical Journal*, January, 1863.

of eczema, in which the elementary lesions are respectively pustules and papules.

4. That cases of eczema are often met with in which an erythematous state of the skin, vesicles, pustules, papules, and fissures are met with in a combined form.

To this subject I shall direct your attention more particularly after having brought under your notice the less variable symptoms of eczema.

*Symptoms.*—When an eczematous eruption is at its height there are four symptoms which, according to my experience, are almost always present in a greater or less degree. These are—

1. Infiltration of the skin.
2. Exudation on the surface of the skin.
3. Formation of crusts.
4. Itching.

1. *Infiltration of the Skin.*—The infiltration is due to the transudation of the serous portions of the blood through the walls of the vessels into the meshes of the skin. It is upon the infiltration that the exudation on the surface of the skin, the itching, and the formation of crusts to a great extent depend. Remove the infiltration, and the exudation and formation of crusts usually cease, and the itching is moderated, though it may not cease entirely. The infiltration is detected by pinching up a fold of the affected skin between the finger and thumb, and comparing it with a similar fold of a healthy part. The infiltrated fold is, *cæteris paribus*, much thicker than the healthy one, and, the greater the thickness of the fold, the greater the infiltration, and the more inveterate the affection of the part. It has also a doughy feel, especially if the infiltration be at all great, as compared with the elastic feel of healthy tissue. Again, on pressing an inflamed and infiltrated patch with the finger, the redness disappears for the moment, being replaced, however, by a yellowish colour; whereas, on pressing a patch of simple erythema, in which, of course, scarcely any infiltration exists, the redness is replaced for the time by a healthy white colour. There is always more or less swelling of the affected part, which is principally due to the infiltration, but the swelling is not always in proportion to the amount of the infiltration, being more marked in those situations where there is much loose cellular tissue,—beneath the eyes, for example.

2. *Exudation on the Surface of the Skin.*—The exudation may take place constantly or principally when the circulation is excited, or the part exposed to friction, as when the patient scratches it. The observer must not therefore be led astray by the absence of exudation at the time the part is under inspection, but must always ask the patient if the eruption is ever moist, or, to use expressions in more general use in this part of the country, and especially amongst the poorer classes, if it ever “waters” or “leets.” In a few cases of eczema, however, and particularly of the lichenous forms, there is little, if any, exudation, and consequently there are no crusts throughout the whole course of the disease. The exudation is often of a purulent nature, owing to the rupture of pustules, but more frequently serous, coming from the bottom of fissures, from the surface of excoriations, or from the rupture of vesicles. It is occasionally mixed with blood coming from the bottom of fissures, or from lacerations of the skin produced by the nails of the sufferer. It has the property of staining the under-clothing with which it comes in contact, and of stiffening it as starch does. It may be produced artificially by painting over the eczematous surface a solution of potash (say gr. x. of potassa fusa to the ℥j. of water), which, acting as an irritant, apparently stimulates the capillary circulation of the part, and thereby induces absorption of the fluid infiltrated into the tissues. This must therefore be borne in mind in the treatment of infiltrated eczematous patches, and will be again referred to.

3. *Formation of Crusts.*—The crusts, being composed of concrete exudation and exfoliated epidermis, mingled frequently with sebaceous matter, especially when the eruption is on the head, and with particles of dirt, are more or less present on the surface of every exuding eczematous patch—their size and appearance depending upon the length of time during which they have existed, the quantity and quality of the exudation, and the habits of the patient as regards cleanliness. If the patient be very cleanly, and the exuded matter washed off repeatedly, or removed by means of daily poultices, or if the exudation be very slight, the crusts seen on the affected part at any given time may be very thin, and more like scales than crusts, or they may be wanting altogether.

If the opposite hold, and the patient be negligent, the crusts may become very thick and adherent, owing to continual additions to their under surfaces from successive exudations. Not unfrequently cases are met with in which, though the eczema is quite cured, the crusts remain, owing to the negligence of the patient. This, for instance, is a common case:—A poor woman brings to you her child who has had an eruption on the head for years, and nothing done for it. Lice probably wallow about in all directions, and their nits (eggs) adhere to the hair in profusion, while, scattered over the head, large yellow or brown, thick, adherent, dry, and brittle scabs are detected. The hair is cut short, the nits removed by combing and the use of spirit, the lice killed with staphisagria ointment, and the crusts removed by means of poultices, when healthy skin is found beneath. Crusts of this kind, which owe their existence to a past disease, are much drier and more brittle than recent ones, and, by a little experience, such cases can be detected before the removal of the crusts. The size of the crusts is therefore no criterion of the severity of the disease, unless the patient be under your own eye, and you see the rapidity with which new crusts form after the removal of the old ones.

Crusts due to the desiccation of purulent matter are usually thicker and rougher than those following the exudation of serous fluid. Those forming on hairy parts are, *cæteris paribus*, more apt to assume large dimensions than in situations not provided with hair, as they become glued to the hair, adhere very firmly, frequently cause much pain in the attempt to remove them, and are often concealed in great part by the hair itself. Their colour varies much; if the exudation be serous, the crusts have a greyish or brownish appearance; if purulent, as in the pustular variety of eczema, yellow; if blood be mixed with either of these, any shade of brown or black. These are the colours when the crusts are recently formed, but when of old standing they are altered, from mixture with particles of dust and other impurities.

4. *Itching.*—The itching may be of any degree, and constant or intermittent. It is always aggravated by touching the inflamed part, the slightest touch even sometimes giving rise to an irresistible desire to scratch. It gets troublesome when the circulation in the cutaneous capillaries is excited, as by the use of stimulating food or drink, or on getting warm in bed, thus preventing sleep. It is curious how patients seem to rejoice in the application of severe irritants which relieve the itching at the expense of causing much pain. They seem to derive positive pleasure from scratching the part, and often continue to do so till blood flows freely, and the itching sensation is replaced by pain from the laceration of the skin by the nails. Sometimes, along with the itchy sensation, or, instead of it, formication is complained of; that is, a feeling as if numbers of insects were crawling over the skin. This sensation is very distressing to the patient in severe cases, and I have been consulted by those whose lives were thus rendered burdensome to them, and who wandered about from town to town and from country to country in search of relief. Often, independently of the scratching, pain predominates over the sensation of itching, owing to the presence of deep fissures; and sometimes, instead of pain or itching, burning heat is complained of, especially when the patch is acutely inflamed, and when there is a copious eruption of newly-formed vesicles or pustules. This is another point worthy of recollection, as indicating the employment of emollient applications in the first instance. Scratching always aggravates the disease, and tends to bring out fresh crops of eruption. Patients know this very well, but cannot refrain from indulging in a practice which, for the moment, gives relief. Often, in mild cases, where there is not much infiltration, the disease is kept up by the scratching alone, and, in such cases, by allaying the itching and the desire to scratch by local sedatives alone, I have repeatedly effected a cure, so great a stimulus does the scratching give to the disease.

The elementary lesions encountered in cases of eczema may now be studied at greater length. As I have previously observed, they vary much; hence I have ranked them second in importance to the infiltration, exudation, itching, and formation of crusts—four symptoms which are almost always present to a certain extent in a fully-developed eczema, or in some part of its course. By so doing, the observer is prevented from fixing his attention too much upon the former, and being thus led away from the diagnosis of the case. The elementary lesion is of great importance, however. This may be

1st. An erythematous state of skin.

2nd. A vesicle.

3rd. A pustule.

4th. A papule.

5th. A fissure; or a mixture of several or all of these lesions.

1. *The Elementary Lesion, an Erythematous State of Skin.*

—In this case the disease commences as a simple erythema, which is shortly accompanied by exfoliation of the epidermis, but there is as yet no infiltration of the skin, neither is there any exudation on its surface. The diseased process not being arrested at this stage, infiltration of the affected part gradually supervenes, and the disease is now on the confines of a typical eczema. What have we now? We have patches of reddened, scaly, and infiltrated skin, described under the name of eczema squamosum by Hebra, who points out very correctly that this is identical with what is described in dermatological works as pityriasis rubra,—a term which has been appropriated by Devergie, and adopted by Hebra himself, for the designation of a very different affection. (c) If the inflammation advances still further, serous exudation on the surface of the skin is superadded, which concretes into crusts, and we have now to deal with a typical exuding, infiltrated, and itchy eczematous eruption (eczema erythematodes—so called from the elementary lesion being an erythema), covered more or less with crusts, and without, it may be, the vestige of a vesicle. We may thus regard eczema squamosum as the connecting link between a typical eczema erythematodes and a simple erythema. The eruption is now at its height; but, by-and-by, the infiltration begins to yield, and the disease progresses towards a cure. The exudation diminishes, and gradually ceases, the crusts fall off, the infiltration disappears, and a simple erythema only is left, as at the commencement of the process, with this exception, that the inflammation is not usually so marked. This, likewise, in a varying period of time vanishes, the erythema giving way to healthy skin, or to skin coloured more or less with pigment, which in its turn gradually disappears. You will often have the opportunity at the Dispensary of following the evolution of this form of eczema, such as I have now described it to you. The following case, however, illustrates in some measure what I have just been saying:—“Wm. B., aged 42, weaver, was admitted at the Dispensary for Skin Diseases, March 21, 1861, owing to the outbreak of an eczematous eruption, which had commenced two or three months previously near the left ankle, from which it had gradually extended till the above date, when it covered almost the whole of both legs and inner aspect of thighs, the knees, however, being unaffected. The elementary lesion was an erythematous state of skin, the infiltration of skin considerable, the exudation of serous fluid slight, and the itching excessive at times. The inguinal glands were enlarged from the irritation, and several furunculi were scattered here and there. On each arm, occupying the lower third of upper arms and two-thirds of fore-arms, a bright red, slightly elevated, rough and scaly patch of erythema was detected, which was very itchy, but without any infiltration of the skin to speak of, or exudation on its surface. It is not necessary to follow all the reports of this case, but it is interesting, as showing the identity in nature of the erythematous eruption upon the arms and the eczematous eruption on the legs, to know that at one period the erythema of the arms changed its characters, and became converted into an exuding and infiltrated eczema, and that the same treatment, consisting principally of applications of a solution of black soap and tar rubbed into the parts night and morning and the cold douche, which effected a cure of the typical eczema of those parts, removed also the patches of erythema of others.”

Another typical case of eczema erythematodes, showing the connection between that affection and erythema, will be mentioned when I come to speak of the treatment. In many instances, as I shall afterwards point out, while the disease commences with an erythema, the above evolution is interfered with by the development upon the erythematous ground of one or more of the other elementary lesions enumerated at the commencement, as, for example, by a copious eruption of vesicles; but more of this hereafter. An eczematous eruption sometimes assumes an appearance which may be mentioned here, although the lesion at the commencement of the process is by no means of necessity an erythematous state of skin. In this variety there is usually not a vestige of

either a vesicle, a pustule, or a papule (I speak now of the fully developed eruption), but the skin is red, perfectly smooth on the surface, and brilliantly polished and shining in appearance, while the meshes of the deeper structures of the skin are loaded with infiltration. Every now and then this unhealthy cuticle exfoliates, but leaves behind it a new layer as unhealthy as the one which preceded it. I have noticed this form of eczema especially often upon the legs, and not unfrequently upon the scrotum and ears. When the patient scratches the part, which is usually very itchy, excoriations occur and serum exudes, and often blood; and if the scratching is much indulged in, the eruption of course loses the appearance above described, and becomes covered with excoriations and crusts.

2. *The Elementary Lesion a Vesicle.*—As I have before observed, a vesicle is held, by the followers of Willan, to be the invariable elementary lesion in cases of eczema,—an idea which I have no hesitation in saying has been the foundation of more errors in diagnosis than any other in the whole range of dermatology. For, while a vesicle is frequently, it is by no means always, nor even in the majority of cases, the elementary lesion. The vesicular form of eczema usually commences with an erythematous eruption, and upon this ground vesicles are developed, many of which may assume a pyogenic action, and be converted into pustules, in which case we have an assemblage of three elementary lesions, thus giving the lie to the anatomical classification. The vesicles are developed at the orifices of the cutaneous follicles, are small, closely set together, usually rupture early, and the serosity concretes into crusts. It is a very common occurrence for many of them to run together, separating the corneous from the secretory layer of the epidermis over a considerable extent. In these cases, the corneous layer usually gives way quickly, so that the exudation has not had time to be secreted to such an extent as to raise the cuticle much higher than the height of an ordinary vesicle; but, where the corneous layer is very thick, as on the soles of the feet and palms of the hands, it does not give way readily; the secretion of serum goes on increasing, and large bullæ may be formed,—a circumstance which requires to be borne in mind, else the observer may fall into an error of diagnosis which I shall refer to afterwards. Although the vesicles do not usually remain long intact, the vesicular stage may be kept up by the formation of successive crops of vesicles, but, even in this case, they usually disappear after infiltration of the skin becomes pronounced and the disease thoroughly established. When the vesicular stage is gone, and the disease is at its height, it will be well for you to study carefully the appearance of the affected part in the cases which come under your observation. The infiltrated patches are red and inflamed, but the redness is not uniform, being studded with innumerable points of a deeper red, thus giving to the parts a remarkable punctated appearance,—an appearance which, when well marked, serves to distinguish the eczematous eruption from all other diseases of the skin, and which Devergie claims to have been the first to describe. These points correspond to the orifices of the glands, like the vesicles which preceded them; they are owing to the congestion of the skin being more pronounced at the glandular orifices than elsewhere, and to the occurrence of minute excoriations—the result of rupture of the vesicles. It is principally from these that the serous fluid exudes, often in great abundance, and which afterwards concretes into scabs. This stage of eczema corresponds to the eczema rubrum of some authors, the eczema madidans of others. Devergie points out that the punctated appearance, when not well marked, may be brought out more characteristically by rubbing firmly into the affected part a solution of carbonate of potash in water.

3. *The Elementary Lesion a Pustule.*—This is the so-called impetigo of authors (a convenient word to retain, as expressive of the pustular form of eczema), which should on no account be ranked as a separate disease. The pustules, like the vesicles, usually form upon an erythematous ground, but, as I have before observed, their formation is sometimes secondary, vesicles being at first developed, the contents of which gradually change from serum into pus. The pustules are often somewhat larger than the vesicles, and remain longer intact; otherwise, the pustular form of eczema runs exactly the same course as the vesicular, and, when the pustular stage is gone, and the crusts removed, we observe the same punctated, exuding, itchy, and infiltrated patches, the description of which it is unnecessary to repeat. The pustular

(c) “*Traité Pratique des Maladies de la Peau.*” Par Alph. Devergie. Ed. II., p. 442.

variety of eczema occurs oftenest on hairy parts at the orifices of the hair-follicles, as, for instance, on the head and chin, constituting cases of the so-called impetigo capitis and impetigo menti. Physicians in this country, following in the footsteps of Willan, have not yet been induced to regard impetigo as a mere variety of eczema,—a point which is generally conceded by both French and German dermatologists; but they are, as a rule, far too good observers not to have noticed a mixture of vesicles and pustules on many patches of eczema, and a frequent transformation of vesicles into pustules; hence the origin and meaning of the term eczema impetiginodes.

4. *The Elementary Lesion a Papule.*—This form of eczema is described as a separate disease by most authors under the name of lichen—a name which it is well to retain, as designating an eczema the elementary lesion of which is a papule. But a careful study of this affection has led me to the opinion that it would be doing violence to the natural affinities of lichen to look upon it in any other light than as a mere variety of eczema. The eruption commences in the form of small, red papulæ, which may be isolated one from the other, and scattered here and there (*lichen disseminatus*) or confluent, forming elevated, rough, and furrowed patches of various shapes and sizes, in which, owing to the coalescence of the papules, the elementary lesion is sometimes difficult to establish, and all the more so as vesicles and pustules are not unfrequently developed during the course of the disease. The affected part is very itchy, and, as the patient scratches it incessantly, the symptoms are aggravated; infiltration of the skin becomes very marked, and exudation of serum, pure, or mixed with pus or blood, takes place, which concretes into crusts. While English and French writers, with a unanimity which is quite extraordinary, describe lichen as a separate disease from eczema, few of them have failed to observe cases of the former in which the likeness to eczema is so great, that they have given to them the name of lichen eczematousus, or eczema lichenoides (synonymous with the term lichen agrius). But let us take a short description of this eruption from one of the standard authors. Hardy, for example, than whom a more accurate observer does not exist, writes of it thus:—"The skin becomes red, and upon this red surface small papules make their appearance, which become excoriated, and secrete a serous fluid in considerable abundance. Amongst these papules some vesicles of eczema are detected, which give way, and are followed by superficial ulcerations, from which serum exudes and concretes into crusts. From this mixture of vesicles and papules there results a state of parts which has as much the appearance of an eczema as a lichen, and which throws great difficulty in the way of a correct diagnosis. (d) Now, what have we here? We have a most accurate description of a typical exuding eczema, the only difference between it and the vesicular eczema of Willan being, that the principal lesion is a solid elevation (a papule), instead of one filled with serosity (a vesicle). I hope I have convinced you, then, that an eczema lichenoides is a true eczema, and not a separate disease; and, if so, let me finally point out to you that the dry lichen of authors is merely a less advanced stage of eczema lichenoides. The following case—and you will meet with many such—shows that, under the influence of treatment, eczema lichenoides may assume all the characters of the typical dry lichen of authors:—

"Catherine B., aged 14, was admitted at the Dispensary for Skin Diseases, September 30, 1861, affected with eczema lichenoides of a year and a-half's duration, occupying both popliteal spaces, and extending upwards for some way upon the posterior surfaces of the thighs. The patches were moist and distinctly papulated; considerable infiltration was detected; the itching was severe at times, and serous fluid exuded on scratching. There was an enlarged gland on the side of the neck. Cod-liver oil was prescribed internally; a solution of black soap was rubbed into the parts night and morning, and whenever the eruption was itchy, and the local cold douche was applied repeatedly. On October 10, ten days after the commencement of the treatment, the serous exudation had ceased, and the eruption now presented all the characters of a typical lichen as described in dermatological works. The patches were dry, rough, papulated, and the natural furrows of the skin greatly exaggerated. The infiltration of the skin and the itching, though moderated by the treatment, still continued."

(d) "Leçons sur les Maladies de la Peau," par le Docteur Hardy. Première partie. Ed. II., p. 88.

But it may be said that lichen is occasionally a perfectly dry eruption throughout its whole course. Granted, although this is the exception to the rule; but it is merely because the inflammatory process has been arrested short of the exudation stage. Cases such as these must be put upon a par with cases of vesicular eczema in which the vesicles do not burst, but become shrivelled and dry up, and in which the eruption subsides without the occurrence of exudation. It must be allowed, however, that in the lichenous varieties of eczema exudation is more frequently wanting than in the vesicular, but this, combined with the fact of the elementary lesion being a solid elevation, instead of one containing serum, is not enough to constitute a separate disease, as the eruption otherwise follows essentially the same course, and is amenable to the same treatment.

There is another variety of papulated eruption to which it is necessary to direct your attention for a few moments, one which is described in all dermatological works with which I am acquainted as a separate disease altogether, under the name of prurigo, but which is merely a variety of lichen, and consequently of eczema. This is an eruption of papulæ scattered over the skin, and identical with the papulæ of lichen, notwithstanding that most writers try to establish differences between them in point of size, colour, etc. Now, if the patient is harassed with itching, and scratches himself much, the summits of the papulæ, being torn by the nails, become covered with yellowish or blackish crusts, owing to the exudation of serum or of blood. In addition to this, red and excoriated streaks and lines covered with coagulated blood are detected here and there upon the skin, being likewise produced by the nails of the patient. This is the so-called prurigo. But if the sensation of itching is not so severe, or if the patient refrains from scratching, these lacerations are not to be seen, and the eruption is one of lichen (*lichen disseminatus*). To be more plain, the difference between a lichen and a prurigo is, that in the latter the patient scratches the eruption more than in the former, and consequently produces abrasions of the skin. This is surely not sufficient to separate prurigo from eczema, although the word prurigo may be retained to indicate this form of eczema. You will find it noted in books that in prurigo the cutaneous envelope is thickened and becomes darker in colour, owing to an excessive deposit of pigment, but you will find that this is one of the features of all long-standing cases of eczema, no matter what the form or what the elementary lesion, as it is due to the continued irritation and congestion of the skin.

The pruriginous form of eczema occurs more or less in all chronic cases of scabies and phtheiriasis—the diseases due to the presence of the itch-insect(e) and the louse respectively—and often in cases of urticaria; and I believe implicitly that a great many cases have been set down as instances of simple prurigo, when a more careful examination would have proved them to be pruriginous eruptions called out by the scratching induced by the presence of the itch-insect, or louse, or by the occurrence of an attack of urticaria.

And, lastly, you will often find the pruriginous form of eczema on one part of the body, and one or more of the other varieties of eczema on others, and in no instances more frequently than in cases of scabies.

## ORIGINAL COMMUNICATIONS.

### ON THE STUDY OF THE CIRCULATION OF THE BLOOD.

[Being a Paper read before the Physiological Section of the British Association for the Advancement of Science, October, 1862.]

By GEORGE ROBINSON, M.D.

Fellow of the Royal College of Physicians of London; late Lecturer on the Practice of Physic in the Newcastle-on-Tyne College of Medicine, etc.

It is now more than two hundred years since Harvey's great discovery was given to the world, with a distinct intimation on his part that, having established the vital law of the blood's incessant motion in a definite course, he left the innumerable problems connected with its mode of action in inducing the other phenomena of life to be investigated by posterity. The labour of each succeeding generation has collected additional proof,

(e) For a detailed description of these diseases see my work on the "Parasitic Affections of the Skin," pp. 104 to 145. London: Churchill and Sons. 1861.

were proof wanting, of the correctness of his opinion as to the dependence of all secondary functions on this great instrument of vitality; and at the present time we know that not only the actions of animal life, but the functions of the nervous system, and the operations of the mind itself, all depend on the general permeation of the tissues of the body by streams of its vitalising fluid. But, while fully recognising the value of the knowledge thus obtained, it is surely not altogether creditable either to English patriotism or English science that, notwithstanding the enormous advances since made in every department of natural philosophy, and the corresponding increase in the facilities for prosecuting physico-vital researches, so little has been done towards elucidating the manner in which the blood's motion acts in the production of its numerous and diversified effects. Nor should we, as Medical Practitioners, be content to regard as wholly unintelligible mysteries a series of actions and relations not only of the greatest interest in connexion with the healthy phenomena of life, but which also play a most important part in the production and removal of disease. An investigation of this extensive and important field of inquiry is therefore in every respect desirable, but as it is still surrounded by certain obstacles which have long interfered with the successful prosecution of these researches, and as that success will most certainly and rapidly be obtained by the combined efforts of men familiar with different departments of natural knowledge, I have ventured to submit to the assembled representatives of British science a few considerations and suggestions on this subject.

Much has been said and written on the hostile reception of Harvey's doctrines by his contemporaries, and it is generally assumed in a congratulatory spirit that prejudices such as he had to encounter are no longer extant among us. But with every allowance for the immense progress since made in the tolerance of differences of opinion, and the general desire now felt to make truth itself the sole test and turning point of all philosophical inquiries, I cannot but perceive even in the present day some indications of that preference of the ideal to the real, the imaginative to the demonstrative, the assumed to the existent, which led our predecessors to cling so obstinately to the unmeaning jargon of a metaphysical physiology in the face of Harvey's simple intelligible exposition of a vital mechanism and action, a natural cause and effect. To the refined ears of his contemporaries, fully satisfied with their own descriptions of invisible currents of invisible animal spirits, his reduction of the heart to a mere force-pump, and his reasoning on the hydraulic uses of the valves of the blood-vessels must indeed have sounded very harshly, and from the general neglect of natural philosophy as a part of Medical education—a neglect still too prevalent—we can perhaps scarcely wonder that his views respecting the circulation should have appeared too gross for the purposes of so sensitive and elaborate an organism as the human body. But have we never in our own time heard doubts originating in a too exclusive study of the lowest forms of animal life, as to the sufficiency of the heart for the uses which it was evidently intended to serve, or assumptions of mysterious attractions and repulsions which are supposed to supplement if not to supersede the simple instrument of Nature's choice in maintaining the incessant motion of the blood? And is there not a general belief, not only among the great mass of Medical Practitioners, but even among some of the cultivators and teachers of the Medical art, that the physics of the circulation constitute only a problem of abstract science, of remote interest even to the physiologist, but wholly devoid of utility as regards the objects of practical Medicine, and, therefore, if studied at all, forming a province of inquiry adapted rather to the natural philosopher and engineer than to the Physician?

That I have not exaggerated this disinclination to investigate the physical phenomena attendant on the blood's motion is illustrated by my own experience. It is now nearly twenty years since I first published the results of some attempts to apply the principles of hydraulics to the explanation of the mechanism of vascular effusion and absorption, and though those views have never been refuted, and the received laws of endosmosis and exosmosis are evidently only applicable to stagnant liquids, and are quite incapable of accounting for the occasionally rapid passage of fluids into and out of the blood-vessels of the living body, I still find in most of the systematic works on physiology a mere repetition of old, and but partially correct doctrines on this subject, instead of a full discussion of controverted points, and a judicious use of the laws of physical science in elucidating the phenomena connected with

the circulation of the blood. But on what other principle of research than that adopted by Harvey himself can we ever hope to obtain the desired knowledge? The laws of optics and acoustics alone enable us to understand and appreciate the exquisite mechanism and arrangements of the eye and ear. The structural peculiarities of the organs of respiration, speech, motion, etc., are all subservient to, and designed in the strictest accordance with, the general principles of physics involved in each particular function. And why should the *modus operandi* of the blood-currents alone be considered an exception to that beautiful harmony of Nature which connects by one universal code of laws the living and inanimate forms of matter, accomplishing in this instance by one of the most simple and universally diffused of all natural forces those subtle changes and rapid alternations of action which invest the circulation of the blood with some of the most recondite and imposing attributes of life?

It is only requisite that the principles of hydraulics be themselves first clearly understood, and that their application be in every case rigidly regulated, modified, and controlled by a careful study and close observance of the physical and vital conditions and peculiarities of the vascular and other structures, and we may then confidently hope that some of the appreciable effects resulting from the wonderful arrangement of blood-currents in the living body will ultimately be traced to their immediate causes, and so be rendered more available for the relief of human suffering. Such labours, judiciously and perseveringly directed, could not fail to give an impulse to physiological and pathological studies that would react most beneficially on practical medicine. And in no place could such an effort be more auspiciously inaugurated than in the University of Cambridge, itself a cradle of British physical science, and which shares with its sister University the honour of an academic connexion with our immortal countryman. I therefore most respectfully venture to submit to the Council of the British Association for the Advancement of Science the propriety of appointing a sub-committee to co-operate in any way that may be thought desirable with the Royal College of Physicians of London (which is in a special degree interested in the full development of Harvey's discovery and in everything connected with his fame) for the purpose of investigating the physics of the circulation, and so rendering more intelligible the connexion existing in the living body between the motion of the blood and the performance of the secondary functions of life.

## CLINICAL MIDWIFERY.

By FRANCIS H. RAMSBOTHAM, M.D.

Physician-Accoucheur to the London Hospital, etc.

(Continued from page 369.)

It occurred to me to see the following seven cases of dangerous or severe laceration in labour during the five years between January 1, 1840, and December 31, 1844:—

### *Ruptured Uterus.*

*Case 195.*—On October 23, 1840, at 1 a.m., a Medical friend sent for me to Mrs. F., living in Finsbury, in labour of her second child. She had been delivered of her first by craniotomy, by a well-known Professor of Midwifery, and consulted me on the 21st as to the propriety of having labour brought on prematurely. On careful examination of the pelvis internally, I came to the conclusion that from the promontory of the sacrum to the pubes there was not more space than two inches and three-quarters; and, as she thought herself nearly eight months advanced in pregnancy, I advised that no time should be lost in an attempt to anticipate her proper period; she therefore began to take some infusion of fresh ergot the next morning. She took four doses, one every four hours. She began to feel labour pains after the second dose, and at 9 p.m. the membranes broke spontaneously. Her Medical attendant was called at 10.30 p.m. The os uteri was then almost entirely dilated, and the pains were frequent and naturally strong. Labour went on very well till 12.30, when, without any warning, in the *aemé* of a pain, the uterus ruptured itself transversely in the anterior part of the neck. She immediately cried out that something had given way within her; the usual symptoms of lacerated uterus showed themselves, and the head, which had engaged somewhat in the brim, receded. My friend discovering immediately what had happened, sent for me, and at once proceeded to deliver

by turning. When I arrived, I found he had got one foot down, but he could not extract the breech. With some difficulty I got the breech down, and the arms and shoulders; but the head would not pass, and I was compelled to perforate it behind an ear, and evacuate a part of the brain before it would escape. I was obliged to introduce my hand for the placenta, and felt the rent distinctly. The woman rallied somewhat after delivery; but soon flagged again, and she died on the 27th. On a post-mortem examination, we found the conjugate diameter of the pelvis measured exactly two inches and three-quarters, and the interior edge of both the pubic bones at the pelvic brim were quite sharp; on the right side, so much so as to pain the finger considerably when pressed hard against the part. There is no doubt that this sharp ridge had predisposed the uterus to lacerate; because by resting upon it, as it must have done during pregnancy, inflammation and softening of the substance, and perhaps thinning, must have taken place, which would so weaken the texture of the organ as to render it incapable of withstanding the powerful strain upon it during the tension of the uterine contractions. Denman indeed says that "the uterus may be worn through mechanically, in long and severe labours, by pressure and attrition between the head of a child and the projecting bones of a distorted pelvis; especially if they be drawn into points or a sharp edge."

#### *Ruptured Uterus.*

*Case 196.*—On November 16, 1840, at 8 a.m., I was requested by a Professional friend to see Mrs. H., living in Doctors' Commons, in labour of her sixth child. Her pelvis was narrow, and she had always suffered lingering labours. The labour progressed very favourably till twelve o'clock at night, when she was suddenly seized with a violent constant pain at the lower part of the abdomen, superseding the pains of labour, which entirely disappeared. I found her under a state of extreme depression, with great abdominal tenderness; there had been more external hæmorrhage than is usual in these cases; she had been vomiting a dark, coffee-ground-like matter, and was affected with painful hiccough. I could feel the child's head easily through the parietes of the abdomen, but no part *per vaginam*. There was a large rent evident to the touch at the back part of the cervix uteri, through which the child and placenta had both passed into the abdominal cavity. I carried my hand, without increasing the rent, easily into the abdomen, and found the feet lying against the diaphragm. Taking hold of them, I first extracted the fœtus without any difficulty, and then the placenta. I thought she would die speedily; but by the aid of opium and stimulants she rallied wonderfully, and lived more than nine days.

#### *Ruptured Uterus under Abortion—Recovery.*

*Case 197.*—On December 20, 1843, I was sent for by one of the district Surgeons to the Royal Maternity Charity to Mrs. W., Shoreditch. She had flooded more or less for fourteen weeks; and very considerably for some days. She considered herself seven or eight months advanced in pregnancy. I found my friend had just removed from the uterus a blighted ovum larger than a man's fist. The flooding ceased directly it was taken away, but the reason for my friend wishing me to see the case was that he felt what he considered to be a transverse rupture of the anterior part of the cervix uteri. I detected one most clearly, extending nearly across the whole front, and I could feel the posterior wall of the bladder through it distinctly. It appeared to me that the peritoneum was not implicated, yet how it occurred was a mystery. It is scarcely possible that both my friend, who is a highly practical as well as scientific man, and myself should be deceived. We each made a most careful examination, as it is natural we should under the circumstances, and neither of us had the least doubt of its nature. The woman had some pain and fever after, but she eventually recovered well. This case puzzled me a good deal: we could hardly expect that however much softened by disease the structure of the uterus might be, it would burst in expelling an ovum of the size mentioned; but we meet sometimes with perplexing cases in midwifery, for example:—Some years ago my father had sent to him from the country an uterus and ovum of about six months' development. The os uteri was thick and dilated only to the size of a sixpenny-piece, and the ovum had escaped entire, the membranes being still whole, through a rent in the cervix into the abdominal cavity. It is scarcely to be believed that the uterus would lacerate its structure while the membranes of the ovum were unbroken, yet so it was in this case.

He intrusted the preparation to one of the officials at the Hospital for preservation, but it was unfortunately allowed to spoil. My father has recorded this case, the 84th, part 1st of the first edition of his "Observations in Midwifery."

#### *Burst Perineum.*

*Case 198.*—On June 3, 1841, at 11.30 p.m., a Professional friend sent for me to Mrs. H., a publican's wife, in Tooley-street, aged 48, in labour of her first child. The membranes broke on the morning of the 1st, but there was but little or no uterine action till the morning of the 3rd. The labour went on slowly, as might have been expected; and the head was on the perineum, which was very rigid, at 7 p.m. It began to thin first towards the anus, while the anterior part was very thick; and in the *acmé* of a strong pain, while he had his hand on the part, he observed it give way close to the anus, leaving the fourchette entire. The vertex, which was somewhat protruded between the labia, receded, and passed through the new opening. The child was dead, and the skull very compressible. I arrived ten minutes after the child was born, and found the funis hanging out of the new opening. I passed it through the vulva, and brought the placenta away. I found a laceration about two inches long occupying nearly the whole of the perineum. Both the rectum and the fourchette were uninjured; the part of the perineum which remained entire was the anterior portion, about three-fourths of an inch in extent. I passed my finger through the opening in the perineum and out at the vulva, so that there could be no mistake. An opiate was given and a poultice applied. Next day she had slept well and passed urine. On the 7th the edges were slightly sloughy, the bowels had acted freely, and the motions had been retained voluntarily. The slough soon separated, healthy granulations sprang up, adhesion of the sides took place, and by degrees the part entirely healed. I do not know whether she became pregnant after.

#### *Burst Perineum.*

*Case 199.*—On April 7, 1842, at 7 p.m., I was sent for by a Medical friend to Mrs. B., Stepney, aged 22. She had been delivered of her first child at 4 p.m. The membranes broke early in the labour, which had been lingering. While the head was on the perineum it pressed very much back towards the anus, and, fearing the perineum would burst, he called in a neighbouring Practitioner. They were both using their best efforts to preserve the parts from injury, and, while he had his hand on the perineum, he felt that a transverse slit took place near the anus. The head passed through the vulva, but directly it was born a shoulder and elbow came through the perineum. He pushed the arm upwards and forwards, and directed it through the vulva. I found a jagged laceration in the perineum, about two inches in length, extending from the sphincter to within half an inch of the fourchette. The fourchette was entire; the sphincter was partly torn. I put in two sutures, directed the bowels to be kept in a confined state for a week, and the catheter to be used twice a-day, but they sloughed out, and a large portion of the perineum also. On the 13th, the slough which appeared on the edges of the laceration began to separate, as well as those occasioned by the sutures. No fæces ever passed through the opening, but there was always a small portion on the poultice. The sphincter had a moderately retaining power; the general health was tolerably good. The part completely healed, and the aperture perfectly closed in three months, but the vagina remained much contracted. She got quite well, and, as soon as she could be moved, went into the country.

#### *Burst Perineum—Twins.*

*Case 200.*—On July 20, 1843, at 4 a.m., I was sent for to Mrs. S., Islington, whom I was engaged to attend. It was her second labour. The first was very lingering, owing to the tuberosities of the ischia approaching too near each other, and thus contracting the pubic arch. The infant was born dead, and a considerable sloughing of the posterior face of the vagina took place, for which I was consulted. This healed with an extensive cicatrix. In her second pregnancy she was placed under my care, as her first attendant, being a relative, did not wish to take charge of her. The first part of the second labour went on very well, though slowly; and about six hours after the membranes broke, the head was in the pelvis, with the face forwards. I could then feel both the eyes and the nose distinctly, and with each pain

the head was being pressed strongly against the band formed by the cicatrix, which appeared to be relaxing. I expected it would become a complete face case; but the vertex was directed downwards, and the forehead remained behind the pubes. After I had continued to support the perineum uninterruptedly for two hours, the band at that time having become much relaxed, the pains being very strong, and the head being so far protruded that the anterior fontanelle was external, I felt the perineum near the anus become suddenly thinned; it burst, the head receded from the vulva, and made its escape through the laceration. The body instantaneously followed. Having separated the child, I detected another presenting by the feet. The membranes almost immediately broke, and the feet came through the same aperture. I extracted the trunk and head as carefully as I could. Both children were living. The placenta were protruded into the vagina; and fearing to run the risk of increasing the laceration, I passed both funes through the vulva, intending to extract them that way. The constriction, however, was so great, that I could not bring them through it; I was therefore obliged to direct the funes back again through the newly-made opening, when, applying a slight degree of traction, I delivered them without difficulty. The portion of the perineum near the fourchette left entire was about an inch in extent. The sphincter was uninjured, and the motions were always retained at will. A poultice was applied; the urine for some days removed by catheter, and the ordinary Surgical appliances had recourse to. On the fourth day the lacerated surfaces were in a sloughy state; the slough separated kindly; healthy granulations sprung up; the perineum puckered considerably; no adhesion took place, but cicatrisation commenced at the edges. It was now evident that union of the two granulating surfaces would not take place, and in consultation with a Hospital Surgeon the frænum was divided. The healing process went on very favourably, and in eight weeks from her confinement she might be considered well. The entrance of the vagina was of course much enlarged; but she experienced no inconvenience either from pressure on the part in sitting or from prolapsed uterus. Unfortunately, in the course of a few months, unequivocal symptoms of incipient phthisis showed themselves, and I sent her to live at Ventnor. She had no other child; but while at Ventnor, in 1845, I was sent for to see her under a miscarriage; and she died in the latter part of that year of the pulmonary disease.

*Laceration of the Left Labium in Labour.*

Case 201.—On April 30, 1842, at 11.30 p.m., I was requested by one of the district Surgeons to the Royal Maternity Charity to visit Mrs. C., in the Hackney-road, one of the patients, who had been delivered by a midwife of her first child at 5 p.m. I found her in great agony from a swelling of the left labium, which was larger than a man's doubled fist, and livid. On the inside there was a longitudinal laceration of two inches in length, and the whole labium was filled by a firm, dark coagulum, infiltrated into its cellular structure. She had lost a great quantity of blood from the part, and had fainted, and a draining of blood was still going on. I removed a coagulum sufficiently large to fill an ordinary breakfast cup. The bleeding and pain both immediately ceased. A poultice was applied. On the fourth day, after the swelling and blackness had entirely disappeared, suppuration was commencing, and in a little more than a fortnight the cavity was filled up and the part was healed.

8, Portman-square.

(To be continued.)

CASE OF  
ABSCESS OF THE SPLEEN, DISCHARGED  
INTO THE LEFT LUNG.

By A. A. MANTELL, M.D.,  
Bengal Medical Service.

J. D., a European, and father of five healthy children, aged 62, and perfectly grey, was placed under my care on January 31 of the current year. He had just arrived in a boat from the coast, where he was employed by Government as a superintendent of a lighthouse. He was accompanied by his wife, who gave the following history of his case:—

She stated that during their thirty-seven years of married

life he had always been a strong, healthy man; that as a pilot he had seen much service, and that for many years he had been a very free liver, his favourite drink being rum. He had not been subject to fever, but had had a slight attack of ague before his present illness set in. As far as she could recollect, he had never had any affection of the chest, nor had he ever complained of pains in the loins or abdomen. His appetite was always good, and his bowels invariably regular. His present illness commenced five months ago with sore throat and difficulty in swallowing; he also complained of pain in the right side of his neck.

The soreness of the throat and difficulty of swallowing continued to increase, and on December 31 last he became much worse; on the following day he was unable to masticate his food, and his speech became thick. During the whole of this period his general health was good, but he was unable to take food in the solid form.

On January 25 he coughed up some dark-coloured blood and matter of a very offensive character. From this time his breathing became difficult, a hacking cough set in, and he daily expectorated small quantities of blood and matter.

On the evening of the 30th he was still worse, expectorating large quantities of the same kind of discharge, and unable to lie horizontally, in consequence of the extreme dyspnoea. During this night he had no sleep, and his wife did not expect him to live till morning.

I saw him for the first time on the following afternoon; he was sitting in a bent posture; his countenance was dusky, and his lips livid; he was at times delirious, and breathing with much noise and difficulty; he had a slight but frequent cough, and with it expectorated an offensive sanguineo-purulent fluid, of a dark brick colour.

He was free from fever, and had a tolerably strong pulse of 84. His tongue was clean; he complained only of his throat, and pointed to it as the seat of pain; nothing, however, abnormal could be felt externally, or seen internally; there was partial paralysis of his tongue, which rendered his speech thick, and difficult to be understood. His lungs gave no evidence of disease—resonance was good on percussion, and the only abnormal sound present was a mucous râle. No enlargement of the liver or spleen could be detected; and he did not complain of pain when his abdomen was examined by pressure and percussion. Ordered nourishing diet constantly, and a stimulant mixture.

February 1.—He has passed a restless night, especially the early part of it. At times he was delirious, and on several occasions it was feared he would be suffocated by the accumulation in his chest. This morning he appears somewhat better; there is less delirium; his respiration is not so noisy; and the expectoration has somewhat abated; his pulse is 86, and firm; he walks about the room occasionally, in spite of orders to remain quiet, and once nearly fainted in consequence of the exertion. He passed urine once during the night; it was clear, and of a natural colour. His bowels not having been relieved for two days, he was ordered an aperient draught.

2nd.—He appears much better this morning, as he has slept the greater part of the night; his pulse is still 86, and of the same character. He can now lie in the horizontal position without much distress. From his improved condition prognosis more favourable. 2 p.m.—At this hour I was summoned suddenly to see him, and on arrival found that alarming hæmoptysis had set in; he had coughed up half a pint of pure blood. Nothing stopped the hæmorrhage, and in about twenty minutes he died.

*Inspection Twenty-one Hours after Death.*—Body pale, but well nourished considering his age. Brain not examined. On removing the trachea, pharynx, etc., the greater cornu of the hyoid bone of the right side was found in a state of caries, and the diseased part was surrounded by a small abscess, which had apparently burst into the upper part of the pharynx. The apex of the right lung was slightly adherent, and the bases of both lungs were firmly adherent to the diaphragm, especially the left; their structure was healthy, but engorged with frothy blood and serum. Heart natural, with empty cavities. Liver smaller than usual, gall-bladder containing greenish bile, and one large black calculus. On endeavouring to remove the spleen, it was found adherent to the diaphragm, and so soft and pulpy that it broke to pieces under very slight pressure of the fingers; the cause of this was an abscess which occupied its structure, and was now nearly empty; the walls of it were thin, and what remained of the parenchyma was infiltrated with fetid matter and blood

of a brick-red colour, similar to that which had been expectorated during life. The abscess had burst into the left lung, a communication being established between it and the spleen. The fatal hæmorrhage was due to rupture of a branch of the left pulmonary artery. The left kidney was hypertrophied, and the right contained an abscess the size of a hen's egg, filled with yellow matter. The stomach was lined with a thin layer of coagulated blood, which had been swallowed during the fatal attack of hæmoptysis. The other viscera were healthy.

*Remarks.*—In remarking upon this case, I may start by saying that its nature was not suspected during life, nor was there a single diagnostic symptom present. That an abscess had communicated with the trachea, bronchi, or lungs, there could be no doubt, but its situation was not ascertainable. The disease of the os hyoides gave rise to the only symptoms complained of by the patient, viz., pain in the neck, and difficulty of mastication and deglutition, resulting, as they must have done, from irritation or destruction of the right hypoglossal nerve. The history of the case from the beginning in no way elucidated the disease; there had been no antecedent periodic fever of any severity or duration, nor had there been any symptoms of acute or chronic splenitis. The slight attack of ague, spoken of by his wife as having occurred before his present illness, was probably a shivering fit, happening at the suppurative period, but whether this was indicative of matter forming in the spleen, kidney, or throat, it is impossible to say. In consequence of the rarity of this affection, little has been written concerning it. Abercrombie mentions in his work on "Diseases of the Stomach and other Viscera of the Abdomen," that he never saw but one case of splenic abscess, and that its nature was not detected during life; in it the only symptoms were emaciation and debility, and after death the kidneys were found diseased. He records cases met with by others in which the abscess had burst twice into the colon, once into the cavity of the abdomen, once into the stomach, once at the umbilicus, and once after a blow received in the left side, which was followed by the subsidence of the tumour, and a discharge of thick and fetid matter with the urine. Dr. Morehead, in his excellent "Clinical Researches on Disease in India," published in 1856, states that he had never seen a case of abscess of the spleen. In Copeland's "Medical Dictionary" I find the following remarks upon the disease:—"Abscess of the spleen is generally, but not necessarily fatal: some cases of recovery said to have taken place are not very conclusive. The diagnosis appears to be always difficult." Dr. Nasse, of Bonn, has recorded the history of a case in which the matter made its way from the spleen through the diaphragm into the lung, and was expectorated in great quantities, the patient afterwards recovering. As abscess of the spleen is comparatively rare, such cases must necessarily be much more so; but there is no reason wherefore abscess in this organ should be less likely to be recovered from than abscess of the liver. Rokitsansky observes, that, in a favourable case, the abscess may be circumscribed by adhesive inflammation, and, being inclosed in a sac formed by obliterated parenchyma, which has been converted into fibrous tissue, may be borne for a long period; a partial absorption of the pus may take place, and, the remainder becoming inspissated, be reduced to a calcareous, greasy pulp, or even to a hard concretion. The more common termination of this disease is for the parietes of the abscess to put on inflammatory action and suppuration, by which the matter is discharged into an adjoining organ or part.

Cuttack, Bengal.

## REPORTS OF HOSPITAL PRACTICE

### IN MEDICINE AND SURGERY.

#### THE LONDON HOSPITAL.

##### THREE CASES OF INTESTINAL OBSTRUCTION.

[Communicated by Mr. POWELL, M.B. Lond., Resident Medical Officer and Registrar.]

*Case 1.*—*Sudden Pain in the Abdomen—Vomiting—Constipation—Suppression of Urine—Death on the Eighth Day—Autopsy—Constriction of Jejunum.*

H. H., aged 25, a bootmaker by trade, was admitted November 3, 1862; under the care of Dr. Little.

The patient, a spare-made man, presenting the usual cachectic appearance of his class, stated that he had always enjoyed fair health until about four years ago, when he was laid up by an attack of "inflammation of the bowels." During this illness he was unable to bear the slightest pressure on his abdomen, the bowels were not open for four or five days, and he suffered much from nausea and occasional vomiting. He was confined to bed for a month, but gradually regained his previous standard of health, and considered himself "as well as ever."

On the Wednesday previous to his admission, shortly after partaking of a hearty meal, he was seized with sudden pain in the belly, inducing a feeling of faintness and great depression. These symptoms were quickly followed by nausea and vomiting, the ejected matters consisting at first of half-digested food, and subsequently of a thin green fluid. The bowels had acted a short time before the commencement of the attack, but not since. He had noticed that he passed less water than usual. He remained under treatment at home, gradually getting worse until the following Monday, when he applied to the Hospital for advice.

When admitted he was in a state of great prostration, with feeble pulse, cold extremities, sunken and anxious countenance. Complained of great pain in the abdomen, which he was unable to refer to any particular spot, and which was not increased by pressure. Felt very sick, and shortly after admission vomited a quantity of dark-green fluid. The surface of the abdomen was flat and symmetrical, and no information was afforded by a physical examination. He was ordered warmth to the extremities, and injections of beef-tea, brandy, and laudanum. In the course of a few hours he had rallied considerably, and on the following morning expressed himself as being in less pain. He had been sick at intervals during the night; nothing whatever had passed by the bowels, and the quantity of urine passed did not amount to more than two or three ounces.

No material change took place until the next day (Wednesday), when he began to sink rapidly, and died early on the following morning, eight days from the first commencement of the attack. During the whole of his illness nothing whatever passed by the bowels, and for the twenty-four hours immediately preceding his death the urine was entirely suppressed.

*Post-mortem Twenty Hours after Death.*—There was nothing worthy of note in the cranial or thoracic cavities. On opening the abdominal cavity, the intestines were found adherent to its parietes and to each other in several places by bands of old lymph. On the left side a portion of the intestine was adherent to the abdominal walls. Underneath this a part of the jejunum had slipped, and was constricted against the sharp edge of the mesentery. The intestine at the seat of stricture was on the point of ulceration. Above this the gut was considerably dilated, but below much reduced in size. The parts were restored to their natural situation with ease. Bladder contracted and empty.

*Case 2.*—*Vomiting—Constipation—Diminution of Urine—Death on the Ninth Day—Autopsy—Diaphragmatic Hernia.*

Mary F., aged 18, admitted January 20, 1863. Since the age of two years she has always had delicate health, suffering from cough, and at variable intervals from attacks of sickness and indigestion. A week previous to her admission, just after a fit of coughing, she felt severe pain in the epigastrium, inducing a sensation of nausea and extreme faintness, and succeeded by vomiting and constipation. She remained under treatment at home without deriving any benefit, the constipation continuing, and the vomiting persisting unabated. During this time it was noticed by her friends that she passed scarcely any water.

When admitted she was evidently in a sinking state. The countenance was flushed and anxious, tongue dry and red, and pulse feeble and fluttering. She complained of an ill-defined, uneasy sensation, which she constantly referred to the epigastrium as its seat. Pressure over this region was painful. The abdomen was flattened and symmetrical. Shortly after being placed in bed she vomited a quantity of green viscid fluid, and continued to do so until her death, which took place on the evening of January 21. About an hour previously she passed a small quantity of urine and fæces, for the first time since the commencement of her illness.

*Post-mortem Sixteen Hours after Death.*—On exposing the thoracic and abdominal cavities, a portion of intestine was seen appearing in the right pleural cavity. This proved to be

the pylorus, together with a portion of the duodenum, which had passed on the right side of the œsophagus through an opening in the diaphragm. The aperture was sufficiently large to admit the hand, and was continuous with that for the œsophagus. At a point about three inches from its commencement the duodenum was twisted upon itself, and compressed against the edge of the diaphragmatic opening. At this spot there was a dark ring extending round the gut. The colon contained faecal matter throughout its whole extent. In the bladder were a few drachms of urine.

*Case 3.—Sudden Pain in the Abdomen—Vomiting—Constipation—Sixteen Ounces of Urine Passed Daily—Death—Autopsy—Strangulation of Intestine (ileum) in a Slit in the Mesentery—Rupture of Intestine, and Escape of Intestinal Matter into the Peritoneal Cavity.*

Robert M., aged 45, a porter by occupation, admitted March 9, 1863. Suddenly while at work felt a sharp pain in the abdomen, which induced faintness and nausea. The bowels had acted three times in the course of a few hours preceding the attack. He was a muscular, spare-made man, and had always enjoyed good health. When admitted into the Hospital, he complained of severe twisting pain in the abdomen, referred principally to the neighbourhood of the umbilicus, and not increased on pressure. The pulse was rapid and feeble, skin moist, and extremities cold. He vomited at intervals a quantity of thin green fluid. The abdomen was uniformly distended, and somewhat tympanitic. He was ordered warmth to the extremities, some brandy, and a dose of opium. An enema was administered which brought away some faecal matter.

April 10.—Feels better; pain relieved; complains of thirst, and continues to vomit.

11th.—Complains of no pain. Passed some bloody slime by the bowels. Shortly after this great prostration came on, with an anxious, sunken expression of countenance, thready pulse, and cold clammy perspiration.

Died on the morning of March 12. He passed from sixteen to twenty ounces of urine daily.

*Post-mortem Sixteen Hours after Death.*—Veins of omentum distended, and its small arteries minutely injected, at parts producing patches of vivid redness. Small intestines were distended by gaseous matter, and had lost their natural polish. A quantity of dark grumous fluid was effused into the peritoneal cavity. Two feet of the lower portion of the ileum had passed through an opening in the mesentery. The constricted portion was almost black in colour, and presented several patches of superficial ulceration. At one point the gut had given way, and allowed its contents to escape into the peritoneal cavity, giving rise to the peritonitis which caused this case to be so rapidly fatal.

### GUY'S HOSPITAL.

#### MELANOTIC TUMOUR DEVELOPED IN A MOLE—EXCISION—SECONDARY FORMATION OF MELANOTIC TUMOURS IN THE INTEGUMENT AND NEARLY EVERY INTERNAL ORGAN.

(Under the care of Mr. THOMAS BRYANT.)

THOMAS G., aged 30, a potter, was admitted into Guy's Hospital on January 15, 1863, under the care of Mr. Bryant, with a melanotic tumour, the size of an orange, on the margin of the right axilla, and numerous tubercles, from the size of hemp-seeds to nuts, in the integument of the abdomen.

It appeared that two years previously a mole, which was situated over the ensiform cartilage, began to enlarge, and about the same time the tumour on the margin of the axilla made its appearance. He applied for Surgical advice to St. Thomas's Hospital, when the mole was removed, but as the growth immediately returned on the spot, a second operation was performed two months after, in May, 1862.

From this time the axillary tumour gradually enlarged, and at different dates smaller tubercles made their appearance in the abdominal walls.

When admitted into Guy's, the man was pale and cachectic. His pulse was very weak, and his powers were failing; tonics, wine, and good diet were administered with little benefit, as the tumours rapidly increased, and fresh ones made their appearance.

In a few weeks a dry cough appeared, followed after a

time by pneumonic expectoration, and from this time he gradually sank, without any other definite symptom, dying on March 14, 1863.

It may be added that he had no head symptom.

*Autopsy by Dr. Wilks.*—A number of nodules were on the body, consisting of soft cancer containing pigment, none absolutely black. On removing the brain, fluctuation was felt in the left hemisphere towards the median line, and, on cutting it through, a very loose growth was found, about the size of a walnut, consisting of a distinct vascular wall for outline, and within very little more than a few threads passing across it, and within these some serum. When this flowed out, almost a complete cavity was formed. It thus appeared at first nothing more than an inflamed cyst, but there was sufficient structure in the adventitious material in the walls to show its cancerous nature, and its resemblance to other growths on the body; there was apparently, however, no pigment. The lungs were full of tumours; probably about half of each was thus occupied; many of these were very large, as large as an egg. When cut they were found mostly of a brownish hue, of different degrees of intensity and shade: some almost white, others brown, from the presence of pigment. The bronchial and mediastinal glands were similarly affected. The heart had on its front surface, and imbedded in the walls of the right ventricle, a tumour the size of a marble, which was also cancerous, and contained a small amount of pigment. The liver was full of pigmental cancer; the tubera were smaller than those in the lung, and were situated more upon the surface of the organ. The spleen contained also two masses. The lumbar glands were also diseased, and contained much pigment; as also were the mesenteric. There were also a few growths in the pelvis, and one black nodule growing from the anterior wall of the mucous membrane of the bladder. There was no disease in the kidneys.

#### SECONDARY MELANOTIC TUMOURS IN THE INTEGUMENT OF THE LEG AFTER EXCISION OF A MELANOTIC TUMOUR DEVELOPED IN A MOLE.

(Under the care of Mr. THOMAS BRYANT.)

Mary R., aged 30, a married woman, was admitted under Mr. Bryant into Guy's Hospital, on April 3, 1862, with multiple melanotic tumours in the right leg in different stages of development, some like millet-seeds beneath the integument, others infiltrating the skin, and others, again, which had softened down and ulcerated, leaving cancerous surfaces. These tumours had all appeared after the excision of a like growth in a congenital mole on the tibia sixteen months before her admission. The mole first began to enlarge two years previously, and after eight months' increase it was excised, these secondary tumours appearing directly after.

The glands of the groin were also enlarged when she was admitted. Under these circumstances nothing could be done by way of operation, and she left the Hospital in May, 1862.

A model of this limb may be seen in the Guy's Museum.

### METROPOLITAN FREE HOSPITAL.

#### TERTIARY SYPHILIS WITHOUT HISTORY OF ANY PRIMARY OR SECONDARY STAGE.

(Under the care of Mr. HUTCHINSON.)

THE two following cases came under care on the same day, and as they seemed to me to present good illustrations of a state of things which we not unfrequently meet with in practice, and which has not received the attention its importance claims, I venture to record them. I refer to the occurrence of tertiary symptoms of an unmistakable character in married persons who deny all history of primary or secondary ones. Of course, the denial of previous symptoms by the patient herself must never rank as of the slightest value as evidence, unless corroborated by other facts, of which the Surgeon can himself judge. But very often in the cases to which I refer these corroborative facts are very strong indeed. For instance, the woman may have borne several children, none of whom have suffered in any marked degree. Although not a conclusive one, this is a weighty fact against the belief that the patient herself has ever suffered from self-acquired constitutional syphilis. Still, however, the chief reason for believing that cases of the kind alluded to are not infrequently *bonâ fide*, is afforded by their common occurrence. We so frequently hear histories similar to those recorded in

the two subjoined cases, that it is impossible not to believe there is some truth in them :—

*Case 1.—Nodes and Ulcerated Throat Twenty-four Years after Marriage—No History of any Previous Symptoms—The Younger Children Free from Suspicious Symptoms.*

Mrs. E., a healthy-looking woman, aged 42, came to me on February 17, on account of a large diffused node in front of the right tibia. She described the nocturnal pain as having been very severe. The node first formed a year ago, and she then attended Mr. Childs, who told her it was to be attributed to the same cause as a badly ulcerated throat from which she then suffered. She had never had sore-throat before. A portion of alveolus came away. At the time of the development of the sore-throat and node she was living very badly, owing to her husband being out of work.

On the most careful cross-questioning, I could obtain no history of any other symptoms in the least resembling those of constitutional syphilis. It will be seen that these only date back one year. I could feel no doubt that the node was syphilitic, and Mr. Childs, from the expression he used to her, evidently took the same view a year ago. She obtained most marked relief from the medicine ordered by Mr. Childs. Now for the married history. She married at 17, and was three years married before she conceived. Both she and her husband were throughout in excellent health. Her first child, born four years after marriage, died at six weeks old, after a short illness. Second birth, dead-born at seven months, after a fall; third died, aged thirteen months, of measles; fourth is living, aged eleven, and in good health; the fifth I saw, a healthy lad, aged ten; teeth good; a sixth is five, and a seventh three, and the eighth is a baby, aged ten months. The last I saw, and he appeared in excellent health. In addition to the above, Mrs. E has had two miscarriages.

Without being too definite as to how the taint was derived, I think it must be admitted that she is now the subject of a late tertiary form of syphilis, and that her younger children have not shown specific symptoms. Her youngest, born since the first manifestation of the taint, is healthy. My own suspicion is, that it is an instance of slight taint derived by foetal contamination. The father is stated to have shown no symptoms.

*Case 2.—Nodes, Ulcerated Throat, and Disease of Nasal Bones Seventeen Years after Marriage—No History of Previous Symptoms—Younger Part of Family Healthy.*

Mrs. M., aged 41, came to the Hospital on February 17. She had a very large perforation of the hard palate, and diseased bone in the nares. Her nose was depressed, and she had also on the forehead large depressions without scars. Respecting these latter, she stated that she had noticed the bone falling in for some years, but did not recollect ever having had any swelling; on other parts of the head she had suffered much from painful swellings. The throat and palate had been ulcerated for seven years, and began at a time when she was pregnant with twins.

*Married History.*—She married at 17, being then in excellent health. Was confined a year later of a dead-born child, and was very ill at the time. Then followed a series of miscarriages; and it was seven years later before she had a living child. This child, a girl, is now aged 17, a stout, well-grown young woman, pallid, but without any evidences of special cachexia; teeth well formed; no keratitis. It should be stated that, after her first confinement, the mother regained good health, and remained well. The next was a boy, now aged 14, and healthy. The next is a girl, aged 12, delicate, but with no specific ailments. The twins come next—two boys, both living, aged 7, and in good health. The last is a girl, aged 2, whom I saw, stout, well-grown, and without any cachexia. In addition to these, still living, there have been born five others (at various positions in the family), which have died in infancy. In none of these, nor in any of the living ones, can I obtain the slightest history of symptoms allied to syphilis in infancy. All died of acute diseases. Her husband is reported to be healthy, but to have a peculiar “scaly breaking-out” on his shoulder.

In this case, as in Mrs. E.'s, given above, it is probable that the mother has obtained the taint by foetal contamination, although the children have never themselves suffered from the disease in a sufficiently concentrated form to show symptoms. Observe that, supposing the father to have had syphilis before marriage, his first living child was not born till eight years afterwards, so that there was time for the taint to have passed into a latent and feeble form.

## ISLINGTON DISPENSARY.

### SUBACUTE GLAUCOMA, AFFECTING BOTH EYES SUCCESSIVELY, SUCCESSFULLY TREATED BY IRIDECTOMY.

(Communicated by Mr. SPENCER WATSON.)

ELIZABETH R., aged 62 years, a single woman, a dressmaker. She had generally had good health, and was of spare habit, with no marked diathesis. During the last twelve months she had been nursing a sick sister, and her rest had been very much disturbed. For three months past (May 15, 1862) she had noticed a gradually increasing dimness of vision in the right eye, and had observed that the flame of the candle seemed as if surrounded by prismatic colours in the form of a halo. She had had no pain till within the last six days, but pain of a pricking and burning character, with some lachrymation and conjunctival injection, then begun to alarm her. She therefore applied to my colleague, Dr. Sutton, at the Islington Dispensary, by whom she was directed to apply to me.

May 15.—The right cornea is dull and steamy, and the pupil larger than the left, and very sluggish. There is vascular injection of the sclerotic and conjunctival vessels, and increased tension of the globe. Ophthalmoscopic examination fails to give any distinct view of the fundus. Nevertheless, she can read No. 16 of Jaeger's test types, *i.e.*, letters rather less than  $\frac{1}{4}$  inch long.

June 17.—Vision has now become much worse. She can scarcely distinguish letters of the largest type. The field of vision is contracted to the form of a horizontal slit of twelve inches long and three inches high. There is constant pain in the eyeball and brow, which keeps her from sleeping, or wakes her up after a few hours' rest. The cornea is insensible when touched by the end of a feather. Up to this date the treatment has been tonics, succeeded by iodide of potassium, leeches to the temple, and atropine drops, but without any arrest of the symptoms. I had advised iridectomy some weeks previously, and to-day I removed a piece of iris from its upper and outer part.

On the following day (June 18) she had experienced great relief, and had slept soundly.

July 2.—There has been no pain for some time past. The tension is normal, but vision is not improved.

It subsequently became evident that a cataract was forming in this eye, and on October 24 I removed it by a modification of Schufl's operation, but with only partial success; for, four or five days after, a sharp attack of inflammation came on, induced probably by a too early attempt at using the eye, and the pupil became completely closed up by lymph and opaque capsule. At the same time there was some increase of tension in the globe, and occasional pricking pain. I accordingly, on December 16, preparatory to tearing through the secondary cataract, removed a second piece of iris from the inner side, with very good effect, as the tension became normal, and vision was somewhat improved, at the same time that the pain and inflammatory symptoms quite disappeared. Still, however, there remained opaque membrane across the pupil, which seriously interfered with clear vision; and on April 7, 1863, having got the pupil completely under the influence of atropine, I tore through this opaque membrane with a single needle, and with the best results, as will be seen by the following note :—

On April 27, aided by a two-inch convex lens, she can read No. 12 of the test types (great primer), and recognises features at one or two feet distance. On making an examination with the ophthalmoscope, I find the optic nerve entrance somewhat paler than usual, and shrunken, but otherwise healthy. The retina generally seemed somewhat congested.

The symptoms of glaucoma in the left eye were first noticed by the patient on July 17, 1862, when she found that vision was less distinct than usual, and that the flame of a candle or any artificial light had a coloured halo round it. This, it will be observed, was just one month after the first iridectomy in the right eye, and therefore not to be attributed to any sympathetic affection, the right eye being at this period perfectly quiescent.

October 18.—Severe pain in the left eyeball and brow came on, and the cornea appeared dull and superficially abraded in its central region; and on the 23rd the pain was constant, and of a deep, aching character. There was great sclerotic and conjunctival vascularity and increased tension of the eyeball. She can only just read the largest type (No. 20), the letters

being  $\frac{7}{8}$  of an inch long. The cornea is dull and insensible, and the iris discoloured. Pulse 104.

24th.—I performed iridectomy in the left eye, upwards and inwards. Since this date the symptoms have quite disappeared, the pain and inflammatory redness having subsided within the first day or two, and vision having steadily improved up to the present date (April 6, 1863), when I have the following note:—

April 6, 1863.—Left eye—Tension and field of vision normal; the entrance of the optic nerve is pale, and the vessels rather tortuous. With a biconvex lens of five inch focal length, she reads No. 2 type (pearl) which is about the size of the police reports in the *Times*, and can do needlework, and even thread her own needle, without the slightest distress. The amount of deformity produced by the operation is so slight as to be scarcely observable without raising the upper lid by the finger.

### LEEDS INFIRMARY.

#### DISEASE OF THE MITRAL VALVES—MURMUR WITH THE SECOND SOUND ONLY—CLINICAL REMARKS.

(Under the care of Dr. HARDWICK.)

JOHN K., aged 21, a miner, residing at Barnsley, was admitted into the Leeds Infirmary on December 1, 1862. He has worked in a coal-pit since he was nine years old. He admits that he has only been moderately temperate. His family history is good, all the immediate relatives being alive and healthy. He has never had rheumatism, and never suffered from illness of any kind till three and a half years ago, when his present ailment began with shortness of breath, cough, palpitation, and pain at the heart. For a long time he has expectorated much mucus, and frequently blood also, after a hard day's work. There has never been any dropsy. Since the commencement of his illness he has often been laid up for a few days with distress at his heart and dyspnoea; excepting this, he has continued to work as a miner. He is short in stature, and somewhat stoutly built. Countenance rather gorged and livid. There is no dropsy. He has much cough, and spits up a good deal of frothy mucus. Dyspnoea is marked. The lungs are abundantly resonant; mucous râles are heard at the bases. Over the region of the heart there are the scars left by cupping. The natural præcordial dullness is slightly increased in a downward direction. The impulse of the heart is somewhat heaving; action rather irregular. At the base of the heart both normal sounds can be distinctly heard. Below, and to the outer side of the nipple, these are exchanged for a long, soft murmur and a natural sound. The murmur occurs in point of time during the natural second, and almost half way through the first sound. The clear termination of the first sound is heard exactly as the apex of the heart is felt to beat between the ribs. The murmur is scarcely traceable two inches to the left of the nipple, while on the inner side of the nipple it can be heard as far as the lower end of the sternum. Midway between the point where it is best heard, and the junction of the second costal cartilage with the sternum (at which spot the sounds of the aortic valves are most distinct) the two natural sounds can be heard, then the murmur somewhat resembling a reduplicated second sound. In this position the murmur is heard at the natural interval of rest, that is, just before the first sound. The bruit is not heard at all in the back. The liver is full and slightly tender; urine thick with lithates; tongue coated; bowels regular; pulse irregular, both as to time and force. The treatment adopted was saline mixture, ℥j, with twenty drops of compound spirit of ether, to be taken every four hours.

January 5.—Much relieved. Expectoration has ceased. Ordered ferri citrat., gr. x.; tr. digitalis, gts. x.; aquæ, ℥j; tr. die.

On January 16, when he was discharged, the following note was made. All the general symptoms are gone except some dyspnoea. Heart's action and murmur much the same.

*Remarks by Dr. Hardwick.*—As murmurs with the second sound of the heart, dependent on lesion of the mitral valve, are extremely rare, I thought the above case of sufficient interest to be published. It might be asked on what grounds the diagnosis rests. First, it seems clear that the disease was in the mitral valve, because the usual general symptoms were well-marked dyspnoea, lividity, general

congestion, engorged liver and kidneys, irregularity of heart and pulse, etc. Also because the murmur was heard most distinctly under the nipple, while the sounds over the aortic valves at the base of the heart were distinct and clear. Secondly, the murmur was evidently with the second sound. A casual examination of the case would have readily mistaken it for an ordinary mitral murmur, accompanied by an intensified second sound, as not unfrequently happens. But a little careful attention easily proved that this clear sound was exactly synchronous with the beat at the apex of the heart, which, on account of the impulse being increased, was more readily noted. Besides, the first sound could be gradually traced down from the base, where both sounds were clear. The direction in which the murmur could be heard was also consistent, being towards the lower end of the sternum, while it was only traceable a very little way towards the back, and in this it was unlike most mitral murmurs. That the bruit was not owing to aortic regurgitation is evident from the fact that the second sound was distinct enough over the aortic valves; or, to express it in other words, the natural second sound was not replaced by a murmur, but only drowned by one at the apex of the heart.

#### DISEASE OF THE AORTIC VALVES, WITH REGURGITATION, CAUSED BY VIOLENT EXERTION.

(Under the care of Dr. HARDWICK.)

J. W. K., aged 15, was admitted on February 21, 1863, for slight rheumatism. He had suffered from a severe attack of rheumatism two years ago, but was not aware that his heart had been affected at that time. He had only worked a little more than a year, and during the whole of the time, notwithstanding his age, he had been a "striker" to his father, who is a blacksmith. He stated that he had frequently worked more than ten hours a-day.

He is not remarkably strong or well developed for his years. He has had no palpitation or dyspnoea, and is not aware that there is anything wrong with his heart. The action of the heart is regular, but a little more heaving than normal. There is a distinct double murmur heard over the aortic valves. The pulse is full, splashing, and visible; so characteristic of aortic regurgitation as to cause the disease to be examined for at once. He was ordered liq. ammon. acct., ℥ij; sp. ether nitric, ℥ss. 4tis horis.

February 26.—All rheumatic symptoms have disappeared. He was shortly afterwards ordered iron, and discharged in good general health on March 13.

#### MARKED AORTIC REGURGITATION BROUGHT ON BY VIOLENT WORK—CLINICAL REMARKS.

(Under the care of Dr. HARDWICK.)

Fred. W., aged 19, was made an out-patient, for disease of the heart, on December 16, 1862. He was a puny, delicate-looking lad, not appearing more than fourteen years of age, although he stated that he was nineteen. He had been suffering the last few months from dyspnoea and palpitation. He had never had rheumatism. On examining the heart, there was found a well-marked double murmur over the aortic valves, the second being the louder and longer of the two. His pulse was splashing and visible. On inquiry being made about unusual exertion, the patient said he had worked for above a year in the Middlesbro' Iron Works. His duty was to lift and carry heavy scraps of iron, and he was paid "by the piece." He also stated that the overlooker at length took him away from the work because, in order to earn a large wage, he was accustomed to do above a man's work, and they thought he was damaging his health.

*Remarks by Dr. Hardwick.*—I have reported these cases because they illustrate so well the causes of disease of the aortic valves, when so far advanced as to allow free regurgitation. The grand cause is violent exertion requiring the breath to be held, especially muscular exertion of the arms. Sometimes, as in one of the above cases, the starting-point is found to be a constitutional disease, and generally rheumatism. The fact of violent exertion being in nearly all cases the cause, explains why aortic valvular disease with regurgitation rarely occurs before eighteen, or at least sixteen, years of age, and why it is almost entirely confined to men in the prime of life, the period when muscular exertions are most called for and practised. The two cases quoted above, although exceptions as to age (the patients being mere boys), are very good examples of the cause, since the hard labour to which each was subjected for a long time was unwarrantable. The same explana-

tion shows why the disease is comparatively unfrequent amongst women. All this is a great contrast to what we find in mitral disease, which is occasionally seen as early as six or seven years of age, and is common enough in women. The reason is clear, then, why aortic regurgitation is generally met with in savvies, workers in iron, especially strikers, those constantly employed in lifting heavy weights, etc. I may mention, as another good illustration of the manner in which this disease is produced, a case that came under my notice a few weeks ago. On examining a man for life insurance, who was in easy circumstances, about five feet six inches in height, and not very muscular, I found marked aortic regurgitation; and on my mentioning that such disease was usually produced by violent exertion, he voluntarily stated that he had been in the habit of throwing 56 lb. weights to show his strength, and that he had "puzzled many a strong man" by whirling one of these weights round his head as any one would wave a hat. Besides violent muscular exertion in the strong, less severe efforts in the weak, or those unaccustomed, will produce the same results; and more especially if the aortic valves have been slightly damaged by previous endocarditis.

Medical Times and Gazette.

SATURDAY, MAY 9.

PHYSICIANS' FEES—GIBBON v. BUDD.

It has so happened that within the last few months the question of the honorary character of Professional fees has been raised and argued in the courts of law with regard both to barristers and Physicians. The members of the Bar may consider that by the solemn judgment of the Court of Common Pleas in *Kennedy v. Brown*, all questions as to their legal right to remuneration have been definitively set at rest. It is now settled law not only that a barrister cannot maintain an action by virtue of an implied contract, on the principle that the labourer is worthy of his hire, but also that an express agreement between him and his client respecting his remuneration will not be binding. We cannot congratulate the Physicians on having attained an equally satisfactory adjustment of the law in regard to their fees. An important decision has indeed now been pronounced on the subject by the Court of Exchequer, in the case of *Gibbon v. Budd*. The members of the Royal College of Physicians are no longer in the doubt into which they appear to have been thrown by the injudicious tinkering of this portion of the law attempted by the Medical Act, 1858; but even that doubt was better than the present certainty.

It may be interesting to take a brief view of the state of the law as to Physicians' fees before the Act. This will be found in the marginal note to *Vitch v. Russell*, 3 Q. B., 928, concisely summed up as follows:—"A Physician has in general no legal right of action for his fees, but he may have it by actual contract, the onus of proving which, in an action for such fees, is on the plaintiff." Thus the difference between the situation of a Physician and a barrister was that

the former could bind himself and his patient by an express agreement, while the latter was and is under an absolute incapacity to contract in the matter of his Professional remuneration. In neither case could any implied contract be presumed. The honorary character has attached to Physicians' fees from time immemorial, and in *Chorley v. Bolcot*, the first case in point in the Reports, the argument on behalf of the plaintiff seems to have rested entirely on a quotation from Tacitus, put forward to show that the "medici" at Rome could recover their fees by action. Lord Kenyon, after throwing a doubt on the fact of the "medici" being a class corresponding to our Physicians, goes on to say,—"But, at all events, it has been understood in this country that the fees of a Physician are honorary, and not demandable of right. And it is much more for the credit and rank of that honourable body, and perhaps for their benefit also, that they should be so considered. It never was yet heard of that it was necessary to take a receipt on such an occasion, and I much doubt whether they themselves would not altogether disclaim such a right as would place them upon a less respectable footing in society than that which they at present hold." This state of the law was in fact satisfactory both to the Profession and the public, and no change was wished or called for. In the Medical Act, 1858, however, the following provision was introduced:—

"Every person registered under this Act shall be entitled according to his qualification or qualifications to practise Medicine or Surgery, or Medicine and Surgery, as the case may be, in any part of her Majesty's dominions, and to demand and recover in any court of law, with full costs of suit, reasonable charges for Professional aid, advice, and visits, and the costs of any medicine or other Medical or Surgical appliances rendered or supplied by him to his patients. Provided always that it shall be lawful for any College of Physicians to pass a bye-law to the effect that no one of their fellows or members shall be entitled to sue in manner aforesaid in any court of law, and thereupon such bye-law may be pleaded in bar to any action for the purpose aforesaid commenced by any fellow or member of such College."

This provision having become law, the obvious course for the Royal College of Physicians to adopt was at once to pass a bye-law in the terms provided for by the Act; and, had they done so, the present complication could never have existed. But while recognising the advantages of a continuance of the honorary system by making a bye-law preventing any fellow of the College from suing under this section, that body has (why we know not) left its members first of all to get the interpretation of the clause settled by a lawsuit, and then to enjoy the consequent benefits which we shall presently advert to.

The action of *Gibbon v. Budd* was, as our readers will remember, brought by a Physician to recover £21 for fees, and was tried before Baron Bramwell at Guildhall, when a verdict was found for the plaintiff for that amount, subject to the reservation of a point as to the construction of the above section of the Medical Act. Mr. Lush, Q.C., subsequently obtained a rule nisi for a new trial, or to set aside the verdict and enter a nonsuit, on the ground that a Physician could not recover fees without a special contract.

"On Thursday week, in the Court of Exchequer, Mr. Serjeant Parry and Mr. H. T. Cole, in showing cause against the rule, contended that the Medical Act required that all persons practising the Medical Profession should be registered according to their qualifications. The plaintiff was duly registered, and, as a member of the College of Physicians, he had a right to the remedy specially provided by the 31st section of the Act.

"Mr. Lush, Q.C., and Mr. Dowdeswell, in support of the rule, contended that the statute was not an enabling statute, intended to confer upon a Physician the right to sue; but, on the contrary, imposed upon him a liability to register before he could sue at all; but he was still obliged to make a special contract before he could maintain an action. The law with regard to a Physician's right to recover his fees was in precisely the same state now as it was before the passing of

the Medical Act, except that he must be registered. If he failed to show a contract, he had no remedy left to him. The Act made no difference, and gave no right that he had not before. The Act did not compel Medical men to register, but invited them to do so, pointing out that if they did not they should not recover their fees in courts of law. Unless the Act of Parliament created a liability which without the Act would not exist, then Physicians had no right to recover. Their rights are not enlarged by the 31st section. They have a right to sue according to their registered qualification. A Physician always could recover fees if he made a contract, and that was his position now. There still must be an actual promise to pay.

"Their lordships were unanimously of opinion that the plaintiff was entitled to recover, and discharged the rule.

"Rule discharged accordingly."

Thus we have a decision by the full court that members of the Royal College of Physicians are entitled to recover their fees without express contract. We have previously in these columns called attention to the results that must inevitably follow. The public will now become universally aware that a change has come over the character of the remuneration of Physicians. Independently of the consequent loss of caste, we repeat our former assertion, that a diminution in the pecuniary gains of the Profession must be expected. Physicians' fees will now be assessed according to the views of common juries; and what those views are, every general Practitioner who has ever had occasion to bring an action for his charges knows but too well. The words of Lord Kenyon, which we have quoted above, apply now as well as they did in his day. We would press those words upon the attention of the College of Physicians, and invite them to stop the consequences we have alluded to by at once extending their bye-law to the whole of their members, and restoring to the remuneration of all Physicians its former honorary character.

#### THE ARMY MEDICAL DEPARTMENT.

THERE can be no doubt whatever that the Army Medical Department is very unpopular at the Medical schools—spite of the amended edition of the Warrant of 1858 which has just appeared—and it is not to be wondered at that the more accomplished of our young Medical men hold themselves aloof from the public service.

We have been told, upon undoubted authority, that it is no idle threat of the Commander-in-Chief, that a Medical officer should be made to pay the expenses of any recruit passed by him if subsequently rejected. Not only has this order been carried out, but it is still being acted upon. Its application also we understand is not circumscribed within very narrow limits—such, for instance, as cases of manifest negligence upon the part of the recruiting Surgeon.

A Medical officer is the *only* person connected with recruiting who receives no extra pay of any kind for the performance of the most responsible and essential part played in the enlistment of a soldier; but this consideration does not protect him. We do not believe that the Commander-in-Chief has any authority to enforce this claim. We cannot find that any published documents vest him with it, and we verily believe that if it were resisted it would be found that the Horse Guards authorities are quite powerless. The 59th clause of the Mutiny Act is very clear indeed upon this subject.

The mortality in the Army Medical Department is about 30 per 1000. Service in it entails expatriation, and often the performance of menial and unprofessional offices, such as those connected with branding soldiers; and there is a high probability of eighteen years' service in the subordinate position of Assistant-Surgeon for any one now entering the Department!

That noble spirited public servant, General Outram, might well have given us some words of sympathy, and left us his prophecy that the next war would settle these things *terribly* in favour of the army Surgeon.

Heaven preserve us from war, say we; but in the present

troubled state of our foreign relations, we defy any one to say how soon it may appear, and it will then be patriotism alone which will take men into the army, for there are no other temptations held out to members of our Profession.

#### THE WEEK.

##### ARBITRATION AND AWARD IN THE CASE OF ADAMS AND PROPERT.

WE have received the following for publication, and heartily rejoice that the affair has been brought to a satisfactory and honourable settlement:—

"We, the undersigned, having been delegated with full and unrestricted authority to arbitrate in the matter in dispute between Mr. John Propert and Mr. William Adams, arising out of the late trial of 'Russell v. Adams,' are of opinion that the subjoined document, signed by Mr. John Propert, should be considered as a satisfactory and an honourable settlement of the question at issue between these gentlemen.

"FORBES WINSLOW, 23, Cavendish-square.

"FRANCIS HIRD, 17, Clifford street.

"London, May 5, 1863.

"I am willing to admit that I ought to have complied with the request conveyed to me in Mr. Macrell's letter, dated December 30, 1861, and have conferred with that gentleman, as Mr. Adams' legal adviser, in relation to the charge of breach of promise brought by Miss Russell against Mr. Adams, previously to my forming any opinion of my own respecting its truth. I now recognise if I had done so much annoyance to both Mr. Adams and myself would have been obviated.

"I also regret that anything done by me should have led others to suppose that I advised or originated the legal proceedings taken by Miss Russell against Mr. Adams. I was, no doubt, misled by certain *ex parte* statements, but was influenced by no personal feelings of animosity to Mr. Adams, but solely by a desire to protect the daughter of a deceased member of the Medical Profession alleged to have been cruelly treated.

"Whilst solemnly declaring that the motive governing me in these painful proceedings was strictly benevolent in its character, I nevertheless freely allow that, having been deceived by erroneous information, I unwittingly exposed myself to the imputation of acting imprudently towards Mr. Adams, whom I now conscientiously believe to be innocent of the infamous charge which Miss Russell attempted to establish against him in a court of law.

"JOHN PROPERT.

"6, New Cavendish-street, May 5, 1863."

##### PARLIAMENTARY.

THE great events of the week have been the discussion on Mr. Gladstone's proposal to impose on the charities of the United Kingdom the payment of income-tax; the surpassingly able speech in which, on Monday night, he supported his proposition, and his quiet withdrawal of the measure when he discovered that neither eloquence nor casuistry would induce his hearers to accept it. Mr. Gladstone's speech was a masterpiece, which, perhaps, he himself has never excelled. But its fundamental errors were patent. Exemption from a tax is not equivalent to a donation from the State, for the State may have no right to impose the tax; and the income-tax is not a tax on the entire property of the country, but a tax on certain individuals only. All will fully concur with much that Mr. Gladstone advanced with regard to the motives which lead men to bequeath large sums to charities; all fully admit that to designate such motives as charitable is to prostitute the term, and few will require convincing that the management and results of numbers of so-called charities merit the splendid invective which he hurled against them. But these arguments are beside the question. The income-tax being a tax on persons, it is the people relieved in our Hospitals, educated in our free schools, and maintained in our alms-houses on whom the burden would fall. That a grasping, hard-fisted miser of the sixteenth century tried to save his soul and redeem his name from utter detestation by leaving his property at the last moment to found a Hospital, is no

reason why the State should now, in the nineteenth, reduce the number of sick in that Hospital, by taking some hundreds yearly from its funds. Deathbed legacies to charities are, as Mr. Gladstone says, not to be encouraged, and ought therefore be laid under contribution. Granted; but let the contribution be in the shape of a heavy legacy duty, not a tax which will vary from year to year with the necessities or fears of Government. Before the money comes into the coffers of the charity, mulct it as heavily as you please, but when once it has been the source of sustenance to the helpless, health to the sick, and education and shelter to orphan children, it must be sacred from the tax-gatherer. If certain charities do not fulfil the intentions of their founders, if they are sources of idleness and improvidence, and if their revenues are misapplied, the plan is clearly to reform them; but this will not be done by deducting sevenpence in the pound from their annual incomes.

In the course of his speech, Mr. Gladstone acknowledged that the objections urged to the impost told most strongly in the case of Hospitals, and he went so far as to hint that Parliament might grant a subsidy to those charities to recompense them for their diminished income. It had been shown by Lord R. Cecil and Mr. Malins, in the preliminary debate of Thursday, the 30th ult., that, in the case of St. Bartholomew's, the sum proposed to be taken would support forty in-patients all the year; but, as the patients generally did not remain longer than four or five weeks, the effect would be that in the twelve months 400 in-patients would be excluded by such taxation from its wards. Add to St. Bartholomew's the case of eight or nine other great Hospitals, and there would be no fewer than 4000 patients shut out from the London Hospitals alone in consequence of this measure. Every argument, however, which applies to Hospitals would equally apply to educational and other eleemosynary institutions. That the latter are mismanaged in a manner which Hospitals are not, calls for the interference of Parliament, but moral imperfections are not punishable by taxation, either in the case of individuals or corporations. The repugnance with which Mr. Gladstone's measure was generally regarded was evidenced by the enormous deputation, headed by the Duke of Cambridge and the two archbishops, and including men of all shades of political opinion, which besieged the minister in Downing-street on the morning of the 4th.

"On Thursday, the 30th ult., in answer to a question by Mr. M'Evoy, Sir R. Peel stated that considerable inconvenience arose in Ireland from the committal of dangerous lunatics to county gaols by the magistrates instead of to asylums, particularly in the counties of Donegal and Wexford. When the new lunatic asylums were completed an alteration in the law would be effected.

"On Monday, the 4th inst., the Naval Medical Supplemental Fund Society Winding-up Act Amendment Bill was read a second time, after a short debate.

"On Tuesday, in reply to a question by Mr. Moffat, the Chancellor of the Exchequer said that the report of the commission of international inquiry on the sugar duties which lately met in Paris was virtually completed.

"Debates on Mr. Walters' resolution on Education and Mr. E. Bouverie's motion on the Act of Uniformity divided the evening."

On Wednesday night, the house went into committee on the Security from Violence Bill. A return to the sensible old system of brute punishment for brutalised men, notwithstanding Sir G. Grey's opposition, speaks well for the good sense of the house. We agree with Mr. Marsh, that corporal punishment is one of the very best of punishments, because nobody likes it. Occasionally, people are found breaking windows to get sent to gaol; but nobody ever breaks a window to get a flogging. Even hanging may appear a desirable mode of death; and we have lately had more than one case of murder where the ostensible reason given by the criminal was that he wished to be hanged, but we never heard of a crime being perpetrated in order to qualify for the

cat. We have no doubt that the maximum punishment of 150 lashes at three separate whippings of not more than fifty each, to which the house agreed, will be an effectual quietus to the garotters.

#### THE ELECTION OF A PHYSICIAN AT THE DERBYSHIRE GENERAL INFIRMARY.

At a special general meeting of the Governors of the Derbyshire Hospital, a sharp discussion arose on the question of whether a young Physician or an established General Practitioner would be the most eligible person to perform gratuitous services, for the advantage of the town and neighbourhood. The form the question took was, whether the Physicians to the Infirmary should be reduced to one, and the Surgeons increased to four. The true point at issue, we opine, was, whether the town and neighbourhood of Derby could afford practice for two consulting Practitioners in Physic. Some of the speakers, as was probably to have been expected, indulged in those odious things—comparisons. The following is an elegant extract from a Mr. Gisborne's speech:—

"For my own part, I believe that the general Practitioner, if he be a man of some experience, will perform the duties of the office better than some young recruit, for the bulk of young Physicians have had very little experience—they are not tried like young Surgeons, and the consequence is that they are as verdant as a leek."

The meeting ultimately came to the conclusion that the number of Medical officers should remain as before.

#### ST. GEORGE'S HOSPITAL.

A VACANCY having occurred in the Surgical staff of the Hospital, by the death of Mr. H. C. Johnson, Mr. Henry Lee, who it will be recollected not long ago left King's College Hospital, will now be elected full Surgeon at St. George's. Many of Mr. Lee's friends thought that there was a certain risk in his changing his sphere of labour, but the result proves that his judgment was sound. We understand that several gentlemen have been ready to come forward as candidates for the office of Assistant-Surgeon, vacant by Mr. Lee's resignation. The only names, however, which have publicly transpired are those of Mr. Brodhurst, Mr. Naylor, and Mr. Hornidge. It has been usual for the Governors of St. George's Hospital to fill up the vacancies as they occur from men of their own School—a principle which we believe is still very strongly advocated at that institution; but on the present occasion the friends of Mr. Naylor (the senior candidate among the St. George's men) have advised him, on account of his health, not to add the arduous duties of Assistant Surgeon to his other already numerous Professional engagements. It is not a little curious that within two years of Mr. Hawkins' and Mr. Cutler's retirement from St. George's, Mr. H. C. Johnson and Mr. Gray should have been removed by death, and that Mr. Athol Johnson and Mr. Naylor should have hesitated to undertake the duties on account of their state of health. Under the circumstances, the Governors have thought it right to recruit their staff by candidates from the general ranks of the Profession, and we understand that Mr. Brodhurst, although not a St. George's man, will meet with very general support, both from the Governors and from the Medical staff.

#### TERMINATION OF THE AFFAIR OF PROPERT AND ADAMS.

It is with the most sincere pleasure that we announce the entire and full termination of this unpleasant business. In another paragraph it will be seen that two gentlemen—than whom none others could be better fitted for the task, and whose award was sure to meet with universal acquiescence—have investigated the matter on behalf of the litigants, and have come to a decision. As a fitting and graceful consequence, we are glad to say that Mr. ProPERT has called on Mr. Adams,

and expressed his regret in the most frank and honourable manner at the anxiety to which Mr. Adams had been subjected. This is as it should be. To be deceived by distressed women, *humanum est*. There is nothing to be ashamed of in that. Nay, it is on the whole indicative of a better disposition than the hard and callous temper of some men who boast that "they are never taken in." But to acknowledge a mistake frankly, when fully convinced of it, is also a sign of a generous temper, and the fact of making such an acknowledgment not only wipes out past grievances, but elevates the person making it to a higher position than before. Meanwhile, we may announce that the subscription to defray Mr. Adams's law expenses is proceeding vigorously, and that we believe Mr. Probert will contribute handsomely towards it. A committee has been formed, which embraces the names of the most eminent members of our Profession in town and country, with Mr. J. B. Walker, of 17, Clifton-gardens, W., as Honorary Secretary and Treasurer.

#### DECAPITATION.

WE have all heard the story of the beheaded nobleman whose *caput mortuum* is said to have pronounced the words, "Thou liest," when the executioner presented it to the bystanders as "the head of a traitor," and as physiologists we may have sought the foundation of the story, if foundation it had, in a reflex contraction of the facial muscles after death. The following account of some experiments in the Paris slaughterhouses is furnished by the correspondent of the *Times*. It is curious, as illustrating the time during which excitatory phenomena will continue in the facial and other muscles of decapitated animals. The idea that sensation is equally persistent is out of the question, although such appears to have been the conclusion of the experimenters.

"The Conservator of the Paris slaughterhouses, being of opinion that the mode of slaughtering oxen by knocking them on the head with a heavy metal instrument must cause the animal excessive pain, endeavoured to discover another mode to avoid this suffering, and at the same time to preserve the slaughtermen from the danger to which they are exposed in the performance of this disagreeable duty. He thought that enervation would accomplish his object, and his opinion was founded on the doctrine taught by physiologists, who assert that the separation of the spinal marrow at once destroys animal life. Experiments were tried on more than 100 oxen, and it was demonstrated that although the ox was more quickly put to death, his sufferings were not the less excruciating, inasmuch as his entire vitality was preserved, and that death did not ensue until after an agony of fifteen or sixteen minutes. These experiments were repeated on calves and sheep, and, in place of merely cutting the spinal marrow, the head was separated from the body, in order to observe the degree of vitality which would still remain in each of the separated parts. A calf was suspended, and a butcher's boy cut his head off with a knife. This operation was accomplished in a quarter of a minute. The head was immediately placed on a table, and it lost two ounces and a half of blood in the space of six minutes. During the first minute all the muscles of the face and neck were agitated with rapid convulsions, and during the two following minutes the convulsions assumed another character. The tongue was stretched out of the mouth, which opened and closed alternately; the nostrils opened, as if the animal experienced a difficulty of breathing. The convulsions became more active when the tongue or nostrils were pricked with a needle. When the hand was applied to the mouth or nostrils, respiration was felt to be continued by the air entering and coming out. When a finger was brought within an inch of the eye, in the direction of the pupil, the eye was quickly closed, as if it wished to avoid the touch of the finger, and the same result followed at several intervals. At length the eye did not close until the eyelid was touched. It was remarked that the eye remained closed as long as the finger remained in contact with it. These phenomena became gradually weaker, and ceased entirely after four minutes. Even then, when the spinal marrow was pricked with a needle, the convulsions recommenced in the

entire face, tongue, and eyes. After the sixth minute all contraction ceased. While these experiments were being performed, the body, which remained suspended, was greatly agitated. The agitation ceased gradually, and was replaced by contractions, which continued more than an hour. But this was always observed, in whatever manner the throat was cut. Forty calves and fifty sheep were decapitated, and they all presented the same phenomena. The director of the Paris slaughterhouses convinced himself by these experiments that an ox suffered more by being decapitated than by being struck down with a heavy bar of iron; and that the bar, by producing an immediate stupefaction, prevents the animal from suffering, while the bleeding, immediately effected, deprives him of life before the head recovers sensation."

#### ACTION AGAINST A DENTIST FOR THE ADMINISTRATION OF CHLOROFORM.

A CURIOUS trial has recently taken place at Philadelphia. The plaintiff, thrown from a car upon his head, was taken up insensible, but was able to resume his occupations next day. About three months after this, he went to Dr. Winslow, a dentist, for the purpose of having several teeth extracted. Chloroform was administered in large quantities, during intervals, for three-quarters of an hour. On leaving, he staggered like a drunken man, and afterwards he became worse, his articulation being indistinct, paralysis of the left side coming on on the fourth day. After a prolonged period, he was enabled to partially resume his employment as a driver, and brought this action for the loss this sickness had caused him. Dr. Longshore, who had attended him during this illness, gave his opinion at the trial that the paralysis was induced by the chloroform, adding that chloroform is never administered without some degree of paralysis resulting, although this is only usually temporary. Dr. Harreson stated that he knew of a case in which paralysis was caused by chloroform. Indeed, so dangerous is the use of this agent, that it is not employed at the Pennsylvania Hospital. For the defence, it was set up that Dr. Winslow was a graduate, twenty years in practice, and eminently skilled in the use of chloroform. Paralysis is never a result, whatever the quantity administered; and it probably resulted in this case from the injury to the head previously received. Professor Gross testified that chloroform was regarded by the Profession as a proper agent for the relief of pain. Since 1842, he has given it to all classes and at all ages, without any ill effect, and believes the paralysis in this case did not arise from its use. In one case, the Professor had administered eight ounces of chloroform, the patient being kept under its influence during three hours. It is, of course, a dangerous agent, and so is laudanum, etc. Judge Hare, in charging the jury, laid down the principles of Medical responsibility in very clear terms:—

"If a Medical Practitioner," he said, "resorts to the acknowledged proper sources of information, if he sit at the feet of masters of acknowledged high reputation, and does as they have taught him, he has done his duty, and should not be answerable for the evils which may result from errors in the instruction he has received. Medical opinion varies from time to time. What is taught at one period may be discovered to be erroneous at another; but he who acts according to the best known authority, is a skilful Practitioner, although that authority should lead him, in some respects, wrong. If, however, you should decide that chloroform was an improper agent, or that it was erroneously administered in this case, you will then have to consider whether the paralysis was the result of its administration. . . . If the patient were, from previous circumstances (as the injury of the head), predisposed to paralysis, it might well happen that the extraction of the teeth without the chloroform, or the use of chloroform without the extraction, would bring on the attack. Even if this were the case, still it would not be just to make the defendant liable for consequences which he could not foresee, which were not the ordinary or probable results of what he did. He was only bound to look at what was natural and probable, to what might reasonably be anticipated. Unless some such guard is

thrown around the Physician, his judgment may be clouded, or his confidence shaken by the dread of responsibility at the critical moment, when it is all-important that he should retain the free and undisturbed enjoyment of his faculties, in order to use them for the benefit of his patient."

The verdict was for the defendant.

## LOCAL REPORTS ON SMALL-POX.

I. *The Epidemic in St. Marylebone.* By R. D. THOMSON, M.D., F.R.S., Medical Officer of Health to St. Marylebone, and President of the Metropolitan Association of Medical Officers of Health.

FROM the migratory character of the inhabitants of this extensive district, disease of an epidemic nature is very liable to be introduced among its people. As a proof of the fluctuation of its population, it is sufficient to quote the fact that, although during the ten years 1851-61 the births exceeded the deaths by 10,649, the population only increased during that period by 3984. It is not to be wondered at, therefore, if, with this mixture with strangers, small-pox is scarcely ever absent from the parish. But, instead of isolated cases occurring at the present time, we find it spreading in every direction. In the early and middle parts of 1862, the average number of cases of small-pox occurring at eleven Medical and Charitable Institutions was 1 per month; but, in September, 10 cases were attended at one Dispensary in the southern parts of the district. The cases seemed after this to decline, but in December 3 were returned; and in January, February, March, and April, the numbers were, respectively, 11, 11, 21, 41; while the deaths amounted to 4, 2, 1, 8. It must be remembered that these do not include private persons affected with the disease, but simply those who have applied for relief at the public Institutions, the returns being most liberally forwarded every week to the Medical Officer of Health by the resident Medical Officers. The Medical Officer of Health is thus enabled to point out where vaccination and re-vaccination is more immediately required; although the origin of the contagion has been usually traced to foreign sources. Several patients have been sent to the Small-pox Hospital, but latterly this means of safety has failed, by the Hospital being full. The guardians are now looking out for a temporary Hospital; bills have been issued urging the people to have their children vaccinated and themselves re-vaccinated, with the threat that if the Vaccination Act is not complied with, legal measures will be adopted, as the assistant-overseer has been appointed to carry out the law. The vaccinations by the district vaccinators have increased from 213, 230, 244, in January, February, March, to 405 in April, which nearly reaches the number of births in that month. For some years the clergy and masters of schools have agreed that before admitting a child to school it shall be examined to ascertain if the vaccine cicatrix is present. This may account for the fact that the disease has proved hitherto mild among children under ten years of age, and that many of the returns of sickness are of persons above that age, while the deaths are almost exclusively among the unvaccinated. A method has been partially adopted in this district which adds considerably to the number of vaccinations. The vaccinators obtain from the District Registrar the addresses of the children born, and report to the Medical Officer of Health those who refuse to have their children vaccinated. By him a letter is addressed to the parents, stating the law, and the penalty for its infringement, and that if resisted a prosecution will be instituted, he being authorised by the local authority to take such steps. Few refuse to listen to this appeal.

II. *On Small-Pox in St. George, Hanover-square.* By R. DRUITT, M.R.C.P., etc.

HAVING been requested to contribute a short account of the quantity of small-pox, I may first say with thankfulness that I have not seen one case in private practice, and that the following figures are mainly derived from returns and other documents which came to me as Medical Officer of Health.

The entire number of cases of which I have learned the existence in the Hanover and Mayfair sub-districts, *i.e.*, the old upper part of St. George, Hanover-square, north of Piccadilly, from December to April 25, is 24.

No death from small-pox had occurred in this part of the parish since December, 1860, when the porter at Lansdowne-

house died of it. In the four quarters ended Lady-day, 1859, there had been 1 death, and 5 cases not fatal. In the similar period ended Lady-day, 1860, 33 cases were known to have occurred, including 14 in public practice, and 2 fatal cases. In the year ended Lady-day, 1861, were 10 cases, besides two heard of in private practice, one of which mentioned above was fatal. Up to Lady-day, 1862, four cases; no death. There were no fresh cases heard of till December, 1862, when one case in private practice was heard of in Park-lane, and shortly afterwards a woman came with the eruption on her to a house in Robert-street, Grosvenor-square. She was immediately sent to the Small-pox Hospital.

In January, 1 mild case occurred in Hart-street. In February, 2 cases in the house in Robert-street, 1 of a young man who came ill with small-pox to South Moulton-street; 1 in Mount-row; and 1 case of a man who had been sent to the Fever Hospital, and took small-pox there; 2 cases heard of in private practice in Bruton-street. In March, 5 cases, one of which was a child, in the house in Robert-street, which died. Up to April 25 there had been 5 more cases in public practice. Besides these, an infant, three weeks old, which had been born in Charing-cross Hospital, was discharged with the small-pox on it, and died in this parish. An epileptic patient, aged 30, died of it in Piccadilly on April 25; and 2 cases were heard of in private practice in Mint-street.

Out of these 24 cases, 11 were 14 and under; 7 adults. Ages of the remainder not known. 12 had been vaccinated, 5 had not been; of these one was a child of 10 months, who died in Robert-street, and whose parents had only lived there three weeks; 1 was a child who had had small-pox already; and 1 the newly-born infant.

The estimated poor population in the Hanover and Mayfair sub-districts, amongst whom 17 of the 24 cases occurred, is 13,000, out of a total population of 33,000.

To show the impediments to vaccination, it may be mentioned, that in March a messenger was sent to inquire after 126 children, born and registered in Mayfair in 1862, whose vaccination had not been registered. Of the 126, 31 had been vaccinated by Mr. Jay, the able public vaccinator, 36 by some one else, 22 had not been vaccinated, 29 had gone away, and 6 had died.

Every precaution is taken against the spread of the disease by the guardians of the poor and the sanitary committee. A proper carriage has been for years used for the conveyance of the sick, and a detached building fitted up for their reception. Every means is adopted to encourage vaccination, such as sending round to inquire from house to house, especially for children born in the parish. The schools, containing nearly 2000 children, are visited, and the unvaccinated sifted out. As a specimen, in one school 323 children were lately examined, and 7 of the number were found unvaccinated. These were either newcomers, or from amongst the lowest and most improvident class. The *girls* were clean; many of the *boys* and *infants* very dirty, and several with diseased skins. I quite endorse the sentiment, that with a fluctuating population like that of the lower orders in great towns, universal vaccination is hopeless, and that, even if it were attained, the population is so dirty that it would hoard up the germs of small-pox till a favourable season calls it into activity.

Out of our whole number, 2 were sent to the Small-pox Hospital, 7 were received into the small-pox wards in the workhouse, and 1 into each in turn. These wards have received altogether 56 patients from February 7 to April 29—*viz.*, 8 as above, 46 from Belgravia, whose history will be given by Dr. Aldis, 1 nurse in the workhouse, and 1 infant born there.

P.S.—Five patients have been received from Pimlico between April 29 and May 7.

## REPORT ON THE PHYSIOLOGICAL ACTION OF PODOPHYLLIN.

By FRANCIS ED. ANSTIE, M.D., M.R.C.P.,

Assistant-Physician to the Westminster Hospital, and Lecturer on Toxicology to the School.

(Continued from page 328.)

*Experiment VIII.* was a repetition of *Experiment VI.* Forty minims of the alcoholic solution, containing three grains of

podophyllin, were injected into the peritoneum of a healthy young cat at 1 p.m.

Symptoms of alcoholic intoxication were produced, and reached their climax in about an hour and a-half, thenceforward subsiding.

3.5 p.m.—The cat vomited, and this was repeated several times: the animal also uttered cries.

3.14 p.m.—The cat passed solid fæces, and directly afterwards a semifluid evacuation.

4 p.m.—Purging has been almost incessant since it was first noticed. The motions are quite fluid, and latterly have consisted of mucus deeply stained with what appears to be bile.

4.30 p.m.—The cat has just passed a motion which is stained with blood, and consists otherwise entirely of gelatinous mucus.

8 p.m.—The purging has continued at intervals till a short time since, but it has now ceased. The cat has become violently convulsed; the convulsions recur every two or three minutes. Respiration loud and panting. Circulation 120.

8.30 p.m.—The convulsions have ceased, and the animal lies quite insensible on its side, breathing very laboriously about ten per minute.

9 p.m.—Respiration has ceased; the heart beats feebly.

9.3 p.m.—Heart stopped.

On post-mortem examination the peritoneum was found free from inflammation. Throughout the small intestine, and to a less degree in the large, the mucous membrane was highly congested, and thick, bloody mucus was effused on its surface. The liver was natural in appearance; gall-bladder empty.

*Experiment IX.*—Eight minims of the alcoholic solution, containing half a grain of podophyllin, were injected into the peritoneum of a full-grown rat at 12.58 p.m. The animal was strong and lively.

1.15 p.m.—The animal develops strong symptoms of alcoholic poisoning. Left to itself, it crouches with its eyes closed; roused up, it moves slowly, dragging the hind quarters.

From this time the symptoms of alcoholic poisoning steadily developed, and by 3.50 the animal was lying on its side insensible, and occasionally convulsed. Respiration 64. Circulation 130. At this time the rat began to pass pellets of fæces every two or three minutes; the latter ones were mixed with mucus and a little blood.

At 4.10 p.m. the respiration, which had been growing more and more feeble, ceased, and circulation was arrested two or three minutes later. The rapidity with which the animal succumbed was evidently chiefly due to the influence of the alcohol.

Post-mortem examination showed that the peritoneal cavity was free from any traces of inflammation.

The large intestine was occupied by two or three pellets of semi-solid fæces of the usual colour, with a little mucus, and exhibited no inflammatory colour. The small intestine appeared vividly congested, and contained thick mucus in considerable quantities. Liver of natural appearance.

*Experiment X.*—This was a repetition of the last experiment. Eight minims of the alcoholic solution were injected into the peritoneum of a rat (not quite so large or strong as the last) at 1.14 p.m.

In this case the symptoms of alcoholic poisoning were even more rapidly developed in an extreme degree. At 3.2 the animal was lying on its side unconscious. Respiration 75; circulation 160; frequent clonic convulsions. Respiration became quite changed in character in the course of another hour; by 4 p.m. it had become gasping and very slow, and the temperature had sunk very low; the convulsions had now ceased. In this condition the animal remained with hardly any change for about two hours longer, when the breathing ceased, and the heart ceased shortly afterwards.

Post-mortem examination showed appearances almost exactly identical with those observed in the last experiment, though no actual purging had taken place during life.

*Experiment XI.* was a test experiment with alcohol. Eight minims of sp. vin. rect. (P. L.) were injected into the peritoneal cavity of a rat, full grown, and about as large as the subject of the last experiment. The animal very rapidly became stupified, and developed, in succession, paralysis of the hind-quarters, insensibility of the surface, complete unconsciousness, and convulsions. Death took place in eight hours, respiration ceasing a minute or two earlier than circulation. Post-mortem examination showed no inflammatory

changes either in the peritoneal cavity or in the alimentary canal.

The conclusions which result from the experiments so far detailed are as follows:—

I. Podophyllin, when injected into the peritoneal cavity of dogs, cats, or rats, has no irritant action upon the serous membrane unless it remain unabsorbed, lying for some time in contact with it.

II. Podophyllin, when injected into the peritoneal cavity, passes (except the excess, *vide Experiment V.*) into the blood, and exercises a special influence of an irritant kind upon the mucous membrane of the intestines (usually of the small intestine only.)

III. As a secondary result of this irritation, or perhaps as a mere consequence of the squeezing of the gall-bladder by the abdominal muscles in repeated efforts at defecation, bile is occasionally poured out in large quantities, but this is by no means necessary.

IV. Neither poisonous doses, nor those which produce what may be called a medicinal effect, appear capable of exciting any inflammatory process in the liver.

V. For all these reasons it appears pretty certain that podophyllin, in the animals above mentioned, does not act directly on the liver; and that the catharsis produced is due to increased secretion from the intestine, consequent on the specific irritation of its mucous membrane.

(To be continued.)

## REVIEWS.

*Clinical Medicine. Observations Recorded at the Bedside, with Commentaries.* By W. T. GAIRDNER, Physician to the Royal Infirmary of Edinburgh, and Lecturer on the Practice of Medicine. Edinburgh: Edmarstone and Douglas. 8vo. 1862. Pp. 741.

DR. GAIRDNER'S work does not profess to be a systematic treatise on the practice of Medicine. It is rather, as the author observes in his preface, an attempt to render into written words the substance of clinical teaching, the very facts observed, the very ideas suggested by the facts, and as nearly as possible the very doubts, difficulties, successes, and failures actually encountered by a teacher of some years' experience in communicating with his pupils at the bedside in cases of more than ordinary interest. In this attempt, we are bound to say that Dr. Gairdner has been eminently successful. He is unquestionably a most careful observer and able exponent of nature, and his descriptions are so graphic that the reader may readily fancy himself at the bedside, and taking part in the consultation on each individual case. The work is a collection of lectures and memoirs, prepared from time to time, and now published with but slight alterations. In some instances, the same subject is treated of in fragmentary portions of different lectures delivered at long intervals. This plan possesses the merit of exhibiting the exact impressions which the author intended to convey to his hearers at the time, and makes the lectures of particular value to his old pupils; but we venture to suggest that the work would be more prized by the general reader and the busy Practitioner with a little condensation and re-arrangement in this respect.

The work contains some excellent remarks on the mode of studying clinical medicine and on case-taking, which are evidently the words of a profound thinker and of a sound Practitioner. They would have formed an appropriate introduction, instead of being placed at the end of the book. It is Dr. Gairdner's practice to dictate at the bedside the more important facts bearing on the history and progress of a case, and not to leave the disentangling of the intricacies of mingled fact and theory which generally enter into a patient's story to the ready pen of an assistant. He objects to any fixed method in recording cases, as tending to interrupt unreserved communication with the patient, and as imparting a dry and pedantic character to the Physician's inquiries. It too often happens that amidst the paraphernalia of a complicated method the true nature of a patient's disease is entirely overlooked. Speaking of the difficulty sometimes experienced in arriving at the truth in a patient's story, Dr. Gairdner observes:—"There is but one method of getting over these difficulties—*gain the heart of your patient*, and you have gained the key to his case; fail in this,

and you may labour in vain with all the systems and all the notes in the world to help you. Nay, it is precisely when your patient is most perverse, or fanciful, or stupid, that your note-book and your fixed and formal questions do most mischief. The least appearance of art on your part—the faintest trace of what may be construed as impertinent curiosity or skilful management, suffices to baffle your inquiries. The patient's mind is on the rack, and he either takes refuge in sullen silence, or indulges in answers made to suit what he fancies to be your particular whim. He is all attention to your words, and gives much more consideration to them than to his own feelings. If you are busy with your pen or pencil, so much the worse."

Space will not permit us even to allude to many of the important subjects ably discussed in this volume. We would particularly commend, however, to the student and practitioner the chapter on Cardiac Murmurs. We have never before seen this difficult topic treated in so able, lucid, and practical a manner. The student will find here the entire subject in a nutshell, and put in such a manner that he cannot fail to understand it. The descriptions of cardiac murmurs, and the observations on thoracic disease generally, are illustrated by numerous ingenious and most instructive diagrams.

Another chapter contains some interesting observations on aneurisms, and particularly on contraction of the pupil and laryngeal spasm as symptoms of aneurism of the arch of the aorta. Cases are recorded showing the latent character sometimes assumed by pneumo-thorax, while the "tactile sensation," and the "*râle crépissant sec à grosses bulles*" of Laennec are recognised among the physical signs of emphysema.

Continued fevers are discussed at great length, and the author advocates the specific distinctions between typhus, enteric fever, and relapsing fever. In reference to this point, the following remarks deserve attention:—

"No one can pretend to have had access to all, or nearly all, the fever cases of London, during however short a period. But in Edinburgh, Dr. Begbie and myself probably have seen, or have had the means of knowing about, very nearly all the fever cases; and therefore when I declare to you, that within my experience for ten years past no instance has occurred of a decided origin of enteric fever in a group of typhus cases, or of typhus fever in a group of enteric cases, I am entitled to say that I have obtained very strong evidence in corroboration of the view that these two diseases are, in reality, different diseases, and not mere varieties of the same disease."

Some interesting observations are made on the mental state of patients suffering from enteric fever. Cases are recorded where this resembled a sort of reverie, or cataleptic stupor, with dilated pupils, and contrasted strongly with the typhomania and contracted pupils of typhus.

Dr. Gairdner's remarks on the treatment of disease are thoroughly sound. He does not aim at striking into a new path, and he pushes to no extreme. While he receives with reserve and applies with caution the dicta of past experience, he does not consider himself at liberty to give an arbitrary denial to conclusions founded on the long-continued observation of distinguished Physicians. Accordingly, he has not lost faith in blood-letting as a remedy for pneumonia, but he believes it to be very useful in fit cases, although very apt to be made a bad use of in incautious hands. In the treatment of pneumonia, he puts great trust in antimony, in doses of from  $\frac{1}{16}$ th to 1 grain. Even in cases of great debility he does not look upon it as contra-indicated, although he then combines it with diffusible stimulants. It is important to observe that he regards the ordinary physiological effects of antimony as quite opposed to its therapeutic action, and that whenever they occur he makes it a rule to suspend the remedy or diminish the dose. In the treatment of pneumonia, as well as of other acute diseases, he strongly condemns the indiscriminate employment of large quantities of alcoholic stimulants. He gives alcohol, not as food, but as an adjuvant to food. While agreeing with the late Dr. Todd in thinking that alcohol may diminish the frequency of the pulse, and restrain the tendency to delirium in acute disease, he demurs to the inference that delirium and other bad symptoms, if increased under small doses, are to be kept down by giving much larger quantities. He regards flushing of the face and increased feverishness as a contra-indication to alcohol, rather than a reason for increased administration. Hence he has never had occasion "to sluice the head well with cold water, or to use any of the other means recommended in Dr. Todd's fourteenth lecture, in order to distinguish 'the coma of

alcohol' from 'the coma of disease,' in cases of accidental over-stimulation."

In the treatment of scarlatina, all local applications to the throat are objected to, and the patient is recommended to inhale the steam of hot water from the beginning to the end of the fever.

The various remedies for cholera are discussed, and all heroic treatment is shown to be worse than useless. The treatment indicated by the pathology of the disease, as well as most commended by experience, consists in supplying fluid to the blood by the intestines, the skin, and the lungs. This is effected by making the patient drink cold water in abundance by the mouth, by enveloping the body in wet cloths covered by a sufficiency of blankets, and by surcharging the air of the apartment with vapour. This plan of treatment was advocated so long ago as 1832 by Mr. John G. French, of London.

Some excellent remarks will be found on the treatment of delirium tremens, which the author regards as a spontaneously curable disorder. The ordinary routine practices by opium, stimulants, digitalis, or Cayenne pepper are strenuously condemned, and the author trusts mainly to good nursing and attention to diet, having recourse to opium in small doses in protracted cases only, and always discontinuing it if the pupils become at all considerably contracted under its use. Thirty cases under the author's care, with only one death, and that from double pneumonia, bear witness to the success of the treatment. Dr. Gairdner exposes a popular error adopted by several recent writers, viz., that delirium tremens is often due to the individual *having stopped drinking*. He shows that the truth is exactly the other way, and that the disease does not depend on the ceasing to drink, but that the ceasing to drink depends on the commencement of the disease.

Thoracentesis, according to the plan of Dr. Bowditch, of Boston, is recommended in cases of pleuritic effusion with much distension. The remarks on this subject, together with a letter from Dr. Bowditch, giving the results of his extensive experience of the operation, are well worthy of attention.

In the treatment of dysentery, Dr. Gairdner has obtained great advantage from large emollient enemata, containing from five to ten minims of creasote, and repeated twice or thrice daily.

Lastly, Dr. Gairdner is a strong advocate for Dr. Christison's plan of treating renal dropsy with saline diuretics. So far from acting injuriously on the kidneys, he maintains that when diuretics fail, it is only in rare instances that other remedies will be found of material service. He observes:—

"Looking to the accumulated evidence of my own experience and that of others on this subject, I confess I am quite at a loss to understand the modern bias in favour of diaphoretics and purgatives, as opposed to a diuretic treatment, except upon the ground of a theoretical prejudice, adopted without due consideration of the facts of clinical experience."

We have said enough to convince our readers of the great merits and thoroughly practical nature of Dr. Gairdner's work. It is one which adds materially to the author's high reputation as a pathologist and clinical teacher, and reflects great credit on the Edinburgh School of Medicine. The University of Glasgow has been fortunate in securing the services of so able a clinical professor.

*Handbuch der Praktischen Medicin.* Von Dr. HERMANN LEBERT.

*Handbook of Practical Medicine.* By Dr. LEBERT, Professor of Clinical Medicine in Breslau. Two vols, 8vo. Tubingen. 1862. Third Edition.

THE works of Professor Lebert have been so long and so favourably known in England, that the task of introducing to our readers the third edition of his "Practical Medicine" will be very simple. Indeed, the book speaks for itself in more ways than one, for its career has been both short and brilliant. It is scarcely three years since the first edition was brought out, and although consisting of two immense volumes of above 1000 pages each, not only has a third edition been called for, but the work has already been translated both into the Russian and Dutch languages—facts which speak in its favour more plainly than words. As it would be out of the question for us to attempt even to give an idea of the contents of two such enormous volumes as now lie before us, we think it will be more interesting to our readers if we devote the space at our disposal to a brief *resumé* of Lebert's

views on small-pox—a subject which appears to be the chief Medical topic of the day.

First, as regards the pathology of the disease. The inflammation, he says, begins in the rete mucosum, and superficial layer of the cutis vera; but that is merely the secondary result of the blood-poisoning. The blood itself he finds to have undergone a peculiar change. It is of a dark, dirty colour, has very little tendency to coagulate in the vessels after death, and a very great tendency to stain the tissues with which it is in contact—for example, the endocardium, and inner coat of the arteries. Dr. Newkomm, Lebert's assistant, has also found a peculiar large form of crystals in the blood of small-pox, the true nature of which has not yet been ascertained. Next, as regards the condition of the internal organs, Lebert remarks that in two-thirds of his cases, which appear to be tolerably numerous, enlargement and softening of the spleen was present. The organ was of a dark red colour, and showed the Malpighian corpuscles unusually distinct. This condition of the spleen was noticed in children as well as in adults.

In about one-half of the cases examined the solitary glands of the small intestines were found enlarged, but not ulcerated. In nearly all the cases the brain and cerebral membranes were congested, and, at the same time, there was an unusual amount of fluid in the ventricles and under the arachnoid. The quantity of fluid in the pericardium was also observed to be in general increased. The lungs were almost invariably congested, and in several of the cases pulmonary apoplexy was found. Pneumonia, on the other hand, was very rare, although the contrary has been observed to be the case at Berlin.

Ecchymosis of the pleuræ, pericardium, and of the mucous membrane of the stomach was also occasionally noticed.

In one-fourth of the cases only were pustules to be found in the larynx, trachea, and bronchi, although they were constantly present in the gullet. And what was still more remarkable, in only three cases were pustules seen in the œsophagus. Lebert concludes, from his own observations, that chicken-pox, cow-pox, and small-pox are merely different grades of the same disease, and consequently that a person may be infected with true small-pox either from a case of chicken or cow-pox. Moreover, he says that the more general the epidemic, the greater is the relative proportion of mild cases. Small-pox is contagious in all its stages, but less so during incubation than in the progress or in the decline of the eruption. The infection is communicated either by the inhalation of contaminated air, or by contact. He looks upon small-pox as the most infectious of all diseases, and says that, in the Zurich Hospital, he frequently found that the convalescents from typhus took small-pox, while the convalescents from small-pox rarely took typhus.

As regards treatment, we need only make one observation, namely, that, in order to prevent pitting, Lebert adopts the simple plan of covering the face with nicely-adjusted strips of common sticking-plaster (leaving, of course, the openings of the mouth and eyes free). He keeps the plaster on for five or eight days, and thinks it acts as an abortive by virtue of the pressure it exercises on the pustules.

*A Systematic Handbook of Volumetric Analysis, or, the Quantitative Estimation of Chemical Substances by Measure.* By FRANCIS SUTTON, F.C.S. Pp. 278. Churchill and Sons. 1863.

IN no department of human knowledge have such wonderful changes been wrought during the last few years as in that usually denominated chemistry. To the advance of chemistry are due innumerable new sources of wealth, comfort, and happiness. It has fed, lighted, warmed, and clothed us by products that were entirely unknown even by name to our forefathers, and, in so doing, it has had a greater influence on the progress and direction of civilization than all the other sciences combined.

As a rule, chemical processes have been hitherto so complicated and tedious, that none but the thoroughly initiated have dared to attempt them—a circumstance which has proved an insurmountable obstacle to their general adoption in many branches of inquiry, and perhaps in none more so than that of practical medicine. The requirements of the times, however, having at length imperatively demanded their simplification, here, as everywhere else, necessity has been found to be the mother of invention; and thanks to Gay-

Lussac, Liebig, Bunsen, and others, we are now in possession of the volumetric method of analysis, which is of such simplicity that almost any well educated Medical man, without the possession of special chemical knowledge, may apply it with, comparatively speaking, little loss of time or much trouble. In the work before us, Mr. Sutton has begun by giving a very good description of the various kinds of apparatus necessary in volumetric analysis, and after the apparatus and the requisite standard solutions (a) have been obtained, we imagine that almost any one would, with the book in his hand, in the course of a few evenings, so far master the subject as to be able to make a tolerably good quantitative analysis of the urine, the chapter devoted to which includes the estimation of almost every constituent likely to be required. It includes, for example, the analysis of urea, uric acid, sulphates, phosphates, chlorides, sugar, albumen, solid matter, and saline constituents, together with the estimation of the free acid, ammonia, and specific gravity. In order to prevent disappointment, we must request our readers to bear in mind that the work gives nothing more than a description of the methods of analysing the urinary ingredients; it says nothing about their physiological and pathological bearings. These, therefore, must be learned elsewhere.

We would at the same time venture to remind our younger readers (many of whom will probably purchase the book, which we cordially recommend to their attention, as being the most complete work of its kind in the English language) that there is no royal road to a knowledge of chemical analysis, and that, notwithstanding these improved methods of research, brains as well as books are still required for their successful application.

*A Yachting Cruise in the Baltic.* By S. R. GRAVES, Commodore of the Royal Mersey Yacht Club. London: Longmans, 1863.

THIS very pleasant volume has a special claim on Medical reviewers, for, although its author is a layman, he has been assisted in its production by Dr. Moore, of Dublin, and by the Rev. Professor Haughton, of Trinity College, the former having furnished translations of several documents from the Swedish and Danish languages, and the latter having revised the book as it passed through the press.

From the Carlisle Station to Glasgow—from Glasgow away over the salt water to Copenhagen and Gothland—catching glimpses of Thorwaldsen's masterpieces, the Ethnological Museum, and the Princess Alexandra and her sisters, listening to the Dannevirke, and joining in the festivities of a Danish wedding—then away to Stockholm, St. Petersburg and Moscow, the interest of Mr. Graves' book never flags. The author is neither a mere saunterer through galleries nor a mere amateur sailor; he has picked up all sorts of information as to the people, their manners, and institutions; he has visited the Hospitals, and obtained minute accounts of their management and success. A perusal of the description given in the appendix of Frederik's Hospital, Copenhagen, and of the Seraphim Hospital, Stockholm—the latter taken from an address by Professor Sautesson, and both translated by Dr. Moore—will well repay the Professional reader. The Foundling Hospitals of St. Petersburg and Moscow furnish also a theme of great interest. In the former is a *salle* for the reception of prematurely-born infants. "It is under the care of Dr. De Burgo-Clave, and is furnished with beautifully elean cradles, made of double cases of copper, through which circulates water at any temperature required by the Physician. The little out-casts, wrapped in warm flannels, sleep away their time in these cradles, watched by skilful Physicians and nurses, and find in the charity of Holy Mother Russia a shelter which their unnatural and sinful parents would not, or perhaps we should say, could not give."—p. 223.

Although giving a very favourable description of the management of the Foundling Hospital of Moscow, Mr. Graves believes that these institutions do more moral harm than physical good. Of 42,555 children born in the maternity charity connected with the hospital, 2979 of whom

(a) The author has, in Part III., described the mode of preparing the different standard solutions, but we would recommend our readers to purchase them ready-made, as it is difficult and laborious to prepare them correctly. The cheapest way for the Medical man is therefore to buy them from the Professional chemist. We may also here mention that although we are treating the work from a Medical point of view, the chief part of it is devoted to the analysis of substances used in commerce, agriculture, and the arts.

were born in wedlock, only 86 were taken home by their mothers. A full and perfect register is kept at the Hospital, but children are very rarely reclaimed. The author asks, "Can it be that maternal feeling is less acute in Russia, or does the knowledge that the care taken of their children in this great infantine sanatorium is so superior to home training, cause Russian mothers to smother their natural solicitude for their children's welfare? Be it which it may, this institution can only be regarded as a wholesale system for the encouragement of vice, and the destruction of those maternal feelings for offspring without which woman becomes undeserving of the name."—P. 285.

We have not room for further quotation, but we heartily commend "The Cruise" to our readers. It will fill up most pleasantly a good many spare half hours. It is the very book for a sunny parlour window after work is over.

## PROVINCIAL CORRESPONDENCE.

### LIVERPOOL.

It would seem impossible to write anything about Medical intelligence from this neighbourhood just now without referring to the case of Dr. Waters, of Chester. The plaintiff is now expressing great anxiety for the full elucidation of the parentage of the poor little infant who has the misfortune to be Mary Whalley's child. She offers, in fact, a reward of £100 for the discovery of its father. A meeting of the Profession was held at Birkenhead last night, which was well attended, and at which resolutions were passed with reference to Dr. Waters similar in their import to those of the Liverpool meeting.

As to the meeting at the Medical Institution here, I do not remember ever to have attended one at which there was more cordial unanimity, or a more hearty sympathy with the purpose in hand. The personal acquaintance with Dr. Waters which several present were fortunate enough to have, and which enabled them to speak from their own knowledge of the utter improbability of such a man being obnoxious to such a charge, helped, I doubt not, to deepen the assurance which appeared to be felt by all, that a wilder and wickeder lie was never fabricated than that which formed the basis of the action of Bromwich *v.* Waters.

Had it been possible to have reported all that was said at the meeting, the feeling of disgust at the Medical evidence for the plaintiff would have been even more strongly marked than it appears to be in the account in your columns. I feel no doubt that the three gentlemen who lent themselves to this attack upon Dr. Waters have forfeited no small amount of the respect of their Professional brethren in this place.

The inveteracy of the persecution to which Dr. Waters has been subjected may be inferred from the fact mentioned by Dr. Vose in his opening address, that for months detectives have been employed in hunting up the details of Dr. Waters' life, to find, if possible, some more material that might render the charge against him credible; but, as always happens when a really innocent man is attacked, the very intensity of the efforts made to convict him serves the more clearly to set his character in its true light. There is evidently a secret history of the proceedings on the part of the plaintiff's backers, which it would be interesting, if not very edifying, to trace. I hope we, as a Profession, shall not forget the great credit due to Mr. Welsby, Dr. Waters' leading counsel, and to those who instructed him, for the tact and firmness with which the case was conducted. The wisdom of accepting a verdict for forty shillings only, in the action for slander against Miss Bromwich, was well shown in the fact that this concession elicited from Baron Bramwell the expression of his entire and hearty concurrence with the verdict of the jury; while at the same time it formed a practical proof that Dr. Waters' purpose was not to make money, or retaliate upon those who had so cruelly wronged him, but simply to vindicate his honour. His actions for slander were, in fact, brought to *compel* his accusers to have their allegations brought to a public trial, and to prevent them from backing out of the contest, which there is good reason to believe they would have been glad enough to do had Dr. Waters been willing to allow them.

With regard to the manner in which Serjeant Shee con-

ducted the plaintiff's case, I do not know what may be the feeling among lawyers, but I think that the licence of counsel and moral right—not to say decency—must be widely different, if it be considered within the limits of etiquette for an advocate, who is compelled by the answers of his own witnesses to abandon the hypothesis upon which his case in great part depended, to extemporise another on the spot, and enforce it by rhetoric instead of evidence; and further, to personally insult an antagonist whom he knows to have no possibility of defending himself. Yet all this the learned serjeant did. He quietly dropped the hypothesis that the pretended victim had been drugged, and adopted the equally revolting one that the alleged crime had been perpetrated while the woman was unconscious from the effect of her hysterical fits. During the peroration of his speech, he frequently brought his closed fist within a few inches of Dr. Waters' face. It must have been, however, some mitigation of the force of his denunciations, to remember that they came from the man in whose forensic conscience Palmer was an injured innocent.

One question which some have raised in connection with this trial—whether it is right or desirable to make uterine examinations without the presence of a third person—is, as far as I have been able to ascertain, practically answered in the affirmative by those in this town who have most to do in that line of practice; and it is found that, in a large proportion of cases, the patient herself prefers that no one but her Medical man should be present at these examinations. Speaking of this case to a non-Medical gentleman, who has for many years occupied a public position here, he said "Medical men ought to be protected to the farthest extent in the treatment of cases of this nature, otherwise there will be many diseases going unremedied, because Medical men will be afraid to undertake them." I think that this is pretty much the state of feeling in reference to this question among most sensible people. In fact, if a Medical man is not to be trusted to make any necessary examination without the supervision of some one else, I do not see why he should be trusted to see any female patient alone.

To turn now to the more strictly Medical part of my letter, I regret to say that fever is just now beginning to take a more decided hold than it has hitherto done on some of the worse parts of the town. In Toxteth-park there is a great deal, and this day as many as thirty-six cases were admitted from the Liverpool district into the Workhouse. Small-pox has lately increased; but the number of cases previously was so small, that though the difference in the proportion of cases existing now, when compared with that of last year, is considerable, the absolute number is not large for such a town as this. I believe there are at present not more than a dozen pauper patients in Hospital with this disease, and several of these are unvaccinated sailors. These unvaccinated men come mostly from the coast of Africa, but some from our own colonies. From Nova Scotia there are one or two now under treatment, and they state that vaccination is by no means a prevalent custom out there. With regard to the enforcement of vaccination among our own poor, I was told the other day by one of the district Medical officers here, who is very energetic in the vaccine part of his duties, that, do what you will, it is highly probable that a great many children pass unvaccinated, and will do so, unless there be some law rendering it imperative that the vaccination of every child should be registered within a certain time after its birth. As it is now, it may be possible to fine the parents if a child remains unvaccinated after the age of three months; but, unfortunately, it is at present nobody's business to find out if children are unvaccinated, and nobody performs that business with his usual efficiency.

At the last meeting of the Medical Society, Mr. Neill gave some interesting details of a case in which the alcoholic extract of the "Calabar bean," or "ordeal bean," had been used for the purpose of contracting an obstinately-dilated pupil. A young gentleman, who had received a blow on the eye from a stone, came under Mr. Neill's care about three weeks after the receipt of the injury. Blood had been effused into the anterior and posterior chambers of the eye. This had been absorbed; but the pupil remained about four times its natural size, and vision with that eye was much confused, and the pupil did not act under the stimulus of light. Veratria had been rubbed in, but without producing any benefit. A drop of the fluid extract, which was stated to be equal in strength to about five grains of the powdered bean, was put into the injured eye. In ten minutes the pupil had begun to act, in thirty minutes it was equal in size to that of the other

eye, and at the end of an hour it had contracted to a mere pin-point. The patient could read without difficulty, no constitutional symptoms were produced, and the other eye was not affected. The next day the contraction had very much gone off, but not so as to allow the pupil to return to its former condition. The patient was continuing the use of the remedy on alternate days, and with progressive benefit. Mr. Neill thought this agent would prove very useful in cases where it was expedient to dilate the pupil for purposes of exploration, etc., and would prevent the disagreeable confusion of vision which remains while the pupil is dilated after the use of belladonna or atropine.

## GENERAL CORRESPONDENCE.

### THE CASE OF BROMWICH *v.* WATERS.

LETTER FROM DR. FRANCIS H. RAMSBOTHAM.

[To the Editor of the Medical Times and Gazette.]

SIR,—I must again ask you for a few lines in your journal for the purpose of replying to the letter of Messrs. Kimber and Ellis.

My being in Edinburgh when I last wrote to you, and not having my note-book at hand, must explain an inaccuracy into which I inadvertently fell, and for which I beg to apologise to those gentlemen.

I was under the impression that a week at least had elapsed from the time when I was first applied to in the Chester case and the day when I saw the young woman professionally; but my memory having been refreshed by reference to letters and some very imperfect memoranda, I believe I am correct in stating that on February 4, a gentleman, whose face appeared familiar to me, and whom, indeed, I at first took for an old pupil, called on me, and asked me some Medical questions. He requested me to make an appointment to meet a certain Physician, which I did by naming two o'clock on February 6. It is quite possible that he may have said something about its being a case of seduction, but I have no recollection of that, and he certainly did not mention the name of Dr. Waters. However, I have a perfect recollection of his asking me what my fee would be for this consultation, by which I naturally concluded that my connection with the case would terminate at that interview. On arriving at the house, instead of the Physician I expected, I met Dr. Lee, who told me he had seen the patient a few days before. There were present in the room an elderly lady, whom I afterwards knew to be Miss Bromwich, and the gentleman who had called on me, and we were requested to adjourn to the next room—a bedroom—where the young woman was. I made an examination, and expressed my surprise to Dr. Lee at finding the uterus so healthy. On our return in a few minutes to the sitting-room, the question was put to me, in what state I found the uterus; when I replied, perfectly healthy, or words to that effect. I was then informed of the nature of the charge, which until that time I was not acquainted with. I am pretty sure that I recommended at that interview that the case should be abandoned, and was answered, that it had gone too far for that course being taken. I said, also, that my evidence would be of no service to them; the reply to which was, that I could speak to the state of the uterus when I examined, and therefore it would be useful, or, they must have me, or something to the same purport. At any rate, if what I have stated did not take place at that time (which I firmly believe), it did on a subsequent occasion. I considered, as I had spoken to a matter of fact, there would be no use in objecting to appear as a witness, if called upon to do so.

In regard to my willingness to give evidence, my letter inquiring when the trial was likely to come on, which Messrs. Kimber and Ellis have published, was written nearly six weeks subsequent to my examination of the young woman; and as it appeared to me, after that examination, that I should most likely be required to proceed to Chester, I thought any show of disinclination to do so would be worse than useless.

Again, in reference to what my opinion of the case may be at this time, I wrote to Mr. Kimber, on February 10, in reply to a full detail of Whalley's version of the story which he sent me, "But this is only one side of the question; when the other is heard, circumstances may appear which will very much modify our judgment."

I trust Messrs. Kimber and Ellis will acquit me of any intention to state what is not true, and,

I am, &c.

FRANCIS H. RAMSBOTHAM.

8, Portman-square, May 4.

## OBITUARY.

### MR. HENRY CHARLES JOHNSON.

MR. HENRY CHARLES JOHNSON, whose loss the Profession have to lament, died at the early age of 54. He had long suffered from some disease of the kidneys, and it was known among his friends that for years he had been the subject of renal calculus.

Mr. Johnson entered upon his public career in the year 1833, when he was appointed Lecturer on Anatomy at the then newly-instituted School at Kinnerton-street, in connexion with St. George's Hospital. He was appointed Assistant-Surgeon after an unusually sharp contest, on December 15, 1843, and became full Surgeon to the Hospital on February 4, 1853.

Of an unusually amiable disposition, Mr. Johnson appears to have made a very large circle of friends, and to have enjoyed the confidence and esteem of a very large number of patients among the upper classes of society.

His numerous Professional engagements prevented him from devoting much time to the literature of his Profession; and it is somewhat remarkable, in this age of letters, that Mr. Johnson has not left any contribution to Medical science which bears his name.

It says much for the esteem in which Mr. Johnson was held, that, although it was generally known during the last year of his life that he was unable to perform his duties at St. George's Hospital, yet that both those who formerly supported him, and those who had opposed him, united in their endeavours to make his position at the Hospital as agreeable as possible.

Mr. Johnson had expressed a wish to die Surgeon to St. George's; and while his colleagues cheerfully undertook his duties, the Board of Governors were always unanimous in their willingness to extend his leave of absence. He died, retaining his post, on April 28.

## LEGAL INTELLIGENCE.

### COURT OF EXCHEQUER, MAY 4.

(Sittings in Banco, before the LORD CHIEF BARON, Mr. Baron MARTIN, Mr. Baron BRAMWELL, and Mr. Baron WILDE.)

CLAY *v.* ROBERTS.

This was an action, by a Physician at Manchester, for libel, complaining of certain letters in the *Lancet* which imputed to him that he met homœopathists in consultation.

The declaration averred that, by the etiquette of Physicians and the Medical Profession generally, it was improper and disgraceful to meet homœopathists in consultation, and that it was injurious to the character and practice of Physicians to have it supposed that they did so. It then went on to set out the allegations complained of, and connected the plaintiff with them.

The defendant pleaded, among other pleas, as to so much of the declaration as was founded on the allegation that by the etiquette of the Profession it was considered disgraceful to meet in consultation homœopathists, that it was not so considered.

To this plea there was a demurrer.

Mr. Keane, for the plaintiff, was called upon to support the declaration. He contended that as the articles in the *Lancet* were only consistent with the desire of the writer to impress upon the public that the plaintiff's conduct was improper and disgraceful, he was estopped from denying it to be so, and that although the word disgraceful was not to be found in the libel itself, yet the substance in the imputation in it was that, according to Medical etiquette, the conduct imputed to the plaintiff by it was disgraceful.

The Lord Chief Baron said the defendant thought it disgraceful when he published the libel, and he did not think so now. Why should he not traverse the allegation?

Mr. Keane: If he has altered his opinion he should apologise, and not put the plaintiff to costs.

Mr. Thomas Jones appeared for the defendant, but was not called upon, the Court being of opinion that the plea was a good answer to so much of the action as it related to if made out.—Judgment for the defendant.

## REPORTS OF SOCIETIES.

### HARVEIAN SOCIETY OF LONDON.

FEBRUARY 19, 1863.

Dr. FULLER, President, in the Chair.

THE paper for the evening was read by HARRY LOBB, Esq., on the

USES AND VALUE OF GALVANISM AND ELECTRICITY IN GENERAL PRACTICE.

The author commenced by stating that it was not to be supposed that galvanism was only useful in the hands of the specialist, but that there was a wide field open to its use in general practice; and after some remarks upon the resemblance of the nerve and galvanic currents, proceeded to describe the apparatus he recommended for general use, consisting of, first, the electro-magnetic and magneto-electric machines for producing energetic interrupted currents, for stimulating and revulsive effects; and, secondly, the Pulvermacher galvanic battery for the generation of the continuous galvanic current. These are all that is necessary for general practice, producing the ordinary results in electro therapeutics, and can be highly recommended for their portability, cleanliness, and non-liability to get out of order. Mr. Lobb then demonstrated the action of each apparatus, describing the necessary conductors, and their application to the eye, the teeth, the uterus, the muscles, nerves, etc. He also described the method of employing the electric bath as a general stimulant, stating how valuable electricity was in diagnosing the seat of obscure diseases; that frequently the organ in fault was found to be quite remote from the suspected one. He gave the following explanation of the term "Faradisation," now frequently met with in the writings of Medical electricians:—"The term Faradisation was applied by Dr. Duchenne, of Paris, to the application of electricity derived from the secondary or finer wire of the electro-magnetic battery to the treatment of disease, out of honour to our distinguished countryman, Professor Faraday, who observed that whenever an insulated wire was brought within the influence of a wire along which a current of electricity was flowing from the positive to the negative plate of the voltaic battery, a current in the opposite direction was induced in the secondary wire of a higher degree of intensity than the current in the primary wire. Making use of this fact in conjunction with the previously-discovered one, of the increase of intensity caused by winding the insulated wires in a helix round a core of soft iron, the electro-magnetic battery was invented, and it is the application of the induced current derived from the secondary or finer wire of this battery to which the term 'Faradisation' has been applied." Mr. Lobb then proceeded to the therapeutics of galvanism, first explaining the great value of electricity in all cases of chronic rheumatism, stating that he had frequently cured rheumatic paralysis of long-standing in one or two sittings. He always applied, first, a sharp current upon the skin over the affected muscles, by means of dry metallic conductors, then stimulated each paralysed muscle to contract with the aid of moist conductors. The treatment by galvanism of the following affections were then explained in order:—Neuralgia by means of the continuous galvanic current; constipation, mixed, continuous and Faradisation; chlorosis, amenorrhœa, dysmenorrhœa, mixed; its value in Midwifery practice to arrest hæmorrhage, to stimulate the uterus to contract, to excite premature labour, or expel a polypus; its uses in chest affections, asthma, aphonia, in indigestion; in affections of the nervous system, paralysis, functional, reflex, and organic; anæsthesia, chorœa, delirium tremens; in muscular debility, spinal curvature, knock-knees, and bow-legs; confidently prognosticating that before many years the orthopædic Surgeons would set aside the use of the knife and of irons, and depend upon electricity for a cure. Its value in inveterate ulcers and carbuncle, and its probable application

in malignant disease, concluding with the method of its administration in drowning, chloroform accidents, and poisoning. Mr. Lobb then described several cases lately treated by him in the London Galvanic Hospital, particularly some cases of dropped hands, the result of poisoning by lead, which he had been the means of rapidly curing, also a very interesting case of torticollis, and a very uncommon instance of complete rheumatic paraplegia, quite cured by the continuous galvanic current in three months. The author hoped that the time was not far distant when every educated Practitioner would be as familiar with the application of galvanism in the treatment of disease as he now was with the administration of drugs; each aided the other, and their judicious combination was now producing results hitherto undreamt of; numerous cases formerly abandoned as incurable were now amenable to treatment, and advancing science was continually adding to their number. Mr. Lobb concluded a very interesting and suggestive paper by requesting the members to investigate the subject, and experiment upon the value of galvanism as a therapeutic agent, promising ample reward for labour.

## MEDICAL NEWS.

UNIVERSITY OF ST. ANDREW'S.—The following gentlemen having passed the necessary Examinations were, on April 28, admitted to the Degree of Doctor of Medicine:—

Alfred Butler, London; Hugh Campbell, London; Charles Allen Chevase, Smethwick; James George Davey, Northwoods, near Bristol; Peter Hood, London; Christopher Francis Hutchinson, Bridlington; Walter Walker Lennox, Hamilton; Charles Hills Macintosh, Torquay; John Wadham Robinson, London; George Taylor, Derby.

The following gentlemen also passed the necessary Examinations, and will receive the Degree next year:—

Josiah Sidney Smith, Tiverton; James Walsh, R.N.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 5th inst., viz.:—

Edward Chaffers, Enfield, near Accrington, Owen Gimbly, M.D. St. Andrew's, and L.S.A., Banbury, and Benjamin Whitehead Parker, L.S.A., Farington, Lancashire, students of St. Thomas's Hospital; John Bunyan Foster, Huntingdon, Duncan Francis Sinclair, Halstead, Essex, and Richard Shillitoe, Hitchin, Herts, of University College; Paynton Pigott, Great Wilbraham, Cambs., and John Babington Williams, Sydney-street, Brompton, of St. George's Hospital; Henry Parr Mallam, L.S.A., Oxford, and Walter Henry Cope, L.S.A., Buckingham-street, Strand, of the Charing-cross Hospital; Walter Thomas Beeby, M.D. St. And., Kilburn, and Ebenezer Atherton, Bingley, Yorkshire, of Guy's Hospital; Belling Harvey Mudge, Bodmin, Cornwall, and Francis Drake Pearce, L.S.A., Kingsbridge, Devon, of St. Bartholomew's Hospital; Francis Molineaux Fawcett, Yarm, Yorkshire, and Francis Albert Davey, Bath, of King's College; Walter Colman, Wymondham, Norfolk, of the London Hospital; George Herbert Clifton, Burwell, Cambs., of the Middlesex Hospital; Joseph Foster Armstrong, South Shields; and Thomas Cooke Parson, of Bristol.

The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 29th ult., and when eligible will be admitted to the Pass Examination:—

William Bell, T. H. Spilsbury, G. E. Shuttleworth, and W. T. P. Wolston, students of King's College; George Weller, J. H. Gray, William Taynton, and Ebenezer Shedd, of the London Hospital; S. F. Leach, George Rendle, and H. R. Smith, of Guy's Hospital; Frederick Ruffe and W. D. Dunn, of Birmingham; T. B. Burton and P. G. Philips, of St. Mary's Hospital; N. W. Fairles and F. M. Beckett, of St. Bartholomew's Hospital; William Liddard and H. A. Reeves, of the Middlesex Hospital; F. H. Hodges, of Bristol; Peter Harding, of University College; and C. G. Pauli, of Glasgow.

THE FELLOWSHIP.—At a meeting of the Council of the Royal College of Surgeons on the 4th inst., Mr. John Burton St. Croix Cross, of the 11th Hussars, was admitted a Fellow, having been elected at a previous meeting; diploma of membership dated August 11, 1837. Mr. William Travers, of the Charing-cross Hospital, has just passed the Preliminary Examination for the Fellowship, having been admitted a Member on April 17, 1860.

Admitted on the 6th inst.:—

Wm. Wilcox, Cardigan, South Wales, Edwin Turner, Dudley, Worcestershire, Charles Edward Covey, Basingstoke, John Legge Currie, Bungay, George Hunt Orton, Narborough, near Leicester, Matthew Trevan, L.S.A., Padstow, Cornwall, and Caleb Samuel Hilton, M.D. St. Andrew's, and L.S.A., Preston, Lancashire, students of St. Bartholomew's Hospital; Elijah Baxter Forman, Derby, Frederick Long, East Dereham, Frederic Thomas Hindle, Askerne, near Doncaster, and Thomas Jackson, Whitehaven, of Guy's Hospital; Charles Augustus Greaves, L.S.A., Derby, John

Palmer Way, L.S.A., Southsea, Hants, and Edward Sutcliff, Camberwell, of St. Thomas's Hospital; Charles Edward Cockerton, Aberystwith-terrace, Islington, and James Flack, Shoreditch, of the London Hospital; William John Allkin, Manchester, of the Charing-cross Hospital; Edwin Holbosen Green King, Portsmouth, of King's College; James Lawton Andsen, Moseley, near Manchester, John Ward, M.D. St. Andrew's, Glossop, Derbyshire, Thomas Elmes, Limerick, John William Taylor, M.D. St. Andrew's, and L.S.A., New Malton, Yorkshire, and William Smith, Spilsby, Lincolnshire.

At the same meeting of the Court, Dr. Thomas Alexander O'Flaherty, of H.M.S. *Britannia*, at Portland, passed his Examination for Naval Surgeon; this gentleman had previously been admitted a Member of the College, his diploma bearing date July 19, 1859.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, April 30, 1863:—

Frederick Sutton, Marton Vicarage, Gainsborough, Lincolnshire; Henry Stubbs, Brierley-hill; John Morton, Holbeach, Lincolnshire; Fred. Gordon Brown, Finsbury-circus, E.C.; John Reddrop, Tiverton, Devon; John William Taylor, New Malton, Yorkshire; John David Frankish, Christchurch, New Zealand; Thomas Edward Mason, Deal, Kent; Albert Weaving, Oxford; Charles Phineas Langford, Higham, Norfolk.

The following gentleman also on the same day passed his First Examination:—

Thomas Sanders, University College.

#### APPOINTMENTS.

\* \* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BUSS, H., M.D., has been appointed Surgeon to the 1st Administrative Battalion of the Tower Hamlets Royal Volunteers.

CAMPBELL, DUGALD, M.D. Univ. Glasg., has been elected Medical Officer to the Parochial Board of the Parish of Alva, Stirlingshire.

CLOUSTON, THOMAS S., M.D. Edin., has been appointed Resident Physician and Superintendent of the Cumberland and Westmoreland Lunatic Asylum, Garlands, near Carlisle.

COX, ARTHUR, M.R.C.S. Eng., has been appointed Medical Attendant to the Watford and Kilsby District of the London and North-Western Railway Friendly Society.

EARLE, J., M.R.C.S. Eng., has been appointed Medical Officer to the Altrincham Union Workhouse.

ELLIS, GEORGE VINER, F.R.C.S. Eng., has been appointed Examiner in Anatomy and Physiology at the University of London.

FARRE, FREDERIC J., M.D. Cantab., has been appointed Examiner in Materia Medica at the University of London.

HALL, J., M.D., has been appointed Assistant House-Surgeon to the General Hospital, Nottingham.

LARMUTH, MARK O., M.R.C.S. Eng., has been appointed Medical Officer to the Salford Union Workhouse.

MURRAY, W. FETTES, L.R.C.S.E., has been appointed Resident Surgeon to the Birmingham and Midland Counties Lying-in Hospital and Dispensary.

PARKES, EDMUND A., M.D. Lond., has been appointed Examiner in Practice of Physic at the University of London.

RINGER, SYDNEY, M.B., has been appointed Assistant-Physician to University College Hospital.

SIBSON, FRANCIS, M.D. Lond., has been appointed Examiner in Practice of Physic at the University of London.

STURGES, O., B.A., M.D., has been appointed Physician to the Chelsea, Brompton, and Belgrave Dispensary.

WALSH, R. P., M.D., has been appointed to the Commission of the Peace for the County Fermanagh, on the recommendation of the Earl of Erne, Lieutenant of the County.

#### DEATHS.

CHAVASSE, HOWARD S., M.R.C.S. Eng., at Sutton, Coldfield, Warwickshire.

CLARKSON, JAMES, L.R.C.S. Edin., Assistant-Surgeon R.N., on February 7.

COLEY, RICHARD MALLET, M.B. Oxon., at Cambray-place, Cheltenham, on April 25, aged 47.

CROZIER, Dr. A. W., of the 104th Regiment, on March 7, at Deyrah.

LUCAS, FRANCIS NORMAN, M.D., at sea, on the voyage homeward from Queensland, aged 29.

STEEL, JOHN, L.R.C.S. Edin., at Bradford, Yorkshire, on April 25.

UNIACKE, Dr. JAMES, of Cork, on April 24.

**THE CASE OF STONE v. STONE AND APPLETON.**—In this case a rule for a new trial has been refused.

**THE SOURCE OF THE NILE.**—Captain Speke has telegraphed to Sir Roderick Murchison, through the Foreign Office, that "on the 27th of March he was in north latitude 14 deg. 30 min. on the Nile; that all was well, and the Nile" (it is to be presumed its source) "settled."

**ROYAL COLLEGE OF PHYSICIANS.**—An address of congratulation on the marriage of their Royal Highnesses the Prince and Princess of Wales has been presented through the Home Office to the Queen, and graciously accepted; and on Wednesday, the 29th ult., Dr. Watson (President), Dr. Budd (Senior Censor), Dr. Alderson (Treasurer), and Dr. Pitman (Registrar), had the honour to present an address on the auspicious event to the Prince of Wales at Marlborough House. The addresses, which bore the corporate seal, were as follows:—

"TO THE QUEEN'S MOST EXCELLENT MAJESTY.

"Most Gracious Sovereign,—

"We, your Majesty's most loyal and dutiful subjects, the President and Fellows of the Royal College of Physicians of London, crave permission to lay before your Majesty our humble but fervent congratulations on the marriage of their Royal Highnesses the Prince and Princess of Wales.

"We hail their auspicious union, which has filled the land with rejoicing, as promising a renewal of the inestimable blessing which this nation has long enjoyed in the bright example of your Majesty's domestic life.

"We further rejoice in it, through the hope and belief that to your Majesty it has already brought much joy and consolation, and will remain a source of felicity.

"With thankfulness, therefore, and with trust, we pray that Divine Goodness may support your Majesty under your heavy trials, may guard your Majesty's health, and largely increase the happiness of your Majesty and all your Royal Family."

"TO HIS ROYAL HIGHNESS THE PRINCE OF WALES.

"May it please your Royal Highness,

"The President and Fellows of the Royal College of Physicians of London humbly but ardently desire to congratulate your Royal Highness on your most auspicious marriage. We firmly believe that at no former period of English history has the heart of the whole nation been so warmly attached to its Sovereign as it now is to our most gracious Queen, and to all her Royal Family. Hence the universal joy, the irrepressible ardour, with which the nation welcomed the arrival of the Princess whom Fame had truly reported to be in every way worthy of your Royal Highness's choice. Therefore, in common with all her Majesty's subjects, we rejoice in a union which promises all that could be desired for your Royal Highness and the Princess of Wales, as well as for the best interests and future prospects of the realm; and we pray that Divine Providence may shower down its choicest blessings on both your Royal Highnesses, and grant you uninterrupted health and happiness through a long life, cheered by the devoted affection of a loyal and contented people."

**BARNES v. HORNE AND WIFE.**—In this case, tried at Guildhall before Mr. Justice Williams, the plaintiff, a young Surgeon, sought to recover damages for a very serious slander alleged to have been uttered by the female defendant, who had accused him of having treated her unskilfully during her confinement. The defendants pleaded that what had been stated was true. The jury found for the plaintiff—Damages, £5.

**GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.**—Certificates having been produced to the Committee of the conviction of Evan Thomas, at Liverpool, for perjury, and of the conviction of Robert Wrixon, at Reading, for forgery, the Registrar was directed to erase the names of those persons from the Medical Register.

**UNIVERSITY COLLEGE, LONDON.**—The Council held their monthly meeting on Saturday. Mr. Sydney Ringer, M.B., Professor of Materia Medica, was appointed Assistant-Physician at the Hospital. The attention of the Council was called to the urgent need of public support for the Hospital, and to the fact that the committee at their last meeting were indebted to the treasurer for a loan of £500, to enable them to make payments on account to butcher and baker.

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**—At a meeting of the College, held on the 5th inst., the following gentlemen were elected examiners for the ensuing year:—*Examiners for Letters Testimonial and Fellowship*—Christopher Fleming, Jerome Morgan, George H. Porter, Benjamin Wills Richardson, M. Harry Stapleton, Edward E. Stoker, Jolliffe Tufnell. *Examiners in Midwifery*—Henry Croly, Robert Johns, E. J. Quinan. *Examiners in General Education*—Thomas Byrne, John Murray, G. F. Shaw.

**VOLUNTARY ABSTINENCE.**—Martha Batten, a prisoner in Reading gaol, refused to take food for eighteen days. She gave in on seeing the stomach-pump. On a former occasion she fasted seventeen days. She is now in a lunatic asylum.

**APOTHECARIES' HALL OF IRELAND.**—The examination for the annual prize of five guineas, granted by the Council to Apothecaries' apprentices, for the best answering on a given subject in Pharmaceutical or Pathological Chemistry, was held at the Hall on Monday and Tuesday, the 4th and 5th inst. The Prize was awarded to Mr. Alexander Duke, and an Honour-certificate was given to Mr. John O'Dwyer, for distinguished answering.

**THE NEW GARDEN ACT.**—An Act of Parliament for the better protection of gardens in cities and boroughs has just been printed. It is now enacted that gardens in squares and other places of fifty years' standing may be freed from neglect or encroachment, and vested in the Metropolitan Board of Works, or other corporate authority, or vested in a committee of rated inhabitants, for keeping the same as a garden or pleasure ground, otherwise the same may be vested in a board or parish to be kept as an open place or street, in such manner as may appear most advantageous. Protection is to be given to open spaces from encroachment. Bye-laws are to be made for the management of gardens, etc., and before they come into operation they are to be submitted to one of the judges of the common law courts or to the justices in quarter sessions.

**ILLEGAL MEDICAL PRACTICE IN FRANCE.**—The Medical Profession in France seems to have greater confidence in the efficacy of penalties in suppressing illegal practice than is entertained in this country. Petitions have recently been presented to the Senate, calling for amendment in the Act inflicting such penalties. This law dates back some sixty years, and its deficiency consists in not having declared the *maximum* and *minimum* of the fine to be imposed, leaving the magistrate free to fix its amount according to his view of the circumstances. But the Court of Cassation, in the numerous appeals which have been made to it, has always declared that in the absence of this fixation of *maximum* and *minimum*, no fine other than that for ordinary police contraventions, the *maximum* of which is fifteen francs, can be enforced. This obviously makes the whole prosecution a farce; and the law has more than once been about to be amended, when political troubles have happened to intervene and prevent this. The petitioners hope for better things under the present *régime*.

**BRITON MEDICAL AND GENERAL LIFE ASSOCIATION.**—The ninth annual meeting of the shareholders and policyholders of this Association was held on April 30, at their chief offices, 429, Strand, W.C. George H. Barlow, M.D., occupied the chair. The retiring directors, Dr. G. H. Barlow, Mr. George Chapman, and Mr. Wilson Ansell, were re-elected. A dividend at the rate of 6 per cent. per annum, free of income-tax, on the subscribed capital of the company, payable on Thursday next, was then declared. The Chairman announced that the bonus was being calculated, and they anticipated it would be very favourable for shareholders and policyholders. Dr. Richards proposed—"That the thanks of the meeting are due and are hereby given to the town and provincial Medical officers for their valuable services during the past year." The Rev. Dr. Major seconded the motion, which was carried unanimously. Dr. Lloyd, in returning thanks, considered it an honour to represent a company which was conducted so prudently, honestly, uprightly, and energetically. (Hear, hear.) A hearty vote of thanks to the chairman for presiding brought the meeting to a close.

**THE DEATHS IN THE LAST QUARTER.**—The late mild winter has been very unhealthy. The Registrar-General's last Quarterly Return states that,—“If the deaths in last quarter are compared with the mean number of two corresponding quarters in 1861-62, the increase for England was nearly 6 per cent.; for London and the North Midland Counties, 25 per cent.; for the South-eastern and South Midland Counties, and Yorkshire, 7 per cent.; for the Eastern, South-western, and West Midland Counties, about 12 per cent., while for the North-western division the increase (0.3 per cent.) is hardly appreciable; and for Lancashire, which constitutes the most important part of it, is found an actual decrease of the mortality. If the sixteen most important cotton districts of Lancashire are taken, there was an increase of deaths in five, a decrease in the remaining eleven. The increase was greatest in Chorlton (16 per cent.) and Old-

ham (21 per cent.) The decrease was great in Wigan, Warrington, Leigh, and Bury, in which places it was 17 and 18 per cent., greatest in Preston and Burnley, where it was 20 and 24 per cent. This is a brief statement of the facts, whatever may be the solution of the problem which it suggests.” So much for the effects on health of the cotton famine.

**THE WAKLEY TESTIMONIAL.**—At a meeting held at the house of Mr. Hancock on the evening of the 20th ult., the Hon. Secretary (Mr. D. O. Edwards) presented a report on the past proceedings. This report stated that some Practitioners of the metropolis had thought it desirable that some testimonial should be presented to Mr. Wakley, as an acknowledgment of his great public services. This proposition was widely accepted by the Medical Profession, and 200 influential gentlemen formed themselves into a general committee for the purpose of carrying it out. It was resolved that a suggestion should be made for the limitation of the subscription to two guineas individually, which had the effect of materially curtailing the amount. A meeting was held, at which highly complimentary resolutions were passed, and subscriptions were received. The auditors' report was read, vouching the accounts. The following resolutions were then passed:—  
1. “That the report read be adopted, and that the funds collected be offered to the University of London, to be vested in trustees, and for the purpose of founding an annual Medal Prize, to be called the Wakley Medal, and to be given to the candidate for the M.B. degree of the University of London, who shall show the greatest proficiency in Medical Jurisprudence.  
2. That the Chairman, Treasurers, and Secretaries be requested to confer with the authorities of the University of London on the above subject.  
3. That the members of the General Committee and all others who have promised subscriptions be requested to forward the same, and that further subscriptions be received up to May 30, after which date the lists will be closed. Subscriptions may be paid to the above account at Messrs. Drummond and Co., Charing-cross, or to the Treasurers, Dr. Forbes Winslow, Cavendish-square, and Mr. Godrich, Thistlegrove-house, West Brompton.  
4. That the thanks of the meeting be given to the Treasurers and Secretaries for their exertions in promoting the movement, and that those thanks are especially due to Mr. Godrich and Mr. D. O. Edwards, by whose exertions it has been chiefly advanced.  
5. That the thanks of the meeting are due, and are hereby tendered, to Mr. Hancock, the Chairman of the present meeting, for his courteous and dignified conduct in the chair.”

**SMALL-POX IN MARYLEBONE.**—On Tuesday afternoon a lodging-house keeper, named Onslow, of 61, Marylebone-road, attended before Mr. Yardley to lodge a complaint against the workhouse authorities of St. Marylebone for refusing to admit his servant, Anne Calvert, who was suffering from small-pox, into their infirmary. On the magistrate remonstrating with the overseer, the latter replied that he was sorry to say it was not the only case, for just as he came to the court-room another person requested an order from him to admit his son, who was also suffering from small-pox. The Hospitals were all full, and they did not know what to do. In company with the committee appointed by the guardians, he went to Highgate, Hampstead, Hornsey, and other suburban places, in order to see if they could not get some empty house or houses in which to place patients suffering from the disease, but as soon as they mentioned the nature of their business to the agents or landlords, they at once refused to let their premises. The number of cases was fearfully on the increase in the parish, and, unless the patients were isolated, the spread of the disease might be dreadful. Some steps he thought ought to be taken in the matter by the Government. That morning it was brought under their notice that ten persons were suffering from the disease in one room. That day, in company with their committee, he was in the Small-pox Hospital when a deputation from Clapham came and begged that admission might be given to some of their parishioners. This could not be granted them, as the place was full. It was not a matter of money. They had just paid £3 15s. for a room for one week. The only place they were likely to get in their own locality was near the vestry of the church at St. John's-wood. Near it, on one side of the path, was the clergyman's residence, and on the other that of the beadle and bell-ringer. The latter was thought a proper place by Sir James Hamilton, but it was objected to on the ground that it would drive the people from the church. Accordingly no place whatever had been found.

They had advertised for houses, but without the least success either in town or suburbs. They had now sent round to the other parishes in London to know if they would join them in erecting an iron Hospital in some of the outskirts. Their Small-pox Hospital only received four patients.

UNIVERSITY OF LONDON.—EXAMINERS FOR 1863-1864.  
—*Classics*—Rev. Charles Badham, D.D., and Rev. Joseph William Blakesley, B.D. *Mathematics and Natural Philosophy*—Wm. Henry Besant, Esq., M.A., and Edward John Routh, Esq., M.A. *The English Language, Literature, and History*—Rev. Joseph Angus, D.D., and Joshua Girling Fitch, Esq., M.A. *The French Language*—Professor Charles Cassal and Antonin Roche, Esq. *The German Language*—Professor Kinkel, Ph.D., and C. H. Schaible, Ph.D. and M.D. *The Hebrew Text of the Old Testament, the Greek Text of the New Testament, and Scripture History*—Rev. Samuel Davidson, D.D., and William Aldis Wright, Esq., M.A. *Logic and Moral Philosophy*—Professor James F. Ferrier, LL.D., and Edward Poste, Esq., M.A. *Political Economy*—William B. Hodgson, Esq., LL.D., and Richard Holt Hutton, Esq., M.A. *Experimental Philosophy*—Professor George Downing Liveing, M.A., and Balfour Stewart, Esq., M.A., F.R.S. *Chemistry*—Professor Wm. Allen Miller, M.D., F.R.S., and Professor Alex. Wm. Williamson, Ph.D., F.R.S. *Botany and Vegetable Physiology*—Joseph Dalton Hooker, Esq., M.D., F.R.S., and John Lindley, Esq., Ph.D., F.R.S. *Geology and Palæontology*—Professor John Morris, F.G.S., and Professor Andrew C. Ramsay, F.R.S. *Law and the Principles of Legislation*—Herbert Broom, Esq., M.A., and Professor Joseph Sharpe, LL.D. *Practice of Medicine*—Professor Edmund Alexander Parkes, M.D., F.R.S., and Francis Sibson, Esq., M.D., F.R.S. *Surgery*—Thos. Blizard Curling, Esq., F.R.S., and John Hilton, Esq., F.R.S. *Anatomy*—Professor George Vincr Ellis and Professor Peter Redfern, M.D. *Physiology, Comparative Anatomy, and Zoology*—George Busk, Esq., F.R.S., and William Scovell Savory, Esq., M.B., F.R.S. *Midwifery*—Wm. Tyler Smith, Esq., M.D., and Charles West, Esq., M.D. *Materia Medica and Pharmaceutical Chemistry*—Professor Alfred Baring Garrod, M.D., F.R.S., and Frederick J. Farre, Esq., M.D. *Forensic Medicine*—Professor Wm. Augustus Guy, M.B., and Wm. Odling, Esq., M.B., F.R.S.

ROYAL INSTITUTION OF GREAT BRITAIN.—ANNUAL MEETING, FRIDAY, MAY 1, 1863.—The Duke of Northumberland, K.G., F.R.S., President, in the chair. The annual report of the Committee of Visitors for the year 1862 was read and adopted. The amount of contributions from members and subscribers in 1862 amounted to £3079 13s.; the receipts for subscriptions to lectures were £560 14s.; the total income for the year amounted to 4630 8s. 1d. On December 31, 1862, the funded property was £29,341 2s. 2d.; and the balance at the bankers, £804 3s. 4d., with six Exchequer Bills of £100 each. A list of books presented accompanies the Report, amounting in number to 161 volumes, making, with those purchased by the managers and patrons, a total of 558 volumes (including periodicals) added to the library in the year. Sixty-two lectures and twenty-one evening discourses were delivered during the year 1862. Thanks were voted to the President, Treasurer, and Secretary, to the Committees of Managers and Visitors, and to Professor Faraday, and the other Professors, for their services to the Institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year:—*President*—The Duke of Northumberland, K.G., F.R.S. *Treasurer*—William Pole, Esq., M.A., F.R.S. *Secretary*—Henry Bence Jones, M.A., M.D., F.R.S. *Managers*—Sir William George Armstrong, F.R.S.; the Rev. John Barlow, M.A., F.R.S.; Sir John Peter Boileau, Bart., F.R.S.; George Busk, Esq., F.R.C.S., F.R.S.; George Dodd, Esq., F.S.A.; Sir George Everest, C.B., F.R.S.; John Peter Gassiot, Esq., F.R.S.; Sir Henry Holland, Bart., M.D., D.C.L., F.R.S.; Sir Roderick I. Murchison, K.C.B., D.C.L., F.R.S.; James Nasmyth, Esq.; William Frederick Pollock, Esq., M.A.; Robert P. Roupell, Esq., M.A., Q.C.; the Lord Wensleydale; Charles Wheatstone, Esq., D.C.L., F.R.S.; Colonel Philip James Yorke, F.R.S. *Visitors*—Hon. and Rev. Samuel Best; George J. Bosanquet, Esq.; Archibald Boyd, Esq.; John Watkins Brett, Esq.; Bernard Edward Brodhurst, Esq.; John Charles Burgoyne, Esq.; Montague Chambers, Esq., Q.C.; George Frederick Chambers, Esq.; Christopher Darby Griffith, Esq., M.P.; Captain Frederick Gausson; Kenneth

Macaulay, Esq., M.P., Q.C.; Edmund Packe, Esq.; the Earl of Rosse, F.R.S., Chancellor Univ. Dublin; the Earl Stanhope, D.C.L., F.R.S. Pres. Soc. Antiq.; George Tomline, Esq., M.P. General Monthly Meeting, Monday, May 4.—William Pole, Esq., M.A., F.R.S., Treasurer and Vice-President, in the chair. The Secretary announced that His Grace the President had nominated the following Vice-Presidents for the ensuing year:—Sir Wm. G. Armstrong; William Pole, Esq., M.A., F.R.S., Treasurer; the Rev. John Barlow, M.A., F.R.S.; Sir Henry Holland, Bart., M.D., D.C.L., F.R.S.; Sir Roderick I. Murchison, K.C.B., D.C.L., F.R.S.; the Lord Wensleydale. John Graham, M.D., and Cosmo Howard, Esq., were elected Members of the Royal Institution. The following Professors were re-elected:—William Thomas Brande, Esq., D.C.L., F.R.S., Hon. Professor of Chemistry; John Tyndall, Esq., F.R.S., Professor of Natural Philosophy; Edward Frankland, Esq., Ph.D., F.R.S., was elected Professor of Chemistry. The presents received since the last meeting were laid on the table, and the thanks of the members returned for the same.

## BOOKS RECEIVED.

The Report of the Northampton General Lunatic Asylum for 1862.

\*.\* A visit with thirty-five patients to Llandudno, in North Wales, for change of air and scene, was undertaken and carried out by Dr. Wing, the Medical Superintendent, with the best results. He writes:—

"It was delightful to see those who had (some of them for many years) been restricted to a narrow range, climbing the mountain or wandering along the beach, collecting specimens illustrative of natural history, or objects of interest and curiosity; contemplating the magnificent scenery; enjoying the bracing effects of the sea bath, or the invigorating breeze, while gliding on the surface of the water in the sail boat; exercise on foot, in rambling excursions into the neighbourhood; riding on horses, ponies, or donkeys; drives in vehicles of various descriptions; picnic parties; railway trips to localities of historical or scientific interest, or of scenic beauty, including the ancient town and castle of Conway, the city of Bangor, and the Menai Straits, with the wonderful tubular suspension bridges, parts of the Isle of Anglesea, and the mountain of Pen-Maen-Mawr, of which several made the ascent. Minor enjoyments were not lost sight of. Shopping and marketing were gratifications to some, especially the ladies. The house commanding a near and uninterrupted view of the sea, the telescope was brought into frequent requisition, and many observations were taken of the passing vessels."

Edinburgh Veterinary Review for May, 1863. Edinburgh: Maclachlan and Stewart.

\*.\* Prof. Gamgee continues the exposition of his views on Morbid Condition of Horses' Feet. They are worth the study of every man who is dependent upon the organs in question.

Edinburgh Medical Journal for May, 1863. Edinburgh: Oliver and Boyd.

\*.\* Contains a full account of the discussion on the case of Bromwich v. Waters which took place at the Medico-Chirurgical Society of Edinburgh. Prof. Simpson introduced the case, and gave the evidence on both sides with a running commentary. Dr. Ramsbotham, who was present, stated the motives and reasons for his appearance as a witness which his letters to the public journals have contained. One of the most remarkable passages in the case was the evidence, obtained by commission, of Dr. Gully, the Hydropath and Homœopath. Amongst other extraordinary statements, he said that, from the small size of the vagina, etc., he believed Whalley to be a woman of small sexual desire; and, he added, that, having examined as a phrenologist her bump of amativeness, he had come to the same conclusion. Dr. Simpson asserted, on the authority of Dr. Moir, who was present, that Dr. Lee is known to consult professionally with Dr. Gully. We hope there is some mistake here.

Dictionary of Chemistry and the Allied Branches of other Sciences. Part III. By Henry Watts, B.A., F.C.S. London: Longman and Co.

\*.\* This number commences with the conclusion of Arsenic, treats of the important subjects of Atomic Weight, Atomic Volume, and when we say that the initials W. O. are appended to these articles, our readers will understand that they contain the cream of matter. The article "Beer," by the Editor, is remarkably full and clear, and, with regard to adulteration, is comforting rather than otherwise.

The Englishwoman's Journal for May, 1863. London.

Pharmaceutical Journal for May, 1863. London: John Churchill and Sons.

Dental Review for May, 1863. London: J. W. Davies.

Catalogue of the Library of Murray's Royal Institution, Perth. By M. W. J. 1863.

Address of the Hon. William B. Reed to the Democratic Central Committee at Philadelphia. London: N. F. Mackintosh. 1863.

## NOTES, QUERIES, AND REPLIES.

¶c that questioneth much shall learn much.—Bacon.

Dr. Aldis's Report on Small pox will appear next week.

J. M. A. B.—Consult a Physician, follow his advice, and do not read Medical books.

*The Forthcoming Election of Pensioners at the Royal Medical Benevolent College, Epsom.*—We wish to appeal to those of our readers who are subscribers to this charity, on behalf of Mr. Stratford A. Eyre, who is one of the nine candidates for the five vacancies announced. The published account of the candidates sets forth that

“Mr. Eyre, M.R.C.S., was a Surgeon in the army from 1812 to 1819, and in general practice in London from 1820 to 1857, when, from ill health, he was compelled to relinquish it, although, from the expense of bringing up a large family, he had been unable to realise any independence. The income required by the laws will be subscribed by his relatives.”

We may add that from private information we can testify to the services rendered by Mr. Eyre to his country. When Hospital-mate of the 13th Infantry, on the 30th of March, 1814, at La Cole, in Lower Canada, he was with 102 men of his regiment under fire from nine o'clock in the morning until four in the afternoon. The attack of the Americans was successfully resisted, but of the 102 English officers and men present, 58 were killed and wounded, and for his services on that occasion Mr. Eyre received the appointment of Assistant-Surgeon to his regiment. Mr. Eyre's subsequent career both in the army and in private life has been unblemished. Misfortunes have overtaken him as they do the best and bravest, and he now asks from his Professional brethren an asylum for the remainder of his days. We trust that his appeal, backed as it is by the highest names in our own Profession and in the army will not be in vain.

*Deterioration of the Population of France.*—The Paris correspondent of the *Times*, writing in reference to this year's conscription of 100,000 men, notices the fact of the increasing number of recruits rejected on account of physical imperfection.

“This ogre, called the conscription, swallows up year after year the flower of the youthful rural population. Those who are left behind are comparatively short in stature, feeble in frame, and infirm. It is stated on authority which has not, I believe, been contested, that, out of 1000 youths registered as the contingent to be furnished by certain cantons, 731 were rejected by the Revision Board as unable from physical defects to bear arms. Napoleon I. used to boast that he had 100,000 men to spend every year, and his incessant wars, and incessant calls upon the population to support them, have produced what we now witness. To this, as well as to the laws on the division of property, is attributed the fact that the population for the last ten years has stood still, where it has not actually diminished, while that of other European countries has increased.”

A writer in the *Siccle* on the other hand refers the impoverishment of the population “to the excessive labour in manufacturing districts, and the want of gymnastic exercises in public schools. While the mind of the pupil, he observes, is crammed with Greek and Latin, to enable him to attain the modest distinction of *Bachelier des Lettres*, the body, which also needs cultivation and force, is completely neglected. True, the gymnasium is found in the Lyceum, but it is like the dead languages which the pupils are forced to acquire, they have no more relish for it than for Sophocles. He contends that all bodily exercises, gymnastics, fencing, swimming, riding, etc., should become not merely a neglected accessory, but the indispensable complement to education.”

THE YEAR BOOK OF THE NEW SYDENHAM SOCIETY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I find from perusing your weekly letters that collateral matter comes under admission to your Journal. I therefore trouble you with a question respecting the new Sydenham Society. Hitherto an annual contribution as little as (I think) deservedly appreciated has been circulated amongst the subscribers; and my object in addressing this letter to you is to ascertain if the year-book is to be continued. A circular was issued some time since respecting this book, in order, I suppose, to know the feelings and opinions of members regarding it. I presume, from its being still sent out, that it has met with favour amongst our brethren. All persons with whom I have had any converse on the subject have invariably and without hesitation denounced the work. Perhaps the merits of the year-book may be more fully discussed by the publicity given to the subject.

I am, &c.

Watford.

THE CALABAR BEAN AS A NEW OPHTHALMIC AGENT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—During the last fortnight I have been making experiments at the Kent County Ophthalmic Hospital by applying to the conjunctiva of both healthy and diseased eyes a solution of extracts of different strengths of the Calabar bean, as advised by Dr. Argyle Robertson in a paper read before the Edinburgh Medico-Chirurgical Society, February 4, 1863, and these experiments have been attended with the most satisfactory results, contraction of the pupil occurring shortly after its application to the same extent as dilatation of the pupil occurs after a solution of atropine has been dropped into the eye. Mr. Becker the House-Surgeon, will in the course of a short time forward to you a detailed statement of the cases; but, as there is great difficulty in procuring the Calabar beans, perhaps you will publish this letter at once. So far as I have given it a trial, I quite think with Dr. Argyle Robertson “that in the Calabar bean we possess an agent that will soon rank as one of the most valuable in the ophthalmic pharmacopœia.”

I am, &c.

JOHN WOOLCOTT, F.R.C.S.,

Surgeon to the Kent County Ophthalmic Hospital.

11, Brook-street, Grosvenor-square, and Maidstone, May 6.

DR. FOWLER'S “MEDICAL VOCABULARY”—IMPUTED PLAGIARISM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A few days after the announcement of the referees' award in this matter, my publisher applied to Mr. Churchill, asking that the objectionable preface to the second edition of Dr. Mayne's work might be withdrawn from circulation.

To this most reasonable solicitation you will be surprised to hear that Dr. Mayne has replied through his publisher in the following words:—“I cannot comply with the request of Mr. Renshaw.”

I am therefore again constrained to beg the indulgence of a space in your pages, to publicly ask Dr. Mayne to accord me that reparation which, as a man of honour and a gentleman, he must feel that I am entitled to.

I have disproved, to the satisfaction of the referees, every statement which Dr. Mayne committed himself to in respect of the dates of announcement and publication of my “Medical Vocabulary.”

Despite his production, after a period of four months, of certain alleged proofs in substantiation of the imputed plagiarism, I have also conclusively shown that the serious charges brought against me are totally devoid of foundation.

The Profession will therefore, I am sure, consider me justified in now asking of Dr. Mayne to cancel and cause to be expunged every disproved allegation of his in the aforesaid preface which relates to myself.

I am, &c.

ROBERT FOWLER, M.D. Edin.,

Author of “The Medical Vocabulary.”

145, Bishopsgate-street Without, May 4.

THE VALUE OF AN ERLANGEN DIPLOMA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you have the kindness to let me know how the Medical Act affects a licentiate of Apothecaries' Hall of Ireland duly registered, but holding the German Medical diploma of Erlangen? Can he write himself Doctor? Can he write himself M.D.? Can he put either or both of these titles on his door or window? What fee (or if any) can he charge in virtue of it? or what general authority does it give him under the sanction of the law? One does not wish to act illegally, nor yet to forego any advantages that may be gleaned from a diploma which has cost money, time, and care. I understand some cases have been decided in England bearing on my queries; if you would furnish me with the facts of them I would be much your debtor, and feel greatly obliged.

I am, &c.

John's Bridge, Kilkenny, May 1.

J. T. C.

[\*\* No qualification gives a right to practise, or any substantial privilege, unless it be registered. The question of using the title of Dr. is, we think, an open one.—Ed.]

AN ASSISTANT'S PRIVILEGES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

INFORMATION WANTED.—SIR,—I will feel obliged in the extreme if you will answer in the next issue of the *Medical Times and Gazette* the following question:—A gentleman, after being cured of gonorrhœa by me (for he told me not to let my master know of it), and paying liberally for same, which, of course, I put into the till of my employer, subsequently called on me to write for him two or three prescriptions for separate venereal affections, which I did, not copying from any prescription in my master's day-book, neither did I directly or indirectly copy from any prescription belonging to him; in fact, using nothing but his pen and ink. To whom does the fee paid for writing the same belong, master or your humble servant,

AN ASSISTANT?

May.

\*\* If the assistant had been a curate, and if some newly-married man, during the honeymoon, had sent him a teapot or a bag of sovereigns, plus the fee already paid to the rector, out of gratitude for the happiness conferred, depend upon it that the rector would make him disgorge every farthing. “An Assistant” should have no secrets from his master, and should leave it to the master's generosity.—Ed.

“ASTIGMATISMUS.”

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your correspondent “Quærens” seeks the derivation of “Astigmatismus,” a word not so recently introduced as he supposes, but suggested by Professor Whewell, and mentioned as his suggestion in the 1854 edition of Mackenzie's “Practical Treatise.” Donders writes (*Astigmatismus und cylindrische Glaeser*):—“Rev. Dr. Whewell has, wie Mackenzie, Mittheilt das gebrechen, welches Airy von seinem linken ange beschrieb, mit dem namen Astigmatismus bezeichnet. Dies wort ist abgeleitet von a priv. und στίγμα von στίζω, punge, und soll ausdrücken dass Strahlen, die von einem Punkt ansgeben, sich nicht wieder in einem Punkt vereinigen.”

Sneller, in the preface to his test types, does not intend, I think, to define astigmatism by the words which Quærens quotes, but to describe and explain one of the attendant disturbances of vision. Astigmatism might be defined as a condition in which the eye possesses differences of refractive power in its different meridians. Let us suppose the horizontal to be the meridian of greatest, and the vertical the meridian of least refraction, rays from any luminous point, falling upon the cornea in the horizontal meridian, will then have a nearer focal union than rays from the same point falling in the vertical meridian. Between the forms of vertical rays and the forms of horizontal there will be a line, the focal interval of Sturm, studded with the foci of intermediate meridians, and the eye is called astigmatic because it has no focus, point, or stigma in which all the rays falling on the cornea from a single point can be united.

I am, &c.

R. B. CARTER.

Stroud, Gloucestershire, May 4.

THE VACCINATION ACT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—You relate a very graphic and heroic adventure of exploration with l'Officier de Santé in search of the vaccine, ending in the difficult problem, how to bring costermongers, *et hoc genus omne*, under Vaccination law. The revelation arrived at, however nugatory, is most creditable to your united investigation, and if it may not bring such defaulters to book, it the more strongly inculcates the practice of vaccination where the field is open to it. After all our national and Parliamentary exertions to forward vaccination, shall those means to an end be as though they had never been—a farce, a dead letter,—which is the fact at present? There was a great mistake and blunder in making an Act and appointing no public functionary, as matter of duty, to see to its enforcement. The Boards of Guardians, so far as the poor are concerned, could see to it by the Relieving Officers or the Registrars, and the Registrars could attend to other classes; but the Registrars, who have equal or more trouble with this than with births and deaths, are only allowed a paltry threepence per case, and that only when they have a return to the notice issued. That the enforcement of the Act would be a great public benefit in the way of preventing and keeping out small-pox, as well as rendering each case of vaccination more sure, must be patent to all; and that by regularity it would furnish Medical men severally with fresh lymph, always at hand, must also be palpable. What now is the fact? Ignorance, prejudice, and apathy, as you say, among the poor, stultify the means, and it

is only when a fright of small-pox comes that they press forward for vaccination; and what then is the result? A crowd is vaccinated in a hurry, many never appear a second time at the appointed place, and vaccination necessarily suffers in the estimation of the very parties who are themselves mostly to blame for its inefficiency.

Begging that these remarks may not be deemed intrusive, and that you may further, with your ability and pen, this desirable object of making the Vaccination Act a worker and no longer a sleeper,  
I am, &c. AN OLD SURGEON.

P.S.—I believe I am right in remembering that Denmark, from the beginning, had a compulsory vaccination, and that it has been more free, in consequence, from small-pox than any other country.

## HEALTHY VACCINE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg humbly to draw attention through the medium of your valuable periodical to a peculiar but interesting advertisement that has been set forth to the Medical Practitioners of the parish of Islington by the Medical officer of that said parish, which is to the following effect:—"That a vaccine depot will be instituted at the Medical officer's offices, where vaccine lymph may be obtained by Practitioners, and for it a return of vaccine lymph is to be given by the Practitioner; thus, if he receives two charges, he is expected to return double, and so on."

Now, Mr. Editor, the question which arises in my mind, and which has been so often hinted at in your valuable articles is, that what we want, more especially at this time, is pure vaccine lymph, and, what is more, to know the source from which that lymph is obtained. Now, I ask how is this to be ascertained for certain when we are to have a general vaccine depot, where promiscuous vaccine lymph is given by any Practitioner in the parish, and no doubt the greater amount of it by those whose lot it is to vaccinate the poorer classes of suffering humanity? In private and in public practice the great object is to see the child, and know the history of its parents. Will the Medical officer guarantee that he will have full information of this, or will he not rather have to trust entirely to the Practitioner, whose time is already so fully taken up that he cannot enter into details concerning every child that is brought to him as public vaccinator. Will not it rather have a tendency to cause abortive vaccination, irritable vesicles, and a decomposed lymph, and, in place of giving vaccination a fair trial, make a mockery of it, and so depreciate it both in the eyes of the public and the Profession? I am, &c.

FREDERICK DAWSON, Jun., M.R.C.S.E., L.S.A., L.M.

1, Union-place, and 3, Englefield-road, Islington, N.

## THE BULB OF THE OVARY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In a review of Dr. Savage's "Illustrations of the Surgery of the Female Pelvic Organs," which appeared in your last impression, the writer expresses his belief that I have confounded the venous plexus, known as the "pampiniform," with the structure to which, some years ago, I gave the name of "bulb of the ovary." I venture to think that I have done nothing of the kind. Long before I commenced the series of dissections from which resulted the plates which illustrate Dr. Savage's book, I was well acquainted with the pampiniform plexus, as it is described in anatomical works and in the dissecting rooms. I subsequently found, and was, I believe, the first to describe, a structure which lies along the inferior margin of the ovary and for some distance under the Fallopian tube, in every way similar in character to that which is placed on each side of the orifice of the vagina, and which is so intimately associated with the name of Kobelt. In the bulb of the ovary, as in that of the vagina, the venous structure is surrounded by bundles of organic muscular fibre; these contract, and produce a state of erection, which, in the former case, helps very much, in my opinion, to retain the ovary in a position favourable for the application of the fimbriated extremity of the Fallopian tube during ovulation. This suggestion was contained in the communication I made to the Anatomical Society of Paris. I did not imply, as Vireow seems to have understood, that I considered the erection of the bulb of the ovary as the sole means by which this wonderful mechanism was brought about, and which still remains partially unexplained. I only inferred that it was an element in the process which, up to that time, had not received any attention from physiologists. It has done so, however, since; for Dr. Savage, in his preface, correctly states the facts when he says that M. Rouget's first mention of the "bulb of the ovary" was long after my communication to the Anatomical Society of Paris; and when he adds that M. Rouget's "illustration is an imitation of the organ" as shown in the drawing which M. Leveillé had previously made from my dissection.

Indeed, Dr. Savage's preface is so clear on all these points, that a competent critic should scarcely have permitted himself to assume that any confusion between the pampiniform plexus and an erectile structure was possible. As, however, the reviewer of the book in question has done so, I beg that you will kindly insert this letter in the next number of your valuable Journal. I am, &c. J. REEVES TRAER, F.R.C.S.

47, Hans-place, S.W., May 4.

The following is the passage in the review to which Mr. Traer refers in the above remarks:—"We believe, however, that the existence of this plexiform mass of veins" (called by Mr. Traer bulb of ovary) "has been long recognised by anatomists under the name of ovarian or pampiniform plexus." So have we learnt, and so have we taught; but what do anatomists really say? "The arteries penetrate the ovary along its attached border; the veins correspond, and the ovarian veins form a plexus near the ovary, named the pampiniform plexus."—"Quain's Elements of Anatomy," by Sharpey and Ellis. From the extreme branches (of the blood-vessels in the ovary) the blood is returned by the veins which pass to the base of the ovary where they are very numerous.—Fig. 370, b—which shows the plexus of veins in connection with the lower border of the ovary in transverse section. "They form near the ovary, and between the folds of the broad ligament a plexus termed ovarian or pampiniform."—Fig. 369, d—which represents a dense plexiform mass occupying the situation where Mr. Traer has placed the "bulb of the ovary."—*Cyclop. Anat. and Physiology*, art. "Uterus," p. 552. It appears therefore that anatomists include in the term "pampiniform plexus" the whole of the veins emerging from the lower border of the ovary and lying between it and the spermatic and utero-ovarian veins. Since M. Rouget recognised an "enormous venous

mass" beneath the ovary, we know not how he could have "overlooked the bulb of the ovary" as he is said in the preface to Dr. Savage's work to have evidently done.

## ORIGINAL LECTURES.

## PROFESSOR HUXLEY'S LECTURES

AT THE

## ROYAL COLLEGE OF SURGEONS.

## LECTURE VI.

*(Being the Fifth of Six Lectures on Classification, and on the Characters of the Principal Groups of the Animal Kingdom.)*

IF we now turn to the other column of classes of invertebrate animals (*supra*, p. 259), the four first on the list, viz., *Cephalopoda*, *Branchiogasteropoda*, *Pulmonata*, and *Pteropoda*, have a number of well-marked characters in common. In all, the nervous system is composed of three principal pairs of ganglia—cerebral, pedal, and parieto-splanchnic—united by commissures. All possess that remarkable buccal apparatus, the odontophore,—whence I have ventured to propose the name of *Odontophora* for the group. The circulatory and respiratory organs vary a good deal, but none are provided with double lamellar gills upon each side of the body.

The *Lamellibranchiata* stand in somewhat the same relation to the *Odontophora* as the *Annelida* to the *Arthropoda*. The *Lamellibranchs* have the three fundamental pairs of ganglia of the *Odontophora*, but they possess no trace of the odontophore. Furthermore, they are all provided with bivalve external pallial shells, the valves being right and left in relation to the body. No shell of this kind is found in any of the *Odontophora*. Almost all *Lamellibranchs*, lastly, have a pair of lamellar gills on each side of the body, and all are provided with auriculate hearts. No doubt the *Odontophora* and the *Lamellibranchiata* properly form parts of one and the same sub-kingdom, MOLLUSCA, and the three classes which follow, viz., the *Aseidioida*, *Brachiopoda*, and *Polyzoa*, are usually included in the same sub-kingdom.

But the difficulty of framing a definition which shall include the last-named classes with the *Lamellibranchiata* and *Odontophora* is almost as great as in the parallel case of the *Annuloida* and *Annulosa*, while, on the other hand, the *Ascidians*, *Brachiopods*, and *Polyzoa* exhibit many features in common. Thus the nervous system is greatly simplified in all three classes, consisting, in the *Aseidioida* and *Polyzoa*, of a single ganglion, sending perhaps a commissural cord round the gullet. In the *Brachiopoda* the chief ganglia, which appear to be the homologues of the pedal ganglia of the higher mollusks, and are connected by a circum-œsophageal cord, are combined with accessory ganglia, but these do not seem to be identifiable with the pedal or the parieto-splanchnic ganglia.

Again, the fact that the heart, when present, is of a simple tubular or saccular character, and is devoid of any separation into auricle and ventricle, constitutes a wide difference between these three classes and the higher Mollusks. On the other hand, these classes, which may be conveniently denominated MOLLUSCOIDA, resemble one another in the fact that (so far as I am aware there is only one exception, *Appendicularia*) the mouth is provided with ciliated tentacula, disposed in a circle, or in a horse-shoe shape, or fringing long arms; that it leads into a large, and sometimes an exceedingly large, pharynx; and that in two of the three, at least, that system of cavities communicating with the exterior, which has been called the "atrial system," is greatly developed.

I cannot doubt, then, that the *Molluscoida* form a natural assemblage; but until the precise characters, if any exist, which unite them with the *Mollusca* proper can be clearly defined, I am inclined to think it might be better, as in the case of the *Annuloida*, to recognise them as a separate division of the Animal Kingdom.

The next two classes—the *Actinozoa* and the *Hydrozoa*—constitute one of the most natural divisions of the animal kingdom—the CŒLENTERATA. In all these animals the substance of the body is differentiated into those histological elements which have been termed cells, and the latter are primarily disposed in two layers, an external and an internal, constituting the "ectoderm" and "endoderm."

Among animals which possess this histological structure, the *Cœlenterata* stand alone in having an alimentary canal, which is open at its inner end, and communicates freely, by

means of this aperture, with the general cavity of the body. In a large proportion of these animals the prehensile organs are hollow tentacles, disposed in a circle around the mouth, and all (unless the *Ctenophora* should prove to be a partial exception to the rule) are provided with very remarkable organs of offence and defence, termed "thread cells" or "nematocysts." These, when well exhibited, as, for example, by the common freshwater polype (*Hydra*), are oval, elastic sacs, containing a long coiled filament, barbed at its base, and serrated along the edges. When fully developed, the sacs are tensely filled with fluid, and the slightest touch is sufficient to cause the retroversion of the filament, which then projects beyond the sac for a distance, which is not uncommonly equal to many times the length of the latter. These fine filaments readily penetrate any delicate animal tissue with which they are brought into contact, and in the human skin cause great irritation. Nor can it be doubted that they exert a similarly noxious influence upon the aquatic animals which are seized by, and serve as prey to, the *Actinozoa* and *Hydrozoa*. Characteristic as these organs are of the Cœlenterates, however, it must not be imagined that they are absolutely peculiar to the sub-kingdom; some nudibranchiate *Mollusca*, such as *Eolis*, are armed with similar weapons, and the integument of certain *Turbellaria*, and even of some *Infusoria*, is provided with bodies which seem to be of a not altogether dissimilar character.

No Cœlenterate possesses any circulatory organs, unless the cilia which line the general cavity of the body can be regarded as such; and a nervous system has, at present, been clearly made out only in the *Ctenophora*. Here its central mass occupies a position which is very unlike that in which the principal masses of the central nervous system are found in other invertebrate animals, being situated upon that side of the body which is diametrically opposed to the mouth.

Whatever extension our knowledge of the nervous apparatus of the Cœlenterates may, and not improbably will, receive from future investigators the positive characters afforded by the histological features of their substance, and the free opening of their alimentary canal into the general cavity of the body, are such as to separate them, as a sub-kingdom, as sharply defined and devoid of transitional forms as that of the *Vertebrata*, from the rest of the Animal Kingdom.

Great difficulties stand in the way of any satisfactory grouping of the remaining classes, if we are determined to remain true to the principle that the definition of a group shall be true of all members of that group, and not true of any others,—a principle which lies at the foundation of all sound classification.

In possessing cilia as locomotive and ingestive organs; in being provided with a contractile water receptacle with vessels proceeding from it (in some cases at any rate) into the substance of the body; in their tendency to become encysted and assume a resting condition, the *Infusoria* undoubtedly exhibit analogies with the lower *Annuloida*, such as the *Turbellaria*, *Rotifera*, and *Trematoda*.

But the entire absence, so far as our present knowledge goes, of a nervous system, the abrupt termination of the gullet in a central semi-fluid sarcodic mass, and the very peculiar characters of the reproductive organs, of the *Infusoria*, separate them widely from the *Annuloida*, though it seems to me not improbable that the gap may hereafter be considerably diminished by observation of the lower forms of *Turbellaria*.

At present the *Infusoria* are usually regarded as forming part of the same sub-kingdom as the *Spongiada*, *Rhizopoda*, and *Gregarinida*, and as closely allied to them. But, so far as I am aware, no definition can be framed which will yield characters at once common to, and distinctive of, all these four groups; and recent discoveries tend to widen so greatly the hiatus between the *Infusoria* and the other three classes, that I greatly doubt if the sub-kingdom *Protozoa* can be retained in its old sense.

But if the *Infusoria* be excluded from it, the remaining groups, notwithstanding the imperfection of our knowledge regarding some of them, exhibit a considerable community of partly negative and partly positive characters.

The *Spongiada*, *Rhizopoda*, and *Gregarinida*, in fact, are all devoid of any definite oral aperture; a considerable extent, and sometimes the whole, of the outer surface of the body acting as an ingestive apparatus. Furthermore, the bodies of these animals, or the constituent particles of the compound aggregations, such as the Sponges, exhibit incessant changes of

form—the body wall being pushed out at one point and drawn in at another—to such an extent, in some cases, as to give rise to long lobate, or filamentous, processes, which are termed “pseudopodia.”

Finally, all these classes agree in the absence of any well-defined organs of reproduction, innervation, or blood circulation.

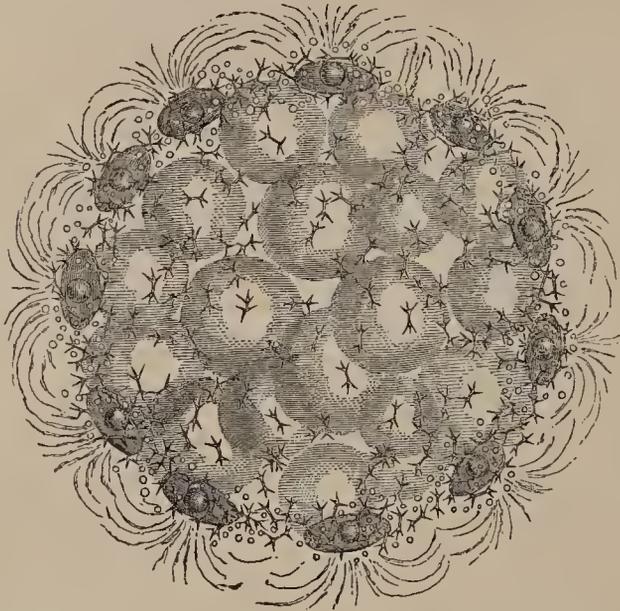

In my first lecture upon Classification, I passed very briefly over the class *Rhizopoda*, intending to return to the discussion of its limits, and of the value of its subdivisions, when discussing the subdivisions of classes generally. But as time will not permit me to enter at any length upon the greater part of this branch of my subject, I will content myself with briefly stating the conclusions at which I have arrived from a careful study of the extant literature of the subject, combined with some old investigations of my own.

It appears that three, or perhaps four, types of structure obtain among the *Rhizopoda*—

1st. That of the *Amœba*—Rhizopods with usually short pseudopodia, a nucleus, and a contractile vesicle.

2nd. That of the *Foraminifera*—Rhizopods devoid of nuclei and of contractile vesicles, and, for the most part, with long pseudopodia, which commonly run into one another and become reticulated.

3rd. That of the *Thalassicollæ*, provided with structureless cysts containing cellular elements and sarcodæ, and surrounded by a layer of sarcodæ, giving off pseudopodia, which commonly stand out like rays, but may and do run into one another, and so form networks.

*Sphaerozoum ovoidimare* (after Hæckel), one of the *Thalassicollæ*.

While a fourth type of structure is probably furnished by those anomalous creatures, the *Acinetæ*, the radiating processes of which serve as suctorial tubes down which the juices of their prey are conveyed.

That the *Rhizopoda* are divisible into at least three groups, corresponding to the three first-mentioned types of organisation, seems to me unquestionable; but it is another matter, and one on which I offer no opinion, what should be the exact limits of these groups, and what denominations we ought to employ for them. And it must be recollected that, so long as naturalists are unacquainted with the sexual method of reproduction of these animals, they are, to a certain extent, working in the dark.

In conclusion, I may sum up the results of this lecture by stating that, in the present state of our knowledge, the whole Animal Kingdom is divisible into eight categories or groups, no two of which are susceptible, in the present state of knowledge, of being defined by characters which shall be at once common and diagnostic.

These groups are the

	<i>Vertebrata.</i>	
<i>Mollusca.</i>		<i>Annulosa.</i>
<i>Molluscoida.</i>		<i>Annuloida.</i>
<i>Cœlenterata.</i>		<i>Infusoria.</i>
	<i>Protozoa.</i>	

I leave aside altogether the question of the equivalency of these groups; and, as I have already stated, I doubt the per-

manency of one—the *Infusoria*—as a distinct primary division. Nor, in view of the many analogies between the *Mollusca* and the *Molluscoida*, the *Annulosa* and the *Annuloida*, do I think it very improbable that hereafter some common and distinctive characters may possibly be discovered which shall unite these pairs respectively. But the discoveries which shall effect this simplification have not yet been made, and our classification should express not anticipations, but facts.

I have not thought it necessary or expedient, thus far, to enter into any criticism of the views of other naturalists, or to point out in what respect I have departed from my own earlier opinions. But Cuvier's system of classification has taken such deep root, and is so widely used, that I feel bound, in conclusion, to point out how far the present attempt to express in a condensed form the general results of comparative anatomy departs from that embodied in the opening pages of the “*Régne Animal*.”

The departure is very nearly in the ratio of the progress of knowledge since Cuvier's time. The limits of the highest group, and of the more highly organised classes of the lower divisions, with which he was so well acquainted, remain as he left them; while the lower groups, of which he knew least, and which he threw into one great heterogeneous assemblage,—the *Radiata*—have been altogether remodelled and rearranged. Milne Edwards demonstrated the necessity of removing the *Polyzoa* from the radiate mob, and associating them with the lower Mollusks. Frey and Leuckart demonstrated the subregal distinctness of the *Cœlenterata*. Von Siebold and his school separated the *Protozoa*, and others completed the work of disintegration by erecting the *Scolecida* into a primary division, of *Vermes*, and making the *Echinodermata* into another. Whatever form the classification of the Animal Kingdom may eventually take, the Cuvierian *Radiata* is, in my judgment, effectually abolished: but the term is still so frequently used, that I have marked out those classes of which it consisted in the diagram of the Animal Kingdom (p. 259), so that you may not be at a loss to understand its application.

## ORIGINAL COMMUNICATIONS.

### ON THE EFFECTS OF THE SOLUTION OF THE CALABAR BEAN ON THE ACCOMMODATION OF THE EYE AND ON THE PUPIL.

By J. SOELBERG WELLS,

Ophthalmic Surgeon to, and Lecturer on Ophthalmic Surgery at, the Middlesex Hospital.

In a paper recently read before the Edinburgh Medico-Chirurgical Society (February 4, 1863), my friend Dr. Argyll Robertson called the attention of the Profession to the interesting fact that the Calabar bean possesses the peculiar property of stimulating the sphincter pupillæ and the ciliary muscle to contraction. He not only fully ascertained, in a series of ably-conducted experiments, its power of causing contraction of the pupil and of the ciliary muscle when a drop of its extract is applied to the conjunctiva, but also proved its efficacy in counteracting the paralyzing effect of atropine upon the pupil and the accommodative power of the eye.

Professor Christison some years ago gave an interesting account of the properties of the Calabar bean(a), and of some experiments which he made with it upon himself. Having swallowed twelve grains of the bean, he was soon seized with giddiness and extreme weakness, together with other symptoms of severe poisoning, the heart and pulse becoming exceedingly feeble and tumultuously irregular. But it does not appear to have caused any impairment of vision.

Messrs. Bell and Co. having some weeks ago kindly procured for me some of the beans from Edinburgh, and prepared some solutions of various strength, I have been enabled to make repeated experiments with the extract, the results of which have fully borne out Dr. Robertson's experience. I gave a portion of the strongest solution (one minim of which corresponds to four grains of the bean) to Mr. Bowman, and at his request applied a little to his eye, and he has kindly

(a) “On the Properties of the Ordeal Bean of Old Calabar, West Africa,” by Robert Christison, M.D., etc., etc., read before the Royal Society of Edinburgh, February 5, 1855.

furnished me with the following valuable notes of his personal experience of its physiological effects:—

“We are much indebted to Dr. Robertson for calling attention to the influence of the Calabar bean on the ciliary muscle and on the iris. His paper is conclusive as to the reality of these effects, and my friend, Mr. Neill, of Liverpool, informs me that he has found the pupil to be contracted by it even in cases of dilatation of the pupil, the result of injury. This would seem to imply a direct specific action on the circular muscular fibres of the iris, and if so, in all probability also on the tissue of the ciliary muscle,—an action of stimulation producing a result the precise reverse of that of atropine.

“I gladly took advantage of the solution of the bean which you brought me, and of your offer to note its effects on my eye. The inside of the left lower lid was touched at 5.5 p.m., on April 30, with, I suppose, about a tenth part of a minim of the solution. Both my eyes are alike in optical power, and are in all respects normal. The pupils had a diameter of rather more than one line. The contact caused a slight smart for a minute.

“In five minutes (5.10) I experienced a decided tight feeling referrible pretty accurately to the ciliary region of that eye, as if something were creeping about in it.

“In ten minutes (5.15) this continued, together with occasional rather sharp pains in the ciliary region. An attempt to read with both eyes instantly increased this pain, and the type was confused, as if by a disturbance of the power of accommodation.

“In thirteen minutes (5.18) the near point of the left eye (Jaeger, No. 1) was at six and three-quarter inches, that of the right eye being fifteen inches, thus indicating a spasm of accommodation in the left, and a diminished power in the right eye. With this change, the effort to look at the type or optometer with either eye, or with both, much aggravated the sense of distress in the left eye. The type looked smaller with the right eye than with the left. The far point seemed the same as before in each eye.

“In twenty minutes (5.25) I could see Jaeger 17 at fifteen feet, but with the left eye with a remarkable oscillation in the distinctness, so that the type came and went, at one instant quite clear, then indistinct, which coincided with the sensations present in the ciliary region, as if the ciliary muscle was undergoing irregular contractions. The left pupil was now observed to have become rather suddenly contracted to the size of a large pin's head; and to avoid repetition, I may state that this contraction continued to the full amount for eighteen hours, then gradually relaxed during about three days, after which it was like its fellow. As it gradually dilated, it also resumed gradually its mobility under light, whether falling on its own or the opposite retina, or on both. With the sudden contraction of the pupil came also a sudden twilight gloom, as of an eclipse of the sun, much more marked when the left eye only was open. But this gloom soon lessened, owing, probably, to the retina, by continuance, becoming accustomed to the quantity of light admitted, and on the next day it was hardly noticeable.

“In twenty-five minutes (5.30) the pupil being extremely small, we noted the astigmatism. The vertical bars of a window were seen clear and sharp at from six to ten feet, the horizontal bars within the same range having thin edges, slightly hazy, but rendered clear by a concave cylindrical glass of fourteen inches focus suitably placed. Distant objects seen by the left eye through a concave spherical glass of fifty inches focus were very decidedly diminished in size.

“In thirty minutes (5.35) the near point by No. 1 of Jaeger was for the left eye at six and a-half inches, for the right eye only at ten and a-half inches, not nearer or further off, and even at this distance indistinct, whereas with the left eye the letters were crisp and clear. To this better sight of the left eye two causes contributed,—the larger size of the retinal image from greater nearness of the type to the eye, and the smallness of the pupillary aperture. With the left eye the near point for vertical lines was at eight and a-half inches, for horizontal lines at six and a-half inches. With the right eye the near point for vertical lines was at eleven and a-half inches, for horizontal lines at seven and a-half inches. The strained feeling of the left eye was less after half an hour, but did not quite cease till the next morning. The attempt to read continued somewhat painful all the evening, and even next day both eyes were somewhat uneasy in sustained vision of near objects, with both eyes or either of them.

“Eighteen hours afterwards (noon on May 1) both eyes

were alike as to accommodation, and in both the near point for vertical and horizontal lines was one inch nearer the eye than natural, viz., for horizontal lines near point seven inches, vertical lines near point nine inches; and at twenty-four feet each eye could read No. 18 of Jaeger, only the letters were more sharply defined with the left, and looked rather smaller. The pupils were then,—

The eyes in shade, R  $\bigcirc$  L  $\bigcirc$ ; in the light, R  $\bigcirc$   $\bigcirc$  I.

“By way of comparison I accurately examined the accommodation for horizontal and vertical lines with each eye on May 9, and found both eyes alike; the near point for horizontal lines being nine inches, and for vertical lines ten inches for each,—one inch more remote from the eye than after eighteen hours from the instillation of the solution of the bean.”

I will now pass on to the description of a case of paralysis of the circular fibres of the iris and of the ciliary muscle of the right eye (the left being perfectly normal) which presented itself most opportunely at the Middlesex Hospital on April 25, and afforded me an excellent opportunity, not only of fully testing the efficacy of the bean, but of making parallel and comparative experiments upon the two eyes, and watching, step by step, its effect upon the healthy and the paralysed structures.

Mrs. D., aged 26, was admitted an out-patient of the Middlesex Hospital April 23, 1863. She is suffering from paralysis of the constrictor pupillæ and of the ciliary muscle of the right eye. This affection appears to be of rheumatic origin, for about three months ago she was seized with a severe attack of rheumatism of the right side of the face. A day or two afterwards the sight of the right eye became affected, so that she could not see to read or to thread a needle when both eyes were open; she was also troubled with diplopia, to free herself from the annoyance of which she was obliged to close the right eye when sewing, etc. About the same time she also noticed a marked increase in the size of the pupil of the right eye. Her sight and health had previously been always good. There is nothing in her history or symptoms that would point to a specific or cerebral cause of the affection of the eye.

April 25.—The state of the two eyes was ascertained to be as follows:—

*Right Eye.*—The pupil is widely dilated (about four lines) and immovable. The sight is much affected, for she can only read No. 16 of Jaeger, but not closer than eighteen inches from the eye. With a convex glass of six inches focus she can read the finest print (No. 1), the near point then lying at five and three-quarter inches, the far point at six and a-half inches from the eye. This proves that there is still a minimum of accommodation, and that the eye is very slightly hypermetropic. The truth of the latter statement is proved by the fact that she can only read No. 19 at a distance of eighteen feet, but that with a convex glass of sixty inches focus she can read No. 18. A drop of a strong solution of atropine (gr. iv. to ʒj of water) was then applied to this eye, and four hours later the eye was again examined. The pupil was found to be slightly more dilated; the state of vision being the same as before, except that No. 1 could only be read with a convex glass of six inches focus at six and a-half inches, the last remnant of accommodative power had been temporarily destroyed.

The left eye was quite normal. Reads No. 1 at four inches, and, at a distance of eighteen feet, No. 16.

There was not the slightest impairment of the movements of the eye, and the refracting media and inner tunics were perfectly normal.

Within the next five days some solution of the Calabar bean was tried twice with marked effect, but as my time would not permit me to watch the course of the effect continuously during several hours after the application, I shall pass on at once to a detail of the last experiment (May 4), which I must be excused for giving somewhat at length, as it is interesting to watch step by step the peculiar action of the bean upon the pupils and accommodation of the two eyes.

May 4.—At 10.30 a.m. the condition of the two eyes was again tested.

*Right Eye.*—The pupil, stationary, measures three and a-half lines in diameter (the effect of the last experiment upon the pupil does not appear to have quite subsided, for previous to the last application of the bean, last Thursday, the pupil measured four lines). Can only read No. 16. In order to ascertain how much the dilatation of the pupil might influence

the state of vision, a diaphragm, having an opening one-third of a line in diameter, was placed before this eye, and it was found that this greatly improved the sight, for with it she could read words of small type (No. 4) from thirteen to sixteen inches, but not a word of No. 2. At a distance of eighteen feet can only read No. 19; with convex 80, No. 18; with diaphragm, No. 16; with diaphragm and convex 50, No. 16.

*Left Eye.*—Pupil, active, measures two lines in diameter. Can read No. 1 at four inches, No. 16 at 18 feet; with convex 80, only No. 19; with concave 50, only No. 20. At 11 a.m., a large drop of the strong solution of Calabar bean (one minim corresponding to four grains) was applied to the conjunctiva of each eye. It gave rise to a slight sensation of burning in the corners of the eye, and in about five minutes the lids felt heavy and leaden, as if they could hardly be lifted. At the same time, a peculiar sensation, as of something jumping and buzzing about the eye, was experienced, and a darting pain was felt in the ciliary region.

Fifteen minutes afterwards (11.15) objects about the room appear dark and misty. The smarting has ceased in both eyes, but the heavy, leaden feeling of the lids continues; the darting, jumping sensation in the ciliary region is less, and is intermittent, but is aggravated by an attempt to read.

*Right Eye.*—The size of pupil is diminished to two and one-third of a line, perfectly stationary. She can now read the finest print (No. 1) from ten and a-half to fourteen inches. At a distance of eighteen feet cannot read No. 20. *Left Eye.*—Pupil measures one and one-third line, active, slightly oblong in transverse diameter; can read No. 1 only from three and a-half to five inches. At eighteen feet can only read No. 20; with concave 14, No. 16, but the letters appear very dark. In reading either near at hand or at a distance there is a constant oscillation in the sight of both eyes,—at one moment she can see distinctly, at the next the print becomes clouded and fades from her sight.

At 11.30. *Right Eye.*—Pupil measures two-thirds of a line, stationary. Can read No. 1 from eight to eleven inches. Cannot read No. 20 at eighteen feet. With concave 14, can read No. 18; cannot read No. 16 with any concave glass.

*Left Eye.*—Pupil measures two-thirds of a line, active, heart-shaped, the base being upwards. Reads No. 1 from three and a-half to five and a-half inches; cannot read No. 20 at eighteen feet; with concave 6 can read No. 18 but indistinctly; with concave 7, No. 19; cannot see No. 16 with any concave glass. She complains of "blacks" floating about before her eyes. In testing her near and far point for No. 1, she is obliged to bring the print first to about her near point, and then gradually to move it further and further from the eye. She could not at once read it at the far point; this being particularly the case with the left eye. The type does not appear larger or nearer to her, only darker.

11.45.—The effect upon the accommodation is beginning slightly to wear off upon both eyes, but not upon the pupil.

*Right Eye.*—Pupil measures two-thirds of a line. Reads No. 1 from ten to twelve inches. Can now decipher No. 20 at eighteen feet; with concave 24, No. 18; concave 14, only No. 20. *Left Eye.*—Pupil measures two-thirds of a line. Reads No. 1 from three to ten and a-half inches; can see No. 20 at eighteen feet; with concave 14, No. 18 plainly; concave 6, only No. 20, not No. 19.

12. The eyes do not smart now; objects in the room appear more light. *Right Eye.*—Pupil measures one line. Can read No. 18 at eighteen feet; with concave 36, No. 16. *Left Eye.*—Pupil measures one line. Reads No. 1 from four to fourteen inches; No. 19 perfectly well at eighteen feet; with concave 20, No. 16.

At 12.7.—She could not read No. 1 with the right eye; only No. 2 from fifteen to nineteen and a-half inches.

12.15. *Right Eye.*—No alteration in the size of the pupil. Can now again see No. 1 from sixteen to eighteen inches, but only for a moment, the letters then become veiled, and disappear. On first looking she could see No. 16 quite plainly at eighteen feet, but in a moment or two the letters became clouded, so that she could only see No. 18. The myopia has almost disappeared on this eye, for with concave 50 she can only read No. 18, not No. 16. *Left Eye.*—Pupil the same. At a distance reads No. 19, not a word of No. 18. With concave 24, No. 16 very plainly.

1.20. *Right Eye.*—Pupil still measures one line. Cannot see smaller print than No. 12, this best at twenty-two inches from the eye. With a diaphragm can see No. 1 at about

fourteen inches, but only very indistinctly. Can see No. 18 very plainly at eighteen feet, also with concave 50. *Left Eye.*—Pupil still measures one line. Reads No. 1 from four to seventeen inches; can see No. 18 very dimly; with concave 24, No. 18 distinctly. The reason of her being unable with either eye to see No. 16 at a distance may be due to the unfavourable light upon the test type.

2.15. *Right Eye.*—The pupil has increased to one and a-quarter line. Can see no print smaller than No. 12, this from twenty-three to fifty-one inches; with the diaphragm only No. 4 from sixteen to twenty-one and a-half inches. Can see No. 18 very plainly at eighteen feet. The eye has again become slightly hypermetropic; for she sees No. 18 worse with concave 50, better with convex 80. *Left Eye.*—Pupil still measures one line. No. 1 from four to seventeen inches. With concave 30, No. 16 indistinctly at eighteen feet distance.

3.30. *Right Eye.*—The pupil dilated to one and a-half lines. Can see No. 12 from thirty to fifty-one inches; with diaphragm No. 4 from seventeen to twenty-one inches. At eighteen feet No. 18 very plainly. Cannot now see No. 18 with concave 50, only No. 20; with convex 60, No. 18. *Left Eye.*—Pupil dilated to one and a-quarter line. Reads No. 1 from four to seventeen inches; at eighteen feet, No. 18 very dimly, but very fluently with concave 40.

5.35. *Right Eye.*—The pupil now measures two lines. Reads No. 12 from twenty-seven to forty-five inches; with diaphragm can read No. 4 from eighteen to twenty-two inches. A bright light being thrown on the test type, she can read No. 18 at a distance of eighteen feet; with diaphragm can read No. 16; still better with convex 80; with convex 60, only No. 18; with concave 50 No. 20 appears very dull. *Left Eye.*—The pupil has regained its normal size, viz., two lines; can read No. 1 from four to sixteen inches, and can now see it for the first time at once at the far point, being no longer obliged to move it gradually further off until this point is reached. At eighteen feet reads No. 18 fluently; with convex 80, only No. 20; with concave 30, No. 16 with difficulty; with concave 24, No. 18 distinctly. She is much fatigued by the examination, and complains of frontal headache.

Tuesday, May 5, 5 p.m.—*Right Eye.*—Pupil dilated to three lines; cannot read No. 12, only No. 16; at eighteen feet No. 18; also with convex 80, but not with convex 60; with concave 50 cannot read No. 20. *Left Eye.*—Pupil measures two lines. Reads No. 1 from four to thirteen and a-half inches; at eighteen feet, No. 18; with concave 24 also No. 18; convex 80, No. 20. She complains of headache, and of considerable dimness in both eyes.

May 7, 10.30 a.m.—*Right Eye.*—Pupil measures three and a-half lines. Reads No. 16; with diaphragm, No. 4 from seventeen and a-half to twenty-one inches; at eighteen feet, No. 19, words of No. 18 but indistinctly; with convex 60, No. 18 easily; with diaphragm, No. 16; with concave 50, only No. 20. *Left Eye.*—Pupil measures two lines. Reads No. 1 from four to fourteen and a-half inches; at eighteen feet only No. 19 at first, then the letters of No. 18 break upon her; with convex 80, only No. 20; with concave 30, No. 16.

May 11, 10.30 a.m.—*Right Eye.*—Pupil is smaller than two days ago, measuring now only three lines; her sight is also better, for she can read No. 12 to-day from twenty-four to thirty inches, and with diaphragm No. 2, at eighteen feet can read No. 18, and words of 16 with convex 80; with concave 50 only No. 20 indistinctly. *Left Eye.*—Pupil measures two lines. Reads No. 1 from four to sixteen inches; at eighteen feet No. 18, and words of No. 16; with concave 36 No. 16 fluently, with convex 80, No. 20 indistinctly.

These experiments illustrate most fully the peculiar action of the Calabar bean upon the size of the pupil and the accommodation of the eye. Not only was the pupil of the healthy eye rapidly contracted, but even the paralysed pupil, which before the application measured three and a-half lines, was contracted to two-thirds of a line (the size of a pin's head) within half-an-hour after the instillation of the extract. The maximum of contraction of the pupil was the same in each eye, but the left regained its original size sooner, it also always remained active under the influence of light, whereas the right was quite immovable. The sight of the right eye also rapidly improved, for within a quarter of an hour of the application she could read with it the very finest print, and this whilst its pupil was two and one-third lines in diameter. The effect upon the ciliary muscle was more marked in the left than in the right eye, for in the former the near point was

approximated to three inches, the far point to five and a-half inches; in the right eye the near point was never brought closer than eight inches, nor the far point nearer than eleven inches. Stronger concave glasses were consequently required for distant objects by the left than by the right eye. The effect upon the accommodation also ceased much sooner in the right than in the left eye, for in the former the myopia had disappeared five hours after the application, whereas six days afterwards the sight of the left eye for distant objects was still improved by a concave glass of thirty-six inches focus.

My next experiment will be to test the curative influence of the Calabar bean upon the paralysis of the pupil and accommodation, and to ascertain whether we cannot succeed by periodic applications of a very weak solution of the bean in exciting the sphincter pupillæ and the ciliary muscle to gentle contraction, without fatiguing and weakening them by over-stimulation.

16, Savile-row, W.

## ON IRIDECTOMY IN DESTRUCTIVE ULCERATION OF THE CORNEA.

By **ROBERT B. CARTER, M.R.C.S.E.,**  
Fellow of the Royal Medical and Chirurgical Society.

THE value of iridectomy in destructive ulceration of the cornea, although long since established by Von Graefe, and fully recognised on the Continent, has not, I think, in this country, received the attention that is its due. The operation is certainly not performed often enough by surgeons in general practice, and, even in some ophthalmic hospitals, does not hold the position to which it is entitled. The following case affords an excellent illustration of its advantages:

G. R., a farm labourer, aged 53, applied to me on February 5, on account of an injury to his right eye. He is a feeble, decrepit-looking man, grey, and partially bald, who might pass for ten or fifteen years more than the age he acknowledges.

On January 28 (eight days previously) he received a blow on the eye from a twig. With the apathy characteristic of his class, he continued to work, in spite of loss of vision and increasing pain, until his employer sent him to seek assistance.

I found the conjunctiva of the right eye so much injected, that a pterygium of long standing, on the nasal side, could scarcely be distinguished from the surrounding vascularity. The cornea was nearly perforated by a grey, sloughing ulcer, about three lines in diameter, surrounded by a zone of dense opacity. The ulcer not being perfectly concentric with the cornea, but situated somewhat towards its outer and lower margin, the zone of opacity reached the margin in this direction; while, on the upper and inner side, above the pupil, it left a crescentic portion, which, although steamy and turbid, retained sufficient transparency to show the dark brown colour of the iris, but not to show its fibrous structure. There were no vessels proceeding to the ulcer, nor (except at the pterygium) encroaching upon any part of the corneal margin. Vision was limited to a dim quantitative perception of light, the patient perceiving the direction of the window, but not its outline, nor its sash-bars. There was severe pain, with nocturnal exacerbation, a feeble, quick pulse, and a worn, suffering aspect. The tension of the globe was not at all, or only very slightly, increased, and was certainly not greater than in the left eye, which, however, was already showing traces of sympathetic irritation. The injured organ had been covered by a folded handkerchief, but not treated in any way whatever.

Prior to experience of the good effects of iridectomy, it would have appeared to me certain, under the conditions I have described, that the impending perforation would be followed by iritis, probably passing on to complete disorganisation of the eye, and involving great likelihood of sympathetic destruction of its fellow.

I placed the patient upon a couch, and made an immediate iridectomy, removing the superior sixth of the iris. The pain of the operation was very acute; and, after applying Arlt's compress, I directed the patient to wait until the pain subsided. It was my intention to see him again, to prescribe an active tonic and sedative treatment, and to give him some general directions. As soon, however, as he became somewhat more easy, he left the house without my knowledge, and did not return until the following Sunday, the 8th of February. He

then stated that all pain had ceased three hours after the operation, that he went back to work in the afternoon, and that he had deferred visiting me until Sunday, in order not to lose time. The compress had remained undisturbed, and, on removing it, I found the conjunctival injection much diminished, the section healed, the turbid crescentic portion of cornea cleared, the zone of opacity narrower and less dense, the ulcer receiving red vessels from below, and nearly filled up by plastic lymph. Perception of light had become qualitative, the patient being able to see a sheet of white paper.

As the case had done so well without medication, I re-applied the compress, and sent the man back to his work. On the 11th, the improvement being confirmed, and the patient able to count fingers, the compress was left off, and a band substituted for it. On the 22nd, there remained very little conjunctival injection, the vessels that repaired the ulcer had dwindled away; the place of actual excavation was marked by a well-defined dense cicatrix, its upper border just reaching to the centre of the natural pupil, and the rest of the cornea had regained perfect transparency. The patient could read No. 16 of Jäger's test-types without assistance, or No. 14 by the aid of a ten-inch bi-convex lens, and I found that he could do very little more with the uninjured eye. Such a degree of amblyopia is not uncommon among elderly agricultural labourers, who, even when able to decipher simple words, never read, and who have never been accustomed to exercise their eyes about small objects of any kind. Their wives are preserved from a similar condition by using their eyes about needlework.

The patient was directed to discard all coverings from the eye, and to apply a mild astringent lotion (arg. nit., gr. ij., ad. ℥j.) for the removal of the remaining conjunctival vascularity.

The case above cited is only singular from the absence, at first accidental, of medical treatment; and, this feature excepted, my note-book would furnish several of similar import. In all of them, however, iridectomy was followed by the administration of quinine, or bark and ammonia, with or without opium, and by the local application of atropine and poultices, so that I was unable to determine the precise curative influence of the operation itself. Still, the operation has been the turning-point of every case, and the invariable precursor of rapid recovery. Before I practised it, I used to see occasional destruction of the cornea; but such a result has never followed its performance.

It must be confessed, I think, that we do not understand the *modus operandi* of iridectomy. In these corneal cases there is seldom increased tension, and there can hardly be (as suggested by Dr. Mooren in iritis) any retention of morbid matters behind the iris. A very complete division of the radiating fibres of the ciliary muscle is effected when the section for iridectomy is properly made, that is, when it is sufficiently far back, although the circular fibres are left intact. Is it possible that this division may produce a salutary change in the ocular circulation? The surgeons who practise division of the ciliary muscle by puncture seem to think that their procedure exerts some such influence. I tried it in a case of irido-choroiditis with marked, but very temporary benefit, and its repetition was not only useless, but a source of irritation. Shortly afterwards, I saw a patient in whom division of the ciliary muscle, by another surgeon, had been followed by extensive detachment of the retina—a result that the operation is obviously well calculated to produce. It is easy to conceive that the point or edge of the knife may itself detach and push inwards the retina in some cases, and that in others hæmorrhage or effusion under the choroid may produce the same effect. Since then I have entirely abandoned the operation, believing it to be, at the best, a very uncertain and imperfect substitute for iridectomy, and to be beset with many disadvantages and dangers from which iridectomy is wholly free.

The method of performing iridectomy is worthy of a passing notice. Mr. Bowman has sanctioned, by the great weight of his precept and example, such a rapid withdrawal of the knife as may produce a gush of aqueous humour, and a probable prolapse of the iris. Mr. Ernest Hart has recently advocated the same way of withdrawing the cutting-needle after the smaller incision required for artificial pupil. There is, however, among many operators of large experience a growing opinion that this gush of aqueous humour, and this prolapse of the iris, by the sudden shock to, and displacement of, the lens that they produce, are fertile sources of cataract after the operation, even where the anterior capsule has remained perfectly

intact. Until this opinion be disproved, it will be safest to withdraw the knife with extreme caution, and to seize the iris by the introduction of proper forceps within the anterior chamber. This manoeuvre is, to say the least, perfectly unobjectionable; it avoids a risk that may be actual, and that we cannot at present call chimerical, and it is perhaps more surgical than the more hurried and less careful method of procedure.

The precise steps of any operation must vary somewhat, however, in the hands of different surgeons; and the essential point is only to do the right thing at the right time. Scores or hundreds of elderly persons lose their eyesight every year by sloughing of the cornea, resulting from some trifling injury; and in all, or in nearly all of these cases, an iridectomy at any time prior to perforation would prevent the threatened mischief. The sufferers are mostly labourers, stone-breakers, hedge-trimmers, and so forth, who can seldom procure the services of an ophthalmic specialist; and it is in the hope of calling the attention of my brethren generally to a simple and effectual means of cure, that I have ventured to seek publicity for my fragment of experience in the matter.

Stroud, Gloucestershire.

## ON ANEURISMAL TUMOURS INVOLVING THE NECK.

By JOHN COCKLE, M.D.

Physician to the Royal Free Hospital.

I HAVE ventured to make "Aneurismal Tumours of the Neck" the subject of a Medical communication, inasmuch as the region named may, with respect to such tumours, be regarded as neutral ground, to be explored alike by the Surgeon and Physician; for while, on the one hand, the Surgeon is rightly entitled to place some among such tumours in the category of Surgical Aneurism, the Physician, on the other hand, vindicates his right to share in the study by showing that others not unfrequently spring from the depths of the chest, and that the cervical tumour is but the extension of the primary disease. It were, indeed, to be desired that science could effect for us a more perfect allotment of these cases, each department taking its own. This, however, would imply a degree of perfection to which present science can scarcely ever even approach, much less attain. We must, then, either simply register our cases for the benefit of the future, or re-study them in connexion with the discovery of each new and important sign. We may thus hope to meet to some extent the difficulties of diagnosis.

In furtherance of this object, I have to detail the particulars of a very instructive case of aneurism of the neck which has recently fallen under my notice.

James R., aged 45, drover, a short, stoutly-built, muscular, and remarkably good-tempered Irishman, was admitted an in-patient under my care, at the Royal Free Hospital, May 22, 1862, for supposed subclavian aneurism.

*Previous History.*—He was in excellent health until six months ago, when, without any cause he could assign, he felt stiffness and pain about his collar-bone and shoulder, and soon after a swelling in this situation, which gradually got larger. He had drunk freely of spirits.

*Inspection.*—The countenance is healthy, natural, and free from anxiety; the lips of florid colour; the breathing is normal, both as regards the act and the number of inspirations. Cardiac impulse, normal in site, but very slight. A bipartite tumour extends from between the second and third right intercostal spaces to the angle of the jaw, the line of division being about two inches above the clavicle. The lower portion of the tumour, extending from the left end of the sternum to the outer third of the clavicle, is larger, though somewhat less prominent than the upper and smaller tumour, which is round and lobulated, and tends to press the jaw towards the left side. The right jugular vein is somewhat full, but patent, and courses round the external surface of the tumour. The sterno-cleido-mastoid muscle is displaced, and seems atrophied. The concussion impulse shakes the upper half of right chest and neck. The right external mammary artery visibly pulsates. No trace of œdema exists, or any other sign of venous congestion. The right pupil is contracted, being somewhat less than half the size of the left. There is, also, congestion of the right conjunctiva, more particularly at the

inner angle of the eye. The tongue is always detruded to the left.

*Measurement.*—The upper tumour measures four inches in its transverse, and two and three-quarters in its vertical diameter. The lower sac five inches in its transverse, and two and a-half in its vertical diameter. The right upper arm measures nine inches at its middle portion, the left arm ten and a-half inches.

*Palpation.*—Cardiac impulse very weak, otherwise normal. Left radial pulse quickened, ranging at 90; normal in volume. Entire absence of pulsation in the right radial, ulnar, and brachial arteries. The carotid artery is, apparently, felt beating above the upper sac. The right temporal artery beats in unison with its fellow. The lower sac is so tense over the two inner thirds of the right clavicle, that here this bone cannot be felt; but at its outermost edge it ends abruptly, as if the sac had caused absorption of its remaining portion. The impulse over the sacs, especially the lower, is heaving, simply systolic, and unattended by thrill. The impulse is very liquid, especially along the inferior border of the lower sac. The beat is synchronous in both sacs, and with the left radial pulse. The temperature of the head is uniform; also that of both arms. The sensibility of the right arm is normal, but its motility decidedly lessened.

*Percussion.*—Dulness is bounded by the third right rib, that is, at a point a little below the visible site of tumour. Some amount of dulness exists towards the left of the sternum. Over the remaining portions of the chest the sound is perfectly normal.

*Auscultation.*—The heart's sounds are replaced by faint murmurs, variable in intensity and rhythm; some days the first murmur, at others the second, predominating. Faint double murmur is heard up the aorta to the bounding line of the tumour. Over both sacs, singularly pure and clear, double quasi-cardiac sounds are heard, without the faintest trace of murmur. The respiratory sound is audible over the entire extent of both lungs, and, as a rule, perfectly pure. Occasionally, the sound seems slightly bronchial at the upper part of the right lung.

*General Symptoms.*—Beyond the pain alluded to, occasional starting in sleep, and a certain amount of difficulty in intonation; in the earlier history of the case, there was not a symptom to note. This difficulty of intonation originated probably in a double cause—direct pressure of the upper sac upon the larynx, and, probably, pressure upon the recurrent nerve. Neither, during the subsequent progress of the case, with the exception of cough (and this not excessive), did one additional symptom occur. The patient was mostly cheerful, taking exercise in the ward, as he would not suffer the restraint of bed. But the symptoms existing became greatly intensified. The pain in the right side of the neck and shoulder recurred every day or two, mostly at night, in agonising paroxysms, often extending to the opposite side. So extreme, also, on several occasions was the sense of impending suffocation, that he was compelled to be instantly lifted out of bed, to prevent asphyxia. There was also observed slight paroxysmal dysphagia. The tumours gradually increased in size; and over one pouch in the upper sac the integument as gradually thinned and acquired a livid colour.

On August 7, the danger of rupture of the upper sac was most imminent; the integument deeply livid and thinned. Impulse was less marked, but still very liquid. I now determined, as a last resource, to try and coagulate the blood in the upper sac by passing through it, for five minutes, a strong electro-galvanic current. Here it was readily borne, but when the sponges were applied to the lower sac, the effect was insupportable, even for a moment. After the galvanism, the ice bag was applied, and rest enjoined.

By the following day the upper sac had become nearly solid, the impulse almost gone, and the sounds much less clear. The sac, however, gave way at the threatening point, and an oozing followed, which continued for four or five days, when the current was again applied. Early on the following morning the patient was unluckily allowed to leave his bed, and soon after the sac again gave way over a fresh spot. About seven ounces were lost almost at a gush. Unconsciousness immediately followed, the surface rapidly cooling, but the heart and lungs still acting, though laboriously. Soon after the last and fatal rupture, the right pupil regained its size, both being in a state of moderate dilatation. The first

sound, hitherto heard over the sac, became of indeterminate character, but the clear second sound had entirely ceased. The cardiac and aortic sounds were now masked by the noisy respiration over the lungs. Dr. Sibson, who was present a few hours after the sac gave way, directed my attention to the marked elevation of temperature of the right side of the head. This, however, gradually subsided. The sac gave way at seven o'clock in the morning, and the patient died at seven o'clock in the evening. In addition to the use of the ice bag, iron and the iodide of potassium were fairly tried in the treatment of this case. The sacs were supported by straps of leather plaster—a method to which, in nearly every case of external aneurism, I attach very great importance. I may, perhaps, be excused mentioning that, after examination of this case, the opinion ventured on was, that it was one of aneurism of the aorta, involving the innominate, subclavian, and carotid arteries. But this was, probably, rather a lucky guess than a warrantable diagnosis.

Dr. Sibson was kind enough to make the post-mortem examination, and I am indebted to Mr. Gant for the following description of the aneurism and its relations:—"Commencing as an aneurism of the ascending and transverse aorta and innominate artery, the sac projects backwards immediately above the root of the right lung, which has undergone no pressure; then, inclining to the right of the trachea, the aneurism ascends to the hyoid bone in front of the common carotid. The right subclavian artery arises distinctly from the sac, but not involved in it. The canal of the artery is completely impervious. The right common carotid also distinctly arises from the sac, but is quite pervious. The right pneumogastric nerve may be seen passing down to the aneurism in this situation, but, as this nerve courses over the sac beneath the first rib, the two become inseparably united. The right recurrent branch is distinctly seen winding round the subclavian just at the point where this artery springs from the aneurism. The right internal jugular vein is unobstructed, but the right innominate vein is flattened and evidently compressed, as it passes downwards more anteriorly than usual over the innominate portion of the aneurism. The superior cava is quite free and normal in its course. The left innominate vein is compressed, and the upper portion of the manubrium sterni partially absorbed. The bodies of the vertebrae corresponding to the posterior aspect of the sac are not eroded. The root of the right lung and the trachea over which the aneurism has passed upwards have escaped pressure. The left carotid and subclavian arteries arise as usual from the aortic arch, and neither of them involved. To the extreme left the œsophagus is seen passing downwards without marked obstruction beneath the aortic arch, and reappearing in its normal situation. The root of the left lung is here also seen apparently unobstructed. Posteriorly to the sac are seen the right carotid artery, internal jugular vein, and right pneumogastric nerve over which the sac has passed. On the left of the sac is the hyoid bone above, and the trachea also in immediate relation to this aspect of the sac, but apparently not incommode by it. Externally, the cords of the right brachial plexus emerge scarcely pressed upon, as the scalenus lies between. Anteriorly, the sac is overlaid by the right sterno-mastoid muscle, the deepest portion of which is inseparably connected with the sac in this situation, and which in its course divides the tumour into two unequal portions by its merely tendinous portion being left." I have merely to superadd that the heart is enlarged, and has undergone extensive degeneration; its various orifices are free and healthy. The dilatation of the aorta commences at the beginning of the ascending portion. Very extensive degeneration of the vessel exists. Large cretaceous plates and nodules extend from the very origin of the vessel to the termination of the thoracic aorta, where they abruptly ceased.

*Pathology.*—The general pathology of aneurism is so well known, that there are only two points in connection with it tempting me to dwell upon. But these are of a daily increasing interest. I allude to the occasional variation of size of the pupil, and the nature and origin of the sounds heard over the sac. The pupil varies in size in proportion to the amount of blood admitted to the brain. It is also directly controlled by the sympathetic nerve. Although it is matter of ordinary experience that the size of the pupils undergoes marked change in transient or permanent derangement of the cerebral circulation, I have not been successful in finding a sufficient number of recorded cases of such

derangement, limiting change to a single pupil, to warrant any definite conclusion. We can, however, speak with greater confidence respecting the changes induced by disordered innervation. For direct experimental proof, we are in reality indebted to the original experiment of Pourfour du Petit, performed in the year 1727. He proved the sympathetic to be an ascending nerve, by showing that division of its cervical portion was followed by contraction of the pupil and congestion of the conjunctiva. About 130 years later, Budge and Waller confirmed this result by a most accurate series of experiments, and further showed that, in respect to its action on the pupil, the cervical filament of the sympathetic served simply as the conductor of an influence, the true source of which was centred in a portion of the medulla spinalis, corresponding to the last cervical and sixth dorsal vertebræ. This portion they designated the cilio-spinal tract. It was a natural inference from their experiments that, on division of this portion inclusive, the radiating fibres of the iris become paralysed, and the aperture of the pupil narrowed by the immediate contraction of the unopposed antagonists—the circular fibres—supplied through other channels. Mere physiological excitation of the cilio-spinal tract determines, according to them, dilatation of the pupil in amount corresponding to the degree of stimulus. The last well-known addition by Bernard to the catalogue of phenomena determined by division of this portion of the sympathetic, is the singular increase of temperature in both external and internal parts above the injury. These physiological facts have been recently systematically applied to Clinical Medicine by Dr. Ogle, to whose valuable essay I must refer you. It has been pointed out by an acute and competent observer that contraction of the pupil is significant of thoracic or cervical aneurism. And so, at times, it is, but not more significant of aneurism than of any other kind of thoracic or cervical tumour causing pressure, either on the cilio-spinal tract, or on the cervical ganglia of the sympathetic. Again, possibly not more significant of any of the above states than of disease of the meninges, or tissue proper of the tract, or even of the abdominal ganglia of the sympathetic. It is true that this condition of the pupil has, up to the present, been more frequently found in connexion with aneurism; but this arises partly from insufficient observation, and partly from the fact that aneurism is, relatively at least, much more frequent than any other form of intrathoracic tumour. Hence, on observing change of size of the pupil, we are only warranted in inferring irritative or paralyzing pressure on the tract, the pathologic cause of which we are to seek through other means. I have notes of several cases of supposed non-aneurismal affections of the heart producing either dilatation or contraction of the pupil, but which would occupy too much time to enter into now. It would therefore be hazardous to generalise the sign at present, although of value in any doubtful case. It is difficult at times to differentiate pathological from what is called physiological difference of size of the pupil. A very slight variation might possibly characterise some small, though most dangerous, aneurism—dangerous not from its size, but from its tendency to early rupture—or it might be significant of any other change involving these portions of the sympathetic system. There may be also question whether occasionally such contraction of pupil might not be more indicative of modification in the cerebral circulation than of nerve pressure. To the case I have brought before you I would apply this observation, directing your attention to the singular fact of the almost immediate restoration of the pupil to its normal size upon rupture of the sac. We can hardly suppose, had paralyzing pressure during so many weeks been the cause of the contraction, that the function of the nerve would have been so speedily restored. There is also another singular occurrence deserving attention from the perversion of the ordinary physiological sequence. Only after rupture of the sac, and restoration of the pupil to its size, did marked elevation of temperature about the head ensue.

(To be continued.)

DEATH OF MR. ARMSTRONG, OF CARLISLE.—We regret to have this day to announce the death of Mr. E. Armstrong, Surgeon, at the age of 48 years. He was a shrewd and sound Practitioner, and a strictly honourable member of the Profession. Mr. Armstrong filled several public appointments, such as those under the Factory Commissioners and the Board of Guardians.—*Carlisle Journal*, April 21.

REPORTS OF HOSPITAL PRACTICE  
IN  
MEDICINE AND SURGERY.

GUY'S HOSPITAL.

DOUBLE OVARIAN DROPSY—OVARIOTOMY—  
DEATH.

(Under the care of Dr. OLDHAM and Mr. THOMAS BRYANT.)

EMMA C., aged 32, was admitted into Guy's Hospital on April 10, 1863. She was a married woman, and had had one child two years previously. The abdominal tumour had been observed for two years, and was first noticed on the left side. Its growth had been gradual till November 23, 1862, when she was tapped, and 23 quarts of a dark-coloured fluid drawn off. She soon, however, rapidly refilled, and when admitted measured 48 inches in circumference. Her general health was tolerably good.

On April 15, ovariectomy was performed in a private room, and with only a few spectators present. On opening the peritoneum, an adherent cyst was at once opened, and it was then found that the whole of the tumour was firmly adherent to the peritoneum. With some difficulty this was separated, but the adhesions were so firm that Mr. Bryant at times believed that he must have been separating the peritoneum itself from its abdominal attachments. This, however, was not the case. The tumour was firmly connected to the peritoneum in every part, the stomach, liver, and omentum being involved. The cyst was at last separated, the omentum being divided and ligatured as the operation proceeded, and the pedicle in the left side fastened by three whip-cord ligatures. The right ovary was also found to be similarly affected, and the tumour was situated in the pelvis behind the uterus. This was also removed, the pedicle being fixed by two whip-cord ligatures. It must be added also that during the operation the bladder was found intimately connected with the cyst wall, and considerable care was required to prevent injuring it. The abdominal incision was at least eight inches long, having been increased to give more room. After the operation the edges of the wound were brought together with silver sutures.

After the operation, the patient went off to sleep for an hour and a-half, and was awakened by vomiting. Six hours afterwards her pulse was 90, and of good power. Tongue was moist. The sickness, however, continued. The abdomen soon began to swell and to become painful, and in twenty-two hours after the operation she died from peritonitis.

After death the evidences of general peritonitis were most marked. The viscera were otherwise healthy.

RECURRENT FIBROID TUMOUR OF THE LEG—  
REMOVAL — RECOVERY — RETURN OF THE  
DISEASE LOCALLY AND IN THE LUNGS —  
DEATH—AUTOPSY.

(Case under the care of Mr. COCK.)

This case, at the time of the first operation, was the subject of a clinical lecture by Mr. Cock, which is fully reported in this Journal, March 8, 1862. Although the tumour, Dr. Wilks said, contained no cancer cells, it was still "a growth of some activity." This turned out to be correct, as it soon returned locally, and at length in the chest. The return and destructive nature of this disease, Dr. Wilks remarks, shows its highly malignant nature, whilst, at the same time, it was probably one degree less malignant than true cancer.

A man, aged 23, was admitted for a tumour of the soft recurrent fibroid variety from the upper part of the right thigh, January, 1862. Mr. Cock removed the tumour. In September it returned, and grew rapidly. He was admitted into the Hospital in November. It was subsequently found that the right side of the chest was much larger, and there were other signs denoting that he had probably a growth in the thorax.

*Autopsy, from Dr. Wilks' Records.*—The body was spare. There was a large tumour, about the size of the head, at the upper part of the right thigh. Its surface was ulcerated and fungating. The leg was œdematous. The right side of the chest was much enlarged, and a soft tumour was seen coming through the sternum at its upper part. On removing the sternum, the chest was found to contain a large tumour. The right side was filled with it, and the lung compressed back.

It also filled the anterior mediastinum, and covered the heart, reaching to the left side of the chest. In fact, it involved the sternum, so that this bone was broken in removing it, the growth having penetrated into its substance. It was difficult to say in what tissue the disease had commenced. The great bulk of the tumour was outside the lung, but both the lungs were filled with large, round, independent masses of the disease. The material was very soft, and at first appeared like medullary cancer, but, on closer examination, it was found not to be so vascular, and did not give out a milky juice on pressure. The microscope showed it composed of oval nuclei and delicate fibre. There was no deposit in any other organ.

THE LONDON HOSPITAL.

CLINICAL REMARKS ON A CASE OF ABSCESS IN  
THE BLADDER, IN WHICH THE BLADDER WAS  
INCISED AS IN THE LATERAL OPERATION FOR  
STONE.

(Under the care of Mr. H. J. ADAMS.)

APRIL, 1863.—A little boy, aged five years, was brought into the theatre, six or seven weeks ago, for vesical exploration. Mr. Adams made the following remarks to the class on the case:—

"The case which I am now about to present to you is that of a little boy who is labouring under severe irritation of the bladder, with the ordinary symptoms of stone. The child has a constant desire to make water, the effort being attended with, and followed by, great pain; the urine dribbles away at night, and he is constantly pulling his prepuce, which has become elongated and sore. He has lately become emaciated, and is altogether very ill. The history of the case is remarkable, for it appears that the child has laboured under symptoms of vesical irritation since he was a year and a-half old. About a year and a-half ago the symptoms had increased in intensity, and he was admitted into the Hospital under the care of Mr. Gowlan and myself, the impression being that he had stone in the bladder. He was repeatedly sounded, and something like stone was occasionally felt, but at other times nothing of the sort could be detected. The water was at this time of the usual character, and, in the absence of the decisive symptom of stone—as his symptoms were mitigated by the use of warm baths and tonics, combined with alkalies—he was attended as an out-patient, to be re-admitted as occasion demanded. The father tells me that he always observed a deposit in his water, the nature of which was not made out. As the symptoms have lately much increased in intensity, I have therefore determined to inject the bladder and explore it under chloroform, and to cut him at once if a stone is detected. All this, gentlemen, is plain sailing, but what am I to do if no stone can be detected? Shall I cut into the boy's bladder whether I can feel a stone or no? This is a question of the very greatest importance, and I wish to direct your attention to this point, for a stone may still exist, although it cannot be felt with the sound; it may be encysted, and nothing short of cutting can relieve the case. I must tell you that numerous cases have occurred in Hospitals and in private practice, where Surgeons have cut for stone, and where no stone could ever be found, as none existed. I witnessed this once myself, and the patient, as is usual, got quite well after the operation. The Surgeon was formerly advised to provide against this contingency by always carrying a stone in the waistcoat pocket, to be ready to show the patient or his friends after the operation of lithotomy. Now, what is the condition of the bladder in these cases of abortive lithotomy, where such mistakes (for they are mistakes) have arisen? I think that in most of these cases the false impression is conveyed by the end of the sound being brought into contact with the muscular columns of the detrusor urinæ in a state of hypertrophy; and I can illustrate my opinion by another case, which I shall bring before your notice presently, where the columns or rugæ of the bladder are easily recognised by the sound, and in which many of the symptoms of stone exist. There are also other conditions giving rise to such symptoms, as strumous prostate, cancer of the bladder, etc. I now inject the bladder with warm water, having first drawn off the urine, which is clear. I pass the sound, and explore the bladder, but I cannot satisfy myself of the presence of a stone. I therefore, in concurrence with the general opinion of my colleagues, shall send the child back to bed, so that we may examine further into the condition of the urine, in which it is thought that possibly albumen

may be found, and I do this the more readily because the nurse says that the child has occasionally passed worms per anum. I shall watch the case carefully, and, if the symptoms are not ameliorated, I shall cut the child, stone or no stone, under the idea that a free exit to the urine may possibly relieve him."

The urine was tested, and no albumen was detected; and the use of carbonate of iron and the oil of the male fern, to be followed by castor oil, were separately used to get rid of the worms. But no relief attended these means. The catheter was not again employed, and the urine flowed involuntarily, and became exceedingly ammoniacal and fœtid. Mr. Adams introduced the case again before the class, with the view to perform the lateral operation; but he guardedly stated to the class that it was from the urgency of the case alone, and not from any decided opinion of the existence of a stone, that he felt himself imperatively called upon to operate.

The child was placed under the influence of chloroform; the legs were held by assistants, and the neck of the bladder was incised by Blizard's beaked knife. A small quantity of sandy matter escaped with the first flow of the urine, and a large quantity of disgustingly stinking urine, loaded towards the last with fœtid pus, escaped; the bladder was carefully searched, but no stone was found.

The case was regarded as one of abscess of, or communicating with the bladder, which Mr. Adams supposed had probably originated in scrofulous deposit in the prostate gland or in the neighbourhood of the neck of the bladder.

Immediate relief followed the operation, and the child left the Hospital quite well.

#### TUMOUR OF THE PHARYNX REMOVED BY THE ÉCRASEUR.

(Case under the care of Mr. LITTLE.)

A. B., aged 73, was admitted into the London Hospital for a tumour of the throat. He stated that six months before, when shouting, he "felt something burst" in his throat, but that he spat up no blood or matter; ever since he had had a lump in his throat, which prevented his breathing with his mouth shut, or swallowing solids easily.

On admission, a tumour could be felt and partly seen. It grew from the posterior wall of the pharynx, and projected forwards against the soft palate, and blocked up the posterior nares. It extended downwards about an inch below the epiglottis, and upwards nearly to the skull. This projecting portion was slightly grooved at its base nearly in its entire circumference. The tumour was firm to the touch, had the characters of a fibrous growth, and was moveable on the vertebral column. There was no glandular enlargement. The patient had difficulty in swallowing solids, and his breathing and speech were considerably interfered with. The tumour was not increasing, and did not cause any pain.

On consultation, it was determined to remove as much as possible with the écraseur.

The écraseur was armed with a fine wire rope, inelastic, and very flexible. This wire was bent to the shape of the tumour, so that the écraseur would become applied to the tumour just below the soft palate. The lower loop of wire was passed downwards into the lower part of the pharynx, and held in its place with the finger, whilst the upper—the soft palate being drawn forwards—was pushed over the upper part of the tumour. The wire, being well passed towards the vertebræ, worked into the groove at the base of the tumour, and in two or three minutes the projecting portion was removed without any hæmorrhage. It was necessary to remove the tumour quickly, although the risk was increased thereby, as respiration was much interfered with during the operation. The patient felt no pain, and was at once able to swallow better, and to sleep without stertor. The wound granulated healthily, and he was discharged well in a fortnight.

The removed portion, which was about two inches in length by one and a-quarter at its widest part, had the appearance of lymphatic gland tissue, with remains of extravasation of blood in various parts. It consisted of masses of corpuscles, like old pus globules or lymphatic gland corpuscles, infiltrated in the healthy tissues of the mucous membrane. The nature of the growth was doubtful. "Perhaps," Mr. Little said, "it was merely an enlargement of the tonsil-like glands in the neighbourhood of the orifices of the Eustachian tubes." Dr. A. Clark thought an abscess had commenced, and had become arrested in its development. The history seemed to favour this explanation.

### THE ROYAL LONDON OPHTHALMIC HOSPITAL.

#### ENCEPHALOID DEPOSIT IN THE ANTERIOR PORTION OF THE EYEBALL.

(Under the care of Mr. DIXON.)

THE following case is unusual, as presenting an encephaloid growth within the globe, wholly unconnected with the retina:

Thomas A., a seemingly healthy boy, 12 years old, the fourth child of labouring people in Lincolnshire, was brought to the Hospital about the middle of November. His parents are living, and he has five sisters and four brothers, all in good health. The right eye presented the following appearances:—There was a very slight vascular zone in the sclerotic, hardly any increased redness of the conjunctiva; the cornea was perfectly clear. Little, if any, pain had been felt. The greater part of the anterior chamber was filled with a nodular, yellowish mass, slightly reddened, with vessels resembling, in an exaggerated form, the fibrinous deposits seen in severe syphilitic iritis. About the upper sixth of the iris was left uncovered by the mass, and appeared unchanged in tissue, and of the same grey colour as that of the healthy eye. It was stated that the morbid appearances had first been noticed about three months before the boy came to London. The deposit slowly increased, until it nearly filled the anterior chamber. Then considerable redness of the globe suddenly set in, the cornea became slightly hazy, and the sclerotic adjoining the outer margin of the cornea began to bulge outwards, as if the growth were about to perforate. The adjacent portion of cornea also appeared infiltrated and softened.

Mr. Dixon removed the globe on the 18th of December. On making a section of it, the retina, throughout its whole extent, appeared healthy, the vitreous body was transparent, and no sign of disease could be detected posterior to the ora serrata. The lens was pushed outwards behind the ciliary processes, but had perfectly retained its transparency. The new growth was firm, smooth, and nodular, opaque, and of a yellowish-grey colour. It seemed to have originated from the outer ciliary processes, and, after perforating the adjacent portion of the iris, the outer half of which it had destroyed, had spread across the anterior chamber until it reached the inner edge of the cornea. It had also destroyed the sclerotic near the outer edge of the cornea, in which situation the tumour was covered only by conjunctiva. The pupillary margin of the iris was lost in the tumour, but the inner half of the iris and of the ciliary processes were perfect, although already adherent to the morbid growth. Examined microscopically, the whole mass presented fibres intermixed with compound cells in various stages of development.

#### FATTY CONCRETIONS IN THE CANALICULUS.

Ellen A., aged 37, applied at the Hospital on December 8, 1862, on account of a small lump near the inner corner of the right eye. It had existed about three years, and at first was taken for a sty. It occupied the situation of the lower canaliculus, and was about the size of a dried grey pea, and hard to the touch. Pressure upon it did not produce any oozing from the punctum. Mr. Dixon passed a fine probe into the sac, along the canal, and then laid open its upper wall. With a scoop five or six bodies of a brownish-grey colour were removed. They were closely packed together, resembling in size and shape the seeds of the dog-rose; instead of being hard and earthy, like ordinary dacryoliths, they readily yielded to pressure, having about the consistence of wax. They appeared to be wholly composed of fat, melting and burning away on the application of heat, without leaving any earthy residue.

### ST. BARTHOLOMEW'S HOSPITAL.

#### ERYSIPELAS OF HEAD AND FACE, CONSEQUENT ON A NEGLECTED SCALP WOUND, IMPLICATING THE LARYNX — TRACHEOTOMY — DEATH ON THE FOURTH DAY AFTER THE OPERATION.

(Under the care of Mr. WORMALD.)

[For this and the following case we are indebted to Mr. Vernon, House-Surgeon.]

P. F., a gigantic Irishman, aged 31, applied at the Hospital on March 17, on account of erysipelas of the face and scalp,

resulting from a contused scalp wound of a week's date. He was admitted under Mr. Wormald's care. After his admission, the erysipelas involved the whole head and face, so as to render his features indistinguishable, and spread to some distance down the neck. Under the liberal use of stimuli and nourishment the swelling began to diminish, and he appeared progressing well.

Suddenly, on the evening of March 21, the mischief spread to his nostrils, and from thence to his fauces and larynx; he could not swallow, and when Mr. Vernon, the House-Surgeon, came to him, he found his dyspnoea so extreme, that he decided on at once opening the trachea. The trachea was situated at an unusual depth, and could only be reached through much infiltrated tissue; free bleeding occurred, so that, owing to this and to the extreme depth of the trachea, the knife was very sparingly used in the latter part of the dissection. When the trachea was reached and opened, a long bivalve tube was introduced; the relief to his distress was very manifest, and the bleeding was speedily controlled without the use of ligatures. Considerable emphysema occurred in the surrounding tissues, and it became evident that a longer tube would be required; the longest that could be procured was then inserted without much difficulty, but even now it became necessary to fit a second tube into the upper aperture of the inner tube, to increase its length, and to enable it to be secured in the wound. Wrapped in blankets, and breathing steam, he had a comfortable night, and in the morning he could swallow without much trouble beyond occasional cough.

His progress was from this time satisfactory, the erysipelas steadily subsiding; for the next forty-eight hours he was sensible, could take abundance of fluid nourishment, and slept fairly with the assistance of morphia injected beneath the skin.

On the morning of the 24th, a densely foggy one, he flagged, had much cough, with a considerable increase of thick mucus discharged through the tube. During a fit of coughing, some bleeding occurred from the wound; its source was not evident, and, as he was breathing to some extent through the larynx, the tubes were removed. For a time he rallied and improved, but again failed, and in spite of nourishment, which he took eagerly and without difficulty, he slowly sank, dying apparently from mere exhaustion just 100 hours after the operation.

Having lost his left arm five years since by a machinery accident, he invariably throughout his illness lay on his right side, but up to the last, as far as could be ascertained, his lungs remained sound.

*Post-mortem Examination Twenty-six Hours after Death.*—The wound looked sloughy and discoloured. The surrounding parts were infiltrated with a dirty puriform fluid, which had completely encircled the trachea, separating it from the œsophagus, and had then made its way down into the "posterior mediastinum," almost to the "roots" of the lungs. The upper lobe of the right lung was tightly bound down by old adhesions; the posterior portion of this lobe was congested, but, with this exception, the lungs were throughout sound. There was no distinct evidence of the recent congestion about the fauces or larynx. The knife had divided the fourth, fifth, and sixth tracheal cartilages. The edges of the aperture were irregular and ulcerated. The entire length of the trachea was of a vivid red colour, from intense inflammation. Immediately below the incision were some small patches of ulceration, clearly due to the pressure of the end of the tube.

#### SUICIDAL WOUND OF THROAT—DEATH FROM ACUTE PLEURISY—AUTOPSY.

(Under the care of Mr. PAGET.)

J. K., aged 50, admitted under the care of Mr. Paget, having gashed the front of his neck immediately below the hyoid bone. None of the important structures of the neck were severed, but, having been brought from a distance of some miles, he had lost a good deal of blood from some small vessels which required the ligature.

For some time he was in a state of extreme depression, and on the fourth day after his admission he was attacked with acute pleurisy on the left side; in spite of treatment, he rapidly sank, and died a week after his admission.

*Post-mortem.*—The wound looked discoloured. The other parts around appeared healthy. The muscles of the larynx were dissected out, and separated from each other by a layer of well-formed pus, which had tracked its way down to the

anterior mediastinum. Both pleuræ were covered throughout with soft, recently-formed lymph. The left pleural cavity was full of clear fluid, and the lung was much compressed. Lungs themselves healthy.

SATURDAY, MAY 16.

#### HOSPITAL PHARMACY.

If slang is the language of a class, we must admit that, as a Profession, we are in this respect no way behind our neighbours. The slang pharmaceutical especially meets us everywhere. A private Practitioner who dispenses his own physic directs his assistant to prepare a bottle full of *Mist. Mag. co.*, or *Haust. rob.*, or blames him if he finds the drawer empty which should hold an abundant supply of *Pil. Cathartic*, or *Pil. pro tussi*. Nor do we blame him in this. He knows what the cabalistic labels signify, and so does his assistant. To him the rose smells quite as sweet although he may call it a *chenopodium*. It answers his purpose to have his favourite pills, mixtures, and draughts ready mixed for immediate use, and no one need trouble himself to interfere with any fancy designation he may choose to apply to them. But what we are now going to quarrel with is the slang pharmaceutical, variety nosocomial. We protest against the extension of this liberty to public establishments, to Hospitals for the supply of Medical aid to the poor, with the conjoined object of instructing the rising members of the Profession. We do not object to the practice of keeping ready prepared a limited number of such pills, mixtures, etc., as must be in daily use in any large Hospital. Where some hundreds of patients have to be prescribed for and supplied with medicines (which, whether they really require them or not, they will be dissatisfied at not being drenched with), the thing is almost a necessity. But this should be kept within reasonable bounds, and the special formulæ ought not to be so numerous as to be capable of being bound up into a volume constituting the *Pharmacopœia* of an individual Hospital. The flagrancy of this offence is indeed such as we ourselves had no conception of until we saw that the *Pharmacopœias* of only thirteen Hospitals, even when similar formulæ in use at more than one Hospital were only printed once, would form a closely-printed volume of 152 pages. This volume of recipes, compiled by Mr. Squire, is our authority for what we have said and for what we shall say upon the subject.

First, then, we say that it is unfair to the student of any Hospital, who has quite enough on his hands for meeting the requirements of examining boards, to lay upon him the necessity of studying any such special *pharmacopœia*, as he must do if he is to comprehend the operation of any kind of medicine prescribed by the Physician whose practice he is attending. It is a task which we feel convinced that not one student in twenty will undertake, and the result is, that such as do not undertake it leave their Hospital not only with the

most obscure notions of therapeutics in general, but with no practical knowledge whatever of the doses in which simple drugs ought to be prescribed under varying circumstances. When entering into practice for themselves, they are driven to the use of formulæ, the combinations of which they never appreciated, and find themselves for a long time hampered by a want of familiarity with the art of prescribing on their own account. They are taught a routine practice, not, as they should be, the habit of independent thought and a readiness in the extemporaneous combination of drugs.

Next, we say that the practice of prescribing by a Hospital Pharmacopœia casts a veil of mystery over the treatment of patients, which we are certain the accomplished members of the staff would be the first to repudiate. But such is the case. What would a stranger in a Surgical ward of Guy's Hospital, for example, understand by a direction to use the Unguentum Metallorum, or in St. Thomas's by the prescription of Mistura Dyspeptica or Mistura Emolliens? The London Hospital Pharmacopœia contains a formula for Mistura Glacial, and even when the prescription of a Physician refers to a pill or mixture, some terms of which convey a definite idea to a visitor, he must not consequently infer that he at all comprehends the character of the medicine prescribed. Thus, the Pulv. Rhei. c. soda of University College Hospital contains a preparation which its name would not imply that it contained, namely, grey powder; and the Mistura Mucilaginis of the Westminster Hospital contains both tincture of opium and dilute sulphuric acid. The difficulty and the evil are the same when in the published reports of cases the medicines administered are mentioned by the names under which they stand in the Hospital Pharmacopœia.

These objections to the use of Hospital Pharmacopœias might indeed be overcome by confining the latter to the region of the Apothecary's dispensary, while the Physicians and Surgeons in prescribing for any patient did so in the usual way, without reference to the special name under which his combinations might be known below stairs. But still, as matters stand now, both students and strangers would be liable to be deceived, inasmuch as the very preparations which find place in the London Pharmacopœia are travestied in that of the Hospital. To some extent a fair reason may be assigned for departures from the authorised formulæ, namely, that the omissions and substitutions tend to cheapen the medicines dispensed without damaging their efficacy or materially altering their action upon the system. Thus the confections of the London Pharmacopœia are mostly prepared with treacle in place of the sugar or honey directed to be used by the College. The compound decoction of aloes, in six out of the thirteen Hospitals mentioned by Mr. Squire, is made without saffron or tincture of cardamoms, and in two of the six the quantity of liquorice used to render the dose less nauseous is most unkindly reduced also. Four of the Hospitals, according to the same authority, make some changes in the preparation of the Mistura Ferri composita, all, however, retaining the quantity of sulphate of iron directed by the College. Thus, Guy's omits the sugar, and substitutes decoction of liquorice for the rose-water. The Westminster and London Hospitals prepare it with water, replace the spirit of nutmeg by some cloves or cassia, and omit any sweetening ingredient; while the London Ophthalmic prepares it merely with sulphate of iron, carbonate of potash, myrrh, and water. We should not be disposed to criticise these changes very closely if the tampering with the College formulæ went no further than this. But we shall have no difficulty in showing that some of the Pharmacopœia preparations are more or less seriously modified by the substitutions, omissions, or additions they undergo; that, in fact, prescribed in the same doses as those of the London College, their action will be more powerful, less powerful, or altogether of a different character. We ask, if this be true, how it is to be expected that a student will be able to obtain by observation in his Hospital that knowledge of the doses and operation of

the Pharmacopœia preparations which he should possess before entering into actual practice? Take the following instances:—The Confectio Sennæ of St. George's, St. Mary's, and the Middlesex Hospitals contains jalap in the proportions of 15, 40, and 20 grains to the ounce, and that of Middlesex bitartrate of potash also. The decoction of Pariera Brava of University College Hospital is made with  $\text{ziv.}$ , and of St. George's with  $\text{zv.}$  of pareira instead of  $\text{5x.}$  to the pint, and a compensation for the deficiency attempted by using a larger quantity of water, and so prolonging the ebullition. At University College Hospital the Infusum Sennæ Compositum contains half the quantity of senna directed to be used by the College, and a little more ginger, the deficiency in purgative power being made up with sulphate of magnesia; in fact, it is a salts and senna mixture. At the same Hospital the Linimentum Opii consists of powdered opium and olive oil, and the preparation which corresponds to the Linimentum Opii of the College is called Linimentum Saponis c. Opio, containing, however, as does also that of the Consumption Hospital, a deficiency of tincture of opium. Lastly, for we need not multiply these examples, the Unguentum Creasoti of the Skin Hospital is prepared with  $\text{mvi.}$  in place of  $\text{3ss.}$  of creasote to the ounce of lard, and contains also  $\text{gr. x.}$  of red precipitate and  $\text{3ss.}$  of mercurial ointment. In what is called, at this Hospital, Unguentum Creasoti *co.*,  $\text{gr. xx.}$  of carbonate of lead and  $\text{3ss.}$  of palm oil are used in place of the mercurial ointment in the above preparation. Surely all this is calculated to mislead.

Besides all this, it will already have become apparent to our readers that the same name does not in different Hospitals at all imply the same thing, while similar things pass under different names. A few more illustrations of this may not be amiss. The Collyrium Belladonnæ of St. George's is made with two grains, and at Guy's with twenty grains of extract to the ounce of water. The nitro-muriatic acid bath at Guy's is made with  $\text{3ix.}$  of nitric acid and  $\text{3xvi.}$  of hydrochloric acid, at St. George's with  $\text{3xxiv.}$  of nitric and  $\text{3xxxvi.}$  of hydrochloric acid, and at London Hospital with  $\text{3xv.}$  of nitric and  $\text{3xxx.}$  of hydrochloric acid to 30 gals. of water. The Confectio Ferri of London, St. Mary's, St. Bartholomew's, and Westminster Hospitals is made with  $\text{3ij.}$  of sesquioxide of iron to  $\text{3vi.}$  of treacle, while at University, Consumption, and Middlesex it is prepared with equal weights of these two ingredients. In preparing Infusum Chirettæ, twice as much chiretta is used at the Westminster as at the Consumption Hospital. Lotio arnicæ *mont.* is made at St. Mary's with  $\text{3ij.}$  of the tincture to  $\text{3j.}$  of water, while at Middlesex the tincture in the same quantity of water is in the homœopathic proportion of *seven minims.* Lotio Hydrarg. Bichlor. varies in strength from  $\text{gr. } \frac{1}{3}$  to  $\text{gr. i.}$  of corrosive sublimate to the ounce of water, and Black Wash from  $\text{3\frac{3}{4} gr.}$  to 15 gr. of calomel to  $\text{3j.}$  of limewater. This last preparation passes under the several names of Lotio Hydr. Chlor., Lotio Hydr. Cinerea, Lotio Hydr. Nigra, Lotio Nigra, and Lotio Hydr. Oxyd. Lotio Rubra at St. George's is prepared with sulphate of copper, at King's with sulphate of zinc, and at the Skin Hospital with corrosive sublimate. But perhaps one of the most dangerous of all the instances of this sort of confusion is to be found in the Pulvis Bismuth. *co.*, which at the Consumption Hospital and Guy's signifies a powder for internal administration, and at the Skin Hospital one containing chromate of lead and vermilion, evidently for external use. We might occupy page after page by quotations of this sort from Mr. Squire's book. We pass on, however, to draw attention to some of its curiosities.

It is remarkable, though perhaps not "passing strange," that the most striking of these are to be found in the Pharmacopœia of a special Hospital. It is possible that there may be some hidden value, some specific virtue in combining a variety of medicines, and especially in very minute doses; and certainly the claims of experience, if put forward, must be allowed. But

for all this, some of the following are, as we say, *curious* examples of what ingenuity can do in this way. The following is the formula for the Pil. Aloes c. Ferro. at the Skin Hospital:—Aloes,  $2\frac{2}{5}$  gr., oxysulphuret of antimony,  $\frac{3}{10}$  gr., sulphate of iron,  $\frac{1}{10}$  gr., capsicum,  $\frac{3}{10}$  gr., extract of gentian,  $\frac{3}{10}$  gr., glycerine, q. s. At the same Hospital an Unguentum Hydrarg. c. Plumbo (c. zinco should have been added) contains certainly so many shots, that one of them must hit the desired mark, and thus save an infinity of troublesome thought. It is thus composed:—Acetate of lead, 10 gr., oxide of zinc, 20 gr., calomel 10 gr., palm oil,  $\frac{1}{2}$  oz., citrine ointment, 20 gr., lard to 1 oz. This Hospital, as might be anticipated, is strong in baths. Two of them contain sulphur, viz., the balneum boraci co. and the balneum sulphuris co., and both are directed to be prepared with perhaps the most grossly adulterated article in the London Pharmacopœia, namely, precipitated sulphur. The Skin Hospital perhaps is specially favoured by the druggists, but we fear if any one were to attempt imitation of these baths with the article so called, as generally supplied, nothing but disappointment would result. Two ounces of borax and two ounces of precipitated sulphur in thirty gallons of water form a bath which does seem to us to savour of—well, never mind what. A similar remark applies to the balneum conii co., where two ounces of extract of conium and a pound of starch are used to the thirty gallons. The starch may be of service; but have the Medical authorities of the Hospital ever satisfied themselves that the extract of conium contains any of the volatile active principle of the hemlock, on which, if on anything, the operation of the preparation must rest? Let us suggest an improvement,—try the succus conii. But there are other curiosities in this book. Here is the very chemical Haustus Colch. comp. of St. Bartholomew's—Vinegar of colchicum, 20 min., carb. of magnesia, 10 gr., mint-water to  $\zeta$ iss. This has certainly the authority of Scudamore. At the same Hospital, Linimentum Saponis comp., containing soft soap, solution of ammonia, spirits of wine, oil of origanum, and oil of turpentine, and is directed to be prepared with *boiling* water. Perhaps the Apothecary uses his own discretion in not following this formula to the letter.

We have now said enough to stimulate our readers to study this extraordinary volume of Mr. Squire's. It is as entertaining as a novel—a capital book for the half-hour following dinner. We do not know whether the Latinity is always that of the Hospitals, or whether such names as *cataplasma carbonas*, *cataplasma fermenti*, *frigida*, and *solutio ruber* are to be regarded as mere oversights of the editor. But for all this, much instruction may be derived from it, to say nothing of its perusal being sure to originate some serious thoughts respecting the provision made for the poor by the Medical charities in London.

### THE WEEK.

#### ROYAL VISIT TO NETLEY HOSPITAL.

THE first public act of the Queen has been to visit the Royal Victoria Hospital, which was opened about two months since. This Hospital is intended for the reception of invalid soldiers from foreign stations, and just now contains about 600 fine old soldiers, chiefly from India. The Queen intimated her intention on the morning of May 8 to visit the Hospital on the afternoon of the same day, and Colonel Wilbraham, the Commandant, received instructions at the same time to make arrangements for ensuring privacy. The Queen landed about half-past three, attended by the Prince and Princess Louis of Hesse, Prince Alfred, Sir Charles Phipps, Lord Charles Fitzroy, Sir James Clark, and others. She spent nearly two hours in the Hospital, and visited almost every part. Colonel Wilbraham, C.B., Inspector-General Dr. Anderson, Major Ravenhill, R.E., Deputy-Inspectors Longmore and Maclean, Professors Aitken and Parkes, Staff-Surgeons Pierce, Nicholson, McLeod, and, in fact, all the Hospital staff, followed her.

She sent several times for Mr. Longmore and Dr. Maclean to inform her of the state of men whom she saw very ill in bed, and she went up to the bedside of a great number of men and asked them questions about themselves. Altogether she must have spoken, in a most kind and touching way, to thirty or forty sick men, and she made Colonel Wilbraham and Dr. Anderson explain to her all the arrangements for their comfort. She then looked at the rooms of the Army Medical School, and visited the quarters of the married soldiers. In fact, she most thoroughly inspected the whole place, and went into many more wards than had been intended by the officials, who were afraid she would be fatigued. She did not appear to be so, although she must have walked some miles. The Hospital looked in beautiful order, and she is understood to have been pleased with everything except the accommodation for the married women. She looked well in health, but had, when not speaking, a sad and careworn expression; she was very gracious, and her voice was beautifully clear and sweet, though she spoke in rather a low tone. When she smiled her face wonderfully brightened up. She was evidently greatly interested in her visit, and yet it was as clearly a trial to her. The old soldiers were delighted to see her, and one man, who lay almost dying in bed, told her he thanked God he had been permitted to see her before he died. Prince Alfred, who was with her, looked quite strong and robust. The Princess Alice spoke to several of the soldiers' wives, and seemed as much interested in the place as her mother. Prince Louis also seemed both interested and pleased. Luckily, the day was extremely fine, and the Hospital and grounds were looking their best.

#### PARLIAMENTARY.

THE debates in Parliament during the past week have not been prolific in matters of interest to the Profession. On Thursday, the 7th inst., Sir Robert Peel, in answer to a question by Mr. Longfield, stated that he did not intend to defer the Bill for Vaccination in Ireland until the Government should have determined upon the course they would pursue with regard to the Vaccination Acts in England. As the measure in question referred only to Ireland, he did not see the necessity of postponing it. Friday was signalized by the announcement from the Chancellor of the Exchequer that he intended to extract the last irritating element from the Budget, by abandoning the club licenses, and by the rejection by the Select Committee of the proposed Amalgamation of the Metropolitan and City Police. The Prison Minister's Bill, the City Traffic Regulation Bill, and Mr. H. Seymour's motion on the Occupation of Waste Lands in India, bearing as it did on the cultivation of cotton in that country, have been the chief matters of social importance discussed. On Wednesday the second reading of the Railway Accidents Compensation Bill was moved by Sir J. Fergusson. Mr. Longfield moved, as an amendment, that the bill be read a second time that day six months. This was seconded by Mr. Bentinck, and, after a short debate, the bill was thrown out by a majority of 20. It may be admitted that the existing law does at times press hardly upon companies, and that fraudulent claims are occasionally made, and impose both on Medical Practitioners and on juries. But the principle on which the bill was founded was neither in accordance with law nor justice. Mr. Longfield, we think, rightly characterised the bill as "monstrous" and "indecent." He said:—

"The first section of the bill provided that no person should be entitled to compensation in consequence of an accident from the railway company unless his life were insured, thus limiting arbitrarily and indecently the amount at which human life was valued. But what was the rate at which railway directors seemed to appreciate human life? The bill on their behalf divided railway passengers into three classes, which were appraised by the hon. baronet at the rate of £400 in the case of a first class, £300 in the case of a second, and £200 in the case of a third class passenger, that being the estimate which

the directors had the modesty to put upon human life as represented in those three different classes. (Hear, hear.) Now, in the days of Athelstan, there was a tariff of human life, in accordance with which a man was fined £13 for killing a peasant, the tariff increasing in amount up to £1500 in case of a monarch. (A laugh.) He could not say what was charged in the case of baronets, for they came later. (A laugh.) There was also under the Irish law what was called an *eriach*, or stipulated rate of payment in the case of persons who happened to be killed by accident or negligence; and, if the present bill passed, the various companies would have to keep, not only railway offices, but also insurance offices, of which the tariff was to be regulated by the Board of Trade, the directors, in addition to their other powers, being now anxious to have the privilege of killing the public at the rate of so much per head. (Hear, hear, and laughter.) If such legislation were sanctioned, it would, he supposed, shortly come to pass that a regular fixed scale would be established by which the life of a sheep would be appraised at 40s., a cow at £15, a horse at £50; the loss of an eye at so much, general mutilation at so much more, until the *maximum* of £400 was reached in the case of the life of a first-class passenger. (A laugh.) Such was the nature of the legislation which the hon. baronet proposed, legislation called for by the existence of no grievance which he had proved, by nothing stronger than the assertions of railway companies themselves. (Hear, hear.) He should remind the hon. baronet that committees had sat to inquire into the subject of railway accidents, and that reports in reference to it had been made from time to time, not by pettifogging lawyers, but by most competent and disinterested persons connected with the Board of Trade. Mr. Lowe, in giving his evidence before one of those committees, that of 1858, stated that he regarded Lord Campbell's Act as the only security which the public had against railway accidents. He might add that one of the reports which had been made to the Board of Trade in relation to these accidents showed that 38 persons had been killed, and 498 injured, as the result of two collisions, while in the case of one of them the accident was proved to have been attributable to neglect on the part of the signalman, a youth of 19, who was paid only 14s. or 15s. a week. (Hear, hear.) In 28 instances the negligence of the inferior servants of railway companies had been the cause of accidents, and it was monstrous, he contended, that the House should be asked to throw its protection over those companies to the extent which the hon. baronet proposed. He for one objected to human beings being placed in the same category as cattle, and to having human life sacrificed to the greed and cupidity of railway directors."

The legal objections to the bill were enforced by the Solicitor-General and Mr. Bovill. As was to be expected, the supporter of the bill indulged in various sarcasms on "compassionate Doctors." Our Profession can well afford to disregard Sir J. Fergusson's imputation, as false as libellous, that partnerships exist between pettifogging lawyers and Doctors in railway accident cases, and that there is a class of Doctors and solicitors who make it a practice to get them up.

#### IDENTIFICATION OF PERSONS FOUND DROWNED.

ON Saturday last, Dr. Richardson conducted an inquiry which may ultimately be often resorted to in those medico-legal investigations in which the question of identity is involved. On the preceding Wednesday an inquest was held by Mr. Humphreys, the coroner for East Middlesex, on the body of a man who had been found drowned in the Thames, and who was assumed to have been the murderer of the unfortunate girl Emma Jackson, who was found some weeks since with her throat cut in a brothel in St. Giles. The witnesses who knew the supposed murderer were taken to view the body of the deceased man on Wednesday, but the body was so decomposed, the face so black, and the tissues so swollen, that they were utterly unable to offer any opinion. To prevent the case from falling through, Dr. Richardson suggested, first to Dr. Lankester, and afterwards to Mr. Humphreys, that probably the features of the dead man might be greatly restored. Mr. Humphreys thereupon requested Dr. Richardson to make the attempt, and

deputed Dr. Edmunds to take part in carrying out the operation. The process adopted by Dr. Richardson consisted in immersing the body in a salt water bath for two hours; then the face was raised from the water and exposed to chlorine; and finally the arteries leading to the face were injected with chlorine water containing chloride of zinc and a little sesquichloride of iron. The decomposition of the tissues was so great that the operations were attended with much difficulty, but the results judicially were all that could be desired. The face was brought from dark black to a pale ash colour, the tumefaction was reduced, and all the witnesses on viewing the body after the process were enabled to depose without hesitation that the body was not that of any man whom they had ever seen; while one witness (Stoke) swore positively that it was not the person who attended Emma Jackson when he saw her last. Dr. Richardson and Dr. Edmunds were also enabled to determine that the dead man was a young man of 21 or 22, whose beard had not been shaven, and whose whiskers were imperfectly developed. While we may look upon this inquiry as fruitful in its results practically, we may add the fact that Dr. Richardson believes that in future much more perfect results may be secured, and we may hope that by improvements in the different steps of the proceedings, any dead body, the tissues of which are not actually destroyed, may be so far restored as to be identified. This is a new feature in Forensic Medicine, and one which may render service to the public, and reflect credit on modern Medical science.

#### TOXICOLOGICAL NOTES:—UPAS TIEUTÉ; SULPHATE OF IRON; THE TOOT-POISON.

It is well known to toxicologists that there are two Javanese poisons which bear the name of Upas—the Upas Tieuté and the Upas antiar. Confounded as the two are by popular writers, they are perfectly distinct in their properties. The Upas Tieuté owes its activity to the presence of strychnia, which was found in it by Pelletier and Caventou. The activity of the Upas antiar, on the other hand, depends on a neutral principle—Antiarin. Upas antiar, in small doses, acts as an irritant; in larger, it paralyses the heart, or causes death by convulsions and coma. A case of poisoning by Upas has lately appeared in the *Times*, transferred from *Galignani's Messenger*. If the case be authentic, it was clearly one of poisoning by the Upas Tieuté; the symptoms were as nearly as possible identical with those produced by a small poisonous dose of strychnia. The patient is said to have recovered. An instance of the poisoning of a number of sheep by sulphate of iron has recently been reported to the Central Society of Agriculture in Paris. Sulphate of iron belongs to the class of uncertain irritants. Like trisnitrate of bismuth, nitrate of potash, and several other salts, it is quite capable of producing violent effects and death when given in large quantities; and yet persons have swallowed a considerable amount of green vitriol with comparative impunity. Its effects on some of the lower animals would seem to be as uncertain as on man. Two drachms have made a dog a martyr to science in twenty-four hours, whilst the same quantity has scarcely affected another. A rabbit has taken forty grains without apparent injury. It would seem, from the recent occurrence in France, that the salt, although poisonous to the Ovine Ruminants, is harmless to the closely-allied *Bovidae*. In France, sulphuric acid is commonly used in the maceration of the pulp of beet-root for cattle food. A farmer, who fed his sheep on the pulp so prepared, added by way of experiment 1800 grammes of sulphate of iron to every 1000 kilogrammes of beet-root. The sheep fed on the pulp thus medicated soon fell sick, and many of them died. The alimentary canal was found inflamed, and yielded, on analysis, sulphate of iron. The cows, however, which had been fed on the same pulp, were unaffected. That it was the

iron salt which poisoned the sheep was proved by the fact that sheep fed on the same beet-root minus the iron continued perfectly healthy. The whole subject of the comparative effects of poisons on different species and genera of animals would well repay investigation. Sulphur, for instance, which to man is only a mild laxative even when given in considerable quantities, is said to be, in proportionately large doses, a fatal poison to the horse. The effects of opium on man and animals are not identical,—in the former sopor, in the latter convulsions, are the leading phenomena. Toxicological facts seem hopelessly ultimate. Of the cause of such differences we are as ignorant as we are of the reason why ordinary phosphorus should be a fatal poison and amorphous phosphorus an inert powder. Dr. Lauder Lindsay's paper on the Toot-poison of New Zealand, read before the British Association at Cambridge, describes an agent which, although little known in this country, is producing disastrous effects amongst the flocks and herds of the New Zealand settlers. The amount of property lost by graziers through its instrumentality has been in some instances as much as 75 per cent. The Toot, or Tutu plant, is the *Coriaria ruscifolia*, and belongs therefore to a genus, many of whose species have been proved to be poisonous. The Toot-poison is narcotico-irritant. In man it produces coma, delirium, and convulsions, and, during convalescence, loss of memory and vertigo. In cattle and sheep the symptoms are vertigo, stupor, delirium, and convulsions; curious staggerings and gyrations; frantic kicking and racing or coursing, and tremors. The seeds, contained in beautiful dark purple luscious berries, resembling the blackberry, and equally tempting to children, and the young shoots, like asparagus in taste and appearance, are the poisonous portions of the plant. The former cause the greater number of accidents to man, the latter to cattle. In both it seems that a certain predisposition is necessary for the poison to take effect. Depressing influences render both more liable to suffer from it, whilst it is quite possible for animals to become completely habituated to its use. The discrepancies between the accounts given by different writers of the poisonous properties of various *Coriarias* may perhaps be explained by the facts observed by Dr. Lindsay in the case of the Toot-poison. An underfed or starved animal just landed from a sea voyage is sure to be poisoned if it be allowed to luxuriate on the pleasant-looking succulent Tutu shoots, whilst for one that has been habituated to its influence, the same plant is believed by the colonists to be as nourishing and as safe as clover.

#### THE CASE OF TURK v. BARKER.

ANOTHER action for wrongfully confining an alleged lunatic was tried at Westminster before Mr. Justice Byles on May 11. Proceedings, however, in this instance were taken against the relieving officer of the Parish of Lambeth for having placed the plaintiff in the Workhouse Lunatic Asylum, and not against the Medical man who signed the certificate on which the officer acted. The verdict of the jury was a natural consequence of the highly-seasoned articles on the liberty of the subject, and the cruel injustice of confounding violence with insanity, which were so plentiful in the public journals a few months ago.

"The plaintiff, it appeared, was a commission agent, and a member of the Commercial Sale Rooms, and had carried on business for thirty years. He was a married man, having several children, some of whom were grown up, and some lived at home; one of those living at his house was a young woman of sixteen or seventeen years of age, and another was a little boy of nine or ten. On the 24th of May last year the defendant went to the plaintiff's house, having a cab outside with two men in it, and telling the plaintiff that he had heard he was conducting himself in an outrageous and violent manner, had him placed in the cab and driven to the workhouse, where he was placed in the lunatic ward and visited by the Surgeon, who for two or three days could not pronounce any positive opinion as to his sanity, as he was vehemently excited at his

position; but after that time he came to the conclusion that he was of sound mind, though very excitable from the effects of drinking. This was the plaintiff's case.

"For the defendant, the cross-examination of the plaintiff and his witnesses, and the witnesses called for the defendant, disclosed that the plaintiff's children had gone to the defendant to complain of their father's outrageous conduct to them, and of his violence, and he had told them to go to a magistrate, but the magistrate declined to interfere. The defendant, as relieving officer, thereupon thought it his duty to do so. He had frequently threatened to murder his children and himself afterwards. The neighbours had heard his violent threats, and one of them had protected his daughter, whom he had slapped and shaken, and threatened to turn out of doors. He called his boy 'the devil's darling,' and often threatened to thrash him, but he kept out of his way. He breakfasted usually in bed, but got up in time for business. He got intoxicated at times, but denied that he could recollect having caressed and kissed the back of an arm-chair on one occasion, unless a lady were in it. His subscription to the Commercial Sale Rooms had been declined to be received because of complaints of his violent conduct, and Dr. Cronin had given a certificate, dated May 24, 1862, certifying that the plaintiff 'was of unsound mind, aggravated by drink, and wholly unfit to be at large; that his conduct both at home as well as abroad was outrageous, and that he was continually threatening his own life and that of his children.' Acting on this certificate, and believing it to be his duty, the defendant, as relieving officer, had had the plaintiff removed to the lunatic asylum of the workhouse.

"His lordship, in summing up, said that the defendant was legally wrong, and a verdict must go against him; but on the question of damages his lordship left it to the jury to say what damage the plaintiff had received. What had happened to him had probably been most beneficial to him, and there was no pretence for imputing any malicious motive to the defendant, who, mistakenly no doubt, had simply acted as he believed it to be his duty to do; urged on by the complaints of the plaintiff's children and what he heard from the plaintiff's neighbours, and believing the responsibility of acting in the matter to be cast on him.

"The jury, after a short consultation, to the surprise of every one in court, found a verdict for the plaintiff—Damages £20.

"His lordship immediately gave leave to stay execution."

## LOCAL REPORTS ON SMALL-POX.

(Continued from page 487.)

III. *A Short Report of Small-pox in Belgravia, showing the Origin, Gradual Progress, and Spread of the Disease.* By C. J. B. ALDIS, M.D. Cantab., Medical Officer of Health for St. George's, Hanover-square.

THE disease first occurred at St. George's Hospital in a school-boy, aged 7, who resided in Lloyd's-place, Brompton, and was admitted into the Hospital on October 24, 1862, for fever; but the "fever" turned out to be small-pox; whereupon the patient was placed in a private room, instead of being sent to the Small-pox Hospital. The new remedy, *Sarracenia Purpurea* was tried, and he was discharged cured on November 14. Four other patients, aged between 11 and 20, became infected with the complaint, besides a student of the Hospital, residing in Shaftesbury-crescent. As far as I could ascertain, all these patients had been vaccinated. A man, aged 30, unvaccinated, died on November 22, at No. 2, Robert-street, Pinilico. He had refused to be taken to the Hospital. The disease also attacked five women, whose ages varied between 20 and 50, during the same months. They were vaccinated, and resided in Hugh-street West. I then summoned a special meeting of the Nuisances Removal Committee, on November 27 last, to consider the appearance of small-pox, and to adopt such means as might be deemed expedient. It may be incidentally stated, that although measles had been epidemic during the month of November, yet it did not prove fatal in a single instance until December 4. Several cases also of secondary measles and of anomalous eruption occurred in the district. (a) But to return to our subject. It appears,

(a) It may be interesting to mention that an infant, while under my care during the present epidemic, at the Surrey Dispensary for syphilis covering the whole body, became affected with distinct small-pox, which disappeared, and with it vanished the syphilitic eruption. I have seen lepra disappear during the convalescence from measles.

then, that the disease was imported into St. George's Hospital at the north corner of the district, from Brompton, in October; that it was conveyed by one of the pupils to Shaftesbury-crescent at the eastern extremity. I then traced it to Hugh-street West, and other streets situate in the central portion; subsequently to the end of Pulford-street, in a south-easterly direction near the Thames; then to the south-western boundary. On former occasions, many of the earlier cases of small-pox have happened in houses near the river. The eruption in some cases has been of so mild a form as not, at first, to be deemed that of small-pox; but during its progress, the specific character of the pustules proved it to be variolous. Very young children have mostly escaped the influence of the epidemic, owing, no doubt, to their being protected by previous vaccination.

The following is a table of the number of cases of small-pox which I have registered in the Complaints of Nuisances book from—

November 18 to 26 inclusive	.	.	.	.	8
January 2 „ 28 „	.	.	.	.	6
February 4 „ 28 „	.	.	.	.	6
March 3 „ 26 „	.	.	.	.	46
April 1 „ 23 „	.	.	.	.	41

107

But it must be remembered that only one case of sickness from small-pox was generally registered at the time of making each complaint, and that several of the family of the person whose disease was entered often became infected. The total, therefore, which is exclusive of the five patients in St. George's Hospital, may fairly be increased. Moreover, it may be assumed that cases of small-pox have happened in private practice which have not come to my knowledge; and although the complaint has almost been confined to the dwellings of the labouring classes, still it has spread to some few persons in better circumstances. The total number of cases reported to the Committee amounted to 141, of which 39 were sent to Mount-street.

Out of the preceding cases of sickness, the following deaths occurred:—

Date.	Sex.	Age.	Vaccinated.
Nov. 22	Male	30	No.
March 9	Female	20	Yes.
„ —	„	1 month	No.
„ 11	„	22	No.
„ —	„	6 months	No.
„ 12	Male	6	No.
„ 13	Female	24	No.
„ 15	Male	18	Yes.
„ 17	„	36	Yes.
„ 28	„	10 weeks	No.
April 7	Female	39	Yes.
„ 8	„	3 weeks	Yes.
„ 9	Male	1	No.
„ 10	„	6 weeks	No.
„ 13	„	5 months	Yes.
„ 14	Female	38	No.
„ 16	„	40	Yes.
„ 20	Male	40	Doubtful.
„ —	„	22	No.
„ 24	„	6	Yes, when the small-pox appeared.

I may produce, as an example of the localising of zymotic disease from insanitary conditions, a family consisting of the father and mother with six children, who resided at No. 2, St. George's-place. One of these suffered from measles in January last. Three had been attacked with scarlet fever, followed by renal disease in one instance, when I visited the house, and tried to induce the mother to allow them to be taken to the Infirmary in Mount-street, but she refused. Two of the children having afterwards been attacked with typhoid fever, I went again with the Rev. Mr. Gedge, to urge her to permit the children to be taken away, when she declined a second time. One of the latter patients died, and small-pox subsequently appeared in one of the other children, which also died. At length two others, upon being seized with small-pox, were sent, by the mother's wish, to Mount-street from this perfect pest-hole. Three children, however died, one from typhoid fever and two from small-pox. The house was in so bad a state that I reported it to be unfit for human habitation, which

the Committee have approved. It is important to recollect that the population of the Belgrave sub-district has gained 15,000 within ten years, and that a great number of the houses occupied by the labouring classes contain a family in each room. The frequent custom among the Irish of holding "wakes," to which neighbours crowd, and the dead body lies festering with small-pox, or some other zymotic disease, greatly adds to the danger of infection.

IV. On Small-Pox in the City of London. From Notes supplied by H. LETHEBY, M.D., etc., etc.

In the City the force of the epidemic has not been severely manifested. Here and there in the western district, and in the worst parts of the eastern, it has shown itself, but the total number of cases of sickness from it among the poor since April 1 has been but 34; and the total number of deaths among all classes in the City since that time has been only 10. The truth is, the City had its visitation of the disease in the spring of 1860, and then vaccination was pretty extensively practised, so that the population is at present tolerably well protected. Not, indeed, so completely as it should be, for scarcely anything is so slovenly done as vaccination. During the epidemic of 1860, I collected the records of 223 cases of small-pox, all of which occurred within the City, and of which 62 were fatal. 122, or rather more than half of the whole number, were reported to have been successfully vaccinated, and 24 as not having been vaccinated at all; the others had either been vaccinated without success, or had furnished uncertain returns. The general results of my inquiries were, that of the fatal cases, 52 per cent. had not been vaccinated, 18 per cent. had, but without success, and 30 per cent. are said to have been vaccinated successfully. Of the cases which recovered, 72 per cent. had been vaccinated successfully, 6 per cent. not successfully, and 22 per cent. had not been vaccinated at all. So that of the fatal cases as many as 70 per cent. had not been protected by vaccination, and of the recoveries 72 per cent. had.

V. Newington. By WM. T. ILIFF, Jun., M.D.

NEWINGTON, with an area of 624 statute acres, and a population of 84,000 at least, has not been exempt from the present epidemic of small-pox. The total mortality therefore in the eighteen weeks ending May 2, was 19, of which 1 occurred in St. Mary's district, 12 in St. Peter's, and 6 in Trinity. As to their ages, three died under 1, seven between 1 and 5, four between 5 and 10, three between 10 and 20, and two between 20 and 30. One aged 14 was registered as vaccinated, and six aged 6 months (?); 1, 5, 7, and 11 as unvaccinated. In two weeks only, viz., those ending January 3 and February 7, were there 3 deaths registered. In the same period of eighteen weeks there were issued 1536 sickness orders for the out-door poor, and these included 67 for small-pox—viz., 13 in St. Mary's, 27 in St. Peter's, No. I. and II., and 27 in Trinity. Of these latter, 19 have occurred in the last three weeks in nearly equal proportions. Ten cases in addition have been received into the workhouse; the first two originated therein, and were mild; of the others, all but one have been admitted from without. They are placed in a ward at the top of the Infirmary, and there is little doubt but that the Board of Guardians will, if necessary, erect a temporary Hospital on a piece of ground three acres in extent, not far from the Workhouse. The number of vaccinations and re-vaccinations is very large, and bills are regularly posted every week, drawing attention to the prevalence of small-pox, and urging vaccination. A complaint was brought under my notice of a boy, eight years of age, being unvaccinated; and on carefully perusing the several Vaccination Acts in case it should be deemed right to summon, it appeared that unless I could produce proof of the original vaccination notice having been served on the mother, i.e., eight years ago, no proceedings could be taken for a penalty, and that no fresh notice on my part, nor on the Registrar's, would be sufficient to comply with the words of the Act. The issue was never tried, for I found the mother and child were both going into the country the next day; and, I believe, had they remained, that consent could have been obtained without recourse to arbitrary proceedings. The great variety in the appearance of the pock-marks on the arms of children deserves special notice, and it will be worthy of careful investigation as to their relative value, *quoad* exemption from small-pox.

VI. *Absence of Small-pox at Eltham.*

DR. DAVID KING, Medical Officer to the Eltham sub-district, writes:—"I have great thankfulness in stating that in the Eltham District, Plumstead Board of Works, there have been no cases of small-pox for some years."

VII. *Clapham.* From Dr. J. MacDONOUGH, Medical Officer of Health for Clapham District.

I HAVE been located in Clapham about thirty years. We had a few cases of small-pox occasionally as in other districts, but nothing like an epidemic until 1859. In that year there were 77 cases among the Union poor, and 5 deaths. In 1860, there were 72 cases and 5 deaths. In 1861, there were 55 cases and 1 death; and in 1862, there were 11 cases and no death (among the parish poor). During the above periods there were amongst all classes—in 1859, 9 deaths; in 1860, 6 deaths; in 1861, 6 deaths; and in 1862, 1 death. In the present year, 1863, there were 27 cases and no death amongst the Union poor up to May 9. The present epidemic began in the beginning of April last, and is now amongst all classes. My oldest patient is 57 years; she was in childhood duly vaccinated; a lady in affluent circumstances. My patients are of all ages and circumstances up to the above age. A woman over 40 years, who nursed her husband, a man about the same age, assured me she had the small-pox when a girl, and a girl about 14 years, whose mother declares that this girl had the small-pox when a child, and who showed me pits left by it, both are now ill of small-pox. Vaccination and re-vaccination are going on briskly, scarcely anything else moving. The Guardians of this Union have provided a small-pox infirmary, and a carriage at the call of any who may apply for it.

VIII. *Small-pox and Vaccination in Paddington.* By Dr. J. B. SANDERSON, Medical Officer of Health.

THE diffusion of small-pox in the Parish of Paddington has, up to the present time, been very limited. Since the beginning of the year only 7 deaths have been recorded in a population of 83,000. About 25 cases have come under my notice, most of which have been treated by private Practitioners; 9 of these cases have occurred very recently, and within a few yards of each other, in the immediate neighbourhood of the dust-yards on the north bank of the Paddington Basin. The houses invaded are for the most part inhabited by persons occupied in dust-sifting, who, from their mode of life, and their reckless disregard of all precautions, are particularly liable to contagion. The sanitary condition of these houses is unsatisfactory. The usual appliances (apparatus for the supply of water to the closets, proper dust-bins, etc.) have been provided in compliance with sanitary orders, but have been as speedily destroyed by the occupants, so that for the present I am compelled to content myself with rude and ineffectual substitutes. Among such a population it is difficult, even with the utmost vigilance, to secure general vaccination.

The measures which have been taken to check the further progress of small-pox are the following:—

1. *Domiciliary visitation of infected neighbourhoods for the purpose of seeing that the people avail themselves of the existing facilities for Vaccination.*—This measure I regard as paramount in importance. The duty has been performed partly by myself, principally by my inspector. I now know that almost all the children in the streets adjoining the locality principally infected have been vaccinated, and I confidently anticipate that, in that direction, the disease will spread no further. The inspector is now visiting others to which it has not yet extended, and there it may be hoped that its invasion may be anticipated. This measure is incomparably more effectual for the promotion of vaccination than any other. It could be carried out everywhere in the metropolis without difficulty, were it not that in many districts the number of inspectors is insufficient, or that these officers are occupied in matters not belonging to their sanitary duties.

2. *Service of special notices requiring compliance with the Vaccination Act.*—Wherever, in his visitations, the Inspector finds vaccination neglected, he requires, by written notice, the parent or the individual, as the case may be, to apply for vaccination to some Medical Practitioner within a stated period, at the expiration of which he repeats his visit. If he finds that the notice has been neglected, he reports the case to the Board of Guardians, who thereupon promptly take proceedings under the Act.

3. *Circulation of handbills.*—These are worded in homely language, and are circulated only in streets and places inhabited by the poor, for it is by no means desirable to increase the already unreasonable alarm which prevails among the upper and middle classes.

4. *Provision for the reception and treatment of small-pox cases.*—In this matter the Guardians and Sanitary Committee have taken active steps. A report has been prepared by the latter on the cost and most suitable situation for the erection of a temporary building, and there is no doubt that in the event of its becoming necessary, the Guardians will be prepared to meet the emergency with the same promptitude with which they have hitherto acted.

IX. *Westminster.*

IN the parishes of St. Margaret and St. John, Westminster, 20 deaths were recorded during the month of April as being attributable to small-pox, and 18 had not been vaccinated. Every effort is being made to arrest this outbreak by having the houses thoroughly cleansed and limewhitened, and inducing the poor to send their children for re-vaccination. Bills have been issued for this purpose, and during the month of April 1300 children and other persons have been vaccinated. As yet no place has been provided where cases of small-pox can be sent to, but the Medical Officer of Health suggests that if not the whole, yet a portion of one of the Workhouses should be cleared for the admission of small-pox cases, and that all the Practitioners in the neighbourhood should have the privilege of sending cases into the Workhouse whether they arise in the persons of paupers or otherwise. He has also recommended to the parochial authorities that the fee received by the Registrar of Births and Deaths for entering cases of vaccination should be likewise paid to the vaccinator who forwards the duplicate certificate, and thus give him a direct interest in forwarding to the Registrar of Births and Deaths that evidence of vaccination by which alone a just estimate can be arrived at of cases which remain unvaccinated after the prescribed period of three months. If this were done, it would be impossible for any large number of children to remain unvaccinated. Already in the present month there are seven deaths from small-pox, and at present the disease is but little decreased.

## REVIEWS.

*Clinical Memoirs on the Diseases of Women.* By ALFRED H. M'CLINTOCK, M.D., F.R.C.S., late Master of the Dublin Lying-in Hospital, etc. 8vo. Fannin and Co.

THIS work comprises sixteen distinct Memoirs, illustrated by thirty-five well-executed wood engravings, distributed throughout the text. Eleven of these Memoirs treat of as many particular diseases of the sexual organs: one is devoted to "Stone in the Bladder;" one to "Hæmorrhage after Parturition;" another to the "Semeiological Value of the Pulse in Childbed;" and the remaining two to "Dropsy, and Cystic Disease of the Ovum." The contents are set forth in twenty-two pages of index, from which the extent of information given and the variety of details discussed may be inferred.

The author's style is simple, clear, and fluent, and he brings the labours and theories of other writers, foreign as well as British, to bear in a most happy way upon his own observations; and thus, while the reader is made acquainted with the literature of the subject, he sees the various opinions and practice of its contributors brought to the test of more extended clinical observation and practice.

Each Memoir is an exhaustive treatise on the disease of which it treats. Very numerous illustrative cases are recited, not in obscure and wearisome detail, but in a few well-digested lines, which at once portray all the important features of the case. Speaking of an attributed cause of prolapsus uteri, he remarks:—

"I feel satisfied that the frequency of cervical hypertrophy and elongation of the os and cervix uteri, and its influence on the production of prolapsus, has been greatly over-estimated by M. Huguier and some others, and therefore the practice they recommend—viz., excision of the cervix uteri—if justifiable at all, should only be resorted to in a few exceptional cases."

The author's experience of pessaries leads him to speak in the following terms of their use:—

"A very large majority of (my) patients derived from their use the greatest relief and comfort, the uterus being kept in its proper place, and the instrument occasioning comparatively no annoyance. By judicious use of the pessary—the size of the instrument being from time to time reduced, till its diameter about equals the normal diameter of the vagina, and it can at length be safely dispensed with—cases may be cured."

Some interesting cases of excision of inverted uteri are recorded. The *écraseur* was used in three cases, and in each with perfect safety. The relative value of the several modes of removal of uterine tumours is fully discussed in the *Memoir on Polypus of the Uterus*. When the pedicle of the tumour is small, not thicker, for example, than the little finger, Dr. M'Clintock prefers torsion; and when the pedicle exceeds this size he prefers the *écraseur* to the knife or scissors, "on account of the security which this mode of operating gives against hæmorrhage." Fatal hæmorrhage has followed excision by the scissors. On six occasions the *écraseur* was used "with the most satisfactory results." "In using the instrument," he says, "I have generally found it necessary to bring the bulk of the tumour beyond the external genital orifice; and this necessity it is that limits its range of applicability. The use of the ligature (he says) alone as a means of extirpating uterine polypi is destined ere long to become nearly obsolete. As an auxiliary or supplemental means, in conjunction with excision, the ligature will continue to hold an important place. In ten instances I removed uterine polypi by means of the ligature alone, and three of these women died some days subsequently to the operation. I will not say in consequence of it; the reader shall have an opportunity of determining that point for himself. . . ." He shows that out of 69 cases of deligation occurring in Dr. R. Lee's and in his own practice, 12 patients, or 1 in 5, died; while there was no death in 59 cases in which the removal was effected by other means. He further shows that peritonitis, phlebitis of the uterus, pelvic abscess, phlegmasia dolens, and low fever are the chief consequence of ligature of uterine tumours, produced apparently by their decomposition within the body. Fearing similar consequences, Dr. M'Clintock objects to the removal of fibroid tumours by gouging, as advocated and practised by Mr. Baker Brown.

We are glad to find our author adopting a more precise definition and an intelligible nomenclature for extravasations of blood in the neighbourhood of the uterus. Under the head "*Pelvic Hæmatocele*" he includes cases of extravasation on either side of the pelvic peritoneum, the term "*Uterine Hæmatocele*" being restricted to extravasation of blood into the substance of the uterus.

The extreme interest and importance of pelvic hæmatocele is fully illustrated in the memoir devoted to this lesion, of which Dr. M'Clintock is inclined to assign a very common cause. "So great," he says, "is the proportion of instances where difficulty of menstruation has preceded the hæmatocele, that we regard dysmenorrhœa as one of the predisposing causes of the complaint."

With regard to the causes of mammary inflammation and abscess, the author repudiates the opinion that lacteal distension even predisposes to them. He assigns another cause. "A very large proportion of cases of mammary abscess had some form of sore nipple previously. On a few occasions I have had an opportunity of observing the inflammation of the breast to supervene immediately and directly upon the ulceration or fissure of the nipple, as though it were an extension from it; whilst in other cases the gland became affected secondarily, in the same way as do inguinal glands from irritation of the vulva or of the urethra."

From some incidental remarks on ulceration of the womb, it appears that, if he does not think that this condition exists less frequently than has been represented, he is at least of opinion that it does not usually produce the severe symptoms which have been attributed to it. "Dr. James Henry Bennett," he says, "himself tells us that inflammatory ulceration of the cervix uteri during pregnancy is of frequent occurrence, and the most prominent of all the symptoms occasioned by its presence during the puerperal state and after abortion is hæmorrhage."

"I cannot offer (Dr. M'Clintock goes on to observe) any decisive opinion derived from my own experience in this matter. This much I can say, that many patients affected

with chronic inflammation and ulceration of the os uteri have been delivered under my care, who, nevertheless, had no subsequent attack of hæmorrhage or extraordinary amount of lochial discharge; and that in none of the cases of secondary hæmorrhage (after parturition) which were submitted to ocular examination, was there any ulceration present."

Such extracts as the foregoing will hardly do our author justice; those who want to be better informed on the subjects of which the book treats, must read it themselves. They will find it pervaded by a kindly tone and a full appreciation of the labours of others; and its dictates are ever directed by the large experience, sound practical knowledge, and excellent judgment of the author, whose book is at the same time an acquisition to Medical literature and to the established renown of the Dublin school.

*Reports in Operative Surgery.* Series the Eighth. By Dr. BUTCHER, Surgeon to Mercer's Hospital.

WE have had occasion before to notice the several series of admirable Surgical reports which have emanated from the pen of Dr. Butcher, and which have materially assisted in placing him in the high position he now holds amongst the Dublin Surgeons—a race of men to whom Surgery has been vastly indebted, and who are looked up to with respect and veneration wherever our art is practised.

This new and eighth report consists of details of five cases of deformity and disease in which the author has put in force with great success the most bold and scientific treatment. The first is an instance of elephantiasis of the lower extremity which was, if not cured, at least materially remedied by ligation of the femoral artery. This case in particular is one of great interest, and does Dr. Butcher much credit.

The second case is an instance of excision of the knee-joint for incurable disease, constituting the fourth where the author has operated with success. The details of this operation and treatment are told with the utmost care and minuteness. The warm criticism on the conduct of those Surgeons who have not taken sufficient care to select their cases, and thus have seriously damaged this excellent operation, is certainly well deserved.

The fourth and fifth cases are instances of large tumours of the upper jaw which were removed with success, and the fifth case detailed is a remarkable instance of hare-lip which Dr. Butcher succeeded in entirely remedying by a well-planned and well-executed operation.

We can award the author the same amount of praise which we bestowed upon him when we noticed his last series. The cases are admirably reported, and the illustrations are striking, and we should think faithful. We would recommend the careful study of the present series to every operating Surgeon.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON AN EPIDEMIC OF CHOREA.

By M. F. BRICHETEAU.

THIS small epidemic occurred in one of M. Monneret's wards at the Necker Hospital, where M. Bricheteau was at the time an *interne*. On October 26, it contained 28 patients, 6 suffering from phthisis, 5 from hysteria, 3 from uterine affections, 3 from heart disease, 3 from brain affections, 2 from typhoid fever, 2 from rheumatism, 1 from gastric fever, and 2 from chlorosis. In the afternoon a young girl was brought in, suffering from the most intense chorea, which had come on the evening before after some dispute. In the course of the evening, one of the hysterical patients, who had formerly had chorea, began, after a hysterical paroxysm, to exhibit some movements, which at the end of twelve hours became so violent that she was obliged to be tied down. She lay at the opposite end of the ward to the chorea patient. On the 27th, two other hysterical patients, who had been in the Hospital for two months or more, were seized much about the same time with chorea—one after a hysterical paroxysm, the other spontaneously. On the 28th, two new cases occurred; on the 29th there was no new case; but on the 30th there were two additional cases, and on the 31st there was another: so that between the 26th and 31st of October eight patients

contracted chorea in this ward; and in all probability the epidemic would have become propagated to the neighbouring ward, had not measures for arresting it been taken—these consisting in the isolation of the patients. Of the nine patients, the four last attacked, as their chorea was only of a medium intensity, and they were able to walk, were at once discharged. The five others, whose violent movements compelled them to be kept in bed, were placed in a separate pavilion, the other patients being prevented access to them. After this no case occurred.—*Gazette des Hôpitaux*, No. 46.

## EXCERPTA MINORA.

*Influence of the Relative Ages of the Parents upon the Sex of their Offspring.*—M. Boudin, in a communication addressed to the Académie des Sciences, comes to the following conclusions:—1. The masculine sex predominates when the father is the oldest, and the feminine when this is the case with the mother. 2. There is a tendency to equilibrium in the sexes, but still with a slight predominance of the female, when the father and mother are of like ages.—*Gaz. des Hop.*, No. 25.

*Operations for Stone in Russia.*—Dr. Ebermann stated to the St. Petersburg Medical Society that according to the reports of the Russian Civil Hospitals for 1856-59, there had been 231 cases of lithotomy, of which 194 terminated in recovery, and 37 in death. Within the same period lithotripsy had been executed only 5 times, all the patients recovering. During the years 1857-59 there had been 6 lithotomy operations performed at the Obuchoff Hospital, St. Petersburg, 3 of the patients recovering, and 3 dying. In the various provincial Hospitals, since 1856, there have been 54 lithotomy operations, 41 having proved successful, and 13 fatal.—*Petersburg Zeitschrift*, No. 1, 1863.

*Discharge of a Portion of the Pancreas by Stool.*—The *Wien. Allgem. Med. Zeitung* (1863 No. i.) refers to the favourable issue of a case some six months since reported in its columns, in which a portion of the pancreas was discharged by stool, and found amidst the fæces. The patient is now perfectly well, and has departed on a long journey.

## GENERAL CORRESPONDENCE.

ON THE MEANS OF CONTROLLING HÆMORRHAGE  
IN THE REMOVAL OF SCROTAL TUMOURS.

LETTER FROM J. FAYRER, M.D.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the *Medical Times and Gazette* of February 7, 1863, Dr. Quinlan, of Dublin, alluding to the removal of scrotal tumours, remarks, that recent operators have not acknowledged Dr. O'Ferrall's method of controlling hæmorrhage, though they have had recourse to it in these operations. He also remarks, "that since the publication of Dr. O'Ferrall's plan of elevating the scrotum to drain it of blood, a complete change has occurred in these operations."

Dr. Quinlan is, perhaps, not aware that they are of almost weekly occurrence in Calcutta, that the tumour is invariably elevated to drain it of part of its blood before it is removed, and that such has been the case for many years—long before 1844 or 1845, when Dr. O'Ferrall's plan was made known.

The late Mr. Brett, of the Hon. E.I. Co.'s Service, in his work on "Surgery in India," printed in Calcutta in 1840, mentions elevation of the tumour to drain it as one of the preliminary steps of the operation. *Vide* page 94:—"The tumour should be turned over on the abdomen to allow of the veins being somewhat emptied of their contents."

We now use a clamp, of which I enclose a sketch of my own design, or a running cord with a brass ring, a suggestion for which we are indebted to Dr. Mactier, B.M.S., and we have comparatively little dread of hæmorrhage, which, I must add, in my experience of these operations, is more formidable in its arterial than venous form.

I have no desire to detract from the originality of Dr. O'Ferrall's invention, but I and my colleague, Mr. Partridge, have frequently had recourse to this proceeding, unaware that it was claimed as an original invention, or was anything beyond what the circumstances of these cases naturally suggested.

If Dr. Quinlan will refer to the *Medical Times and Gazette* of September 13, 1862, he will see that the most modern

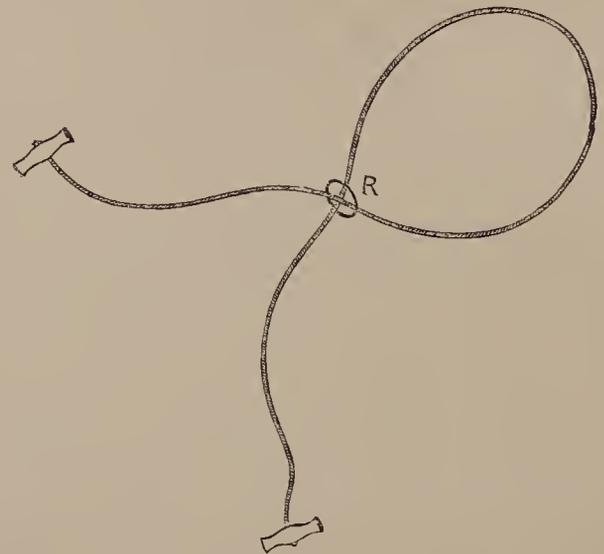

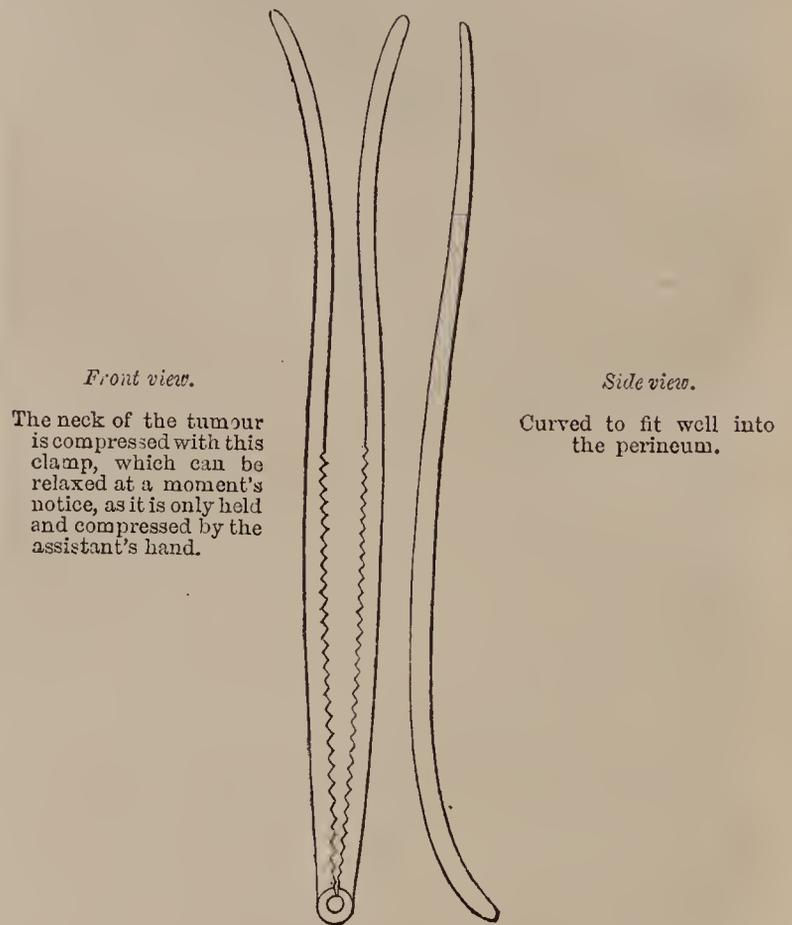

mode of performing this formidable operation is considerably modified since Dr. O'Ferrall's plan was published, and since Hoo-Soo, sank after being on the table upwards of an hour and a-half.

I am, &amp;c.

J. FAYRER, M.D.,

1st Surgeon Medical College Hospital, Calcutta.  
Calcutta, April 3.

## STEEL CLAMP.

A cord, strong and twisted, like those of window sashes in England, running through a brass ring (R), and enclosing the neck of the tumour. It is fitted with a handle at each end, like that of a cork-screw, to pull tightly on. This is a most efficacious tourniquet.

**THE LEVÉE.**—Amongst the gentlemen attending the levée held by H.R.H. the Prince of Wales on behalf of Her Majesty, on Wednesday, were Sir C. Locock, Mr. Coulson, High Sheriff of Cornwall; Doctors—Breslin, E. Phillips, F. G. Read, Dickson, Lyon Pfayfair, C.B., F. Bird, Hinxman, Ramsbotham, T. K. Chambers, C. Rutherford, Scott Alison.

**DR. B. W. RICHARDSON.**—The Philosophical Society of America, held at Philadelphia, have elected Dr. Richardson, the author of the essay on the "Cause of the Coagulation of the Blood," a member of their body. This is the fourth foreign society which has conferred the like honour on themselves and on the distinguished English physiologist.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 28, 1863.

Mr. PARTRIDGE, President, in the Chair.

DR. A. T. H. WATERS read a paper on

A REMARKABLE CASE OF INJURY OF THE HEAD, IN WHICH THE RIGHT RESTIFORM BODY AND THE RIGHT POSTERIOR COLUMN OF THE SPINAL CORD WERE DIVIDED TRANSVERSELY, WITH REMARKS.

The following is a brief abstract of the case:—John M'Bride, a sailor, aged 23, was admitted into the Liverpool Northern Hospital about noon on February 19, 1863. He had received a blow on the side of the face on the previous day from a capstan bar, which stunned him for a short time. On presenting himself at the Hospital he was able to walk with assistance. When seen by the author he was in bed. He was quite conscious, understood everything, and spoke rationally and distinctly, although articulation was not quite perfect. He complained of slight dizziness of the head, and slight numbness of the right side of the face and of the right arm and leg. He was unable to swallow, and had constant hiccough. The face was dusky, the breathing quiet, the pulse 100 and regular, the tongue was protruded in a straight line, the uvula was drawn to the right side. There was partial loss of power over the right side of the face, and right arm and leg; both these limbs could, however, be readily raised. He could open and shut both eyes. The pupils were rather dilated, the eyeballs constantly rolling about. No affection of vision or of hearing was complained of. The right side of the face and the right arm and leg were of higher temperature than the corresponding parts of the opposite side. The patient said he could distinctly feel when touched on either side of the face, on either foot, leg, or arm. Sensation appeared slightly less perfect on the right side than on the left, but on both sides it was good. The patient died somewhat suddenly at five p.m. on the day of admission, after an ineffectual attempt to swallow. He had survived the accident about twenty-four hours. After death the cranial bones and the vertebræ were found unfractured. The cerebrum was healthy. There was a considerable quantity of slightly coloured fluid at the base of the skull and in the spinal canal; the venous sinuses were very full of blood; the right hemisphere of the cerebellum was slightly and very superficially lacerated on its under surface, close by the side of the right restiform body. The medulla oblongata at its posterior aspect and right side was the seat of an extravasation of blood lying beneath the pia mater. This extravasation was into the nervous substance, and was connected with lacerations of that structure. The parts having been hardened in spirit, two transverse lacerations were found connected by a vertical one. The first or superior laceration involved the right restiform body about its middle; the laceration extended to within a very short distance of the median furrow of the fourth ventricle behind; to the outer side and in front the laceration extended as far as the line of origin of the eighth pair of nerves. Blood was effused between the lacerated parts, and separated them from each other. The nervous substance in the adjacent parts was also infiltrated with blood. The median furrow of the fourth ventricle was pushed a little towards the left side. As far as it was possible to judge, this laceration involved the whole, or very nearly the whole, of the fibres of the right restiform body, and a portion of the grey matter spread out on the floor of the fourth ventricle. None of the roots of the eighth pair of nerves were torn, but the laceration extended close to the superficial origin of the glosso-pharyngeal and par vagum, and no doubt involved their deep fibres. The second or lower laceration was situated just below and to the right of the nib of the calamus scriptorius. It had divided that part which is known as the posterior pyramid and the tract outside of it, which is the continuation of the posterior column of the spinal cord. The laceration extended about two lines into the nervous substance; it stopped behind at the median fissure, and externally it did not extend beyond the line of attachment of the posterior roots of the spinal nerves. Blood was effused as at the upper laceration. These two lacerations were connected by a

vertical one, which ran down along the inner side of the restiform body, and terminated below by joining the inner part of the lower laceration. The lungs were loaded with black blood. The heart was healthy. The author remarked that the importance of the case was in the fact that the parts which were formerly supposed by most physiologists, and still are, by some, to be the sensitive tracts, were divided on one side without loss of sensation ensuing. The case was remarkable as presenting us with a repetition in a healthy man of those experiments so often performed on the lower animals by the physiologist—namely, division of certain portions of the cord or medulla. The result of the case tended to confirm the views recently advanced by some physiologists, that the posterior columns of the cord and the restiform bodies are not the channels by which the posterior roots of the spinal nerves communicate with the sensorium, and to refute the opinion that those structures are concerned in that function. With regard to the minor symptoms, they for the most part agreed in a remarkable manner with the lesion which was found. So severe a laceration of the restiform body could scarcely happen without involving the deep origin of the facial, the glosso-pharyngeal, and the pneumogastric nerves. Hence the symptoms of paralysis about the face, etc., which had been referred to. The immediate cause of death appeared to have been a sudden arrest of the function of breathing.

Dr. HERMANN WEBER made a contribution to the pathology of the

## CRURA CEREBRI.

After some preliminary remarks on the rare occurrence of diseases of the crura cerebri uncomplicated with other affections of the brain, Dr. H. Weber related the following case:—A man, aged 52, affected with disease of the aortic valves, hypertrophy of the left ventricle, and rigidity of the larger arteries, had during the last years of life frequent tinnitus aurium, a dull but moderate headache, disturbed sleep, and anxious dreams. Two months before death, there occurred sudden paralysis of the right side of the body (limbs, trunk, and face) as to motion and sensation, and of the muscles of the left eye, supplied by the third nerve, with dilatation of the left pupil; disturbance of vision only slight—viz., imperfect double vision when using both eyes combined, and impaired accommodation when using the left eye alone; the other special senses and the intellectual faculties unaffected; slow and irregular pulse; obstinate constipation; increased temperature in the paralysed limbs. The paralysis of the right side of the face, the soft palate, the tongue, and the trunk had been from the beginning less complete, and became gradually much diminished, as well with regard to motion as to sensation; that of the limbs, on the contrary, remained almost complete with respect to motion, while the sensation gradually improved. The paralysed muscles of the left eye regained their function only very imperfectly; and the left pupil, too, remained much dilated. The obstinate constipation continued. About eight days before death, symptoms of broncho-pneumonia and pleuritis, especially of the right side, came on. Death took place two months after the seizure. *Post-mortem Examination.*—Phenomena of recent broncho-pneumonia and pleuritis occupying the greater portion of the right lung, and existing only in a very limited manner in the lower lobe of the left lung. Hypertrophy of the left ventricle of the heart, with disease of the aortic valves (rigidity through atheromatous deposit, stenosis of the orifice, and insufficient closure). Extensive atheromatous affection of the arterial system, and especially of the cerebral arteries. Hæmorrhage into the inferior and internal portion of the left crus cerebri, the cavity being about six-tenths of an inch long, and five-twentieths of an inch broad, and as deep; it was situated close to the surface, and in immediate contact with the third nerve, the nerve-fibres of which were degenerated. The tissue of the crus round the cavity was hardened in the thickness of about one-fifteenth of an inch. The remainder of the left crus and the other portions of the brain were normal. Dr. Weber remarked that the diagnosis in this case had been comparatively easy. The sudden paralysis of the right side of the body, with paralysis of the third nerve of the left side, and with immunity of the mental faculties and special senses, pointed unmistakably to an affection near the base of the left hemisphere, and in immediate connexion with the third nerve, therefore also the crus cerebri. The fact that none of the other cranial nerves were affected indicated that the morbid condition was confined to a small spot, and the existence of the disease of the arterial system recognised during life rendered hæmorrhage more

probable than any other alteration. Dr. Weber thought under similar circumstances an almost accurate diagnosis might be always ventured. The author then gave an account of the two only cases of an analogous nature which he had met with in Medical literature; the one related by Andral ("Clinique Médicale," tome v., p. 339, 1834), the other by P. H. Green (*Medico-Chirurgical Transactions*, vol. xxv., p. 195), the main symptoms of both cases being in accordance with those observed by himself. He then touched upon the symptoms produced by section of the crura cerebri in animals, especially the circus movements described by Magendie, Lafarque, Longet, Schiff, and other physiologists, the absence of hemiplegia, and the occurrence of hyperæsthesia on the side of the lesion noted by Schiff. Dr. Weber did not endeavour to explain the discrepancy between the results of vivisections and the symptoms of disease in man. He alluded, however, to the differences in the pathological and experimental lesions themselves, and also in the connexion of the different portions of the brain between themselves in man and animals. He wished by no means to disregard the results of the physiological experiment; but, on the contrary, thought that, whenever any discrepancy existed, we ought to be very cautious in drawing inferences from pathological observations. He therefore did not consider as certain, but only as probable results of lesions of the centre, the internal and lower portions of the crura cerebri in man (the only parts which were diseased in the three cases related):—1. Almost perfect paralysis of the limbs of the opposite side as to motion, and great impairment as to sensation. 2. Less complete and more transitory paralysis of the opposite side of the trunk, of the face, soft palate, and tongue, as to motion and sensation (leaving the muscles of the eye intact). 3. A similar, but perhaps more permanent, impairment of the pneumogastric and sympathetic nerves of the opposite side. 4. A great retardation in the functions of the intestinal canal. 5. Immunity of the intellectual faculties and special senses. 6. Paralysis of the third nerve on the side of the lesion, if the latter affects the nerve substance adjacent to the point of issue of that nerve.

Dr. MERYON, after alluding to the service rendered by Dr. H. Weber, in his paper on the Crura Cerebri, and in his former contribution to the pathology of the Pons Varolii, expressed his opinion that, if every case of cerebral disease were as carefully examined as this had been, the numerous instances of discrepancy which we hear of between the anatomical disposition of the nerve fibres in the encephalon, and the symptoms which present themselves in structural lesions of the brain, would soon become the rare exceptions. He illustrated his proposition by adducing—1. The case described by Dr. Weber, in which a correct diagnosis had been formed as to the seat of the disease in consequence of the third cerebral nerve being implicated in the hemiplegia; and, 2. The case reported by Dr. Waters, the symptoms in which clearly pointed to the medulla oblongata, and to that portion of it in the immediate neighbourhood of the nucleus of the facial nerve, as the locality of the lesion; and referred to the observation of Dr. Cazalis, of the Salpêtrière, who has described the imperfectly palsied eyelid as a diagnostic sign of facial paralysis dependent on intra-cranial disease, and the perfectly fixed lid in affections of the facial nerve only. Dr. Meryon vindicated the theory of the posterior columns of the spinal cord and the corpora restiformia being tracts of sensitive impressions to the sensorium, notwithstanding the solution of continuity of the nerve fibres of the restiform body in Dr. Waters' case, and showed how such impressions may be conveyed to the brain by the intimate connexion of a portion of each posterior root of the spinal nerves with the posterior vesicular columns, and substantia gelatinosa in the grey matter, and partly by those bundles of nerve fibres which pass out again from the grey substance into the lateral white columns.

Dr. WATERS said the case he had brought under the notice of the Society was remarkable from the peculiar nature of the lesion that was sustained. With perhaps one or two exceptions, he was not aware that any case of a parallel character had ever been placed on record. The results of the case, as regarded the symptoms, did not in the slightest degree invalidate the views of Sir Charles Bell as to the function of the posterior roots of the spinal nerves, but they were quite in opposition to the theory that the posterior columns of the spinal cord and the restiform bodies were the tracts along which sensitive impressions were conveyed to the sensorium.

The partial division of the grey matter on the floor of the fourth ventricle—generally believed to be the continuation of the central grey matter of the cord—without any loss of sensation following on the side opposite to the lesion, seemed rather opposed to the view that decussation of the conductors of sensitive impressions takes place all along the spinal cord; for, although only a portion of the grey matter was divided on the right side, yet if the sensitive fibres decussate before reaching the medulla oblongata, the left side of the body ought to have had a diminished sensibility, whereas the opposite was the fact—sensibility was diminished on the right side. The existence of increased temperature on the side of the lesion was also an interesting phenomenon; this and the somewhat flushed condition of the face were symptoms somewhat similar to those which follow an injury to the sympathetic. The author alluded to a case reported by M. Begin, in Longet's "Anatomie et Physiologie du Système Nerveux," where one antero-lateral column of the cord was divided by a sharp instrument, the posterior columns and the central grey matter being uninjured. In that case there was loss of power of the affected side, but no loss of sensation. The case he had reported, coupled with that of M. Begin, and taken with the experimental and pathological cases which have been already brought forward, seemed to prove beyond doubt that neither the posterior columns of the cord nor the restiform bodies were concerned in transmitting sensitive impressions. In conclusion, the author dwelt on the importance of a careful observation of such rare cases as the one he had related, which constituted, in fact, a repetition in man of the experimental inquiries so often made by physiologists. Such cases, when correctly observed, might serve to establish important physiological doctrines, as not being open to the objections which might be advanced against the results of vivisections in the lower animals, or the facts observed in disease in man.

Dr. WEBER said that the Author's case was like his, in that there was increase of temperature on the side of the body opposite the lesion. In his (Dr. Weber's) case this increase only lasted seven or eight days, which was about the time the temperature was increased after section of the sympathetic.

Dr. THOS. K. CHAMBERS gave a contribution to the therapeutics of

#### CONTINUED FEVER.

*Analysis of 214 Cases of Continued Fever*:—108 treated on "general principles;" 106 treated on a uniform plan of continuous nutriment and hydrochloric acid. The first series occurred during the six years ending September, 1857; the second series during the five and a half years ending March 31, 1863. *Reasons for the Cases being Fairly Comparable*.—1. They are each a consecutive series. 2. They are spread over a considerable period of years. 3. All treated by the same Physician, and under similar circumstances. 4. Diagnosed and recorded by independent registrars. 5. The equality of the cases is shown by the equality of the mean duration of their convalescence. Of the first series—of 13 entered as typhus, 3 died; of 39 entered as typhoid, 16 died; of 56 of doubtful type, 3 died; of 108, total of continued fever, 22 died. Of the second series—of 19 entered as typhus, none died; of 48 entered as typhoid, 2 died; of 39 of doubtful type, 2 died; of 106, total of continued fever, 4 died. Excluding from the first series 2, and from the second 1, who died within two days of admission, and gave therefore little scope for judging of the effects of treatment, there remains somewhat less than 1 in 5 as the death-rate under the first treatment, and less than 1 in 35 as the death-rate under the second treatment. Therefore the second method of treatment is a powerful means of preserving life. Details of treatment were given, and some remarks made on the action of emetics.

Dr. WEBER said that, fifteen years ago, when he was a student at Bonn, the usual treatment of fever was by hydrochloric acid alone, without food. Fifteen drops of the diluted acid were given four, five, or six times a-day. The mortality was about sixteen or twenty per cent., the cases being typhoid. The fever was, on the whole, more violent than here. Dr. Weber thought it would have been better to have made a comparison between the treatment by hydrochloric acid and no treatment.

Dr. MURCHISON had listened with much interest to Dr. Chambers' communication, inasmuch as the treatment recommended closely resembled what he had followed at the Fever Hospital during the last eighteen months. The treatment of typhus and allied fevers by the mineral acids was a very old

one; it had long been the favourite treatment in many parts of Europe, particularly in Germany and Sweden. At the same time, he had not that implicit faith in it which Dr. Chambers appeared to have, and he must protest against Dr. Chambers' inference, that his treatment was calculated to prevent fifteen out of every eighteen deaths from fever. Dr. Murchison had employed the mineral acids, in conjunction with abundance of fluid nutriment, and wine when indicated, in upwards of 1500 cases; and although he had often seen the most marked improvement (cleaning of the tongue, etc.) follow the use of the acids, his statistical results had been much less favourable than those now communicated to the Society. He was convinced that, with more extended experience, Dr. Chambers would be compelled to modify his opinion. Dr. Chambers' statistics were open to several fallacies. 1. The cases selected for comparing the results of different plans of treatment had occurred at different periods, instead of at the same time. 2. In both series the form of fever had not been determined in a large proportion of the cases, and no details had been given to enable any one to judge of their severity. Many of the cases "of doubtful type" had probably been examples of simple fever, which was rarely fatal under any method of treatment. The results would be materially affected by the proportion of cases of simple fever or febricula in either series. 3. The rate of mortality in the first series, treated "on general principles," was far above the average mortality from fever in general Hospitals, and hence it was not a fair standard of comparison. The total mortality in this series (including febricula) had been 20 per cent., for typhus alone, 23 per cent., and for enteric fever no less than 41 per cent. 4. The ages of the patients suffering from the different forms of fever had not been given. Age exercised little or no influence over the rate of mortality of enteric fever; but in the case of typhus, the results of different methods of treatment could never be satisfactorily compared without taking the ages of the patients into consideration. Under 20 years of age, typhus was rarely fatal; about 50, the mortality was nearly 60 per cent. 5. The number of cases was too small to warrant any decided opinion as to the advantages of the treatment recommended. The second series included only 19 cases of typhus, and 48 of enteric fever, diagnosed as such. A Practitioner, with extensive experience in fever, might often have under his care 20 cases of typhus in succession, without losing a single case, but then if he lost 5 cases, the mortality would be 20 per cent. During last autumn, of 41 successive cases of enteric fever under Dr. Murchison's care, only 2 died, 1 from perforation of the bowel, and the other from acute tuberculosis—lesions not likely to have been cured by any treatment—yet the rate of mortality for the entire year had been considerably greater. Most of the 43 cases had been severe, but in none had a drop of hydrochloric acid been administered. Dr. Murchison doubted if the hydrochloric acid possessed advantages over the other mineral acids. Although he believed that the treatment of continued fevers by the mineral acids, together with a uniform system of nourishment, was justified by our knowledge of the pathology of fever as well as by experience, he was confident that Dr. Chambers' statements were calculated to make those who heard them too sanguine as to the results to be obtained from it.

The AUTHOR, in reply, said that all statistics were open to the objection raised by Dr. Murchison, that they were not long enough. His statistics were not brought forward as conclusive, but as a help to further inquiry, and he would grant that it might be found that the mortality was slightly different if further series of cases were compared, but not so as to affect the practical conclusion. His reason for bringing forward the two series of cases, the subjects of the paper, was that, being equal in number, and being pretty much under the same circumstances, they were fairly comparable. The difference in the mortality might be due, it was said, simply to a general difference in the mortality of the fever at the two quinquennial periods; but he had found that the mortality from fever in the two periods was as nearly as possible equal, taking Dr. Murchison's statistics as his authority. He did not bring forward the cases to exemplify the acid treatment, but rather as evidence of the value of continuous nutriment. In fact, he believed that the acid was beneficial principally in a subsidiary manner in preparing the digestive mucous surface for the nutriment. That it did thus produce a beneficial change was evident from the cleaning of the tongue. In reply

to Dr. Waters, the author said that wine was given in both classes, but in both, on account of the expense, it was only given in cases in which it was strongly required. The treatment by acids in Germany was not successful, from being relied on solely, and not supplemented by nutriment.

## THE PATHOLOGICAL SOCIETY.

TUESDAY, APRIL 14 AND 21.

Mr. PRESCOTT HEWETT, President, in the Chair.

Dr. WILKS read a report on Dr. Dickinson's case of

### APOPLEXY OF THE SUPRA-RENAL CAPSULE.

I have examined the supra-renal capsule which was submitted to me, and find it, as Dr. Dickinson states, in an apoplectic condition, using the term apoplexy, according to an absurd custom, as synonymous with effusion of blood. It appears as if some large vessel had ruptured in the interior of the organ, and then the blood had infiltrated through the tissue. On placing sections in water, the whole of the blood could be washed out, leaving the organ in a healthy state. I have on several occasions met with this condition, and have passed it by as of little moment, and should have done so on the present occasion had I not lately received a pamphlet from Professor Mattei, of the University of Siena, in which this subject of effusion of blood in the organ, or apoplexy as he also styles it, is considered. He quotes the case of a man, sixty years of age, who died with severe abdominal pains, and in whom such apoplexy was found, all other organs being healthy, and he considered that death was due to this. He also mentions the case of a fœtus, which died at birth from pressure on the cord, and here no organ was found in an abnormal state, except the capsules, which were affected with apoplexy by infiltration. He thinks therefore that death may be due to apoplexy of the supra-renal capsules, and that this is brought about through the agency of the sympathetic. Although, as before said, I have met with this condition, but have hitherto attached no importance to it, yet the statement which I have quoted from one who has evidently paid some attention to the changes in the supra-renal organs must not be passed over, and therefore will necessitate some further observations of pathologists.

Dr. HENRY DICK presented two

### YOUNG ITALIAN GREYHOUNDS SUFFERING FROM RICKETS,

and of which he gave the following history:—The mother is eight years old, and the father two years old. There were eight pups in the litter, four of which remained with the mother and were perfectly healthy, and four were removed after the lapse of twenty-five days; two of them were sickly, but got well by being fed on boiled meat and bread and milk. Those two which were presented to the Society were fed upon meat, bread, and broth, but the animal food formed the largest proportion. After being thus fed for three weeks, they began to exhibit a difficulty in walking, particularly on their hind legs. A little afterwards the articulations became swollen, and the fore-legs began to bend. Their eyes were running, but their appetite remained good. At one time their whole body was so painful that they could not bear to be touched. They now present those symptoms of rickets which are observed in the human subject. They are bow-legged, have swollen articulations, and large stomachs. Dr. Dick considers those specimens conclusively demonstrative that rickets is not identical with scrofula, and does not owe its origin to hereditary syphilis, as it is sometimes believed, but thinks that it is induced by improper or insufficient food. Too much animal food or bad milk in early life will, he believes, induce rickets, and for that reason rickets is found not only in the poorer, but also in the better classes.

Dr. DICK also presented a microscopic specimen of part of a

### POLYPUS REMOVED FROM THE ANTERIOR PORTION OF THE URETHRA.

This piece, examined under the microscope by Mr. William Adams and himself, exhibited epithelial cells and delicate fibrous tissue. Dr. Dick believes that polypus in the anterior part of the urethra is rare, but occurs more frequently in the prostatic portion. M. Velpeau presented to the Académie de Médecine of Paris, last year, a paper on the rarity of such excrescences in the anterior portion of the urethra.

On a question by Dr. GIBB on the means used in making the diagnosis,

Dr. DICK replied it was done by the assistance of the urethroscope. He believes that those excrescences are similar to those in the trachea described by Dr. Gibb. In operating, they bleed on the slightest touch, but are easily detached with the instrument.

Dr. BRINTON reported on the specimen of disease of the liver exhibited by Mr. Holthouse for Dr. Basham. It was, as had been supposed at the last meeting, malignant.

Mr. GAY brought before the Society a child, two years' old, who had a peculiar form of

#### MALFORMATION OF THE GENITALS.

There was epispadias, and the penis was so rudimentary that it seemed to form but a valve to what looked like a fissure in the lower wall of the abdomen. The scrotum and testes were normal.

Mr. HOLMES asked if the symphysis pubis was deficient, if the bladder was normal, and if any attempt at cure by operation was contemplated.

Mr. GAY had passed a sound into the bladder, but had not discovered anything abnormal. He did not know how it could be remedied by operation.

Dr. BRINTON said that in one case of large epispadias his colleague, Mr. Simon, had operated. There were pressing reasons for the operation. The operation was to divert the stream of urine into the rectum. It was successful for a time, but the patient died of one of the unfortunate Hospital diseases which so often attack patients after operation. In a case of epispadias deformity in a female, an operation for the relief of the deformity was contemplated, but attempts produced such excessive prolapsus that it was abandoned.

Next were brought forward patients on whom had been performed excision of the ankle—Syme and Pirogoff's amputation—as previously announced.

Mr. CANTON brought before the Society a case in which excision of the ankle-joint had been performed by Mr. Hancock in the Charing-cross Hospital, in 1857, for strumous disease of the bones. The patient did well after the operation; he was in bed five months, and in twelve months was able to walk with a stick. He was still well, and had an extremely useful limb. Mr. Canton then gave the particulars of another similar case, but the patient, a boy two years of age, had not attended, as he had promised.

Mr. BRYANT then showed a case in which he had performed Pirogoff's operation in September, 1860. [This case is recorded in this Journal March 9, 1861.] The patient, who had been in bed ten weeks, walked in three months. He had gradually gone on well, was at work, and the limb was a very good one.

Mr. LITTLE then showed a patient on whom Mr. Maunder had performed Pirogoff's operation for injury to the foot from a railway accident. After the operation there was some inflammation of the leg, but the patient ultimately did well, and walked in six months.

In reply to Mr. CANTON, Mr. BRYANT stated that the tendo-Achillis was divided in his case.

Mr. HOLMES then brought forward a patient on whom he had performed Syme's operation in April, 1862, for strumous disease of the tarsal bones. The stump healed quickly, and the patient could bear on it in five weeks, and now walks quite well.

Mr. HENRY THOMPSON then brought forward

#### THREE CASES OF SYME'S OPERATION.

He had performed the operation six times, but was only able to show three of the patients. One was a woman about 35 years of age, on whom he had operated four or five years ago. There was no sloughing of the flaps, but the healing was slow. She, however, recovered with a good stump, and walked in four months, and still walked quite well. The next was a boy 10 years of age, on whom he had operated a year and a-half ago. He walked well, with a simple boot without a spring. In the third case the operation had been also very successful. The patient, a woman, had been operated on seven years ago, and now walked several miles a-day in her occupation.

Mr. GAY then exhibited

#### TUMOURS REMOVED FROM A CHILD WHO HAD CONGENITAL MALFORMATION OF THE GENITAL ORGANS.

See the report of this case in this Journal, April 4, 1863.

Dr. Montgomery was requested to examine and report on the specimen.

Dr. GIBB brought forward the following

#### ILLUSTRATIONS OF LARYNGEAL OBSTRUCTION.

1. *Disease of Turbinate Bones and Floor of Nostril, with Exudation of Fibrin.*—Patient, a lady of 35, with disease of the throat for twelve years, and discharge from back of the fauces of lumps of fibrin. The epiglottis was pendant, almost flat on the glottis, and serrated. Inflammation, ulceration, and partial destruction of turbinate bones of right nostril, extending to its floor and the velum palati. The nostril was divided into two cavities. This was seen by rhinoscopy. Had been a great sufferer for years. Local and constitutional treatment was curative.

2. *Organic Aphonia from Foliated Growths on the True and False Vocal Cords.*—Young man of 24, with a syphilitic history. Aphonia and dysphonia for twenty-two months, depending upon several foliated growths on the true and false vocal cords of both sides. At times he was quite dumb. Under treatment the voice returned in five months, and he spoke well in two months after.

3. *Organic Aphonia for Five Years from a Tumour on the Right Vocal Cord.*—Young lady of 29, with hoarseness at first of twelve months, followed by aphonia for five years, supposed to be hysterical. This depended on an oblong growth, involving the surface of the right vocal cord nearly its whole length. Persevering local treatment gradually discussed the growth, and speech was recovered in six months.

4. *Organic Aphonia for Three Years from Tumours on Both Vocal Cords.*—Young woman from Essex, aged 22, aphonic for three years. She had been treated for consumption at one of the Hospitals, but the lungs were sound. Small growths were present on both vocal cords, one close to the left arytenoid cartilage. The voice did not return until the end of nine months.

5. *Varying Aphonia, from Two Small Growths on one of the Cords.*—This was in a young lady of 20, supposed to be phthisical. Voice weak, and at times a whisper, for eighteen months. Two dark crimson growths were present on the surface of the left vocal cord, which, although they did not interfere with its action, nevertheless impaired phonation. In three months local and general treatment brought about a cure.

6. *Impaction of a Piece of Walnut-shell below the Glottis.*—Young gentleman of 13, who had had a piece of walnut-shell impacted in the larynx below the cords, namely, in the sub-glottic space. Tracheotomy had been performed, but as the spasms continued, a laryngoscopic examination was made, and showed a piece of shell laying cross-wise, from left to right, below the cords. This was subsequently expelled spontaneously.

Mr. POLLOCK then showed a specimen of  
RUPTURE OF THE INTERNAL CAROTID WITHIN THE SKULL  
FROM VIOLENCE.

The patient was brought to the Hospital after an injury. His leg was bent, the contents of one orbit were lying on the cheek, and the upper wall of the orbit was completely smashed. There was no history as to how the accident had occurred. There was a great deal of arterial hæmorrhage, and this was arrested by pressure on the carotid in the neck. The patient died in three hours. At the post-mortem examination, the base of the brain was found to be very extensively injured, and the internal carotid artery was found to be wounded. This was probably from some spicula of bone, as its osseous canal was quite uninjured.

Mr. PRESCOTT HEWETT said there was recorded but one case, and that a doubtful one, of rupture of the internal carotid by injury to the carotid canal. In the case related by Mr. Pollock, no doubt the wound of the artery was from some spicula of bone which had been forced into the artery. It was very like one recorded by Nélaton. A Medical student in a quarrel received a thrust from an umbrella, just under the left upper eyelid. No immediate symptoms followed, and nothing much was thought of it; but soon afterwards the right eye began to protrude; hæmorrhage took place from the right nostril. Soon after this M. Nélaton saw him, then there was extensive pulsation behind the eye. An aneurism formed by injury of the carotid and cavernous sinus was diagnosed. In order to prove this an experimental injury was made on the dead subject; the point of an umbrella being thrust into the orbit in the same direction, just such an injury as had been conjectured to exist in the patient was produced. The student died of extensive hæmorrhage, and at the autopsy there were found an injury of the carotid artery and cavernous sinus.

## HARVEIAN SOCIETY OF LONDON.

MARCH 19, 1863.

Mr. W. SEDGWICK, Vice-President, in the Chair.

DR. J. BURDON SANDERSON read a paper on  
ASTHMA.

After stating that the definition of asthma as a species of disease must be founded exclusively on the study of its development during life, with but little assistance from morbid anatomy, the author proceeded to describe the phenomena of an attack, dwelling particularly on the nocturnal onset of the affection, and the complete remission of all the symptoms during the intervals. The characteristic elements of asthmatic dyspnoea were stated to be, (1) excessive expansion of the chest; (2) resisted but forcible efforts to expire; (3) diminution of the exchange of air in the chest, and consequent venous condition of the blood. In the asthmatic state the chest is arched forwards in extreme inspiration, the diaphragm sinks below its normal level, so that its power is lost, while the almost fruitless efforts to renew the air in the chest are accomplished by elevation of the upper ribs. The expiratory muscles of the abdominal wall are in excessive action, but, in spite of their efforts, air is expelled from the chest with extreme difficulty and in small quantity. The condition of the blood which is thus produced gives rise to the sensation of want of breath, and impels the patient to make conscious and voluntary efforts to get rid of the used air, which is as it were locked up in his chest, so as to enable himself to obtain a fresh supply. In order to arrive at an explanation of this remarkable state, so different from every other form of dyspnoea, the circumstances must be considered under which it is developed. Asthma comes on during those hours of the night in which sleep is ordinarily most profound. At night the respiratory function is modified; the quantity of air exchanged is diminished. This diminution is partly, though not entirely, dependent on a change in the respiratory function of the vocal cords, which in nocturnal breathing approach each other more closely than in the waking state, that muscular action by which they are kept apart is relaxed. The more profound the slumber the greater the relaxation, and the narrower the chink of the glottis (*e.g.*, in snoring expiration). Assume for a moment that this natural relaxation becomes excessive. As the laryngeal resistance is normally greater to the egress than to the ingress of air, the chest falls more and more with each respiration, the inspiratory power of the diaphragm lessens, the exchange of air is diminished, the blood becomes less arterial, and thus, without any agency beyond the intensification of that condition of respiration which exists in natural sleep, all the elements of asthma are developed. In short, it is possible to account for asthma as a result of disorder in the respiratory function of the glottis. But if it be remembered that the muscular fibres on which this function depends are governed by the same nerve as the contractile fibres of the lung tissue (as is shown by the experiments of Donders and others), it will be readily admitted that if in asthma the respiratory fibres of the glottis are relaxed, those of the lung are in a similar state of relaxation, which would afford an additional explanation of the remarkable dilatation of the chest. This view accords perfectly with what is known as to the intimate relation of asthma and emphysema. Emphysema cannot be regarded as the cause of asthma; it would even be more correct to speak of it as its consequence. Emphysema results from resisted but powerful efforts on the part of the expiratory muscles to expel air from an expanded lung. This is precisely the state of things in asthma. But the relation between the disease and the lesion is rather that of community of cause than of consequence. Temporary over-expansion of the lung is a constituent of asthma; permanent expansion cannot exist without emphysema. Under the head of "Diagnosis," the author distinguished between asthma and spasmodic dyspnoea, in all forms of which the relation between the inspiratory and expiratory act is the reverse of that which holds in asthma,—*e.g.*, in the spasmodic dyspnoea of phthisis, acute bronchitis, and dwelt on the importance of determining the relative duration of the inspiratory and expiratory act, which may be best effected not by listening to the chest, or observing its movements, but by the auscultation of the larynx. As regards treatment, the author had found that no remedies were useful during the attack of asthma excepting stimulants, of which

ipecacuanha in large doses, alcohol, and coffee were instanced as most important.

The PRESIDENT, at the close of the discussion, announced that the next meeting would take place on April 2, when Dr. Pollock would read a paper "On Pneumothorax."

## OBITUARY.

## THE LATE JOHN CHALLICE, M.D., F.R.C.P. EDIN.

WE are sorry to record the decease of John Challice, M.D., F.R.C.P. Edin., the active and popular Medical Officer of Health for Bermondsey. Dr. Challice, after an education by no means adequate to his very great abilities, was initiated into the Medical Profession at a very early age by the method then customary, of a five years' apprenticeship, partly passed with a Surgeon Apothecary in Bloomsbury, and partly with Mr. Coleby, who carried on an enormous practice amongst the working men in Bermondsey. It was during his residence in Bermondsey that the first outbreak of cholera occurred, in 1832, and Mr. Coleby had a great reputation for his successful treatment both of that terrible pestilence and of the epidemic diarrhoea which accompanied it. His chief remedy was the dilute nitric acid in large doses; and there is little doubt that although it occasionally failed, as every other remedy does in the stage of prostration, yet that it was so markedly successful in very many cases that the Bermondsey people looked upon Mr. Coleby's treatment almost as specific. Young Challice then went through the Medical curriculum at King's College, where his good nature, and frank, manly bearing and shrewd common sense made him a favourite with his fellow-pupils, as well as with his Professors. After passing through the prescribed courses of lectures, and devoting a short space to study in Paris, Challice established himself as a General Practitioner in the neighbourhood of Hanover-square;—a step which he took partly because he believed that he should get into practice rapidly through his connexions, and partly because of his attachment to one of his preceptors, the late Herbert Mayo, F.R.S., with whom he was on terms of the closest intimacy, and who had the highest opinion of Challice's sagacity and discernment.

In due course of time he married, and removed to a large house in Southwick-crescent; but finding that his practice did not increase fast enough to satisfy his active and somewhat restless temperament, he embraced an offer made him by Mr. Coleby, who retired with a large fortune, which he had accumulated by thrift and ceaseless industry out of the petty gains derived from attending the honest artisans of Bermondsey, and who introduced Challice as his successor.

Here he was hard at work for years; at first devoting himself to the poorer classes, who formed the *clientelle* of his predecessor, and then gradually acquiring a large practice amongst the wealthy manufacturers and tradespeople. His unremitting labour during the cholera epidemics of 1849 and 1854, when, sending his wife and family away to a place of safety, he remained, sometimes without taking his clothes off for three or four days and nights, attending to all comers; his assiduous promotion of all sanitary improvements, his sagacity and clear-headedness, soon procured him the general confidence of the Southwark community. They made him Chairman of the Board of Guardians, and looked upon him by general consent as the public "guide, philosopher, and friend." From the parochial, his influence soon made itself felt in the political world, and there is no doubt but that whatever candidate received the support of Dr. Challice, was the most likely man to be at the head of the poll in the Southwark elections. He had always retained a knot of influential friends and patients at the West-end, and the circle of such friends was immensely increased in proportion as he was felt to be the depository of no small amount of political influence. He soon became at home with the leading members of the Liberal party, amongst whom the late Sir William Molesworth had the greatest possible affection for him, and frequently sought his society. After Sir William Molesworth's return, he publicly thanked him as the author of his successful election, and up to the time of his death showed him the strongest marks of gratitude, and constantly took his advice. He was also intimate with the late Thomas Wakley, Esq., M.P., between whom and Challice there was a remarkable similarity in person and mental endowments. Both pre-eminently English in stature, feature, and complexion, with a

gift of winning, easy, flowing speech, immense appetite for the excitement and turmoil of political work, and that indescribable stamp of common sense and self-confidence which insures the confidence of others. Thus flattered and courted by eminent politicians, and feeling himself endowed with singular capacity for political life, it cannot be wondered that his thoughts soared above general practice in Bermondsey, and that from being an *habitué* of the lobby, he should desire to enter the portals of the House of Commons along with many whom he felt to be less qualified for public business than himself. Propositions were made to him that he should stand for Southwark and that his expenses should be borne by his constituents, and there is no doubt that he looked forward to it eagerly. Meanwhile, he was constantly before that part of the political public which is formed of great town constituencies, and attended sedulously to their interests. His labours against cholera, his personal and unrequited devotion to the poor in their calamity, and his efforts to raise the condition of the working classes, were followed by his constant presence at deputations, committees of the House of Commons, etc., on all great social questions. We believe that he did great good by his exertions to procure a purer water supply for London, and that whatever good there was in the Gas Acts was due to him. He established the baths and wash-houses in Bermondsey, and caused such immense sanitary improvements to be made that, as his friends often said, *if he had been a Frenchman* he would have had the thanks of the Government and the ribbon of the Legion of Honour. His great objects of ambition were to be M.P. for Southwark and coroner for Middlesex, whenever that office should become vacant by the death or resignation of Mr. Wakley. In this latter idea he was greatly encouraged by Mr. Wakley himself, who pronounced him the fittest person to be his successor;—this we say of course without prejudice to the present able and accomplished coroner, who was not then generally known as a likely candidate. As a stepping-stone, he accepted the deputy-coronership for East Middlesex, under Mr. Humphreys. At last the time seemed to have come. The death of Sir Charles Napier was announced, and then or never was the time for Challice to stand for Southwark. But the crisis was too much for him. Whilst dining with a political friend that day, and talking over his prospects, he felt his right arm drop as he was carving a chicken, and knowing that he had been smitten with paralysis, and muttering something about not feeling well, he left the table, and went home. That was the death-blow to his hopes. He recovered his health completely to all appearance, but was obliged to give up all hopes of Parliament, resigned the deputy-coronership, and, when Mr. Wakley died, he wisely, after a short hesitation, left the field open to Dr. Lankester. He yearned, too, for his old position at the West-end, and having already taken a respectable Scotch degree of M.D., and having found it impossible to attend to the drudgery of general practice, he removed to Great Cumberland-street. He had a singularly clear mathematical head, was one of the best whist players in London, and remarkably bold and inventive as a speculator. It may be well believed therefore that he had before now endeavoured to realise the means of attaining the objects of his ambition by various speculations; these were not uniformly successful, but in the last year or two his fund of suggestion and combination was much in request, and his administrative abilities caused him to be much sought out by the promoters of public companies. As a politician, he was liberal, but conservative in tone, and with nothing of the low, venomous stamp. He despised mob government. His knowledge of modern history, and of all the details of the military and political events from the French Revolution to the present time was most full and accurate, and although it is generally understood that the historical works which have appeared with his name were written by his wife, yet he only wanted the time, and not the knowledge, to shine as a political writer himself. At last, however, in the midst of apparently recovered health, in full prosperity and happiness, he was again stricken with apoplexy, and died on the 11th inst. after two hours' illness.

Dr. Challice's career suggests one or two useful morals. How infinitely more useful his great capacities and talents would have been had they received the pruning and training of a Cambridge education! How much to be regretted that his introduction to the Profession should have been amongst a class who set the example of attaining the quickest possible result by the least scientific means! If, by the mere force of

sagacity, and his own large experience, he were, as we believe he was, a thoroughly clear-sighted and successful Practitioner, how must his powers of usefulness have been enhanced had the modern refinements of scientific Medicine received the attention that was squandered on the sterile soil of politics? How it may be wished that his enormous powers and buoyant energy, that seemed to exult in overcoming difficulties, had been given unreservedly to Medicine, and that he had moved amongst politicians as a great Physician instead of being distinguished amongst Physicians as a great politician! And a great Physician he would have been had he been content to follow Medicine, and not have tried other seemingly shorter paths to wealth and fame. But these are mistakes which may be easily condoned. Men get into grooves, and are helpless. There never walked a more honest, affectionate, generous, self-denying, true-hearted man, and his shrewd good sense and generosity will never be forgotten by the large circle of friends who now lament his decease.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 7th inst., viz. :—

Vivian Weame, Helstone, Cornwall, Septimus Terry, Northampton, Horace Cooper, Caversham, and John Warrington Haward, Leicester-square, students of St. George's Hospital; John Stevenson Harvey, Boulogne-sur-Mer, George Frederick Walford Meadows, Otley, Ipswich, and William Milward, Seabrook, Brighton, of Guy's Hospital; Edmund Pope, L.S.A., Puddleton, Dorsetshire, and Richard Theodore Grubb, Cahir, Ireland, of the London Hospital; Joseph Peeke Richards, Oxford-terrace, Islington, and Cornelius Benjamin Fox, Truro, Cornwall, of King's College; Frederick Henry Alderson, Ipswich, and William John Wey, Plymouth, of the Middlesex Hospital; Thomas Stowell, Brighton, and Hutton Joseph Webber, Tunbridge Wells, of St. Bartholomew's Hospital; James Mortimer Fuller, St. John's-wood, of University College; Robert William Tibbits, Ashton, Bristol; Richard Hison Daly Johnson, Liverpool; George Brauston Valentine Nash, L.S.A., Liverpool; William Clarke, L.F.P. and S. Glasg., Longsight, near Manchester; John Burdett Wilby, Leicester; Edward Gibbs, Birmingham; and Ebenezer William Edlin, L.F.P. and S. Glasg., Manchester.

Admitted on the 9th inst. :—

Charles John Pyle, Amesbury, George Edward Pyle, Amesbury, William Edward Soffe, L.F.P. and S. Glasg., Bungay, Suffolk, James Smith Turner, Margaret-street, Cavendish-square, Charles Hinds, Barbadoes, and Martin de Galway Hurstone, Chester-street, Hyde-park-corner, students of the Middlesex Hospital; Francis Henry Wood, New Romney, Thomas Holyoake, Kinver, Staffordshire, John Brockwell, Cleator, Cumberland, and Thomas Miles, Totness, Devon, of Guy's Hospital; William Jones, Llangorse, Brecon; Thomas John Peatfield, Edwinstowe, Notts, and Edmund Vallance, Brighton, of St. Bartholomew's Hospital; William Adolphus Frederick Bateman, L.S.A., Richmond, Surrey, and Henry John Hunt, Melksham, Wilts, of King's College; Richard Prior Wintle, Earl's-court-terrace, Keusington, and John Henry Conuell Whipple, M.D. St. Andrew's, Plymouth, Devon; Henry Summerhayes, Crewkerne, Somerset, of St. Thomas's Hospital; James McBride, Rathfriland, Co. Down, Ireland; Joseph Septimus Steward, L.R.C.P. Lond., Usemor-hill, Cumberland; John Charles Compson, Stourbridge, Worcester; Alfred Ollivant Francis, Derby; Samuel Swabey, Prince Edward Island.

The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 12th inst., and when eligible will be admitted to the Pass Examination :—

George Eastes, H. C. Hilliard, W. T. H. Wood, and J. W. Barrett, students of Guy's Hospital; H. J. Branson, Charles Heaven, and A. J. Moseley, of St. George's Hospital; J. C. Wilkins and J. B. Watson, of the University College; Edward Brewster, of the Charing-cross Hospital; J. A. Grindrod, J. A. Eatock, Thomas Sutton, and W. H. Sutcliffe, of Manchester; W. H. Lightbody, C. J. Bennett, and David Wright, of Edinburgh; J. L. Morris and John Williams, of Glasgow; C. H. Battersley and H. W. Battersley, of Dublin; A. O. Haslewood, of Newcastle; A. P. Evans, of Birmingham.

Passed on the 13th inst. :—

David Jones, Thomas Richard Phillips, William Lewis Hughes, Isaiah deSouche, and Charles Peyton Moreton, students of Dublin; Henry Parry Chandler and Henry John Ryder Bush, of the Middlesex Hospital; Thomas Gray Pratt and Charles Frederick Oxley, of Edinburgh; Ebenezer Diver, of University College; Robert Wood, of the London Hospital.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, May 7, 1863 :—

Samuel Woodman, Finchley-road, St. John's-wood; Caleb Gargory, Birmingham; George Wyatt Sharp, Great Cumberland-street; William Allin Thompson, Oxford; Thomas Pilkington, Enfield, Accrington, Lancashire; John Spencer Ferris, Bradford-on-Avon, Wilts; Thomas Brewer, Halifax.

## APPOINTMENTS.

\* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BAKER, JOHN WRIGHT, M.R.C.S. Eng., has been elected Surgeon to the Derbyshire General Infirmary.  
 BASTIAN, H. CHARLTON, M.A. Lond., M.R.C.S., has been elected a Fellow of the Linnæan Society.  
 BRANDE, Dr. W. T., has been re-elected Hon. Professor of Chemistry at the Royal Institution of Great Britain.  
 CORNER, Dr. MATTHEW, M.D. St. And., has been elected Surgeon to the Tower Hamlets Dispensary.  
 FRANKLAND, E., has been re-elected Professor of Chemistry at the Royal Institution of Great Britain.  
 GASCOYEN, GEORGE GREEN, F.R.C.S. Eng., has been appointed Assistant-Surgeon to St. Mary's Hospital.  
 GILMORE, SAMUEL, L.R.C.P. Edin., has been elected Medical Officer for the Workhouse Infirmary and Fever Hospital of the Castleblayney Union.  
 GRIFFITHS, GORREQUER, M.R.C.S.E., L.M. Dub., has been appointed House-Surgeon to the London Surgical Home.  
 HOLLAND, Sir HENRY, M.D., has been nominated Vice-President of the Royal Institution of Great Britain.  
 JOHNSON, JOHN WHITAKER, F.R.C.S. Eng., has been elected Honorary Consulting Surgeon to the Derbyshire General Infirmary.  
 WATSON, Dr. PATRICK HERON, F.R.C.S. Edin., has been appointed Surgeon to the Royal Infirmary of Edinburgh.

## DEATHS.

ARMSTRONG, ELLERAY, M.R.C.S. Eng., at Carlisle, on April 18, aged 48.  
 BRAME, SAMUEL SHARMAN, M.R.C.S. Eng., at Lowestoft, Suffolk, on April 17, aged 49.  
 CHALLICE, JOHN, M.D. Aberd., etc., at 13, Great Cumberland-street, Hyde-park, on May 11, suddenly, to the inexpressible grief of his widow and children, aged 49.  
 COUCH, RICHARD QUILLER, M.R.C.S. Eng., at Penzance, Cornwall, on May 8.  
 ELLIOTT, Dr. JOHN, of Dublin on board the *Golden Fleece*, en route to Madras, on April 27, aged 25.  
 EVANS, GUSTAVUS, M.D. Glasg., at Dalston, Cumberland, on May 9.  
 HODSON, THOMAS L., M.R.C.S. Eng., at Liverpool, on May 5, aged 46.  
 REID, Dr. DAVID BOSWELL, at Washington, United States, on April 5, late of Edinburgh.  
 ROWE, WILLIAM HENRY, M.R.C.S. Eng., at 12, Grafton-street, Brighton, on May 9.  
 SMART, THOMAS BARKER, M.D. Aberd., at Scarborough, late of Hulton Bushel, on April 25, aged 45.  
 TRONSON, JOHN MORTLOCK, M.D., St. And., Surgeon R.N., at Sydney, New South Wales, on January 30, aged 53.  
 WHEELER, WALTER D., M.R.C.S. Eng., at New York, late of Clifton, on April 6, aged 62.  
 WHITFORD, ANTONY, M.B. Lond., of Shepherd's House, Cranbrook, Kent, at St. Columb., on May 8, aged 29.

THE statements which appeared in the *Times* and other daily papers, to the effect that Dr. Jenner is to attend the Queen to Balmoral this spring, is incorrect.

THE COLLEGE LECTURES.—Professor Gulliver, F.R.S., will resume his lectures on the 2nd proximo, when he will deliver six lectures on the Blood, Chyle, and Lymph, in continuation of his former course on these subjects, and will be succeeded by Professor Solly, F.R.S., who will deliver six lectures on the Brain, and some of its Diseases, commencing Tuesday, June 16.

F.R.S.—From among forty-five candidates, the Council of the Royal Society have recommended for election the following, one in three:—Colonel F. M. Eardley Wilmott, R.A.; Revs. Dr. A. P. Stanley, Dr. G. Salmon, and R. Harley; Dr. F. W. Pavy, Professor D. Oliver, Messrs. E. W. Cooke, W. Crookes, J. Fergusson, F. Field, J. R. Hind, C. W. Merrifield, W. Pingelly, H. E. Roscoe, and S. J. A. Salter.

DEATH OF DR. REID.—Many Edinburgh citizens will learn with regret the death of Dr. David Boswell Reid, well known by his labours in regard to ventilation. Dr. Reid, who has been for some years in America, died at Washington on April 5. The death was sudden, and caused by congestion of the lungs. Dr. Reid had been appointed by the Government Medical Inspector to the Sanitary Commission, and he was about to leave Washington, to be employed in ventilating the new military hospitals which have been erected in different parts of the country. Dr. Reid was a native of Edinburgh, grandson of the celebrated Hugo Arnot, the historian of Edinburgh, and was himself at one time an extensively-employed and successful teacher of chemistry here. His connexion with the ventilation of the

Houses of Parliament is but too well known. He ventilated St. George's Hall, Liverpool—the only building in the world, he said, in which his principles of ventilation have been completely carried out. The ventilation of this building is considered very successful. Dr. Reid began his public career in Edinburgh as assistant to the late Dr. Hope, Professor of Chemistry in the University. He was also a candidate for the Chair when Dr. Hope resigned.—*Scotsman*.

ANTHROPOLOGICAL SOCIETY OF LONDON.—At the fortnightly meeting of this Society, on Tuesday last, Dr. Hunt, President, in the chair, a paper was read by Professor John Marshall, F.R.S., on the "Microcephalic Brain of an Idiotic Boy, aged 12." The brain in question weighed eight and a-half ounces, being about one ounce and a-half smaller than "Gore's case" of an idiotic female, aged 42. The particulars of the paper will appear at length in the *Transactions* of the Society. A paper was also read by W. Bollaert, Esq., F.R.G.S., on the "Past and Present Populations of the New World," in which the author gave many interesting examples of the moral depravity and physical deterioration of the free blacks and mixed breeds of South America. A discussion supervened, which was joined in by Messrs. Hunt, Bouverie, Pusey, Seemann, Blake, Bendyshe, and others.

ST. BARTHOLOMEW'S HOSPITAL.—COLLEGE EXAMINATIONS.—*Winter Session*, 1862-63.—Senior Scholarship in Medicine, Surgery, and Materia Medica: 1. "Not awarded;" 2. S. Hall and H. Mackintosh. Senior Scholarship in Anatomy, Physiology, and Chemistry: 1. F. W. Richards; 2. L. Powell. Hichens Prize: H. Mackintosh. Practical Anatomy, Senior (Foster Prize): 1. J. T. Evans; 2. G. A. Coates; 3. A. H. Brewer; 4. C. D. Pearless; 5. J. W. Snook; 6. A. S. May; G. Bennett and F. G. Cropp; 9. J. Raven. Practical Anatomy, Junior (Treasurer's Prize): 1. T. Cuddeford; 2. T. Cole; F. Bateman and A. C. Farrington; 5. G. F. Webb; 6. W. Iliffe; 7. R. Broughton.

THE BONE OF CONTENTION.—The French palæontologists continue to assert their conviction of the authenticity of the jaw-bone found at Moulin-Quignon. *Galignani's Messenger* states that meetings have taken place at the Garden of Plants between four distinguished Fellows of the Royal Society, representatives of English geological and palæontological knowledge—MM. Prestwich, Falconer, Burk, and Carpenter, and MM. Quatrefages, Desnoyers, Gaudry, Lartet, and other well-known men of science, under the presidency of Dr. Milne Edwards, of the Institute, to discuss, and, if possible, to decide on the authenticity and antiquity of the flint hatchets and human jaw in question. Sir John Bowring, being in Paris, was invited to the conference. The results of the examination, though by no means of a positive character, have, on the whole, served to confirm the doubts expressed by the British geologists as to the trustworthiness of these particular specimens of ancient civilisation. That large quantities have been fabricated and sold by French workmen admits of no question; but the genuineness of many of those found at St. Acheul was established by the unanimous opinion of the conference, as was the fraudulent character of the greater number of those found at Moulin-Quignon.

DEATH OF DR. GUSTAVUS EVANS.—An inquest was held at the village of Dalston, Cumberland, on Monday, before Mr. W. Carriek, Surgeon, and a respectable jury, upon the body of Mr. Gustavus Evans, M.D., who died suddenly on Saturday last. It appeared from the evidence of Barbara Nixon, the woman with whom the deceased lodged, that he had been subject to acute pain in the head and neck for some time past. On Friday night, on his return from visiting a patient at Barnard Castle, he complained that the pain was very severe. Next morning after breakfast he took his usual walk in the garden, and smoked his pipe there for half an hour, after which he went up into the drawing room. On his landlady going into his room shortly afterwards she found him lying on the floor, as if he had rolled off the couch. He said to her, "Let me rest;" but in about twenty minutes he became insensible, his last words being, "Oh, Mrs. Nixon, can you spare —." He never completed the sentence. His partner, Dr. Cornelius Hall, of Carlisle, was sent for during the day, and also Mr. Brown, Surgeon, Carlisle, but their efforts to relieve the patient were unavailing, and he died about nine o'clock in the evening. It appeared that the deceased had been in the habit of using chloroform and chloric ether to relieve the

pain with which he was afflicted; and it was stated in evidence that bottles containing chloroform had been found in his conveyance since his death. One of these contained water, and as much chloroform as would be taken for a dose. Dr. Hall stated that he had no reason to suppose that the deceased was suicidal; on the contrary, his circumstances were comfortable, his mind was tranquil, and on the day before his death he had expressed his intention of taking a rest from his Professional duties and trying a change of air. A post-mortem examination of the body had been made by Mr. Brown, Mr. Hall, and Mr. Page, and they arrived at the conclusion that death had been caused by an overdose of chloroform. The coroner having summed up the evidence, the jury returned a verdict of accidental death, in accordance with the Medical testimony. The deceased was highly respected in the neighbourhood of Dalston, and also in Carlisle, where he practised for many years. Among the poorer classes he was especially esteemed, for he seemed ever to have their welfare at heart. The Dean of Carlisle alluded to the melancholy event in his sermon at the cathedral on Sunday afternoon.—*Times.*

**UNIVERSITY COLLEGE, LONDON.**—The distribution of prizes to the Students of the Faculty of Medicine in University College, London, took place on the 11th inst., Dr. Parkes, F.R.S., Fellow of the College, former Professor of Clinical Medicine, in the chair. The Atkinson Morley Surgical Scholarship, £45 per annum, for three years from June, 1862, was awarded to William John Smith, of Basingstoke; the Longridge prize of £40, for general proficiency in Medicine and Surgery, to William Henry Griffin, of Banbury; and the Filliter Exhibition, in Pathological Anatomy, £30, to Thomas Griffiths, of Carmarthenshire. Gold medals were awarded for acquirements in Clinical Medicine (Dr. Fellowes, winter term, 1861-62), to J. Talfourd Jones, of Brecon, South Wales, and Frederick Thomas Roberts, of Carmarthen; in Anatomy and Physiology (Professor Sharpey, M.D., F.R.S., Dean), to Bryan H. Allen, of London; in Anatomy (Professor Ellis), Senior Class, to Charles Bradley, of Nottingham; in Chemistry (Professor Williamson, F.R.S.), to J. Pearson Hughes, Llandovery; in Comparative Anatomy (Professor Grant, M.D., F.R.S.), to John Comyns Leach, of Crediton, Devon; in Medicine (Professor Jenner, M.D.), to Palemon Best, of St. Ives, Cornwall; in Surgery (Professor Erichsen), to Herbert Everitt, of Norwich. The remarks made by Professor Parkes on this occasion are so well worthy the careful attention of every student of Medicine, that we purpose placing them before our readers in our next Number.

**WESTMINSTER HOSPITAL MEDICAL SCHOOL.**—DISTRIBUTION OF PRIZES.—On Monday, the 4th inst., the distribution of prizes to the students of the Westminster Hospital took place in the board-room of that institution, the Dean of Westminster being in the chair, supported by the Hon. P. Pleydell Bouverie, M.P., Treasurer, Mr. Grainger, F.R.S., etc., and the Medical Officers and Lecturers. The Very Rev. Chairman opened the proceedings with a few observations appropriate to the occasion, and expressing the pleasure he felt in presiding at such an interesting ceremony, and then delivered the several prizes, consisting of handsomely-bound books and Surgical instruments, to the various successful candidates. The following is a list of the prize men:—*First Winter Session.*—Anatomy and Chemistry: Mr. Charles St. Aubyn Hawken and Mr. George E. L. Pearse, Medal, Certificate, and Chadwick Prize, £6. *First Summer Session.*—Botany, Materia Medica, and Practical Chemistry: Mr. George E. L. Pearse, Medal, Certificate, and Chadwick Prize, £4; Mr. William Yates, Certificate. *Second Winter Session.*—Anatomy, Physiology, Medicine, and Surgery: Mr. William Gandy, Medal, Certificate, and Chadwick Prize, £6; Mr. Albert L. Peacock, Medal and Certificate. *Second Summer Session.*—Forensic Medicine and Midwifery: Mr. William Gandy, Medal, Certificate, and Chadwick Prize, £4. *Third Winter Session.*—Clinical Medicine and Surgery: Mr. George Mowat and Mr. William H. Kempster, Medal, Certificate, and Chadwick Prize, £5. Dental Surgery: Mr. A. L. Peacock, Prize; Mr. J. B. Oliver, Certificate. Midwifery: Mr. J. B. Oliver, Prize. Chadwick Prize: Mr. Frederick P. Edis, Prize; Mr. William Gandy, Second Prize. Anatomy: Mr. Ralph Burnham, Prize; Mr. William N. Symonds, Certificate. Physiology: Mr. George E. L. Pearse, Prize; Mr. George P. Bate, Certificate. Surgery: Mr. William Gandy, Prize; Mr. Algernon N. Watts, Certificate. Chemistry: Mr.

Bate, Prize; Mr. Richard Bugden, Certificate. Clinical Medicine: Mr. F. P. Edis, Prize. Clinical Surgery: Mr. F. P. Edis, Prize. Dental Surgery: Mr. Charles St. Aubyn Hawken, Prize. Prosector's Prize: Mr. Brownlow North Hyatt, Mr. C. St. Aubyn Hawken, Mr. G. E. L. Pearse, and Mr. Albert L. Peacock. A vote of thanks to the chairman having been proposed by Mr. Holt and acknowledged by the Dean, the proceedings terminated.

**THE DUBLIN HOSPITALS.**—The Dublin correspondent of the *Times* extracts the following particulars from the Sixth Report of the Board of Superintendence of Dublin Hospitals which has just appeared. "The Report contains the results of their inspection of each of the Hospitals, nine in number, which receive grants from Parliament, to ascertain if the comforts of the patients were duly provided for, the buildings kept in sufficient repair, and the general management satisfactory. The Westmoreland Lock Hospital, for the reception of women of an unfortunate class, is described as much improved. The average daily number of beds occupied throughout the year was 86½, and the patients remained in Hospital an average of thirty-four days. During the last year, 104 of the patients on being discharged are said to have returned to their friends, and 71 have gone into some of the Dublin Penitentiaries. The House of Industry Hospitals are the Hardwicke, the Whitworth, and the Richmond, which accommodate respectively the following average number of patients throughout the year, 55½, 64, and 96½. In Stevens's Hospital the average number was 184, and 2414 cases were treated to a termination during the year. The average number of beds daily occupied in the Meath Hospital was 65 in the infirmary, and 15 in the fever wards. The Cork-street Fever Hospital provided for 90 daily. The management of the Rotunda Lying-in Hospital is favourably mentioned; 978 labour cases, and 178 chronic patients were received during the year; the average daily number of beds occupied by the former was 26; the number of lying-in cases was less last year than any year since 1778, which is ascribed to the prevalence of fever in the Hospital. In the Coombe Lying-in Hospital, 389 labour cases, and 35 chronic were admitted during the year; and in a populous and very poor district of the metropolis 1199 cases have been attended to during the year. St. Mark's Ophthalmic Hospital received 223 patients during the year. The Governors observe in their last report that this Hospital is at present one of the most perfect sanitary institutions of its kind, and the Board states that the admirable arrangements made for internal and external patients fully warrant this testimony. The last is the Hospital of Incurables, into which 24 were admitted during the year, and which is said to be conducted with much efficiency and economy, while the comfort of the patients is most carefully attended to. Some of the others are said to be defective in the matter of economy; but in other respects the reports are all more or less favourable. The rate of mortality in the several Hospitals is as follows:—Lock Hospital, 0.86 per cent.; Hardwicke, 8.5; Whitworth, 6.14; Richmond, 3.52; Stevens, 2.81; Meath, infirmary, 3.74—fever, 7.66; Cork-street, 5.70; Rotunda Lying-in Hospital, 8.13—unusually great, in consequence of fever; Coombe Lying-in Hospital, 2.7."

**UNIVERSITY OF LONDON.**—Yesterday, a meeting of the members of the University of London and their friends was held in the Convocation-room of the University, Burlington-house, Piccadilly, for the admission of candidates for degrees. Earl Granville, K.G., the Chancellor of the University, presided. The following Medical degrees were conferred:—M.D.—Charles Hilton Fagge, Guy's Hospital; John Henry Galton, Guy's Hospital; Morell Mackenzie, London Hospital; Walter Bassett Ramsbotham, University College; Joseph Rutter, University College; Robert Bowie Walcott, St. Thomas's Hospital. M.B.—Richard Dawson and Edward Thomas Tibbits, University College; Frederic Marsdin, King's College; Henry Colley March, St. Thomas's Hospital; Horace Jeaffreson, St. Bartholomew's Hospital; John Bayldon, Surgeons'-hall, Edinburgh; William Dale, Leeds School of Medicine and Middlesex Hospital; Frederick Stockwell, St. George's and Bath United Hospitals. In the course of his address, the Chancellor thus referred to the proposal of granting degrees to women:—There was one question to which he would for a moment refer that was not of inferior importance to any that had engaged the attention of the senate,—he alluded to the question whether women as well as men should be admitted to the degrees of that University.

In any remarks he might make, he felt perfectly convinced that his friend on his right (Mr. Grote) would readily protect the ladies, and affirm that they were equally competent to obtain honours in any pursuit they might feel disposed to attempt. The argument which was chiefly enforced by those who wished for the admission of women to degrees was based on the liberal character of the University. It was also stated that the great object of such an University was to promote knowledge, and that persons estimated knowledge very much in proportion to the value they found attached to it. It was then argued that that value would be greatly appreciated by a certificate emanating from a body like that of the London University, which would be recognised by the world at large. Eminent examples of gifted women were quoted in support of the argument, and among those whose names were mentioned was the name of that modest, unassuming, and deeply scientific woman, Mrs. Somerville. And it was said that a certificate of that kind, bearing testimony to the acquirements of women, would greatly assist them in obtaining employment by persons who would not readily take their own word. On both sides it was admitted that there was no question as to conducting the education of men and women together; but that the only question was whether women should be examined or not. Now, it was held by those who did not agree to this proposition that there were great and serious objections to the system proposed. It was felt that men and women were different in quality of talent and in intellect, and that to teach them and educate them exactly in the same manner would do injury to each and to both in combination. It was also felt that the field of exertion for the talents of men and of women lay in different directions, and that what might even be a merit in the one sex, might be a fault in the other. Besides this, it was doubted whether it was desirable to expose women—members of the gentler sex—to that spirit of competition, and—which the very character of the thing itself implied—to that struggling and striving, as it were, for domination and power to which their admission to academical degrees would lead. These were some of the reasons which influenced their Chancellor (a laugh) to commit what he certainly felt to be a most ungallant act—that of giving his casting vote against the proposition. From conversation with men and with women on the subject, he believed there was not one woman in a hundred who was not for the exclusion of women from University examinations.

BOOKS RECEIVED.

The Shilling Guide to the London Charities for 1863; showing in Alphabetical Order the Name, Date of Foundation, Address, Objects, and Annual Incomes, Number of People Benefited by, Mode of Application to, and Chief Officers of, every Charity in London. By Herbert Fry. London: Robert Hardwicke. 1863.

\*.\* Curious as well as useful information is to be obtained from many a book of the directory class, and we have seen few directories from which more of both kinds may be extracted than from Mr. Fry's "Guide to the London Charities." Under the term "Charities," the author appears to include institutions having endowments either for the benefit of body or mind. Hence, many neither usually associated with the idea nor with the term "Charity" find a place in his list, such, for instance, as the University of London, Westminster School, Merchant Taylors' School, etc. We do not wonder at the Chancellor of the Exchequer casting a wistful eye at the enormous sums of money which are yearly expended—well or ill—in charitable institutions. Here are the incomes of some of the metropolitan Hospitals, obtained, we presume, from authentic returns:—St. George's, £10,000; King's College, £6,000; London Hospital, £17,500; St. Mary's, £4,000; St. Thomas's, £30,000; St. Bartholomew's, £29,000; (this is surely a misprint, the income of St. Bartholomew's we believe to be nearly double the sum stated); Westminster, £7,800; Victoria-park Hospital for Consumption, £6,162; the Brompton Hospital for Consumption, £8,628; the German Hospital, £3,600; the Fever Hospital, £1,878; the Royal Free Hospital, £6,000; the Metropolitan Free Hospital, £2,091; the Great Northern Hospital, £916; the Hospital for Sick Children, £3,500. So much for legitimate medicine, but illegitimate is equally liberally supported. The income of the Mesmeric Infirmary is stated at £7,918, and that of the London Homœopathic Hospital is returned at £1,735.

A Manual of Chemical Analysis, Part I. Qualitative. By Henry M. Noad, Ph.D., F.R.S. London: Lovell Reeve and Co. 1863.

Who to Consult; or, a Book of Reference for Invalids. London: Aylott and Son. 1863.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

G. K. P.—Apply to Dr. F. Hawkins, Registrar. The fee is £5 5s.

G.—A legal British Medical and Surgical diploma.

Dr. Moor's paper on Placenta Prævia is in the printer's hands.

C. P.—Our usually acute and well-informed contemporary, the *Lancet*, has been the victim of a hoax. It gravely announced last week, as a fact, that Mr. Propert had contributed *ten guineas* (!) to the Adams defence fund. Such a donation would be ridiculous for Mr. Propert to offer. There is a story that he asked five friends how much he ought to give, and that they advised him to limit his donation to ten guineas; but we understand that the friends were tailors, and that therefore the donation they recommended is but a fraction of what may be expected from Mr. Propert.

We copy the following letters from the *Manchester Examiner and Times*:—

[“ADVERTISEMENT.”]

“To the Editor of the *Examiner and Times*.”

“SIR,—In reference to the report of the ‘Alleged Libel upon a Manchester Physician,’ in yours of to-day, I beg to observe that the action was not, as there stated, against the *Lancet*, but against Dr. Roberts, of this city. It is not easy, from your report, for the public to understand the case, which is simply this:—Dr. Roberts, in a series of letters, some anonymous, published in the *Lancet*, charged me with meeting Homœopaths in consultation, and stated that such conduct was considered by the Medical Profession as improper and disgraceful, and he offered to find three cases in proof.

“Subsequently, however, Dr. Roberts withdrew the cases, not being able to substantiate them, and in one of his pleas he alleged ‘that it was not disgraceful or improper to meet a Homœopath in consultation,’ being directly contrary to the position first taken by him, and a contradiction which has yet to be reconciled. The court held, on the argument, that even if such had been admitted to be true, it was *not improper or disgraceful to meet Homœopaths*, and that so far the plea demurred to was good. But as to the letters in question, it was stated that if the object of the defendant was maliciously to place me in an invidious position, and to injure me in my Profession, the publication of them might be actionable, which is substantially the question yet to be tried.

“Yours respectfully,

“101, Piccadilly, May 8, 1863.

“CHAS. CLAY, M.D.”

[“ADVERTISEMENT.”]

“ALLEGED LIBEL UPON A MANCHESTER PHYSICIAN.

“To the Editor of the *Examiner and Times*.”

“SIR,—It is with much regret that I feel compelled to trouble you in consequence of a letter of Dr. Clay inserted in your issue of Saturday last.

“It is not the fact that I stated in my letters to the *Lancet* that Dr. Clay's meeting Homœopaths was ‘improper and disgraceful,’ or that I ‘withdrew the cases’ mentioned by me, ‘not being able to substantiate them.’

“It was Dr. Clay, in his declaration, that used the words that it was ‘improper and disgraceful’ for him and other Medical Practitioners to meet Homœopaths; and in my second plea I alleged that his statement was not correct. My instructions to my counsel were that, although contrary to the usual etiquette, it was not ‘disgraceful’ to do so; as a minority of the Profession disagree to this rule, and no Physician or Surgeon would refuse to meet them if such refusal proved detrimental to a patient in danger.

“To this plea Dr. Clay demurred on the ground that I could not deny (what in fact I had not stated) that it was ‘disgraceful’ to meet homœopaths, and it was on this demurrer that the judgement of the Court of Exchequer was given in my favour.

“Mr. Baron Bramwell stated, in the course of the argument, that the declaration of the plaintiff was libellous on the Profession, but *not my letters*; and the whole court gave judgment that my plea was good and his declaration bad, thus deciding that my letters were not libellous, and, consequently, that no action was sustainable upon them.

“Dr. Clay, from his letter, evidently leads you to believe that there is a question yet to be tried in the action. Now he well knows, or ought to know, that the decision of the court goes to the whole cause of action, and that if he should, from any motive whatever, go to trial, he will have to pay for his experiment, as the court, after its decision, *must* set aside any verdict which might by possibility be given in his favour.

“The cases mentioned by me, in which Dr. Clay had met Homœopaths, so far from being *withdrawn*, were, under a judge's order, obtained by *him*, actually supported by me; and the particulars of the cases were given by me to the court under my plea of justification.

“In conclusion, I have to state that I was at first advised by my solicitors that my letters were *not* libellous, and that, consequently, I had a good defence to any action which the plaintiff might bring; and upon that advice I acted, and the result has proved its soundness.

“If I had done anything wrong in the course I pursued, I should have been ready to make an ample and suitable apology; but I have only been discharging the duty which I owe to myself and to the other members of my Profession by the line of conduct I have pursued.—I am, sir, your obedient servant,

“WM. ROBERTS, M.D.

“10, Chatham-street, May 11, 1863.”

THE MEDICAL OFFICERS OF H.M.S. “ORPHEUS.”

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Seeing in the *Medical Times and Gazette* of Saturday last that Dr. J. M. Tronson, Surgeon, and M. Coates, Assistant-Surgeon, were supposed to have been lost in H.M.S. *Orpheus*, I beg to inform you that neither of these gentlemen was in the ship at the time she was wrecked. Mr. Jas. Clarkson was the only Medical officer lost on that melancholy occasion.

Dr. Tronson died at Sydney on January 30, having been left behind at sick quarters. I have enclosed an account of his death, published in the *Sydney Morning Herald*. Mathew Coates, I imagine, had left the ship previous to her departure from Sydney for New Zealand.

I am, &c.

Dr. MCN. JOHNSTON,

Assistant-Surgeon H.M.S. *St. Vincent*.

“Mr. J. M. Tronson, M.D., F.R.G.S., R.N., Surgeon of H.M.S. *Orpheus*, died at his residence, No. 43, Hunter-street, on Friday, the 30th Jan. The funeral took place on Saturday afternoon, with all the honours due to his rank as an officer in the British naval service. Dr. Tronson was only thirty-three years of age. He entered the naval service in 1852, and accompanied the Arctic Expedition in 1854. He also served through the Russian war, and went up the Gulf of Tartary in H.M.S. *Barracouta*. He was likewise actively engaged in the China war, for which he received a medal.”—*Sydney Morning Herald*.

## THE ARMY MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In what time may one entering the Army Medical Department reasonably expect the rank of Surgeon? I am, &c. MEDICUS.

[The rate of promotion varies. If it go on as at present, we should think in from fifteen to eighteen years.—Ed.]

## QUALIFICATIONS IN SYDNEY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I should feel greatly obliged to any one of your numerous readers if I could obtain any definite information whether a Medical man, properly qualified to practise Medicine and Surgery here, is equally so in Sydney, Australia, without his undergoing any further local examination. I am, &c. CHIRURGUS.

London, May 12.

[We believe so.—Ed.]

## THE EFFECT OF PERI-RENAL EFFUSION OF BLOOD.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I shall be obliged by a reply to the following queries:—

A boy, aged 7½ years, received a kick from a man in the right loin over the region of the kidney. About three weeks after this he dies, apparently from exhaustion, and with symptoms of enteritis, vomiting, and great abdominal distension. These symptoms came on suddenly. A post-mortem examination was made nineteen hours after death, when the only abnormal appearances noticed were:—1st. The body much emaciated, and a complete absence of fat from the abdominal walls and omentum; 2ndly, An inflammatory redness of the small intestines (no effusion of lymph); and 3rdly, A quantity of coagulated blood in the cellular tissue surrounding the right kidney. All the other organs in abdomen and thorax were healthy. The brain was not examined.

Would a Surgeon be justified in stating that death was the result of the blood acting upon a previously weakened constitution from want of food, exposure, etc.; and would the existence of the clot, together with the bruise over the kidney, be sufficient, in the absence of any other cause, to account for death under such circumstances?

What length of time can blood remain, supposing it to be effused in the cavity of the abdomen, without undergoing change of colour, etc.?

I am, &amp;c.

A SUBSCRIBER AND CONSTANT READER.

## THE PREVENTION OF PITTING IN SMALL-POX.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—With reference to the notice of Dr. Smart's plan for preventing pitting in small-pox, referred to in your last number, and also with reference to the application of calamine with a like object, recommended by Mr. Henry George, of Kensington, in a late letter of his to the *Morning Herald*, allow me to quote a few sentences of a paper of mine "on the Treatment of Continued Fevers and other Acute Diseases," which appeared in the *Dublin Quarterly Journal of Medical Science*, No. LXIX., p. 204:—

"In this, and in the two preceding cases (of small-pox), I had the faces of the patients constantly covered with mucilage of starch, except for a few minutes each morning, when they were sponged off with tepid water, to exhibit the true state of affairs, and to apply the starch afresh. Just seven years ago, when small-pox was present in this city (Cork) and neighbourhood, I tried this application in several cases in the General Hospital in Ballincollig, then under my charge, and I found that in each instance it allayed the sense of heat and itching so much complained of by the patients, and completely prevented their tearing the pustules from their faces. In the *Dublin Hospital Gazette* for 1856, p. 72, I wrote a short account of this plan, and its excellence in small-pox, and other skin diseases of an inflammatory nature; and having used it in the cases just now related, I am able to state that (whether post hoc or propter hoc), no personal deformity ensued."

Since these sentences were written in September last, small-pox has been very prevalent in this city, and I have largely tried the above plan with unvarying success. I have seen calamine used also, and various other applications, but without the good result which has constantly attended the application of starch; and I consider the simplicity of its use in the hands of nurses one of its strongest recommendations.

I am, &amp;c.

T. W. BELCHER, M.A., M.D. Trin. Col., Dub.,  
L.K.Q.C.P. Irel., Physician Extraordinary  
to the Cork Fever Hospital.

Cork, May 8.

## DR. MAYNE'S ANSWER TO DR. FOWLER'S REQUIREMENTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I request you will in fairness allow me to correct the wrong impression sought to be created to my prejudice by Dr. Fowler in last week's *Medical Times*.

Mr. Renshaw's note (referred to by Dr. Fowler) to Mr. Churchill of April 21 ran as follows:—"My dear Sir,—Having full confidence in your sense of justice, I must, now the referees have given their decision in favour of Dr. Fowler, ask you to withdraw from further circulation the preface to Dr. Mayne's 'Vocabulary,' which contains charges and statements now declared to be devoid of truth."

Its terms appeared to me to be he designedly offensive, inconsistent with fact, and anything but happily conceived for obtaining the rather important favour he asked.

I deny that "the referees have given their decision in favour of Dr. Fowler," as adventurously stated by Mr. Renshaw, but, on the contrary, clearly understand that they have emphatically condemned his and Dr. Fowler's "appropriation" of "the idea, the very title of my original 'Medical Vocabulary' of 1836" as unjustifiable, "so long as the copyright of the original work existed." This charge, at least, and I must still hold that it inevitably involves the other charges, has not been "declared to be devoid of truth." I could not, therefore, comply with the very modest request of Mr. Renshaw, the suggester and instigator, as stated by Dr. Fowler, and as found by the referees, of the entire wrong committed, so easily as that gentleman seemed to wish. Neither can I listen to the similar demand now made by Dr. Fowler, while he has the hardihood to persist in that mal-appropriation which the referees have branded as unjustifiable.

I must first know what he and Dr. Fowler mean to do as to the withdrawal of their indefensibly assumed "Medical Vocabulary." If then satisfied of fair acting on the occasion, I shall willingly modify the preface in my next edition to strict accordance with the findings of the referees. Their decision, I deferentially bow to, out of respect for their disinterested

endeavours to carry out a difficult and delicate investigation as pleasantly for the erring party as matters could allow.

It is amusing to remark how Mr. Renshaw grounded his request upon "full confidence in your sense of justice!" Where was his sense of justice when he appropriated my work, and induced Dr. Fowler to take the responsibility of that appropriation which the referees have so unequivocally stigmatised? I am, &c.

Leeds, May 12.

R. G. MAYNE.

## APPOINTMENTS FOR THE WEEK.

May 16, Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m.; Charing-cross, 1 p.m.

ROYAL INSTITUTION, 3 p.m. Professor Max Müller, "On the Science of Language."

18. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1½ p.m.; Samaritan Hospital, 2½ p.m.; Lock Hospital, Dean-street, Soho, 1 p.m.

19. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

ROYAL INSTITUTION, 3 p.m. Professor Tyndall, "On Sound."

20. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Middlesex, 1 p.m.

HUNTERIAN SOCIETY, 8 p.m. Dr. Fowler, "On a Case of Laceration of the Vagina during Labour—a Medico-legal Question."

21. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.;

London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.;

Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.

HARVEIAN SOCIETY, 8 p.m. Clinical Meeting.

ROYAL INSTITUTION, 3 p.m. Professor Ansted, "On Geology."

22. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

ROYAL INSTITUTION, 8 p.m. Prof. Roscoe, "On the Sun's Chemical Action."

## EXPECTED OPERATIONS.

King's College Hospital.—The following Operations will be performed on Saturday (to-day) at 2 p.m. :—

By Mr. Fergusson—Forcible Extension of Elbow; For fistula in Ano; For Hare-lip (two cases).

## ORIGINAL LECTURES.

## PROFESSOR HUXLEY'S LECTURES

AT THE

## ROYAL COLLEGE OF SURGEONS.

## LECTURE VII.

*(Being the Sixth Lecture on Classification, and on the Characters of the Principal Groups of the Animal Kingdom.)*

MR. PRESIDENT AND GENTLEMEN.—In my last lecture I endeavoured to point out to you the grounds upon which naturalists have arrived at the conclusion that the classes of the animal kingdom may be arranged together in larger groups or divisions, such as have been termed “provinces” and “subkingdoms.” If the time at my disposal for the consideration of the classification of the animal kingdom permitted me to do so, I should now, in the logical order of my discourse, take the opposite course, and again turning to the list of classes, I should endeavour to indicate in what manner they may be subdivided into sub-classes, orders, and lesser divisions. But it is needless to say that such a task as this would require many lectures, while I have only one to dispose of; and I propose to devote that one to a consideration of the classification of the class, which is in many respects the most interesting and the most important, of any in the animal kingdom,—the class *Mammalia*.

A great many systems of classification of the *Mammalia* have been proposed, but, as any one may imagine from the nature of the case, only those which have been published within the last forty or fifty years, or since our knowledge of the anatomy of the class has approached completeness, have now any scientific standing ground. I do not propose to go into the history of those older systems, which laboured more or less under the disqualification of being based upon imperfect knowledge, but I shall direct your attention at once to the important step towards dividing the *Mammalia* into large groups, which was taken by M. de Blainville, a very eminent French anatomist, so far back as the year 1816. M. de Blainville pointed out that the *Mammalia* might be divided into three primary groups, according to the character of their reproductive organs, especially the reproductive organs of the female. He divided them into “*Ornithodelphes*,” “*Didelphes*,” “*Monodelphes*,” or, as we might term them, *Ornithodelphia*, *Didelphia*, *Monodelphia*. Now, I do not mean to assert that M. de Blainville defined these different groups in a manner altogether satisfactory, or strictly in accordance with all the subsequently discovered facts of science, but his great knowledge and acute intuition led him to perceive that the groups thus named were truly natural divisions of the *Mammalia*. And the enlargement of our knowledge by subsequent investigation seems to me, in the main, only to have confirmed De Blainville's views.

The division of the *Ornithodelphia* comprises those two remarkable genera of Mammals, as isolated in geographical distribution as in structure—*Ornithorhynchus* and *Echidna*,—which constitute the order *Monotremata*.

In these animals the angle of the lower jaw is not inflected, and the jaws are devoid of true teeth, one of the two genera only (*Ornithorhynchus*) having horny plates in the place of teeth. The coracoid bone extends from the scapula to the sternum, with which it is articulated, as in birds and most reptiles, and, as in many of the latter, there is an episternal bone. There is no marsupial pouch, though bones wrongly termed “marsupial” are connected with the pelvis. But the structure of the female reproductive organs is that to which the *Ornithodelphia* owe their name. The oviducts, enlarged below into uterine pouches, but opening separately from one another, as in oviparous vertebrates, debouch, not into a distinct vagina, but into a cloacal chamber, common to the urinary and genital products and to the feces. The testes of the male are abdominal in position throughout life, and the vasa deferentia open into the cloaca, and not into a distinct urethral passage. Such a passage traverses the penis, but is open and interrupted at the root of that organ. In both sexes, the ureters pour the renal secretion, not into the bladder, which is connected with the upper extremity of the cloaca, but into the latter cavity itself.

In the brain, the *corpus callosum* is inconspicuous, though the question how far it can properly be said to be absent requires much more thorough investigation than it has yet received, and the optic lobes are double and not quadruple,—they are *Corpora bigemina* and not *quadrigemina*. We are but very imperfectly acquainted with the reproductive processes of these animals, but it is probable that the young are devoid of a placenta. The mammary gland has no nipple.

Like the *Ornithodelphia*, the division *Didelphia* contains but a single order, the *Marsupialia*, the great majority of which, like the *Ornithodelphia*, inhabit Australia. They almost all have the angle of the lower jaw inflected, and all possess true teeth. The coracoid is, as in the higher Mammals, ankylosed with the scapula, and is not articulated with the sternum. All have the so-called “marsupial” bones or cartilages—ossifications or chondrifications of part of the tendon of the external oblique muscle of the abdomen—and the females of almost all possess a fold of the skin of the abdomen above the pubis, constituting a “*marsupium*,” or pouch, within which the young are nourished and protected in their early helpless condition.

The oviducts open into a vagina, which is commonly more or less completely divided into two separate passages. The testes of the males are lodged in a scrotum suspended in front of the penis, and the vasa deferentia open into a complete and continuous urethra, which, as in the female, is the passage by which the urine escapes from the bladder, and is perfectly distinct from the passage for the feces.

The corpus callosum is imperfectly developed, but the optic lobes are *corpora quadrigemina*.

The allantois of the embryo is arrested in its development, and gives rise to no placenta. The umbilical sac acquires a large proportional size, but whether it plays the part of a placenta for the short period of intra-uterine life, or not, is unknown.

The young are born of very small size, and in a singularly imperfect condition, but being transferred to the marsupium, and becoming attached to a long nipple, they are supplied with milk until they are able to provide for themselves—the milk being, at first, forced into their mouths by the action of a muscle spread over the mammary gland.

The *Monodelphia* have the angle of the lower jaw not inflected, and they may or may not be provided with teeth. They never possess “marsupial” bones. The uterine dilatation of the oviducts is always considerable, and whether they have common or distinct apertures, the vagina is a single tube, whether partially divided by a septum or not. The testes may vary much in position; but, if they are lodged in a scrotal pouch, it is never pendulous by a narrow neck in front of the penis, as in Marsupials.

The urinary bladder opens into a distinct urethra, which receives the vasa deferentia in the male.

The corpus callosum is very variable in its development; the optic lobes are divided into four portions.

The young are nourished within the uterus until such time as they are competent to suck milk from the teats of the parent, and to this end the chorion always develops processes or villi, which are well supplied with vessels brought to them by the allantois. These processes becoming interlaced more or less closely with corresponding vascular developments of the wall of the uterus, and so forming a “placenta,” an interchange of constituents takes place between the foetal and the maternal blood through the separating walls of the foetal and maternal vessels. In this manner, throughout its prolonged intra-uterine life, the Monodelphian foetus is supplied with nourishment and gets rid of its effete products.

As the three groups instituted by De Blainville are capable of being thus clearly differentiated one from the other, the distinctions between them having been only more and more clearly brought out by the subsequent progress of knowledge, I can see no ground for refusing to adopt his classification or for denying him that credit to which he is fairly entitled for apprehending these distinctions. Certainly, the later proposition, to divide Mammals into two great groups only, *Placentalia* and *Implacentalia* (a) cannot be regarded as any improvement upon De Blainville's system, as it ignores the important fact that the two divisions of the “*Implacentalia*” are separated by characters of fully as great importance as those which distinguish the *Placentalia* and *Implacentalia*.

But whether *Ornithodelphia* and *Didelphia* are regarded (as I believe they ought to be) as two of the three primary separate

(a) Substantially originated, as will be seen below, by Eschricht in 1837.

"sub-classes" of the class *Mammalia*, or whether they are looked upon only as subdivisions of the *Implacentalia*, there is no doubt that they are and will remain distinct natural assemblages, the subdivisions of which present no very great difficulties.

FIG. 1.

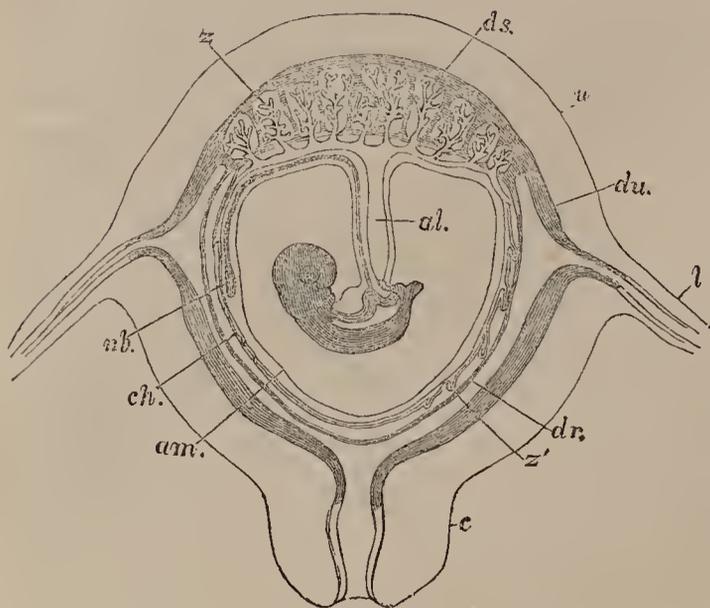

FIG. 1.—Diagrammatic section of a human pregnant uterus, with the contained ovum (Longet). *u*, uterus; *l*, oviduct; *c*, cervix uteri; *du*, decidua uteri; *dr*, decidua reflexa; *ds*, decidua serotina; *ch*, chorion; *am*, amnion; *al*, allantois; *nb*, umbilical vesicle; *z*, villi which form the foetal part of the placenta; *z'*, villi over the rest of the chorion, which take no part in the placental function in man.

It is otherwise with the sub-class *Monodelphia*—which contains at least a dozen orders, the arrangement of which into groups, not only in detail, but in principle, is, and long has been, a subject of much difficulty, and consequently of controversy.

Sir Everard Home (b) is commonly quoted as the originator of one of the two systems of classification in vogue at the present day, but his vague statements and confused notions respecting the varying characters of the placenta of the *Monodelphia* hardly entitle him to that honour, which, in my opinion, belongs rather to that eminent man, Karl Ernst von Baer, of whom it can be truly said that he has touched no subject without throwing a flood of light upon it. Towards the end of his famous essay, "Untersuchungen Über die Gefäßverbindung zwischen Mutter und Frucht," published in 1828, the following passage occurs:—

"In the first place, I have taken pains to show that the ova of mammals are only variations of a single type, and if we except the ova of the Marsupials, concerning which I can form no judgment, all consist of the same parts, all have a placenta, and, in all, some portion of the chorion is smooth. The foetal placenta consists everywhere of the same elements, but in its external disposition offers the most remarkable differences. It is either—

1. Merely applied to the maternal placenta, and
  - a, continuous and zone-like. *First form.*
  - b, divided into many parts. *Second form.*

Or 2. It and the maternal placenta grow together, and they lie,

- a, in a zone round the egg. *Third form.*
- b, at one end of it. *Fourth form.*

These differences, however, are gradually developed, and, at first, are less marked."

The *first form*, described in the text of the work, is that met with in the fig. It is what is now commonly termed a *diffused placenta*, but Von Baer, more accurate than most of his successors, indicates the confinement of the placental villi to the middle of the chorion—its prolonged poles remaining bare—by the term "gürtelörmig," zone-like. The *second form* is that exemplified by the cow and sheep, the *cotyledonary placenta*. The third is the carnivorous placenta, termed *zonular*. The fourth, the placenta of man, called now-a-days *discoidal*.

The most important circumstance pointed out by Von Baer, however, is one which has been greatly overlooked, if

(b) "Comparative Anatomy," vol. iii.

not wholly ignored, in subsequent discussions—the fact that the differences in the *form* of mammalian placenta are subsidiary if compared with their differences in structure, more particularly in regard to the extent to which a maternal element enters into their composition.

Eschricht, in the admirable memoir, "De Organis quæ Respirationi et Nutritioni Fœtus Mammalium inserviunt," which he published in 1837, repeats the ideas of Von Baer, apparently without being aware of the fact, and enlarges upon them as follows (p. 30):—

"Restat, ut succinctam expositionem Mammalium afferamus secundum varias quæ in iis observantur, placenta formas.

"A ceteris omnibus mammalibus marsupialia et Monotremata separanda sunt, quibus nulla est placenta. Cætera omnia in duas familias dividenda, quarum alteri placenta uterina caduca, alteri non caduca est. Huic mammalia primata et unguolata omnia adnumeranda sunt, inter quæ ruminantia ob singularem cotyledorum formam cæteris opponi possunt.

"In mammalibus placenta uterinam caducam habentibus tres mihi occurrere videntur placenta typi, quorum primus gliribus, secundus feris, tertius simiis et homini proprius est."

In this passage Mammals are clearly divided, in the first place, into placental and implacental; and the former are then subdivided into those which have a non-caducous and those which have a caducous uterine placenta. The Cetacea and Ungulate Mammals constitute the former group; the Rodents, Carnivores, Apes, and Men the latter.

In 1843, an accomplished English zoologist, Mr. Waterhouse, published a highly instructive paper on the "Classification of the Mammalia," (c) in which the following passage occurs:—

"Taking the general form of the Brain into consideration, the placental Mammalia would appear divisible into two sections: first, those in which the cerebrum is generally of a rounded form, obtuse in front and provided with distinct convolutions; and secondly, those in which the cerebrum is destitute of convolutions, or nearly so, and usually contracted in front. The first division would contain the *Quadrumana*, *Carnivora*, *Cetacea*, *Pachydermata* and *Ruminantia*, and the second would contain the *Cheiroptera*, *Insectivora*, *Edentata*, and *Rodentia*."

But although Mr. Waterhouse puts forward thus clearly the facts upon which a cerebral classification of the *Mammalia* might be based, with his customary judgment, he immediately afterwards expresses great doubt as to the value of any such classification:

"But are we in a condition to take for a basis of classification of the *Mammalia* the structure of the brain? I think not, though in the case of the *Marsupialia* it has afforded characters serving to separate that from other sections, and to indicate its proper position in the system. I am not prepared to follow those naturalists who would, in the present state of information, take this organ as one of primary importance in the distribution of the order of the placental series of Mammals. I cannot adopt the two great sections of this series as apparently indicated by the smooth and anteriorly contracted cerebrum on the one hand, and the convoluted cerebrum, with its rounded anterior portion on the other. Were I to do so, I should find it necessary to remove some of the Lemurs from their group on the highest order of the first section, and to place them in the second section."

In the succeeding year, 1844, M. Milne-Edwards, one of the most distinguished physiologists and zoologists of modern France, proposed, in a highly philosophical paper upon zoological classification in general (d), a method of subdividing the *Mammalia*, essentially similar to that put forward incidentally by Von Baer and Eschricht, but lacking, as I conceive, what is the great merit of the latter writers, namely, the clear perception of the classificatory value of the intimate structure of the placenta and the entrance or not of a decidual uterine element into its composition. M. Milne-Edwards dwells with great force (as Mr. Waterhouse had previously done) upon the closeness of the general structural affinities which unite the *Rodentia*, *Insectivora*, *Cheiroptera*, *Quadrumana*, and *Bimana* of Cuvier together, and shows that

(c) *Annals and Magazine of Natural History*, 1843, vol. xii., p. 399.

(d) "Annales des Sciences Naturelles." Serie 3. Tome 1. "Considerations sur Quelques Principes relatifs à la Classification Naturelle des Animaux."

these affinities are denoted by the discoid placenta which they possess in common.

The diffused placenta (under which head the cotyledonary placenta is included) is stated to be the characteristic of the *Ruminantia*, *Pachydermata*, *Edentata*, and *Cetacea*; while, lastly, the "*Carnivora* and seals (*Amphibies*) are distinguished from all the rest by their zonular placenta."

The singular genus *Hyrax*, which Cuvier endeavoured to prove to be a true Pachyderm, is considered by M. Milne-Edwards to form one of the series of Mammals, with a zonular placenta, and to represent in that series the Pachyderms in the series with diffuse placentation, and the Rodents, in the series with discoid placentation.

M. Gervais, in France, and M. Vogt, in Germany, have adopted the placental classification of Milne-Edwards; while, in 1857, Mr. Waterhouse's proposed, but immediately rejected, cerebral classification was substantially revived by Professor Owen, in his paper "On the Characters, Principles of Division, and Primary Groups of the class Mammalia," published in the Journal of the Linnean Society; though it should be added that Professor Owen made certain additions to the nucleus furnished by Mr. Waterhouse which are unquestionably original.

Thus the *Lisencephala* of Professor Owen is simply a new name for the group of Mammals ("in which the cerebrum is destitute of convolutions, or nearly so") indicated by Mr. Waterhouse; and "*Gyrencephala*" is a like verbal equivalent for Mr. Waterhouse's group of Mammals characterised by having the brain provided with distinct convolutions. But Mr. Waterhouse does not mention Man at all, while Professor Owen creates a new sub-class, *Archencephala*, for the genus *Homo*, and substitutes the name *Lyencephala* for *Implacentalia*, formerly applied to the *Ornithodelphia* and *Didelphia*.

In attempting to decide between the various classifications thus presented to us, the canons by which our judgment must be guided are simple enough. It is obvious, in the first place, that the definition of a group, whether that definition be based on cerebral or on placental characters, must be true, as a matter of fact, if any value is to be attached to the classification of which that definition forms a part.

And, in the second place, it is clear that the definition of each group must be distinctive, that is to say, it must not include the members of other groups.

Applying the second canon to the classification last mentioned, it appears to me to collapse at once.

The sub-class *Lisencephala*, for example, is thus defined:—

"The corpus callosum is present, but connects cerebral hemispheres as little advanced in bulk or outward character as in the preceding sub-class; the cerebrum leaving both the olfactory lobes and cerebellum exposed, and being commonly smooth, or with few and simple convolutions in a very small proportion, composed of the largest members of the group. The Mammals so characterised constitute the sub-class *Lisencephala*."—*L. c.*, p. 14.

On the other hand the sub-class *Gyrencephala* receives the following definition:—

"The third leading modification of the Mammalian cerebrum is such an increase in its relative size, that it extends over more or less of the cerebellum, and generally more or less over the olfactory lobes. Save in very few exceptional cases of the smaller and inferior forms of the *Quadrumania* the superficies are folded into more or less numerous gyri, or convolutions, whence the name *Gyrencephala*, which I propose for the third sub-class of Mammalia."—*L. c.*, p. 18.

I am quite unable to see what these so-called definitions define. If, for example, we place the brains of an ant-eater, or a capybara side by side with that of a genet—the two former being *Lisencephales*, the latter one of the *Gyrencephala*—either "definition" will apply equally well to either of the three brains. All three have slightly convoluted brains; in all three the olfactory lobes and cerebellum are more or less uncovered; and nothing in the definitions of the sub-classes of this cerebral classification would enable any one to say that any one of these three brains belonged to one sub-class rather than another.

Since Mr. Waterhouse pointed out the fact, no one has doubted that, as a general rule, the brains of the so-called "*Gyrencephala*" are more convoluted, size for size, than those of the "*Lisencephala*;" and the relations of the size and the zoological position of an animal to the characters of its cerebral surface have long since been well discussed by Gratiolet,

Darvete, and others. But it is exactly because the rule is only a general one, and has many exceptions, that the degree of cerebral convolution must be rejected as the basis of the definition of any large group of Mammals.

Thus far, we meet, in Professor Owen's definitions, with a certain foundation in fact, though it may not be such as is fitted to afford ground for classification, but the group "*Archencephala*" is in a more unfortunate position. Our first canon comes into operation, and we must reject it, because the matters of fact stated in its definition are untrue. The words stand thus:—

"In man the brain presents an ascensive step in development, higher and more strongly marked than that by which the preceding sub-class was distinguished from the one below it. Not only do the cerebral hemispheres overlap the olfactory lobes and cerebellum, but they extend in advance of the one and further back than the other. Their posterior development is so marked, that anatomists have assigned to that part the character of a third lobe; it is peculiar to the genus *Homo*, and equally peculiar is the "posterior horn of the lateral ventricle," and the "hippocampus minor," which characterises the hind lobe of each hemisphere."—*L. c.*, pp. 19—20.

These are the assertions which have been repeated over and over again during the last few years, but thanks to the exertions of the able Conservator of your Museum, it is in my power to lay before you visible and tangible facts, which prove these assertions to be wholly devoid of foundation.

The third lobe, characterised by extending further back than the cerebellum, is said to be "*peculiar to the genus Homo*."

I place before you casts of the cranial cavity, accurately representing the relative positions of the parts of the brain of a gorilla, of a chimpanzee, of an orang, of a *Cynocephalus*, and you observe that the posterior, or third lobe, of each projects further back than the cerebellum, in just the same sense as a man's can be said to do so, and in some cases, as in the baboon, to a much greater extent.

The assertion that the third lobe, as defined by Professor Owen, is "*peculiar to man*," is therefore demonstrably contrary to fact.

"*Equally peculiar is the posterior horn of the lateral ventricle*."

Side by side upon the table are two dissections, made in the same way, the one of the brain of an orang-utan, the other that of a man, taken at hazard by Mr. Flower, who has been good enough to dissect both.

Every one in this theatre, I imagine, can see perfectly well that the orang has a posterior cornu, which, in proportion to the size of its brain, is just as long and nearly as much incurved as that of the man, while it is a good deal wider at its commencement.

In fact, even if the posterior cornu had not been demonstrated (as it has now been) in the brain of numerous genera of apes, this one example would sufficiently demonstrate the assertion, that the posterior cornu is "*peculiar to the genus Homo*," to be simply untrue.

Lastly, as to the hippocampus minor—which is also said to be "*peculiar to man*"—that structure is, as you perceive, as distinct in the orang's as in the man's brain, so that the third term of the definition of the "*Archencephala*" is as contradictory to plain fact as the other two.

Even were the posterior lobe, the posterior cornu, and the hippocampus minor peculiar to man, as supposed by the definer of the sub-class "*Archencephala*," instead of being, as they really are, structures far better developed in some of the lower apes than in him, their classificatory value would be extremely doubtful, seeing that they are among the most variable of structures in the human brain. The casts upon the table of a Tartar's and of an Australian brain will demonstrate to you how insignificant may be the projection of the posterior lobe in one man and how great it may be in another. While the practical anatomists and demonstrators whom I address will be familiar with the singular variability of the posterior cornu and the hippocampus minor—structures which, without any assignable cause or noticeable external modification of the structure or of the functions of the brain, may present every degree of development, from absence to great size.

So little, indeed, is any zoological value to be attached to such a character as the degree of projection of the posterior lobe, that closely allied apes present us with most singular

differences in this respect. Thus the group of South American monkeys which comprises the Squirrel monkey (*Chrysothrix*), the posterior lobes of whose brain project beyond the cerebellum far more than they do in man, contains also the Howling monkey (*Myceles*), in which the posterior lobes cannot be said to project at all. And within the last two days, Mr. Flower has discovered (and the cast upon the table enables me to demonstrate the fact to you) that in, at any rate, one species of Gibbon, the Siamang (*Hylobates Syndactylus*) the cerebellum projects behind the posterior lobes, while, in the three other genera of anthropoid apes, the posterior lobes of the cerebrum project behind the cerebellum.

FIG. 2.

### ORIGINAL COMMUNICATIONS.

## ON ANEURISMAL TUMOURS INVOLVING THE NECK.

By JOHN COCKLE, M.D.

Physician to the Royal Free Hospital.

(Continued from page 505.)

WITH regard to the sounds that may be heard over an aneurismal sac, the main question to decide is, are they simply conducted from the heart or are they of local

origin? If it is maintained that they are generated in the heart, it is clear that every change of sound of sufficient intensity occurring there should be re-echoed in the sac. The sac would, according to this view, be but the reflex of the condition of the orifices of the heart. Should these be normal, simple double sound ascends the sac; if, on the contrary, an obstructed aortic outlet occur, then systolic murmur usurps the place of the first normal sound in the sac. Should regurgitation co-exist, then double murmur replaces there the normal tic-tac of the heart, so that the mere fact of a double sound or murmur audible over certain aneurismal sacs, provided it were simply unchanged in respect of character, or even exaggerated in respect of quantity, would in itself constitute no valid argument against the ordinary assumption that such sound was engendered in the heart, and simply conducted along the arterial walls, or even multiplied over the inner surface of the sac; but any decided change, as respects the very nature and quality of sound, if limited to the sac, would furnish ground for the opinion that such sound was not of cardiac origin. Indubitable, though faint, double murmur, originating either in the heart or aorta, could never change into pure, quasi-cardiac sounds in a sac more or less remote. On the contrary, if the conduction theory were true, such murmur ought, beyond doubt, to be transmitted to the sac. I infer, then, that the sounds heard in the sacs of the case I have detailed resulted from simple collision between the aortic column of blood and the semi quiescent mass within the sacs, the walls of the latter being entire and in a given state of tension. Such conditions would appear necessary, remembering that, immediately after the rupture of the upper sac, the first sound merged into one of indeterminate character, and the second sound ceased altogether. The ground for the assertion that the sounds were the result of uncompleat blood reaction is based upon the fact that there could have been no shock either from the expansion and contraction of the sac, as in the upper one mere integument intervened, and all capacity for elastic reaction must have been destroyed.

Now, if this reasoning concerning the mode of production of vascular sound be consequent, a still further generalisation may be attempted. For, if two sounds in orderly succession, and undistinguishable from the so-called cardiac sounds, can be produced in an aneurismal sac, under circumstances which positively exclude all participation of the heart, and, consequently, that of any valvular mechanism, no fallacy is involved in the inference that the sounds produced at the orifices of the heart may acknowledge an analogous simplicity in their mechanism, and that the valves may play less a principal than an accessory part in the acoustic phenomena of the heart than is generally assigned to them.

I do not, however, press the conclusion, or assert that this really obtains, but only urge that we ought, in the face of such facts, to reconsider the current doctrines, and satisfy ourselves whether or not they are beyond further controversy.

It will not be denied that the original valvular theory of the heart's sounds has been sent back more than once to the physiologist to amend, and bring more into harmony with anatomico-physiological facts. It was at first supposed that the blood during ventricular systole forced up the valves from their somewhat angular position, bringing them to a sudden dead lock at the plane of closure, and that this arrest produced the first cardiac sound. Some years subsequently Baumgarten, Chaveau, and Halford much later, demonstrated that the valves rise prior to ventricular systole. In the diagram by Halford the auriculo ventricular valves are represented already dome-shaped before the final contraction of the ventricle. Dr. Markham has also contributed to our knowledge by his anatomical demonstration of those elastic fibres, the recoil of which assists in the direct elevation of the valves. It has been since argued that the contraction of the ventricle upon the contained mass of blood produced sudden valve tension, causing the first sound.

Some years ago I pointed out that during the period immediately preceding ventricular systole, a layer of blood, formed by the confluent streams of the cavæ and of the pulmonary veins, would rest upon the auricular face of the valves, and that the first sound might be caused by the reaction of the lower column of blood, urged by systole against this layer, comparatively at rest. From continued study of the sounds heard in aneurismal tumours, I am still more impressed with the correctness of the view. The common explanation, then, that the sounds result from simple valve

tension alone, must, I take it, be modified, unless it can be shown that the blood layer alluded to does not exist, or, that existing, it does not modify the cardiac systolic sound.

I take this opportunity of directing attention to the Essay of Dr. Leared upon the "Production of Sounds and Murmurs in the Circulating System." His experiments are very original, and, I think, on most points conclusive.

We both agree that the sounds of the heart and vessels originate primarily in the blood, and that the vibrations of the vascular walls are of subordinate importance. But we differ respecting the outlet at which the sounds, heard over the heart, are developed. Dr. Leared holds that the first sound originates at the aortic outlet, from the reaction between the blood in the ventricle and the superposed column in the aorta. I, as already stated, suggest that it is at the auriculo-ventricular orifices. My reasons for differing are these: Suppose a murmur to be heard at the aortic mouth, and yet a normal sound towards the apex of the heart, how is this on Dr. Leared's theory to be explained? He might, perhaps, anticipate my objection by the rejoinder, that the sound originated at the pulmonic outlet. I then could only meet his assertion by an indirect test. Let us assume that some pathologic change—say at the mitral orifice—had caused a murmur of medium intensity to replace the first normal sound, the line of direction of such murmur is most generally towards the left axilla, rather than up the aorta. This fact would seem to indicate that the origin of sound is rather at this orifice than at that of the aorta. However this may be, such conceptions of the production of sound are not weakened by any of the earlier physiological experiments, such as hooking up the valves or pressing with the finger forcibly on the vessel. It appears to me that from such experiments we may only draw this conclusion,—that any obstacles in the blood-stream excite therein ripple and sonorous vibration; and, viewing the matter pathologically, we must admit that, when valves are curled up by disease, and orifices and vessels have undergone either fibroid, cretaceous, or atheromatous degeneration, they can be but little susceptible of any sensible degree of vibration.

I am, however, quite aware that certain objections offer with regard to this theory of sounds and murmurs excited by primary undulations in the blood; but I do not know that such objections are of more force than those which could be urged against the view that such sounds or murmurs originate in the solid structures. It may be that some musical sounds depend either upon perforation of the valves, or upon the free vibration in the blood-stream of membranes attached to them. Certain grating, sawing, and other harsh murmurs are also possibly produced by physical peculiarities of the orifices. But this much is clinically certain, that they fall most frequently into error who attempt by means of such peculiarities of sound either to interpret the precise nature, or to measure the extent, of the organic change existing at the orifices of the heart.

*Diagnosis.*—In few affections, whether of purely surgical or medical character, is the differential diagnosis of more importance, or, at times, of greater difficulty than in cases of aneurismal tumours which involve the neck. The records of Medicine supply an unusually large contingent of cases as unanswerable evidence that the diagnosis has been occasionally so mistaken that, to say the least, very many unnecessary operations have been sanctioned by high authority, sometimes from confounding these tumours with lesions of essentially diverse nature; at others, from an erroneous estimate of the vessels involved, or even of the precise nature of the affection involving them.

It may therefore be advisable to consider briefly, first, with what non-aneurismal affections of the neck true aneurism may be confounded; and, second, the difficulties incident to the attempt to isolate disease in any vessel connected, either directly or more remotely, with this region. It seems scarcely credible how many aneurismal tumours have been mistaken for ordinary strumous abscess. The difficulty of diagnosis must, beyond doubt, have been at times extremely great, or experienced Surgeons would scarcely have been misled. It is not to be supposed that anyone would mistake for abscess a tumour with well-marked pulsation. We must bear in mind that the cervical region is a special and most common seat of glandular engorgement; and that suppurating glands, though occasionally receiving impulse from the underlying artery, may be with safety opened should it be desirable. But we are also equally to remember that an

aneurismal tumour may, from the coagula within, become quiescent, and impart, from the narrowed column of blood effecting a channel through the clot, a very diminished impulse, while the discoloured and softened state of the integument may convey a sense of simple fluctuation. Or, again, an abscess may actually occur either within the aneurismal sac, or in the connective tissue between the sac and skin. The error of diagnosis adverted to might probably be thus explained. Certain cysts, again—such as simple hydrocele of the neck, or those more compound growths connected with, or caused by, degeneration of the thyroid gland, when lying directly over, or even at the side of the artery—are, from the very liquid nature of the contained fluid, susceptible of impulse so marked as most accurately to simulate aneurismal tumour.

An interesting case in point occurred some years ago at the Hôtel Dieu. One of the most promising of its Surgeons, Dr. Gosselin, was almost on the very point of operating for supposed carotid aneurism, when the late Baron Roux entered the ward. His opinion being asked, he simply placed his hand upon the tumour, "Swallow," said he. Then, turning to his colleague, whispered, "It is a cyst," and left the ward.

This ready and correct diagnosis was made from the fact of the elevation of both cyst and larynx in one common mass during the act of swallowing, thus proving the tumour to be independent of the artery.

The disease described by the late Dr. Graves, and lately designated "exophthalmic goitre," is characterised by a marked erethism of the thyroid gland, combined with protrusion of the eyeball, and has at times throbbed so violently, and so exactly simulated aneurismal impulse, as to have left even the experienced Dupuytren in doubt respecting the real nature of the case.

Lastly, encephaloid tumour of the neck, embedding and moulding itself around the artery, and receiving, not impulse alone, but causing and conducting murmur, has more than once betrayed the operating Surgeon into error. The circumstance of non-aneurismal tumours causing and conducting murmur is a fact too important to premit.

From the earlier application of auscultation, almost to the present time, it has been thought that the stethoscope could enforce the diagnosis almost without appeal. But this is unquestionably an over-estimate of the power of the instrument, or, more correctly speaking, a false conclusion from the observed phenomena. Many aneurisms yield few or no peculiar signs, and none certainly that are pathognomonic. While, on the other hand, non-aneurismal tumours in contact with, and pressing upon, an artery may yield both shock and murmur. Other glandular tumours, as the thyroid, may, from their own special arterial excitement, yield both shock and fremitus, coincident with murmurs of the harshest and loudest character. But, dismissing these several sources of error, and assuming the general diagnosis correct, that the tumour is actually aneurismal, we have still left the difficult, if not impossible task, of assigning limitation to the track engaged. When we consider, on the one hand, that an aneurism, originating in the aorta, and involving its tributaries, may ascend the neck, even to the angle of the jaw; and, on the other hand, that an innominate or even subclavian aneurism, within the scaleni, may descend the chest, pressing on, or even displacing, the aorta, giving rise to intra-thoracic percussion dulness and murmur, it is obvious that we are at once deprived of the more ordinary grounds of differential diagnosis. In one well-known case the tumour corresponded to the track of the common carotid, and apparently descended to the clavicle. For this supposed carotid aneurism the carotid artery was tied, according to Brasdor's method. After death the case proved to be one of aneurism of the arch of the aorta, which, at its point of emergence from the chest, was so constricted by the first rib as entirely to have deceived the operator. Conversely, in another case, a pulsating tumour appeared between the second and third right ribs, finally extending over the sternum. The symptoms were—cough, hæmoptysis, dysphagia, feeling of cold down the right arm, with burning pain in the throat, syncopal phenomena, and irregular action of the heart. After death, the aorta was found intact, and the innominate artery alone aneurismal. In this case the most practised explorer would, probably, have been at fault. In other instances, so great has been the difficulty of diagnosis, that, although the carotid artery has been ligatured on Brasdor's plan, the operator has confessed himself unable to state what vessel was actually

involved. It was not that his sagacity was at fault, but that the difficulties of differential diagnosis were insurmountable.

It can scarcely be urged that these selections are exceptional, inasmuch as the special literature of this department offers many similar examples. I have only adduced a few, to illustrate the difficulties which beset the solution of the general problem.

(To be continued.)

### A CASE OF PROBABLE VACCINO-SYPHILITIC INOCULATION.

By ROBERT B. CARTER, M.R.C.S.E.

Fellow of the Royal Medical and Chirurgical Society.

THE researches of Mr. Hutchinson have made Medical Practitioners familiar with certain diseased conditions, long confounded with true struma, but now known to be produced by indirect syphilitic contamination. Mr. Hutchinson's own mind leans, I think, towards a belief that this contamination is invariably derived from one or both of the parents, and that its results may always be properly described as those of inherited syphilis.

During the last few years I have had opportunities of seeing many cases of the kind described by Mr. Hutchinson, and have always endeavoured to trace the history of the disease. In the great majority this history has been perfectly clear, and has led irresistibly to the conclusion that Mr. Hutchinson so ably advocates.

In a few cases, from the absence or death of parents, no confirmatory evidence of inherited disease could be obtained; but in these there was nothing to render the fact of such inheritance improbable. Until lately, I felt myself able to adopt Mr. Hutchinson's conclusions without reserve, and entertained no more doubt that the diseased states in question were always inherited than I now entertain that they are invariably syphilitic. A single case has, however, led me so far to modify my views, that I think it necessary to admit the possibility of other sources of contamination.

Some time in August last my attention was called to a little girl, eleven years old, who presented the characteristics of inherited syphilis in a very marked degree. With the exception of the labial cicatrices, she presented all the signs that Mr. Hutchinson describes. She was undersized and feeble, with mis-shapen extremities, earthy complexion, senile aspect, prominent frontal eminences, and depressed ossa nasi, giving to the face a peculiar look of concavity. Her teeth were dwarfed and peggy, the upper central incisors with marked crescentic notches. Her eyes had suffered severely from iritis and interstitial keratitis, and the lymphatic glands of the neck were enlarged. Altogether, her appearance was so striking, that no one conversant with the matter could have passed her in the street without observation.

The parents of this child, and her brothers and sisters, are not only healthy, but are positively exceptional specimens of vigour and good condition. It is nothing to the purpose to say that the father is a magnificent animal, who will not admit having had any illness of any kind within his own memory. The mother is a robust, active woman, who has had no abortions, and no ailments during pregnancy. The other children, taken collectively, form about as fine a family as I ever saw; and one of them is, I think, the finest child I ever saw. The syphilitic one is the eldest; and the next, eighteen months younger, presents no trace of contamination. She is strong, well-formed, active, with pretty features, good teeth, clear complexion, plenty of red blood, firm muscles, and well-shaped extremities;—a general description that would apply to all the rest. The mother states that the eldest child was in perfect health, and as fine a baby as the others have been, until, at between six and seven months old, she was vaccinated. From that time forward she has never been free from a succession of syphilitic ailments; and before that time she showed no sign of anything amiss.

Now, after paying due regard to the tendency of human nature to tell lies about syphilis, and after taking into account popular prejudice against vaccination as a cause of infantile disease, I think the case I have described is inexplicable on the hypothesis of hereditary transmission. I do not think it possible that disease of such severity could have remained dormant until an infant was nearly seven months old,

nor that it could have been so completely exhausted by the first child as to show no trace in the second, or in any subsequent ones. I do not think it possible that the mother of a child so thoroughly tainted could herself altogether escape; and I am driven to the conclusion that in this particular instance the syphilitic virus was derived from some other source than the ordinary one. Except inheritance, I can imagine no other likely source for this form of infection than the vaccination, and I see no difficulty in believing that lymph or blood might convey the poison as readily as spermatozoon.

A single case, of course, proves nothing; but I have thought this one worthy of publicity, in the hope that it may direct the attention of others to the questions it suggests. Hitherto the accusations against vaccination have been vague; but, if we assume that Mr. Hutchinson has proved the specific character of certain conditions, and if we then find these conditions under circumstances that preclude the probability, if not the possibility, of inheritance, we are surely driven to recognise another source of infection besides that with which we are familiar, and to take especial care that we are not ourselves the unwitting means of propagating "inherited syphilis."

Stroud, Gloucestershire.

### ON A NEW MODE OF PROCEEDING IN PLACENTA PRÆVIA.

By W. H. MOOR, M.D.

THE ordinary treatments of placenta prævia are so unsatisfactory in their results, especially with respect to the offspring, that any modification of, or change in them, likely to be of benefit in saving life, should at once be laid before the Profession, that it may be tried, and adopted, if found of use, or rejected, if otherwise; as the opportunities of one man are but slight for testing any new proposition in a thing of rare occurrence.

During the past ten years I have had in my practice six cases of placenta prævia, and, although all the mothers are living, the results with respect to the children have been exceedingly unsatisfactory. My usual practice has been to turn, but in my last case I adopted a different proceeding, an account of which I now give.

Mrs. K., aged 36, was taken in her fifth labour at 8 a.m., the first pains causing hæmorrhage. On examination, the os was sufficiently dilated to permit of the presentation being accurately made out, and nothing could be felt but placenta. During the day pains kept off; but towards 5 p.m. they recommenced, were short and slight, and each one brought blood. About 6 p.m., the os being sufficiently dilated to allow of the introduction of the fingers, I carefully separated the placenta from around the sides and front of the os, leaving its attachment behind untouched. I then passed my fingers beyond the part I had detached, and found the head bearing down. Seizing a portion of the membranes covering it between my fore and middle fingers, I withdrew my hand, losing my hold of the membranes when they were in vagina, by which means I plugged the os with the detached portion of the placenta and the unruptured membranes. Hæmorrhage ceased at once. After waiting fifteen minutes for pain, I gave a dose of ergot with brandy, and repeated it in half an hour, shortly after which good pains came on, and labour progressed and terminated in the natural manner, without further loss or danger, and the mother made a good recovery.

The child, to all appearance a seven-months' one, was still-born, but revived under the Marshall Hall method of artificial respiration; and, although badly nourished and weak, has got on well, and is likely to live.

From these facts I think I may reasonably conclude that had I delivered by turning, the child would have been irrecoverably still-born.

On examining the placenta, I found I had separated about one-third of it from its attachment to the uterus.

Buntingford, Herts.

WE hear that Mr. Henry Thompson, F.R.C.S., is on the point of leaving London for Brussels, to attend on the King of the Belgians, who still continues to suffer from calculus.

REPORTS OF HOSPITAL PRACTICE  
IN  
MEDICINE AND SURGERY.

CASES OF AMAUROSIS IN CEREBRAL  
DISEASE.

BLINDNESS is a common symptom in diseases of the nervous system, and in almost all cases of cerebral amaurosis the condition found by the ophthalmoscope is that known as white atrophy of the optic disc. Sometimes, when seen early, the optic disc is swollen, and the vessels gorged, as if the return of blood from the eye were impeded, as in one of Dr. Russell's patients, but after a time the appearance is pretty much the same as in the other cases—the disc is white, flat, and the vessels small. Atrophy of the optic nerve is sometimes found in patients who appear to be in other respects in perfect health, and again it is found clinically in cases so various that it seems difficult to gain any clear idea as to the value of this symptom. It is found in epilepsy (epileptiform convulsions), paraplegia, hemiplegia, and in association with minor paralysis, as paralysis of the motor nerves of the eye, the third, fourth, etc. A very common series of symptoms preceding this kind of amaurosis is violent pain at the back of the head and in the superciliary region, and frequent and distressing vomiting. These are the kind of symptoms so often associated with tumour of the cerebellum, in which blindness is so common. What is wanted are autopsies in which careful ophthalmoscopic examinations have been made at various stages of the disease during life. In cases of tubercular meningitis in children, when the very rare result—recovery—follows, blindness is not uncommon; and during life, if the ophthalmoscope were used, we should find, no doubt, changes in the eye either analogous to those in the brain, *i.e.*, disease of the choroid, the pia mater of the eye, or the results of pressure on the optic nerve, or the vessels at the base of the brain. The writer has twice made an ophthalmoscopic examination in tubercular meningitis, but in these cases the results were not very definite. In one the note is as follows:—"The optic disc (one eye only was examined) seemed white, but flecked with red minute points, the arteries were small, and the veins very large and dark. The edges of the disc were indistinct, and as if swollen." In another case in the last stage of meningitis, "I found simply that the disc was injected. It had lost the slightly rosy hue of health, and looked like a white spot coarsely smeared with red. The arteries were small and the veins large."

Not long ago the writer saw a young woman, who at first had severe headache on one side, distressing vomiting, and, after a few days, slight numbness in the left hand and left foot. She had then also great intolerance of light, but unfortunately no ophthalmoscopic examination was made. Altogether her illness was of about two or three weeks' duration. Her mind was quite good at that time; but after a few days she became delirious, then blind, and at length died in convulsions. In such a case an ophthalmoscopic examination during life, and a post-mortem examination would have been very valuable. Had she recovered she would probably have been permanently blind. The following case, in the severe pain and the sickness without evident cause, resembles the above, but it differs from it in being infinitely more chronic, and in ending in quasi recovery. The patient did not die, but was blind, epileptic, and hemiplegic. It is interesting, too, as regards the diagnosis early in the case, as the symptoms lead to the suspicion of "gastric fever." In young children sickness very commonly ushers in head symptoms, and it is singular how common it is for patients who have white atrophy to say that "it began by bilious vomiting." In all cases in which a person previously healthy has distressing vomiting, with dimness of sight and pain at the back of the head, the diagnosis should be made very carefully. Of course the vomiting and the amaurosis are not supposed to be necessarily the result of one cause. All we say is, that clinically they often occur together. In one case under the care of the writer there was a distinct cause for each. There was a small tumour near the pneumogastric, which probably, by irritating the nerve, produced the, apparently, purposeless vomiting. There was another tumour at the scella Turcica affecting the optic nerves. Very often the corpora quadrigemina and the pneumogastric are affected by the same tumour, as in tumour of the cerebellum.

HOSPITAL FOR THE EPILEPTIC AND  
PARALYSED.

SEVERE PAIN AT THE BACK OF THE HEAD,  
AND FREQUENT VOMITING, FOLLOWED IN A  
FEW MONTHS BY COMPLETE AMAUROSIS—  
EPILEPTIFORM CONVULSIONS AND PARTIAL  
PARALYSIS.

(Under the care of Dr. BROWN-SEQUARD.)

[Communicated by Dr. HUGHLINGS JACKSON, Assistant-Physician to the Hospital.]

A young woman, aged 19. She had had excellent health up to the age of 18. All the usual questions as to health in infancy, hereditary tendency, etc., were asked, but nothing throwing any light on the origin of the case was found, except that she had had rather a hard place in domestic service.

In August, 1861, she began to suffer sickness and severe pain at the back of the head, and also on the vertex. The sickness came on several times in the day, and she vomited frequently, not after food. At the same time, the eyes "turned into the inner corner," (paralysis of the sixth pair?) and she saw double, but in about a month the eyes were again normal, and the double vision was gone. The headache and sickness still continued. She was admitted into a Metropolitan Hospital, where, she says, she was told her illness was gastric fever; but this is doubtful, as she was cupped at the back of the neck. She was in the Hospital several months, the vomiting still continuing, and when she was discharged she was quite blind. The sight failed gradually, a "thick mist coming over the eyes." She has been blind ever since.

She had subsequently nine fits at various times in the year 1862. They began by a pain in the forehead; her head was drawn back; she fell, was insensible and rigid all over, and afterwards slept a quarter of an hour. She did not bite her tongue. When she came to the Hospital, in the May of that year, she had great weakness of all the limbs, especially in the left side, but no notable paralysis. She was quite blind. The pupils were widely dilated, so that they did not increase in size by atropine. The optic disc was flat, very white, and the vessels very small. The disc was slightly irregular, its edge being ill-defined.

She improved in health, and has been for several months quite well, with the exception of the blindness. This has not improved in the least.

VOMITING AND HEADACHE FOLLOWED BY  
AMAUROSIS AND EPILEPTIFORM SEIZURES—  
INCREASE IN SIZE OF THE HEAD.

(Under the care of Dr. HUGHLINGS JACKSON.)

A boy, aged 10, had been quite healthy until eleven weeks before Dr. Jackson saw him. His mother said that he then had "a bilious attack," and severe pain at the back of the head and at the forehead. He had the sickness, which was very distressing, only one day, but the headache continued for some time. Three or four weeks later he began to see badly, and in three weeks more was quite blind.

When Dr. Jackson saw him, except that he was quite blind, he was in apparent good health. He had no notable paralysis anywhere, but his mother said that in the streets he walked badly. He was also subject to "fits." He would suddenly fall down, but whether there was any convulsion or any real insensibility could not be ascertained. There was another symptom, however, which may perhaps throw some light on the case. His head was getting larger, but his mind was still very good. In many respects the case is like one recorded in the *Hospital Reports* for August 30, 1862, p. 224, and possibly may be due to a similar cause, *viz.*, cancer of the cerebellum. If possible the result of this case will be given. It is noted now chiefly as showing the insidious onset of severe intracranial disease. As usual, the optic discs were very anæmic, and the vessels small.

CASES OF TUMOUR OF THE BRAIN.

BIRMINGHAM GENERAL HOSPITAL.

INTENSE PAIN IN THE OCCIPUT, COMING  
FORWARD TO THE TEMPLES—URGENT AND  
FREQUENT VOMITING—RIGIDITY OF THE  
MUSCLES OF THE BACK OF THE NECK—  
IMPERFECT VISION—TUMOUR IN THE MIDDLE  
LOBE OF THE CEREBELLUM.

[Communicated by Dr. JAMES RUSSELL, Physician to the Hospital.]

THE case from which the following imperfect notes were made

occurred to me in the practice of the General Dispensary in the year 1851.

J. B., aged 51, glass-worker: His last illness commenced about six months before the date of my attendance, but he stated that he had suffered from an attack similar to the one under observation sixteen years previously. He then had severe pain in the head, and giddiness, and was ill, more or less, for three months. He was relieved by the application, at different times, of five or six dozen leeches. After his recovery he continued in perfect health up to the period noted above, save that his bowels were exceedingly costive. His habits were described as being temperate.

During the past six months he had suffered from repeated attacks of severe pain in his head, shifting from the occiput to the temples, and accompanied by giddiness. He had been at home for three weeks with these symptoms when I saw him, and had kept his bed for the three days immediately preceding my visit; he never left it again.

I found him lying on his right side, with his neck immovable, and his head buried in the pillow. He complained of very severe pain in the region of the occiput and of the posterior cervical muscles, and throughout our conversation never moved his head. He stated that he walked well, and I did not think it right to test his power in this respect, from the great pain excited by any movement. His eyesight, he said, had been rather dim for some time, but much more so for the preceding three days. His pupils were natural. He had frequent nausea.

His illness lasted from November 21 to January 18. The intense pain in the head never underwent more than slight and temporary abatement, until about five weeks before death, when it was disguised by delirium, and probably lessened by increasing dulness. It was seated in the occipital region, whence it passed round the head. The neck retained its fixed attitude, so that at last he could not be changed, and was fed by a spoon, and he often lay moaning from his suffering. Some tenderness was felt when the cervical muscles were grasped near their insertion, but no evidence of disease in that situation appeared.

By a strange omission, the state of vision is not again described, but the pupils are repeatedly stated to have been natural until December 13, when they had become dilated and torpid, and the eyes presented a peculiar stare. The only evidence of paralysis which was noticed was indistinctness of articulation, a symptom which increased as his illness progressed. Delirium made its appearance first by night, then frequently, but at first for a brief period only, by day, until he finally declined into a state of fatuity, and passed his evacuations involuntarily. Vomiting was present almost from the commencement of my attendance, and was throughout a very prominent, and sometimes a very urgent symptom. He emaciated progressively, and finally sank.

The functions, other than those noted, were performed naturally; his urine was free from albumen.

*Autopsy.*—The examination was of necessity confined to the head. The cerebrum was examined with great care, but was everywhere perfectly healthy. A tumour was found in the cerebellum, but so entirely buried in that organ, that not the least indication of its presence was afforded until the cerebellum was divided. It was globular; an inch and three-quarters in diameter, and lay chiefly in the middle lobe. It appeared to have an organic connexion with the central white matter of the cerebellum over its entire surface, though the nervous matter was easily separated from it. The surface of the tumour was covered with a gelatinous-looking matter, apparently from infiltration of straw-coloured fluid into the connecting material. It contained a small cavity at its upper part, filled with straw-coloured fluid; the main part lay below this cavity; it was very firm, and seemed made up of a white and grey material intermixed. The tumour had not altered the form of the inferior vermiform process, nor was it connected with the processes passing to the cerebrum.

#### GIDDINESS, FOLLOWED BY INDISTINCT VISION, AND IN THREE WEEKS BY COMPLETE BLINDNESS—HEADACHE—OPHTHALMOSCOPIC EXAMINATION.

[Communicated by Dr. RUSSELL.]

The following case is, and, unfortunately, will probably always remain, incomplete, as the patient has left the Hospital. Its details, however, are very interesting, and, together with the ophthalmoscopic examination, derive much illustration from

the cases lately reported in the *Medical Times and Gazette.* (a) The entire report coincides in some particulars with that of the case by Dr. Bader, inserted in the last number of *Guy's Hospital Reports.*

The patient left the Hospital eleven days after his admission. The history was taken by Mr. Haywood Smith.

H. H., aged 45, boatman. The replies he gave to very minute and careful inquiries indicated a state of perfect integrity as regards all the functions up to the date of his present illness. He has been perfectly temperate and very steady, never having placed himself in the way of contracting syphilis. He has been a hearty eater of meat. His trade has exposed him to cold and wet; and he says that lately he has been living in a damp house. He never met with any accident of importance.

Careful examination elicits a perfectly healthy family history, save that his father drank and had one fit; his mother died of a "bilious complaint."

About ten weeks ago the patient had had a pint or two of beer, but not enough to affect him. Three or four days after he observed a "sort of dazzling sensation" before his eyes, with a dull, heavy pain at the back of his head, but no vertigo. The dazzling left him in a day or two, and has not returned; but the pain increased, and obliged him to leave off work. His appetite failed, and what he took seemed not to digest; but his bowels were not costive, and he had no nausea. After the pain had continued about four weeks the sight became dim; he "could see his way about all right," but could not read; the eyeballs also felt cold. He did not observe that his vision was influenced by differences in illumination; but the blindness increased day by day, and at the expiration of three weeks his sight had totally left him, and he was obliged to be led about. During this time he noticed that his left eyelids would "sometimes stick together." The pain in the head remained little changed; it shifted about, but for the last three or four days has been principally confined to the region indicated by the junction of the occipital with the left parietal bone. His appetite has continued bad, and he felt low. There has been perfect absence of vertigo. He has the aspect of a healthy man, though his face is considerably injected. The eyes have the peculiar stare indicative of blindness; they are frequently winked. A pencil of vessels runs from the inner canthus of the left eye to a very limited patch of opacity at the inner edge of the cornea. The pupils are in a medium state, and quite uninfluenced by light; but during his stay in the Hospital they varied in size. His vision also underwent some changes; generally the blindness was all but complete, but once or twice he distinguished a sheet of white paper, once a wash-hand basin, though not its shape, and once he saw his dinner. The movements of the eyeball were unaffected.

When admitted, his hearing was perfect, but on the next day he complained, for the first time, of "a numbing sensation" in his ears, as of steam let off. At the end of a week it was noticed that he did not appreciate the distance of the speaker. Two days afterwards he was manifestly deaf, required the voice to be considerably raised, and evidently had no idea of the direction whence it came, for he turned his head quite away from the person who addressed him.

Muscular power was intact, with this exception, that he required five minutes to commence expulsion of his urine. He spoke of slight numbness in the ends of his fingers. His intellectual powers were remarkably acute; memory was unimpaired. The sounds of the heart were normal. His urine was quite healthy.

For the ophthalmoscopic examination, I am indebted to my friends, Mr. J. Beddard and Mr. T. H. Bartleet.

The transparent media of each eye were normal. Right eye: the choroid at the fundus appeared unusually vascular, but its vessels were normal. The optic disc, however, could not be distinguished from the surrounding fundus; it was exceedingly red and indistinct, and its position could only be traced by three or four tortuous veins passing into it. With this eye, at the time of the examination, the patient could distinguish strong light from the mirror, and white spots on his bed. Left eye: the vessels of the choroid appeared natural, but the optic disc and its margins presented marked deviations from health; its borders were in part ill-defined, and there were several spots scattered through it of pearly whiteness, as in atrophy of the nerve. The arteries could not be seen, but the veins, four or five in number, were large and tortuous,

(a) Series of eight cases of Disease of the Cerebellum, August 30, and October 18, 1862.

and appeared distended with blood. On the temporal side of the optic entrance (inverted image), at its upper part, were four or five irregular spots of ecchymosis, of florid red, lying close to the edge of one of the veins. On the nasal side (inverted image), at the lower part, was one spot of a brownish hue, looking like blood beginning to change. All these ecchymoses were about the size of a pin's head. With this eye the patient could not distinguish the strongest light from the mirror.

#### CENTRAL LONDON OPHTHALMIC HOSPITAL.

#### AMAUROSIS — OPTHALMOSCOPIC EXAMINATION — HYDROCEPHALUS — AUTOPSY — TUBERCULAR DISEASE OF THE LEFT LOBE OF THE CEREBELLUM — MICROSCOPIC EXAMINATION OF THE EYE.

(Under the care of Mr. HULME.)

For the notes and history of this case we are indebted to Mr. Aldridge:—

L. B., aged 5, a fine healthy-looking child was brought to the Hospital, November, 1862, with the following history:—About March of the same year the child was observed to show an unsteadiness upon her legs, attended with giddiness in her head, the general health being tolerably good; loss of power in the left hand supervened to this; she could not grasp anything, and gradually the left leg began to fail her. All these symptoms slowly increased till June, when the child could hardly stand at all. She was ordered into the country for two months, and returned home with improvement as to the power over her limbs, but complaining of headache, sickness, and gradual impairment of vision.

The symptoms on admission in November were—loss of vision, dilated and insensible pupils; loss of power over the lower extremities; head large; anterior fontanelles closed, but posterior open; pulse 100; tongue clean; skin natural; bowels regular.

*Ophthalmoscopic Examination.*—Media clear; optic disc large and white; outline indistinct and irregular, being encroached upon by the choroid; retinal arteries small and fine, but the veins much enlarged, tortuous and dilated with dark blood, especially beyond the margin of the disc; choroid much injected, and of a universal cherry-red colour.

Small alterative mercurial doses with iodide of potassium were prescribed; the sickness was relieved, but the symptoms gradually progressed, tenderness of the scalp being well-marked, with great intolerance of sound. Towards the end of the month the motions passed involuntarily. The patient then absented herself from the Hospital for two months. When Mr. Aldridge visited the child at the mother's house in March he noted that the head had considerably enlarged, with flushed countenance, clenched hands; motions involuntarily passed; the patient unable to rouse herself up; the right hand was œdematous. On March 18, the child became comatose and convulsed, and died on March 20.

*Post-mortem Examination Thirty-six Hours after Death by Messrs. Hulme and Aldridge.*—The bones of the cranium expanded; posterior fontanelle open; the membranes of the brain perfectly healthy; no deposits on their surfaces either at the upper or lower part of the brain; no effusion between their surfaces. All the ventricles greatly enlarged and full of fluid, distending the infundibulum and membranes at the base, the fluid escaping to the amount of 8 or 10 ozs. by rupture of the brain on its being lifted up; the lining membranes of the ventricles healthy and smooth, free from any tubercular deposit; the substance of the cerebrum healthy; but, on examining the cerebellum, the left lobe was almost entirely occupied by a hard, well-defined tumour, as large as a hen's egg, the condensation of the brain substance around it giving it an appearance as though surrounded by a capsule; the tumour itself was composed of a yellow, cheesy matter, which presented under the microscope the characters of tubercle; the remainder of the cerebellum was hollowed out into a cyst containing fluid, the walls of which were covered with an opaline transparent substance. The optic thalami tracts and nerves all appeared healthy; no tubercle was found in any other part of the brain. There never having been any manifestation of any visceral disease, the lungs and abdomen were not examined.

*Microscopic Examination of the Eye Fifty-six Hours after Death.*—The media were all transparent, the vitreous being of normal consistence; the retinal vessels fine, direct in their course, no rupture or extravasation to be detected, although

the capillaries showed here and there distensions of their diameters, with an accumulation of blood globules at these parts; the optic nerve fibres of the retina were almost entirely wanting, while the nerve-cells retained their normal relative conditions, the rods and bulbs rarely to be found; the choroid was stained with red colouring matter, but no extravasation of blood into its structure. Examination of the optic nerves showed some of the tubes shrunken, others filled with granular contents; cells with dark outlines being infiltrated between the tubules. The course of the disease, Mr. Hulme remarked, appeared to be:—1st. Tubercular deposit with effusion into the cerebellum, further extensive effusion into the ventricles, by which pressure was kept up upon the parts entering and leaving the orbital foramina. The loss of vision probably depended upon the atrophy of the elements of the retina most important to vision, viz., the retinal nerve fibres, and the rods and bulbs, by pressure on the optic nerves and their commissure. The eyes were preserved for examination in a weak solution of chromic acid.

#### GUY'S HOSPITAL.

This is another case in which blindness followed vomiting and headache. It resembles very much cases of disease of the cerebellum, in which these three symptoms are very common, but this part of the brain was free from disease. It is rather singular that there was no paralysis, as the thalamus opticus and the pons Varolii were pressed on. Nerve-substances will, however, bear a great deal of gradual pressure without manifest impairment of function:—

#### VOMITING — BLINDNESS — CEPHALALGIA — SUDDEN DEATH — FIBRO-NUCLEATED TUMOUR IN POSTERIOR LOBE OF CEREBRUM — DISEASE OF OPTIC TRACTS.

(Under the care of Dr. WILKS.)

A. A., living in Tiverton-street, in the Borough, aged 17. Had generally had good health. For more than a year she had suffered from violent retching, coming on several times a day; had also had difficulty in deglutition, so that she seemed to be choked while eating, as though she ate too fast, which was not usually the case.

About eight months before her death she gradually became blind; both eyes were simultaneously and equally affected (it is said). The blindness at last was absolute. She also suffered from pain in the head, especially at the back, but also in front; and on turning her head to the right, and then sharply back to the left, she used to feel something "move in her head," and had an impression of "light on one side," though without really seeing anything. For these symptoms she was attending as an out-patient at Guy's Hospital, under the care of Dr. Wilks. The night before her death she was unusually restless, complaining of headache, and "vomiting a dark blue fluid." In the morning she walked into the front room of the house, complained of "being very bad," lay down on the bed. Her friends thought that she had fainted, but found that she was dead. There was no dyspnoea or lividity.

*Autopsy and Microscopical Examination by Dr. Hilton Fagge, made the same day.*—Body scarcely cold. Head opened first. A considerable quantity of cerebro-spinal fluid escaped on removing it. A large tumour, more than three inches in diameter, was found, raising the convolutions on the left side posteriorly. This tumour was attached by its lower surface, and the greater part of its circumference was covered by the lining membrane of the ventricle, into which it projected. The lateral cornu was in front of it, so that it appeared to have originally grown from some spot in the position of the eminentia collateralis; it pressed forwards, so that the left thalamus was altered in shape; it was less grey in colour than the right, but not very soft. The growth also projected out beyond the median line, so that the pons was much flattened posteriorly and the parts about the origin of the optic tracts. The corpora quadrigemina were so distorted, that only two of them were distinct. The ventricles were dilated, and their angles rounded. The fornix and velum interpositum were present, but appeared stretched out.

On microscopical examination of the tumour, a great deal of it was found to have undergone fatty degeneration, containing fat globules and granule masses. The remainder contained nucleated fibres, elongated nuclei, and much transparent matter (periplast?) with a delicate border. The parts pressed on by the tumour were also carefully examined more than once. The left thalamus, though so altered in appearance, appeared to be of normal structure, a few granule

masses only being found in one specimen. The interior of the pons showed nothing abnormal, nor the corpora quadrigemina. The optic tracts, which were both very soft (the left so much so that it was not traceable as far as the corpora quadrigemina), were found to contain immense numbers of granule masses in their whole length, as far forward as the optic commissure. One of the optic nerves in front of the commissure showed nothing abnormal. The crura cerebri at the base, close to the diseased optic tracts, were normal in structure. The heart was natural in size, not contracted; lungs healthy; liver rather large; other viscera not examined. There can be no doubt that the diseased condition of the optic tracts extended towards the base in the course of their fibres, as the adjacent tissues were healthy. The exact cause of the right tract being involved was not made out; the greater part was out of the way of direct pressure, but its origin from the corpora quadrigemina may have been pressed upon. The patient's complaining of feeling something move in her head, with a subjective sensation of light, when she turned her head sharply, is perhaps worth noting, as the tumour was unusually movable, projecting freely into the ventricle.

**SEVERE ABDOMINAL PAIN AFTER EATING, FOLLOWED BY FEBRILE SYMPTOMS, INSENSIBILITY, AND GENERAL TONIC CONVULSIONS—DEATH THREE DAYS LATER—SMALL TUMOUR PROJECTING INTO THE FOURTH VENTRICLE.**

(Under the care of Dr. WILKS.)

Hannah A., aged 20, a servant living in Bermondsey. Her health was generally good, but she was a sulky, bad-tempered girl. On Tuesday, July 22, after eating a hearty meal of pork, she complained of severe pain in the abdomen. She went up to her room, where an hour or two afterwards she was found lying on the floor insensible, having apparently fallen out of bed. The doctor was called in, who found her gasping for breath, and holding her throat, but he considered it to be "nervous cerebral." During the following day she remained insensible, and the day after that, the 24th, she was admitted into the Hospital. She was then insensible; high febrile symptoms; there was a general tonic convulsion, the arms and legs being stretched out stiffly, and the fingers and toes curved. There was a general lividity and mottling all over the body, but no maculae. These symptoms continued until death next day, the 25th, about exactly three days after the attack.

*Autopsy by Dr. Wilks on the following day.*—The membranes and the brain were quite healthy, except as follows:—On laying open the lateral, with the third and fourth ventricles, a small tumour was seen, of the size of a small bean, attached by a little delicate areolar tissue to the right wall of the iter a tertio ad quartum ventriculum, below the corpora quadrigemina. It projected into the fourth ventricle, so that on opening the latter it was seen filling up the iter. It was detached by a slight touch. It was soft, and apparently composed of cerebral tissue, but the microscope showed that it consisted of delicate nucleated fibre tissue. The lungs were congested, but not excessively so, as found in fever. All the other organs were healthy.

**TYPHUS FEVER—CONGESTIVE PNEUMONIA—STRUMOUS TUBERCLE IN THE CEREBELLUM.**

(Under the care of Dr. GULL.)

William F., a labouring man, aged 28, was admitted into Stephen Ward, under the care of Dr. Gull, on January 12, 1856. He had had a cough for three months. There was no history of contagion. On December 28 he went to work, but was obliged to return in the afternoon, as he was then seized with severe headache and sickness. For three days before he had not felt well. He continued to grow worse until admission. He was then in a high state of fever, the body covered all over with a mulberry rash. He had also cough and expectoration. On the following day the sputa were streaked with blood, and on the 4th, the rash which covered every part of the body had become in places petechial. Ammonia and wine were ordered. At night he was very delirious. He daily grew worse; brandy was then administered, but the breathing became quicker, the spots more livid, and at the same time some small pustules appeared on the legs.

*Autopsy.*—Sinuses and veins filled with blood, pia mater congested, arachnoid slightly opaque in parts, and serum beneath the membrane in excess. The ventricles contained

rather more than a normal quantity of fluid. The surface of the choroid plexus, as well as their substances, contained irregular, firm granular deposits. The internal surface of the lateral ventricles was minutely granular. The septum lucidum was very thin. The lining membrane of the fourth ventricle was somewhat opaque. On the left side of the cerebellum, near the mastoid portion of the temporal bone, the membranes were firmly adherent from the development of hard tubercle nearly half an inch in diameter. Its centre was composed of cheesy substance, and this was bounded by firm semi-transparent tissue about one-eighth of an inch in width. It was composed of fibro-albuminous substance containing highly refracting particles. A somewhat similar but somewhat smaller tubercle was formed in the same lobe of the cerebellum, near the other, and embedded in the grey matter near the surface.

**TERMS OF SUBSCRIPTION.**

*Twelve Months (Prepaid) stamped for post* £1 10 0  
*Six Months (do.)* . . . . . 0 15 0  
*Regularly transmitted by Post throughout Great Britain, and to the most distant of the British Colonies.*  
*The Journal can be obtained of all Booksellers and Newsmen, Unstamped, for £1 6s. per Annum.*  
*Post-office Orders and Drafts on Army or Navy Agents, should be made in favour of Mr. JAMES LUCAS, 11, New Burlington-street, W.*

**CHARGE FOR ADVERTISEMENTS.**

SATURDAY, MAY 23.

**THE MEDICAL COUNCIL.**

THE Medical Council begins its next session on Monday. We are not amongst those who had great expectations of the benefits to be derived from its operations. There are many grievous wants of the Profession which it never can fill up. It cannot make men modest, studious, and public-spirited; it cannot cure Professional jealousy and back-biting; it cannot convert the pretentious semi-charlatan into a scientific man and a gentleman, and it cannot hinder the public from being fools, and running after and rewarding noisy and shallow quacks, whilst they neglect honest working men. Yet it may do something. It may attract the best of our youth from the best public schools by proper arrangements for the preliminary education of future members of our Profession, and it may discourage idleness and want of liberal education. If it cannot make the present what we wish, it may sow seeds for the future.

Should its deliberations be conducted with open doors, and be reported? All English human nature says, yes. If, as the apologists of the close system intimate, some members of the Council are so vain, unpractical, and self-seeking, that they will waste the time of the other councillors by making speeches to the reporters, why the sooner this is known the better. We, as a great Profession, want a Representative Council worthy of us. We want to know what they say and do, and to fix them with the responsibility.

The new Pharmacopœia will no doubt appear in time. Come when it may, it will be received with a chorus of discordant criticism, and will of necessity share the fate of most things which are intended to please everybody. We want settled formulæ for the combinations in most frequent use; but any attempt at an enumeration of drugs, or at presenting the Profession with "prescriptions" will fail. Every man chooses to prescribe for himself.

On the subject of repression of quacks and protection of legitimate Practitioners, we hope the Council will act up to

the limits of its authority. We cannot exterminate quackery ; but we can every now and then give it a hearty kick, and hold it up to the derision of the multitude.

#### THE FOSSIL MAN OF ABBEVILLE.

By the time that our readers peruse these remarks they will have probably learnt that all controversy respecting the authenticity of the human jaw found by M. Boucher de Perthes, on March 28 last, in the high level gravels of Moulin-Quignon, near Abbeville, is set at rest. The narrative of this most important discovery—important not only to anthropology but to geology—has been placed before the readers of the *Medical Times and Gazette* week by week during the last month, and they, like ourselves, have no doubt been struck with the discrepancy which prevailed between the opinions of the French and English geologists on the subject. Those who were well versed in the matter were, however, cognisant of the fact that nearly a fortnight ago Dr. Hugh Falconer, M.D., F.R.S., Mr. Joseph Prestwich, F.R.S., and Professor Busk, F.R.S., proceeded to Paris for the purpose of arriving, in concert with the French geologists, at some definite and reliable result. The scientific “champions of England” met by appointment with Professor Milne-Edwards, Professor de Quatrefages, President of the Anthropological Society of Paris, M. E. Lartêt, Professor Delesse, the Marquis de Vibraye, Professor Hébert, M. Desnoyer, Professor l'Abbé Bourgeois, Dr. Garrigou, M. Gaudry, M. Delanoue, and M. A. Milne-Edwards. Two entire days were spent at Abbeville, during which the whole of the evidences were thoroughly sifted. Much suspicion had been evoked in England respecting the fact that when the jaw from Moulin-Quignon was washed a dirty white colour was exhibited by the condyle, and also that when the flint implements from the same bed were thoroughly washed a dingy whitish colour was shown, markedly distinct from the metallic bronze-like tint of the flint implements and the jaw previous to being washed, and from the well-known colour of the “black seam band” of Moulin-Quignon. According to the statement in *L'Abbeville* of May 15, on Thursday week last, Professor Busk, who had been making various experiments on the colour, etc., of the beds, let a drop of the soil of the “black seam band” fall on the white ivory handle of his penknife. Next day, when it was dry, it exhibited a metallic reflection. However, on washing it, he perceived that the handle of the penknife remained, as before, perfectly white. To Professor Busk this explained the *vera causa* of the non-colouration of the flint implements, and of the whiteness which the interior of the jaw still exhibited. Mr. Busk communicated this discovery at once to Messrs. Falconer and Prestwich, who admitted the fact.

Messrs. Milne-Edwards, Quatrefages, and Lartêt—perhaps the worthiest representatives of French palæontology who could have been selected to perform this difficult task—never doubted the authenticity of the jaw. In the inception of the controversy, while the eloquent and masterly arguments of Dr. Falconer were being published in most of the scientific journals of Europe, the French palæontologists did not experience the slightest doubt of the truth of M. Boucher de Perthes' conclusions. In England a few voices were uplifted in favour of Boucher de Perthes, but out of the circles of practical anthropologists or geologists. Last Friday week, May 15, a day to be ever memorable in the history of geology, the French and English geologists, after due examination, arrived unanimously at the following conclusions:—1. That the jaw found on March 28 by M. Boucher de Perthes at Moulin-Quignon is really fossil. 2. That it was extracted by M. Boucher de Perthes himself from this virgin and undisturbed bed (*banc vierge, ou non remanié*). 3. That the flint implements which had been said to be fabricated by the workmen are incontestably ancient. After all these conclusions had been arrived at, the commission waited on M. Boucher

de Perthes to offer him their congratulations for this, the most important discovery which has ever been associated with his name. After examining into all the reasons, mostly of a technical character, which have actuated these distinguished geologists in the conclusions at which they have arrived, we feel it to be our bounden duty to declare our opinion that the first and second of their conclusions are unequivocally correct. The jaw is ancient; the soil containing it was undisturbed. As regards, however, the flint implements, we cannot, of course, give any opinion on those we have not seen, and of which Mr. Prestwich is stated to admit the authenticity. But the specimen which M. Boucher de Perthes gave to Mr. Alfred Tylor, and which the latter gentleman exhibited publicly at the Anthropological Society on April 21, as well as another specimen which is in England, and which were both derived from the “black seam band,” we still consider to be rank forgeries, and we feel gratified at seeing that Dr. Falconer declined to concur in the verdict which declared their authenticity. The presence of these forged implements, and of the admittedly spurious detached molar from Moulin-Quignon, with the jaw, has no doubt led to a large amount of the suspicion which was attached to the genuine human jaw. Other sources of scepticism were aroused, by reason of the dubious character of the original announcement of the discovery of the jaw to the scientific public, in which the alleged grounds on which its authenticity was inferred were not of a nature calculated to awaken the faith of men conversant with the subject. The jaw has, however, survived all this; the indiscreet support of its ardent friends, the steady opposition of so many illustrious geologists, and the load of rough flints which immediately overlaid it in the gravel-bed, have severally been unavailing to crush it. The fact has now to be admitted, and we trust the sooner the better, that the jaw from Moulin-Quignon is contemporaneous with the deposition of the “black seam band,” which was antecedent to the superjacent high-level gravels of the Somme valley. The bed belongs therefore to one of the most ancient of the drift deposits. We believe that Mr. Prestwich will shortly furnish a paper on the subject to the Geological Society. “What trick, what device, what starting-hole” is now left to the anti-geologists, who allege that because no human bones were to be found in the Somme drift, *therefore* no men lived in it, *therefore* the flint implements were not made by man, *therefore* they were fortuitous fractures, *therefore* man is exactly 6000 years old? We trust that the assailer of the principles of inductive science will pause before he reproduces this flimsy argument; since the days when De Vibraye explored the cavern of Arcy, it has been contrary to the actual fact; and now we have human remains in the tool-bearing drift of Moulin-Quignon, the repetition of the fatuous allegation should at once cease. Man, as evidenced not only by his works of art, but by his actual bones, was contemporary with the *Elephas antiquus*, and *primigenius*, with the old tichorhine rhinoceros, cave-bear, and cave-hyæna, while as yet the waters which then flowed in the Somme valley flowed 100 feet above their present level. One word more, as regards the moral aspect of the question. Too much credit cannot be given to Dr. Falconer, to Mr. Prestwich, and Professor Busk for the frank and manly way in which they have avowed their change of sentiment. The first-named gentleman especially was foremost to recognise the error of his previous written opinion, and to acknowledge the correctness of M. de Quatrefages' conclusion. The opinion which the French zoologist expressed, that the jaw resembles the jaws of many Esquimaux, is one in which we would ourselves be strongly inclined to concur. The following characters were observed by Professor Busk, who made a minute examination of the jaw, and sawed it across in the presence of the commission:—

“The black coating was washed off readily by means of a

sponge, and the residuary spots in the minute hollows were removed by the aid of a tooth-brush. The general colour of the washed surface was a light buff, mottled with brown stains. The outer surface was tolerably smooth, presenting little indication of the superficial erosion commonly seen in old buried bones. There was no appearance of dendritic patches either on the exterior or within, and no infiltration of metallic matter. The substance of the bone was dry and friable, especially towards the alveolar border, but, on the whole, it was tolerably firm under the saw, and the fresh section afforded a distinct odour of sawn bone. The internal cancellated structure was of a faint brownish tinge, and the cells free from any incrustation. The most remarkable appearance observable in the section was the lining of the dental canal with a thin layer of fine gray sand, free from admixture with the black metallic matrix which blocked up the orifice of the canal below the condyle. The section of the fang showed that the dentine, so far as exposed, was white, and in no respect different from that of a recent tooth. The enamel was white and brilliant. The socket towards the upper part was not completely filled by the fang, and the interval was partially occupied by black matrix and sandy particles."

While conceding to the Paris anthropologists, especially to MM. Quatrefages, Paul Broca, and Lartët, the credit of having been the first to interpret correctly the facts of the case, we consider that English science may be justly proud of such representatives as Dr. Falconer, Mr. Prestwich, and Professor Busk. Though these gentlemen at first, and with insufficient materials at their command, may have been led into an erroneous belief, they have been governed by that deference to the inexorable laws of truth to which all scientific men should bow, and they have by their full, frank, and manly admission of the accuracy of Boucher de Perthes, added new honours to the reputations which scientific England has long conferred on them.

### THE WEEK.

#### PARLIAMENTARY.

DURING the past week the principal subjects discussed in Parliament have had no particular bearing on Professional interests, or claims on Professional attention. On the 14th, the Irish Vaccination Bill passed through committee, and on the 18th it was read a third time, and passed. The Naval Medical Supplemental Fund Society Winding-up Act Amendment Bill was read a third time on the 15th, and passed. On the same night, in reference to the traffic in diseased meat, and in answer to a question put by Lord Raynham, Mr. Lowe, the Vice-President of the Committee of Education, announced that her Majesty's Government had received Professor Gamgee's report, and that it would shortly be laid on the table. On Tuesday night, Sir G. Grey promised that the voluminous papers in reference to the trial and commutation of the sentence of Jessie McLachlan should be submitted to the house.

On the 19th, in answer to a question put by General Buckley, as to the admission of fresh cases of small-pox into the workhouse of St. George's, Hanover-square, and other workhouses in the populous parts of London,

"Mr. Villiers said that he had not heard of any fresh cases of small-pox in the workhouse of St. George's or in any other of the workhouses of the metropolis; but he had heard that the malady generally was on the decline. Some weeks ago the Privy Council issued a circular to all the metropolitan unions, urging them to take precautionary measures with a view to the extension of accommodation for patients suffering from small-pox, and the Privy Council further issued a circular to the Poor-law Board, requesting them to urge upon Boards of Guardians to take such measures. Since that time, answers had been received from no less than 25 out of the 40 metropolitan unions, stating that their accommodation was more than adequate for the number of patients. With respect to the workhouse of St. George's, it might be satisfactory to the hon. and gallant general to hear a report had been made with respect to that workhouse within the last few days, from which

it appeared that a wing of the building had been set aside for small-pox patients, that the said wing was capable of accommodating 40 patients, that the greatest number in at any one time had been 30, that the total number admitted since the outbreak of the malady was 58, and that at present there were only 15 in it, the major part of whom were convalescent."

On the same evening, the Lord Advocate obtained leave to introduce a bill to make provision in regard to vaccination in Scotland.

#### ACQUITTALS ON THE GROUND OF INSANITY.

LAST week we noticed a case in which a public officer was condemned and fined by the verdict of a jury for placing a person whom he believed to be a dangerous lunatic under restraint. This week we have to record two instances in which murder was committed by persons who, although clearly insane, were allowed to continue at large. At the Central Criminal Court, on May 14, a woman named Harriet Goodliffe, the wife of an ostler, was indicted for the murder of her infant child by throwing it out of window. Her landlord deposed that "she had on several occasions acted in a manner that induced him to believe she was of unsound mind. Her conduct on April 25, the day of the murder, was particularly strange and incoherent, and it induced him to go to her apartment on three different occasions during that day. The last time he went he saw her standing at the window, the upper part of which was open, and she was hanging with her hands outside the window. The child James was not then with her; on the two former occasions she had the child in her arms." Still the woman remained at liberty, and the result was that shortly after one of her neighbours saw the child fall from the window. Mr. Tandy, of Spital-square, and Mr. Gibson, the Surgeon to Newgate, gave evidence that she was of unsound mind, and the jury on that ground acquitted her. In the Second Court, on the same day, Samuel Robinson, a deaf imbecile, was charged with the wilful murder of Charlotte Haines. Mr. Ribton, who defended the prisoner, raised the question whether a person who was both insane and deaf could be put on his trial. The judge, Mr. Baron Channell, said that the law required that, although a prisoner might be incapable of hearing, the indictment should be read in his presence, and witnesses as to his insanity and deafness examined. The only evidence taken was that of Mr. Gibson, who stated that

"Since the prisoner's committal he had seen and examined him frequently, and believed him to be insane. He had formed this opinion when he first saw him. The prisoner was, moreover, intensely deaf. When addressed in writing he could to a certain extent comprehend the questions put to him, but he had not sufficient intellect to understand the proceedings at a trial or the details of evidence, nor could he challenge a jury."

The jury immediately returned the same verdict as in the former case.

Such occurrences speak for themselves. The public and press will perhaps in time discover that it is a more serious error to treat madness as sanity than to mistake brutality and violence for madness.

#### THE SCOTTISH REGISTRATION OF DEATHS ACT.

THE Profession in England will sympathise with their brethren in the North in any attempt they may make to obtain a repeal of that penal section of the Scottish Registration of Deaths Act by which certificates of the cause of death are exacted by compulsion from the Medical Practitioner. At a recent meeting of the Medico-Chirurgical Society of Glasgow, a resolution was passed to petition Parliament "that the penal section of the Act, as far as it affects injuriously the honour and interests of the Profession in Scotland, be repealed." To say nothing of the manifest injustice of compelling any class or Profession to render gratuitous services to the State, the invidious distinction made between the Profession in England and Ireland

and in Scotland alone calls for a revision of the Act. How humiliating to an honourable and pre-eminently public-spirited body of men the law as it at present stands is, may be gathered from the admission of Sir Robert Peel, who, in introducing the Irish Registration Bill, distinctly alluded to the penal clause of the Scottish Act, and—as quoted by Mr. Walker at the meeting referred to—stated:—

“That from conversations he had had with the President of the Royal College of Surgeons of Ireland, and from information derived from other sources, he had learned that the method of obtaining Professional aid in the compilation of the statistics of the causes of death, as practised in Scotland, was altogether unsuited to the Irish character—that the Professional men in Ireland would never submit to be considered in the least degree inferior to their class in England—that they must be treated as gentlemen, and any attempt to coerce them to submit to the penal system as practised in Scotland would be met with contempt and scorn. Sir R. Peel therefore abandoned all idea of introducing a penal clause in his bill.”

The experience of the working of registration in England shows that a penal clause is entirely unnecessary. Its enactment for Scotland was a piece of mischievous legislation—fastening an insult on a body of highly-educated men, who have been ever foremost to serve the commonwealth, and utterly useless as a means of insuring greater statistical accuracy. We congratulate the Medico-Chirurgical Society of Glasgow and Dr. Ritchie, Mr. Walker, Dr. Thomson, and other speakers, on taking the initiative in this matter.

#### BRANDING IN THE ARMY.

WE understand that instruments for branding soldiers with the letters B.C. have been supplied to some of the military stations. We venture to repeat, what we have already said, that the branding of a soldier at his Regimental Hospital by his Hospital Sergeant, under the superintendence and instruction of his Medical Officer, is a most improper proceeding, and an indignity to the members of the Medical Department. The authorities may depend upon it that there will continue to be a paucity of candidates so long as these things exist.

#### THE WATER OF ST. GALMIER.

WE have to thank the St. Galmier Water Company for a specimen of their water. It is a cool, beautifully clear, sub-alkaline water, possessing most of the virtues of Seltzer water, and containing a good deal of carbonic acid, in such a state of combination that the water does not readily become flat. It is imported in Bordeaux wine bottles, each holding nearly three tumblers, and as the price per bottle is 7d., it follows that one glass costs about 2½d. St. Galmier may compete with Seltzer in the treatment of arthritic and dyspeptic maladies with acidity, and may be used at dinner or supper with any light sub-acid wine or with brandy. The London depôt is at 9, Duke-street, Portland-place.

## LOCAL REPORTS ON SMALL-POX.

(Continued from page 514.)

X. *Holborn District.* By SEPTIMUS GIBBON, M.D., Medical Officer of Health for Holborn District.

THE epidemic is passing, if it has not already passed, over this portion of the metropolis much more lightly than did that of 1859-60. During the former epidemic there were forty-six cases and fourteen deaths, whereas in the present, out of sixty-one cases, there have been only seven deaths.

This satisfactory result is doubtless owing to the stimulus given to vaccination—a result satisfactory only as compared with other years, for it must be borne in mind that this district is seldom free from sporadic cases of small-pox, owing to the character and habits of the population, which includes a large number of Irish and Italians, whose tramping habits expose them to infection, and whose children, if registered

at birth, which perhaps is oftener the *exception* than the rule, are never vaccinated without extraneous pressure. The annual average of small-pox cases amongst the paupers during the six years ending Lady-day, 1862, was thirty-five, and the average number of deaths amongst all classes was fifty-six.

A few cases occurred here in November and December last, but no death resulted. In the week ending January 24, the disease was again imported into the district simultaneously in widely separated localities. It has never exhibited a tendency to spread, even from room to room, much less from house to house, but has for the most part victimised the members of the same family, who had seldom been protected by efficient vaccination. The deaths all occurred to unvaccinated children, five out of the seven to children of ages varying from *four months to two years*, and only two to boys aged ten and eleven years respectively. A like proportion holds with reference to ages of the children attacked, who did not die, viz., about 70 per cent. of the cases were amongst children under three years of age. These facts warrant me in attributing our comparative immunity from the disease to the great extension of vaccination which was effected in the first three months of 1860. That we have had so few deaths, although many of the cases were unprotected and of the severest character, is undoubtedly due to the assiduous attention and skilful treatment of the parochial Medical officers.

As it is one of my specified duties “to take cognisance of all sources of unwholesomeness arising from neglect of vaccination,” in common with other Medical Officers of Health I have endeavoured, as much as practicable with the means at my disposal, to promote vaccination. The measures adopted have been the examination of all school children, the issue of public notices, the service of orders on the unvaccinated, and, lastly, a measure I consider the least troublesome, the cheapest, and the most efficacious plan in a population such as this, where many births go unregistered:—Some of the public vaccinators, at my suggestion, have made a house to house inspection of the children in the poorest and most populous courts and alleys, with a view to vaccinate any who are found not to have been vaccinated. Of course, to have the full value of such preventive visitations, they ought to be periodical, annual, or biennial. The main obstacle to carrying out this plan is the miserable fee allowed by the guardians for the operation, to meet which difficulty I propose that the local sanitary authorities should pay the public vaccinator at so much per house or per family for the inspection, in addition to the 1s. 6d. fee for each successful operation paid by the Poor-law Guardians. In order to prevent any abuse of such visitations—and they might lead to great abuse in respectable streets and places—they ought only to be instituted on the requisition of the sanitary authority and the Medical Officer of Health.

During the former epidemic I had my attention directed to several cases of wilful neglect or refusal of vaccination, the particulars of which I was directed to forward to the Board of Guardians for prosecution; but for various reasons, such as the illegitimacy of the children, the poverty of the parents, etc., that Board did not think fit to institute proceedings. During the present outbreak I have only met with one such case,—it was that of a working coach-builder, who declined to act upon the advice of his Medical attendant and have his two young children vaccinated. The youngest, aged two years, died of small-pox; when, as the parents persisted in their refusal to have the other child, about a year older, protected, I threatened them with a coroner’s inquest, and gave the particulars to the summoning officer. This had the desired effect, which I doubt whether a penalty of 20s. would; the child was vaccinated in time to modify but not prevent the infection. The cow-pox and small-pox ran a simultaneous course.

About three weeks ago, when acting as examiner for a life insurance company, I declined to certify a life aged twenty-seven as eligible for insurance until the man had been vaccinated. He informed me that he was one of a family of nine children, all of whom refused to be vaccinated, because their parents had been prejudiced by some particular case in which they believed that serious disease had been inoculated together with the vaccine matter. His scruples were overcome by my telling him that he must either forego the assurance or be vaccinated. I postponed my report for a week to afford him an opportunity of having the operation performed, at the end of which time he presented himself duly vaccinated. These

are the only two cases of conscientious objection to vaccination that I have met with during the present year. I think that the neglect in my district arises more from apathy and ignorance than from prejudice.

The following extract from the *Times* of Friday, May 15, 1863, has reference to one of the most dangerous foci of contagious disease in London:—

“CLERKENWELL.—Michael Roach, William Hayes, and Michael Collins, the keepers of Nos. 1, 2, and 3, Charlotte-buildings, Gray's-inn-lane, were summoned, at the instance of the Board of Works for the Holborn District, for having their houses so overcrowded as to be prejudicial to the health of the inhabitants.

“Charlotte-buildings is a narrow court, which has long been known as one of the fever dens of the metropolis, and for years past the owners of the houses have been summoned for permitting nuisances and overcrowding. The houses are very small, and contain no more than eight rooms. According to the evidence of Mr. Charles Henry Brown, the inspector of nuisances, he found in the house No. 1, 28 persons; in No. 2, 35 persons; and in No. 3, 29 persons. Several notices had been served on the defendants to reduce the number of their lodgers, but without effect; hence the present summonses.

“Dr. Septimus Gibbon, M.D., Medical Officer of Health for the Holborn District, said that none of the houses should have more than 24 inmates. Each inmate should have at the very least 300 cubic feet of air, but in the rooms in the houses complained of it ranged from 140 to 240 feet. In Charlotte-buildings small-pox and fever were raging, and, if this overcrowding was not put a stop to, he was afraid that the most dangerous results might arise to the community generally.

“The defendants, in reply to the charge, said that they were not aware that they were doing wrong.

“Mr. Barker made an order for the reduction of the number of inmates, so that they should not exceed 24, and gave the defendants until Monday next to comply with it, at the same time telling them that if they did not carry out his order he should inflict the full penalty of 40s. per day.”

#### XI. Rotherhithe. By W. MURDOCH, M.D.

IN the early part of this month I ascertained that there were in this parish about twenty-five cases under treatment, the most of them being of a very mild character. Since January 1, 1863, there have only been three deaths from small-pox among a population of nearly 25,000 souls; namely, one in February, and two in April. During the last week the disease appears to have considerably declined.

All the children in the public schools have been examined by the Medical officers of the parish, and many of them been re-vaccinated. The Board of Guardians also have passed resolutions to meet any emergency which may occur.

I do not think that Rotherhithe has suffered so severely during this present epidemic as many other metropolitan parishes.

#### XII. St. George, Southwark. HENRY BATESON, M.D.

I WILLINGLY give all the particulars I can gather respecting the present epidemic from the materials in my possession. The time included will commence with the week ending Saturday, January 3, 1863, and conclude with that ending Saturday, May 2. During this period there have been registered 39 deaths from small-pox; of these 18 were males and 21 females. The ages reach from 10 days to 48 years; there were 9 under 1; above 1 and under 5, 15; above 5 and under 20, 7; and above 20, 8.

The district of St. George the Martyr is divided into three sub-districts, in which the deaths were distributed as follows:—In the Kent-road sub-district, 16 died out of 19,652 persons; in the Borough-road sub-district, 17 died out of 16,668 persons; and in the London-road sub-district, 6 out of 19,190 persons. Thus 0·81 died per 1000 in the first sub-district; 4·02 in the second; and in the third 0·31.

What has given such immunity to the London-road sub-district I cannot tell, as it abounds with all those causes which tend to foster and spread epidemic diseases, if not create them. The Borough-road sub-district, in which the mortality has been highest, is the worst of the three as regards its sanitary condition, having within it more courts, alleys, narrow streets, and houses unfit for habitation, as well

as being more overcrowded. Six deaths were registered from small-pox in one week. Three deaths are the most that have occurred in one street, and that was Mint-street—one of the worst in the above sub-district; and two deaths in each of two other streets; hence the deaths have been pretty fairly divided. Eleven deaths happened in January, 6 in February, 11 in March, and 11 in April. Amongst the victims were a mother and infant ten days old. The majority of the cases were stated to have been vaccinated; but in coming at the truth upon this point considerable difficulty exists; for when death has taken place, and inquiry is made, the parent or relation, when the child has not been vaccinated, thinks an important duty has been neglected, and will give an evasive answer, or will not speak the truth; consequently, some are said to have been vaccinated when this is not the case. Sometimes there is ignorance about the fact; and sometimes the family have left the house. In two cases, where two of the children who had the small-pox had been vaccinated and two not, the two former died, whilst the latter recovered; and in another case, where three children suffered from this disease, the one out of the three which had alone been vaccinated had the disease the most severely, and was the only one marked.

It is perfectly clear that a single vaccination is not sufficient to ensure freedom from an attack of small-pox, and it is quite as clear, I think, that re-vaccination would; hence it only remains that this subject be strenuously urged upon the attention of the public. If every child was vaccinated within the time prescribed by the law, this might not be necessary, as the generating fresh supplies of the poison would cease. Apparently, however, there exists great difficulty in carrying this out, owing to obstinacy, ignorance, and other causes. The only way open for the present, then, is re-vaccination.

#### XIII. Whitechapel District.

THE following are the cases of small-pox among the pauper population which have been attended by the Medical Officers of the Union, and also the deaths of all persons who have died from small-pox from October 4, 1862, to May 9, 1863. I have no means of knowing the number of cases which have occurred among the ratepayers generally.

For the week ending October 4, 1862, the Medical Officer of the Union attended three cases of small-pox, and one death in the district was recorded by the Registrar-General:—

We extract the following from Mr. Liddle's report on the health of Whitechapel in the first quarter of the present year:—"The present epidemic of small-pox has now prevailed during the last six months, 48 deaths having been registered, and 167 cases of the disease having been recorded by the Medical Officers of the Union during that time. As early as February 2 last, I addressed a letter to the guardians, drawing their attention to the fact that small-pox was very prevalent in the Union. Upon the receipt of my letter, the guardians held a conference with the several vaccinators of the district upon the subject, and the result of the conference was the issuing of notices calling the attention of all persons to the penalty for neglecting to have their children vaccinated. The issuing of these notices has been the means of extending vaccination among the children residing in the district. If the public vaccinators of the district were required not only to perform vaccination at the appointed stations, but also to call at every house in their respective districts where there had been a child born within three months of such call being made, and then to offer to vaccinate the child, the usual excuses on the part of parents, such as the want of time, etc., to take the child to the public station, could not be made, and the result would be that many more children would be vaccinated. It is no doubt certainly better for the successful performance of vaccination that all children should be taken to the public station, but as all parents cannot be prevailed upon to do so, it is absolutely necessary, if vaccination is to be extended to all, that a similar mode to that generally adopted by Medical Practitioners to their private patients should be acted upon, viz., to vaccinate children at their homes. The benefits resulting from vaccination are not exclusively confined, as is often supposed, to the child successfully vaccinated, but the public generally are benefited by each successful case of vaccination, for as the greater is the security given to any child from an attack of small-pox by vaccination, so is the public rendered more safe from the ravages of the disease by diminishing the number of *foci* of communication."

XIV. *Short Report on Small-Pox in Islington.* By EDWARD BALLARD, M.D., Medical Officer of Health.

THE present epidemic of small-pox I consider to have broken out in Islington towards the close of the month of October last. The institutions, etc., from which I habitually receive returns of sickness are the Workhouse, the Infant Poorhouse, two Dispensaries, and the Pentonville Convict Prison, and, in addition to these, I have returns from eight parochial Medical Officers. Now, amongst all these, prior to the month of October, there occurred only 12 cases of small-pox during 1862. During 1861, only 27 cases altogether had occurred. In the month of October, 1862, there were 4 cases returned to me, in November 9, and in December 55. To take the deaths from small-pox. The parish embraces an area of 3127 acres, and a population at the last census of 155,341 persons. During 1861, there occurred but 6 deaths from small-pox. With the exception of 2 in March, there were no deaths registered from small-pox in 1862 until November, when 2 were registered, both cases occurring in unvaccinated children. In December the fatal cases rose to 9. It is scarcely necessary to say that I do not include in the enumeration any deaths in the Small-pox Hospital in this parish, unless of persons who have entered it from Islington. In January of the present year the cases returned to me were 25, and the registered deaths 9; in February the cases were 32, and the deaths 3; in March the cases were 40, and the deaths 13; in April the cases were 60, and the deaths 10; and in the course of the first three weeks of May the cases have been 84, and the deaths in the first two weeks 7. A large proportion of the cases are modified by vaccination. In the workhouse only one case occurred—in a tramp—and none have occurred at the infant poorhouse.

Few cases occurred in the practice of private Practitioners until March, when numerous cases were reported to me, the earlier cases having been almost confined to the poor. Altogether the largest number have been met with in the lowest neighbourhoods, where at all times disease is most rife, and mortality highest. The first cases occurred in that part of the parish in which the Small-pox Hospital is situated, but almost simultaneously the disease also broke out at the opposite extremity of the parish. The largest number of cases have been in persons approaching or above the age of puberty, the young have appeared protected even by an indifferently successful vaccination. Cases of small-pox, indeed, amongst children, with one, two, or three indifferent cicatrices, are by no means rare, but the disease is so greatly modified as to be reduced to little more than a trifling ailment. One can scarcely contemplate without a shudder what this epidemic would have been but for vaccination. To decry it, as some are now doing in the public papers, is cruel and wicked. The fatal cases have been either in unvaccinated or very badly vaccinated children, or in adults whose arms have only exhibited the marks of indifferent vaccination performed in infancy, or who have never been vaccinated at all. One unvaccinated man, who died, had lived for fifty-nine years without having taken the disease before. I have yet had no fatal case registered where vaccination had been thoroughly well performed in infancy.

*Preventive Measures.*—As early as the month of October last year I drew the attention of the Poor-law authorities in Islington to the commencing epidemic, and on my advice they issued a circular to the public vaccinators, urging them to increased vigilance and activity in seeking out unprotected children; and, as the disease extended, small hand-bills were printed, and distributed to every family residing in any street where a case of small-pox was known to have occurred. The parochial Medical Officers were also directed to re-vaccinate all adults who were willing to submit to the operation. In consequence of these measures both the primary and re-vaccinations were enormously increased.

Where small-pox broke out, any charitable schools in the neighbourhood were visited, and the arms of the children examined. As the disease progressed during the early months of the present year, the children in private schools, and other establishments to which the public vaccinators have no access, were re-vaccinated by the Medical attendants of the institutions, etc. The Poor-law authorities decline to put into force their powers under the Compulsory Vaccination Act. For many years past this parish has had a carriage for the conveyance of small-pox cases to the Hospital; but, notwithstanding, numerous cases both from this and other parishes go there in cabs, which, on depositing their fares, immediately go upon the stand in Upper Holloway. Persons have been seen to enter such vehicles shortly after the latter have left the premises of the Small-pox Hospital. Some of the more respectable cab-proprietors in Islington, I am informed, refuse the use of their cabs for the conveyance of such cases.

The parochial officers have directions to send as many of their cases as they can persuade to go there to the Small-pox Hospital, and many have been thus accommodated. There prevails, however, a good deal of prejudice among the poor against taking advantage of this Institution, and large numbers refuse to go there, and consequently have to be treated at home.

During the past week I have had afforded me the assistance of a special vaccine inspector, a Medical man, whose duty it will be to visit all the low neighbourhoods where cases of small-pox may occur, to vaccinate all that he finds unvaccinated, to re-vaccinate all who will submit to the operation, to inspect schools, and to report to me all unsanitary conditions that he observes. The Sanitary Committee of the Vestry have determined to insist upon immediate amendment of the latter conditions, and the Poor-law authorities to receive from me recommendations for the destruction of infected bedding, etc., and for the supply of fresh articles in place of them. The contractor has orders to cleanse *daily* such of the low courts and alleys as I may place upon a special list for the purpose, and a man is engaged to see that the privies in the Irish courts are kept clean, and to disinfect them daily with MacDougal's powder.

In consequence of the great extent to which re-vaccination is now being carried on among all classes of persons, there arose great inconvenience among private Practitioners from the difficulty of obtaining lymph, and keeping up their own supply from primary cases. To meet this, after consulting with several of those in most extensive practice, I have

arranged to receive lymph upon points from all who have primary cases, and to be a medium of communication between them and such as happen to lose their supply. By this plan no time is lost, and any Practitioner on any day that he may be in difficulty can be replenished from the lymph in my hands. The system is working well, and to the satisfaction of all parties. During the past fortnight I have thus supplied over 300 charges to the private Practitioners in Islington, several of whom have publicly thanked me for taking this step.

XV. *North District of Poplar Union, comprising Parishes of Bow and Bromley. Joint Population upwards of 40,000.*  
By THOMAS ANSELL, M.D., Medical Officer of Health for North District, Poplar.

IN this district I am gratified to state that small-pox—at least of a fatal character—has not prevailed extensively; sixteen deaths from that disease only have been registered during the current year. Of these, ten were never vaccinated, three died after vaccination, and three were not recorded—whether vaccinated or not.

The various parochial schools, numbering 1150 scholars, have been re-vaccinated.

Dr. Woodforde, Parochial Surgeon of the Bromley District, informs me that, out of 670 children examined by him, he found 29 unvaccinated, and about 30 per cent. of the scars of previous vaccination unsatisfactory. He also calculates that about 3 per cent. is a probable average of cases of small-pox after vaccination.

All the fatal cases above mentioned took place in that part of the parish adjoining Poplar, where the disease raged violently, and the people of the poorest class.

I would suggest that every Medical man attending small-pox cases should fill up a form similar to the following:—

<i>Small-pox.</i>	
A.B., modified or severe. Vaccinated or non-vaccinated. Fatal or not.	} As the case might be.

And would direct it to be forwarded to the Medical Officer of Health. We should thus get at some test of the preventive value of vaccination.

I may add, as a matter of curiosity, that we have an old woman here who took small-pox, having been vaccinated by Jenner himself.

## UNIVERSITY COLLEGE, LONDON.

As promised in our last number, we now lay before our readers some of the remarks made by Dr. Parkes at the late distribution of prizes in this College, feeling as we do that they are deserving of the attention of every student of medicine, no matter to what school he may belong.

LADIES AND GENTLEMEN,—I am quite sure that you will permit me to offer in the name of this assembly our hearty congratulations to those gentlemen who have so distinguished themselves to-day; not merely because they have gained in honourable rivalry so many medals, but because in gaining them they must also have acquired the things which these prizes typify. They must have acquired habits of industry, accuracy of thought, excellence of memory, and, to a given extent, knowledge of their Profession. And, in congratulating them, I will also express a hope that they will consider these prizes merely as steps, not as goals; as means, not as ends; as incentives to perseverance and progress, not as signals for cessation from labour. Cessation from labour comes to no man, least of all to men of our Profession, with its incessant progress and its ever-widening area. But if there be no cessation from labour, yet as we advance labour becomes less laborious; the grooves of thought become smoother, and the habits which required emulation, and rivalry, and prizes, and medals to excite and sustain them in our youth, become a part of ourselves, and, ceasing to be labours, are transformed into pleasures. Into that career of wholesome and pleasant labour our prizemen of to-day have entered; they must hold fast by what they have won; remembering and encouraging themselves by the remembrance that the first steps of application are the most difficult, and that they have happily passed over that rugged introduction to science which doubtless has both tested and developed their resolution and their industry.

But in congratulating our prizemen, we ought not to forget

the unsuccessful competitors, the gentlemen who have won no prizes. It is possible that these gentlemen will think it rather paradoxical if I congratulate them also, and will consider it no compliment to be told that they are all the better men for being beaten. But something may be said on that score. There is an old saying:—"He stands not surely who never slips;" and certainly there is no such teacher as Failure; how usefully not only in our college exercises, but throughout life, does failure come in to show us our deficiencies, and to admonish us that there is something which must be probed and mended.

Ask any man of experience what has acted most beneficially on his character, and he will refer, not to his successes, but his failures. "Sweet are the uses of adversity." And even in a failure for a college prize may arise an improvement which may act on the whole character. Let any man who has failed ask himself whether there is not something to amend; a want of industry, a want of purpose or method, an over-estimate of himself or an under-estimate of others, and if he rightly conducts and acts upon this self-examination then we may safely venture to congratulate him even on his failure.

There is, however, in every college a third class of students—here I hope a small one—who cannot I am afraid in any way be congratulated, viz., those gentlemen who have not contended for prizes at all. There are some who will not compete, either from idleness, or from fear of being beaten, or by a fancy that one subject may take up too much time, or by what they consider a philosophical contempt for such rewards. But search well into the motive for such inertia, and we shall very seldom find it a sound one. And every one should remember that the working for the prize is the real gain, not the prize itself; and certainly in the working for prizes, in the sustained industry it calls out during the whole session, in the reconsideration of all that has been gone through which it renders necessary before the day of competition, nay, even in the task of answering a number of questions rapidly in a short time on the day itself, are precious means of education which no student is wise to throw aside.

On the whole, the advantages of the prize system so preponderate over its disadvantages, that without it there would be a great falling off in the aggregate amount of learning acquired in a given session; but the full uses of the system will never be called forth until the emulation extends to the whole college; till every student competes, not with the mere wish of proving superior to his neighbours, but as a means of compelling himself to war against idleness and carelessness, and inaccuracy, and distaste, and to sustain the feeling of duty by the stimulus of an honourable emulation.

And now let me say a few words to those students, some of whom, I hope most of whom, are among the prizemen of to-day; I mean those to whom this is last prize anniversary, and who are about to pass out of these gates into the crush and turmoil of the world. They will enter in fact into another college, where education, if differently conducted, is not less real and continuous. And I believe that it may be said for our Profession that intellectually and morally it educates those who practise it as well as any other, and probably better than most. For intellectually what can be a better training for the mind than the science of our day, bold yet cautious; wide yet deep; sceptical yet believing; holding what is old, yet striving for what is new; like Janus having two faces, one looking to the past and one to the future. The true science of our day does really carry out the precept given us for a different matter, viz., "Prove all things, hold fast by that which is good." And in this proving all things lies one of those difficulties which are our best educators. It is no easy matter for the mind to hold the balance even between old and new, and to be neither too stubborn to retain, nor too rash and eager to receive. And yet this is a state of mind which we must sedulously watch and strive to acquire. And I believe that those who are leaving this college will hereafter say that the education they have received here has greatly aided them in the acquirement of this power. For it is the legitimate boast of those who administer University College that, standing on the old ways, they have yet often been the first to open fresh roads, and by happy innovations, which are not destructions, they have greatly advanced and benefited the teaching of Medical Science.

WE understand that Dr. Alex. A. Macdowall, of Helensburgh, was, on Wednesday last, elected a Fellow of the Royal College of Surgeons, Edinburgh.

## REVIEWS.

*Lectures on Syphilitic and Vaccino-Syphilitic Inoculations; their Prevention, Diagnosis, and Treatment.* Illustrated with coloured plates. By HENRY LEE, F.R.C.S., Lecturer on Surgical Pathology at St. George's Hospital, Senior Surgeon to the Lock Hospital and Asylum, etc. London: Churchill and Sons. 1863. Pp. 335.

"THE first edition of these Lectures was published in 1854. The distinctions between the different *modes of origin* of different syphilitic affections were then for the first time pointed out." Mr. Henry Lee must have the full credit of this important step in the acquisition of the true natural history of syphilis. "As observed in practice, the results of (syphilitic) inoculation afford considerable variety; when artificially performed they are much more uniform. Four distinct and well-marked processes may follow syphilitic inoculation: 1st. The inoculated part may become affected with the adhesive form of inflammation, in which lymph is poured out either in the substance or on the surface of the part. 2nd. The absorbents may assume an active share in the morbid process, taking up some of the infected parts, and with them portions of the syphilitic poison." This Mr. Lee calls "lymphatic absorption." "3rd. The inoculated part may, within a few days of the application of the poison, be affected with suppurative inflammation; and 4th. The morbid action may terminate in mortification." Although these processes, "essentially distinct, when once developed, usually maintain their original character until the termination of the disease," the action will, nevertheless, occasionally become changed, and this, if careful attention be not paid, may lead to an error in diagnosis. Thus "it must always be borne in mind that the character of a sore at one time is no certain indication of what it may previously have been, or of what it may ultimately become." A tendency to production of more than one morbid action may arise from a "twofold inoculation" at the same time at one spot. This summary of our author's introduction will put our readers in possession of the truths which Mr. Lee established in 1854. In 1855, M. Clerc arguing from the dogma of Ricord, then in the ascendant, that a person can have syphilis but once, announced the doctrine that the secretion from an indurated sore could not be inoculated on a patient whose system had once become syphilitised. As an *a priori* deduction this was well enough, but as no cases were published, the credit of establishing the doctrine in the only way that can be satisfactory to Medical men lies again with our own countryman, who proved the fact and published in the eighteenth volume of the *Brit. and For. Med.-Chir. Rev.* (1856) the cases on which he based its truth. The present edition of the Lectures brings into a focus the results of Mr. Lee's labours and experience from that period to the present time. We will endeavour to point out what some of these results are, for although they may mostly be gathered from other sources, yet the information is scattered over the pages of a variety of transactions and periodicals.

1. As to the question of unity or variety in syphilitic poison, Mr. Lee takes the view that it is not necessary to assume the existence of more than one syphilitic poison in order to account for the various kinds of sore met with in practice. It is true that the indurated sore and its modifications, a form of disease which has a long incubation, the secretion of which is not pus, but consists of epithelial *débris*, globules of lymph, more or less perfect, or disintegrated, and of turbid serum, which produces a papule, and not a pustule, on artificial inoculation, which is (after the formation of the induration) not auto-inoculable, and which is accompanied by multiple indolent enlargement of the lymphatic glands, and followed by constitutional syphilitic manifestations, is distinct in its course and results from the sore which suppurates, has not a lengthened incubation, produces a pustule when the secretion is inoculated, is throughout auto-inoculable, is accompanied by suppurative enlargement of the lymphatic glands, and is not followed by secondary symptoms. Nevertheless, he is of opinion that the poison may be one, but acting in different modes. The reason he assigns is that "it does not follow, because we can distinctly trace so many morbid processes, that there are the like number of morbid poisons. . . . It is more in accordance with strict inductive science simply to describe the different *modes of action* which occur after impure contact, than to ascribe each to a different

poison." As Mr. Lee wisely abstains from asserting anything more than the possibility of the unity of syphilitic poison, we must say that, while the question is *sub judice*, his hypothesis forms a neutral ground upon which all parties may meet to discuss phenomena. There is much to be said on both sides, and analogy will furnish arguments to each.

2. The diagnosis of the "suppurating sore" is not always to be made at once. It may present at its base an induration resembling that of the indurated or infecting form, and as this induration may terminate quite abruptly, it may be impossible to distinguish the character of the sore by the touch alone. This "phlegmonoid" variety is, however, to be distinguished by the purulent character of the secretion, its auto-inoculability, the suppurating character of the accompanying glandular enlargement, and by the history not giving evidence of a prolonged incubation, etc. The pus from the bubo is specific, reproducing the suppurating sore.

3. The infecting, indurated, or Hunterian sore is not auto-inoculable. But there is a stage when it is so, and that is at a period before the specific induration has formed. And there is a condition when it is so, and that is the condition of irritation, such as may occur accidentally, or be produced by the application of a blister. But the progress of such an inoculation does not resemble the results of inoculation on a patient not previously infected. There is no period of incubation, there is no induration, the spot rarely ulcerates, and, if it does, soon heals. There are some interesting statistics quoted by Mr. Lee in relation to this question of auto-inoculability, which we must not omit to refer to. "In 1856, M. Fournier inoculated a hundred patients from their own infecting sores, and succeeded in his experiments once or twice only. His results were not published until 1858. M. Rollet, in his recent work, mentions having inoculated two hundred patients who had infecting sores with the secretions from their own chancres. He found that those in whom the inoculation succeeded were 6 per cent." "Now," says Mr. Lee, "Fournier's experiments and Rollet's experiments coincide in a wonderful manner with practical statistical details, as carefully observed. During the year 1855-56, I kept an accurate register of such cases, and out of one hundred that had been diagnosed as suppurating non-infecting sores, secondary symptoms followed, as far as I was able to ascertain, in two instances only. . . . The exceptions in all three series of observations may be attributed to the same cause—a *twofold* inoculation. . . . This conclusion is confirmed by the results of the inoculations. . . . The affection produced by the inoculation from the supposed indurated sores was, not an indurated sore of the same nature, but a *pustule*, the characteristic origin of the local suppurating disease."—P. 28.

4. One of the most interesting portions of Mr. Lee's book is that which discusses the pathology of lymphatic absorption, and the mode in which the system becomes infected with syphilis. The greater part of the Fourth Lecture and part of the Second are devoted to this subject, and the whole that he has written upon it deserves careful study. Admitting, as everybody now does, that the lymphatics and blood-vessels are both absorbing organs, we may briefly follow our author in pointing out in what way they act as respects the poison of syphilis. In the first place, there is the fact that lymphatic absorption really does take place in both forms of syphilis, as testified by the development of disease of the same specific nature as the original sore in the lymphatic glands; plastic effusion occurring in the enlargement accompanying indurated chancre and suppurative inflammation in that accompanying the suppurating sore. Next, there is the fact that in neither instance are the glands "of the second order" affected. The contamination does not go beyond those "of the first order." But up to them there is evidence of lymphatic absorption, in the occasional appearance of specific disease in the course of the lymphatics between the sore and the glands. Hence the poison, so far as the lymphatics are concerned, appears arrested in its course to the thoracic duct by the first glandular structures it meets with. "A wonderful change is here brought about. The specific virulent poison, which before was liable to contaminate every living part that it came in contact with, cannot be traced beyond this point. The absorbent vessels between the inflamed glands and the thoracic duct do not ulcerate or suppurate, the glands into which they empty themselves do not become enlarged or inflamed. The influence of the poison is here then gone."—P. 80. What then becomes of it? Mr. Lee says that "neither

observation nor experiment afford any proof that the syphilitic virus is conveyed, *as such*, through the absorbent glands, . . . and we cannot therefore admit that this is the way in which the system becomes infected *after* the specific primary adhesive action."—P. 84. [The italics are ours.] Granting that the veins are the media by which the syphilitic poison gets into the circulation, where does Mr. Lee consider that the venous absorption commences? at the inoculated point, or in the lymphatic glands of the first order? There is evidence of absorption in local disease of the lymphatic vessels, what is there corresponding to this in the instance of the vascular system? Is it quite inconsistent with the facts to imagine that (taking the period of incubation of indurated chancre into consideration) the poison might have passed through the first order of glands, and have been so modified there as to have become incapable of producing in other glands the specific plastic inflammation, at a period *prior* to that at which the induration takes place, either at the inoculated spot, or in the first order of glands? and, finally, on arriving at the blood, together with the process of assimilation of the lymph, it may acquire again during its reproduction in the system, or when this is completed, some of its original properties? At any rate, the words "as such" and "after," introduced by Mr. Lee into a sentence we quoted above, seem to furnish the clue to a difficulty which he himself appears to have felt. In other diseases, as the exanthemata, the period of incubation is the period of reproduction of the poison in the circulation, and this period, during which various complicated changes occur, commences from the moment that the original morbid germ gains access to the blood. It is not complete until the period of incubation is at an end. A patient who has received the poison of small-pox, the incubation of which is about a fortnight, may be vaccinated successfully at a time that reproduction of the variolous poison is going on in the system. So it may be with the syphilitic virus. The system, so far as the introduction of the poison into the blood is concerned, may be infected not *after*, but *before* the specific primary adhesive action occurs. The latter event marks a stage in, and not the beginning of, the process of infection. Let us again use the analogy derivable from small-pox. When this is inoculated, what happens? We have produced a local lesion, what Dr. Gregory calls "a hard, inflamed phlegmon," and after an interval (incubation) an eruption (differing in appearance from the first local result), the true eruption of small-pox. This is the effect of infection of the system. We do not say here that the infection occurs *after* the development of the local lesion, because the constitutional manifestations are consecutive to it. We count the period of incubation from the day of inoculation, and say that the poison then introduced has been incubating, reproducing itself till the day of eruption. Why not apply the same method of explaining phenomena to syphilis? Why not say that the fully developed syphilis is manifested by what we may be incorrectly calling the *secondary* accidents, and that the local lesion only marks a *stage* in the process? We do not wish to be understood as denying that the veins may also be concerned in taking up the poison, we only demur to what we understand to be the conclusion of Mr. Lee, that the absorbing action of the lymphatics necessarily ceases at the glands of the first order. But perhaps he does not mean to assert as much as this.

5. Syphilisation, as it is called, remedial syphilisation, is the subject of the Third Lecture, and is treated of in a masterly manner. When we hear that in Christiania and elsewhere it is the accepted method of cure in cases of secondary syphilis, and find (as we showed in a former review) that it is advocated by so distinguished a syphilographer as Dr. Boeck, no one can say that it is undeserving the prominent place which Mr. Lee has afforded it in his treatise. Mr. Lee admits that in such cases as Boeck and others record an effect is produced. It is not at all necessary to his argument to question the assertion of its advocates that the cure is more satisfactory under this than under any other method of treatment, but he does deny that in these cases the effect is produced by the absorption of the syphilitic virus and the saturation of the system supposed to occur by Sperino and Auzias-Turenne. He denies it on the ground that the absorption of syphilitic poison is marked by a well-ascertained series of symptoms, which leave no doubt as to its presence, and asks, if saturation of the system takes place, how we are to explain the seeming contradiction that the symptoms do not become worse instead of better. It is further worthy to be observed,

as those will recollect who read our review of M. Boeck's work, that Boeck considers that the best matter for syphilisation is to be derived from the soft chancre; in other words, from the form of chancre which is non-infecting. But M. Boeck believes that the soft and hard chancres are the same disease in different degrees of intensity. But, will syphilisation saturate the system? If it does so in the case of a person suffering from constitutional syphilis, it ought equally to be able to do so in persons not suffering in this way. What are the facts? Mr. Lee quotes some experiments of Danielssen, who used the process in the treatment of lepers not affected with syphilis. This observer gives the history of six cases, and with reference to them says: "It appears from the above details that neither one chancre, nor two, nor three, nor six, nor thirty-six, nor one hundred and thirty-six have in the preceding cases induced secondary syphilis, and that therefore the direct operation of the inoculations has been exclusively limited to the spot where the chancres showed themselves." Danielssen, then, clearly used the matter from soft chancres, as directed by Boeck. "If such be the case, we are justified in assuming that no greater number of chancres will produce a different result. And this is confirmed by our experience; for, with one exception, to which we shall subsequently allude, not one of these individuals, previously free from all syphilitic taint, whom I have syphilised, has been affected by secondary syphilis; nor have they shown any signs of the existence of the venereal diathesis in their systems." The exception is this,—it is such a one as serves to prove the rule,—"Syphilisation had been performed upon a leper with the virus of the soft chancre to the extent of nearly four hundred inoculations, when the secretion of an indurated chancre was accidentally inoculated. The inoculated parts healed, but a month afterwards an indurated sore appeared, followed by unmistakable signs of secondary syphilis, showing that the previous inoculations with the chancroidal virus, which had been strictly local in their action, had afforded no protection whatever against true syphilis."—P. 49.

6. *Blood Inoculation of Syphilis.*—In an article last year upon syphilis and vaccination we withheld our assent to the doctrine that syphilis could be conveyed by the inoculation of the blood mainly on the ground that the evidence was unsatisfactory. The case was not proven. The experiments adduced by Viennois, Rollet, and the supporters of the doctrine were open to damnatory criticism. The possibility of this mode of conveyance is, however, now proved quite to our satisfaction, and we give in accordingly. All the conditions of a fair experiment have been fulfilled in that performed by Professor Pelizzari upon Dr. Bargioni. The inoculation was successful; an indurated chancre was produced, accompanied by the specific glandular enlargement, and succeeded by secondary eruption. And, in conceding this point, we necessarily also concede the probability that where vaccine and syphilis have been communicated together by vaccination, the presence of blood mixed with the lymph used may have been, as Rollet and Viennois maintain, the cause in certain instances of the conveyance of the twofold virus. Mr. Lee enters at length into the discussion of the Rivalta cases, which we made the subject of criticism, and carries the investigation to its extreme limit. We must content ourselves, however, considering the length to which we have been drawn on in this review, and because we have a good deal yet to say, to refer our readers to Mr. Lee's admirable chapters upon the subject.

7. There are in the book some acute remarks upon the influence of hereditary syphilis in preventing the inoculation of syphilis, both primary and secondary, and as modifying the course of the disease when contracted. We will quote Mr. Lee's own words:—"Among those who habitually expose themselves to syphilitic infection, it occurs every now and then that an individual is found who never has had the infecting form of the disease, and the question naturally arises, Why has he not suffered in the same way as others who have been similarly exposed? . . . If we say that a patient can have syphilis once only during his lifetime as a rule, and if we find that a certain number of children have hereditary syphilis, does it not appear probable that these children, when they grow up, would have some kind of immunity from further infection, or that, if the disease did appear again in them, it would be in a greatly modified form? . . . In 1812, Dr. Ferguson came to the conclusion that syphilis had become so much mitigated in Portugal, by reason of general diffusion, or other causes, that, after running a mild course, it exhausted

itself and ceased spontaneously." He compared it to the exhaustion of land by cropping for the same kind of seed, while the seed will grow vigorously on another, though inferior soil. "Corresponding with this description appears to have been the effects of the inoculation of the exhausted syphilitic virus of Portugal (though evidently the same disease) into the constitution of the British or other strangers. . . The Portuguese through apathy, and at a dreadful price levied on the generations that are passed, and never, in all probability, to be redeemed by their descendants, appear to have gained a high exemption from both syphilis and variola."—P. 213, et seq. He then proceeds to quote the experience of Mr. Rose, in one of our regiments of Guards, in support of a notion that a similar cause may account for a similar modification of syphilis in some of the lower classes in this country. Mr. Rose found that he could treat such cases among the men without mercury, but that this plan was unsuccessful when attempted with the officers. Mr. Lee suggests this as an explanation of the failure of some experimenters in inoculating syphilis from secondary accidents upon persons who had never had the primary disease.

8. But we must hasten on, passing over the facts which relate to the wearing out of syphilitic protection, as conferred by infection, just as the protection of vaccine against small-pox wears out in time, [to draw attention to our author's remarks upon the communication of syphilis through the medium of non-specific secretions of infected persons. Mr. Lee thus puts it: "There is reason to believe that the ordinary secretion of the body, when derived from a part in a state of increased action, or of inflammation, may produce the same effect" as "the secretions of what are usually called secondary symptoms." We cannot follow him in all the evidence he adduces on this head. The cases he adduces are conclusive, and the doctrine appears to account for those remarkable cases where syphilis has been conveyed by connection, when no local manifestation of specific disease has been discovered on examination of the suspected party.

9. Among all the modes of administering mercury in syphilis, that which Mr. Lee prefers is what he terms the calomel vapour bath. The apparatus for administering it is very simple, so that a patient can give himself his own bath. From fifteen to twenty grains of calomel only are used, but that quantity is allowed to become deposited upon the skin, and thereto remain to become absorbed. It is not desirable that any great amount of perspiration should be induced. From time to time the patient may also be permitted to inhale the vapour. Mr. Lee considers that the effect of the bath thus administered, unlike that of the other modes of fumigation that have been proposed, can be regulated and controlled with great precision.

In concluding now at length our review of this book—and to satisfy ourselves we should almost have to transcribe the whole of it—we can only say that we have read it with the deepest interest. Did not Mr. Lee already hold the highest rank among British syphilographers, these Lectures alone would suffice to place him in that position.

## GENERAL CORRESPONDENCE.

### FARRINGDON DISPENSARY—VACCINATION OF A RICKETY CHILD TWO YEARS OLD—ON THE NINTH DAY PAPULAR ERUPTION—ECLAMPSIA—DEATH ON THE TENTH.

LETTER FROM DR. DRYSDALE.

[To the Editor of the Medical Times and Gazette.]

SIR,—The following case appears to me to present some features of interest, and I trust you may find it worthy of insertion:—

On May 9, I saw with Mr. Towne, near Holborn, a child, aged two years, of whose case the following is an account:—

*History.*—The child was vaccinated on April 30. The vaccination was successful, and the vesicles appeared regularly, and progressed towards maturation. On the ninth day the vesicles were large and filled out, and there was a papular eruption over the body. At 11 a.m. on this day the fits first appeared. These fits were thus described by the father, a tailor, and rather intelligent. The child during the fit frothed at the mouth, its eyes were fixed, its jaws stiff, and it was quite unconscious. The legs, arms, and body were rigid

during the attack, which lasted about one minute. The stiffness was not apparently greater on one side of the body than on the other. The child cried out before the fit came on. No clonic spasms were noticed. Of this fact I convinced myself, by varying the form of my interrogation. From 10 a.m. of May 8 until night there were only two fits; but from 10 p.m. until the following evening at 5 p.m., when I saw the child, the attacks followed each other in rapid succession, sometimes with only five minutes intervals, sometimes much longer. The child cried much, and did not sleep. It was quite conscious during the intervals. On inspection, the child was found to be rickety. The ends of the radii were large, and the other joints tumid; the lower limbs were crooked; the anterior fontanelle was open widely; the chest barrel-shaped. There was a groove on each side of the sternum, and at each laboured inspiration made by the child the softened chest walls sank in. There was no cough nor catarrh. Child had all its teeth, except the canines. The vaccine vesicles were well matured. There were two on the left arm, circular-shaped, and pearl coloured. Around each vesicle there was an inflamed ring, and a red blush and induration extended down the arm. There was also a papular eruption over the body and lower extremities. Breathing was laboured. The child died some hours afterwards, and apparently from extension of the spasm to the muscles of respiration.

It appears to me, Sir, that the above symptoms of spasmodic seizure and death were attributable to the presence of the vaccine poison in the blood of a rickety child. . . Epilepsy is frequently to be traced to the presence of some poison in the blood, such as urea, retained menstrual fluid, or syphilitic poison, when prevented from leaving the constitution by mercurials.

Writers on vaccination have pointed out the danger of non-attention to the periods of dentition. The best time for vaccinating a child is from the second to the fifth month after birth. Before this epoch, children are not liable to be attacked with rickets. Those who have observed the extreme liability of rickety children to spasmodic disease, may agree with me, that, had this child been vaccinated before the cachexia set in, it would most likely have escaped this form of death.

I may mention that I find it by no means an uncommon occurrence among dispensary patients to entertain a superstitious horror against vaccination; and thus, either to have left their children unprotected, or to have been forced into a tardy recourse to this invaluable preventive.

But we can scarcely blame the poor and ignorant in this, when we find members of the Medical Profession so ready to listen to promises of cure for small-pox from saracenia, or some other ephemeral drug, instead of insisting upon the fact, so patent to all good observers, that the present epidemic is due to the neglect of vaccination, or its imperfection.

I am, &c.

CHARLES DRYSDALE,  
M.D., M.R.C.P. Lond., F.R.C.S. Eng.

### HOW TO PREVENT PITTING AFTER SMALL-POX, IN A LETTER TO A PHYSICIAN FROM F. BOWEN, ESQ., M.D., ETC.

MY DEAR SIR,—With much pleasure I accede to your wish expressed this morning with regard to the means I adopt to prevent pitting in small-pox.

An incident happened to me some thirteen years ago which induced me to devote much attention to this subject ever since, not only in this country, but in some of the large continental cities.

In the year 1850, I was connected with the Marine and Emigrant Hospital, Quebec, Canada. I had been directed by the Senior Surgeon, Mr. Douglas, to puncture the vesicles on the face and neck of one of the Hospital patients then suffering from small-pox with a needle dipped previously in a strong solution of nitrate of silver. I felt sceptical as to the success of this treatment, and secretly determined to apply the needle and solution to the vesicles on one side of the face and neck only, and watch the result. I did so. The patient recovered; but the disfigurement was really frightful, for while one half of the face was deeply pitted, the other half was smooth and free from spots, as before the attack. The superintending Medical Officer was not inclined to discharge this patient, but ever and anon produced him before the class

in the lecture-room, where he, poor fellow, was laughed at, while I was twitted. At last the man turned rusty, and threatened to do me some personal injury. To my great relief, he was induced to leave the country, not before a purse, however, had been collected for him, towards which I subscribed most liberally.

Among the many plans recommended, and all of which I have tried over and over again,—charcoal and starch and mercurial plasters; collodion; solution of india-rubber with chloroform; sulphur; iodine; nitrate of silver; down to tripe-water, much in vogue among the poor,—I have found none so effectual, none so easy of application, and none so altogether free from annoyance to the patient, as puncturing the vesicles with a needle dipped in a solution of nitrate of silver. I have used it, I may safely say, over 300 times with most satisfactory results.

1. When do I puncture the vesicles?
2. What kind of needle do I use?
3. What strength of the solution of nitrate of silver?
4. What results from this treatment?

1. About the fifth to the seventh day,—it depends on the development of the vesicles,—when the small vesicles, somewhat depressed in the middle, surrounded by an inflamed margin, and circular, can be seen on the top of each pimple; certainly before the contained matter assumes the appearance of pus. Even in the confluent forms I would puncture, and have always done so; but I cannot speak with the same confidence with regard to results as in the more common or modified small-pox. In the former cases there are generally grave and serious complications of one form or other to deal with, and which tend to an unfavourable issue of the case.

2. The kind of needle I use is the one commonly employed for twisted suture, flat and sharp at the point; it makes its way very easily, carries with it enough of the solution for each vesicle, and its shape favours a slight discharge, on withdrawing the instrument, which can be absorbed by lightly touching the part with a piece of soft cotton-wool held in pliers.

3. The strength of the solution I use is  $\text{℥ss.}$  to the  $\frac{3}{4}$  of water; it is strong enough to effect the change sought to be produced; what more can be required? In twenty-four hours the result is apparent, the vesicle has dried up, no itching or unpleasantness remaining.

4. This results from the treatment; the application in the way recommended is not tedious; the nurse can do it; it does not cause the patient the slightest inconvenience, which is more than can be said of the many disgusting appliances one sees in daily use; and it prevents pitting.

I do not pretend for one moment to say that I offer a new idea to the Profession. I only wish to say, that, having tried all modes of treatment recommended, I am satisfied, after much experience in treating both rich and poor, to abandon them all in favour of puncturing with the needle and solution of nitrate of silver at the time indicated.

I shall feel glad if you will ask some of your Medical friends to try the puncturing, especially now when small-pox is so prevalent in London. The plan proposed may be modified, perhaps improved upon; sooner or later, the time will come, I feel sure, when, from a conviction of the value and advantage of this mode of procedure, it will be adopted as a settled rule for future guidance.

Believe me, my dear Sir,

With great respect,

Your obliged and faithful friend,

62, Upper Berkeley-street,  
Portman-square, W., May 16.

F. BOWEN.

## REPORTS OF SOCIETIES.

### OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 1, 1863.

Dr. OLDHAM, President, in the Chair.

Dr. TYLER SMITH presented a specimen of  
TUBULAR FETATION WITH TWINS,  
sent to him by a Medical friend.

Some discussion having arisen between Dr. Barnes, Dr. Oldham, and Dr. Tyler Smith regarding the relative ages of the twins, it was agreed that the last-named gentleman and

Dr. Braxton Hicks should be asked to examine and report upon it.

Dr. OLDHAM was anxious to direct the attention of the Society to the possibility of performing gastrotomy in some cases of tubal pregnancy where death was about to result from internal hæmorrhage. The main difficulty was the diagnosis, which, however, in sudden tubal rupture was well marked. The danger was so great that it justified any expedient which might have a hope of success.

Dr. BARNES joined with the President as to the importance of the question. He had witnessed two cases in one month; both of them were diagnosed during life, and in one the expediency of gastrotomy had been discussed. In the early stages he thought the difficulty of getting at the sac very great, but after the third or fourth month the operation would be not only feasible but expedient.

A paper was then read by Dr. GERVIS on "A Variety of Chronic Pains in the Back."

Dr. EASTLAKE described, in a short paper, a

#### CASE OF AMAUROSIS FOLLOWING PARTURITION.

This phenomenon had occurred on seven previous occasions under the same conditions, but it did not appear after the first labour. The patient was married, and thirty-four years of age. The blindness, which was total, occurred in both eyes suddenly about the third day after the birth of each child, and lasted on an average from three to five weeks. The patient had never lost more than the normal quantity of blood; she had never taken ergot; there was no suppression of the milk or lochia, nor was the urine albuminous. A careful ophthalmoscopic examination had been instituted, but the evidence adduced was entirely negative. Dr. Eastlake regarded the case as unique, and concluded his paper by stating that the only author who had described any case at all similar was Beer, in his "Lehre der Augenkrankheiten."

Dr. J. G. SWAYNE related a case of

#### CÆSAREAN SECTION.

The woman operated on was a dwarf over forty years of age; her height was only four feet and half an inch, and the deformity of the pelvis was congenital. She was unmarried, and did not apply for Medical advice until the time of labour, when she was first seen by Mr. Henry Grace, of Kingswood, near Bristol, and brought by him to the Bristol General Hospital. Here Dr. Swayne saw her, and advised the Cæsarean operation, which was accordingly performed by Mr. Coe, the senior Surgeon to the Hospital. The section was made in the usual manner by an incision in the linea alba. The child was extracted alive, but the mother died forty-two hours after the operation, from peritonitis. The pelvic deformity was chiefly occasioned by the very peculiar form of the sacrum, the anterior part of which, instead of being concave, projected forwards towards the symphysis pubis, and thus reduced the antero-posterior diameter of the pelvic cavity to one inch and four-fifths. The child is now living.

Mr. SPENCER WELLS wished to know whether the opening in the uterine wall had been left to close spontaneously, or had been closed by sutures. He was not aware whether sutures had been used in any case, but it had struck him that the escape of blood, or of the secretions from the uterine cavity, into the peritoneal cavity might be one cause of mortality after the Cæsarean section; and if so, that sutures might be useful. It was evident that the ordinary-interrupted sutures could not be used, because they would have to be left in the spots where they were applied; but it would be easy to use the uninterrupted suture, so that it might be withdrawn through the uterine cavity and vagina. It would only be necessary to leave both ends long enough, and not tie any knot. There could be no difficulty in doing this, if it were thought desirable; and it might possibly prove to be a means of lessening the mortality after the Cæsarean section.

Dr. GREENHALGH said that four cases of Cæsarean section had occurred in his own practice, besides which he had witnessed three cases in the practice of others. He spoke therefore from some experience of this formidable operation. In two of his own patients, who had arrived at the full period of pregnancy, it was necessitated by extreme distortion of the pelvis: in the one resulting from mollities ossium, who survived the operation three weeks, and then died from rupture of the transverse colon; in the other from rickets, who lived only four days. In both cases the children were born alive, and continued to live. In all the cases the uteri contracted shortly after the removal of their contents, more rapidly in

those where the incision was made in the body, and less so in one case where the opening was effected in the neck of the uterus, on which account Dr. Greenhalgh did not approve of Mr. S. Wells' suggestion of bringing the cut edges together by sutures. He (Dr. Greenhalgh) regretted that in more than one case the operation was not undertaken until much valuable time had been lost, and until after great and ineffectual attempts had been made to deliver, which placed the patients in a bad condition for any operation, and more especially for the one under consideration. He attributed our great want of success, as compared with our continental brethren, to a want of attention to these lesser points. He emphatically expressed his opinion that no Practitioner was justified in performing this operation with a view of saving the child where delivery could be safely effected by craniotomy. Still he considered that if any patient, who had had one or more children destroyed by craniotomy, desired from conscientious motives, after having had all the difficulties and dangers to herself and child from this operation placed before her by several eminent accoucheurs, to risk this operation, with a view of saving her child, as in one of his (Dr. Greenhalgh's) cases, the Practitioner would be fully justified in undertaking its performance.

Dr. BARNES rose to make one or two observations upon the case referred to by Dr. Greenhalgh. In the view of the case and the principle of treatment which guided Dr. Greenhalgh he quite agreed. He was, however, more disposed at first to persevere in attempts to deliver the woman by the natural passages. He was chiefly influenced in this direction by the fact that the child was premature. Had the child been of full size, the idea of so delivering could not have been entertained. But he hoped that if a leg could have been seized and brought down, the body and head might have been drawn through, flattened out between the tumour and the pubic bones; and that the tumour itself, which, although very firm, was not osseous, might yield a little. In this they were disappointed. It was impossible to seize a leg. The course at first entertained by Dr. Greenhalgh, and ultimately adopted, was proved by the post mortem examination to be right. The suggestion made by Mr. Spencer Wells to sew up the wound in the uterus made in the Cæsarean section, Dr. Barnes did not approve. He thought accoucheurs would prefer to rely upon the contractile property of the uterus, to which they were accustomed to trust in the more ordinary emergencies of labour. The blood and other matters did not escape through the wound, but found a ready outlet through the cervix and vagina.

Dr. GRAILY HEWITT remarked that the case brought before the Society by Dr. Swayne was one which could not fail to excite a great amount of attention. There were two aspects under which it was necessary to consider this grave question—the decision as to the performance of the Cæsarean section, and which were likely to present themselves in actual practice. The first class of cases were those in which the delivery of a live child in the natural way was impossible, and the operation was had recourse to in order to save the child. In the second class of cases the operation was resorted to because delivery of the child was found to be impossible under any circumstances. With regard to the first class of cases, it was quite evident that the circumstance determining the decision would be the importance attached to the life of the child compared with that of the mother, respecting which it was well known that differences of opinion existed. This was a question which would probably still continue to be in some degree an open one. In respect to the second class of cases, in which the Cæsarean section was had recourse to for the reason that the fœtus could in no other way be extracted, he wished to make a few remarks. There were doubtless some cases in which the amount of distortion and narrowing was such that no operative attempts, however well directed, would succeed in bringing away the uterine contents; but he believed that some of the cases which had been thought hopeless, except by recourse to the Cæsarean section, would be found capable of being relieved by application of the cephalotribe. This instrument was as yet little if at all practically known in this country, but it appeared deserving of a trial, and was better adapted for breaking up the structures with which we had to deal than other instruments. He quite concurred in the observations which had fallen from Dr. Greenhalgh as to the selection of the proper time for the operation of Cæsarean section. There could be no doubt that the operation was successful in proportion as it was undertaken early; this was shown by statistics. On the Continent the Cæsarean section

was more frequently undertaken. Winckel had operated in thirteen cases, of which eight recovered; this showed what might be done with the operation under favourable circumstances.

Dr. BARNES would beg to intrude once more, prompted by the remarks of Dr. Hewitt concerning the cephalotribe. He had some knowledge of the application of this instrument. In the first case of Cæsarean section which he had seen, which occurred in Paris at the Clinique d'Accouchements twenty years ago, the cephalotribe had been strenuously used all night, yet the Cæsarean section had to be resorted to at last. The deformity was not greater than in this case of Dr. Swayne's, and there was more room at the sides of the aperture of the brim. In Dr. Greenhalgh's case the application of the instrument would have been simply impossible. The cephalotribe was a bulky instrument; it took up a good deal of room where there was none to spare. He did not think the cephalotribe would prove of much service in diminishing the number of cases in which it would be necessary to resort to the Cæsarean operation.

Dr. OLDHAM considered it important to make the incision into the uterus as low down as possible, regarding wounds towards the fundus more dangerous than those towards the cervix. His experience of severe operative Midwifery rather led him to think that Cæsarean section might be performed oftener than had been generally deemed right.

Dr. SWAYNE stated, in answer to the question from Mr. Spencer Wells, that no sutures were used to bring the edges of the uterine incision together, and that entire dependence was placed on the contractility of the organ for effecting that purpose. It was generally considered that sutures were not to be used on account of the danger of uterine inflammation. Mr. Coe, however, regretted that he did not give ergot of rye previous to the operation. Dr. Swayne mentioned that just before the meeting his attention had been directed to the particulars of a case of Cæsarean operation which had been lately performed by Dr. Dyce, of Aberdeen. The woman operated on was a dwarf, and the case was in all respects similar to his own, except that the pelvis was slightly larger. In Dr. Dyce's case unsuccessful attempts had been made to extract the child before the Cæsarean section was resorted to. Dr. Swayne said that this case justified the course he had taken in at once advising the Cæsarean section, without making any previous attempt to deliver by craniotomy.

Dr. SKINNER, of Liverpool, read a paper on the

#### GALACTAGOGUE PROPERTIES OF FARADIZATION.

He illustrated the effects by the records of eight cases, in which the secretion returned after one or two sittings. The effect was permanent, and was produced by a galvanic-coil machine, using from three to six cells of Smee's battery. The current was applied both direct from the axilla to the nipple and intermammary, for about ten minutes for both breasts, and was of no greater intensity than bearable.

A paper by Dr. SHORTT, "On the Medical History of Women in Southern India," was also read.

## THE PATHOLOGICAL SOCIETY.

TUESDAY, MAY 5.

Mr. PRESCOTT HEWETT, President, in the Chair.

A REPORT, by Dr. Wilks, Dr. Murchison, Dr. Harley, and Dr. Bristowe, was read on

#### DR. DICKINSON'S SPECIMEN OF AMYLOID DISEASE.

Having examined Dr. Dickinson's case of "so-called" amyloid disease of the kidney and in the brain, we find that the diseased tissues of the kidney, although not coloured blue under the combined influence of iodine and sulphuric acid, assume, when submitted to these reagents, a deep dusky reddish tint, such as is commonly observed under similar conditions in tissues affected with the amyloid disease; but we find that the tumour from the brain acquires simply the ordinary yellow colour which iodine imparts to albuminous tissues. We are of opinion, therefore, that the deposit in the kidney is undoubtedly of the "so-called" amyloid character; but we do not find any evidence from the reaction that the cerebral tumour belongs to the same class. We should add that the specimens had been kept some time in spirit, and that hence, possibly, their readiness to respond to the usual tests had become impaired.

A report, by Dr. Peacock and Dr. Bristowe, was read on

DR. MARKHAM'S SPECIMEN OF CYST OF THE MITRAL VALVE.

In Dr. Markham's case of mitral-valve disease we recognised:—1. Great thickening of a considerable portion of the mitral valve itself, dependent on the presence of a tough, somewhat glistening fibroid deposit. 2. Continuous with the upper part of this, a quantity of dense but somewhat friable and slightly reddish coloured material; and, 3, in the lower part of this latter material a small horizontal cavity with a linear vertical section, the margins of which had a pale yellowish tint, and were somewhat pulpy. Under the microscope, the fibroid substance first mentioned was found to consist of a coarse fibroid material, which was readily swelled up and rendered transparent under the influence of acetic acid, and which then displayed in the interstices between the fibres a moderate number of elongated, but somewhat indistinct, nuclear bodies. The substance appeared to be as nearly as possible identical with that of fibroid deposits commonly found within, and on the surface of, other organs. The more friable material presented in some places a delicate but irregular fibrillated texture, closely resembling that of coagulated blood; in others, an indistinct gelatinous-looking network, such as is often observed in old clots, or in some forms of inflammatory exudation. It was studded irregularly, but nowhere thickly, with minute granules and oil-globules. Acetic acid acted on it readily, but brought no traces of nuclei into view. The microscopic structure of this material was quite compatible with its origin in mere coagulation of blood. The margins of the small cavity, and the pulp scraped from its inner surface, consisted apparently of exactly the same elements as the material just described. But the tissues were more broken down, and were intermixed with a great abundance of granular matter and of oil-globules of all sizes. The opinion at which we have arrived is, that the disease consisted originally of some fibroid degeneration or change in the mitral valve itself; that subsequently, from some cause or other (possibly, in the first instance, roughness of surface produced by disintegration), the fibrin of the blood deposited itself on the upper aspect of the diseased portion of the valve, and slowly accumulated there; and that the small cavity, like cavities so often found in old clots in various situations, was simply the result of the degeneration and breaking down of a small portion of the coagulum in which it was found.

Mr. GAY brought forward a child who had

SEVERE HYPOSPADIAS.

The penis was imperfectly developed. The urethra opened at the base of the penis. The scrotum was partially cleft, and one testis only had descended. In this, as in the other cases shown by Mr. Gay, there was no defect of development elsewhere.

Mr. BUXTON SHILLITOE then showed a specimen of

HYDATID FROM THE TONGUE.

The patient had had several small tumours, which extended through the whole thickness of the tongue. They were hard, but elastic.

Dr. BRISTOWE thought the specimen was a cysticercus, and not hydatid.

Mr. HILTON had removed three such tumours from the tongue. They were cysticerci, and not hydatid.

Mr. Wilks was requested to report on the specimen.

Dr. BRISTOWE then showed a specimen of

TUMOUR OF THE KIDNEY.

It was like the specimen exhibited by Dr. Dickinson at a previous meeting. It was taken from a man who was killed by an accident. All the organs were healthy except one kidney. The tumour consisted of fibrous tissue mixed with fat.

Dr. WILKS thought that such tumours were not so uncommon as was supposed; they were often called cancer. The so-called cancer of the lung often turned out to be recurrent fibroid. He believed that recurrent fibroid was just as commonly met with in internal organs as in external tumours.

Dr. FULLER then showed the

KIDNEYS OF A PATIENT WHO HAD NOT PASSED URINE FOR THIRTEEN DAYS, AND WHO HAD NO SYMPTOMS OF URÆMIA.

A healthy-looking man came to St. George's Hospital, saying that for four days he had not passed any urine. He had always had good health, except that two years before he had passed some blood in his urine after a squeeze. When he

was admitted into the Hospital, except that he had slight pain in his back, and had not passed urine for four days, he felt quite well. His pulse was quiet and his tongue was clean. A catheter was introduced, but the bladder was empty. For the first three days he was in the Hospital he passed no urine, and then passed about two ounces, pale, and of low specific gravity. He had afterwards pain in the loins, and passed four ounces of urine. He died suddenly on the thirteenth day, whilst sitting up in bed and talking. It was found after death that each ureter was occluded by a calculus.

Dr. MURCHISON showed

A PIECE OF SKIN AFFECTED WITH TYPHUS RASH AND MOLLUSCUM.

The skin was cut from the body soon after death and immersed in spirit, and showed clearly that the rash of typhus was permanent after death. The molluscum, which had affected more or less every part of the body, was in every degree of size, from a distended sebaceous follicle to a tumour the size of a hazel nut.

Dr. MURCHISON also showed a specimen of

OBSTRUCTION OF THE FEMORAL VEIN.

A patient, 60 or 70 years of age, was sent to the Fever Hospital for typhus. He had no very definite symptoms, and was probably convalescing. At first he went on well, when on February 13 the right leg became very much swollen, being tense and brawny from the feet up to the groin, and was red on the surface. This came on in one night. Then a tumour was discovered in the right side of the abdomen, about four inches above the pubes. It was very tense and fluctuating, and its upper margin was convex and easily defined. This tumour was punctured by a trocar, and about two pints of clear urine were drawn off. The leg diminished in size, but the patient gradually sank exhausted. At the autopsy it was found that there was a large sacculus on the right side of the bladder, and this had pressed on the veins, and thus obstructed the return of the venous blood. There was a very slight stricture of the urethra.

The PRESIDENT said that he had known a case in which a sacculus of the bladder, with a stone in it, was found in a hernial sac. In another case, in which a patient had had a tumour in the right iliac fossa, which was supposed to be disease of the cæcum, the tumour was found to be due to a calculus in the pelvis of the right kidney. The kidney was dragged down by the calculus.

## OBITUARY.

### MR. RICHARD QUILLER COUCH.

MR. RICHARD QUILLER COUCH died on Friday, the 8th inst., from sub-acute inflammation of the lungs. He was the son of Mr. Jonathan Couch, of Polperro, the celebrated ichthyologist and naturalist, now publishing a "History of the Fishes of the British Isles." Mr. Couch was born in March, 1817, educated at Plymouth, and subsequently articled to his father, whose tastes he inherited, and, instead of being teacher and pupil, they soon became fellow-students, investigating the natural history of fishes, making observations on the crustacea, and examining the fossils of East Cornwall. Mr. Couch's researches into the metamorphoses of the crustacea were appreciated by naturalists generally, but more especially by Professor Bell, who was then engaged in writing what is now the standard English work on that subject, availing himself of the result of Mr. Couch's investigations, quoting him for many facts then new to science, and in the preface to his work bearing gratifying testimony to the originality and value of his discoveries. The geology of the eastern part of Cornwall was explored with equal thoroughness by Mr. Couch, so that he became an authority on the fossils of the entire neighbourhood. Twenty years ago he wrote the third part of "The Cornish Fauna," published by the Royal Institution of Cornwall, his father writing the first and second parts.

After passing his pupilage, he entered at Guy's, where he was alike esteemed by students and professors for the breadth and accuracy of his knowledge, and his great industry and general ability, gaining, in 1837, the medal for the prize essay for Ophthalmic Surgery, to which branch of his Profession he continued particularly attached, enjoying ever afterwards a widespread reputation as an Ophthalmic Surgeon. In 1844, he settled at Penzance, where he gained a large and respectable practice. He was at once made one of the Secretaries and

Curators of the Natural History and Antiquarian Society, for which he wrote a variety of papers on British fishes, crustacea, and kindred subjects. He became a member of the Royal Geological Society of Cornwall, then Curator, and subsequently Secretary and Curator, contributing to its *Transactions* many valuable papers, and annually writing an elaborate report of the progress made in examining the geology of Cornwall. As a proof of the repute Mr. Couch enjoyed as a man of science, and a naturalist especially, we may state that when the late Prince Consort printed for private circulation "The Natural History of the Dee Side," three copies only found their way into Cornwall, two of which were sent to the Couch family; one to Mr. Couch, of Polperro, another to Mr. R. Q. Couch, and the third to the Royal Institution.

Mr. Couch was a member of the town council and alderman of the borough, and would soon have been mayor.

As President of the Penzance Institute he delivered numerous able and interesting lectures on scientific and general subjects, and was an authority on everything relating to the county—its antiquities, mining, fisheries, and natural history. His publications on the diseases and mortality of miners were elaborate and striking, the results of many years' careful study, and probably did much towards creating the present commission on mining, before whom he gave valuable evidence. His multifarious knowledge on science, literature, and the arts, was such as seldom falls to the lot of one man, and he was as generous in imparting as he was able in acquiring it. His writings were highly appreciated in the United Kingdom and America, and he was held in high esteem by men of science on the Continent of Europe. The deepest sorrow is expressed for his loss.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen having undergone the necessary Examinations for the Diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 19th inst., viz. :—

Alfred Sheen, M.D. St. Andrew's, Leicester, Charles White, Newbury, Berkshire, John Chaundy Clarke, Brill, Bucks, Robert Thomas Nichols, M.D. St. Andrew's, and L.S.A., Greenwich, William Jones, Carmarthen, and Roderick William Henderson, Lower Halliford, Middlesex, students of Guy's Hospital; Robert Maxwell Johnson, Kaffraria, Joseph Brampton Wright, Great Yarmouth, Sagar Vevers Smirthwaite, Burnley, Lancashire, and Evan Thomas, Liverpool, of Edinburgh; Edward Mahony, L.S.A., Richmond-road, Dalston, Samuel Jones Gee, M.B. Lond., Oxford-street, George Miles, Gillingham, Dorsetshire, and David Thomas Williams, Llangistho, Cardiganshire, of University College; Tregenna Biddulph Goss, Newington-place, of the Middlesex Hospital; Charles John Myers, Tottenham, of Charing-cross Hospital; Louis Augustus Norgate, East Dereham, Norfolk, of St. Bartholomew's Hospital; John Mathews, Brecon, S. Wales, of King's College; Brownlow North Hyatt, Shepton Mallet, of the Westminster Hospital; Henry Hummerston Burford, Hamilton-terrace, St. John's-wood, of St. Mary's Hospital; William Jones, Pwllheli, Carnarvonshire; David Jones, Bala, North Wales.

Admitted on the 20th inst. :—

Charles Henry Battersby, Dublin, William Robert Thomas, Manchester, David Evans, Barmouth, North Wales, and Anthony Mann Hawkes, Gloucester-street, Queen's-square, students of the Dublin Schools; Thomas Charters White, Upper Eccleston-place, Belgravia, Arthur Ernest Adamson, Dublin, Alfred John Matthew, London road, St. John's-wood, and Henry Law Kempthorne, Wedmore, Somerset, of King's College; William Frederick Butt, Gloucester, and William Henry Dison Mence, Cambridge, of University College; William Profit Dukes, Brixton, and Charles Richard Price, Bayswater, of the London Hospital; Maurice Cohen Rogers, New Burlington-street, and Thomas Langston, Manchester, of Charing-cross Hospital; Henry Robert Davis, Addison-road, Notting-hill, of the Westminster Hospital; Frederick Lawton, Chiddingfold, Surrey, of Guy's Hospital; William Coleridge Kierlander, Calcutta, of St. Bartholomew's Hospital; Thomas Henry Goodsir, Hull; John Nicholson, Silloth, Cumberland; John Douglas Lawrie, Bradford.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, May 14, 1863 :—

Albert Edward Boulton, Horncastle; Alfred Thomas Rudyard, Bexhill; James Atkinson West Spence, Bedale, Yorkshire; George Robert Norris, King's College; Charles Perks, Queen's College, Birmingham; William Astley Sherratt Dykes, Lodesbrough, Yorkshire; George Clapperton, Lower Broughton, Manchester; George Hurlstone Elliott, Chichester, Sussex; Samuel Hall, Belper, Derbyshire; Thomas Starbuck Woolley, Codnor, Derbyshire.

The following gentleman also on the same day passed his First Examination :—

Henry Edward Armstrong, Newcastle-on-Tyne.

## APPOINTMENTS.

\* \* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BRODHURST, BERNARD E., F.R.C.S. Eng., has been appointed Assistant-Surgeon to St. George's Hospital.  
 BROWN, DAVID DYCE, M.A., M.D. Aberd., has been appointed Assistant House-Surgeon to the South Staffordshire General Hospital, Wolverhampton.  
 CAYLEY, WILLIAM, M.D. Lond., has been appointed Superintendent of Post-mortem Examinations at the Middlesex Hospital.  
 CLARKE, A. CARSON, M.D., has been appointed Resident Medical Officer to the New Workhouse, Crumpsall, Manchester.  
 COWAN, JOHN B., M.D. Glasg., has been appointed Professor of the Practice of Medicine in Anderson's University, Glasgow.  
 DOBBIE, ROBERT, M.D. Edin., has been appointed Surgeon to the County Prison, Ayr, Scotland.  
 EDWARDS, A. M'KENZIE, F.R.C.S. Edin., has been appointed Assistant-Surgeon to the Royal Infirmary, Edinburgh.  
 LATHAM, PETER W., M.B. Camb., has been appointed Physician to Addenbrooke's Hospital, Cambridge.  
 MCCLINTOCK, JOHN R., M.B. Aberd., has been appointed Resident Medical Assistant to Murray's Royal Institution for the Insane, Perth.  
 ORD, GEORGE R., M.R.C.S. Eng., has been appointed Surgeon to the Royal Asylum of St. Ann's Society, Brixton-hill.  
 PADLEY, DR. GEORGE, has been elected Physician to the Swansea Infirmary.  
 PROSSER, THOMAS, F.R.C.S. Eng., has been elected one of the Surgeons to the Monmouth Dispensary.  
 STARLING, J., L.R.C.P., has been appointed Medical Officer to the Chelsea, Brompton, and Belgrave Dispensary.  
 WILLEY, H., M.R.C.S. Eng., has been elected House-Surgeon to the Poplar Hospital.

## DEATHS.

ATKINSON, JOHN, at Kilham, Yorkshire, on May 10, aged 62.  
 BIRCH, JOHN, M.R.C.S. Eng., at Portland-street, Manchester, on May 3, aged 35.  
 CLARKSON, JAMES, L.R.C.S. Edin., at New Zealand, on board H.M.S. *Orpheus*, Assistant-Surgeon R.N.  
 CLIFFORD, ROBERT, M.D., at Brooklyn, New York, late of Dublin, aged 63.  
 CUTFIELD, ALFRED BAKER, M.D. Aberd., at Deal, Kent, on May 11, aged 47.  
 FIELD EDWARD, M.D., J.P. of the Oaks, Framlingham, Suffolk, on May 10, late Royal Artillery.  
 HILLIARD, DANIEL, L.R.C.S.I., at Balmullen, Tralee, County Kerry, on May 7.  
 MCGREGOR, J. BONAR, L.R.C.S. Edin., at College-square North, Belfast, on May 6.  
 POWER, JOHN HATCH, M.D. Glasg., at Harecourt-street, Dublin, on May 14, aged 56.  
 SIBBALD, GEORGE, late of the Royal Navy, at Argyle-square, Edinburgh, on May 4, aged 73.

THE Peabody Trustees are going to build in Victoria-street, Holborn-hill.

WE learn that a testimonial to Dr. Budd will be presented on Saturday (this day), at four o'clock, at King's College.

WE learn that two persons at Leith have been mulcted in £12 damages, for injuring a person's health by mesmerising him.

WE are glad to learn that Dr. Priestley, who has recovered from a severe attack of diphtheria, is wisely going abroad for a few months, before resuming practice. Dr. Priestley shows his long-sightedness and prudence in thoroughly recovering his vigour before he enters on the arduous duties of his Professorship and private practice.

**ACADÉMIE DES SCIENCES.**—Admiral Fitzroy has been elected Corresponding Member in the section of Geography and Navigation in the room of Sir James Clark Ross, by the suffrages of thirty-nine of the forty-five voters who were present. The other candidates were Dr. Livingstone, Captain MacClure, and Admiral Washington.

WE are glad to see that the Liverpool people are testing the qualifications of one Mr. Thornton Jordan, M.D., a gentleman who practises in the "nervous debility" line. He has been summoned before the magistrates, but the case was dismissed in consequence of the absence of the person who was prosecuted. We hear, however, that a fresh summons is to be taken out.

**SALE OF DISEASED MEAT.**—At the Central Criminal Court, on Saturday, the 16th, a butcher named Underwood was sentenced to three months' imprisonment with hard labour for sending to Newgate-market 300 lbs. weight of beef, well knowing the same to be unfit for human food.

**THE ROYAL MEDICAL BENEVOLENT COLLEGE DINNER.**—The total amount of subscriptions announced in the room was about £970. The following is a statement showing the totals of the ordinary income and expenditure of the Royal Medical Benevolent College for the year 1862:—Annual subscriptions, £3114; donations, £1006; dividends, £168; school payments, £5052.—Total, £9340. Ordinary expenditure, £8658.

**KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.**—Dr. Corrigan, President of the above College, received the Fellows and Licentiates of the College, and a large number of other visitors, at a *conversazione* at his residence in Merrion-square, on Saturday evening, the 16th inst. Among those present on the occasion were the Right Hon. the Lord Chancellor of Ireland; the Right Hon. Joseph Napier, ex-Chancellor; Sir Bernard Burke, Ulster King-at-Arms; Dr. Stadfeldt, of Copenhagen, etc.

**UNIVERSITY OF ST. ANDREW'S.**—We are sorry to have to announce the retirement of Dr. Day, on the ground of ill health, from the chair of Chemistry and Anatomy in the United College, St. Andrew's. The old students and graduates of the University will hear of Dr. Day's resignation with great regret. The appointment of Dr. Day's successor is vested in the University court.

**MISS ANNIE RUSSELL.**—At the Court of Bankruptcy, on May 15, Miss Russell, the defendant in the case of *Russell v. Adams*, who had declared herself bankrupt on being arrested for £315 costs, incurred by Mr. Adams in defending the action, applied for her release from custody. Mr. Commissioner Fane characterised the case as "monstrous," and said that he should not release her until she had suffered four months' imprisonment. On the removal of the bankrupt, the Commissioner added with a smile—"I hope she will not sue me."

**DEATH OF DR. JOHN HATCH POWER, F.R.C.S.I.**—It is with very sincere regret we announce the death of Dr. Power, which took place on Thursday, the 14th inst., at his residence in Harcourt-street, Dublin. For many years he ably filled the chair of Anatomy in the Royal College of Surgeons in Ireland; and on the lamented death of Dr. William Porter he was appointed his successor as Professor of Surgery. Dr. Power was an accomplished Surgeon. His valuable work on the "Surgical Anatomy of the Arteries" gave him a widely-extended fame, and his kind, courteous, and gentle manner won for him many friends among his Professional brethren, the students, and the public, by whom his unexpected death will be deeply deplored.

**FEIGNED LAMENESS.**—On Friday, the 15th inst., a private named Smith, of the 5th Fusiliers, was drummed out of his regiment. Smith had been for some time in Hospital for treatment of rigidity of the knee. The Medical Officers, believing that his lameness was feigned, administered chloroform, and the knee was instantly and easily bent. He was tried by court-martial, and sentenced to be expelled the army, and to undergo six months' imprisonment. During the whole proceedings Smith inflexibly maintained his composure, and persisted in his pretence that he is lame.

**HEALTH OF SCOTLAND.**—The monthly return for the eight principal towns of Scotland shows that small-pox has now almost died out in Edinburgh, but has given some signs of becoming epidemic in Greenock. That formidable disease, diphtheria, is on the increase, and in the month of April caused 43 deaths in the eight towns, their aggregate population being less than a third of the population of the London of the Registrar-General. The deaths from small-pox in the eight towns in April were only 20. Of the 2173 persons who died in the month, half were under five years of age. The meteorological returns for April show a month with south-westerly winds prevalent, and much moisture both in humidity of the air and depth of rain.

**ETHNOLOGICAL SOCIETY, MAY 19.**—GENERAL ANNIVERSARY MEETING.—John Crawford, Esq., President, in the Chair. The following were elected office-bearers for the ensuing year:—*President*—John Lubbock, Esq. *Vice-Presidents*—B. Botfield, Esq., M.P.; John Crawford, Esq.; Robert Dunn, Esq.; Lord Talbot de Malahide. *Hon. Treasurer*—F. Hindmarsh, Esq. *Hon. Secretaries*—Thomas Wright, Esq.; F. Galton, Esq. *Hon. Librarian*—L. J. Beale, Esq. *Council*—Luke Burke, Esq.; Professor Busk; T. F. D. Croker, Esq.; Sir A. W. Clavering, Bart.; H. Christy, Esq.; J. Dickinson, Esq.; T. Hodgkin, Esq.; Professor Huxley; David King,

Esq.; Malcolm Lewin, Esq.; Joseph Mayer, Esq.; W. Napier, Esq.; C. R. Des Ruffières, Esq.; E. O. Smith, Esq.; S. R. Solly, Esq.; W. Spottiswoode, Esq.; Dr. Tuke; Stephen Ward, Esq.; S. Wood, Esq.

**SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN IN LONDON AND ITS VICINITY.**—The seventy-fifth anniversary of this excellent Society was celebrated on the 20th inst. at the Albion Tavern. Mr. Stone occupied the chair, and was supported by the Hon. George Denman (the grandson of Dr. Denman, one of the founders), Mr. Baillie (son of Dr. Matthew Baillie, the celebrated President of the College of Physicians), Dr. Watson, Sir Charles Locock, Sir W. J. Fisher, Dr. Babington, Dr. Pitman, and a large number of the most distinguished of the metropolitan Profession. The evening passed off in a very agreeable manner, and donations to the amount of £300 were announced.

**SIR B. BRODIE'S SURGICAL WORKS.**—We are glad to hear that the works of the late eminent Surgeon will be shortly re-published. Mr. Charles Hawkins is engaged in the task of selecting and editing these. The long period during which Mr. Hawkins enjoyed a connexion with the late Sir Benjamin, and the access which he has had to his various manuscripts and papers, afford some guarantee that the reproduction of these important contributions to Surgical science will be judiciously and adequately executed.

**MEDICAL PROFESSION IN THE CANTON OF ZURICH.**—The population of this Canton in 1860 amounted to 267,668. The number of Physicians is 181, *i.e.*, 1 to every 1478 inhabitants. There are also 309 Surgeons of the lower class, or 1 to 866 inhabitants; 1 Apothecary to 9559 inhabitants; 1 midwife to every 661. Dividing the 405 midwives by the number of children born, which in 1861 was 8084, there would be but 19 births for each.

**PESTILENCE IN INDIA.**—The following is extracted from the letter of the Calcutta correspondent of the *Times*, dated April 9:—"The country of Jessore, on the confines of which the Ganges loses itself in those innumerable creeks which constitute the rich Sonderbund marshes, is well known as the source of that cholera which in 1817 infected Lord Hastings's army, and then became, for the first time, the scourge of Europe. In the same country a pestilence like the Egyptian plague, generally preceded by cholera, has long been endemic, and during the last three years—since June, 1860—has spread all round Calcutta and along the line of the East Indian Railway to Burdwan. It has slain no less than 40,000 victims, or 60 per cent. of the whole population affected. By dispensaries and native doctors, Government, always benevolent, in vain attempted to arrest it, but last November, with the last fall of rain, it spent its fury. For miles whole villages are abandoned, and there were none left to bury or burn the dead, whose corse still pollute the air. The report of Dr. Elliott, appointed to investigate the epidemic, reveals horrors which even the technical language of the Medical man does not modify. All is attributed to malaria, and water so filled with decaying organisms that an oily scum floats on its surface. A Bengalee village is always covered with the densest vegetation, for the sake of privacy and fruit, and is destitute of the simplest means of conservancy. Orders have gone forth for the clearance of jungle and the filling up of pestilential pools, but the people are apathetic and hate cleanliness, and probably the next rainy season, in June, will see a recurrence of the plague, described as a remittent, congestive fever, which carries off the victim in periods of from five hours to fifteen days. Fortunately for the tropics, where vegetation is so dense, the great heat destroys or checks malaria; but the four months of rain are deadly."

**PROFESSOR SIMPSON, of Edinburgh, has just left Paris, where he has been staying for the last ten or twelve days. He devoted a large portion of his time to visiting the numerous public Hospitals and private "cliniques" for which this capital is so famous. His presence in these institutions created an immense sensation. By the leading Surgeons and Physicians he was received with much courtesy and attention, while by the students he was regarded as a veritable "lion," all present being anxious to catch a glimpse of, and to derive information from him. The child-like simplicity of Dr. Simpson in his Professional researches is very remarkable. Unlike too many of his *confrères*, at least on this side of the channel, his entire bearing is characterised by a total absence of anything like "scientific pride," while his bland, yet quiet and earnest manner, readily conquers the esteem and admiration of all**

who come in contact with him. On more than one occasion the Professor had an opportunity of showing his peculiar method of putting patients under the influence of chloroform; this we were glad to see, as it has often occurred to us that chloroform is carelessly, clumsily, and very imperfectly administered in France generally; indeed, the abolition of pain, the real object of this most invaluable agent, and one of the scientific glories of the present century, is, through the improper application of the anæsthetic, not accomplished; we are very much mistaken if a similar impression was not made on the mind of Dr. Simpson himself during his stay in Paris. The Doctor, both by precept and by practical demonstration, took great pains to remedy this crying abuse of an agent so intimately associated with his own name, and we hope his remarks may produce the amount of success they are so justly entitled to. Professor Simpson exhibited a great number and a great variety of instruments, obstetrical and surgical, many of them his own invention; and he not only fully explained the peculiarities of their mechanism, but also showed the manner of their application. The greater part of these instruments were greatly admired even by our French brethren. The leading instrument makers of the capital, who, in France may be regarded as hardly of less importance than the Hospital Surgeons themselves, listened to Dr. Simpson's explanations with much interest and attention. The instruments in use here were minutely examined by Dr. Simpson, and their application keenly scrutinized.

BOOKS RECEIVED.

- Fifth Annual Report of the General Board of Commissioners in Lunacy for Scotland.
- \* "The enormous amount of labour, thought, and material buried in these blue-books is absolutely lost on the class who are most fitted to profit by them. Uninviting appearance, painfully elaborate tables, and rigorously business-like style are quite enough to deter a Professional man from assailing them, unless he be the owner of an asylum that has been subjected to criticism, or a junior member of a statistical society anxious to distinguish himself. The present Report, besides its numerical information, from which we learn that the total increase of recognised lunatics during the past year in Scotland has been only 71, furnishes, in the "Entries made by the Commissioners in the Patients' Books of Asylums and Poorhouses," a mass of facts to be hereafter of the greatest value as authentic pictures of the hygienic and moral treatment of insanity in our own times, many of which will speak more forcibly in favour of the civilisation of the nineteenth century than even rail-roads and iron-bridges. What would kind-hearted Bailie Nicol Jarvie have thought of bagatelle-boards, bowling-greens, and periodical literature provided within the precincts of Glasgow City Poorhouse for pauper lunatics?"

Mean temperature .. .. .	52.8°
Highest point of thermometer .. .. .	64.5
Lowest point of thermometer .. .. .	42.2
Mean dew-point temperature .. .. .	46.3
General direction of wind .. .. .	S.W.
Whole amount of rain in the week .. .. .	0.50 in.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Inquirer.—Dr. Kidd promises a reply next week.

Who to Consult shall be noticed in our next. It appears to be a miserable attempt to injure the honourable and well-informed General Practitioner, and to puff the book-making, case-forging, advertising specialists.

Veritas points out the frequency of disgusting advertisements in the American newspapers, promising the relief of female obstructions, etc. etc. The ugly part of it is, that one of the worst of these advertisements proceeds from a She-Physician. If the Americans go on fighting, they will not want to limit the number of their offspring.

We regret that we cannot publish anything more with regard to the Fowler and Mayne controversy.

Wronged.—1. We consider that every Medical man is bound to give his opinion to the person who consults and pays him. 2. If a Medical man is employed by A. B.'s wife's mother, he will naturally give his opinion to the wife's mother, and will act upon his own discretion as to any replies he may choose to make to questions from the husband. 3. According to the facts put before us, the vaccination could not have been the cause of syphilitic infection of the child, for secondary syphilis would not break out three days after vaccination. 4. From the report given, it would appear that the child's malady was syphilis. 5. Also, there can be no doubt that, on December 20, 1861, the Surgeon who examined the wife found warts, excoriations, and other signs of diseases which are usually communicated by infection during connexion. 6. There is nothing in the dates given by Wronged which negatifies the notion that the wife may have contracted her illness in October, although she made no complaint till the end of November. 7. The ocular inspection by the Surgeon who was sent for by the wife's mother on December 20, 1861, was quite proper and necessary. 8. If, as Wronged says, he never had disease himself, he clearly could not have given it; but as to how the wife got it, this is a question upon which we have no other evidence, and will not volunteer an opinion. 9. The Surgeon who finds syphilis in the wife of a man who left her six weeks before, and who is employed by the wife's relatives, may use his own discretion as to advising that the fact shall be communicated to the husband or not. It is a question of general discretion, not of Professional conduct.

Queensland.—Another Andrew Battell.—A white man named James Morrill, a native of Maldon, in Essex, has just been discovered in the Burdekin district, having lived for seventeen years among the aborigines of the north without seeing a white man. He was wrecked in March, 1846, on the Horse-shoe Reef, near the entrance of Port Denison, and escaped in a boat with the captain and other passengers. They drifted northward for many days, and at last were thrown on the coast. All but Morrill soon died. His long residence among the blacks had not caused him to forget his native tongue. He is at present in Brisbane.

The Discoverers of the Source of the White Nile.—Sir R. Murchison has announced in the Times that Consul Petherick, who was supposed to be dead, has effected a junction with Captains Speke and Grant at Goudokoro, on the White Nile, on the 23rd of February. He writes:—

"This discovery of Speke and Grant, by which the southernmost limit of the basin of the Nile is determined to be four degrees south of the equator, is the most remarkable geographical feat of our age, and is, indeed, an achievement of which all our countrymen may well be proud."

Flogging.—A respected provincial Surgeon thus writes to the Standard:—

"I am an old gaol Surgeon, and I notice with much regret the progressive increase of crime. I am an ardent admirer of the present system of prison discipline, as far as regards 'separate confinement,' but I believe that the good which is thus obtained is more than counterbalanced by the almost entire discontinuance of corporal punishment. There is nothing which a man or a boy dreads so much as flogging, and I firmly believe that if the prisoner who is now sentenced to one year of transportation or penal servitude had as many months of hard labour in his present gaol, with a flogging once a month, the decrease of crime would be immense. It might be made known to the said prisoner that if he is ever re-committed he will be flogged twice a month."

Erratum.—P. 523, in the announcement respecting Dr. Jenner, for statements read statement.

MARRIAGES OF CONSANGUINITY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR.—I have just been reading Dr. Gilbert W. Child's most excellent and interesting article on "Marriages of Consanguinity," which appeared in your Journal of April 25. I beg to convey to him, through your pages, a fact with regard to breeding in-and-in in an isolated neighbourhood which was brought to my notice by a friend. A farmer in Essex started with a most excellent and healthy breed of pigs, from which he continued to breed from one sire for some years, until at last one of his sons took his place, and did duty towards perpetuating his species through his sisters, and afterwards his daughters, until at last they became so deteriorated in quality and appearance as to convey to one's mind—had it not been known that not the slightest effort at selection had ever been made to improve the stock from their common parentage—the absurdity of breeding in-and-in. These pigs, about forty in number, were lame and rickety, and had a very foolish, idiotic-looking countenance, indeed, their conduct and appearance were more like drunken pigs than anything else. I do not know, Sir, if you have ever seen pigs in an inebriated state, but I have—produced by eating the pulp of the apples that had got in a state of fermentation, after the juice had been expressed from them for the

purpose of making cider—and very grotesque, stupid, though, at the same time, humorous and pot-valiant animals they are when under the influence of that which makes them tipsy. I think the case of these pigs shows, among many others, that when any one has recourse to breeding in-and-in, some, indeed great, attention should be paid in selecting the most healthy of the stock for the purpose, at the same time not disregarding their general good appearance, and that there should not be any deviation from any of the characteristics necessary to secure a healthy progeny for all time. I am, &c.

Piccadilly, May 12.

II. HODSON RUGG, M.R.C.S.E.

DR. C. MURCHISON'S WORK ON FEVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—My attention has been directed to a misprint in my work on Fever. At page 471, where the characters of the eruptions of typhus and enteric fever are contrasted in a tabular form, the distinguishing characters under the head of No. 8, have been accidentally printed in the wrong columns. It is the eruption of typhus which appears on the fourth or fifth day of the fever, and that of enteric fever which rarely appears before the seventh day. Although these facts are clearly indicated at pages 117, 131, 457, and 470 of the work, a casual reader might carry away an erroneous impression from merely referring to the table in question. As the point is of some importance, I beg those of your readers who possess the book to make the necessary correction. A note pointing out the error will be inserted in all copies of the book sold after this date.

May 18.

CHARLES MURCHISON.

JUNIOR MIDDLE CLASS AND PRELIMINARY PROFESSIONAL EXAMINATIONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—May I ask through your columns the meaning intended to be put on the directions of the General Medical Council of Education on the following subject, viz. :—“From and after the 1st January, 1863, certificates of having passed any junior middle-class examination will not be received, Latin not being made compulsory.” Does this mean that junior middle-class examinations passed before January 1, 1863 will be received; but that such examinations passed after January 1, 1863, will not be received? This is an important question; for I am myself aware of many young men who have not yet commenced their London studies, but who have passed a junior middle-class examination, with a view that such an examination would clear them of all future preliminary examinations by the different examining bodies. In most cases these young men did pass in Latin. If the Secretary or Registrars of the different examining bodies would kindly explain this matter they would oblige many, and especially

Yours, &c.

MEDICUS.

THE ARMY MEDICAL EXAMINATIONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your Correspondent, “Paterfamilias,” advocates the system of holding examinations for degrees, etc., sessionally. He founds his argument on the fact of very few memories being retentive enough to allow of a satisfactory examination, at one time, upon such an extensive range of subjects as the Examining Boards require. If this be true regarding University and College of Surgeons Examiners, how much more so in the case of the Army Medical Examining Board. And, indeed, he adduces in support of the sessional system the non-proficiency of the candidates at the recent examinations of that Board.

The practical deduction from the above statements is this,—viz., that candidates are required to get up for examination a mass of knowledge which the memory no longer retains after the object has been gained for which the cramming was instituted; so that it is much better to go up for the public service examinations at once upon leaving the schools, with the crammed memory still retentive, but with very little knowledge of what constitutes the real practice of the Profession, than to go up with the wider views and the more enlarged experience gained by personal observation during a year or two spent in general practice.

In order to pass the Examiners, cramming is now the student's only resource; and very systematic that cramming must be to master such a range of subjects as was, in February last, presented to the candidates for admission into the Medical service of Her Majesty. There are but few Medical men who could have passed a satisfactory examination in all the branches, however much individuals might excel in particular subjects.

I am not one of those who believe in the ultra wretched condition of the Army Medical officers. No body of men exists without its grievances, real or fancied; but—and this is not egotism—I do object to a system of examination and Examiners by which those best crammed are admitted, and really good men are kept out of the service.

I am, &c.

Scotland, May 11.

ONE OF THE THIRTY-ONE REJECTED.

THE EFFECTS OF THE CALABAR BEAN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The perusal of Mr. Soelberg Wells' paper on “The Effects of the Calabar Bean on the Accommodation of the Eye and on the Pupil,” has afforded me great gratification, as it fully corroborates all my views regarding the effects of the bean and its useful application. There is one effect noted by Mr. Bowran as having been produced by it which I have not perceived. I refer to astigmatism, which, however, I think may possibly be due to the more powerful action of the solution on that part of the ciliary over which the drop is placed. This theory receives some confirmation from an irregularity in the contraction of the pupil (heart-shaped) reported by Mr. Wells as occurring in the sound eye of his patient after the application of the bean.

As I believe many are at present experimenting with this new remedy, I take this opportunity of mentioning that I found the watery solutions, or, more strictly speaking, suspensions of the spirituous extract that I first employed, soon to become decomposed and turn fetid. In consequence, I have now substituted syrup as a suspensory medium, which I hope will prevent the occurrence of decomposition. I previously tried glycerine, which answered well, but its application appeared to cause considerable irritation, on which account I had recourse to syrup. Mr. Hugh Neill, of Liverpool, having perceived the tendency of the aqueous suspensions to undergo decomposition, has also been independently led to the employment of glycerine. I may here add that I have found the capsule of the bean quite inert as regards action on the eye.

I have entered more fully into the consideration of the foregoing points in a “Note on the Calabar Bean,” which is to appear in the June Number of the *Edinburgh Medical Journal*. In the meantime, I may refer to an

incident that occurred to me a few days ago, as illustrative of the beneficial action of the bean. One day last week, on returning home in the afternoon, and taking up a book to read, I found, to my alarm, that the type appeared very indistinct, to such an extent as to prevent my reading with any comfort. Upon further trial, I discovered that the defect lay in my right eye, and that with the other I could see perfectly distinctly. An explanation of the occurrence was at once obtained on an inspection of the eyes,—the right pupil being found widely dilated, which I readily ascribed to the accidental introduction of atropine, a solution of which I had had occasion shortly previously to apply to a patient's eyes; a little of this solution had, no doubt, remained on my fingers, and been conveyed by them to my right eye. I at once applied a drop of the syrup of the extract of the bean, with the effect, after a few minutes, of enabling me to proceed comfortably with my reading. One other application was necessary after the lapse of a few hours, as the effects of the first began to pass off.

I am, &c.

ORIGINAL LECTURES.

PROFESSOR HUXLEY'S LECTURES

AT THE

ROYAL COLLEGE OF SURGEONS.

LECTURE VII.

(Being the Sixth Lecture on Classification, and on the Characters of the Principal Groups of the Animal Kingdom.)

THE latest form of the "cerebral" classification of the Mammalia having thus been shown to be devoid of any sound foundation, I proceed to inquire whether the "placental" classification does, or does not, stand upon a more secure basis, if we take, not merely, with Milne-Edwards, the form of the placenta, but with Von Baer and Eschricht, its structure, into account. It is a well-established fact that two very distinct types of placenta are to be met with in the *Monodelphia*, and that, at the present moment, we have no knowledge of any transitional forms between these two types. The first of these types is that exhibited by the human placenta, the second by that of the pig or horse.

From the commencement of gestation, the superficial substance of the mucous membrane of the human uterus undergoes a rapid growth and textural modification, becoming converted into the so-called "*Decidua*." While the ovum is yet small, this *Decidua* is separable into three portions,—the *Decidua vera*, which lines the general cavity of the uterus; the *Decidua reflexa*, which immediately invests the ovum; and the *Decidua serotina*, a layer of especial thickness, developed in contiguity with those chorionic villi which persist and become converted into the foetal placenta. The *Decidua reflexa* may be regarded as an outgrowth of the *Decidua vera*; the *Decidua serotina* as a special development of a part of the *Decidua vera*. At first, the villi of the chorion are loosely implanted into corresponding depressions of the *Decidua*, but, eventually, the chorionic part of the placenta becomes closely united with, and bound to, the uterine decidua, so that the foetal and maternal structures form one inseparable mass.

In the meanwhile, the deeper substance of the uterine mucous membrane, in the region of the placenta, is traversed by numerous arterial and venous trunks, which carry the blood to and from the placenta; and the layer of decidua into which the chorionic villi do not penetrate acquires a cavernous, or cellular, structure from becoming burrowed, as it were, by the innumerable sinuses into which these arterial and

FIG. 3.

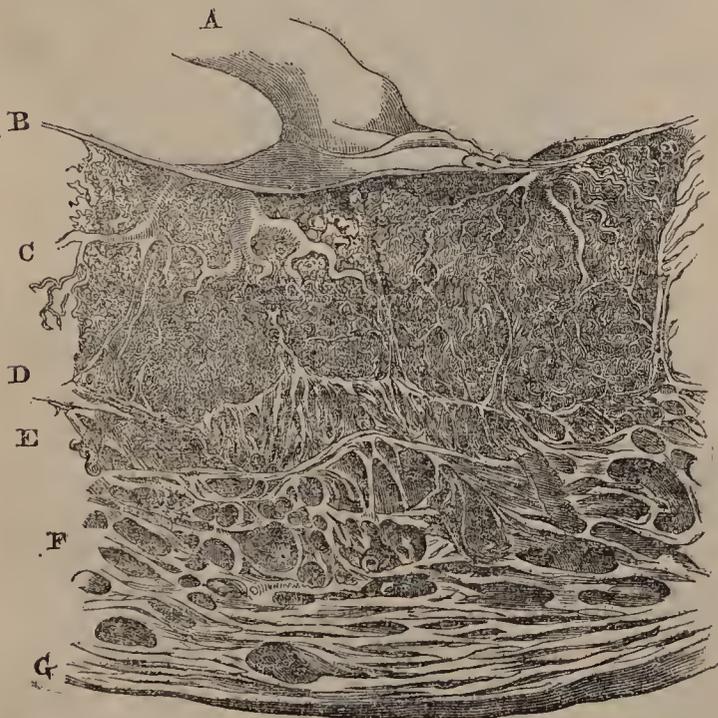

FIG. 3.—Section of the Human Uterus and Placenta at the thirtieth week of pregnancy. (After Ecker.) A, umbilical cord; B, chorion; C, the foetal villi separated by processes; D cavernous *Decidua*; E, F, G, wall of the uterus.

venous trunks open. In the process of parturition, the *Decidua serotina* splits through this cellular layer, and the superficial part of it comes away with the umbilical cord, together with the foetal membranes and the rest of the *Decidua*; while the deeper layer, undergoing fatty degeneration and resolution, is more or less completely brought away with the lochia, and gives place to a new mucous membrane, developed, during pregnancy, throughout the uterus.

In the Pig the placenta is an infinitely simpler structure. No "*Decidua*" is developed; the elevations and depressions of the unimpregnated uterus simply acquire a greater size and vascularity during pregnancy, and cohere closely with the chorionic villi, which do not become restricted to one spot, but are developed from all parts of the chorion, except its poles, and remain persistent in the broad zone thus formed throughout foetal life. The cohesion of the foetal and maternal placenta, however, is overcome by slight maceration or post-mortem change; and, at parturition, the foetal villi are simply drawn out, like fingers from a glove, no vascular substance of the mother being thrown off.

The process by which the mucous membrane of the uterus returns to its unimpregnated condition after parturition in the pig has not been traced.

The extreme cases of placentation exhibited by man and by the Pig may be termed, with Von Baer and Eschricht, from the character of the maternal placenta, "caducous" and "non-caducous," or, from the degree of cohesion of the two placenta in parturition, "coherent" and "incoherent;" or, what perhaps would be better still, the two mammals may be spoken of as "deciduate" and "non-deciduate." (e) But, whatever terms be employed, the question for the classifier is to inquire what mammals correspond with Man and what with the Pig, and whether the groups of deciduate and non-deciduate *Monodelphia* thus formed are natural groups, i.e., contain such orders as can be shown, on other grounds, to be affined.

With respect to the deciduate *Monodelphia*, it is certain that the apes agree, in the main, with man in placental as in other important characters, and, so far as has hitherto been observed (though our knowledge of the placentation of the Lemurs is very defective), their placenta differ from those of Man only in presenting a more marked lobation—a character which occurs as a variety in Man.

The *Cheiroptera*, *Insectivora*, and *Rodentia* agree with Man in possessing a placenta which is not only as much "discoidal," allowance being made for the shorter curve of the uterine walls, as his, but also entirely resembles his in being developed in conjunction with a decidua. This *decidua* always corresponds to at least the *decidua serotina* of Man; frequently there is a well-developed *decidua reflexa*. (f) How far a *decidua vera* can be said to be developed is doubtful.

I am well aware that these statements are in direct opposition to some that have been very confidently put forward. Thus, Professor Owen, in arguing against the views entertained by Milne-Edwards and Gervais, makes the following assertions:—

"The degree of resemblance in outward form between the placenta of the Rat or Hare, on the one hand, and the *Myctes* and *Mucacus* on the other, seems to me to be more than counterbalanced by the difference of structure. The pedunculate and cotylloid placenta of the Rat consists of foetal parts exclusively; the maternal areolar portion is as distinct from it as it is in the cotyledon of the Ruminant, and is a persistent structure of the uterus. The discoid placenta of the monkey includes a large proportion of maternal cellular structure, which comes away with the foetal portion. The difference in the organic interblending of the circulatory organs of mother and offspring, between the *Rodentia* and *Quadrumana* is of much more real importance than the degree of superficial similarity."—(L. c., p. 16, note).

Led by the extraordinary contradictions of some of the

(e) It is, of course, by no means intended to suggest by these terms, that the homologue of the *Decidua* does not exist in the "non-deciduate" Mammals. The mucous membrane of the uterus becomes hypertriphic during pregnancy in both the deciduate and the non-deciduate mammals; but it is thrown off, and so gives rise to a "*Decidua*" only in the one of these two groups.

(f) See upon this subject the recently-published valuable essay of Reichert: "Beitrage zur Entwicklungsgeschichte des Meerschweinchens." Reichert finds a complete, or almost complete, *Decidua reflexa* in Rats, Mice, Guinea-pigs, and Bats; while in Rabbits, Hares, and *Carnivora*, the *Decidua reflexa* only partially surrounds the ovum.

best known facts of embryology (g) contained in the passage I have italicised to look into the matter afresh, I have found that the assertions made therein respecting the placenta of the Rat are as completely contrary to fact as are those respecting the brain of the apes which I have already cited from the same author.

FIG. 4.

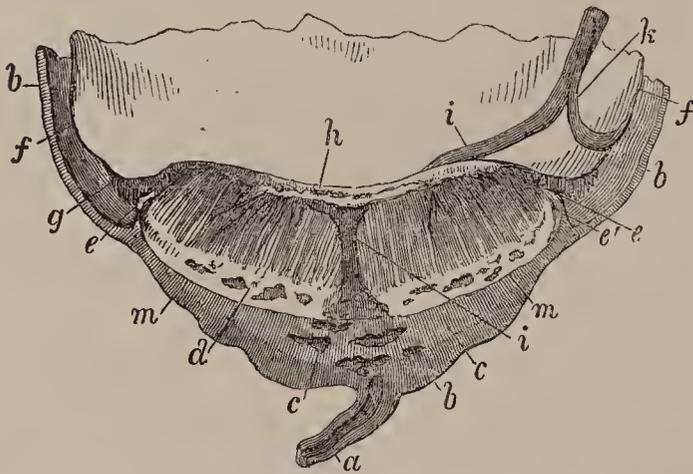

FIG. 4.—Magnified view of a section of the placenta and uterus of a pregnant Rat.

Figure 4 represents a section of the uterus, chorion, and partially-injected placenta of a foetal Rat, one inch and a-quarter long, taken in a direction perpendicular to the long axis of the uterine cornu. (a) is the mesometrium

(g) Eschricht described the placenta of the Rat with great precision, as the following extract will show, six-and-twenty years ago. Is it possible that a hasty perusal of a passage which I have italicised should have misled any of his successors into supposing that Rodents have persistent cotyledons like those of Ruminants? "Placenta fere circularis erat; diametris longior sex lineas cum dimidia explebat, brevior sex lineas. Superficies ovo obversa nonnihil concava erat, externa autem sat convexa, ita ut a margine ad centrum sensim in tumulum surgeret et crassitudinem placenta ad duas lineas augetet. In superficie ejus concava, ovo obversa, tres distingui poterunt regiones; circum centrum, a vasis umbilicalibus perforatum, laminula illa pertenui oblecta erat, quam vasa umbilicalia hic ei cumdare jam observatum est. Circa peripheriam scabrosa apparuit, quasi fila seu vasa abrupta fuissent, in media regione autem inter periphericum et centram levis erat tunica sat distincta vestita. Superficies placenta externa convexa duas regiones obtulit. Peripheria propior inaequalis ad axem longitudinalem ovi latior erat, unam et quartam lineam partem explens; ad latera angustior quartam modo lineam partem explens. Sic media et laevis hujus superficiae regio ovoidea quidem erat ut tota placenta, sed cum axe majore transverse ei insidens. In cumulo hujus superficiae permagnam vas ab utero centrum placenta perforavit. Haud procul a centro quinque vasa minora intervallis sat aequalibus uterum cum placenta jungebant. Superficiae uterinae proxima placenta pars in lamellas facile dividebatur, profundior autem pars eundem illum laminarum innumerabilium contextum exhibuit quem in placenta felina fuimus supra descripsi. Laminulas a centro ad peripheriam sat regulariter ordinatas esse observare mihi visum sum. Inter laminulas illas eandem esse alternationem laminarum foetalium et uterinarum vix dubitare potui, praesertim quum non modo vasa umbilicalia sed ab altera parte sex vasa majora ab utero placenta ingredi vidissem. At uterum examinans nova orta est dubitatio. Uteri cornua antequam ova excisa fuissent, moniliformia apparuerunt, et inter singula ova fortiter constricta. Ita non modo numerus sed etiam forma ovorum extus apparuit quid quod etiam placenta facillime observari videbantur. Intumescenciae, ova includentes, ipsae quidem oviformes erant, sed ad marginem superiorem ad insertionem ligamentorum laterum et ante eadem singulae tumuli speciem praebant, placenta aperte indicantis. Itaque placenta in utero muris ratti non modo quoad foetum, sed etiam quoad uterum certum occupat locum, et embryones omnes in una serie in oppositis uteri cornibus symmetrice collocati sunt, utrum autem capitibus praevius abdominibusque abdomen matris respicientibus, an clunibus praevius dorsisque abdomini matris obversis inquirere neglexi. Verum tumuli placenta indicantes non ipsae fuerunt placenta. Ovis excisis iidem tumuli in utero remanebant ut tubercula fusca tres lineas crassa, diametrum quinque linearum exhibentia. Quod quum observassem, initio tota mea de structura placenta mammalium unguiculorum sententia labefacta est. *Gliribus si ut ruminantibus pars uterina placenta in partu non abstruderetur, mirum sane fuisset, etsi theoria de placenta structura in universum eo nihil caperet detrimenti. Quum vero superficiem uterinam placenta levem observassem, et idem de superficie ipsius uteri ei obversa nunc observarem, tota theoria praece rellit mihi videbatur, secundum quam alternatio quaedam utriusque systematis adsit necesse est. Attamen mox intellexi corpus illud uterum non ipsam partem uterinam placenta esse. Supra jam de vase majore centrali et quinque minoribus circumstantibus sermo erat, quae placenta superficiem uterinam transibat. Eadem vasa jam in ipsius uteri superficie observavam et in aperto erat ramificationem eorum in laminulis ipsius placenta fieri. Corpus uterum transisissimum cellulas plurimas exhibuit, ut fallor, sanguinis coagulati nonnihil etiam tunc continentes. Sic constructum eadem functioni inservire mihi videtur ac similes uteri humani cellulae vel sinus venosi; nec placenta murina aliter a placenta felina discrepare video nisi quod vasa uterina pauciora sed sat magna partem uterinam inrant. Quibus observationibus ductus etiam GLIRIUM PLACENTAS EX PARTE FOETALI ET UTERINA CADUCA HAC ET ILLA LAMINULIS INNUMERIS ALTERNANTIBUS COMPOSITAS ESSE putabo donec melioribus observationibus refutatus fuero.*

traversed by a large uterine vein; (b) is the wall of the uterus becoming looser in texture and traversed by large venous channels in its inner substance (c); (d) is a decidual layer of the uterus of a cavernous structure, whence vascular processes are continued towards the chorionic surface of the placenta. A large vein (i) passes directly from the decidual layer (d), and the uterine sinuses beneath it, to near the chorionic surface of the placenta, beneath which it branches out horizontally. The chorion (f), rendered vascular over its non-placental part by the omphalomesenteric vessels (k), only begins to exhibit villous processes and folds at the point (g). These outermost villi appear to me to be free; but, more internally, they become closely connected with the upper surface of the placenta; and over the central third of the foetal face of the placenta, the umbilical vessels (i), ramify in a radiating fashion, and send prolongations down between the decidual lamellae. The slightest traction exerted upon the cord causes the placenta to separate along the line e, m, e, bringing with it, of course, the cup-shaped decidua d. (h)

It is obvious, from the above description, that the "pedunculate and cotyloid" placenta of the Rat does not "consist of foetal parts exclusively," but that, on the contrary, as Eschricht has so well pointed out, "the organic interblending of the circulatory organs of mother and offspring" is as complete in the Rat, as in Man; and that, therefore, the concluding paragraph of the citation from Professor Owen's paper ought to be reversed.

The *Carnivora* develop a well marked *Decidua*, and their placenta in all genera which have been examined (except the Stoat, according to Von Baer), has the form of a complete zone, or broad girdle, surrounding the middle of the chorion and leaving the poles bare.

FIG. 5.

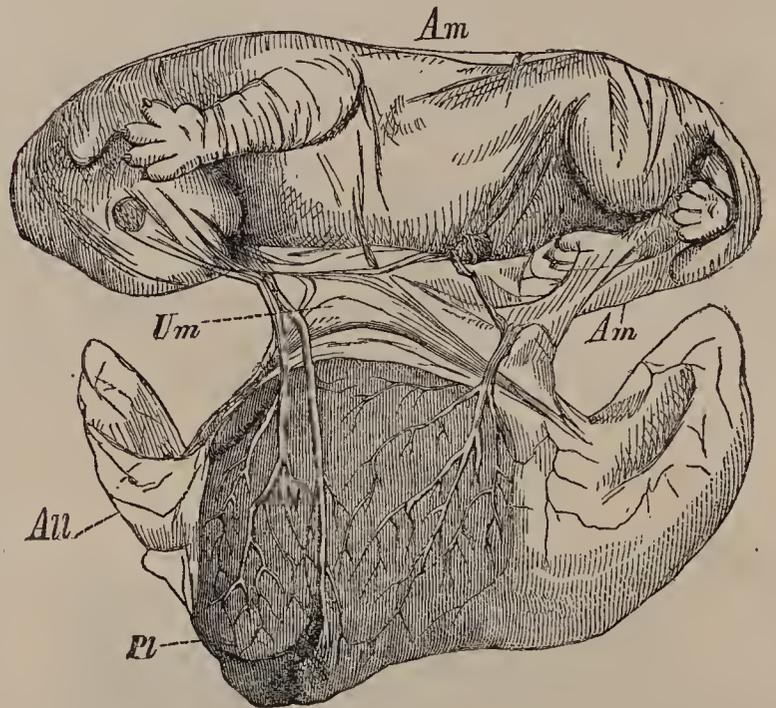

FIG. 5.—Foetal kitten, with its membranes and placenta. The latter is seen from within, the chorion and allantois being opened and everted. Am, amnion; Al, allantois; Pl, placenta; Um, umbilical vesicle. (From a preparation in the Museum of the Royal College of Surgeons.)

Thus Man; the Apes, or so-called *Quadrumana*; the *Insectivora*, the *Cheiroptera*, the *Rodentia*, to which the

(h) My friend, Prof. Rolleston, to whom I am indebted for much valuable assistance in working out this placental question, is of opinion that the cup shaped decidua of the Rat corresponds not only to that part of the decidua serotina which comes away, as a part of the after-birth, in Man, but, in addition, to that part which is subsequently eliminated in the lochia; and that, therefore, the Rat's after-birth, instead of "consisting of foetal parts exclusively," absolutely contains more "maternal parts" than that of Man. In a recently-delivered Rat, Prof. Rolleston writes:—"The uterus possessed no structures in the least resembling a persistent cotyledon. Corresponding to the place of affixure of each foetus, was a funnel-shaped depression of mucous membrane leading down to a hernial protrusion into the mesometrium of the deeper structures, viz, the muscular coat and the arteries and veins penetrating it. The mucous membrane was perfectly formed, and contained glandular follicles. It was no doubt the homologue of the fresh layer of mucous membrane which Dr. Priestley has figured from a human uterus in the ninth month of pregnancy (at p. 99 of his work on the 'Gravid Uterus,') as clothing the muscular stratum of the organ, and separating easily from the decidua serotina."

lowest apes present so many remarkable approximations; and the *Carnivora* (united into one group with the *Insectivora* by Cuvier) are all as closely connected by their placental structure as they are by their general affinities.

With the Pig, on the other hand, all the *Artiodactyla*, all the *Perissodactyla* (save one) and all the *Cetacea* which have

been studied, agree in developing no decidua, or, in other words, in the fact that no vascular maternal parts are thrown off during parturition. But considerable differences are observed in the details of the disposition of the foetal villi, and of the parts of the uterus which receive them. Thus in the Horse, Camel, and *Cetacea* the villi are scattered, as in the Pig, and the placenta is said to be *diffuse*; while in almost all true Ruminants the foetal villi are gathered into bunches, or cotyledons, which in the Sheep are convex, and are received into cups of the mucous membrane of the uterus; while in the Cow, on the contrary, they are concave, and fit upon corresponding convexities of the uterus.

No one, probably, would be inclined to object to the association of the orders just mentioned into one great division of the *Monodelphia*, characterised by its placental structure. But such grouping leaves several important points for discussion. (i) The Elephant, as Professor Owen has shown, has a zonary placenta, and the genus *Hyrax* has been known since the time of Home to be in like case. Hence, as the elephants are commonly supposed to be closely allied with the *Pachydermata*, which possess diffuse, non-deciduate placenta, and as *Hyrax* is now generally, if not universally, admitted into the same order as the Horse, which has a diffuse, non-deciduate placenta, it is argued that placental characters do not indicate natural affinities. A question, indeed, arises, which has not been answered by those who have described the placenta of *Elephas* and *Hyrax*. Is the placenta of these animals simply a zone-like arrangement of villi or cotyledons, in connexion with which no decidua is developed, or is it a true deciduate placenta, resembling that of the *Carnivora* in the essentials of its internal structure as in its external form? Recent investigation has convinced me, that, in both these animals, the placenta is as truly deciduate as that of a Rodent, so that most unquestionably, if the placental method of classification is to be adopted, both *Elephas* and *Hyrax* must go into the same primary division of the *Monodelphia* as the *Rodentia* and *Carnivora*.

But are these facts really difficulties in the way of the placental system of classification?

So far as the case of the Elephants is concerned, I must confess that I see no difficulty in the way of a classification which unites the *Proboscidea* more closely with the *Rodentia* than with the *Artiodactyla* and *Perissodactyla*, the singular ties which unite the Elephants with the Rodents having been a matter of common remark since the days of Cuvier.

In the absence of any definite knowledge of the placental structure of *Rhinoceros* and *Tapirus* it would, perhaps, be premature to discuss the position of *Hyrax*, as determined by its placenta; but if it should eventually appear, as is very probable, that *Rhinoceros* and *Tapirus* have diffuse, non-deciduate placenta, I should have no hesitation in regarding *Hyrax* as the type of a distinct order of deciduate Monodelphous *Mammalia*. *Hyrax*, in fact, hangs by *Rhinoceros* mainly by the pattern of its molar teeth,—a character which affords anything but a safe guide to affinity in many cases.

Concerning the placentation of the *Sirenia* we have no information.

Among the *Edentata*, the Sloths have presented a cotyledonary placenta, and the Armadillos have been affirmed to possess a discoidal one. I am not aware that the minute structure of the placenta has been examined in either of these groups, but I am indebted to Dr. Sharpey for valuable information respecting the placental structure of *Manis*. The surface of the chorion is covered with fine reticulating ridges, interrupted here and there by round bald spots, giving it an alveolar aspect, something like the inside of the human gall-bladder, but finer. The inner surface of the uterus exhibits fine low ridges or villi, not reticulating quite so much. The chorion presents a band, free from villi, running longitudinally along its concavity, and there is a corresponding bald space on the surface of the uterus. The ridges of the chorion start from the margins of the bald stripe, and run round the ovum. The umbilical vesicle is fusiform. This is clearly a non-deciduate placenta, and the cotyledonary form of that of the Sloth leads me to entertain little doubt that it belongs to the same category.

Admitting all these difficulties and gaps in our information, it still appears to me that the nature of the placenta affords by far the best characters which have yet been proposed for classifying the Monodelphous *Mammalia*, especially

(i) "Description of the Foetal Membranes and Placenta of the Elephant." —*Philosophical Transactions*, 1857.

if the concomitant modifications of the other foetal appendages, such as the allantois and yolk-sac, be taken into account. And it must be recollected that any difficulties offered by the placental method attach with equal force to the systems of classification based upon cerebral characters which have hitherto been propounded. If any objections, on the ground of general affinities, are offered to the association of *Elephas*, *Hyrax*, *Felis*, and *Cercopithecus* in the same primary mammalian division of deciduate *Monodelphia*, they are not removed by constructing that primary division upon other principles, and calling it *Gyrencephala*.

[The lecturer concluded his discourse with some remarks upon the propriety of restoring the Linnean order *Primates* as the equivalent of the orders *Bimana* and *Quadrumana* of authors—between which he argued that no structural distinction of ordinal value exists. As the arguments briefly indicated have been fully published in a separate work, it has not been thought necessary to repeat them here.]

LECTURES  
ON  
ECZEMA,

(INCLUDING ITS IMPETIGINOUS, LICHENOUS, AND PRURIGINOUS  
VARIETIES,)

DELIVERED AT THE

Dispensary for Skin Diseases, Glasgow.

By T. McCALL ANDERSON, M.D., F.F.P.S.

Physician to the Dispensary for Skin Diseases; Physician to the  
Deaf and Dumb Institution, etc., Glasgow.

LECTURE II. (a)

GENTLEMEN,—In my last lecture I described to you the most prominent symptoms of eczema, the infiltration of the skin, the exudation on the surface of the skin, the formation of crusts, and the itching. I then passed to the consideration of the elementary lesion, which I told you is either an erythematous state of the skin, a vesicle, a pustule, a papule, or a fissure. I had discussed in detail the first four of these, and the last only remains to be alluded to.

5. *The Elementary Lesion a Fissure.*—This lesion is met with very frequently as a complication of the varieties of eczema which I have previously described, and is oftenest seen on those situations where the skin is naturally thrown into folds, as at the anus, the angles of the mouth, and the joints. When the skin is in a healthy condition, it stretches with ease when the parts are moved; but, when an eczematous eruption is developed, its natural elasticity being gone, it gives way when put upon the stretch, thus giving rise to fissures, which are often deep and proportionately painful. Fissures, however, not unfrequently constitute the principal elementary lesion, though they usually form upon an erythematous ground, as in the vesicular and pustular varieties of eczema. While any part of the skin may be attacked, the most typical cases are to be met with on the hands, owing to the number of the joints, and the incessant and varied movements of the fingers. The number of the fissures varies much; there may be few, or, on the other hand, so many that they cross one another in all directions; and, although at first superficial, they have a tendency, as the disease becomes more chronic, to increase in depth, thereby causing excruciating pain and bleeding, especially on movement of the affected parts. When the eruption is fully established, infiltration of the skin is superadded, and itching, though pain usually predominates. The fissures, when deep, are red and raw-looking, and either serum or blood exudes from them at certain times, thus giving rise to the formation of small crusts, which partially fill them up. Here, then, we have, as in the vesicular variety of eczema, an infiltrated, exuding, and itching or painful eruption, and the only difference between the vesicular and the fissured variety of eczema is that the principal lesion is a vesicle instead of a fissure. This is the disease described in French works under the name of "Eczema Fendillé," and, as it is not portrayed in English dermatological works at all, I take the liberty, in conjunction with my colleague, of applying to it the term *eczema rimosum* (from *rima*, a fissure). A case of this form of eruption

attacking the palm of the hand will be referred to when the treatment is discussed.

The nature of *eczema rimosum* may be more forcibly impressed upon your minds if I remind you of what occurs in cases of "chapped" hands, with which affection most of you must be personally acquainted. The skin is red and superficial fissures occur which take the direction of the natural grooves of the skin. If appropriate treatment is not now adopted, the skin gradually assumes all the characters of a typical *eczema rimosum*, exhibiting an infiltrated, exuding, itching, and painful fissured surface.

To sum up what I have said with regard to the elementary lesions, the five following varieties of eczema may be enumerated, according as one or other of these predominates:—

1. The principal elementary lesion an erythematous state of the skin (*eczema erythematodes*).

2. The principal elementary lesion a vesicle (*eczema vesiculosum*), the typical eczema of Willan and Bateman.

3. The principal elementary lesion a pustule (*eczema pustulosum*, or *eczema impetiginodes*), the typical impetigo of Willan and Bateman.

4. The principal elementary lesion a papule (*eczema papulosum*, including lichen or *eczema lichenoïdes*, and prurigo, or *eczema pruriginosum*).

5. The principal elementary lesion a fissure (*eczema rimosum*), the *eczema fendillé* of the French.

These names—*Eczema erythematodes*, *vesiculosum*, *pustulosum*, *papulosum*, and *rimosum*, are of use in describing cases of eczema, as each expresses in a word that which otherwise would take a long sentence to explain. But instances are seen, over and over again, of the predominance of one of these lesions on some patches and of another on other patches of eczema on the same person; and every one must have noticed cases in which, upon one patch, an erythematous state of the skin, vesicles, pustules, papules, and fissures are detected. To these the simple term eczema should be applied. What can the school of Willan make of such cases?

When a Willanist, deeply imbued with the belief that eczema must exhibit vesicles, has a case under his notice, it is quite painful to observe how he strains his eyes in quest of them, when, perhaps, none are to be found; or how pleased he is if, on a surface which we shall say is covered with innumerable papules, one small vesicle is at last detected, or even a papule, translucent on its summit, so as to give it the air of a vesicle!

You must understand that the symptoms of eczema which I have described have not been discussed in the precise order of their occurrence, as my endeavour has been to arrange them in such a way that the more prominent and least variable features of the disease may be more forcibly impressed upon your minds. Moreover, the symptoms vary much in the order of their manifestation. Most usually one or other of the elementary lesions is developed first of all which induces itching. To allay this, the patient scratches the part, it becomes more inflamed, the eruption breaks out more abundantly, infiltration of the affected part occurs, and this is followed by exudation on its surface, which finally concretes into crusts. In many instances, however, I believe the itching to be the first manifestation, to allay which the patient scratches himself, and thereby calls forth the elementary lesion, the infiltration, exudation, etc. For we know well that scratching the healthy skin is quite capable of producing an eczematous eruption. Of this we have abundant evidence in cases of scabies, where an artificial eczema is often called forth by the scratching induced by the peregrinations of the itch-insect. But the order of occurrence of the various symptoms is of no great moment, so that it is unnecessary to dwell further upon this point.

Ulcers are often met with in cases of eczema, though they are usually small and superficial. They occur most frequently on the legs, where, from the tendency to congestion of the parts,—owing to their distance from the centre of the circulation, their dependent position, and frequent association with varicose veins—they may become very large and deep, and may assume any appearance from the inflamed to the indolent. Eczematous ulcers occasionally assume alarming dimensions, as in the following case:—

"On May 11, 1861, I was sent for to the country for the purpose of seeing a little girl, aged about 10, who had been suffering for three months from a papulated eczematous eruption, principally affecting the back. When I saw her she was confined to the sofa, and, at that time, her whole back, from

(a) These Lectures have been carefully revised, and many alterations and additions made.

the neck to the hips, presented an enormous ulcerated surface. The ulceration was quite superficial, and presented a slightly papulated aspect. It had all the appearance of an ulcer from a burn which was gradually contracting, and cicatrization was proceeding inwards from the edges. At the margin, also, papules and vesicles, containing opaque serum, were detected. Papules were likewise scattered thinly over the body, but especially on the brow. From the surface of the sore semi-purulent matter was exuding. The little girl had been able to run about till within a week of the above date, since which time she had been confined to the sofa. Her general health was, however, good, except that she had suffered a little from the confinement and irritation of the sore.

"Dr. Robert Stewart, of Coatbridge, saw the patient along with me, and we agreed that the sore should be dressed with cod-liver oil, and Fowler's solution administered in gradually increasing doses."

I am indebted to Dr. Stewart for acquainting me with the result of the treatment. In a letter, dated October 22, 1861, he wrote:—"After you saw her she commenced with two drops of Fowler's solution three times a-day. Each dose was increased by a drop each day, so that latterly she was taking thirteen drops of Fowler's solution three times a-day, which had the most charming effect, and produced a decided cure. Altogether she must have taken, in the course of six or seven weeks, two and a-half ounces of the solution. I saw her regularly, and there never was a bad symptom." Cases of this severity are, however, of very rare occurrence.

Eczema is occasionally accompanied by feverish symptoms, especially at the commencement of an attack, but it is very extraordinary to observe how frequently a severe and extensive eruption, even in an infant, is coincident with the most perfect general health and total absence of fever.

A number of names, many of them quite useless, have been coined to express various forms of eczema. Some of these have already been discussed; for example, *eczema rubrum*, *impetiginodes*, *lichenoides*, etc., and, with the exception of the local varieties, which I shall detail afterwards, there are very few others which it is necessary to allude to.

*Eczema simplex* refers to a mild case of eczema; *eczema chronicum* to an eruption of old standing, in contra-distinction to *eczema acutum*, in which it is of recent date, more inflamed, and accompanied by burning heat rather than by itching. *Eczema nummulare* is the name applied to the eruption when it forms small circular patches like pieces of money. They are usually about the size of a crown, and are oftenest situated upon the lower extremities. Devergie remarks that this is the most difficult of cure of all the forms of eczema—an observation which corresponds with one of Hebra's, to the effect that the more limited the eruption the more difficult is it of cure. My own experience confirms these statements in part only; for while I have found limited eruptions less under the influence of internal and of mild local treatment than those which are more generalised, I have also observed that they vanish with great rapidity under the use of more powerful agents, which can be applied with perfect safety.

*Eczema marginatum* is a variety well described both by Hebra and Devergie. The latter, however, notices it under the head of herpes. (b) It commences almost invariably on the inner aspect of the thigh, where it is in contact with the scrotum, and gradually extends circumferentially while it heals in the centre, so that when fully formed there is an elevated eczematous circle, or segment of a circle, sometimes extending from the lower part of the abdomen to the knee, and enclosing skin which is either healthy-looking or coloured by a deposit of pigment, the result of the previous inflammation of the part. It usually occurs on the inner aspects of both thighs simultaneously, in which case the eruptions on the two sides occasionally meet superiorly in the region of the pubis and inferiorly in the perineum. It is met with almost exclusively amongst shoemakers and dragoons (Hebra), a circumstance which is easily accounted for by the continued moisture and friction which these occupations entail in the situations referred to.

Lastly, there is a form of eczema first described by Liévain under the name of *Eczema unisquamosum*. I have never met with a case of it, and Devergie, who speaks of it, has only seen it once during a period of fourteen years. According to him, it has its seat at the root of the nose between the eyebrows, and has a diameter of rather more than one third of

an inch. "After the acute stage has passed away," says Devergie, although he does not tell us what the acute stage consists of, "the secretion takes the form of a single epidermic lamella, which covers the whole of the affected surface. When it falls off it is replaced by another in about eight days, and so on." (c) Having no personal experience of this form of eruption I can add nothing to the above description.

(To be continued.)

## ORIGINAL COMMUNICATIONS.

### ON ANEURISMAL TUMOURS INVOLVING THE NECK.

By JOHN COCKLE, M.D.

Physician to the Royal Free Hospital.

(Continued from page 532.)

THERE is a condition of vessel which may embarrass diagnosis, namely, dilatation of the arch of the aorta and the trunk of the innominate artery, similar to the preparation I now exhibit. Such a condition, if combined with defective aortic valves, and modified by intercurrent anæmia—more particularly if the pressure has condensed the supra-clavicular portion of lung—may much resemble aneurismal tumour. I do not know how, at times, we can accurately discriminate between these affections, unless, in the former case, by its long unchanging nature, the intermitting prominence of the tumour, and the more or general collapse of the vessels. Pain is certainly not distinctive, as I have known it a distressing attendant on such affection.

One other occasional chance of error in diagnosis results from anomaly in the anatomical course of the innominate trunk. No vessel, perhaps, is more liable to variation, both as regards its length and exact position. It may rise higher than usual, and pulsate more strongly, either near the sterno-clavicular junction or at the right side of the episternal fossa. The same result would occur from undue elevation of the arch of the aorta. Unusual shortness of the first bone of the sternum permits the uncovered artery to pulsate with much greater force, and over a wider area than is normal. Professor Dubreuil, of Montpellier, in his valuable monograph upon the "Anomalies of the Arteries," gives a most instructive example, where, from this latter cause, combined with some nervous symptoms, aneurism of the trunk was for a time suspected. I have at present under my care a case in one or two points resembling it. The upper bone of the sternum is short; the arch of the aorta and the innominate artery are felt and seen most violently pulsating, with both carotids and subclavians. Neither thrill nor murmur exists. The chief symptoms are dyspnoea and cough. The radial arteries are even weaker than usual, and the second cardiac sound is particularly sharp and clear. I am not able to say whether the case be aneurismal or not; the woman has been suckling for twelve months. There is, doubtless, organic change, for, in addition to percussion dulness over the upper part of the sternum, is the fact that the symptoms commenced some little time previous to pregnancy.

Before quitting this portion of the subject, it would be a great omission to pass unnoticed the laborious Essay of Dr. Holland on "Aneurism of the Innominate," published in the *Dublin Quarterly Journal* for 1852. His collection of cases of aneurism of the ascending and transverse aorta, and of its tributary branches, is of the most complete and varied kind, and quite indispensable for the study of both Surgeon and Physician. When summing up the differential diagnosis, he thus expresses himself:—"The general symptoms and signs of innominate aneurism have a general tendency to occur at the right side of the body, and those of aneurism of the transverse portion of arch of the aorta on the left."

He, of course, infers therefore that from such distinctive peculiarities the differential diagnosis may be achieved. To the first proposition we may, from obvious anatomical reasons, at once assent. With the second proposition we may also easily agree, if, by transverse portion he implies the portion of the artery situate to the left. But he appears to me to have omitted from his diagnostic formulæ one all-important form of aneurism,—I allude to that either false or true which often arises from the upper part of the ascending and angle of the trans-

(b) "Traité Pratique des Maladies de la Peau." Ed. II., p. 273.

(c) "Traité Pratique des Maladies de la Peau." Ed. II., p. 239.

verse portion of the aorta, often involving the innominate and other arteries. Such a specimen I now exhibit. These aneurisms have a decided inclination to the right. Indeed, it is almost exclusively this form which occasionally passes the first rib, and ascends the right cervical region, rendering the differential diagnosis between aortic, innominate, and other aneurisms of this region almost impossible, when the cervical tumour has attained any magnitude. This opinion is, I think, most fairly warranted, even from the clinical history of many of the cases he himself enumerates.

*Treatment.*—With regard to the treatment of an aneurismal tumour, I am fully aware how little new there is to impart; but I trust any attempt to place treatment on a rational basis will not be deemed inopportune. In every case it is mainly with the accidents—such as the pain, the pressure, or the inflammation—that art is directly concerned, so far as relates to therapeutic agents. Over simple, un-complicate aneurism these agents exercise not even a retarding, much less a curative influence. Such of the class only are of course implied as would be administered internally, with the direct intention of promoting the formation of coagula within the sac; for, it is scarcely necessary to remark that, in no other conceivable sense is an aneurism Medically capable of either check or cure. No one, for example, would dream of attempting to mend by drugs the broken wall of the artery, or to restore its resiliency. He would only seek to supplement the breach by taking advantage of the tendency of the blood to clot within the sac, seeing that nature tries at times by such device to forestall the event of hæmorrhage. The rational aim of the Physician, then, is indirect. It consists simply in the attempt to place the patient under the most favourable conditions for the clot referred to to deposit. He may, by the utmost practicable amount of bodily and mental repose, both slacken the velocity of the blood-current, and break the impetus of the wave. And, provided the degenerative cachexia be not too strongly marked, he may, by solid, reparative diet, increase its plastic element; while, by the restricted use of fluids, and the occasional exhibition of saline aperients, he may lessen its serous element. By such means not only is a concentration of the blood favourable to deposit obtained, but the danger of rupture from fluid pressure on the weakened wall of the sac is lessened. Should saline aperients be contra-indicated, diuretics may be used to meet the requirement. From these iodide of potassium should be selected, more particularly as this agent has lately been invested with the power of inducing clot. This result, however, although from a limited experience, I am inclined to doubt. It must be borne in mind that clot to some amount exists in almost every ancient aneurismal sac. Such are the few and simple means at our disposal in the next to hopeless attempt to treat a simple aneurism. And, so far as bears on one part of the problem—the physical requirement of the blood—we may, at times, in part succeed; but there is one other indispensable pre-requisite, which is, probably, altogether beyond our control; namely, a certain shape and peculiar physical arrangement of the walls of the sac. It is not enough that the blood be surcharged with plastic element, unless the surface it traverses be fitting for the fibrin to settle. Supposing, then, as is most probable, that the attempt meets with insuccess, and that external rupture is imminent, there is yet one procedure which, doubtful though it be, is, in such a crisis, well deserving consideration, namely, electro-galvanism. This method, proposed by Petrequin in “Surgical Aneurism,” has been supposed inapplicable to ordinary aneurism of the large trunks, on the grounds of proximity to the heart, and the fear of coagulating the mass of the blood. But, in a secondary and almost isolated sac, so nearly approaching ordinary Surgical aneurism as that described, the objections urged no longer hold. Here no chance exists of the mischief alleged to follow such a plan in a sac nearer the heart, immediately springing from the larger trunks. The result in the case brought forward though not satisfactory, is still encouraging. Had the proceeding been resorted to at an earlier period, or employed with greater scientific precision, results more favourable might possibly have been obtained. I would hazard one final observation, that it is not alone the mere coagulation of the intra-aneurismal blood that should be attempted, but it is possible that, by the irritative excitement of the current, exudation of plastic matter might also be induced through the remaining covering. If so, not only would an additional barrier be raised, but, with it, the chance of a more perfect and organically adherent coagulum within the sac. If foiled again,

it appears to me that in every case, almost without exception, where an aneurismal tumour of the neck descends within the chest, there is genuine wisdom in the advice of Velpeau, to proscribe Surgical interference. In such cases, the general insuccess of operative Surgery, whether attempted below the sac, or on Brasdor’s plan, is so notorious, that such operations must soon become matter rather of traditional than of current Surgery. Another most important point in the history of innominate aneurisms, is the unquestionable tendency to spontaneous cure. Indeed, with such comparative frequency does this occur, that, balancing the chance with that afforded by operation, it would appear safer, unless in most exceptional cases, to trust to nature rather than the knife. (a)

## ON THE ACTION OF CERTAIN SUBSTANCES UPON PHTHISIS.

By RICHARD PAYNE COTTON, M.D.

Fellow of the Royal College of Physicians, London; Physician to the Hospital for Consumption and Diseases of the Chest, Brompton.

(Continued from page 82.)

### No. XI.—PHOSPHORIC ACID.

PHOSPHORIC ACID has been so long and successfully used as a tonic and antiseptic, especially in cases of depressed nervous power, that some good result might reasonably be expected from its administration in many cases of phthisis. With a view of testing its influence, I prescribed it, as in my previous experiments, in twenty-five cases of chronic and uncomplicated consumption, and carefully noted the results. Of these twenty-five cases, twelve were in the first stage, four in the second, and nine in the third stage of the disease. Fifteen were males and ten females.

Three patients experienced great improvement whilst taking the phosphoric acid, eight improved a little, and fourteen of the cases seemed either to derive no benefit or to become worse. None of them increased materially in weight, the greatest increase not exceeding two pounds, except in one instance, where seven pounds were gained, but in this case it was afterwards found that cod-liver oil had been taken in addition to the phosphoric acid.

Two of the greatly improved cases were in the third stage of the disease, and it was generally observed that most of the improved were either in an advanced condition of disease or belonged unmistakably to what is commonly understood as the cachectic class, leading to the conclusion that the phosphoric acid acted simply in virtue of its general tonic and upholding influences, and not from any specific action upon the tubercular disease.

It was prescribed in doses of fifteen minims of the Acidum Phosphoricum dilutum of the London Pharmacopœia, in a little water two or three times a day. As a general rule it agreed very well with the patients, improving the appetite and diminishing undue secretion, whether from the skin or mucous membranes. In four cases, however, it was discontinued, seeming to produce griping pains in the bowels, together with nausea and diminished appetite.

In estimating its effects, even in the most satisfactory cases, it appeared to me that the improvement was inconsiderable in comparison with what had previously been noticed in some other remedies; whilst several of the patients who either improved very slightly or doubtfully under the phosphoric acid, improved afterwards under other treatment. Four of the patients improved greatly in health when steel wine was taken in conjunction with the acid, the latter being given twice a-day, and the former immediately after dinner. It will be remembered that a combination of steel wine with quinine was formerly found to be productive of good in a considerable number of cases (*Medical Times and Gazette*, August 30, 1862).

Upon the whole, I confess to having been disappointed in the action of phosphoric acid taken singly. In some cases, however, where it has been prescribed either with other tonics or in chemical combination with iron, I have found it of great use in the treatment of phthisis.

From these observations I have arrived at the following conclusions:—1. That the dilute phosphoric acid acts bene-

(a) Read before the Medical Society of London, October 13, 1862.

ficially as a tonic in certain consumptive cases; but that, as a general rule, it is inferior to some of the other mineral acids.

2. That when taken in conjunction with iron its good effects appear to be considerably enhanced.

46, Clarges-street, Piccadilly.

## DIFFICULT PARTURITION IN CONNEXION WITH IDIOCY.

By ARTHUR MITCHELL, A.M. and M.D.,  
Deputy Commissioner in Lunacy for Scotland, etc.

In the *Medical Times and Gazette* of July 12, 1862, I published a paper on the connexion between idiocy and difficult or anomalous parturition. In that paper I gave my reasons for concluding that the act of birth must be regarded as one of the causes of idiocy, or, in other words, that a certain proportion of the idiocy of this country is due to injuries sustained by the child in the process of parturition. After pointing out that the *à priori* argument for such a conclusion is exceedingly strong, I gave a summary of those facts which had come under my observation by which this conclusion could be proved or disproved. As there exists no corresponding information regarding the general community with which the facts alluded to could be compared, I was careful to point out that each reader must draw his own conclusions, while I did not hesitate to give those I had drawn myself. This I thought the fairest way of dealing with the materials I had collected.

It appeared to me, at the same time, that the facts I detailed were, in their aggregate, of so strong a character as probably to lead most readers to that general conclusion to which they had led me, and therefore that a minute comparison with similar facts regarding the general community was not so necessary as would have been the case had they been of a doubtful or less decided character.

Among other facts which I stated was one, to the effect that I had found that 22 out of 494 idiots had been delivered by forceps. This statement has given rise to some misconception as to my views regarding instrumental assistance in midwifery. It seems to be thought that in all these twenty-two cases I considered the idiocy to be referable to injury inflicted directly by the forceps, and inferentially that I thought they had been unwisely used in these cases, and that I had supplied an argument against their use in others. This feeling seems to have been strengthened by my having stated that in nine of the twenty-two cases the use of the forceps was attested by the presence of cicatrices. Now, I neither expressed nor hold such opinions. I was collecting all such facts in the history of idiots as would help us to determine whether the act of parturition might not occasionally injure the child in such a way as to cause idiocy, and whether the risk of this injury was not increased in proportion as parturition was difficult or anomalous; and it would have been clearly a grave omission had I not, in collecting and detailing such facts, ascertained and stated the number of times in which the labour had been so difficult or abnormal as to require instrumental assistance—of which difficulty this was an evidence, the general practice of the country being considered.

The cicatrices, again, were alluded to in proof, so far as they went, of the trustworthiness of my information rather than as evidence of a mechanical injury having been inflicted, of a character to account for the idiocy. That mechanical injury, serious enough to lead to such a result, is sometimes inflicted by the blades of the forceps, I think all will admit. But there was nothing in these twenty-two cases which would justify the conclusion that the pressure of the blades of the forceps, and not the severe or prolonged pressure in the passages, had produced the injury. It is quite possible, indeed, that the opportune use of the forceps may save the child from such injury. But further, neither the forceps nor pressure in the passages produced the idiocy of the whole of these twenty-two cases. This might have been expected, nay, assumed almost as a certainty. My notes, indeed, show that in several of them the idiocy is satisfactorily accounted for by causes altogether apart from the act of birth; but they could not be excluded on this account. I had to embrace every case without exception in a statement showing the frequency of forceps deliveries in a given number of idiots, and intended to show whether the proportion of such deliveries was greater in that

class than in the general community. When we attempt to show the injurious effects of bad sanitary arrangements, we compare the mortality in a district where these exist with the mortality in a district more favourably circumstanced, and, if it be in excess, we accept it as proof of such injurious effects. But we never consider every death in the less healthy district as due to defective drainage; for some may be due to brick-bats and chimney-cans, and the common causes of death are at work there as elsewhere. All deaths, however, must be included on both sides, and it is the excess on the total which we use as a basis for our conclusions. For the same reason, exactly, every case without exception had to be included in a statement showing the frequency of forceps deliveries in a given number of idiots, and intended to be compared with corresponding data regarding other classes. And this was not the less necessary from the circumstance of my not possessing data of a character which would admit of exact comparisons. Other observers may obtain these (though I think the task will prove a difficult one), and I have recorded my results in a form which will permit of their being then used comparatively.

It must always be remembered that my general conclusion rests on the strength of the facts I adduce in their aggregate. I cannot believe that these can be fairly considered, and lead to any other inference than that the act of birth does occasionally cause idiocy, and that this result is in proportion to the difficulty or anomaly of the labour.

The mode of conducting such an investigation as that into the causes of idiocy, which I have pursued when possible, appears to me broader and more satisfactory than that which consists in the detail of a number of striking cases, by which at best we only learn the probable cause in those cases, but which would not establish the steady operation of the cause in question. Yet, though really more satisfactory, it does not perhaps so readily carry conviction. It occurs to me, therefore, that I may record with advantage a few of those cases in which I think that some connexion between the idiocy and the difficult labour is probable. I select them from my notes of forceps cases, but I repeat that I do not say even of these that the use of the forceps, and not the difficulty or length of the labour, accounts for the result.

1. M. J., an idiotic girl, eight years old, was born twelve months after her mother's marriage to a young man. Between the parents there was no blood-relationship, and neither paternally nor maternally was any form of mental or bodily defect hereditary. Both parents were sober and respectable, and they lived in comfortable circumstances, though they were far from wealthy. Her mother, a handsome, healthy, and intelligent woman, was thirty-four years old when the idiot, her first child, was born, and afterwards gave birth to two other children, both sound in all respects. Her father, who was killed by a horse a few years ago, is said to have been a healthy and vigorous man.

The history of the idiot's birth is as follows:—On a Friday afternoon her mother felt occasional labour pains, but it was not considered necessary to send for the Doctor till early on Saturday morning. He arrived at 5 a.m., when he found his patient in such a state that he did not think it right to leave her. Towards midnight another Doctor was sent for, and on his arrival, or soon after, about 1 a.m. on Sunday, the child was delivered by forceps. Though not large, it was a plump and well-formed child, but it was in a very feeble condition at birth, and respiration was established with difficulty, the usual means being resorted to in order to accomplish this. It continued for some time in a weakly state, and its viability was thought doubtful. The mother, who made a good recovery, had abundance of milk, but the child never sucked; as the mother said, "Never could be got to try."

On the left side of the head the blades of the forceps have left two marks. The wounds, of which these are the traces, are said not to have healed readily, and to have "festered." Both cicatrices are quite distinct—one is almost on the cheek, and a little below the opening of the ear, and the other is on the side of the head above the ear. The left eye is distinctly smaller than the right, but there is no squinting and no impairment of vision. The child is partially paralysed on both sides, and walks with great difficulty. This paralysis existed at birth, and is said to be less marked now than it was. She attempts to speak, but cannot do so intelligibly. Her mental condition is that of complete idiocy, and this was evident in very early infancy. Her head is well-shaped, and of good size.

2. E. M., a female, 26 years old, is a complete idiot. She

was born three months after the marriage of her parents, and was her mother's first child. Six were afterwards born, and were all sane. There is no relationship between her parents, and idiocy is not hereditary on either side. Her father is a strong man, but her mother has always been delicate, though labouring under no special disease. While pregnant with the idiot, she was not in robust health, but was always able to move about.

The idiot was born after a labour said to have lasted for four and a half days. This is probably an exaggeration, but it may be assumed that the labour was long and difficult. At the end delivery was effected by forceps. The blades have left no mark about the head.

The child is described as having been well-formed and plump at birth. She is said to have been still-born. She was neither washed nor dressed for many hours after birth. Respiration was established with difficulty. She did not attempt to suck for fourteen days or more. During the first five days of life she was at intervals, as her mother said, "drawn a wee wi' nerves;" but since that time she has never had anything like a fit. She was four years old before she attempted to walk, and she never walked well. She squints, but sees and hears. She has never spoken an intelligible word. Her head is small, but well shaped.

3. A. H., an idiot girl of 13, is illegitimate, and an only child. Her mother is lame, the result, it is said, of hip-joint disease in early life. The idiot was born after a labour said to have lasted for several days, and instrumental assistance was found necessary. The left eye was injured by one blade of the forceps, and there is a bald patch on the right parietal protuberance caused by the other. She squints. She was in a very feeble condition at birth, and was long of sucking. Idiocy was suspected when she was nine or ten months old. She is now an active, strong, full-fleshed girl, but very deficient in intelligence. She has a small but long head.

4. The mother of the idiot when a young girl received some injury about the hip joint or pelvis, which led to permanent lameness and which is believed to have affected the size or form of the pelvis. Her general appearance, nevertheless, is that of a well-made woman. She married and bore twelve children, all of whom were delivered by forceps. Of these, nine were dead at birth, one died when three weeks old, one lives, and is apparently sound, and one is the idiot who grew to manhood, but died recently. In his case convulsions occurred soon after birth. He was either the fifth or sixth child. All her labours were very long and difficult.

5. S. W., an idiot boy, 5 years old. He is the sixth of seven children. At the birth of all but three the forceps was used. Two were dead-born, the forceps being employed in both cases. All the seven children were born after labours more or less protracted.

The idiot, according to his mother, was "worked wi' nerves" for a fortnight after birth, and it was doubtful if he would survive. Slight convulsive seizures occurred occasionally till he was a year old. He squints. He walks well. His head is of good size and shape.

## REPORTS OF HOSPITAL PRACTICE

### IN MEDICINE AND SURGERY.

#### CASES OF HEMIPLEGIA FROM DISEASE OF THE CRUS CEREBRI.

In this Journal for February 28, p. 210, we published a case of hemiplegia in which there was paralysis of the whole of the portio dura, indicating, of course, disease of the pons Varolii. We now give the particulars of two cases of hemiplegia depending on disease of the crus cerebri, in which another cranial nerve was involved,—the third or motor oculi. In these cases the nerve is paralysed on the same side as the lesion, the limbs, on the opposite side. Just so in disease of one side of the pons the portio dura is paralysed on the injured side, the limbs on the opposite.

In our report of the Medico-Chirurgical Society, May 16, is recorded an interesting case of disease of the crus cerebri, by Dr. Hermann Weber. We refer our readers to this communication for valuable information on disease of this part of the brain.

The first case we relate occurred at the Middlesex Hospital, and is reported by Mr. Dunnett Spanton, now Resident Medical Officer at the Sheffield Infirmary. In this case there was, before Mr. Spanton saw the patient, loss of sensation as well as of motion on the right side of the body. This is certainly rare in hemiplegia. Possibly it may have been due to the slight disease of the left side of the pons Varolii. The fact that the sight was not affected at first would seem to show that the whole of the third nerve was not then paralysed. As a rule, along with the paralysis of the external muscles of the eye, the pupil is dilated, the ciliary muscle paralysed, and the sight, for near objects, consequently impaired; but sometimes, though very rarely, the pupil is not affected, whilst the external muscles supplied by this nerve are paralysed. Again, just the reverse, there may be great dilatation of the pupil and paralysis of the ciliary muscle without any apparent affection of the external muscles. In such cases, however, the disease cannot be in the trunk of the nerve nor near its implantation in the crus. Of course, we sometimes have disease of the crus cerebri without paralysis of the third nerve in hemiplegia, as we sometimes have disease of the pons Varolii without paralysis of the portio dura; but when the disease is extensive, then the nerves are involved. When paralysis of these nerves is present, we may be certain as to the seat of the disease.

There is at present, under the care of Mr. Ernest Hart, at St. Mary's Hospital, a patient who has paralysis of the third nerve, and hemiplegia on the same side. Dr. Brown-Séguard saw this case, and believed that the paralysis of the third nerve and the hemiplegia depended on two distinct causes, for, as in the following cases, when there is lesion of one crus cerebri affecting the third nerve, the paralysis of the limbs is on the opposite side. Paralysis of the third nerve is sometimes the forerunner of hemiplegia, but it is rarely co-existent with it.

#### MIDDLESEX HOSPITAL.

#### PARALYSIS OF THE THIRD NERVE ON THE LEFT SIDE, AND OF THE RIGHT ARM AND LEG— DEATH—AUTOPSY—DISEASE OF THE CRUS CEREBRI ON THE LEFT SIDE.

(Under the care of Dr. GOODFELLOW.)

[Communicated by Mr. DUNNETT SPANTON.]

IN connexion with Dr. H. Weber's paper on the "Pathology of the Crura Cerebri," read before the Medico-Chirurgical Society, the following brief notes of a case which occurred in the Middlesex Hospital will be interesting:—

A. H., a man aged 41, was admitted under the care of Dr. Goodfellow in August, 1860, with paralysis of motion and sensation of the whole of the right side of the body. In February, 1861, paralysis of the internal, superior and inferior recti and levator palpebræ muscles of the left eye came on. The sight remained good. Taste and smell were unaffected, the intellectual faculties also. The paralysis of sensation had at this time almost disappeared, but that of motion remained much the same in the right half of the body, including the face, soft palate, and tongue. The patient complained of dull, aching, frontal pain, and of occasional tinnitus aurium. The pulse was slow and weak; the bowels constipated.

About two months afterwards, the power of vision of the left eye had become much impaired, especially manifested in the deficient power of accommodation. Sensation was everywhere perfect, but the motor paralysis continued. Speech at this time became very indistinct, but the patient retained his intellectual powers. The ptosis of the left eye varied from time to time up to a short period before death, when it remained complete.

In June there was ptosis of the right eye for about a week. It then entirely disappeared.

The patient became gradually weaker, bed sores formed, and he died on October 30, 1861.

*Post-mortem Examination.*—Lungs both healthy, except that in the apex of the right there was a small nodule of cretified tubercle. Heart flabby and soft; no valvular disease. Liver fatty, weighing sixty-three ounces. Kidneys small, slightly granular. Left crus cerebri reduced in size, presenting a grey, semi-transparent appearance. At the upper and posterior part, for an extent of about three-fifths of an inch in length, and two-fifths in breadth and in thickness, the tissue was found on section to be hard and dense, like fibro-cartilage. The pons Varolii, at its anterior edge on the left side, was to a very slight extent

similarly affected. Under the microscope the dense structure was found to consist of an imperfect fibrous tissue, with oil-globules, a few compound granular cells, and numerous nucleated cells of various sizes. The left third nerve was much smaller than its fellow, and of a pale bluish colour. Other parts of the brain were healthy.

#### GUY'S HOSPITAL.

PARALYSIS OF THE THIRD NERVE ON THE RIGHT SIDE—GENERAL PARALYSIS, CHIEFLY ON THE LEFT SIDE—CANCER OF THE RIGHT CRUS CEREBRI, AND OF THE RIGHT LOBE OF THE CEREBELLUM, AND IN VARIOUS ABDOMINAL VISCERA.

(Under the care of Dr. GULL.)

The following is another case of hemiplegia, with paralysis of the third nerve, depending also on disease of the crus cerebri, the paralysis of the third nerve being, of course, on the side of the lesion, *i.e.*, the side opposite the paralysis of the limbs. There was, however, cancerous disease in other parts of the brain, so that the case is not so valuable as the one reported by Mr. Spanton.

Eliz. B., aged 40, admitted October 19, 1860, into May Ward, under the care of Dr. Gull. She died October 20.

Dr. Wilks in his record of the post-mortem:—"This woman was admitted with tumours in the neck and breast, which appeared to be cancer. She also had a tumour in the abdomen, which turned out to be a fœtus, of which she was delivered. Soon after admission it was observed that her right eyelid began to droop, and soon perfect ptosis came on, and indeed complete paralysis of the right third nerve, and at the same time some difficulty of speech. Afterwards some loss of power of the limbs, especially the left side. She lay then quiet in bed, in a partially paralytic state, but her mind was perfect."

*Autopsy.*—Large cancerous tumour in both breasts and neck. On raising the dura mater from the surface of the brain, a cancerous tumour, the size of a large pea, was seen growing from the arachnoid surface of the dura mater, near the falx, and causing a corresponding depression in the brain. At the base of the brain, on attempting to remove the organ, another tumour was seen in the right lobe of the cerebellum, and which had some adhesions to the dura mater, so that the structure tore on removing it. This tumour was the size of a walnut, tolerably firm, and was almost entirely surrounded with cerebral structure, except at one spot. The right crus cerebri felt hard to the touch, and when cut through was found to contain a vascular, soft cancerous growth, about the size of a marble, or larger. The third nerve on this side was wasted—its trunk being only half the size of the left one. The ventricles contained excess of fluid. Hemispheres healthy. The liver contained one large cancerous nodule, the size of a billiard-ball. It was very firm and hard, and appeared to be composed of two substances—a border, resembling the white opaque cancer of other parts, and the interior translucent and reticulated, resembling very much the appearance of a boiled turnip, only harder. Spleen full of cancerous masses. The left supra-renal capsule contained a large cancerous mass, which had involved the tissue at one spot. The ovaries were much enlarged by cancer, so that no healthy tissue could be seen in them. A section showed a firm carcinomatous mass, vascular, and emitting the usual milky juice. Both mammæ destroyed by scirrhus cancer, and the pectoral muscles occupied by immense nodules.

The next case is also a complicated one, but here, too, there is hemiplegia, depending, no doubt, on the cancerous nodule implicating the corpus striatum and thalamus opticus. Of course, in disease so high up, not one of the cranial nerves would be involved, *i.e.*, not one in its entirety. As a rule in disease of this part of the brain, only a few muscles supplied by the portio dura about the angle of the mouth, on the same side as the paralysis of the limbs, and on the opposite side of the lesion, would be paralysed.

HEMIPLEGIA ON THE RIGHT SIDE, AND GENERAL CEREBRAL SYMPTOMS—DEATH—AUTOPSY—CANCER IN VARIOUS PARTS OF THE BRAIN, IN THE LUNGS, AND PANCREAS.

John L., aged 49, was admitted into Philip Ward under the care of Dr. Wilks, December 31. He died January 14. He was admitted with cerebral symptoms and hemiplegia of the right side. He was able to be about in the ward, although

he walked with difficulty. He spoke huskily, and was hardly intelligent, so that no good history was procurable. He said that he had had a fit six weeks before admission, and had been paralysed ever since. It was evident that his brain was softened. His chest was not examined. He soon afterwards became worse, and sank into a half-conscious state. It was afterwards said that he had been ill for three or four months. He had lost one eye from an old injury.

*Autopsy*—The brain contained a number of cancerous masses, at least a dozen, in various parts. It was soft and highly vascular. Some were surrounded by recently effused blood. They were mostly in the hemispheres, but there was one nodule at the under part of the junction of the left thalamus and corpus striatum. Most of these were the size of a marble; two were larger. In the left hemisphere there was also much yellow softening of the medullary substance. The cerebellum also contained two portions. Old pleural adhesions. There was a large mass of disease in the anterior mediastinum, and involving part of the right lung, to which it was inextricably adherent. This was the size of the two fists, and consisted of a mass of medullary cancer. It had penetrated the pericardium, and above had reached the vena cava. The tissue of the lung was in part involved, but the disease appeared to have commenced in the glands. The lungs were healthy, except that they were in part encroached on by the cancer. On opening the pericardial sac some protuberances were seen coming from the cancerous mass on the right side. The serous membrane had not given way. The superior cava was surrounded and penetrated by the cancer. On opening it a projection, an inch long, was seen on the posterior wall, thence reaching to the heart. The channel was obliterated only partially by this. The commencement of the brachio cephalic and right jugular was also somewhat contracted. The pulmonary artery and its branches were free. The heart was otherwise healthy. There was a mass of cancerous glands surrounding the pancreas, and affecting its smaller end. When the organ was cut through longitudinally, the right extremity or head was seen to be healthy, but this gradually merged into the cancer.

#### THE LONDON HOSPITAL.

##### A CASE OF DISLOCATION OF THE FEMUR FORWARDS.

(Under the care of Mr. ADAMS.)

WILLIAM A., aged 34, a drayman, was admitted into the London Hospital on April 17 with a dislocation of the right hip. The accident occurred in the following manner:—He was steadying a puncheon of beer let down by a pulley from a dray to the ground, when the barrel was overbalanced, so that he was obliged to support it by pressing it forwards to prevent it falling on him; his arms were extended and his legs were separated, the right being in advance of the left. He sprang backwards to avoid the barrel, as he found himself unequal to its support, and in so doing his body fell backwards to the ground, and he could not tell precisely how his legs were placed at the time of his fall.

He was unable to rise, and was brought at once to the Hospital, being unaware that any serious accident had occurred, as he suffered no pain at the time.

He was a strong, healthy man in appearance, differing from the ordinary type of brewers' servants. Mr. Appleyard, the House-Surgeon, recognised the nature of the accident, and sent to Mr. Adams to see the case, being one of comparative rarity. The patient lay on his back, unable to move his limb; it appeared somewhat short, but by measurement the shortening was by no means evident; the foot was turned out, and a distinct, firm, but irregular tumour could be seen just below the level of Poupard's ligament, and apparently resting on the iliacus muscle. The swelling was recognised at once as the head of the femur, and could be felt to move by rotating the limb outwards, the distance from it to the anterior superior spine of the ileum being about two inches. There was great depression in the situation of the great trochanter, and sinking of the nates. It was pronounced to be a dislocation forwards of the head of the femur, corresponding to what is frequently termed a dislocation on to the pubis; but it is quite clear that it was at some distance from this bone. Under the direction of Mr. Adams and Mr. Appleyard, one of the dressing pupils, Mr. Hawthorn, was directed to sit upon the edge of the sofa on which the man was placed, and

to put his foot into the perineum, so that extension with adduction might be made in this manner from the knee; but no effect on the bone could be thus made. The method by flexion was next tried, the hand being firmly fixed on the head of the femur to prevent its gliding upwards. It also failed. The man was therefore put under the influence of chloroform, and, by the aid of pulleys, the limb was forcibly extended round a post, according to the method adopted in reducing the dislocation into the obturator foramen, and after ten minutes a snap, as if something had given way, was felt, and the head of the bone slipped into its natural position.

The man has made a satisfactory recovery, but there was a good deal of extravasation of blood about the injured parts.

### THE SALISBURY INFIRMARY.

#### CASE OF DISLOCATION OF THE HUMERUS ON THE DORSUM SCAPULÆ.

(Under the care of Mr. WILKES.)

It was not until after reference to the following works that I became aware that dislocation of the humerus on the dorsum scapulæ was so rare an accident. Sir Astley Cooper in his work on "Dislocations," at page 392, Fifth Edition, states that only two cases occurred in Guy's Hospital during thirty-eight years, and, subsequently, he relates seven cases collected from his own and other Surgeons' private practice. Liston, in his "Practical Surgery," Fourth Edition, reports that he had only seen one such case. This is my reason for placing one on record.

About 11 p.m. on March 6 last a drunken soldier was admitted under my care into the Salisbury Infirmary. He had jumped from a second-class carriage running between Warminster and Westbury. He was missed at the latter station, but was soon found and brought in. He had a large scalp wound on the left side of the forehead and temple, a small fissured fracture of the skull in the front part of the temporal fossa, with other wounds of the scalp, face, elbows, and knees, and a dislocation of the left humerus on the dorsum scapulæ below its spine. The head of the bone formed a very marked prominence, and was easily moved and rotated in its new position; the elbow and arm lay by the side of the body, directed somewhat forward, and there was the usual flatness and deficiency below the acromion.

From his drunken state reduction was easily effected, the scapula being fixed by a round towel across the chest; the heel placed in the axilla, and extension made from the wrist. It was reduced before I was aware of it, without noise or jerk. For a week or more the track of the dislocation was distinctly marked by a bruise, which extended from the spine of the scapula, along the inner side of the arm to the elbow, and tenderness on pressure, requiring counter-irritation, subsisted for some time longer.

The man perfectly recovered the use of the arm; the wounds healed, and he left the Infirmary cured on April 15.

My partner, Mr. G. R. Tatum, a short time before attended an unusual form of dislocated shoulder, in which I assisted him, and he has kindly allowed me to publish the case with my own.

A gentleman, about 24 years of age, subject to epilepsy, fell during a fit, in the latter part of February. After consciousness had returned, he complained of severe pain on the inner side of the left arm, about its lower third. No reference was made to the shoulder.

On the second day after the accident he felt pain in the shoulder. On examination, Mr. Tatum found a dislocation of the humerus to the outer side of the coracoid process—described by Sir Astley Cooper as the "partial dislocation of the os humeri upwards." The shoulder was so swollen that there was some difficulty at first in detecting it. There was a protuberance, and more fulness in front than on the sound side. By pressure the head of the bone could be felt forward against the outer side of the coracoid process, whilst behind there was an absence of bony resistance below the acromion. The arm lay naturally by the side. It could be rotated and moved backwards and forwards, and all voluntary power below the elbow was lost. Reduction was easily effected by the same method as in the previous case, and was accompanied with a loud jerk. The injury the median, ulnar, and musculo-spiral nerves had received was considerable, for after reduction the want of power and sensation in the fore-arm and hand continued, and soon after he had acute pains in the

course of the median and ulnar from the arm to the fingers. Leeches and blisters were applied with relief. At the end of a month he had drop-wrist, diminished sensibility of all parts below the middle of the fore-arm, and occasional shooting pains in the fingers. He could raise the arm from the side and flex the elbow, but no power of pronating or supinating the hand, extending or flexing the fingers.

Gentle and frequent friction with the hand over the weakened muscles was used. By the latter part of April the pains had left him, sensation and power were gradually returning in the fore-arm and hand, and he was enabled to leave England for change.

### UNIVERSITY COLLEGE HOSPITAL.

#### CASE OF FATTY DEGENERATION OF THE HEART, IN A YOUNG FEMALE AGED TWENTY-EIGHT, TERMINATING IN SUDDEN DEATH.

(Under the care of Dr. HARLEY.)

SARAH M., aged 28,—very large and fat, florid-complexioned, and puffy-looking,—came to the Hospital as an out-patient on April 14, complaining of symptoms somewhat resembling hysteria. She described herself as being very nervous, and subject to sudden fits of gasping for want of breath, which lasted a few minutes, and then passed off. She said she felt at times as if her strength suddenly left her, and she was obliged to sit down for fear of falling. She frequently vomited after food. Although labouring under these symptoms, she was still able to do her household duties. A mixture containing quassia and iron was prescribed. On the 21st she returned to the Hospital, saying she felt no better, and that she had, in addition to her previous symptoms, pain between the shoulders. The tonic medicine was then changed to gentian and sulphuric acid, after taking which, for a few days, she felt much better and stronger, and continued so until April 28. However, while attending to her usual household duties, she was suddenly seized with a general loss of power and a choking sensation. She partially rallied from this attack twice, but the third time the attack was more severe, and she fell back in the chair, and expired in the course of a few minutes.

At Dr. Harley's request, Dr. Embling examined the body, and the following remarks are from his report:—

*Post-mortem Examination Three Days after Death.*—Decomposition far advanced; neck much discoloured; vessels evidently distended. Brain normal in appearance, rather pale if anything. Lungs healthy; a few traces of old adhesions in the pleuræ. Heart somewhat hypertrophied, pale, soft, and flabby, entirely enveloped in a thin layer of fat. Contained black fluid blood. When the muscular tissue of the heart was examined with the microscope, the striæ of the fibres were found to have almost entirely disappeared, and their position to be occupied by minute fat granules. The oil globules existed abundantly, and were very regularly distributed in muscular fibres. The abdominal organs were all healthy.

PARIS ACADÉMIE DE MÉDECINE.—The election into the section of Operative Medicine has been determined in favour of M. Michon, by forty-four out of seventy-eight voters present. By this choice the Academy departed from the list presented by the section, which placed MM. Broca and Richet before M. Michon. The election of the latter able and older Surgeon seems to have given general satisfaction, while much surprise has been felt that the names of MM. Maisonneuve and Demarquay were not placed at all on the list.

NEW CLINICAL LUNATIC ASYLUM AT PARIS.—The commission appointed for examining into the subject has recommended the establishment at the Farm of St. Anne, near Paris, a new asylum capable of containing 600 beds, and composed of two entirely separate divisions for the respective sexes. In this asylum are to be assembled all the cases of most interest for Medical study, illustrating the modes of curing insanity which may be sanctioned by experience. To this asylum is to be adjoined, but entirely separate from it, a dépôt capable of accommodating forty persons, and to this are to be consigned persons deemed insane by their friends or by the authorities, where these cases will undergo that careful examination necessary to determine their ultimate destination.

SATURDAY, MAY 30.

LIFE ASSURANCE AND THE MEDICAL PROFESSION.

THE practice of life assurance is, for good or for evil, rapidly and steadily extending itself. The majority of the companies have, during the past year, issued more policies than in any previous single year. According to those interested in the "profession" of assurance, we have here the most conclusive of all signs, that, notwithstanding the loss of American cotton and American commerce, the wealth of the country is increasing, and habits of prudence developing themselves amongst the people. Others are heretical enough to hint that the augmented number of life policies indicates in part that the practice of borrowing money upon personal security is becoming more rife. The *Insurance Record*, a paper which a few weeks ago came into existence, poetically speaks of insurance societies "like gems of purest ray serene" shedding their light upon the social system," and "looks prospectively upon a time when life assurance will in all quarters of the globe be regarded as a necessary of existence, and when every man according to his means will be enrolled on this glorious Magna Charta of his country's greatness." But, apart from such notions as these, life assurance is often spoken of as if it were merely the sheet anchor of a number of families liable otherwise to be thrown into sudden destitution; and it would be interesting to know how far we are justified in viewing the subject in this light, in order to see in what degree an estimate of the position of the country, founded on the prevalence of life assurance, is valuable. We would ask the penner of the ecstatic effusion above quoted how many of the policies effected fulfil that destiny which is so often dwelt upon as if it were the only function of life assurance, and actually become a provision for the wives and children of the assured. We should like to learn whether the greater number are not promptly consigned to the strong box of the mortgagee, or deposited with the office to secure advances, and abandoned after fulfilling their temporary purpose, the company thus pocketing the premiums in addition to the legitimate interest on the loan. The practice is very frequent with some companies of making advances upon the security of the bond of the borrower and two or three sureties, upon condition that he shall effect an insurance upon his life for double the amount advanced, depositing the policy as a collateral security. Not only these policies, but also the vast number effected as parts of mortgage securities made upon estates for life or other limited period subject to any of the contingencies usually insured against, must be eliminated from our consideration before we point to the increase of life assurance as a proof of the extension of universal prosperity. Such transactions, indeed, form a profitable investment for the funds of insurance companies, and are a means of extending their business; but

cannot, we apprehend, be said to confer any benefit upon society at large.

We do not, however, now propose to discuss the general advantages of life assurance, nor the question whether its extension be a legitimate subject of congratulation. We are interested neither in the advance nor the retrogression of insurance. We accept, for better or for worse, the fact of its great increase; and whilst we have no wish to change the direction of the wind, we are anxious to warn our professional brethren to trim their sails to the gale, so as not to sustain damage from its force.

The position of the Medical man who is called upon to give information to an Assurance Company touching the hygienic antecedents of his patient is seldom a particularly enviable one. It is, indeed, in many cases, eminently unpleasant and perplexing. The honourable Practitioner will, of course, in reply to the very categorical questions placed before him, either state the truth, and the whole truth, or, as he is perfectly at liberty to do if he pleases, decline altogether to furnish the desired information. Whichever plan he may adopt, it is probable that the relation between him and his patient will by no means be improved should the policy for which the latter is anxious not be granted by the office. We are, it is true, told that the communications between the insurers and the referees are of a strictly confidential character; and that when the office applies directly to the Medical attendant, the intending assured need not be aware of his having been consulted; but cases must occur to every one of our readers in which the patient must be able to make a shrewd guess as to the quarter whence the information which led to the refusal of the policy was derived. And it is not always, as we shall see, that the direct system of communication is adopted.

The service under consideration is one which the Medical Profession are under no contract whatever with society to perform, and which, in this respect, stands on the same footing with the giving of evidence in criminal cases, and the proposed compulsory certificate of the cause of death—a service of a nature most responsible, of vast importance to the interests of the offices, and frequently very repugnant to the Practitioner—a service, in fact, combining all the requisites for entitling the performer to an ample and exceptional remuneration at the hands of those to whom it is rendered. Most of the first-rate offices, indeed, now recognise these principles, to the extent, at least, of communicating directly with the Medical attendant of the "life," and paying him more or less adequately for the required information. But, strange to say, there are some companies which, as our readers are probably aware, are not ashamed to adopt a mode of proceeding by which they virtually tell the Medical man, "We refuse to grant the proposed policy on your patient's life unless we have a satisfactory report from you. At the same time, we will not pay you for that report, and moreover we will not place the slightest confidence in your information when we have got it." Such is, in fact, the ground taken by those offices which enclose the queries to the intending assured, directing him to forward them to the Medical attendant of the "life," and to obtain an answer. The object of this is twofold: first, to avoid becoming liable to the Medical adviser for his fee; and secondly, that the assured may, if possible, be held answerable for any misrepresentation by the referee. Sometimes the proposer is even warned that the validity of the policy will depend on the correctness of the Medical man's report. The system thus indicated embodies an amount of meanness the like of which is not often met with in the business world, and is an insult to the known honour and integrity of our Profession. These proceedings generally result in the certificate being furnished without charge either to the office or the patient—a practice which, as the spread of assurance goes on, is in danger of becoming an intolerable burden to Medical men. The con-

solution often deemed sufficient for the Doctor who does not get paid, that his services being for the good of society are their own reward, does not, as we have seen, always apply in these cases. Assurance transactions are not, as a whole, so universally beneficial to humanity as to render it incumbent on, or laudable in, a Medical man to act in these matters without proper payment, or without his position being rightly defined. The course we propose is very simple; it is merely that the Profession should come to a common understanding to refuse information in any case in which the office does not undertake to give an adequate remuneration for the service. If the Medical men mutually agree that unless the fee is paid by the office they will not reply to the inquiries, those companies which still adhere to the plan of non-payment and distrust will be compelled to follow the example of their more liberal and well-conducted competitors.

It is impossible not to contrast the footing on which Medical men are dealt with by insurance companies with the relations between those bodies and the solicitors. Take a passage from the speech of the chairman at the last annual general meeting of the Law Life Assurance Society: "Gentlemen, you see that the commissions are placed at a sum of 12,000*l.* and odd. Now that is a large sum to be paid for commission; but it is paid in every office, and it has a tendency to bring business to the society, affording as it does compensation to those who take the trouble of paying the premiums and of bringing policies to us." Turn to the report of the meeting of the Mutual, and we find that "Mr. Bolton urged that if they doubled their business by paying 10 per cent. commission it would be beneficial. Other offices paid 10 per cent., and some paid 15 per cent., so that surely the Mutual could do the same." We do not quarrel with the remuneration the attorneys receive for paying premiums. The money employed to render the interests of that profession identical with those of an insurance company is doubtless well spent. But the solicitor is not the only man who fills the position of confidential adviser in many families. Medical men are frequently consulted on the subject of life assurance. We are satisfied that a few miserable savings accomplished by dint of shabby treatment of the Medical Profession will not in the long run be found profitable to any office.

---

### THE WEEK.

#### VACCINATION NO PLAYTHING.

FAR be it from us to say one word to disparage or to limit the employment of one of the greatest boons which Medical science has conferred on the present and past generations. Vaccination needs no eulogy. Its power of limiting the operation of the most loathsome pest which has decimated the human race has now been tested for more than half a century, and new evidence is afforded by every fresh epidemic of variola. But there cannot be a greater error than to suppose that the "pearl on the rose leaf," as Jenner poetically described the vaccine vesicle, is in every case a mere local manifestation, incapable of anything but a benign influence. True it is that, in the enormous majority, it appears to be nothing more; but facts now and then crop up which remind us of the truth that the matter of vaccinia belongs to the class of morbid poisons, and is potent enough in some rare cases to produce grave constitutional disturbance, and even, in peculiar unhealthy conditions, death itself. This, after all, is no more than might have been expected from the first. The most useful therapeutic agents are subject to the same limitation. Every Practitioner knows that idiosyncrasies ever and anon present themselves, in which the smallest medicinal doses of opium, mercury, and many other of the most useful drugs can only be administered with extreme peril. But an acknowledgment of the truth does not invalidate their general usefulness. Vaccine lymph is a *virus* in the true sense of the term. The vesicle is only the local manifestation of the change to which

the whole mass of the blood has been subjected, and can we wonder that occasionally such a transmutation passes the boundary line of perfect safety to the individual? It is needless to say that these remarks have been suggested by the occurrences of the present epidemic. In another part of the Journal we publish a letter giving an account of a case in which death from phlegmonous erysipelas actually occurred after re-vaccination,—a previous attempt to induce the vaccine disease having produced the most serious constitutional disturbance. The death of Sir Culling Eardley has been noticed in most of the daily papers as a consequence of vaccination in an individual who had been previously in bad health, and in whom the operation failed to produce the usual local results. We would not draw too grave an inference from these cases; it is highly probable that they may be explained by accidental circumstances which do not appear; but every Medical Practitioner must have seen instances in which the constitutional affection has passed the usual limits, and where considerable inflammation of the arm has occurred, attended with sympathetic enlargement of the axillary glands. At present, when the doors of London Physicians and Surgeons are besieged by crowds of young ladies and gentlemen applicants for vaccination, who seem to think the operation of no more consequence than a submission to the manipulations of the *coiffeur*, it is necessary that these things should be borne in mind by Professional men. It is even stated that chemists and druggists are driving a good trade in vaccination. If so, we think the fact calls for the direct and immediate interference of the Medical Council, who, if at present they have not powers to stop such practices, should leave no stone unturned to obtain them from the Legislature. To our Medical brethren we say,—Tell your patients when vaccinated that they have to go through the stages of a disease, and that it will not do for them to live as carelessly as they are wont. Tell young men in particular that they must not dine out and indulge in the pleasures of the table or the excitements of fast society during the incubation and maturation of the vaccine vesicle. In a word, that if it be not necessary for them to "purge," it will be at least prudent for them to "live cleanly," whilst an agent, whose protective influence is only a measure of its activity, is leavening the entire organism.

---

#### THE ETHNOLOGICAL AND GEOGRAPHICAL DISCOVERIES OF CAPTAINS SPEKE AND GRANT.

THE great scientific event of the week has been the annual general meeting of the Royal Geographical Society, at which the President, Sir Roderick Murchison, gave a narrative compiled from the journals of the African travellers, Captains Speke and Grant. The discovery of the origin of the White Nile from the middle of the northern boundary of the great inland fresh-water lake, Victoria Nyanza—the stream at its exit from the lake no insignificant rivulet, but a broad cascade, 150 yards in width, leaping over a fall twelve feet in height—might satisfy the craving for adventure of a century. Sir Roderick Murchison has reason to congratulate himself on the verification of a proposition he advanced as an hypothesis eleven years ago, when he suggested that "the true centre of Africa, instead of being a sandy desert, is a great elevated watery basin, often abounding in rich lands, its large lakes being fed by numerous streams from adjacent ridges, and its waters escaping to the sea by fissures and depressions in the higher surrounding lands." Such is the origin of the Zambesi, of the Niger, and it may now be added of the Nile itself. The Victoria Nyanza lake, the north shore of which is nearly coincident with the equator, is 3500 feet above the level of the sea, and about 150 miles in length and breadth. Its chief feeder arises in the famous Mountains of the Moon, now announced to be detached conical hills, the highest of which attains the height of 10,000 feet. Its great outlet is

the Nile itself, but it has numerous others, which converge on the river, and feed it for a course of 150 miles. The river also passes through another lake, the Luta Nzige, which is fed by a stream arising in the same highland district as the feeder of the Victoria Nyanza. But our space will not allow us to follow the travellers through all their geographical discoveries. Their ethnological facts are scarcely second to their geographical in interest. They have traversed three kingdoms never before visited by European. First, the kingdom of Karagwè, a district containing the Mountains of the Moon, which abuts by one of its corners against the west shore of Nyanza at its southern end. Here Speke found a very superior negro race, advanced to some degree in civilisation, having an intelligent king, who befriended him, franking his expenses, and forwarded him with recommendations to the king of Uganda. Uganda is bounded on the east by the Nile at its origin. Its people are described as the French of those parts, sprightly in demeanour, and displaying good taste in behaviour, dress, and houses. Their ruler, Mtesa by name, is absolute in his power; fortunately he showed great kindness and even affection for Speke. He knew well of the navigation of the White Nile by whites, and had occasionally received their bartered goods. This "amiable youth" is described as surrounded by his wives, and delighting in field sports, while one of the rules of his court seems to require the execution of one man per diem for the good of the State. By him Speke was detained as a kind of state prisoner for five months. The northernmost of the three kingdoms is the kingdom of Ungoro. It is inhabited by the same Wahuma race as Karagwè and Uganda, but they are far less advanced in civilisation. Their king is said to be morose, suspicious, and churlish; his chief occupation is the fattening of his wives and children till they cannot stand, and the practice of witchcraft. Hitherto the travellers had no difficulty about interpreters, for one language was common to the three kingdoms, but beyond Ungoro, on to the north, the people spoke an entirely different tongue, and were literally naked barbarians. Those of them who visited Ungoro adopted a scanty dress out of deference to the feelings of the inhabitants, but at home perfect nudity is their normal condition. These in all probability are the Anthropophagi of Herodotus, the true obstacles in every age to the discovery of the source of the Nile. We offer no apology for giving our readers this slight sketch of Sir Roderick's narration, for, not to speak of its intrinsic interest and its scientific importance, the discovery of the origin of the Nile by Englishmen confers an honour on our generation to which no profession or class can be indifferent.

#### MEDICINE IN CHINA.

HOSPITAL reports are generally somewhat dreary productions, but the Sixteenth Annual Report of the Chinese Hospital, Shanghai, is a marked exception to the rule. Dr. Henderson, the Medical Officer to the Hospital, and the author of the Report, has made his little pamphlet an interesting annotated catalogue of remarkable cases, a means of conveying to the Profession at large the results of an experience new and peculiar, and an appeal to the outside world enforced by an unvarnished account of what his art is accomplishing amongst the extraordinary people to whom he devotes his skill and energies. One of the Medical facts he records is the occurrence of pure typhoid fever amongst the natives at Shanghai during the months of November and December, 1862, and the success which has attended in his hands its treatment by hydrochloric acid. He has already in our pages called the attention of the Profession to the value he is disposed to attribute to this remedy. He believes that in typhoid fever the effect of hydrochloric acid is as decidedly beneficial and specific as that of quinine in ague. He explains the good effect of the acid by reference to the excess of ammonia given off from the body during destructive

metamorphosis of the tissues, and argues from the fact that ammonia injected into the veins of animals is capable of producing symptoms of a typhoid character. The same line of reasoning, we may observe, was several years ago taken by Dr. Richardson. A form of dysentery, also of a typhoid character, occurs at Shanghai. In this disease Dr. Henderson found the blood to be more alkaline than in health, and again the acid treatment was followed by the very best results. The prevalence of catarrhal ophthalmia amongst the Chinese is well known. Neglected cases, in which chemosis is so great as to overlap the eyelids and the greater part of the cornea, leaving merely a transparent round spot in the centre like an ordinary pupil, are of constant occurrence. After vainly trying to cure them by the simple application of nitrate of silver, Dr. Henderson adopted the plan of dissecting off all the infiltrated mass of conjunctiva round the whole margin of the cornea, and after allowing it to bleed freely, applying lightly solid nitrate of silver to the raw surface, then soaking a little cotton in a solution of belladonna, and applying it to the eyelids. Perfect rest completed the treatment, which was found never to fail.

The following story is characteristic:—A master of an opium shop was accidentally shot by a Chinese soldier. The ball shattered the knee-joint, and amputation afforded the only chance of recovery. The patient was told this, and efforts were made to induce him to submit to the operation. They were, however, unavailing. The true Chinaman showed his usual philosophy—*i.e.*, he was willing to die, but what could he do with only one leg? His friends were of the same opinion as himself, and entirely refused to sanction the operation. The man began to sink on the fourth day, and died on the sixth. The evening before he died he was asked whether he would now have the leg amputated were it practicable, but no change had come over him. The old excuse was ready. "What would be the use of me without a leg? To have performed the operation against the patient's will would, in case of his death, have placed the operator in an awkward position in relation to the legal authorities. Dr. Henderson frankly acknowledges that, as a rule, the Chinese are not grateful for what is done for them. He writes:—

"Individuals occasionally express their gratitude; but this is nothing to the purpose. I never came to China to gain the people's gratitude, but to try and do them good; and the man who expects gratitude from the Chinese will be woefully disappointed; but though they do not show their thankfulness, they cannot fail to see that the aims and objects of the Hospital are for their good; and though the influence is silent, it is steady and strong in the right direction, and they certainly have great confidence in the Institution and the work carried on in it."

We suspect that the same estimate of gratitude would do no injustice to the mental state of crowds who throng the outpatient rooms of London Hospitals. Human nature is not very different in China and Champs-Élysées; but good work bears its own fruit in every soil, and we heartily wish the author of this Report an overflowing garner.

#### INDECENT ATTACK ON THE MEDICAL OFFICERS OF HEALTH AND VACCINATORS BY A MEDICAL MEMBER OF A VESTRY.

We will not venture to compare the Medical Council to a London Vestry or Board of Guardians, but if any of the members of that Council behave like the members—we blush to say *Medical* members—of some vestries, we need not wonder that they should dislike the presence of reporters. The following curious bit has been sent to us, duly authenticated, as a report of part of the proceedings of the "St. George's" Board of Guardians. The report does not state whether it was St. George's, Hanover-square, or St. George's-in-the-East, and although the presence of a lord would countenance the supposition that it may have been the former, the conduct of the chairman most decidedly smacks of the East-end type. We do not profess to know the

peculiar qualifications of Dr. Brewer to sit in judgment on his Professional brethren, nor on what grounds he ventures to brand them with the basest and most mercenary conduct. He seems, from the speech of Mr. Walton, to have retired from practice, and is not connected, so far as appears in the "Medical Directory," with any Hospital, and is never seen at any Medical society. The name of Brewer shines not on the list of the Pathological, Medico-Chirurgical, Obstetrical, or any other active Society that we know of. He seems to like better the presiding over a Board of Guardians; but, if we may judge from the quiet sarcastic speech of Mr. Walton, they seem capable of taking a pretty accurate measure of the worthy Doctor's pretensions.

"Dr. Brewer pronounces the MEDICAL OFFICERS OF HEALTH TO BE 'UTTER FOOLS' and a 'SET OF IDIOTS.'

"At the fortnightly meeting of the St. George's Guardians on Wednesday, Dr. Brewer (churchwarden) in the chair, a letter on the subject of small-pox was read from the Metropolitan Association of Medical Officers of Health, containing suggestions and hints as to the course to be pursued in endeavouring to check the epidemic.

"On the conclusion of the reading, Dr. Brewer said: 'A most contemptible paper! Most contemptible!'

"Lord Calthorpe asked if the Association was one recognised by Government?

"Dr. Brewer: No, my Lord; this is a combination of these men to cling together to magnify their parochial offices, to the utter degradation of the whole Profession.

"The Clerk to the Board complained 'that these people were getting a serious annoyance.'

"Mr. Walton said there was great difficulty about the matter. If the Medical Officers of Health suggested nothing, there was a cry of 'Oh! there's nothing done,' and if they did anything they were told they should have gone much farther than they had done. How contemptible soever this circular might be considered, they had as yet heard nothing better from the Profession on the subject. If gentlemen in the position of their chairman were to recall what their experience had been when engaged in the Medical Profession, and produce something really valuable, which would supersede productions of this kind, which were now the only information available, they might then better pronounce such suggestions to be contemptible; but it appeared to him that the Officers of Health were in the present instance doing all they could. They had combined their wisdom in a committee, and if the opinions of that combination were not satisfactory, what were they to do?

"A Member asked who paid the fees for the vaccinations which were now taking place, to which the Clerk replied that the parish did so.

"A Member: This accounts for the panic that has been produced in the parish.

"Dr. Brewer: No doubt, no doubt.

"Mr. Walton thought that as members of gentlemen's families and others paid for vaccination, the vaccinators should distinguish in their returns between such persons and those for whom the parish had to pay.

"Mr. Chappell explained that such persons were not charged for by the vaccinators, although the notices advised re-vaccination at the public expense.

"Dr. Brewer: I think you will see, Mr. Walton, at once that those gentlemen you have been lauding so much for doing all they possibly can, have left the matter in a most admirable state of confusion. This is a 'combination of their wisdom.' There is a fire taking place, and they are holding up their hands, and crying 'Fire! fire!' when they are ordered to put it out.

"The meeting then adjourned, this being the last business; Dr. Brewer remarking as he left the Chair,—'They are making utter fools of themselves; I never saw such a set of idiots in my life.'"

## LOCAL REPORTS ON SMALL-POX.

(Continued from page 542.)

XVI. *Hampstead.* By C. F. LORD, Esq., M.R.C.S., Medical Officer of Health.

THE epidemic of small-pox, which has created lately so much alarm in other parts of the metropolis, has hitherto been unknown in Hampstead. Not a single death has arisen from it.

There was not one in the parish from it from June, 1861, to June, 1862, nor has there been one since. Our population is 19,106. The boundary of our parish by Gospel Oak Fields, Kentish-town, is near to the Small-pox Hospital. I hear at present of but one or two cases, which were brought into the parish near Haverstock-hill.

Our school committees have always enforced vaccination of the children. The Hampstead Board of Guardians have always liberally encouraged vaccination, by allowing 3s. per case to the public vaccinator. His vigilance for many years in that relation, coupled with his duties of Medical Officer of Health, have caused him to be very successful in the matter of keeping away all severe or spreading small pox from the parish. Still, it is to be feared that there are many persons existing here who, through carelessness, ignorance, or prejudice, have totally neglected vaccination.

During my public and private experience of over thirty years in this parish, from time to time a slight outbreak of the complaint has arisen. More than once this was traced to lodging-houses, not then under regulation or "licence." Once the origin proceeded from foul linen carried by a laundress in an omnibus; another time from sewage matter which escaped in an open court at a low level in this parish. Children from various parts frequented the same school, but escaped, while adult occupants of the special court suffered with the mitigated form of small-pox, caught through drainage from infected higher-lying ground.

Not long ago the disease was brought into a healthy part of the village from Clerkenwell, through a dress being sent to be "pinked" at an undertaker's who had been furnishing the funeral of a small-pox case. The disease spread to the family next door. A young woman died of the complaint. Her mother came to nurse her from Leicester, and on returning carried the disease into that town.

The following is an extreme illustration of the subtle mode in which small-pox may be transmitted by the ordinary exposures of social life. A young woman was going by Downshire-hill, and recognised a former fellow-servant. The latter said her mistress had sent her "out for a blow of fresh air," as they "in St. Pancras had had small-pox, and little Polly had died of it, but the funeral was all over," etc. The girls parted, but about eight or ten days afterwards I was called to see the former, who had general fever. The following day I predicted small-pox, and the mother told me the above anecdote, adding, "The foolish girl must have frightened herself into the disease; she has done nothing but talk of it since the meeting, and said she felt all over sick at the time." The daughter was removed to the Small-pox Hospital, and died there. She had been previously vaccinated.

It is very important to bear in mind the subtle and latent, or lasting character of this contagion, as shown by these cases, the facility of its transit by clothing and other agents. In this way, perhaps, we may better account for what is called an epidemic of small-pox than by the idea of "hoarding up the germs" of the disease by a dirty population "till a supposed favourable season calls it into activity."

Vaccination and re-vaccination were generally adopted in this place during the epidemic of 1858, under the inspection of Dr. Seaton. Stray cases have since occurred, but they have not spread. One, last autumn, in an outlying hamlet, occurred in a gardener of middle age, who had been "nowhere out of his usual beat, except to remove and turn over a dung-heap," over which "job he felt unusual faint and sick," about a week before his illness. The complaint did not spread in the village, though the man refused to go to the Small-pox Hospital.

It is a serious matter to urge or force the removal of a patient from an airy room or locality to the wards of a Hospital, and thus materially lessen his chances of recovery. Crowding these patients in a densely populated district on any plea whatever is most reprehensible, dangerous in principle, fatal in practice. With this view the Association of Medical Officers of Health have advised temporary buildings or wards "to be opened on the double ground of distance from inhabited houses and facility of approach." It is to be hoped that nothing like or near to the late Queen's Bench Prison, which has been suggested, will ever be sought after or adopted as a temporary small-pox Hospital.

The practice of re-vaccination, which has lately been so much in vogue, is surely a slur on the previous operation. Its performance can only be warranted under the idea that some fault in the character of the lymph used, or the system of the

child vaccinated, existed at the time of the original operation. Idiosyncrasy of constitution, or the wearing out of protective power by change in molecular growth, can have no more weight against vaccination than they have against the whole class of exanthemata, which by one attack are admitted to yield a protective influence through life. It appears to me that it is only when a house or school is specially attacked, that it is expedient to urge that wholesale re-vaccination which in some neighbourhoods in the metropolis, under the present panic, the Doctors and their patients are rushing to accomplish. In nearly every case I have seen of re-vaccination the cow-pock pustule and regular areola and inflammation have never been produced. (a) I presume this to be universally so. On this fact we may base the argument that it is so because the blood or system has been so changed or influenced by the cow-pock, that it cannot admit its second development, and would defy small-pox as much as it did at the time of the first perfect or successful vaccination. When the greatest vigilance has been taken to secure the early perfect vaccination of all, and re-vaccination in every doubtful case, the Profession may surely safely leave the result to fixed and general laws, while a meddling interference is to be shunned as useless and dangerous.

**XVII. Wandsworth.** By G. E. NICHOLAS, M.D., Medical Officer of Health for Wandsworth.

I SEND a statement of the prevalence of small-pox in this sub-district during the period I have held the office of Medical Officer of Health. I submit it in a tabular form, and would beg to suggest the propriety of using this or some similar and perhaps more comprehensive form of table in procuring information from every district in the metropolis, from which could be collected a general table of considerable statistical value.

*Table showing the total Deaths which have taken place from Small-pox in the Sub-district of Wandsworth during the Seven Years, 1856-62; also the Number of Attacks from that Disease, with the Resulting Deaths which have occurred amongst the Parochial Poor during the same period:—*

SUB-DISTRICT OF WANDSWORTH.			
Area in acres, 2,478.		Population in 1861, 13,346.	
Years.	Number of deaths from Small-pox amongst all classes.	Amongst the Parochial Poor.	
		Attacks.	Deaths.
1856	9	61	2
1857	0	0	0
1858	0	1	0
1859	2	16	2
1860	0	26	0
1861	1	23	1
1862	0	3	0

During the present year up to this date there have occurred two deaths and seven cases, two of which were modified from vaccination. The deaths were of persons unvaccinated. From the foregoing table it is seen that this sub-district has enjoyed comparative immunity from the disease. Here, as in other parts of the metropolis, vaccination is being extensively adopted, and amongst the poor there is an increasing desire to avail themselves of its protective influence; which influence, I may add, they regard as a protection against death, rather than as a preventive to small-pox. They believe the former; as a rule, they disbelieve the latter. Whether this be the result of correct observation or not, small-pox after vaccination would appear to be a thing of by no means uncommon occurrence. Hence it becomes a most important question to determine whether more small-pox after vaccination occurs now than formerly, and if so, whether the diminution of its protective influence is due to the present milder character of cow-pox, or to what other cause. I trust your columns will become the exponent of some facts bearing upon this subject.

**XVIII. Small-Pox in St. Pancras.** By Dr. HILLIER, Medical Officer of Health.

WITH a population of 200,000, many of whom are in constant

(a) The puncture or "scratch" inflames after the second day; then assumes speedily the look of a shabby, festering sore, with jagged, irregular inflammation, and hardened base, which soon die quite away. Sometimes the virus appears to make a blunder, and rushes on to create a good deal of cellular effusion, with erysipelatous inflammation around the arm. I ascribe these deviations to natural or acquired irritability of skin or system, and not to any latent propensity to small-pox, as some do.

communication with all parts of London and all parts of the country, it might reasonably be expected that, so long as there is much small-pox in England, St. Pancras would, from time to time, come in for its share. In the year 1862, there were 19 deaths from this disease, 11 of which occurred in the fourth quarter of that year. In January of the present year there were 4 deaths; in February 6, in March 2, and in seven weeks ending on the 16th instant, there were as many as 16 deaths. As might have been anticipated, most of the deaths have been in persons not protected by vaccination. So far as I have been able to ascertain, for every death there have been from 10 to 15 cases of the disease. Assuming 12 to be the number (and I believe this has been not far from the truth), we should have had, since the beginning of the year, about 336 cases in the parish. There has been a very large proportion of cases of small-pox modified by vaccination in this epidemic. During the past week there were, amongst the out-door poor, attended by the parish Surgeons, 34 cases, and in the previous week, 37 cases. Of these, nearly half were sent into the workhouse, and are there being treated in special wards set apart for the purpose; the others have been treated at their own houses, and are, it is to be feared, propagating the disease to their neighbours. In many instances, parties object to being sent away from their homes, and there is no power by which they can be removed against their will. For some time after the Small-Pox Hospital was unable to receive more patients, the directors of the poor in this parish objected to having the cases sent away from their homes to be treated, except those cases which most urgently required to be removed. Their reason for this was, that they had no place suited for the reception of the number of cases which presented themselves. At first wards were fitted up to accommodate six patients; since then room has been found for fourteen more, and at the present time provision is being made for thirty more. The allowance of space for each patient is 1000 cubic feet. The wards are tolerably well adapted for the purpose, were it not for their proximity to the rest of the building, and to a low class of dwellings in Agar Town immediately at their rear. They are not entirely detached, but there are no patients above or below them, and communication is cut off from the rest of the establishment as completely as possible.

The disease has spread to some extent amongst the inmates of the house, about six persons having contracted it there, besides several persons who have come in during the period of incubation of the disease. There has also been an outbreak of the disease in the streets of Agar Town immediately adjoining the special wards, upwards of twenty cases having occurred within a stone's throw of these wards in a period of eight or ten days. Re-vaccination has been carried out in the workhouse and in districts where small-pox has prevailed, so far as persons would allow it. All the public schools are being visited, and steps have been taken to enforce vaccination where it has been neglected, and to have it repeated where that appears desirable. It is the intention of the directors of the poor to take legal proceedings in cases where parties obstinately refuse to get their children vaccinated. So far as I can ascertain, the disease is on the decrease within the last week or ten days.

**XIX. Fulham District.**

MR. BURGE, Medical Officer of Health, writes:—"I am happy to say that no deaths from small-pox have been as yet registered in the Fulham district, though three or four cases of the disease have come under my cognisance. I will report further if necessary."

**THE ABBEVILLE JAW-BONE AGAIN.**—Our readers are already aware that, after an elaborate discussion, the authenticity of this bone has been completely affirmed, and M. Milne-Edwards announced the fact to the Academy of Sciences, M. Quatrefages taking the opportunity of complimenting his English adversaries for the courtesy with which they had abandoned their erroneous prejudices. All seemed terminating in a state of happy harmony, when Elie de Beaumont emphatically declared to the astonished Academy that, whether the jaw-bone and flint implements found were authentic or not, mattered not, for the soil in which they were found was not the *diluvium*, but a formation within historic period. Such a statement from so high an authority has caused much surprise, seeing that it was never made during the period of the discovery, but only when all had agreed as to the results. Detailed proof is naturally demanded at his hands.

## GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

MINUTES OF MEETING, MONDAY, MAY 25, 1863.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

MR. GREEN, *President*, took the chair at Two o'clock, p.m.

*Present—*

Dr. Burrows.	Dr. Alexander Wood.	Dr. Apjohn.
Mr. Arnott.	Dr. Andrew Wood.	Dr. Corrigan.
Mr. Cooper.	Mr. Syme.	Sir Charles Hastings.
Dr. Acland.	Dr. Thomson.	Dr. Sharpey.
Dr. Bond.	Dr. A. Smith.	Mr. Teale.
Dr. Embleton.	Mr. Hargrave.	Dr. Christison.
Dr. Storrar.	Dr. Leet.	Dr. Stokes.

Dr. FRANCIS HAWKINS, *Registrar*.

The Minutes of the last meeting were read and confirmed.

Read the following letter from Mr. Watt:—

"7, Blythswood-square, Glasgow, May 21, 1863.

"Dear Sir,—Feeling myself, from long-continued indisposition, unable to attend the meeting of the General Council of Medical Education and Registration of the United Kingdom, I beg to intimate to you my resignation as a member thereof.

"I am, dear Sir, yours very sincerely,

"J. H. Green, Esq., President of the Council of Medical Education, etc." "GEORGE WATT.

Read the following official notice:—

At a duly constituted meeting of the Faculty of Physicians and Surgeons of Glasgow, held within the Faculty Hall, Glasgow, of date the twenty-third May, eighteen hundred and sixty-three, the Faculty, *inter alia*, elected John Gibson Fleming, M.D. Glasgow, a member of the General Council of Medical Education and Registration, and committed to him full power, warrant, and commission to represent the Faculty in the said General Council, to attend all meetings of the said Council wherever the same may be held, and to act and to do for and on behalf of the said Faculty, in all matters and things which may be brought before said Council, as should appear to him fit and proper; and the said Faculty did thereby vest the said John Gibson Fleming with the whole powers and faculties which the Medical Act contemplates to be vested in a member of said Council.

In faith and testimony whereof, I, Charles Ritchie, M.D., President of the said Faculty, have hereunto set my hand and signature, and the seal of the said Faculty is hereto affixed at Glasgow, this twenty-third day of May, in the year one thousand eight hundred and sixty-three.

CHARLES RITCHIE, M.D., *President*.

Dr. Fleming was then introduced to the Council by Dr. Thomson.

The "Business Committee" of the Meeting of the General Council held in May, 1862, was re-appointed, viz:—

Dr. Andrew Wood, Chairman.	Dr. Thomson.
Mr. Teale.	Dr. Corrigan.
Dr. Embleton.	

The "Finance Committee" of the Meeting of the General Council in May, 1862, was re-appointed, viz:—

Dr. Burrows, Chairman.	Dr. Andrew Wood.
Dr. Sharpey.	Mr. Arnott.
Dr. A. Smith.	

The "Committee appointed to consider Special Claims for Registration" in 1850 was re-appointed, viz:—

Dr. Alexander Wood, Chairman.	Dr. Leet.
Sir Charles Hastings.	Dr. Embleton.
Dr. Bond.	Dr. A. Smith.
Mr. Syme.	

The "Committee on Amendments of the Medical Acts," appointed at the Meeting of the General Council in May, 1862, was re-appointed, with the addition of Dr. Leet, viz:—

Dr. Burrows, Chairman.	Dr. Acland.
Dr. Thomson.	Dr. Andrew Wood.
Dr. Storrar.	Dr. Sharpey.
Dr. Apjohn.	Mr. Hargrave.
Dr. Burrows.	Dr. Leet.

The Committee appointed "to revise the Standing Orders of the Council" in 1861, was re-appointed, viz:—

Mr. Teale, Chairman.	Dr. Stokes.
Dr. Embleton.	

The Committee appointed at the Meeting in 1862, to consider and report upon "The Returns of the Number and Names of Candidates who have passed their respective final Examinations, and the Number of those who have been Rejected, which have been received in compliance with the Twenty-third Recommendation of the Medical Council, and also the Returns received in compliance with the Sixteenth Recommendation," was re-appointed, viz:—

Dr. Embleton, Chairman.	Dr. Leet.
Mr. Cooper.	Dr. Apjohn.
Dr. Thomson.	Dr. Stokes.

1. Moved by Dr. ANDREW WOOD, seconded by Dr. ALEXANDER WOOD—"That reporters be admitted to the meetings of the General Medical Council."

(*First Amendment.*)

Moved by Dr. THOMSON, seconded by Dr. STOKES—"That a Committee be appointed, to draw up and lay before the Council, for its consideration, a plan for the publication of such an authorised report of the proceedings of the Council as may appear desirable."

(*Second Amendment.*)

Moved by Sir CHARLES HASTINGS, seconded by Mr. SYME—"That in all cases in which the General Council have to exercise their functions as a Court of Judicature, relative to the admission of persons on, or rejection of them from the Register, reporters from the press be admitted."

Question put to the vote—"That the original motion be amended."—Negatived.

Dr. ANDREW WOOD required that the names of the majority and minority should be entered on the Minutes.

*Majority—*

The President.  
Mr. Arnott.  
Mr. Cooper.  
Dr. Alexander Wood.  
Dr. Andrew Wood.  
Dr. Fleming.  
Mr. Syme.  
Mr. Hargrave.  
Dr. Leet.  
Dr. Apjohn.  
Dr. Corrigan.  
Mr. Teale.

*Minority—*

Dr. Burrows.  
Dr. Acland.  
Dr. Bond.  
Dr. Embleton.  
Dr. Storrar.  
Dr. Thomson.  
Dr. A. Smith.  
Sir Charles Hastings.  
Dr. Sharpey.  
Dr. Christison.  
Dr. Stokes.

The original motion, "That reporters for the press be admitted to the meetings of the General Council," was then put, and negatived.

Dr. ANDREW WOOD required that the names of the majority and minority should be entered on the Minutes.

*Majority—*

The President.  
Dr. Burrows.  
Mr. Arnott.  
Dr. Acland.  
Dr. Bond.  
Dr. Embleton.  
Dr. Storrar.  
Dr. Thomson.  
Dr. A. Smith.  
Dr. Sharpey.  
Mr. Teale.  
Dr. Christison.

*Minority—*

Mr. Cooper.  
Dr. Alexander Wood.  
Dr. Andrew Wood.  
Dr. Fleming.  
Mr. Syme.  
Mr. Hargrave.  
Dr. Leet.  
Dr. Apjohn.  
Dr. Corrigan.  
Sir Charles Hastings.  
Dr. Stokes.

Read, the following letter from the Home Office:—

[Whitehall, May 19, 1863.]

"Sir,—With reference to your letter of the 6th instant, I am directed by Secretary Sir George Grey to inform you that the Lords Commissioners of the Treasury approve of the distribution of 2000 copies of the *Medical Register*, published by the Council of Medical Education and Registration, to certain public offices, at a cost not exceeding £300 per annum.

"I am, Sir, your obedient servant,

"H. WADDINGTON.

"Joseph Henry Green, Esq., President of the Council of Medical Education and Registration, 32, Soho-square."

2. Moved by Dr. A. SMITH, seconded by Dr. SHARPEY—"That a Committee be appointed to consider the publication and distribution of the Register.

"Dr. A. Smith, Chairman.

"Dr. Fleming.

"Dr. Sharpey."

—Agreed to.

3. Moved by Dr. ALEXANDER WOOD, seconded by Dr. APJOHN—"That a Committee be appointed to consider and report on the applications from foreign or colonial Colleges and Universities for the recognition of their degrees or examinations.

"Dr. Alexander Wood, Chairman.

Dr. Fleming.

Dr. Storrar.

Dr. Apjohn.

Sir Charles Hastings.

Dr. Leet."

—Agreed to.

4. Moved by Dr. CORRIGAN, seconded by Dr. STORRAR—"That the memorial of the Manchester Medico-Ethical Association, respecting amendment of the Medical Acts, be referred to the Medical Acts' Amendment Committee."—Agreed to.

5. Moved by Dr. ACLAND, seconded by Dr. A. SMITH—"That the President be requested to propose to the Council, during its present session, a design for the common seal."—Agreed to.

Confirmed—JOSEPH HENRY GREEN.

MINUTES OF MEETING, TUESDAY, MAY 26, 1863.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

MR. GREEN, *President*, took the chair at Two o'clock p.m.

*Present—*

Dr. Burrows.	Dr. Andrew Wood.	Dr. Corrigan.
Mr. Arnott.	Dr. Fleming.	Sir Charles Hastings.
Mr. Cooper.	Mr. Syme.	Dr. Sharpey.
Dr. Acland.	Dr. Thomson.	Mr. Lawrence.
Dr. Bond.	Dr. A. Smith.	Mr. Toale.
Dr. Embleton.	Mr. Hargrave.	Dr. Christison.
Dr. Storrar.	Dr. Leet.	Dr. Stokes.
Dr. Alexander Wood.	Dr. Apjohn.	

Dr. FRANCIS HAWKINS, *Registrar*.

The Minutes of the last meeting were read and confirmed.

The Solicitor, Mr. OUVRY, stated the case of John Lacey (referred to the General Council by the Branch Council for England), who has applied to be registered as a Licentiate of the Society of Apothecaries of London

1. Moved by Sir CHARLES HASTINGS, and seconded by Dr. BURROWS—"It appearing to the Council that John Lacey has obtained the licence of the Society of Apothecaries, London, on statements similar to those on which he was originally registered, and in respect of which his name was erased from the Register, on the ground that the entry had been fraudulently or incorrectly made, the Council decline to register the said John Lacey on a qualification thus obtained; but, inasmuch as the said John Lacey has not been heard, the question is remitted to the Branch Council for England, with power to reconsider and decide the same, after hearing the said John Lacey, if he shall desire to be heard."

Amendment moved by Dr. CORRIGAN, and seconded by Dr. A. SMITH—"That the Registrar be directed and authorised not to insert Mr. John Lacey on the Register."—The amendment was put to the vote and negatived. The original motion was then put and carried.

2. Moved by Dr. SHARPEY, seconded by Mr. HARGRAVE—"That a copy of the above resolution be forwarded to the Society of Apothecaries of London."—Agreed to.

An application made by Mr. RICHARD ORGAN to the Society of Apothecaries to be examined for their licence, having been referred by that body to the General Council,

3. Moved by Dr. ALEXANDER WOOD, seconded by Mr. TEALE—"That the Court of Apothecaries be informed that the name of Richard Organ was erased from the 'Medical Register' on the ground that he had endeavoured to procure a Licence from Edinburgh by personation. The Council therefore recommend that the Society of Apothecaries should not admit Mr. Organ to be examined."—Agreed to.

Read, a petition from Mr. John Kearney, of Cloanmany, County Derry, for the re-insertion in the Register of his name, and of his qualification from the Faculty of the Physicians and Surgeons of Glasgow, which had been erased in 1861, by order of the General Council, under the 29th Section of the Medical Act (see Minutes General Council, No. 29, p. 2).

4. Moved by Dr. A. SMITH, seconded by Dr. A. THOMSON—"That the Council cannot comply with the prayer of Mr. Kearney's petition."—Agreed to.

Read, an application from Mr. John Potter Sargeant, for the restoration to the Register of his name, which had been omitted from it, under the 14th Section of the Medical Act.

5. Moved by Sir CHARLES HASTINGS, seconded by Mr. LAWRENCE—"That the Council having considered the application of Mr. John Potter Sargeant, to have his name restored to the *Medical Register*, decline to accede to it, unless Mr. Sargeant shall furnish to the Executive Committee satisfactory evidence of character. That the Council delegate to the Executive Committee the duty of inquiring into and deciding on the case, having regard to the requirement of the Council."—Agreed to.

Read the following letter from the Royal College of Surgeons of England:—

"Royal College of Surgeons of England, London, W.C., May 8, 1863.

"Sir,—I am desired to acquaint you that the Council of this College have removed Mr. Robert Jacob Jordan, of George-street, Hanover-square, from being a Member of this College.

"I am Sir, your obedient Servant,

"EDMUND BELFOUR, Secretary.

"[Dr. Francis Hawkins, Registrar General Medical Council.]"

6. Moved by Mr. ARNOTT, seconded by Mr. LAWRENCE—"That the Registrar be directed to erase from the Register the qualification of Mr. Robert Jacob Jordan, as a Member of the Royal College of Surgeons of England."

The Council then took up the case of Samuel La'Mert, referred to them by the Branch Council for England, on April 17, 1863.

Mr. OUVRY read a petition, and a statement with the evidence in support of it, from the Royal College of Physicians of Edinburgh, praying that the name of Samuel La'Mert, a registered Medical Practitioner, be removed from the Register. Mr. Ouvry read, also, the notice served personally on Samuel La'Mert, summoning him to attend the Council. Mr. Ouvry read, also, a written statement submitted by Samuel La'Mert in answer to the statement.

7. Moved by Dr. ALEXANDER WOOD, seconded by Dr. ACLAND—"That it has been proved to the satisfaction of the Council, that Samuel La'Mert, a Registered Medical Practitioner, has been guilty of infamous conduct in a professional respect: 1st. In publishing, or causing to be published, an indecent and unprofessional treatise entitled 'Self-Preservation: a Popular Treatise on the cure of Nervous and Physical Debility, Spermatorrhœa, Impotence, and Sterility, resulting from the Secret Habits of Youth, the excesses of Maturc Age, and the Debilitating Effects of Tropical Climates.' 2nd. In having falsely pretended, both on the title-page of the said treatise, and by advertisements in the public newspapers, that his son, Lima Abraham La'Mert, a Licentiate of the Royal College of Physicians of Edinburgh, was a joint author and publisher of the said treatise. That the name of the said Samuel La'Mert be erased from the *Medical Register*, and the Council hereby direct the Registrar to erase the same accordingly."—Agreed to.

8. Moved by Dr. STORRAR, seconded by Dr. SHARPEY—"That it be referred to a Committee to consider and report whether any, and what, steps should be taken by the Council in relation to the retirement and election of its members, in view of the expiration of the term of five years from its constitution. The Committee to consist of—

"Dr. Storrar, Chairman.

Dr. Andrew Wood.

"Dr. Apjohn."

—Agreed to.

Dr. CHRISTISON read a report from Dr. Garrod, the Secretary of the Pharmacopœia Committee.

9. Moved by Dr. SHARPEY, seconded by Dr. STORRAR—"That the report of the Pharmacopœia Committee be received and printed in the Minutes."—Agreed to.

REPORT OF THE BRITISH PHARMACOPEIA COMMITTEE.

May 25, 1863.

The Pharmacopœia Committee begs to submit the following report of the progress made towards the publication of the "British Pharmacopœia" since the meeting of the General Medical Council in May, 1862.

It will be remembered that, at the above meeting, the manuscript of the "British Pharmacopœia" was laid before the Council almost complete, and was then approved of by that body; but it was found that the printing of the work could not at once be proceeded with, from the fact that the Council did not at that time possess the necessary qualification for holding a copyright, and, moreover, from the wording of the Medical Act of 1858 not giving the legal power of superseding by the forthcoming Pharmacopœia the existing Pharmacopœias of the London, Edinburgh, and Dublin Colleges of Physicians, the General Council deputed to its Executive Committee the task of endeavouring to obtain a Supplementary Act granting the necessary powers, which was accomplished at the end of the last Parliamentary Session.

Shortly before this period, when it became publicly known that the Pharmacopœia Committee had, in the manuscript of the "British Pharmacopœia," made a considerable alteration in the weights to be employed in Pharmacy; and, among other changes, that the Troy grain was proposed to be discarded, and a new grain substituted for it—a grain which would bear the same relation to the Avoirdupois ounce as the Troy grain does to the Apothecaries' or Troy ounce, many objections were raised and remonstrances made to the Executive Committee—amongst others, one by the Royal College of Physicians of London, protesting strongly against such a change of weights, and it was thought advisable by the Executive Committee that a special meeting of the Medical Council should be summoned, that the matter might be definitively and satisfactorily dealt with;—this meeting was held in October last.

After this, the Pharmacopœia Committee made the alterations in the manuscript, rendered necessary by the changes in the weights. The Executive Committee at once commenced arrangements for the printing of the work; making contracts with the printers, previously selected by

the Pharmacopœia Committee, and approving the specimen pages of typography fixed on by the same Committee at its Conference at Edinburgh.

The three Editors, one chosen by each branch Pharmacopœia Committee, also commenced their task; but some little delay occurred at the outset, from the discovery that the approved specimen pages, although well adapted for portions of the work, were not in all respects suited for the whole, and with the consent of the Executive Committee, certain alterations were made in the typography of the first part of the Pharmacopœia; since this time the printing of the volume has steadily progressed, and the Committee has now the satisfaction of laying before the Council proof sheets of the whole Pharmacopœia, with the exception of the preface and appendix.

The manuscript of the former is complete, while the latter only awaits the corrections in the body of the work, before being put into type, which could be readily accomplished in a few days. As this may be the last report which the Pharmacopœia Committee will have to make, it may be advisable to point out to the Medical Council the amount of time and labour which has been devoted to the accomplishment of the work.

The Pharmacopœia Committee naturally separated into three Branch Committees, one in London, a second in Edinburgh, and a third in Dublin, and each commenced its sittings in December, 1858; from that period to the present, the number of sittings and attendances of each branch has been as follows:—

The London Committee has held 158 meetings, and the number of attendances of its members has been 567.

The Edinburgh Committee has held 108 meetings, and the number of attendances has been 657.

The Dublin Committee has held 141 meetings, and the number of attendances has been 627: making a total of 407 meetings and 1851 attendances. These numbers are exclusive of the two Conferences of Delegates, held in London and Edinburgh.

The financial statement of the Pharmacopœia Committee, since the accounts were audited in May, 1862, is contained in the following table:—

FINANCIAL STATEMENT OF THE PHARMACOPEIA COMMITTEE.

Dr.	£ s. d.	Cr.	£ s. d.
To Balance in hand on Audit of Accounts, May 19, 1862 .. .. .	128 13 9	London Delegates at Edinburgh .. .. .	195 6 0
To amount voted by the General Medical Council, May 21, 1862 ..	600 0 0	Dublin Delegates at Edinburgh .. .. .	192 3 0
		Edinburgh Delegates at Edinburgh .. .. .	110 5 0
		Mr. Warrington, Chemist to London & Edinburgh Committees .. .. .	105 0 0
		Edinburgh Secretary, for postage .. .. .	0 13 4
		Dublin Secretary, do. ..	2 0 7
		London Secretary and General Secretary, do. .	2 15 0
		Mr. Glover, for attendance on Pharmacopœia Committee at Soho-square..	10 10 0
	£728 13 9		£618 12 11

Leaving a balance of £110 0s. 10d. in the hands of the General Secretary.

The number of meetings and attendances given in the present Report may probably appear very large; but it must be remembered that in accomplishing the task of publishing a National Pharmacopœia, the Medical Council will have accomplished what has been long looked upon as a great desideratum, but which has hitherto frustrated the efforts of the three Colleges of Physicians of the United Kingdom; and in order to effect this, it was necessary to have a Committee composed of several members of Council from each division of the kingdom, and also to associate with them gentlemen from different learned bodies specially conversant with the subjects.

As but little is now required before going to press, besides the correction of the proofs and the completion of the Appendix, the Pharmacopœia Committee can confidently predict that the National Pharmacopœia will be published not later than October next.

A. B. GARROD, M.D., F.R.S.,  
Secretary to the Pharmacopœia Committee.  
Confirmed—JOSEPH HENRY GREEN.

May 26, 1863.

REVIEWS.

*The Spas of Europe.* By JULIUS ALTHAUS, M.D., Member of the Royal College of Physicians, London, etc., etc. Demy 8vo. Pp. 494. Price 12s. London: Trübner and Co. 1862.

A HANDY, practical, and at the same time thoroughly scientific work, well written, well arranged, and furnished with every convenience for immediate reference. Such a book, from a highly competent authority on the subject, and on a level with the most recent advances in Medical science, fills up an universally acknowledged gap in British Medical literature. It has, moreover, the advantage of being written by one who is no "Water Doctor." There is no tendency in Dr. Althaus' book unduly to extol the virtues of mineral waters in general or of certain spas in particular. As remedial agents of more or less value in properly selected cases, he simply claims for and gives them that amount of study and consideration which they undoubtedly deserve, but which in this country, for various reasons, they have hardly received. Commencing with an account of the origin of mineral springs, he proceeds to consider 2ndly, their physical properties; 3rdly, their chemical composition; 4thly, their geographical distribution; 5thly, their physiological action; 6thly, their therapeutical use. We feel sure that this volume will long be appreciated

as a complete and trustworthy book of reference on the mineral waters of Europe.

*Mentone, the Riviera, Corsica, and Biarritz as Winter Climates.*  
By J. HENRY BENNETT, M.D., Member of the Royal College of Physicians, London, etc., etc. Second Edition. Post 8vo. Pp. 288. Price 5s. London: Churchill and Sons. 1862.

THIS pleasantly written, useful little book embodies the experience of three consecutive winters which the author spent at Mentone for the sake of his health since 1859. It contains many hints and pieces of information which render it worthy of the notice of the Profession as well as of the public. In the present edition he has enlarged the description of Mentone and its neighbourhood. He has also added, in the last hundred pages, an account of Corsica and Biarritz as places of winter residence.

After making trial of most of the reputed health-towns of Southern Europe as winter residences for invalids, Dr. Bennett continues to give decided preference to Mentone on the score both of climate and hygiene.

*Who to Consult; or, a Book of Reference for Invalids.* London: Aylott and Son. 1863.

THE author of this book has such an extremely low opinion of the intellect and the morality of the Medical Profession, that it is very difficult to believe the assertion of the publisher that he is a member of that Profession. That he is "highly distinguished" as a Medical man we certainly do not believe, though it is indisputable that he is "highly distinguished" by some not very enviable qualities, for a more flagrant specimen of bad taste, presumption, and ignorance than is his work, we have never met with. He assumes that each Physician or Surgeon, no matter how eminent, is qualified to treat only a few diseases, and that, when he has under his care any unlucky patient suffering from other than those diseases, he never has the honesty to recommend further advice, but goes blundering on, hoping to hit on a cure haphazard; and the author proposes to amend this sad evil in a beautifully simple manner. The patient is to be taught to diagnose his own malady, and then selecting, under the author's advice, his Medical man, to go to him, saying, "I have such or such a disease, cure me." A dim idea crosses the writer's brain, however, that perhaps people will be slow to believe that the diagnosis of disease is such an easy matter, to be learnt off-hand, from a few simple directions in his book; or, at least, that it is hardly advisable to make so light of it, so he kindly intimates that he has had serious thought of making diagnosis a new specialty for himself, leaving the treatment of the disease to the inferior minds, the men to whom he would graciously recommend the patient; and, he tells us, he should then be practising in the same way as a barrister does! An astounding piece of information, for which we hope we feel duly grateful, for we, in our ignorance, had imagined that the barrister advised how to proceed in legal difficulties, not merely "Who to consult." But we learn many new things from this book, as, that the Apothecaries' Company, to which we fancied we owed very largely the advance in Medical education in the present century, "confines itself chiefly to Chemistry, Materia Medica, and Pharmacy." It naturally follows that the "mere Apothecary" and the General Practitioner are altogether put aside; nobody would, or at least should, think of applying to them for advice.

Patients consulting the book will often reap despair instead of comfort; the sufferer from headache will find it mentioned only as a disease of the brain; the hapless wretch who has diagnosed that he labours under "leucocythæmia" will learn that his case is hopeless unless he has money and leisure for a visit to Edinburgh.

As we do not at all pretend to even approach our author in knowledge of our Professional brethren, or in judicial appreciation of their merits, so we may not criticise his roll-call of the eminent; yet reverently as we look on it, we cannot help observing that some well-known names, as Dr. Gibb and William Adams, are conspicuous by their absence, that some who are known chiefly to devote themselves to science, and some who have left the Profession, are enumerated among the eminent Practitioners; that Physicians are enrolled as Surgeons; that there are only twenty able Dentists in all London: but we will not waste time and space over the book; we should not notice it at all but for the publisher's assertion that it is by "a highly distinguished member of the Medical Profession."

*Almanach Général d'Acachon, A Paris et Bourdeaux.* 1863.

"HEALTH is at best a vain, precarious thing." So sang Gilbert West, the friend of Gray, in the early part of last century. Alas! the truth is as striking now as then; and our countrymen and countrywomen are driven to seek in foreign lands that health which our uncertain climate renders so precarious. In the present day, when all the borders of the Mediterranean are being studded with hotels to ensure something of the comforts of an English home, it seems right to direct attention to a place which presents some peculiar advantages. Cannes, Nice, Mentone, and other places of resort have their respective attractions; but none have as yet the great peculiarity of Acachon, where, in addition to all the natural physical advantages, such as climate, facilities for bathing of an especial kind, there have been created by the enterprise of the Compagnie des Chemins de Fer du Midi, "Les Villas d'Hiver," in the Forêt d'Acachon. These are just suited to attract the invalid, and have already drawn to them the natives of many countries. The chief number of those resorting thither come from Bourdeaux, from which Acachon is distant about forty miles. Fewer English than usual were there last year, owing to the attractions of the International Exhibition. We commend the place and this almanack to the attention of invalids.

## GENERAL CORRESPONDENCE.

### VACCINATION AND RE-VACCINATION—DEATH.

LETTER FROM MR. J. W. WELLS.

[To the Editor of the Medical Times and Gazette.]

SIR,—With a view of affording some information to the Profession of a remarkable case, and also for the purpose of eliciting some opinions from the faculty upon this subject, I have to ask the favour of your insertion of the following details:—

Some members of a family of great respectability being patients suffering from the prevailing epidemic, the mother, aged 55, thought it would be as well to exercise the usual precaution in such cases by herself undergoing the operation of vaccination. I performed that operation on Thursday morning, the 14th, taking good matter from the vesicle of a healthy child; immediately upon making the punctures the patient swooned, for which I ordered the necessary stimulants, and after seeing that she would soon be brought round again, I left.

A visit on the following morning, however, disclosed the fact of very singular symptoms having set in; the arm was much swollen, and had a dark purplish hue, much resembling the colour of bullock's liver, the punctures nearly invisible, and the whole region of the operation presenting the appearance of having been bitten by some venomous reptile. Remedies were applied, but the patient rapidly grew worse; other Professional advice was necessary, and Dr. Bridge, of Argyll-place, Mr. Tatum, of St. George's Hospital, and Dr. MacKenna, of Great Marlborough-street, attended; but the symptoms entirely baffled their skill and experience, and the patient died at midnight of the 18th, of (as agreed by the gentlemen named) phlegmonous erysipelas. It should also be mentioned that I discovered afterwards that the patient had been vaccinated in or about 1833, and prostration almost bordering upon death was the consequence.

From this, the difficult question arises as to the prudence and necessity of re-vaccination in adults: many conflicting opinions have been and will doubtless continue to be, expressed upon this subject, it is with a view of strengthening the matter for argument either way that I have been induced to forward you the particulars of so remarkable a case.

I am, &c. J. W. WELLS,

Assistant-Surgeon of many years' Practice.

32, Great Marlborough-street.

A MEETING of the Fellows of the College of Surgeons will be held in Lincoln's-Inn-Fields, on Thursday, the 2nd day of July next, at two o'clock in the afternoon precisely, for the election of three Fellows into the Council of the College, in the room of Mr. Cæsar Henry Hawkins and Mr. Thomas Tatum, going out in rotation, and of Mr. William Coulson, resigned.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 12, 1863.

Mr. PARTRIDGE, President, in the Chair.

A PAPER, by J. NEWTON HEALE, M.D., was read on

## THE PHYSIOLOGICAL ANATOMY OF THE LUNGS.

The following points in connexion with the physiological anatomy of the lungs have been elicited as the result of investigations made by the author:—First. As regards the pleura. Certain longitudinal channels are to be found in it. These are pervious to air, and are connected with the minutest air-passages in the substance of the lungs by means of tubular passages in the subpleural cellular tissue. They are surrounded by a vascular plexus, derived from the pulmonary system of blood-vessels. Second. As relates to the manner in which the air is distributed throughout the lungs. A remarkable difference is to be noticed in what is ordinarily called the bifurcation of the trachea as it exists in the human subject contrasted with that of other mammalia. In the latter a large trunk is given off from the windpipe before it reaches the spot which is usually called its bifurcation. This trunk goes to the upper part of the right lung. The left bronchus is therefore in those animals the second alternate branch which proceeds from the main air-pipe. Each bronchial tube, instead of splitting up equally into lesser tubes, and thereby forming a dichotomous or a trichotomous division, passes towards the margins of the lobes in a continuous direction, though diminishing in size. It gives off its branches in an alternate manner, and each of the subordinate tubes pursues a similar course. When they have arrived at a certain degree of diminution, a set of membranous tubes, differing in some respects from the bronchial tubes, and also from the air-cells, but being intermediate in character between the two, are sent off from the terminal bronchial tubes. To these membranous tubes the author attaches the name of pedicles. The true pulmonary tissue is quite distinct in its anatomical peculiarities from those of the bronchial tubes, however small these may be. It does not at all resemble them, and they cannot be mistaken the one for the other. The ultimate parenchyma of the lungs is made up of little bodies, to which the author attaches the name of "leaflets." The pedicles connect the terminal bronchial tubes with the leaflets; and many pedicles from different terminal tubes enter each leaflet. This peculiarity in the leaflets causes a very minute anastomosis to take place between the different terminal bronchial tubes, which could not occur if the ordinary description were correct. Third. The author does not profess to have contributed any fresh facts relating to the lymphatics or to the nerves as to their purely anatomical characters. Fourth. With reference to the characters and functions of the so-called bronchial arteries. The author prefers to give the name of sustinent arteries and veins to the blood-vessels usually denominated bronchial. He considers that the latter word implies that they have some peculiar relation to the bronchial tubes, and more especially to the bronchial membrane, which is a destination usually attributed to them. They have in consequence been supposed to be the vessels peculiarly engaged in the pathological condition known as bronchitis. The author's investigations show that every sort of vascular action throughout every part of the lungs, by which any damage to its tissue is remedied, is accomplished through the sustinent vessels exclusively, although the peculiar plexus by which the whole of the mucous surface is covered, and by which the bronchial mucous is supplied, is not in any degree contributed by the so-called bronchial arteries. Physiologically and anatomically, the sustinent and pulmonary systems are quite distinct. While the duty of repairing the tissue of every part of the lungs devolves upon the sustinent vessels, that of bringing the venous blood furnished by the right side of the heart into contact with the air, and of accomplishing the physiological purposes which are aimed at by that arrangement, is intrusted solely to the pulmonary vessels. The purpose for which the vascular plexus is spread out in the mucous membrane is entirely connected with the atmospheric influences, and the large surface which

that membrane affords for the furtherance of that object is thus turned to account, and the plexus itself is consequently in exclusive relation with the pulmonary system of blood-vessels. Modern authors, with the exception of Dr. Harrison, of Dublin, concur in believing that there is some kind of anastomosis between the minute branches of the pulmonary and the sustinent vessels. That gentleman, with great truthfulness and candour, acknowledges that he has not been able to satisfy himself that the presumed anastomosis has not been the result of the rupture of one or both sets of vessels in the act of injecting them. The author of this paper has found that the vasa vasorum of the pulmonary vessels are supplied entirely by the sustinent arteries; and that when the latter have been fully distended, and some degree of violence has afterwards been used, the minute capillaries in connexion with the sustinent arteries which are spread over the interior of the walls of the larger pulmonary vessels have sometimes been made to burst, and a false communication into the canal of one of the pulmonary vessels has thus been made. A channel for the injection having been once established by an accident of this nature, it becomes gradually enlarged in proportion as the injection is afterwards made to flow through the rent, and an unlimited quantity of injection may then be made to flow through the artificial passage. The pulmonary and sustinent vessels cannot be made to communicate with one another by any other means than this. It has been a disputed point as to whether the so-called bronchial arteries are furnished with veins. It is, however, easily shown that sustinent veins accompany the bronchial tubes, returning the residual blood supplied by the sustinent arteries to the internal parts of the lungs; and that other sustinent veins ramify in the subpleural tissue, which collect the blood from the exterior of those organs. Attention is called to the fact that the sustinent veins are furnished with valves, and with cross branches of anastomosis. These last facts are of some importance, not with regard to the lungs only, but also with reference to the blood-vessels, which discharge in other viscera a function similar to that of the sustinent arteries. Fifth. As relates to the distribution of the pulmonary vessels. Modern authors describe the pulmonary arteries as accompanying the bronchial tubes; as continuing to divide again and again, becoming more numerous than the tubes; as giving off branches of supply to the various tissues; as anastomosing with the so-called bronchial arteries; and their residue as being ultimately distributed to the air-cells. The author considers this account to be far from accurate. He finds that the pulmonary arteries never give off branches of supply to any tissue. They never form any anastomosis either among themselves or with any other blood-vessel. They do not become more numerous than the bronchial tubes, since each of these is accompanied by one, and never more than one, pulmonary artery, which pursues in relation to it a perfectly definite and invariable course; and the final distribution of every portion of the pulmonary artery, down to the minutest fragment, is precisely and entirely alike. The whole of it is split up so as to form the remarkable anastomosing plexus in the leaflets. The pulmonary veins commence in the interior of the leaflets by tufts of capillaries. The veins formed from these commencements are placed, in the first instance, at some distance from the bronchial tubes; but as they increase in size they come into contact with them. A remarkably vascular plexus, composed exclusively of pulmonary vessels, occupies the whole surface of the mucous membrane. This is derived as an offshoot from the plexus in the leaflets, and is reinforced in the larger tubes by blood-vessels furnished from the leaflets which cling to the tubes externally, and send perforating branches to the plexus in the membrane. Some ramasculi are also placed externally to the tubes. They collect the blood from the plexus in the membrane, and convey it to the larger pulmonary veins, the formation of which has been described above. There are, therefore, in the first instance, two distinct sets of minute pulmonary veins. One of these, after leaving the leaflets, makes its way at once in a direction towards the left auricle, without undergoing any further exposure to the air. The other is spread over the mucous membrane, and derives the benefit of the atmospheric influence which the surface of that membrane affords, and ultimately joins the other portion. The anatomical distribution of the pulmonary vessels indisputably proves that their physiological function is exclusively in relation with the air supplied by the bronchial tubes, and that it is totally independent of any purpose having relation to the construction or repair of any part of the tissue of the lungs.

(The paper was accompanied by numerous drawings and diagrams.)

Dr. HEALE, at the request of the President, drew attention to the apparatus which he employed. He showed that in injecting the pulmonary arteries and veins with different colours both should be injected simultaneously, so that the two fluids should meet in the capillaries. If the arteries by themselves were injected first, the fluid passing through the capillaries into the larger vessels beyond would prevent the proper injection afterwards of the veins, and *vice versa*. He showed that no anastomosis existed between the so-called bronchial vessels and those of the pulmonary system, as the capillaries of the first could be injected in every part of the lungs without any of the injection reaching any of the other vessels. In speaking of the distribution of the air to the tissue of the lungs, he mentioned that a very free anastomosis was established between the air contained in different parts of the lungs after the bronchial tubes had reached their minutest subdivision. Dr. Heale gives the name of pedicles to the smallest of the bronchial tubes, and that of leaflets to the ultimate subdivisions of the pulmonary tissue. He showed that there was a complex inoculation between different leaflets and pedicles. The equal diffusion of air throughout the lungs is further provided for by tubular passages which ramify in the sub-pleural and interlobular cellular tissue, and communicate with longitudinal channels in the substance of the pleura. Passing to the physiological points involved in the various anatomical details, he remarked that it was usual to speak of respiration as one thing, of circulation as another, and of nutrition as a third; but that in point of fact all three were parts of one and the same physiological operation, and that it was as impossible that the circulation or the nutrition should go on independently of the respiratory processes as that the hands of a watch should continue to point the hour when the mainspring was impeded in its action. Dr. Heale then explained at some length his views with regard to the heart's action in effecting the circulation of the blood, the physiology of respiration, etc.

Dr. LEE said that he did not come into the room until a considerable part of the paper had been read, and he could not tell whether any allusion had been made in it to the nervous structure of the lungs. He requested the author to state whether or not this was the case.

Dr. HEALE replied that he had seen the nerves floating when dissecting the lungs in some fluid. He imagined they followed the course of the bronchial arteries.

Dr. LEE then begged to be informed whether there was any dissection on the table showing the nervous structure of the lungs, and (the author having replied that he had not on the present occasion made any dissections with the immediate object of demonstrating the course or distribution of the nerves) proceeded to say that he had been engaged during the last two years in dissecting the ganglia and nerves of the lungs, and that in these dissections a great system of ganglia and nerves was displayed throughout the lungs; and he considered that without taking into account these nervous structures of the lungs the functions of those organs could not be explained. Dr. Lee finally added that he would not now intrude upon the time of the Society by giving a description of his own dissections.

Dr. DICKINSON gave a description of

A FŒTUS BORN WITHOUT HEART, BRAIN, LUNGS, OR LIVER.

This being, like all others of the same character, was a twin. Both umbilical cords were attached to a single elongated placenta. The imperfect fœtus was devoid of any vestige of head or neck. The upper extremities were present, but were in some respects imperfect. On the anterior surface was a small prominence, which appeared to represent the tip of the tongue. The umbilical cord was surrounded at its fœtal extremity by a small membranous bag, which contained a coil of intestine. The lower extremities were only slightly different from their usual state. The body was generally swollen and œdematous. The spinal column was deficient from the second cervical vertebra upwards. No trace of any cranial bones could be discovered. The clavicles were absent. The integuments were of unusual thickness, owing to a general infiltration of serous fluid. In the cavity of the trunk lay the lower two feet of the intestine, which commenced by a cæcal extremity, and two large kidneys. The ureters, the bladder, the urachus, and a pair of undescended testicles were found in their normal relations. The other viscera were absent. The umbilical

cord contained a large vein and artery. The artery divided on entering the belly into two large branches, one of which passed into the right thigh and side of the pelvis. The other division served for all the rest of the body. It swept upwards to the position due to the aorta on the left side of the spine, and gave off vessels for the left thigh, for the left side of the pelvis, and for the kidneys. It terminated between the shoulders by dividing abruptly into two large branches, which went to each upper extremity. The veins were arranged in an almost parallel manner. There was no communication between the two sets of vessels corresponding to the foramen ovale. The entire encephalon and the upper part of the spinal cord were wanting. The sympathetic ganglia were large, but not numerous. A chain of eight lay along the side of the vertebral column. Numerous filaments maintained the connexion between the sympathetic ganglia and the spinal nerves. Since there was no communication between the veins and arteries of the fœtus answering to the foramen ovale, but the veins throughout the body were simply continuous with the umbilical vein, and the arteries with the umbilical artery, it was inferred that either in the cord or in the body of the monstrosity the usual direction of the blood must have been inverted. If it passed, as usual, from the mother down the umbilical vein, then it must have been continued into the tissues by the veins of the fœtus. On the other hand, if the course of the circulation was not thus reversed in the fœtus, the artery of the cord must have brought the supply from the placenta. This question was discussed, and the author finally adopted a suggestion of the late Dr. Young, which had been worked out by Sir Astley Cooper, that the circulation in such monstrosities is due to the impulse of the heart of the healthy fœtus, which always accompanies them, and which is conveyed through anastomosing vessels between the two cords upon the surface of the common placenta. The blood thus reaches the imperfect fœtus through its umbilical artery, and is thence distributed to its tissues.

Mr. SAVORY said cases like the one just related were especially interesting with regard to the forces concerned in the circulation of the blood. He believed it was now generally accepted that the heart was not the sole agent in the movement of the blood. Of the other forces employed, that which was generated at the capillaries was assuredly not the least. But cases like the present one confirmed this doctrine; for in this, as in some others, especially the case recorded by Houston, it seemed almost impossible, after a careful study of their anatomy, to arrive at the conclusion that the heart of the healthy child was sufficient to maintain, not only its own circulation but that of the monster also. These cases, he thought, might be profitably studied by the light of comparative physiology. Just as in the lower vertebrata—as in fishes—where the small and single ventricle seemed manifestly insufficient to accomplish unaided the circulation through the capillaries of gills and system; just as in some of the lowest of the invertebrata, where, as in plants, the movement is maintained without a heart of any kind, so in these monstrous forms among the highest we must more clearly recognise, in the absence of a heart, the existence of independent forces to circulate the blood.

Dr. LEE said that there was a placenta on the table, all the arteries and veins of which had been injected, and there were two umbilical cords seen passing into this placenta. It was a case of twins, and instead of there being one placenta for each child, as usually occurs, there was here only one for both fœtuses; but the circulation in these two fœtuses was not different from the ordinary circulation. Two umbilical arteries went from each child to the placenta, and conveyed the blood to it, and one umbilical vein returned to each fœtus and carried the blood back. By looking at the fœtal side of the placenta, it would be seen that there were large injected arteries and veins passing between the vessels of both umbilical cords, but the circulation was not altered in consequence. It was a mere anastomosis of the arteries and veins of the two cords in the placenta. The blood of the four umbilical arteries must have circulated through the placenta and returned to the two fœtuses by the umbilical veins, afterwards to circulate through the liver, heart, and other organs in the ordinary manner. The action of the heart of one of these fœtuses could have no influence upon the circulation in the other. The placenta of the malformed fœtus described by Dr. Dickinson was unfortunately not preserved, and hence no one could tell whether there was a placenta connected with the living and another with the malformed fœtus; but it was well

known that in most of these cases of malformation there had not been found a placenta connected with the malformed fœtus, but that the cord had passed into the placenta of the other child. However that might have been, the circulation must have gone on in this placenta as in the one which lay on the table; and it was impossible to believe that the action of the heart of the healthy fœtus could have forced the blood back along the umbilical arteries of the malformed fœtus, and inverted the circulation in the manner first suggested by Dr. Young, and adopted by Sir B. Brodie, Sir A. Cooper, and other physiologists. Dr. Lee then added that he had examined the fœtus described by Dr. Dickinson in its recent state, and found the umbilical vein passing into the abdomen in the usual manner; but there being no liver, heart, nor lungs, the umbilical vein greatly enlarged, proceeded to the upper extremities and kidneys, from which he believed the blood passed into a vessel corresponding with the abdominal aorta, which divided and entered the cord as the umbilical arteries do usually. He (Dr. Lee) thought it impossible to believe that the fœtal circulation was carried on solely by the action of the heart. Both ventricles united to send the blood to the placenta; but the blood, after it had circulated through the capillaries of the placenta, could not return to the liver by the action of the heart; and it was obvious that the great circulation through the fœtal liver could not be referred to the action of the heart, but to the vessels themselves. In all probability the absence of the placenta in Dr. Dickinson's case, if it was wanting, was merely a part of the malformation of the fœtus.

Dr. HEALE called attention to the fact that there must be some force acting on the circulation in the capillaries distinct from that of the heart's pulsation in order to remedy after each pulsation the distension of the blood-vessels, which would otherwise remain in a state of maximum distension, and be unable to yield any longer to the ensuing pulsation. This force, which emptied the capillaries, must be quite as real and important as that which distended them. The changes which occurred during these intervals were precisely those for which the pulsation was calculated to furnish the materials, and they embraced all the strictly vital operations which occurred both in the pulmonary capillaries and in the system at large, and the two balanced each other with the greatest exactness. For, supposing it possible (which it is not) that one or the other should preponderate, the blood would immediately become either too arterial or too venous, as the case might be—a state of things which would necessarily be corrected in the very next pulsation. The heart's action therefore became auxiliary to the action of the capillaries. The placenta of the fœtus accomplished for it precisely what the lungs did for the adult. The difficulty of explaining how the circulation might have been carried on in the acardiac fœtus was materially lessened by these considerations.

Dr. DICKINSON, in reply to the remarks of Mr. Savory, allowed the possible existence of a force which promoted the circulation of the blood independently of the action of the heart. In vegetables the circulation was carried on by this alone; but the higher in the animal scale, the more active the circulation and the more necessary the heart. It could not be supposed that in the human fœtus the circulation could be maintained without this organ. It was almost proved that the circulation depended on the heart of the other twin by the fact that in every case of acardiac monstrosity not only was the monster a twin, but it was attached to the same placenta as served for the other child. If the circulation depended on forces within its own body, there could be no reason why it should not be carried on without this connection. As to the objections of Dr. Lee, that the currents of blood in the cord could not be inverted, Dr. Dickinson stated that, from the fact that there was no communication between the arterial and venous systems in the fœtus, it followed that the circulation must be inverted either in the cord or in the body of the monster. With a healthy child, the blood flowed to it along the umbilical vein, which blood eventually got into the left ventricle, and so was distributed by the aorta and its branches. In the monstrosity where no foramen ovale existed, if the blood passed to its body by the umbilical vein, it must have been carried into the tissues by the veins. Thus in the body the blood must have gone contrary to the usual direction. On the other hand, if the blood was distributed by the arteries after the usual manner, it was evident that it must have been brought from the placenta by the artery of the cord which

was in direct continuation with them. In this case the circulation in the cord must have been inverted. In any case it was necessary to allow the inversion either in the cord or in the body.

## THE PATHOLOGICAL SOCIETY.

TUESDAY, MAY 19.

Mr. PRESCOTT HEWETT, President, in the Chair.

Mr. SPENCER WELLS exhibited

### EIGHT OVARIAN TUMOURS REMOVED BY OVARIOTOMY.

The first was removed from a single woman, 36 years of age, on March 2. One cyst had held thirty six pints of fluid, and a large semi-solid adherent mass was also removed. The patient perfectly recovered. The second was removed on March 9, from a single lady, 29 years of age, who also recovered, though a very large tumour had been adherent. Teeth and hair had grown from the inner membrane of some of the small cysts. The third was a comparatively small cyst, weighing with its contents only seventeen pounds. It was removed on March 16, from a single woman, 36 years of age, who recovered perfectly. The fourth patient had died four weeks after operation of pelvic abscess and secondary pleurisy. She was a single lady, 26 years of age, and the pedicle was so short that it had been necessary to remove the clamp the day after operation. Mr. Wells thought this case another strong argument in favour of keeping the end of the pedicle outside the abdomen. The fifth was a small growth, like a cauliflower, from the right ovary, which had been surrounded by a large quantity of ascitic fluid. It was removed from a married woman, 29 years of age, on March 25. She died fifty-four hours after operation, of a low form of diffuse peritonitis. There had been no pedicle, but the right spermatic vessels had been tied, the ligature cut off short, left inside, and the wound closed, after the plan recommended by Dr. Tyler Smith. Mr. Wells illustrated this specimen by another taken after death from a woman 70 years of age, who had been treated for ascites, but who had a similar cauliflower growth from the inner surface of a ruptured ovarian cyst. The sixth patient had left the Hospital the day before the meeting. She was 61 years of age, the oldest patient upon whom Mr. Wells had operated. There had been very firm adhesions, and one to a long loop of intestine. The seventh cyst was nearly unilocular. It had been free from adhesions, and was removed on April 22, from a single girl, 19 years of age, who was now convalescent, although she had suffered a severe attack of bronchitis a few days after operation. The eighth patient was married, 37 years of age, and was going on well, though still suffering from debility and flatulent distension of stomach and intestines. The operation was performed on April 29, and very extensive adhesions to parietes and intestines had been separated. Mr. Wells added that he had presented every ovarian cyst or tumour which he had removed to the Society; and, in accordance with his annual custom, he now gave the result of all the cases upon which he had operated since the previous session of the Society. At the last meeting of the previous session, in May, 1862, he had operated on 36 patients. Since that meeting he had operated on 27 others, of whom 23 had recovered and 4 died, making a total of 63 cases, with a result of 20 deaths and 43 recoveries.

Mr. SPENCER WELLS also exhibited a

### FIBRO-CYSTIC TUMOUR OF THE UTERUS,

which he had removed by gastrotomy on April 30, from a single lady, 53 years of age. It was a pedunculated outgrowth from the right side of the fundus of the uterus, consisting of a solid fibroid mass, which weighed 16 lbs. 9 ozs., and of a large cyst, which had held twenty-six pints of fluid and four pounds of lumpy masses of decomposed fibrin. There had been no important adhesions, and the tumour had been removed with nearly as much ease as an ovarian tumour, but the patient sank from shock four hours after operation. One ovary—the right—was attached to the tumour; the left was connected with the uterus.

The PRESIDENT said that a somewhat similar tumour had been exhibited at a former meeting of the Society, which had been removed in the belief that it was ovarian. There was a specimen in the College of Surgeons of a similar tumour. One cyst, which had held some fifteen pints of fluid, had been

tapped three times, and it was not till after death that it was discovered to be uterine. He was not aware of any means by which the diagnosis between cystic tumours of the ovary and of the uterus could be established with certainty.

Mr. SPENCER WELLS also presented the parts removed after the performance of

#### GASTROTOMY FOR INTUS-SUSCEPTION.

The symptoms of intus-susception had commenced on April 10 in a child four months old. Purgatives had been given by a druggist, but Mr. Jay, of Park-street, was consulted on the 13th, and recognised the true nature of the case. Mr. Wells was called in by Mr. Jay, and efforts were made to overcome the obstruction by the injection of water, insufflation of air, and the use of a sponge probang, but without any good effect, although the involuted portion of intestine could be reached by the finger passed into the rectum. Gastrotomy was then proposed, but the consent of the parents was withheld until the night of the 14th. By that time the child was almost in a dying state, but it was thought right to try the slender chance of gastrotomy. Mr. Wells opened the abdomen in the median line, just below the umbilicus, by an incision two inches long. The obstructed portion of intestine was at once felt, and easily withdrawn; but it was so tightly jammed into the colon and rectum—or rather the cæcum and ascending and transverse colon were so closely involved by the descending colon—that they were only separated with great difficulty. Still, the reduction was accomplished, the intestines returned, and the wound closed. The intestines above the seat of obstruction being greatly distended by flatus, and a few needle punctures were made in them before they were replaced. The child continued to sink, and died five hours after operation. Mr. Wells added, that the fact of the possibility of withdrawing an involuted portion of intestine being thus established, it might be hoped that the operation would be successful if performed early enough, especially on patients of a less tender age.

Dr. Fox exhibited for Dr. WYATT a specimen of

#### ANEURISM OF THE DESCENDING AORTA.

The chief symptoms during life were cough, dyspnoea, and consolidation of the whole of the left lung. The pulse was quick, but the heart's sounds were normal. The patient died suddenly from hæmorrhage. An aneurism of the descending aorta was found. It had opened into the left bronchus, and hence the fatal hæmorrhage. The bronchial tubes were full of blood, and the lung was quite solid.

Mr. SYDNEY JONES then showed the

#### SKULL-CAP OF A PATIENT WHO HAD BEEN TREPHINED TWICE.

A man, 29 years of age, had a lacerated scalp-wound on May 29, 1861. There was considerable loss of blood, and he was therefore taken to the Hospital. There was a wound on the right side of the head, and the periosteum was exposed for about the extent of a shilling. It was not detached. He did well for ten days, but on the eleventh he began to be feverish, and on the fifteenth had two distinct rigors. On the eighteenth tinnitus aurium, convulsive fits, and intolerance of light. His motions were passed involuntarily. He was trephined at 1 p.m. over the parietal bone, and pus was found between the bone and the dura mater. He was relieved, but on the 19th and two following days he had many fits, and then no more until the 28th. At that date a puffy swelling was noticed over the occiput. The patient was again trephined in this position, and pus found between the bone and the dura mater. He again improved, but six days later, *i.e.*, on the thirty-fourth or thirty-fifth day, he had pain in the left thigh, and an abscess was found there. He died on the forty-ninth day. At the autopsy, except at the thigh, no secondary deposits were found.

In reply to the President, Mr. JONES said that there was no pus in the arachnoid cavity.

The PRESIDENT said the case was a very rare one. He had never seen a case in which pus was between the bone and dura mater only. This was just the kind of case on which Pott dwelt so much, and which was now-a-days so seldom met with.

Mr. SYDNEY JONES exhibited

#### CYSTICERCUS REMOVED FROM THE LIP.

It was situated deeply in the muscular substance of the lip.

Mr. SYDNEY JONES exhibited a

#### FOREIGN BODY WHICH HAD BEEN IN THE PALM OF THE HAND SEVERAL MONTHS.

A gentleman ten months ago lacerated the palmar surface of

the thumb. The wound healed in a month, and remained healed four months; and then a sinus formed, and again healed; and for the third time reopened. Mr. Jones succeeded in removing from the palm a small piece of stick, part of a walking stick.

Mr. SYDNEY JONES next showed a

#### TUMOUR REMOVED FROM THE ORBIT.

A man, 48 years of age, noticed, three months after a blow, a small tumour above the tendo oculi. It grew at first slowly, and then rapidly. There was no obstruction to the flow of tears, but, as the tumour was growing rapidly, it was removed. It was connected with the periosteum, and a piece of the ethmoid was removed with it. The tumour on section exuded a creamy fluid, which contained a large number of nuclei.

Dr. BRISTOWE exhibited a specimen of

#### INTESTINE (?) PASSED PER ANUM.

It was passed by a patient who had obstinate constipation with vomiting. Dr. Bristowe was not able to give a clear account of the case, and he was not quite certain that it was intestine. It was about the calibre of the intestine, and yet there were no villi, no follicles, and no muscular fibres. It was very much decomposed.

Dr. HARLEY, who was appointed to report on the specimen, said that sometimes hysterical women would swallow pieces of the intestine of some animal.

Mr. HULKE presented a specimen of

#### POLYPOID OUTGROWTHS FROM THE INNER SURFACE OF THE LARGE INTESTINE.

Some were simple rounded eminences, others pedunculated bodies, varying from a quarter to one inch in length, with a simple globose, or lobed extremity. Most were single, but some, by the union of their apices to those of neighbouring polypi, formed a loose net. The longest occurred just below the sigmoid flexure of the colon. They were thickly scattered over the entire surface, from near the ileo-cæcal valve to within three inches of the anus, where there was the depressed scar of a former ulcer. A couple of thin membranous folds penetrated with apertures of various sizes, occurred at the sides of the scar, and furnished the clue to the origin of the nets. The patient from whom the preparation was taken had laboured under chronic dysentery. Microscopical examination showed that the polypoid bodies were simple outgrowths of the mucous and sub-mucous tissues, and not cancerous.

Dr. SANDERSON showed a specimen of

#### FIBROUS TUMOUR SURROUNDING THE LEFT URETER.

The patient was admitted for ascites depending on cirrhosis of the liver. There were no symptoms referable to the kidney or ureter.

Dr. SANDERSON also showed a specimen of

#### COMMUNICATION BETWEEN THE ASCENDING DUODENUM AND THE TRANSVERSE COLON.

A man, thirty years of age, had had epigastric pain and vomiting fifteen days. He vomited several pints of a watery pulsatious fluid, never feculent. He had several such attacks before. There was a pouch communicating with the lower part of the duodenum and with the transverse colon; the latter was guarded by a valvular aperture.

Professor CZERMAK showed

#### PORTIONS OF EPITHELIAL GROWTHS FROM THE LARYNX,

which he had removed by means of simple curved forceps on several occasions from a young man, aged 25, who suddenly lost his voice in 1860. He likewise exhibited drawings illustrating the appearance of the larynx when the disease was first diagnosed, its progress and extension to the epiglottis, and other parts. Under the microscope their structure was found to be wholly composed of epithelial cells.

Dr. GIBB said the Society was much indebted to Professor Czermak for bringing forward this interesting case, as it was an illustration of so large an amount of disease. He (Dr. Gibb) had succeeded in the removal of growths from the larynx on several occasions, and in nearly all their structure was epithelial, with the presence of minute fibres, and nothing malignant about them.

Dr. GIBB exhibited the

#### LARYNX OF A CHILD AFFECTED WITH DIPHTHERIA.

It had been sent to him by Dr. Davies, of Putney. She was ten years old, and each tonsil when first examined was covered with a diphtheritic patch. She was progressing favourably,

but was suddenly seized with symptoms threatening suffocation. Tracheotomy was performed with great relief, but she gradually sank six hours after in a semi-comatose state. The lungs were a little congested, the trachea and bronchi highly injected, but no diphtheritic membrane beyond the larynx. The epiglottis seemed especially affected.

Dr. GIBB showed diagrams of the larynx from a case of

TOTAL LOSS OF THE EPIGLOTTIS, WITH APHONIA FROM ULCERATION OF THE LARYNX AND PHARYNX.

In October, 1862, a lady had been ill with sore-throat for twelve months, and aphonia for six. She had no cough nor chest symptoms. She could swallow fluid but not solid food. Her throat was at times painful, with a pricking sensation on the right side of the fauces. She was very nervous, and expectorated a quart of mucus in the twenty-four hours. Large and deep ulcers were present at the back and other parts of the pharynx. The epiglottis was wholly destroyed. The interior of the larynx was red, œdematous, and irregularly prominent; the colour and shape of the vocal cords could not be recognised. Ulcers were seen on the aryteno-epiglottic folds, but the arytenoid cartilages were intact. There was no feeling of suffocation at any time—a noteworthy fact. Under local and constitutional treatment the ulcers healed, the swelling diminished, and the voice gradually returned, and she has remained well, although without an epiglottis.

DESTRUCTION OF THE EPIGLOTTIS, ARYTENO-EPIGLOTTIDEAN FOLDS, ARYTENOID CARTILAGES AND VOCAL CORDS, WITH INCURABLE APHONIA.

This was one of the worst cases that had ever come under Dr. Gibb's observation, for the laryngoscope showed the most fearful ravages. The uvula was almost gone, the soft palate was, for the most part, adherent to the wall of the pharynx. The epiglottis was wholly gone, and the aryteno-epiglottic folds were mostly destroyed, their remains being transformed into fleshy tubercles surrounding a narrow crescentiform glottis. The arytenoid cartilages were destroyed, as also were the vocal cords. Everywhere evidences of great destruction of tissue were visible. There was incurable aphonia, and a constant noisy inspiration. The patient could only swallow pultaceous food. Some months afterwards he died from bronchitis, to attacks of which he had been frequently subject.

## MEDICAL NEWS.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, EDINBURGH.—DOUBLE QUALIFICATION.**—The following gentlemen passed their First Professional Examinations during the recent sittings of the Examiners :—

Robert Lawson Tait, Mid-Lothian; Thomas J. Denton, Yorkshire; Henry L. James, Derbyshire; James S. Mathews, Edinburgh; Valentine Stone, Newark-on-Trent; Robert Sheils, Edinburgh; Richard Cranke, Ulverstone; Andrew Brown, Biggar; Thomas Sheriff, Northumberland; William G. Stevens, Ardrossau; William Tindal, Montrose; John Allen, Malta.

And the following gentlemen passed their Final Examinations, and were admitted L.R.C.P. Edin. and L.R.C.S. Edin. :—

Wynne Staton Ranson, India; John Aston Hill, London; William Wright Milligan, Dumfriesshire; Malcolm Brodie, Lochgilphead; Charles MacDouagh, Dublin; William Coutts, Aberdeenshire.

**ROYAL COLLEGE OF SURGEONS, EDINBURGH.**—The following gentlemen passed their First Professional Examinations during the sittings of the Examiners :—

Archibald B. Telford, Motherwell; Robert Mackelvie, Wigtonshire; Angus Macdonald, Aberdeen; Bernard Doyle, County Down; John Thomson, Morayshire; Geo. H. Turnbull, Roxburghshire; Robert Gunn, Caithness; William Skene, Helensburgh; Robert B. Thomson, Fochabers; G. Rankine White, New York; William James Dickson, Auchtermuchty; William H. Semple, Stranraer.

And the following gentlemen passed their Final Examinations, and obtained the Diploma of the College :—

William Henry Cecil Tessier, London; Robert M'Rinnell Duncan, Dumfries; William Walker, Ayrshire; Samuel Gourley, Shannon; Robert Potter, County Limerick; James Barry, County Cork; James Bourke, County Limerick; Walter Reid, Fife; Peter Murray Braidwood, Madras; William Jeffrey, Berwickshire; John Brown, Haddington; Alexander Ingram Spence, Edinburgh; Roderick Macleod, Inverness-shire; John Charles, Lasswade; Alexander Montgomerie Bell, Edinburgh.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, May 21, 1863 :—

Joseph James Ideson, Colne, Lancashire; Robert Lloyd Jordison, South Ockendon, Essex; Fred. Henry Alderson, Ipswich; Benjamin Maurice, Redlands, near Bristol; Marwood Sanderson, Rochester-street, Vincent-square; Joseph Needham Scrope Shrapnel, Ventnor, Isle of Wight.

### APPOINTMENTS.

\* \* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BURNIE, THOMAS, L.R.C.P. Edin., has been appointed Junior Resident Surgeon to the Birmingham General Dispensary.

CHATER, SIDNEY, M.R.C.S. Eng., has been appointed Surgeon to the Metropolitan Dispensary, Fore-street, Cripplegate.

CLARKE, W. FAIRLIE, M.A., M.R.C.S. Eng., has been elected Surgeon to the St. George's and St. James's Dispensary.

COE, ROBERT W., F.R.C.S. Eng., has been re-elected Surgeon to the Bristol General Hospital.

COWELL, GEORGE, M.R.C.S. Eng., has been appointed Medical Officer to the Royal Pimlico Dispensary.

FREEMAN, JOHN HENRY, M.R.C.S. Eng., has been elected Medical Officer of Health for the Parish of St. George-in-the-East.

HASLEWOOD, JOHN A., M.R.C.S. Eng., has been elected House-Surgeon to the Morpeth Dispensary.

KEMP, CHARLES G., M.R.C.S. Eng., has been appointed Dentist to the Leicester Infirmary.

KING, HENRY, L.R.C.P. Edin., has been appointed Surgeon to the Brideswell Dispensary District in the Athlone Union.

PURVIS, J. P., M.R.C.S. Eng., has been appointed Surgeon to the West Herts Infirmary, Hemel Hempstead.

ROBERTS, W. R., M.R.C.S. Eng., has been appointed House-Surgeon to the Birmingham and Midland Free Hospital for Sick Children.

WIGLESWORTH, ARTHUR, M.R.C.S.E., was appointed Honorary Surgeon to St. Ann's Dispensary and Eye and Ear Institution, Liverpool.

WILLIAMS, ARTHUR WYNN, M.D. St. And., has been elected Physician-Accoucheur to the St. George's and St. James's Dispensary.

### DEATHS.

FRAME, ARTHUR J., M.D., at Grenada, West Indies.

GARRARD, STAMP, M.R.C.S. Eng., at Atherstone, Warwickshire, on May 19.

GIBSON, THOMAS, L.S.A., House-Surgeon to the Dispensary, Morpeth, Northumberland, on March 12.

GRAY, WILLIAM, L.R.C.S. Edin., of Kinross, at Pardovan, Linlithgowshire, on May 12.

HANNA, WILLIAM, L.R.C.S. Edin., at Mill-street, Belfast, on May 22.

KEITH, J., M.D., at Wemyss-place, Edinburgh, on May 12, aged 79.

MCNAB, WILLIAM, M.R.C.S. Eng., at Ware, Herts, on May 23, aged 81.

ROWE, JOHN, in practice prior to 1815, at Cornwall-street, Plymouth, on May 16, aged 84.

ROWIZOTTE, G. A., at Brompton, S. W., on May 16, aged 53.

TYLER, HENRY WILLIAM, Surgeon in H.M. Indian Army, at Hampstead, on May 25, aged 44.

WALKER, THOMAS OSBORNE, Sen., at Crick, Northamptonshire, on May 10, aged 80.

MR. H. LEE's lectures and operations on Mondays at the Lock Hospital have been discontinued.

**THE ROYAL VICTORIA HOSPITAL.**—The following General Order has been issued in reference to the Queen's late visit to the Netley Hospital :—"General Order, No. 825, Horse Guards, S.W., May 14, 1863. His Royal Highness the Field Marshal Commanding in Chief has received the Queen's commands to express the satisfaction Her Majesty derived from her visit to the Royal Victoria Hospital at Netley on the 8th inst., when Her Majesty was highly pleased to observe how carefully and amply the comfort and requisite attendance upon the sick soldiers were provided for. Her Majesty was particularly gratified by the order, cleanliness, and regularity that pervaded the establishment throughout. By command. (Signed) J. Yorke Scarlett, Adjutant-General."

**THE ELECTION OF PENSIONERS AND FOUNDATION SCHOLARS AT THE ROYAL MEDICAL BENEVOLENT COLLEGE.**

—At the election, which took place on May 21, the following were the successful candidates :—*Pensioners*—Mary Mutlow, 10,461 votes; Stratford Alfred Eyre, 9611; Harriet Sawyer, 7943; Grace Pidcock, 6956; Rebecca Scott, 5259. *Foundation Scholars*—George Henry Heald, 6550 votes; Francis George Wride, 6495; Matthew Lee Smith, 6417; Francis Beauchamp Johnson, 4679; Thomas G. F. R. Hobbes, 4395.

\* \* \* We have been requested by Mr. Eyre to return his most grateful thanks to those gentlemen and ladies who aided him with their votes and influence.—Ed.

CAMBRIDGE, MAY 16.—The following elections took place this day at Downing College:—1. To Foundation Scholarships: Norman Maccoll, Christ's College; Charles Thinger Questel, Sidney College; John Henry Robson, St. John's College,—to Scholarships of £50 per annum for three years, with rooms and commons; John Buckley Bradbury, (a) Caius College, to a Scholarship of £50 per annum for three years. 2. To minor Scholarships: Kimm, Schroeder, to Scholarships of £40 per annum for two years.

ACCIDENTAL POISONING AT BRADFORD.—During the past week several persons named Johnson, living at Bradford, exhibited symptoms of arsenical poisoning. Dr. Lodge, who was called to see them, found that all had been taking a mixture of cream of tartar and magnesia as a medicine. On analysis, the cream of tartar was found to contain arsenic, and the poison was also detected in the vomited matters. The poisoned drug was finally traced to the shop of a chemist named Potter. The Professional gentlemen who, in addition to Dr. Lodge and his assistant, Mr. Lee, have been engaged in treating and investigating the cases of poisoning, and making the chemical examinations, are Dr. Macturk, Dr. Brown, Dr. Goyder, and Mr. F. M. Rimmington, analytical chemist.

LARGE DOSES OF DIGITALIS IN DELIRIUM TREMENS.—Dr. William Bowman relates an interesting case of delirium tremens in which he administered large doses of digitalis. Two and a-half ounces of the tincture, made according to the London Pharmacopœia, from very fine digitalis leaves, were administered in half-ounce doses in the course of eleven and a-half hours. "The case, although a very severe one, was unaccompanied by any preternatural heat of the head. The first dose lowered the pulse (which was originally 80) permanently eight beats, but it was again raised by the second. The second, third, and fourth doses had no effect upon the number of the beats, but rendered them irregular at times. The fifth dose, however, brought down the pulse at once to 48, at which it remained most of the time for several days, producing no ill effects whatever, and merely rendering the patient languid." Mr. Bowman prefaces the narrative of this case with some interesting observations upon the experience of other Practitioners with this drug.—*Canada Lancet*, No. 2.

DEATH OF MR. THOMAS HILL, MEDICAL BOOKSELLER.—Mr. Thomas Hill, after very severe trials of life, died at the age of eighty-three on Monday, May 25, at the residence of his tried and faithful friend, Mrs. Hester Tadloo, of No. 47, Gerrard-street, Soho. In recording the death of Mr. Hill, we shall bring to remembrance a name known to most of the senior members of our Profession. Mr. Hill was partner with the late Mr. Burgess; this firm was long established in Great Windmill-street, and for many years carried on a large business. Mr. Hill was unassuming and obliging in his manners, and had secured the regard of many friends; but he had outlived nearly all who had known him in better days, so that he had to endure much poverty in his last years. The contemporary firms known to our fathers were—Burgess and Hill, Callow and Wilson, Cox and Son, Samuel Highly, and Thomas and George Underwood. Mr. John Wilson died last year. With Mr. Hill's death is lost the last link connecting the names of the Medical booksellers of the last with those of the present generation.

TRANSMISSION OF SYPHILIS BY VACCINATION.—Much interest has been excited in Paris by a case read before the Academy by M. Dévergie, purporting to be an example of transmission of syphilis by the vaccine virus in a boy fifteen years of age, who, seven months previously while a patient for pleurisy, had been vaccinated in the St. Eugénie Hospital. At the end of the seventh month he presented himself at the St. Louis with syphilitic tuberculous disease of the skin. Unfortunately nothing is known of the boy during the seven months which intervened, nor of his parents, nor of the other children who were vaccinated on the same day with the same virus. Inquiries have, however, been set on foot respecting these matters, and the results will be hereafter communicated to the Academy. In the meantime M. Ricord announced to the Academy that the great number of facts of this kind now published had overcome his scepticism, and that he was now a believer in the transmission of syphilis by vaccination. He comes to the conclusion with great regret, for he is unable to see what guarantee we can have of virus being taken from

children not infected by syphilis, the symptoms of which may be only subsequently exhibited. M. Depaul regarded M. Ricord's fears with regard to healthy vaccine virus as exaggerated, although he has long been a believer in the possibility of the transmission of syphilis by it. But after all, this is a very exceptional occurrence, and among the many thousands of infants vaccinated at the Academy it has never once been met with—the children whence the virus is derived being, however, carefully selected. M. Depaul also is of opinion that an infant, the subject of syphilis, almost always exhibits signs of it from the period of its birth. This statement M. Ricord stated his thirty years' experience qualified him to deny, the symptoms always appearing at a more or less remote period from birth, and in this opinion MM. Cloquet and Dévergie entirely concurred.

SARACINEA PURPUREA IN SMALL-POX.—The following result of a trial of the *Saracinea* has been communicated to the *Times* by Mr. Cosmo G. Logie, Surgeon-Major Royal Horse Guards (Blue). Eleven men of Mr. Logie's regiment which is stationed at Windsor, contracted the disease. After expressing his disbelief in the perfect protecting power of vaccination, he writes:—"Some time ago, seeing a paper written by Assistant-Surgeon Miles, of the Royal Artillery, on the efficacy of the North American plant called the *saracinea purpurea*, or pitcher-plant, in the treatment of small-pox among the Indians, my colleague (Mr. Agnis) and myself have given this remedy, which has been imported into this country by Dr. Miles to the house of Messrs. Savory and Moore, a fair trial, and I am happy to say the eleven cases in our hands have recovered under its peculiar influence. This remedy I consider a boon to the public, for this reason—it is so easily managed; any one can make a decoction or infusion of the root like tea. An ounce of the root is sliced and infused in a quart of water, and allowed to simmer down to a pint, and given in two table-spoonful doses every four hours, while the patient is well nourished with beef-tea and arrowroot. Four of the cases in my Hospital have been severe confluent cases; they have throughout the disease all been perfectly sensible, have had excellent appetites, been free from pain, and have never felt weak. The effects of this medicine, which I have carefully watched, seemed to arrest the development of the pustules, killing, as it were, the virus from within, thereby changing the character of the disease and doing away with the cause of pitting, and thus avoiding the necessity of gutta serena and india-rubber applications, or of opening the pustules. In my opinion, all anticipations of disfigurement from pitting may now be calmed, if this medicine is given from the commencement of the disease. Before leaving this subject, I may here caution the public that the useful part of the plant is its root, as recommended by Dr. Miles, and it can only be obtained from Messrs. Savory and Moore, to whose house alone it has been imported. With the usual kindness of Dr. Gibson, the Director-General, I have been amply supplied with it for the use of my regiment. So much am I impressed with the efficacy of it in small-pox over the old mode of treatment, that I hope to hear of it in every country gentleman's medicine chest, and before long that we shall see no more faces as described by Dickens, like the interior surfaces of sliced muffins."

MEDICAL CERTIFICATES OF DEATHS.—At a meeting of the Medico-Chirurgical Society of Glasgow, held on the 12th inst., the following petition to Parliament was agreed to:—"Unto the Honourable the Commons of Great Britain and Ireland, in Parliament assembled; the petition of the members of the Glasgow Medico-Chirurgical Society humbly sheweth, —That your petitioners are legally qualified members of the Medical Profession, and practise in Glasgow and the larger towns of the west of Scotland. That your petitioners suffer under a serious grievance, inasmuch as they are required, under the Births, Deaths, and Marriages (Scotland) Act, to render gratuitously certain very important Professional services of much value to the public, and that under heavy penalties. That while your petitioners recognise the important public benefits which the Act is calculated to confer, and are therefore willing to place their services at the disposal of the authorities, they feel that the requiring of gratuitous Professional services under a penalty is opposed to the spirit of all British law, and places the Medical Profession in Scotland in a degraded and invidious position. That your petitioners request the attention of your honourable House to the

(a) For proficiency in the Natural Sciences.

fact that their co-practitioners in England are exempted from the oppressive operation of such an enactment, in as far as penalties are concerned; and further, that it was found expedient to abstain from introducing any penal clause into the Births and Deaths (Ireland) Act, which has just passed both Houses of Parliament and received the Royal assent. May it therefore please your honourable House to take your petitioners' case into consideration, repeal the penal clause referred to, and thus place your petitioners on the same footing as their co-Practitioners in England and Ireland, and your petitioners, as in duty bound, will ever pray.—Wm. Lyon, M.D., Fellow of the Faculty of Physicians and Surgeons, and President of the Medico-Chirurgical Society. Signed at a meeting, and for behoof, of the Medico-Chirurgical Society, held in the hall of the Faculty of Physicians and Surgeons.—Glasgow, May 12, 1863."

ROYAL COLLEGE OF SURGEONS IN IRELAND.—INAUGURATION OF THE ALBERT HALL.—It was some time since determined by the President and Council of the Royal College of Surgeons in Ireland to place in their new Examination Hall, which has recently been beautifully decorated in the Italian style of art, a bust of his late Royal Highness the Prince Consort, obtained from the Queen's sculptor by the direct permission of Her Majesty; and to confer upon the room the name of the "Albert Hall." His Excellency the Lord Lieutenant, through whose kindness Her Majesty's sanction had been obtained, having graciously consented to inaugurate the Hall, Thursday, the 21st inst., was fixed for the ceremonial. At half-past four on that day the Council assembled in their robes, and shortly before five His Excellency arrived at the College, and was received by the President, Dr. Mackesy, of Waterford, who conducted him to the Hall. Among those already assembled in the Hall were the Lord Mayor, the Lord Chancellor, the Lord Justice of Appeal, the President and Vice-President of the College of Physicians, and a large number of the Fellows and Licentiates of the College of Surgeons. The Lord Lieutenant having taken his seat, the President—Dr. Mackesy—read an address, in the course of which he explained the object of the meeting, and briefly alluded to the history of the College. In concluding, he requested his Excellency to inaugurate the bust of his late Royal Highness the Prince Consort, and to name the Hall the "Albert Hall." The bust having been uncovered, His Excellency the Lord Lieutenant spoke as follows:—"In proceeding to fulfil the high and pleasing duty which, in the name of the Royal College of Surgeons in Ireland, I have undertaken to perform, while I acknowledge in passing the courteous terms of the address directed to myself personally, I consider it a very great privilege to be associated in any work or function with a body so eminent, so useful, and so honoured as your own. The services which your College has rendered to suffering humanity are already counted by scores of years, and will soon be counted by centuries. You have adverted with just pride to the ever-widening circle that the extent of our dominions continually throws open to the healing and humanising influences which radiate from this centre, and which, far from being confined to merely physical benefits, salutary and even sublime as these are, tell largely upon the intellectual vigour and moral health of the nation. It is in entire harmony with the essential character and purpose of such a society and such a mission that you have resolved to perpetuate within these walls the lineaments, and to give this hall the name of our late beloved and lamented Prince Consort. For with that name and memory are inseparably blended all things most bright and pure, and just, and true—a pity most sensitively awake to the wants and sufferings of his kind—a courage so firmly poised that there was no error which it was not ready to meet with steadfast gaze, no truth for which it would not have braved the world—a purity in which his features were moulded, and his life was steeped. Let this be named the 'Albert Hall.'" His Excellency then left the Hall, and, after a brief inspection of the College, took leave of the President and Council. It is an interesting fact that the original petition of the "principal Surgeons of Dublin," praying for the foundation of the "Royal College of Surgeons in Ireland," was presented, in the year 1781, to "His Excellency Frederick Earl of Carlisle, Lord Lieutenant General and General Governor of Ireland," the grandfather of the present popular and justly-esteemed viceroy. Thus after the lapse of nearly a century the grandson, who is ever ready to lend the influence of his high station to advance the interests of

literature and science, and to promote the welfare of the people over whom he rules, is found cherishing the institution commenced under the auspices of his ancestor. The petition alluded to, and the counter-petition of the corporation of Barber Surgeons are reproduced *in extenso* in Vol. VIII. of the *Dublin Quarterly Journal of Medical Science*, pp. 236, *et seq.*

PRESENTATION OF A TESTIMONIAL TO DR. GEORGE BUDD.—On Saturday last a testimonial, consisting of a massive silver candelabrum with three branches and movable top to receive a flower-vase, was presented to Dr. George Budd, upon the occasion of his retirement from the chair of Medicine, by a number of his old pupils. A numerous-attended meeting was held in the great hall of King's College, the Rev. the Principal being in the chair, and most of the staff of the Hospital being present. Dr. Lavies, in presenting the gift, said that "the meeting was assembled to tell Dr. Budd some of the thoughts which pressed on them when, after a long and patient career as Professor of the principles of Medicine in the College and of its practice in the Hospital, he was about to seek in partial retirement the rest to which he was so justly entitled. Nearly a quarter of a century had passed since he accepted the chair, and during that time hundreds of men had listened to his lectures and Hospital teaching, and hundreds had passed into practice in various parts of the world. What they thought of him was eloquently told by the offering made that day, and expressed individually by the numerous letters received from various quarters, and which would form part of the testimonial. The meeting had to think of Dr. Budd in four characters—Lecturer, Hospital Teacher, Consulting Practitioner, and Friend. Dr. Watson had predicted the success of his lectures, and all must admit that it had been a real pleasure to enter his class. His agreeable manner, eloquence, and earnestness, would be remembered by all. In the Hospital he was always most attentive to the students, taking deep interest in all who were willing to learn, while his own acumen and discernment, and his excellent clinical lectures, were the admiration of all. They could never meet Dr. Budd at the bedside without pleasure and instruction to themselves, and advantage to their patients. As a friend, all would own that their relation to him had been softened and beautified by his kind and conciliatory manner; a friendly word and cheerful smile for all. An attentive ear for every trouble, affectionate and paternal advice whenever it was sought, he was one well entitled to be called 'the student's friend.' And it was the same with his relations outside those walls; as no word of unkindness, still less of malice, ever escaped his lips, so were such words never directed against him. He had not a single enemy; loving his fellow-men, he was beloved by all." Dr. Lavies concluded with these words: "I trust I have not exceeded the bounds of delicacy in speaking of you thus, my dear Dr. Budd, in your presence. This latter portion of my theme is one on which I love to dwell; for I am sure that I only speak the sentiments of those I represent when I say that, greatly as we appreciate your unquestioned talent, we feel that you shine most brightly and conspicuously in your character as a sincere, simple-hearted friend—as a Christian gentleman. If I have said too much, forgive me. Let me only add, that it is our sincere hope that your future life may be as happy as that which is past has been useful; and let me assure you that you will carry with you into your retirement the hearty goodwill and the grateful regard of all those who have had the good fortune to be numbered among your pupils. I am certain that nothing could add to your pleasure in receiving this simple assurance, but as we desire to give you some tangible and visible evidence of our regard, we beg your acceptance of the piece of plate upon the table before you,

'Parvum non parvæ dignus amicitiaë,'

a small pledge, indeed, but bearing no relation whatever in its size to the large and affectionate friendship which prompts us to offer it." Dr. Lavies then concluded a most able and eloquent address, by bidding Dr. Budd, "as a teacher in the lecture-room and in the Hospital, respectfully, gratefully, and affectionately, farewell." When the cheering which followed had subsided, Dr. Budd, who was evidently much affected, rose and replied, that "It was impossible for him to describe what he felt. It was very gratifying to feel that the services of so many years had been so warmly recognised; but he was at a loss to express his high appreciation of the kindness of his old pupils, as shown by the magnificent testimonial with which they had just presented him. He remarked upon

the gratifying evidence of sympathy shown by the presence upon the occasion of many who had come from great distances, and, doubtless, at considerable inconvenience to witness the presentation. He briefly sketched the rise and progress of King's College Hospital during the quarter of a century which had almost elapsed since first he became connected with the Institution, and showed how, from the old workhouse of St. Clement Danes the present noble building had gradually grown up to confer immeasurable benefit upon the suffering poor, and to fill a most important place in the education of the Medical Profession. The Profession, he remarked, had made great advances during this period, socially, as evidenced by the improved position and education of its members, and scientifically, as shown by the great improvements which year by year had marked its progress. He had had personally no small reason to note this latter fact, from the difficulty he had found in making his lectures upon Medicine keep pace with the rapid advancement of science. He had found wherever he went King's College men occupying prominent positions, and testifying, in this way, to the high standard of education which the College had helped to raise; and it was a source of gratification to him, in resigning the chair of Medicine, to know that it would be ably filled by one who had done so much to improve our knowledge of the pathology of the kidney, and was besides, himself a King's College man—Dr. George Johnson. He begged to thank his old pupils warmly and affectionately for their kind appreciation of his efforts as a teacher, and for the expressions of personal attachment which were even still more gratifying to him. A vote of thanks to the principal was then proposed by Dr. George Johnson, and seconded by Dr. Miller, and the proceedings, which had been of a highly interesting character, then terminated. In addition to the candelabrum, an elegant blotting-book and envelope case were presented to Mrs. Budd.

**PERMANGANATE OF POTASH AS A DISINFECTANT.**—Dr. Ploss speaks in the highest terms of the disinfecting power of this substance. It effectually removes all smell from the most stinking suppurating sores and discharges. Most remarkable results of this kind have followed its injection, repeated several times a-day, in cases of cancer of the uterus—half a drachm to 8 oz. of distilled water being a good proportion. In the case of open wounds and ulcers, all the dressings covering them should be moistened with the solution. No means succeeds more rapidly than this in removing the disagreeable smell of the hands after the performance of autopsies, for which purpose a stronger solution (ʒss ad ʒj.) may be employed. It is far superior to chlorine in its effects, which are not, as is the case with that substance, fugitive. For this reason it is a superior prophylactic, applied to the hands of accoucheurs, to chlorine in puerperal fever. In ozæna it is strongly to be recommended, the solution (ʒss ad ʒviii.) being introduced into the nares by means of a caoutchouc syphon. In bad smells of the mouth, resulting from carious teeth, it is an admirable means, a little cotton wool being moistened in a weak solution. Finally, the permanganate is to be recommended as a wash for stinking feet. This remedy deeply stains linen it comes in contact with, but the spots may be removed by means of the sulphate of iron.—*Varges' Zeitschrift*, N. S., vol. i., p. 187.

**THE INDUCTION OF PREMATURE LABOUR BY MEANS OF NITRATE OF SILVER.**—Prof. Giordano, of Turin, states that premature labour may be much more effectually induced by the application of solid nitrate of silver to the cervix uteri than by any other mode. Having introduced it within the cervix, he imparts to it repeated, but slight, rotatory movements, so that most of the surface may undergo the process of cauterisation. While most of the other procedures are difficult, inoperative, or even sometimes dangerous, this one is of the most easy execution, is prompt and complete in its results, and is followed by no ill consequences. A case is narrated in which cauterisation was performed, on account of deformed pelvis, at 9 a.m. of the one day, and the fœtus was expelled at 8 a.m. the next day, the placenta following in an hour afterwards.—*Omodei's Annali*, vol. clxxxii., p. 407.

### BOOKS RECEIVED.

- The Physical, Moral, and Intellectual Condition of the Deaf and Dumb. By James Hawkins. London: Longman and Co. 1863.  
British Journal of Dental Science, May, 1863. London: John Churchill and Sons.

### NOTES, QUERIES, AND REPLIES.

*He that questioneth much shall learn much.*—Bacon.

*Subscriber and Constant Reader.*—Yes.

*M. R. C. S.*—We think not. Certainly not all.

*Dissatisfied.*—The Star or the Briton Assurance Companies.

*Ωμεγα.*—We believe so, provided that the member of the College is a registered Practitioner, and dispenses his own medicines.

*Tympanum* should communicate his name and address in confidence, as an action may be pending.

*P. R.*—We never recommend Practitioners. Apply to the Physician or Surgeon of highest character with whom you are acquainted.

*Mr. Edwin E. Day.*—Dr. Barnes' paper on the Induction of Premature Labour will be found in the Third Volume of the *Obstetrical Transactions*, p. 107.

Through inadvertence, the name of Mr. Liddle was omitted as the contributor of the Local Report on Small-pox in Whitechapel in our last Number.

We believe it to be for the public interest that the office of public vaccinator should be in few hands, so that each vaccinator may have a good number of patients. Thus he will keep up a good succession of healthy vaccine lymph from healthy children, and will not be driven to resort to dried matter, nor yet be tempted to use that from amrs which display imperfect or irritable vesicles.

*Vivisection.*—Sensible people, when they have had their say, hold their tongues; others have a gift of absurd reiteration. The Royal Society for Preventing Cruelty to Animals is of the latter category; a few preachers, fanatics, sentimentalists, and doctors out of work make speeches year after year about vivisection, and bring a respectable cause into discredit by their exaggeration.

*The Hotel Dieu of Montreal.*—The first number of the *Canada Lancet*,—if, as its editor, Dr. W. E. Bowman, asserts, one of the smallest Medical periodicals in existence, certainly not the least promising,—contains the following account of the origin of the Hotel Dieu, at Montreal, a Hospital now containing upwards of 200 patients, independent of those in the private wards, besides 30 old men, 30 old women, 43 boys and 25 girls not under Medical treatment:—

"The Hotel Dieu Hospital of this city owes its existence to a few gentlemen, who, in 1640, incorporated under the name of 'Société de Notre Dame de Montréal,' obtained the cession of the Island of Montreal from M. de Lauzon, intendant of Dauphiné, in France, who had himself received it on condition of establishing a colony, but who could not induce persons to emigrate thither. On the 18th of May, 1642, these gentlemen, a Mdlle. Mance, with a few hardy men, prepared to act as soldiers, or in any capacity which circumstances might require, cast anchor at Pointe à Callières, opposite to where the Royal Insurance buildings now stand. The Iroquois—the most audacious among Indian tribes—soon manifested impatience at their presence, and kept up incessant warfare. The colonists were unable to gather fuel, fruit, berries, or roots, without running the risk of being killed or wounded by the wily savages, who were ever lying in wait for them. In 1644, the first Hotel Dieu was constructed, on the site it afterwards occupied for upwards of 217 years, near what was afterwards called Little St. Joseph-street, on the north-east side of the Catholic cathedral. The original building was of wood, 24 x 60 feet, and consisted of a kitchen, a room for Mdlle. Mance, another for the servants, and two for the sick. No sooner was it completed, than it was filled with wounded, for the Iroquois still kept up their incessant raids. A short time after its construction, the funds were exhausted; but Mdlle. Bullion, who had already contributed 20,000 francs from her purse, added 60,000 livres more, on condition the poor should be received and cared for without charge. But even these funds were insufficient, and the exhausted state of the exchequer, and still more the small number to which the ceaseless activity of the Iroquois had now reduced the colonists, determined the latter to return to France. The energy of Mdlle. Mance, however, deterred them. She visited her native country, and returned to the colony with men and means. In 1650, the Hurons, most of whom had been Christianised, were completely exterminated by the more warlike Iroquois. The latter, from recent successes, now became still more insolent, destroyed the houses erected around the Hospital, and murdered the inmates. The history of the Hotel Dieu for many years subsequently is one of continued trials, dangers, and alarms. But now and again an Iroquois, wounded and captured in his attempt to murder, would be carried into the Hospital, his wounds dressed, and when restored to health dismissed with kindness, to tell his wondering comrades what the pale-faced women had done for him—how they had watched by and prayed to the Great Spirit for him—how they had carried food to his lips when he was hungry, and moistened them when parched with fever. And in this way Christianity, baptised in blood, was insensibly introduced among them."

#### SMALL-POX IN THE HOLBORN DISTRICT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the Local Report on Small-pox for the Holborn district, which appeared in your last impression, there is an error which I desire to correct. In saying that the district is never free from this disease, I give the average number of deaths for the six years ending Lady-day, 1862, as five and six-tenths (5'6), not fifty-six, as printed. The former mortality is the correct one, and is itself sufficiently discreditable in a population of only 46,317.  
I am, &c.

3, Finsbury-square, E.C., May 27. SEPTIMUS GIBBON, M.D.

#### A "DIETETIC DEPÔT."

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—We beg to inform you we have established the "Dietetic Depôt"

for the purpose of supplying invalids with any articles of food they may be ordered to take by their Medical attendants, and intend supplying nothing that is not thoroughly genuine. We pledge ourselves to make up any Jellies, soups, broths, or any other food strictly according to the wishes of the Medical gentleman ordering them.

We are, &c.

G. VAN ABBOTT AND Co.

Dietetic Depot, 5, Princes-street, Cavendish-square,  
London, W., May 21.

COMIC SONG IN RIDICULE OF VACCINATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Now that small-pox and vaccination are in everybody's mouth, I send you a copy of an old comic song, which was given me by my friend Hector Arney, Esq., and which well represents the fanatical prejudices of sixty years since, when "cow-pock inoculation" was accused as the cause of all sorts of heathy diseases and propensities. I hope it may amuse your readers as much as it has

37, Hertford-street, W., May 24, 1863.

R. DRUITT.

"The Marvellous Physicians; or, the Blessings of Cow-Pock Inoculation.

"Tune—'Down, derry down.'

"Three Physicians of Loudon for Yorkshire set out,  
Where an earl's noble stomach was storm'd by the gout;  
And to guard the good Peer from all future assault  
They physick'd him into his family vault.

With a down, down, hey derry down.

"Well paid by his heir, they departed for town,  
Saying, 'We'll travel up since my lord travels down;  
But at Newark we'll sup, where let each down his throttle  
Pour a large dose of Port without shaking the bottle.'

Derry down, etc.

"At their inn three roast fowls Dr. Calomel chose,  
Which fat Dr. Fingerfee didn't oppose:  
'And,' cried Dr. Isaacs (tho' he was a Jew),  
'Pray garnish dem fowls wid a sausage or two.'

Derry down, etc.

"Tho' the wine was as thick as the three Doctors' heads,  
They had three pints a-piece, and then called for their beds;  
Molly chambermaid stared when, with looks mighty grand,  
Dr. Calomel bid her pull off his right hand.

Derry down, etc.

"When Calomel's hand was pull'd off and put by,  
Dr. Fingerfee growl'd, 'Hussey, take out my eye;'  
Dr. Isaacs, more mild, said, 'Wrap dese up in towels,  
And mind you don't lose dem, my love, dey're my bowels.'

Derry down, etc.

"In the pantry the chambermaid stow'd all these articles  
Of the three learned Doctors, profound in cathartics;  
But a hound, whilst they slept, and ne'er dreamed of the matter,  
Swallow'd up all their property out of the platter.

Derry down, etc.

"Cried the maid the next morning, 'I've lost through magicians  
A hand and an eye of two Christian Physicians;  
Then the wizen Jew Doctor, as thiu as a lizard,  
How he'll grumble in all he has left that's his gizzard.'

Derry down, etc.

"But invention arrived in the midst of her crosses,  
And bade her repair, not lament o'er her losses;  
'A blind thief hangs,' says she, 'on the gibbet hard by,  
I'll go cut off his hand—but then how get an eye?'

Derry down, etc.

"By chance a tom cat had expired in the night,  
And his eye served for Fingerfee's lost orb of sight;  
Then a hog had been butchered, a porker well grown,  
Whose chitterlings Jews might mistake for their own.

Derry down, etc.

"Dr. Calomel rose—in this farce the first actor—  
And put on the hand of the blind malefactor;  
Dr. Fingerfee next drew his purse from his pocket,  
Tipp'd Molly, and popp'd the cat's eye in his socket.

Derry down, etc.

"Isaac stow'd the intestines, and all left the inn,  
'I've cheated two Christians,' said Moll with a grin;  
'And how mad the Jew Doctor would be should he know  
That half his inside is hog's liver and crow.'

Derry down, etc.

"Dr. Calomel muttered, 'I can't understand  
Since we came from the North what ails my right hand;  
Not content with its fees, as I walk thro' the street  
It dives into all the folks' pockets I meet.'

Derry down, etc.

"'My disorder,' said Fingerfee, 'claims more remark,  
For I ne'er can close my left eye in the dark;  
So wakeful I've grown, that this morning at four  
I sprang out of bed at a mouse on the floor.'

Derry down, etc.

"Dr. Isaacs exclaimed, in a pitiful note,  
'Dear broders, you see how I've dirtied mine coat;  
'Tis a wonderful thing, but I can't pass a slough  
Till I've roll'd myself in it, just like an old sow.'

Derry down, etc.

"Now, success to the learned of famed Warwick-lane,  
Their profession far be it from me to profane;  
I shall hurt no Physicians, I trust, in the nation,  
By a laugh at such methods of In-o-cu-lation.

With a down, down, hey derry down."

IN-O-CU-LATION.

VACCINO-SYPHILITIC INOCULATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your last Number contained a communication from Mr. Carter, of Stroud, recording what he considers an instance of constitutional syphilis

communicated by vaccination. If such a thing does ever occur, which I, for one, have grave doubts of, I do not think Mr. Carter's case need be construed as an instance in point. One short sentence in that gentleman's communication explains to my mind the whole mystery. He writes—"The syphilitic one is the eldest." Is not this perfectly consistent with what we know of the history of transmitted syphilis?

One of the parents, in all probability the father, contracts primary syphilis; he afterwards marries, and the first of his offspring bears the brunt of the disease inherited from the affected parent. I grant it is exceptional for the succeeding children to show no trace of cachexia; but I think I can point out instances of the same thing occurring in which the disease has been undeniably hereditary. The first child appears to manifest the symptoms of the poison inherited in a very concentrated form, and the succeeding progeny, if showing it at all, do so in a very mitigated degree, so mitigated, indeed, as to be easily forgotten by the parents, and not to be recognised by Medical eyes at the age of ten years.

The worst instances of inherited syphilis are unquestionably those in which both parents have laboured under the primary disease, and in these I have usually found that two or three of the first pregnancies occurring after, have terminated in abortions, then the first living child has manifested the cachexia very strongly, and succeeding ones in a diminishing ratio. Where but one parent has transmitted the disease, one or two children are, as a rule, all that evince the characteristic symptoms.

I am, &c.

Nottingham.

SAMUEL D. HINE, M.R.C.S. Eng.

TIN VESSELS DESTROY THE FLAVOUR OF COFFEE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I read in your Journal of April 25 an interesting letter by Dr. Drutt on Beer v. Coffee, and that gentleman appears to be of opinion that, if good coffee could be procured by the working classes, it would be attended with beneficial results.

I am aware of the difficulty which there is in procuring good coffee, but I believe much depends upon the metallic vessel in which the coffee is made. For my own use I am accustomed to make coffee, by infusion, in a white metal silvered coffee-pot; but a few months since I happened to discover that when coffee was made, either by boiling or infusing, in a tin vessel, i.e., iron coated with tin (block tin), the flavour of the coffee was completely destroyed, and its colour changed from the natural to a dirty opaque colour, having a most disgusting taste.

In order to remove all suspicion, I procured coffee myself from several different shops, both with and without chicory, and at various prices. Having carefully examined two vessels, I made the coffee by gently boiling for a few minutes in one vessel, and infusing another portion in the other, when the flavour and the colours of the coffee were destroyed precisely the same as when it was made by my servant. The tin vessel in which the coffee was boiled was nearly new, having scarcely any appearance of rust in the interior, but the tin vessel which was used for infusing the coffee had been in use some years previously, and had more of the tin worn off, though it was quite clean. I afterwards procured a new enamelled iron saucepan, and boiled several samples of coffee in it without finding any impairment of the liquid coffee; and, lastly, the experiment was tried in a copper vessel, tinned in the inside, without causing any alteration in the taste, colour, or flavour of the coffee. I therefore infer that it is the iron, and not the tin itself, that spoils the flavour and appearance of coffee, unless, however, any galvanic action exists between the tin and the iron. The water which I used was that which is supplied to the town by the waterworks.

I am, &c.

Southampton, May 22.

HENRY OSBORN, M.R.C.P. Lond.

TUMULI ON THE COTTESWOLD HILLS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—There are two kinds of tumuli scattered upon the Cotteswold Hills, containing human bones and other remains of man, as flint and bone implements, and bones of animals, the teeth of boars, horses, cattle, and parts of their jaws and other bones. The one set of tumuli are round, formed of loose stones rudely heaped over either lunula remains and flints, with marks of fire cremation or sacrifice, or over a grave built of dry walling, and covered with rough, unhewn stones, like the roof of a house, and containing the remains of several individuals, of both sexes and all ages, from infancy to old age. The tops of the graves are covered with loose stones, collected off the surface of the land, to the depth of a foot or two, and lastly with earth. They have been ploughed over, and cultivated, in some instances, for years, and are called giants' graves, from the large stature of the persons buried there. Sometimes they are found lengthways, with the face towards the rising sun; in other instances doubled up, as if they had been placed in the sitting posture.

In some instances these tumuli are twenty yards across. Although the bones in the graves are not burned, yet the ashes contain the remains of the burning of animal and human bones. The skulls found in the round tumuli present the low development and measurement of those described by Sir C. Lyell and Huxley, and may have belonged to the ancient Celts, or the first migration of human beings to the central part of England, and may be of the same antiquity as the human bones discovered in the caves.

The long and chambered tumuli are not uncommon. They contain chambers communicating with each other like pig's sets, made of very large, flat, unhewn stones, such as are often used for stiles in stone wall countries, and covered over with loose stones. The large stones are sunk a little way in the ground to support the large covering stones, and the spaces between them neatly walled up and packed around with flattened stones to support them, and, lastly, covered over with loose stones. Some of these tumuli are sixty yards long and thirty yards wide, and from seven to fifteen feet high, and contain many chambers, and also stone graves, with burned animal and human bones, pottery, very rudely marked, and teeth of animals, etc.

The human bones belonged to people of ordinary stature, rather above the average height, and the skulls are of superior development, some of them equal to any of the present day, offering a great contrast with those found in the round tumuli. These chambered tumuli may have been the burial places of the optimates, or higher classes, at, and for some time before, the Roman invasion. The shape of the skulls would support the assertion of Julius Cæsar, that the Belgæ were a mixed race of Germans and Celts.

Some difference of opinion having arisen regarding the size and sex of the individual skeletons, the following paper is subjoined to assist others in investigating such interesting subjects:—

*The Characteristics of the Male and Female Skeleton.*—The lower jaw bone, sacrum, pubis, ilium, last lumbar vertebra, the humerus, femur, calcaneum, and astragalus, are the bones which are stated to possess distinctive differences in the male and female skeletons.

Civilisation, residence in large towns, and crossing the races of men, diminish the distinctive characters of the sex, and often obliterate the most prominent marks, which are easily distinguished in purer and more barbarous races. In large towns males often present female characters and females those of the male, and the bones of the one may so approximate in form to those of the other, as to render it extremely difficult to distinguish between them. It has been ascertained that mental culture alters the form of the head. The development thus induced does not enlarge the whole, but only certain parts—as the vault where the intellectual part of the brain is situated—for the circumference of the base of the skull is smaller in civilised man than in the roaming savage, who constantly exercises the organs of sense. And this disproves the assertion that cases of difficult parturition are on the increase among civilised nations, for the base of the brain, which is the most unyielding part of the head, is lessened. Unless deformed by disease, females of large towns suffer less in parturition than the strong and muscular residents of the country; the muscles of the former, being thin and emaciated, offer less impediment to that process than the more developed and stronger ones of the latter.

The lower jaw is larger in the male than in the female, the condyles and coronoid processes are longer and wider; a line drawn from the condyle to the outer angle is nearly vertical. The rami are wider, deeper, and more square; the base is larger, longer, and more curved from its angle to the symphysis; the teeth are larger; the alveolar processes, and the anterior and posterior surfaces are deeper. In the female, a line drawn from the condyle to the posterior angle of the jaw is more oblique; the rami and teeth are smaller, and the base forms a smaller and more acute angle. The lower jaw, and the other bones of the skeleton before puberty, afford no distinctive characters.

Old age, the loss of teeth, and the absorption of the alveolar processes, alter the form of the male jaw, render the line from the condyle to the posterior angle more oblique, and diminish the square and oblong character of its ramus and its depth. The female jaw becomes very shallow and projecting from age and loss of teeth, its anterior surface grows oblique, forming a closer approximation with the nose, or nut-crack chin. The head of the male is larger than the female, the bones are thicker, and the ridges and processes stronger. The face is less oval, and the cause of difference depends upon the size and shape of the lower jaw.

The sacrum is longer, straighter, less curved, and narrower in the male than in the female. But the sacrum deviates from its typical form in different subjects, the other bones of the pelvis are lighter and thinner, and the ala of the ilia are more expanded, their depth is lessened, and the circumference of the brim increased. The articulation with the coccyx is larger and wider, and that with the sacrum rounder. The bones of the leg are shorter, smaller, and more delicately formed in the female than in the male. The femur is more curved, and the length varies from fifteen to seventeen inches; the head is scarcely above the trochanter; a line drawn from the head of the femur to its internal condyle forms a wider space in the female than in the male; between the shaft of the bone and that line the calcaneum and astragalus are smaller in the female. The humerus may be smaller and its circumference less.

The average height of man varies between five feet five inches to five feet eight inches; woman between five feet and five feet three inches. The apex of the trunk in the male is downwards, in the female upwards.

The form of the female skeleton is constructed so as to adapt it for the office of the production of offspring, and to fulfil the social duties thereby imposed, while the male structure shows strength in the large size of the head and body, to enable him to protect and provide for his partner and offspring by mental or physical exertion.

The height of a person may be correctly ascertained by measuring the length of the femur and tibia. A femur seventeen inches may belong to a male and the average height, or to a female above that height. A line drawn from the upper part of the trochanter to the end of the outer condyle indicates about the fourth of the height of the body. A femur fifteen inches long, of delicate structure, small circumference (not exceeding three inches), with the head on a line with the trochanter, or a little above it, a triangular lower jaw, with small teeth, a small calcaneum and astragalus, and fine and delicate-looking vertebrae, would induce one to conclude that they were the remains of a female below the average height. A femur exceeding twenty inches, stout and strongly marked, with a square lower jaw and large teeth, a flat, long sacrum, large calcaneum and astragalus, strongly marked vertebrae, and thick skull bones, would lead to the conclusion that they were the remains of a male skeleton exceeding five feet ten inches in stature, or the average height.

The normal forms of animals are the strongest and most enduring; in uncivilised life the delicate and abnormal perish in infancy. Thus the sexual characters are more strongly marked upon the bones of savages. Civilisation secures a larger number of abnormal formed infants to live to manhood. Such may become active members of society, but their skeletons lose the characters of the sex. The protection of residence, clothing, and food secures greater bulk of body, for the ancient armour of the Tower was found too small for the average sized men of the present day, but perhaps not of symmetry.

Symmetrical and normal forms give activity and power, and enable an individual to undergo fatigue. The savage races surpass the civilised ones in their power of walking and running, suffering cold and hunger, and exposure to weather, which superiority depends upon the strength and power of their symmetrical structure, and it becomes still clearer when such forms are compared with the result of civilisation upon human, and domestication upon animal forms.

Cheltenham, May 18.

HENRY BIRD.

P.S.—The antiquity of the tumuli and their contents may be estimated from two to three thousand years. The care with which they were constructed, the contents, and the presence of burned bones and ashes, may prove that a belief then existed in the Supreme Being, that they offered sacrifices, and believed in the resurrection of the body and the immortality of the soul. The absence of coins, gold, silver, or bronze, may prove that these burial places or elementary pyramids were constructed (the round ones) in the earlier part of the stone period, and the larger and long ones in the latter part of that state of civilisation. The Romans invariably used mortar in their stone buildings; and coins, abundance of pottery, shells of oysters and mussels, teeth of cattle, horns, tessellæ, and carved and worked stones indicate the sight of a Roman villa or town, which are common in the sheltered valleys beneath escarpments, on the hills and the extensive earth-works formed upon most of the tops of those hills which command the valleys and extensive views of the surrounding country.

## ORIGINAL LECTURES.

## A CLINICAL LECTURE

DELIVERED AT

## ST. THOMAS'S HOSPITAL.

By FREDERICK LE GROS CLARK, F.R.C.S.,

Surgeon to the Hospital.

*Deformity of the Foot—Fracture of the Leg—Fracture of the Fore-arm—Injury to the Spine—Fracture of the Skull—Exostosis of the Humerus.*

GENTLEMEN,—The cases (a) which I shall bring under your notice to-day are such as you will frequently meet with in your future practice, and on that account they are deserving of your attention. The record of rare cases of injury or disease has a statistical value; but in relative value to you, as Practitioners, they are inferior to those which you will soon, yourselves, be called on to treat, when you enter on the duties of your Profession.

The first case to which I shall refer is one of very simple character, though often, I believe, misunderstood, and consequently maltreated.

R. F., aged 13, was admitted into the Hospital on November 2, 1862. Two months since he sprained his left foot whilst at play, the sensation at the time being as if something had given way on the inner side of the ankle-joint. When admitted, the foot was very much everted, resting, as he walked, more on the inner than the plantar surface. The internal lateral ligament was much stretched, and the common extensor tendon stood out in bold relief when an attempt was made to invert the foot; the peronei tendons were also thus rendered tense, but in a much less degree. An apparatus was adjusted to the foot and leg, by which, through the medium of a screw movement, the foot could be gradually brought into its normal position. This was worn for about a month, at the end of which time the tension of the muscles was completely overcome, and the foot retained its normal position when at liberty. A boot with an iron support was ordered, and he was directed to wear this for some time, until the deltoid ligament has regained its natural length and power of resistance.

In the foregoing case the deformity was referred to an injury, probably the joint may have been previously feeble, though the other ankle was strong. The tension of the extensor tendon first attracted notice, and seemed to be the active cause of all the mischief; but the history of the case, and a more careful examination, satisfied me that the muscle was only taking advantage of a relaxed ligament, and the proper treatment was to supply the deficient support, and not to deal summarily with the offending tendon. The result proved that this opinion was correct; for the muscles were perfectly amenable to control when sufficiently and properly antagonised. I believe such cases have often been subjected to tenotomy, probably to the permanent enfeebling of the foot. It is very different where the muscles are shortened from tonic spasm; though, I may remark, in these cases patience and careful extension will effect a good deal. But I feel it my duty to warn you against the indiscriminate employment of this simple and tempting operation; for divided tendons do not always unite; indeed, it is questionable whether many do as the rule, and therefore they should not be cut through unless the necessities of the case demand it. The tendo-Achillis shows a greater aptitude for reunion than smaller tendons.

A patient who was the subject of fracture of the tibia and fibula is about to leave the Hospital, and I will briefly relate his case, for the sake of making one or two remarks on the treatment adopted.

J. A., aged 40, a painter, was admitted on December 2, 1862. Whilst at work at a railway station, in stepping from the platform on to the rails, his right foot slipped, and he fell with the leg bent under him, and felt the bone snap before the knee reached the ground. On admission speedily afterwards, the limb was very much swollen, and both bones were broken near their centre, the deformity not being great, although the fracture of the tibia was very oblique, and in a

direction downwards and outwards. The limb was first laid on an outside splint; but as the swelling had further increased on the following day, and there was more displacement, a long back splint was substituted: cold lotion was applied over the leg. The swelling subsided very slowly, and there was great difficulty in keeping the fractured ends of the tibia in position, not so much from one riding over the other as from the tendency of both fragments to bow inwards, thus forming an obtuse angle at the seat of fracture. To obviate this a stout piece of gutta percha was moulded to the inner side of the leg, and under this there was afterwards placed a soft compress, the whole being confined by a bandage firmly applied from the ankle to the knee, the outside splint being still retained as before; this was done after the patient had been under treatment for a fortnight. The effect was entirely satisfactory; the displacement was thus quite controlled; and at the expiration of six weeks, union without deformity was sufficiently complete to place the limb in a gum bandage.

The points of practical interest to which I wish to direct your attention are the swelling of the leg and the means adopted to correct the deformity. Effusion is a necessary consequence of all fractures; but extravasation of blood is usually limited in quantity, and inflammatory or congestive exudation does not come on until after the lapse of some hours at least. Now, in this case the swelling immediately followed the accident, and its amount, at so early a period, satisfied me that it was due to extravasation of blood; indeed, I at first apprehended that some artery had been torn, and ice was for a short time applied. It is important to distinguish between the swelling of extravasated blood and that of transudation; and I believe the above test, as to time, is a sure one. But, again, it is desirable to distinguish between this condition resulting from venous and arterial extravasation. The latter is, in my experience, very rare in simple fracture; indeed it is wonderful, considering the proximity of the arteries to the bones, that it is so rare. In the above case, the tension of the leg was never such as is witnessed in arterial extravasation, and there was no interruption to the arterial circulation; moreover, the patient was not depressed as he would have been from the loss—for such it is—of arterial blood; therefore I concluded that it was general or venous extravasation. Then, as regards the deformity. The fracture was produced in a very usual way, by the indirect agency of the weight of the body, when the limb was placed in a position favouring the injury. The obliquity of the fracture was not in the most usual direction, which is downwards, forwards, and inwards, and thence the character of the displacement. You have often heard me deprecate the employment of pressure to keep a displaced fracture in position. Where relaxation of the muscles or extension fail, it is rarely of any avail, and often positively mischievous, to employ pressure. But the present case was an exceptional one; the displacement was not the usual riding of one fractured end over the other, but the bending inwards of the tibia; and this, as you have seen, was corrected by acting upon its two extremities, as well as upon the protected seat of fracture. If the deformity had been the consequence of one fragment overlapping the other, no good would have resulted from pressure, but probably serious mischief, by producing ulceration at the point of prominence; in this way a simple fracture may be readily converted into a compound one; therefore I say that this practice is applicable only to exceptional cases.

There are few fractures which require more constant attention than those of the fore-arm, especially if the injury be accompanied by contusion or laceration, as in the case I am about to relate.

R. E., aged 69, a carpenter, was admitted on December 4, 1862. He had been knocked down by a cab, the wheel of which passed over his fore-arm; both bones were broken near their centre, and the skin was contused and superficially lacerated; there being also considerable effusion in the neighbourhood. The arm was first laid on a palmar splint, and the wound dressed. At the expiration of a week the ordinary front and back splints, suitably padded, were applied, and kept in position with tapes and buckles. Daily examination was requisite for a time, that the wound might be dressed, and the proper adjustment of the fracture ascertained. At the expiration of six weeks the union seemed firm, the wound was healed, and there was free motion without deformity.

I do not refer to this case as presenting anything remarkable, but to impress upon you the principles upon which these fractures are to be treated. In an especial degree it is requi-

(a) Reported by Messrs. Greaves and Way.

site to remember that muscles act very differently on a broken lever, from that which is their natural action whilst it retains its continuity. In the fore-arm we avail ourselves of the assistance of the interosseous membrane in the treatment of fracture; for the principle of management consists in keeping the bones apart by the adjustment of convex or padded splints, to counteract the tendency of the pronator muscles to approximate them. The comfort of the patient, the repose of other muscles, and the parallel relation of the bones are best consulted by placing the arm in a sling, semiflexed, and with the thumb upwards, for the palmar splint ought to be long enough to support the hand, and thus prevent it from acting by its weight on the lower part of the radius, except where that bone is broken near to the wrist, and then the hand should hang down. The above case occasioned some trouble at first, and exemplified the importance of constant examination to prevent a deformed union. The next case to which I will direct your attention is one of injury of the spine, followed by unusual symptoms.

G. E. F., aged 22, a sailor, was admitted on November 1, 1862. He stated that he had been struck by a cab, and that, in falling, he had seized the revolving wheel, and was thus brought violently to the ground. On admission he was perfectly sensible, said he should soon be "all right," and made no special complaint. A careful examination failed to show any injury beyond a trifling bruise on the leg and a scratch on the face. There was no evidence that the head had been struck, but there was some tenderness on percussion over the upper dorsal region. The only other peculiarity which attracted attention was the character of his breathing, which was a long inspiration succeeded by a rapid expiration. Though the injury seemed but trifling, the House-Surgeon thought it desirable to admit him. Shortly afterwards he vomited his supper. At ten o'clock, being three hours after the accident, he had a fit, resembling epilepsy. There was tetanic spasm of the anterior muscles of the trunk (*emprostotonos*), and of the flexor muscles of the limbs, with a marked depression of the pulse: these symptoms lasted for five minutes, during which time he was unconscious. Through the night these attacks recurred at intervals of from ten minutes to half an hour, and lasted sometimes for a quarter of an hour. By order of the House-Surgeon, the head was shaved and ice applied, and an active purge administered. His pulse continued to sympathise as at first, the circulation being depressed in power, and sinking from 80 to 60, whilst the fits lasted. Towards morning he lay for some time in an insensible state, with the eyes upturned. A careful examination of the head and spine were again made at the morning visit, but no evidence of injury could be detected; the patient was perfectly rational, free from any signs of loss of power or sensibility in the lower limbs, and complaining of nothing but general soreness, the consequence, no doubt, of muscular cramp. On the second night he slept a little, and had no further recurrence of the fits; the bowels were relieved. He still complained of pain on pressure in the upper dorsal region. The treatment was still expectant. From this date he continued to improve, and in the course of a few days was discharged at his own request, free from untoward symptoms, but with a caution to avoid all source of excitement or much exertion for a time.

I have narrated this case more on account of the singularity of the symptoms, than from any practical interest which is attached to it. The injury appears to have been confined to the spine; and the patient had never, according to his own statement and that of his relatives, been subject to fits of any kind before. The concussion of the spine—for as such, I presume, it must be regarded—produced none of the ordinary symptoms accompanying such injury; and the only explanation which the actual symptoms suggest, is that the true spinal centre was the special seat of lesion, and thence the tetanic spasm affecting the trunk and limbs, and constituting so important a feature in the fits. The absence of any violent expiratory effort, and the depressed condition of the pulse, both as regards its strength and frequency, distinguish these attacks from well-marked epilepsy; and there seems no reason to ascribe them to any other exciting cause than the accident. As regards the treatment it was necessarily expectant, and I should not have been at all surprised had more permanent symptoms of injured spinal cord supplanted these intermittent attacks. To keep the patient quiet and on a low diet, to administer a purge and keep his head cool, was all that could be done under

the circumstances. The issue of the case proved that there could have been no organic lesion.

A patient with injury to the skull has recently left the Hospital, on whose case I wish to make a few remarks:—

J. G., aged 17, was admitted on October 31, 1862. Whilst at work he was knocked down by one angle of a falling box of bricks striking him on the forehead. He rallied speedily from the stunning effects of the blow, and was immediately brought to the Hospital. On admission he was quite sensible, though a little drowsy. He complained of no pain in the head; the pulse was natural, as were the eyes, with the exception of some suffusion of the conjunctiva. About two inches above the orbital ridge, and near the centre of the frontal bone, was a horizontal wound of the scalp, from which blood oozed freely; this was about two inches long. On clearing the blood from this wound, the skull was found to be fractured, and a fragment of bone, about half an inch in breadth, and two and a-half inches in length, was driven in and depressed so as to place the outer table on a level with, or even a little beneath, the inner table of the surrounding bone. On more careful examination, some comminution was discovered, and it was also evident that the inner table of the fragment covered a larger area than the outer, being fractured with a squamous or bevelled edge. Pulsation, synchronous with the heart's action, was apparent in the wound as the blood welled up. Head to be shaved, and cold lotion applied. The wound was supported with a strip of plaster. Milk diet. November 1.—He passed a quiet night, with sleep; no pain in the head; slight oozing of blood still; feverish and thirsty; pulse 92; skin hot; eye suffused; bowels relieved by a purgative. He is perfectly sensible and less drowsy. A light poultice to be laid over the wound. 2nd.—Less feverish; no pain in head. 3rd.—Continues free from head symptoms. The pulsations in the wound can still be seen as before. Wound looks healthy. 4th.—General condition good. The depressed piece of bone appears stripped of its periosteum, and white at the bottom of the wound. The raised edges of the circumference of sound bone are sharp and distinct. Pulsations still seen deeply in the right corner of the wound. 5th.—Free from pain; health appears good; functions all healthily performed; discharge from the wound more copious. Diet to be improved. From this time the daily report simply records improvement in health and in the condition of the wound, without the occurrence of any untoward symptom; and after the lapse of about five weeks, a fragment of exfoliated bone, about one inch and a-half long, and about a-third of an inch wide, was removed from the wound, where it was confined only by granulations. It was a thin plate, consisting evidently of the outer table only. The patient was presented, at his own request, with the wound still unhealed, but healthy, and he has since attended from time to time as an out-patient.

The interest of this case is in the existence of so severe an injury with the absence of cerebral symptoms; and this association is suggestive of considerations of practical importance. I may remark that the boy had been previously an inmate of our Hospital with a severe injury of a similar nature, to which the scars on his scalp bore witness. I saw him soon after his admission, having been sent for; and you will remember the speculations as to what I should do, and how I should proceed in elevating the depressed bone; and I believe not a little surprise was felt by some of you that I at once decided not to interfere in any way with it. I then explained to you that the mechanical injury to the bone and its depression were not sufficient to justify such interference, in the absence of any cerebral disturbance, but that it was not improbable symptoms might present themselves which would give a different complexion to the case, and require an operation. As it turned out, no such step was needed, for the dreaded symptoms never made their appearance. The symptomatic fever, as it is termed, which occurred on the following day, was nothing more than the reaction which ushers in the healthy reparative effort, after the infliction of a severe injury with shock. It is that which we look for, and indeed desire, so long as it can be controlled, as it was in this case, by a light diet and free evacuation of the bowels. The important lesson, therefore, to be impressed on you by this case is, that you are to be guided by the cerebral symptoms as to interference in fracture of the skull with depressed bone, and not by the mechanical injury to the bone, and the possible future symptoms to which it may give rise. I do not mean that this remark should be accepted without

exception or reserve. A large fragment of bone may be driven into the brain without producing any apoplectic symptom, as I have often seen; and its relations may be such that, without materially complicating the injury, you may elevate it. In such case it would be right to do so, for its presence in such a position is certain to create mischief sooner or later. But I hold it to be bad practice in cases of limited fracture with depression to anticipate symptoms. In the present instance, if I had done so, I have very little doubt that I should have placed the patient in great jeopardy, for I could not have raised the depressed fragment without seriously enlarging the chasm; and you must remember that the use of the trephine is in itself a serious, I may say dangerous, infliction, and one which all prudent Surgeons would avoid where it is possible to do without it. The risk of sloughing of the dura mater, and consequent tendency to protrusion of the brain, render the statistics of this operation anything but satisfactory.

You may naturally inquire why there were no symptoms of compression of the brain attending this circumscribed depression of bone. The only explanation I can offer is, that there must have been space around the fracture for expansion corresponding to the amount of depression; and this view seems to be confirmed by the distinct pulsation which was visible at the bottom of the wound synchronous with the pulse. I did not think it right to thrust a probe in for the purpose of ascertaining this, and I am therefore unable to say further whether or how far the dura mater was lacerated.

I may, advantageously to you, contrast the foregoing case with one which has been more recently under your notice. This was under the care of my colleague, Mr. Solly, and in many respects his case presented a singular analogy to mine. The patients were of the same age, or nearly so; the accident occurred in a similar way, by the fall of a brick on the head, an angle of the missile striking the vertex, and producing fracture with depression. The patient in like manner recovered soon from the shock. But here the analogy ceases: he became the subject of a severe epileptic seizure soon after his admission, and when I saw him on the following morning he was very dull and drowsy, a condition which was augmenting as time passed on. A large fragment of bone had been driven into the brain, but not to any depth. Under these circumstances, I did not hesitate, when asked, to express my opinion that the depressed fragment should be elevated. This was done, but, unfortunately, the patient did not long survive, as the amount of injury was very great. The dura mater and brain were both found lacerated, and pus was diffused over the surface of the brain for some distance around the wound.

The last case to which I shall direct your attention is one of exostosis of the humerus.

W. D., aged 12, was admitted on December 12, 1862. He stated that he had received a blow on the upper part of the arm about a year since, and from that he dates the swelling. Attached to the inner side of the humerus, and just clear of the axilla, was a hard, immovable, globular tumour, irregular on the surface, and about an inch and a-half in diameter, with a somewhat contracted attachment to the bone. He complained of no pain, except a tingling sensation down to the fingers, when the tumour was struck or pressed on. The brachial artery and basilic vein were stretched over its most prominent part. Having satisfied myself that it was an exostosis, I made an incision about three inches in length parallel to the brachial artery; this, together with the basilic vein, being carefully drawn aside, and a small artery tied and divided, some fibres of the coraco-brachialis muscle were found spread over the morbid growth. When these were cut through the exostosis was exposed, surrounded, as is commonly the case, with a bursal capsule. This being dissected back, and the surrounding parts carefully retracted, the connexion between the growth and the humerus was severed with one sweep of a pair of long and narrow bone forceps. The growth was almost entirely bony, consisting of cancellous structure, with capacious cells, and an investment of thin cartilage. The wound was held together with metallic sutures, and the boy made a good recovery.

This is not a very frequent position for exostosis. The only other case which I have had under my care was one in which the patient, also a boy, was the subject of three or four of these excrescences on the arm, and as many on the femur and tibia. Probably the accidental injury mentioned had nothing to do with the growth, as the blow was received on the outer side of the humerus, and the growth was from the inner side.

## ORIGINAL COMMUNICATIONS.

## ON AN IMPROVED MODE OF USING REFRIGERATION AS AN ANÆSTHETIC AND AS A REMEDY.

By JAMES ARNOTT, M.D.

It is now, I believe, universally admitted that, by the application of intense cold, pain may be certainly prevented in the numerous operations in which the incision is confined to the skin and the superficial textures; and few will dispute that, in these operations at least, its perfect safety gives it a great advantage over ether or chloroform. But the general opinion is, that it is more troublesome to use it than chloroform, and that it is more apt to fail in producing anæsthesia from some oversight or error in the application. This idea has prevented many from employing refrigeration, except in cases where the patients have objected to chloroform, or where there was more than the ordinary risk from its use. In Hospital practice, the longer time occupied in effecting congelation has made chloroform be preferred in almost every case. In consequence of this, many deaths have occurred from the administration of the latter in the most trivial operations—in the extraction of a toe-nail, the opening of an abscess, or the cutting off a wart.

There is nothing singular in this objection, arising from the supposed difficulty or trouble in the use of intense cold. Some of our most valuable remedies have only become generally adopted when the mode of administering them has been simplified. Artificial respiration, galvanism, and several measures resorted to in the treatment of stricture and stone, may be adduced as examples. But the most striking instance of this is found in a therapeutical agent more nearly connected with our present subject. Although sulphuric ether, when properly employed, is not inferior as an anæsthetic to chloroform, the greater trouble attending its administration would have probably very much lessened the use of etherisation, had no easier mode of effecting it been discovered. Chloroform is a more dangerous agent than ether, and has on this account been banished from some of the principal Hospitals in North America and France, yet so much valued by the great majority of Surgeons is its greater ease of administration, that the honour of discovering this means of facilitating anæsthesia, has been almost as keenly contested as that of the great discovery of etherisation itself.

Congelation has hitherto been generally produced by placing the freezing materials on the part to be benumbed. In order to ensure success, care must be taken that the ice shall be well pulverised and rapidly mixed with the salt or salts constituting the frigorific. The mixture must be applied by means of gauze, or some other thin permeable material; and when the part is not in a horizontal position, a gutta-percha cup fitted to it may be required to keep the frigorific in contact with the skin. Now, all this trouble may generally be avoided by the adoption of an expedient similar to that employed in the therapeutical application of extreme heat. It is rarely the case that a burning substance is applied directly to the part; instead of this, an iron, which has been previously heated in the fire, is used. In a similar way, an iron, or a brass, or copper implement, of appropriate shape, may be previously cooled in a freezing mixture, and applied with the greatest accuracy to any accessible part in whatever position this may be. A small, flat laundry iron, which may be used for pounding the ice, will also answer in a great many cases as the refrigerator. If an extensive or continued refrigeration is required, two such irons, immersed in a semi-fluid mixture of two or three pounds of ice and salt, may be necessary to replace each other, just as two hot irons are often required for cauterization.

When a metallic body of this description has been cooled to below zero of Fahr., it will often arrest the circulation of the skin the instant it touches it; but more frequently it must be moved and gently pressed on the part for a few seconds, so as to bring a continuous fresh surface in contact with it while the blood-vessels are compressed.

Another expedient, partly resembling that just described, and partly that hitherto in use, consists of a thin metallic bottle (tinned iron or aluminium) completely filled with the frigorific mixture. A Florence flask will sometimes answer the same purpose.

I think the above description is sufficiently minute, and that the Surgeon, by the adoption of this method, will no longer have to complain of difficulty or trouble in using congelation, either entirely to prevent pain in minor operations, or to prevent the more acute portion of pain, or that arising from incision of the skin, in operations of a deeper or severer kind. In the preface to his work, entitled "Ten Years' Operative Surgery in the Provinces," Mr. Prichard states, that he "refuses chloroform in the lesser operations wherever ice and salt can be conveniently applied." By means of the metallic refrigerator almost every part will be accessible. The complaint made by Messrs. Perrin and Lallemand in their recent and very complete work on "Surgical Anæsthesia," that congelation has been too much restricted to certain operations will probably, by this improvement of the process, have no longer any foundation; but that, if I may be allowed to use the words of these writers, "on peut prévoir le moment où, grace a la réfrigération, l'anesthésie pourra être étendue à toute la pratique usuelle de la chirurgie," page 651.

It is not, however, in being a safe anæsthetic that the principal value of congelation consists. I am anxious to see it more generally employed as a prompt and certain antiphlogistic in all accessible inflammations. The extraordinary remedial powers of congelation in the various forms of chronic rheumatism, which I have related in former publications, may be attributed partly to its anæsthetic and direct antiphlogistic virtues, and partly to the peculiar counter-irritation which it excites. As promptness of action is eminently characteristic of this remedy, it would be especially serviceable in many of those inflammatory and painful diseases to which soldiers and sailors are liable, and which are at present cured with so much difficulty as to render them long unfit for their duties. Amongst these may be reckoned sprains and inflammatory affections of the joints, wounds, irritable ulcers, headache, lumbago, and other painful affections, inflammation of various glands, ophthalmia, erysipelas, and other diseases of the skin.

Being convinced, from no little experience, that a short application of intense cold, produced by a frigorific mixture of appropriate strength, constitutes a certain and speedy remedy of every accessible inflammation, as well as a means of preventing pain in operations, without the risk of sudden or (which has been much more frequent) consecutive death attending the use of chloroform, I do not deem that portion of my time misspent which has been employed in devising and describing such a simple and easy mode of making this application as may lead to its more general adoption.

London.

## ON THE USE OF THE LARYNGOSCOPE.

[A Paper read at the Medical Society of London, April 20, 1863.]

By GEORGE JOHNSON, M.D., F.R.C.P.

Professor of Medicine in King's College, London; Physician to King's College Hospital.

In the laryngoscope we have a most interesting and important addition to our means of investigating and treating the diseases of the larynx and trachea. No unprejudiced observer who has given attention to the subject can deny or doubt that this instrument, throwing, as it does, literally a new light upon a very common, painful, and dangerous class of diseases, is of the highest practical value. By the aid of the laryngeal mirror not only are we enabled during life to see the condition of the larynx with almost as much ease and distinctness as when the parts are exposed to view after death, but the treatment of laryngeal diseases has been greatly facilitated and improved, and will doubtless be still further improved.

In illustration of the improved treatment of laryngeal diseases, it may suffice to refer to performances which, without the aid of the laryngoscope, would have been simply impossible,—I mean the removal of tumours from the interior of the larynx. This has been done by Czermak, (a) and, I believe, by others on the Continent, by Dr. Walker, jun. (b) of Peterborough, and by our Secretary, Dr. Gibb. Operations of this kind will become common, when, with a diffused knowledge of laryngoscopy, suitable cases for operation are recognised. Important additions to our knowledge of laryn-

(a) See the second edition of his monograph "Der Kehlkopfspiegel und seine Verwerthung für Physiologie und Medizin," p. 117.

(b) *Lancet*, November 9, 1861, p. 444.

geal diseases are being made almost daily, so that the materials for an entirely new history of the whole subject are constantly accumulating. In order that this good work may proceed as rapidly as possible, it is desirable to increase the number of labourers in this most interesting field of research. It is to be hoped that henceforth all teachers of Medicine and Surgery in the various Schools will encourage their pupils, and give them every facility to acquire a practical knowledge of laryngoscopy.

There is no valid reason for making a specialty of the laryngoscope. Any one after a short course of training and practice may use the instrument with ease and success, and every Practitioner should endeavour to acquire the requisite knowledge and practical skill.

One of the chief objects which I have in view this evening is to offer some suggestions on this method of examining the larynx. While I hope to give useful hints to those who are commencing the art, I must crave the indulgence of those amongst my audience who are skilled and experienced laryngoscopists. To them I am aware that many of my remarks must appear trite and commonplace.

Here it may not be out of place to indicate very briefly the successive steps by which our present knowledge of laryngoscopy has been arrived at. It is a well-known fact that the first observer who successfully practised auto-laryngoscopy, and published the results of his observations, was a distinguished professor of music in this town, M. Garcia, who has honoured us with his presence here to-night. M. Garcia's "Physiological Observations on the Human Voice" were published in the *Proceedings of the Royal Society* in 1855. This publication became known to Dr. Türk, of Vienna, and induced him to use the laryngeal mirror in the wards of the General Hospital, of which he is the chief Physician, during the summer of 1857. In the early part of the year 1858, Dr. Türk lent his mirrors to Dr. Czermak, who set to work with great zeal and energy, who soon made the important step of introducing the large ophthalmoscope reflector as a means of concentrating artificial light, and who has since done more than any other individual to excite an interest in the subject, and to diffuse a knowledge of it throughout the civilised world. Garcia's paper is, without doubt, the fountain-head from which our present knowledge of laryngoscopy had its source and origin. In Czermak's earlier publications, Garcia's name is inseparably connected with the laryngoscope. Thus the title of his work published in 1858 was "Physiologische Untersuchungen mit Garcia's Kelkopfspiegel" ("Physiological Researches with Garcia's Laryngoscope.")

Long before the date of Garcia's publication attempts to examine the larynx had been made independently by various observers. These attempts had been but partially successful. So far as I know, the very earliest application of the laryngoscope was made by Dr. Babington, who showed his instrument at a meeting of the Hunterian Society in March 1829 (c). The instrument was essentially the same as that now in use. "It consisted of an oblong piece of looking-glass set in silver wire with a long shank. The reflecting portion is placed against the palate, whilst the tongue is held down by a spatula, when the epiglottis and upper part of the larynx become visible in the glass. . . . The Doctor proposed to call it the 'glottiscope.'"

It was long after this that Liston (in his "Practical Surgery," 1840) referred to the use of a dentist's mirror for obtaining a view of the glottis.

In the *Traité Pratique de la Phthisie Laryngée*, par MM. Trousseau et Belloc, 1837, there occurs the following passage, p. 179:—"Depuis plusieurs années, nous nous occupons de la confection d'un *speculum laryngis*. On connaît celui de M. Selligie, très ingénieux mécanicien, qui, atteint lui-même d'une phthisie laryngée, dont il est complètement guéri, exécuta, pour son Médecin, un *speculum* à deux tubes, dont l'un servait à porter la lumière sur la glotte, et l'autre servait à rapporter à l'œil l'image de la glotte réfléchié dans un miroir placé à l'extrémité gutturale de l'instrument." The authors go on to say that this instrument is very difficult of application, and that not one patient in ten could bear its introduction.

The late Mr. Avery worked long and successfully in the construction of a laryngoscope, and of other instruments for

(c) *Medical Gazette*, Vol. III., p. 555, and *British and Foreign Med.-Chir. Rev.*, January, 1863, p. 299.

examining internal organs (d), but he published nothing on the subject.

Lastly, in 1844, Dr. A. Warden invented a prismatic speculum, with which he succeeded in seeing disease of the glottis in two cases. (e)

The instruments required for the practice of laryngoscopy are few and simple, namely, a reflector to condense the light of the sun or of a lamp into the fauces, and a small mirror which, being placed beneath the uvula and soft palate, reflects the image of the larynx to the eye of the observer.

*The best position for the concave reflector is on the forehead, and not in front of one eye.*—In a short paper which I lately published in the *Medical Times and Gazette* (February 14, p. 157), I stated that, so far as I knew, it had up to that time been the invariable practice to use a perforated mirror, to fix it in front of one eye, and to look through the central opening into the mouth of the patient. I have since learnt that, in Paris, the practice of placing the reflector on the forehead is very general; and I find that Dr. Moura-Bourouillou, in his interesting "*Cours Complet de Laryngoscopie*," published in 1861, insists on the advantage of using a non-perforated mirror and placing it on the forehead, so that the laryngeal image may be seen by both eyes (p. 17).

I have met with very few persons who, having tried both methods, fail to appreciate the great convenience and advantage of having the reflector on the forehead rather than in front of one eye. The chief advantages of the method which I advocate are these. We avoid the discomfort and inconvenience resulting from the effort required to keep the eye applied to the small opening in the reflector; we have the free and unimpeded use of both eyes, and, consequently, find it much easier to direct the light into the patient's throat, to keep the laryngeal mirror in the required position, and to practice any other manipulation which may be required either for diagnosis or treatment. With the reflector in front of one eye, it should be observed that, even if the operator succeed in using both eyes for looking into the throat, there is an uncomfortable strain upon the eyes, in consequence of one eye having to look through a concave glass while the other is uncovered. The effect of this arrangement must be to make an inequality in the focal distances of the two eyes.

With the reflector on the forehead, immediately above the eyes, the eyes may be more or less completely shaded from the direct light of the lamp or of the sun, whereas with the reflector in front of one eye, both eyes are necessarily exposed to a fatiguing glare of light. Another incidental advantage attending the position of the reflector on the forehead is that we thus get a more free movement of the reflector in all directions—this free movement being required for the practice of a simple method of auto-laryngoscopy to which I shall presently advert.

Again, the central perforation not being required in the reflector placed on the forehead, we get rid of the dark spot in the centre of the luminous disc which exists when the light is reflected from a mirror whose centre is not silvered. But are there advantages in the practice of looking through the centre of the reflector which in any degree compensate for its inconveniences? I know of none, and I believe that the practice would never have existed but for the fact that when Czermak, to the great advantage of laryngoscopy, adopted the large ophthalmoscope reflector as a means of concentrating the light, he continued the use of the perforated mirror, perhaps without having fully considered the very different conditions which attend the exploration of the eye through the small opening of the pupil, and that of the larynx by light reflected from a mirror of considerable size placed above it at the back of the wide-open mouth.

I have recently received two long and interesting letters from Professor Czermak, with reference especially to the best position for the reflector. He says, "I acknowledge with pleasure that it is comfortable, and, in most cases, of no obvious consequence or disadvantage to place, as you have suggested, the reflector in front of the forehead." He maintains, however, that if you have to look far down the trachea you can use only one eye, and that this is best placed behind the aperture in the reflector, so as to look "in the direction of the axis of the luminous cone." In reply to this argument I say that in practising laryngoscopy we do *not* look down the tube of the trachea; but we see only the image of the larynx

and trachea as it is reflected from the flat surface of the laryngeal mirror. And in these days of stereoscopes and binocular microscopes, and even binocular ophthalmoscopes, it surely will not be denied that we get a more complete and satisfactory view of the interior of the larynx and trachea when the light from the laryngeal mirror has unimpeded access to both eyes than when one eye only is used.

M. Garcia states, with regard to the use of a perforated mirror, that he tried it in order that Drs. Williamson and Sharpey might observe his larynx while he experimented upon himself. He found, however, that this was not attended with any marked advantage. They could see the reflected image of his larynx as well by looking over the top of the mirror as by looking through its perforated centre. (f)

It appears to me that sufficient reasons have been adduced for placing the mirror on the forehead rather than in front of one eye. Until quite recently, all the reflectors in this country have been made to come to the front of the eye. Messrs. Weiss and Son have sold some hundreds of this kind. It may be interesting to those who possess these instruments to know that, by simply shortening the hook which attaches the reflector to the frontal band, the reflector may be brought to the middle of the forehead. The alteration can be made very speedily, and at a most trifling cost.

My friend and colleague, Mr. Mason, has lately had an instrument made by Mr. Matthews, in which the reflector is connected to the frontal band by means of a ball and socket-joint. In my opinion, any slight superiority in the movements of such a joint is more than counterbalanced by the greater space which the instrument occupies, and the consequent necessity for a case inconveniently large for carrying in the pocket.

With regard to the introduction of the faucial or laryngeal mirror, the beginner has to bear in mind that the mirror having been warmed over the lamp, so as to prevent its being dimmed by the breath, is to be introduced so as to slightly raise the uvula and soft palate, while we carefully avoid touching the tongue and the back of the pharynx, which are the most sensitive parts of the throat. I believe that the experience of most observers is in accordance with my own, namely, that in the majority of cases, even of patients who are suffering from acute disease of the larynx, the careful introduction of the faucial mirror is attended with surprisingly little inconvenience.

The mirror, be it remembered, does not come near the larynx or the epiglottis, but is placed far above these parts, and in contact with the uvula and soft palate.

I have never found it necessary to use the bromide of potassium, which has long been supposed to have the effect of lessening the reflex sensibility of the fauces, nor have I any experience of the bromide of ammonium. My friend Dr. Routh tells me that in one case, finding the throat very sensitive, and being anxious to make a thorough examination, he administered a small dose of chloroform by inhalation with the best results. This very day I repeated Dr. Routh's experiment in the case of a patient whose throat was unusually sensitive, and with good effect.

The tongue is one of the most frequent and most serious impediments in the way of laryngoscopy. There are various modes of dealing with this unruly member. Sometimes—though very rarely until after a considerable amount of training—the patient has sufficient control over the tongue to hold it down by a voluntary effort while the laryngeal mirror is introduced; in nearly every case, however, the tongue requires to be kept out of the way by some mechanical means. The plan which usually answers best is to hold the tip of the tongue between the thumb and forefinger, and to draw it gently forward over the lower teeth. This may be done either by the operator or by the patient himself, the thumb and finger which hold the tongue being covered by a cotton glove, or by a towel or napkin. In some cases a metallic tongue-depressor may be used with advantage, or the tongue may be kept down by the pressure of the forefinger of the operator's left hand. Practically, it is often found that the effect of depressing the front of the tongue is to make it arch upwards at the back so as nearly to touch the palate. This arched position of the tongue obstructs the passage of the light to and from the larynx, and often is attended with nausea in consequence of the tongue coming in contact with the mirror.

(d) "Introduction to the Art of Laryngoscopy." By James Yearsley. 1862.

(e) *Brit. and For. Med.-Chir. Rev.*, January, 1863, p. 210.

(f) "Notice sur l'Invention du Laryngoscope," per Paulin Richard p. 14. Paris. 1861.

For these reasons, the attempt to depress the tongue is usually less successful than its gentle traction forwards.

It is important to practise the introduction of the laryngeal mirror with the left hand as well as with the right. In applying nitrate of silver or other local remedies to the interior of the larynx, the plan is, while the patient or an assistant manipulates the tongue, for the operator to introduce the laryngeal mirror with the left hand, and with the right to apply the remedy to the larynx by means of a camel-hair brush or a sponge on a curved whalebone.

One of the most useful means of acquiring aptitude in the examination of the larynx is the practice of *auto-laryngoscopy*. Various methods of auto-laryngoscopy have been proposed and practised. The simplest, and, on the whole, the most satisfactory plan, is one devised by myself, and which, I think, may fairly claim to be called "the ready method." This method has the advantage not only of being very easy of execution, but also of requiring no special apparatus. The concave reflector on the forehead, and the laryngeal mirror required for the examination of patients, with a common looking-glass and a lamp, constitute the whole of the apparatus. The method is this: Sitting at a table of a convenient height, I place a looking-glass, at a distance of about eighteen inches, in front of me, and a moderator or gas-lamp on one side of the glass, but two or three inches further back, so that the light may not pass directly from the lamp to the mirror. The light of the sun may be used when available. Now, with the concave reflector on my forehead, I throw the light, as it were, into the open mouth of my own image in the looking-glass; then introducing the laryngeal mirror into my mouth, I see the reflection of my larynx and trachea in the glass before me, and any one looking over my head or shoulder can see the image at the same time. This method therefore serves for auto-laryngoscopy and for demonstration. In other words, the experimenter can by this means see his own larynx, and show it to others; and this method certainly possesses some advantages over that employed with such wonderful success by Professor Czermak.

In the first place, Czermak's plan requires a special and costly apparatus. I learn from Messrs. Weiss that scarcely more than one in a hundred of those who have obtained laryngoscopes from them have purchased the apparatus for auto-laryngoscopy. The instrument is too costly and complicated to allow of its coming into general use. My own method is certainly a much easier and a more ready one. I find that while holding the laryngeal mirror with my right hand, and changing the position of my head and neck so as to obtain different views of the larynx and trachea, I can, with the greatest readiness, keep the light directed where it is required, by adjusting the frontal reflector with my left hand. This adjustment of the light cannot so readily be made with Czermak's apparatus, on account of the distance at which the reflector is placed.

For beginners in the art of laryngoscopy this method affords a very useful means of training and practice. One of the chief difficulties at first is to keep a steady light in the patient's throat. Now, the student after arranging his looking-glass and his lamp, may direct the light from the frontal reflector into his own open mouth in the looking-glass. This process scarcely differs from that which he will have to practise on his patients. Then, having learnt to keep the light steady, he may practise the introduction of the faucial mirror, and he will soon see the interior of his own larynx and trachea. I have seen more than one of my Medical friends succeed in doing all this within less than half-an-hour of their first attempt.

It is important to observe that in practising this method of auto-laryngoscopy both eyes may and ought to be protected from the glare of the lamp. The lamp is most conveniently placed by the side of the glass to the left of the operator. The right eye is then shaded by the lower margin of the reflector on the forehead, and the left eye, which would otherwise be exposed to the direct light of the lamp, may readily be shaded by one or two fingers of the left hand placed at the edge of the reflector. The fingers thus placed serve at once as a shade for the left eye, and a means of moving the reflector when the direction of the light has to be changed.

In the practice of auto-laryngoscopy and in the examination of others it is of considerable importance that the experimenter should have the power of readily changing the direction of the light, so as at once to adapt it to the varying position of the body, which is often required for the thorough explora-

tion of the larynx. A feebler light, which can readily be reflected in any required direction, is of more practical value in laryngoscopy than a stronger light which is fixed.

I differ entirely from Dr. Walker, (g) of Peterborough, in his estimate of the practical advantages of the direct illumination of the fauces by a concentrated *fixed* light, as compared with that by means of a reflector attached to the head of the observer.

The light from the reflector may be somewhat less intense, but it is much more handy. The light from a good moderator lamp, when thrown into the throat by the reflector, is sufficient for all the purposes of laryngoscopy, and I have repeatedly obtained a very good view of the larynx by the light of an ordinary composite candle. All observers agree in stating that the light of the sun, when it can be obtained, is the best means of illuminating the throat. The patient sits with his back to the sun, and the operator directs the light into the throat by means of the reflector, taking care not to burn the throat, by bringing the rays to a small focus. Solar caustic, be it remembered, is as powerful as lunar caustic.

I have found, as others must have done, that the concave reflector is very useful as a means of illuminating the throat, for the purpose of examining the tonsils, palate, and pharynx. Placing a lamp or a candle by the side of the patient, or using sun-light when available, the operator, with the reflector on his forehead, throws the light into the throat, and has both his hands free to do whatever requires to be done—to depress the tongue, and to apply caustic or other local remedies.

In cases of diphtheria and scarlatina, by this method of illumination a thorough examination of the throat can be made in a much shorter time than by the ordinary method. And thus the operator incurs less risk of infection from inhaling the patient's breath, or having the morbid secretions coughed into his face.

## REPORTS OF HOSPITAL PRACTICE IN MEDICINE AND SURGERY.

### SAMARITAN HOSPITAL.

#### FIVE CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

[From notes by Mr. E. PARSON, House-Surgeon.]

In our Number for March 14, 1863, we published five cases of ovariectomy, which all terminated successfully, under the care of Mr. Spence Wells, in the Samaritan Hospital. We now publish five other cases which have been observed in this Hospital since our last report. Four of them have resulted in recovery; only one death having taken place of the whole ten cases.

*Case 1.—Large Semi-solid Ovarian Tumour—Tapping—Ovariectomy—Recovery.*—M. S., unmarried, age 36, applied to Mr. Wells in January, 1863, with a very large multilocular ovarian cyst. She measured 48 inches round the body at the umbilicus, 31 inches from one ilium to the other, and 24 inches from sternum to pubes. Increase in size had commenced about two years before, and during the last few weeks it had been very rapid. She returned to Oxford, and Mr. Wells wrote to Dr. Acland, suggesting a preliminary tapping. She was tapped on February 1, and thirty-six pints of fluid removed. Dr. Acland wrote to say "There remains a large partially-solid mass, not readily movable. The poor creature's fate is sealed without the operation." She was accordingly admitted on February 27, and Mr. Wells performed ovariectomy on March 2. Dr. Jottrand, of Brussels, Mr. Partridge, and many other visitors were present. The incision was six inches long, from one inch below the umbilicus. The cyst was universally adherent anteriorly, but it was easily separated. The adhesions on the solid mass on the left side were very firm, and considerable force was required to break them down. After emptying the large cyst, the tumour was gradually withdrawn, and a long pedicle on the right side secured by a clamp. The left ovary was healthy. The peritoneal cavity was carefully cleansed by sponging, and the wound closed by silk sutures. The patient rallied tolerably well,

but reaction was rather deficient all the evening. At night, finding some oozing of viscid bloody fluid around the pedicle, Mr. Wells applied a ligature tightly beneath the clamp, as this did not seem to compress the pedicle perfectly. After this she passed a good night. One opiate enema was given, the only one which was needed. The clamp was removed on the third day after operation. The bowels acted on the fifth day; and, although she was a feeble, nervous person, she recovered well, and has been heard of since she left the Hospital as in excellent health.

*Case 2.—Multilocular Ovarian Cyst—Ovariectomy—Recovery.*—E. C., unmarried, aged 36, admitted March 13, 1863. She had been an out-patient, under Dr. Rogers, occasionally for about two years, the abdominal enlargement having commenced about four years ago. She had been obliged to give up a situation as housemaid, and had been dressmaking. She had been admitted twice before for a few days, under Mr. Wells, and had been advised to wait until there was clearly a necessity for surgical interference. At length she became subject to severe pains in the left side, was unable to earn her living by the needle, and was admitted for operation. The diagnosis made on March 14 was "multilocular cyst of left ovary. No parietal adhesions." The girth at the umbilicus was thirty-five inches, measurement from sternum to pubes seventeen inches. Mr. Wells performed ovariectomy on March 16. Dr. Jottrand of Brussels, Dr. Gream, etc., were present. Mr. Parson gave chloroform. An incision, five inches long, was made from the umbilicus downwards; the parietes were very thick and vascular, the rectus and adipose layer both very thick. The cyst was quite free anteriorly. One large cyst was emptied, and then the whole tumour passed outwards, with some assistance from pressure. A small clamp was applied on the pedicle on the left side. The right ovary was healthy. There was some oozing of blood from superficial vessels, but none were tied, and the wound has closed in the usual manner. Two small opiates that evening, and one on the third day, were the only medicines required. The remains of the pedicle became quite dry, and adhered so firmly to the clamp that it was not removed till the eighth day. The bowels did not act till the eleventh day. The catamenia came on at the usual time, and had passed off on April 7. She rapidly gained strength, and left the Hospital on April 13 in excellent health.

*Case 3.—Ascites—Tapping—Removal of Small Ovarian Tumour—Death.*—A married woman, 26 years of age, was first admitted December 22, 1862, with considerable enlargement of the abdomen from fluid which was evidently free in the peritoneal cavity. She had been married eight years, and had had one child seven years ago; none since. The catamenia had been quite regular, and without pain, until the spring of 1862, when there was pain at each period, extending round from the right iliac region to the back. Soon after the first severe attack of this pain the abdomen began to enlarge, and she suffered from dysuria for about three months. The abdomen increased in size, and she was tapped in the London Hospital in October, 1862, sixteen pints of fluid having been removed. She was bandaged tightly for three weeks after the tapping, but the fluid soon began to collect again. Mr. Wells tapped her in December, and removed twenty-nine pints of clear fluid. There was nothing in the nature of the fluid to decide whether it was ascitic or ovarian. The patient left the Hospital on January 10, 1863, and returned again in February, with the abdomen full of fluid. It still seemed to be free in the peritoneal cavity, but as the uterus, though movable, was rather low down, the cervix large, and pushed to the left side, and there was marked dulness in the right loin, it was thought that there was disease of the right ovary, although nothing could be felt through the abdominal wall anteriorly. Accordingly, an exploratory incision was made on February 21, and after removing twenty-six pints of clear fluid, a growth, about the size of a small cauliflower, was found to occupy the place of the right ovary. Nothing more was done, and the wound was closed. It healed by the first intention, and the patient recovered without a bad symptom; but the ascitic fluid re-collected rapidly, and it became a question whether the tumour should be removed, or tapping repeated. It was known that the ovarian tumour was small, and its attachment broad; but the prospect of repeated tapping was so hopeless, that the earnest desire of the patient to have the tumour removed was complied with, and Mr. Wells performed the operation on March 25. Union of the incision made on February 21 being complete, the lower half was included in

the incision at this second operation, and it was carried an inch nearer to the pubes. An opening was made just large enough to admit the hand midway between the umbilicus and symphysis pubis—the ascitic fluid allowed to escape—and the ovarian tumour drawn forwards, with the intention of placing a ligature round its base. But it broke away completely from its attachments, and there was free bleeding, mostly venous. There was no pedicle, the diseased ovary preserving its natural relations with the uterus, but having a broad base of attachment between the posterior surface of the uterus and the cæcum, following the course of the right spermatic vessels where they cross the psoas muscle. Both artery and vein were tied by a silk ligature, the ends of which were cut off short, and the knot allowed to remain within the abdomen. The bleeding then ceased, the abdomen was carefully sponged, and the wound closed. The patient rallied fairly after operation, and did not suffer pain; but vomiting became troublesome. She seemed pretty well all the next day; but on the second day vomiting became urgent and exhausting, and she died fifty-four hours after operation, apparently exhausted by the vomiting and the rapid formation of serum in the peritoneal cavity. On *post-mortem* examination about forty ounces of dark red serum and two ounces of blood-clot were found in the cavity; a little recent lymph showing slight peritonitis. There were some old adhesions between the left broad ligament and colon, thickening of the capsule of the liver, and fatty degeneration of this organ. There was a thrombus in the enlarged right spermatic vein, extending about an inch above the spot where the ligature remained firmly tied. The tissue included in the ligature was dead and fetid, the dead portions probably weighing about half a drachm. There was no evidence of any process of attempted capsulation, or covering up of the ligature and slough by any effusion of lymph.

*Case 4.—Removal of an Ovarian Tumour Weighing Thirty-seven Pounds from a Woman 61 Years of Age—Recovery.*—A married woman, 61 years of age, mother of six children, the youngest of whom is 18, was sent to Mr. Wells in March last by Dr. Giles, of Oxford. A large multilocular ovarian cyst filled the whole abdomen, from the sternum downwards. It had only been of two years' growth, and the increase of late had been rapid. The girth at the umbilicus was thirty-eight inches, and eighteen inches from sternum to pubes. It was evident that ovariectomy was her only resource, and, as she was in good spirits, and the general health still unbroken, it was decided that her age alone was not a sufficient reason for refusing to make the effort to cure her. She was admitted on April 8, and the operation was performed on the 13th. Mr. Parson gave chloroform. Dr. Giles, of Oxford, Dr. Llewellyn Williams, etc., being present. After exposing the cyst by an incision from the umbilicus five inches downwards, some very firm parietal adhesions were separated, and a large cyst was emptied. As it was withdrawn, a long coil of small intestine was found to be adhering to it by its mesentery. This was carefully separated, and it was then found that the proper pedicle could not be safely separated from the cæcum above or the bladder below; the clamp was accordingly placed round the neck of the cyst rather than on the pedicle. A little blood which had escaped from the torn adhesions was then sponged away, and the wound closed as usual. She had three opiate enemata during the night on account of pain, but was very comfortable all the next day, without pain or vomiting. On the third day the clamp was removed, and on the fifth day the upper sutures. The lower sutures were left two days longer, as they appeared to prevent the surface of the pedicle from sinking into the abdomen. Some delay in the healing process was caused by these two lower sutures producing a slough; but recovery went on very satisfactorily. The bowels acted freely on the tenth day, and continued to do so without pain, occasionally assisted by injection of warm water. The note on May 9 was—"Convalescent; sitting up; still a slight purulent discharge from lower angle of wound."

On the 18th she left the Hospital. The fluid and solid portions of the tumour removed weighed together thirty-seven pounds.

*Case 5.—Ovariectomy—Bronchitis—Venesection—Recovery.*—S. B., unmarried, aged 19, was sent to Mr. Wells, by Mr. Rumsey, of Cheltenham, as a very favourable case of ovariectomy. The abdomen was filled by an ovarian cyst, nearly unilocular, free from adhesions, and she was otherwise healthy. The girth at the umbilicus was thirty-six inches, and the distance from sternum to pubes sixteen inches. She was admitted April 17, and the operation was performed on

the 22nd—a week after the cessation of the catamenia. Mr. Parson gave chloroform; Dr. Boulton, of Horncastle, Mr. Macilwain, etc., were present. The operation was of the simplest possible description. An incision, four inches long, downwards, from one inch below the umbilicus, exposed a non-adherent cyst, which was tapped, and withdrawn as it was emptied. A small pedicle on the left side was secured by a clamp, the cyst cut away, the right ovary felt to be healthy, and the wound closed by sutures, without the slightest exposure of any of the viscera. There were fourteen and a half pints of fluid removed, and the cyst weighed seventeen ounces. She went on for two days perfectly well. The stitches were removed on the 24th, and the wound was quite healed. On the 25th symptoms of bronchitis, with pulmonary congestion, came on—cough, very viscid expectoration, raised with much difficulty, thirst, hot skin, and pain under the sternum. The pulse was 100, respiration 32. Acetate of ammonia was given freely, and hot linseed poultices were applied to the chest. On the 26th, all the symptoms were aggravated. Early in the morning the pulse was 130, the respiration 40. At 11 a.m., the respiration being still 40, and the pulse 140, Mr. Wells took eight ounces of blood from the arm. The patient immediately felt great relief; the pulse fell to 120, respiration to 36, and free perspiration came on. Ten grains of chlorate of potash were given every two hours. A little champagne was given during the night. During the next day the respiration was about 40, and pulse 120. Expectoration very viscid. Five minims of ipecacuanha wine were given with each dose of chlorate of potash. On the 28th all medicine was discontinued, as the pulse had fallen to 100, respiration to 36, and the cough and dyspnoea had nearly disappeared. It was curious that, notwithstanding the obstinate cough, the abdominal wound had healed perfectly, and she never complained of the slightest pain in the abdomen. The clamp was removed on May 1. A little pus escaped from the lower angle of the wound for a few days, but she was quite convalescent fourteen days after the operation, and left the Hospital in good health on May 23.

### MIDDLESEX HOSPITAL.

#### EPILEPSY ARISING FROM AN INJURY TO THE THUMB.

(Under the care of Dr. GREENHOW.)

E. R., aged 16, domestic servant, was admitted as an out-patient November 5, 1862. She had run a splinter of wood the distance of an inch underneath the left thumb-nail four months previously. Much pain and irritation ensued, and at the end of a week she had an epileptic fit, and had had five subsequently, at uncertain intervals, before presenting herself at the Hospital. The wound was still open and painful on pressure. The fits were preceded by a sense of numbness in the thumb, rapidly extending up to the shoulder, when a feeling in the shoulder-joint came on as if it were being wrenched, accompanied by dyspnoea, and pain in the cardiac region. In a few moments the fits followed, in which the patient lost her senses, became convulsed, and usually bit her tongue. After the convulsions subsided she always fell asleep. She had not suffered from convulsions while teething, and had neither had fits previous to her accident nor been subject to hysteria. When seen she was quite free both from headache and vertigo. Catamenia normal; bowels regular; tongue clean.

Thumb to be dressed with warm poultices. ℞ Liq. bichlor. hyd.; tinct. cinchon. co., āā ʒiiss.; aq. cinnam., ʒj. ter die.

November 17. — Had had a fit, in all respects resembling the former ones, on the 14th inst. Wound healing. Pergat.

January 30, 1863.—Has had no fit since the last report. Wound quite healed. Pergat.

March 6.—Discharged quite well.

### HOSPITAL FOR THE EPILEPTIC AND PARALYSED.

#### UNILATERAL EPILEPTIFORM SEIZURES, ATTENDED BY TEMPORARY DEFECT OF SIGHT.

(Under the care of Dr. HUGHLINGS JACKSON.)

In the two following cases there was, as well as the epilepsy,

some temporary defect of sight. As a clinical fact, this is common in cases of epilepsy in which the convulsions are unilateral. Sometimes in such cases the temporary defect of sight passes into a permanent one, but more frequently epileptiform seizures follow amaurosis. Such is, we repeat, the clinical fact, but the causes of the temporary loss of sight are very various, being due in some merely to a passing defect of the accessory apparatus of the eye, and in others to defects in the circulation of the retina itself. In a case of epileptiform convulsion in a patient who had recently suffered from syphilitic rash, recorded in this Journal, January 31, 1863, the slight defect of sight appeared to be due to want of parallelism of the eyes from convulsive action of the external rectus muscle on the side of the body affected, as this muscle was afterwards paralysed in the hemiplegia which followed a severe attack. In other cases there appears to be evidence that the defect of sight is due to some change in the circulation of the retina itself, and these are more likely to be followed by amaurosis. A young, robust-looking man consulted Dr. Hughlings Jackson, November, 1862, for epileptiform convulsions on the left side. He had then had only one complete attack. In this case the sight failed in the beginning of the paroxysm. A few months afterwards he lost the sight of both eyes. In a case now under the care of Dr. Brown-Séguard, at the Hospital, there has been complete amaurosis for twelve months, followed by epileptiform convulsions on one side.

The attacks of coloured vision in the second case are interesting, but the patient's description is not very exact. It would seem that light entering the eye was temporarily broken up into various colours, as it is more permanently in organic affections, as retinitis, in which patients frequently complain of seeing a "rainbow" round the flame of a candle.

As will be seen by referring to a series of cases recorded in the Hospital reports of this Journal, June and July, 1861, the convulsions in epilepsy from syphilis are generally unilateral. In the following cases there was no evidence of any taint. It is singular that both these patients should have had tapeworm. In the first no worms were passed after taking a dose of the oil of male fern; the other patient did not attend again after taking it:—

A married woman, 38 years of age, consulted Dr. Hughlings Jackson, November 25, 1862, for attacks of convulsion of the left arm and left side of the face. The sight also was affected during the attacks.

She had been delivered four months before, after a natural labour. The child she brought with her was healthy. She was suckling, but her general vigour and health seemed good. There was, however, another condition which might exercise an important influence,—before her confinement she had passed tapeworms.

Fourteen days after her confinement, whilst in bed, she noticed that the first two fingers of the left hand moved. The movement lasted ten minutes. For one month nothing further of the kind occurred. Then, one day whilst at tea, she felt a glimmering over the eyes, then "it took the elbow, next the hand, so that all the fingers worked together," and her face was drawn to the left side. She then became insensible. She did not bite her tongue. She was "black in the face." She did not sleep after the fit.

She had had many abortive attacks since, but no actual fit. They all began with a kind of glare before the eyes, and then the arm became rigid, and the fingers "worked." She would get her husband to pull the fingers back, and this relieved her. After the attack she could use the arm as well as ever. Iodide of potassium was given.

October 2.—She had had one severe attack in the hand, which, she said, her husband "stopped" by pulling back the fingers, but as it was ten minutes before it ceased, very likely the effect was not due to his interference. As she had had tapeworms at one time, a drachm and a half of the oil of male fern was ordered; castor oil to be taken before and after. To continue the iodide.

November 28.—She did not pass any worms after the draught. She had had no actual fits, and complained of nothing except a "glare" before the eyes, and pain, chiefly in the region of the malar bone. She spoke thickly, and this had been so since one attack of movement in the left side of the face. It moved, she said, just as the hand did.

December 11.—Only one slight attack. Her sight, as usual, was affected, and after it she saw "colours and figures."

METROPOLITAN FREE HOSPITAL.

EPILEPTIFORM SEIZURES — AURA FROM THE THUMB—ATTACKS OF COLOURED VISION.

(Under the care of Dr. HUGHLINGS JACKSON.)

ALICE F., a married woman, aged 49, was admitted an out-patient, under the care of Dr. Hughlings Jackson, on November 28, 1862. Until about seven or eight months ago she had had good health, and indeed looked still in fair health, and was very intelligent. She had not menstruated for twelve months, and complained a good deal of "sinking," of faintness, weakness, etc.,—symptoms so common at the change of life. Until the attack to be described she had had no definite ill-health, except a pain in the right arm of no very special character, so far as could be ascertained.

Five weeks before she had a tingling sensation in the right thumb. It began under the nail, and extended about as high as the styloid process of the radius, and then "went to the face." The part of the face first attacked was the upper lip on the right side; next, the whole of that side of the face, and the tongue also; "it took her speech away for five minutes." She was not at all insensible. She had great pain in the arm, but the leg was not affected in any way. She had had about twenty of these attacks before admission.

It is interesting to note that, before any question of any kind was asked, she said that catching the shuttle with the thumb and finger, and even touching the thumb, would sometimes bring on the fit. She gave a circumstantial account of this. She had also attacks in which there was coloured vision, which were distinct from the seizures just described. The first was about four days before the seizure described above.

This patient took iodide of potassium. At her next visit she was better, and had only had one attack. It was now ascertained that she had had tapeworms three years ago.

December 19.—She had had no fit, but "had had the colours dreadful." It affected the right eye only, as she shut each eye in turn, in order to ascertain. The coloured vision was attended by pain in the right superciliary region. Both the pain and the colour came and went suddenly, lasting each time about ten minutes. She could see things in spite of this peculiarity, but rather dimly. The colours were violet, white, and orange, and seemed about three yards distant. At other times the sight was good, and she had no pain. She had not at any time during these attacks any vertigo or insensibility, but numbness of the right leg. She had considerable pain still from the elbow to the fingers, but this was constant. A dose of the oil of male fern was prescribed.

GUY'S HOSPITAL.

PURPURA—SMALL-POX (?).

(Under the care of Dr. WILKS.)

THE following is another instance of purpura supposed to be due to small-pox. We refer our readers to two cases recorded in the Hospital Reports of this Journal, April 11, 1863, for some valuable information on the subject, embodied in clinical remarks on those cases by Dr. Gull and Dr. Wilks:—

Martin T., aged 21, admitted April 23, 1863. He died the same afternoon. He was brought in a cab to the Hospital, but was too ill to give any account of himself. The whole surface of his body was livid, or extremely congested, and his face and hands presented numerous small papules. His breathing was very difficult, of a character indicating some swelling of the fauces. Mr. Stocker, who alone saw him, judging from his general appearance, and from the prevalence of variola, thought that the man was suffering from small-pox. There was no actual purpura on the body, nor was there any hæmorrhage from any part.

Autopsy, by Dr. Wilks.—The body was that of a remarkably fine, strong, muscular man. It was of a purple colour, from extreme congestion of the cutaneous capillaries. The appearance of a papular eruption seen during life was now scarcely perceptible. Blood was oozing from the mouth. The interior of the pharynx as well as the trachea, etc., was of an intense purple colour, as the outside of the body. The mucous membrane of the glottis was swollen. A few minute points were visible, which suggested the commencement of variolous pustules, but there was no proof that they were of

this nature. The pleuræ were healthy, but their surface was covered by purpuric spots. The lungs were extensively congested; every part was full of blood, and some apparently extravasated into the tissue. In the veins leading to the heart the blood was very dark and fluid. There was ecchymosis of the inner surface of the stomach, but no effusion of blood. Other organs healthy. The head was not examined.

SATURDAY, JUNE 6.

SURGICAL HONOURS.

IN spite of all that has been written, said, and done, with the intention of widening the entrance to the high places in the great Surgical corporation of Lincoln's-Inn-Fields, it is clear that any success which has been gained is, to a great extent, neutralised by the centralising and conservative tendencies of the present age Medical. Formerly, when the Council of the College were self-elected, it was in the nature of things that they should be exclusive. They were London Hospital Surgeons, and, their idea of excellence culminating in themselves, they could conceive of no merit, unless it were the result of the process which had elaborated their own. But now that the election rests with the great body of the Fellows, it is curious to observe how the same veneration for metropolitan training has been imbibed by the electors with their accession to power. It is true that last year a good precedent was set by the return of Mr. Paget, of Leicester, but this year, although there are three vacancies to be filled, we have only heard the name of one provincial Surgeon—Mr. Turner, of Manchester—mentioned as a probable candidate. All the other candidates are metropolitan, and, with one exception, they are all attached to London Hospitals.

We object to this exclusiveness for many reasons; amongst them, not the least important is the effect it has of narrowing the field open to able and ambitious young men, who look forward to obtain the high honours of their Profession. We know of no reason why one-half the seats in the Council of the College should not be filled by Surgeons from the provinces. The opportunities of practice offered by Manchester, Liverpool, Birmingham, and other of our large towns are, in the aggregate, as wide as those to be found in London itself. But a young Surgeon whose ambition and ability lead him to indulge in an occasional day dream of filling the Presidential seat of the College, knows that to leave London for never so extensive a practice in a great manufacturing or trading town would be certain ruin to his hopes. So with the Army and Navy, a Surgeon who enters either of the public services cannot, whilst he remain in them, rise to the highest honours in his Profession. The result is that for every inferior post in the London Hospitals there are half-a-dozen applicants. Men of the highest abilities and attainments wear out the best part of their lives in Assistant-Surgeoncies, thinking themselves fortunate if, when in charge during the absence of the higher functionary, a stray operation fall to their lot.

The other day we were dozing over the pages of a respected Medical contemporary in the Library of the College of Surgeons, when we were woken up by the entry of two old friends—old fellow-students of ours at St. Magog's. Like ourselves, they were both on the shady side of forty, and we recollect them both prize men at the school, and House-Surgeons to Crusher. One of them—Freshfield Sharp—looked sleek and rosy, the very personification and type of success. Sharp is Surgeon to the Infirmary at West Thrington; he does a large practice, is married, has a family, and has achieved a first-rate Surgical reputation with wealth and position in his county. The other, Dryhope Pure, is now Assistant-Surgeon at St. Magog's, and grinder, or, in modern phrase, College Tutor to the school. He has hung on at the Hospital ever since we were students, has stood three times for vacant Assistant-Surgeoncies, was at last successful, and now lives in two rooms in a dingy street at the West-end, where, for an annual consideration, he is allowed the privilege of putting his plate on the door. Poor Dryhope! the grey locks on his temples and crow's feet tell his tale. His private patients may be counted with the weeks of the year. His public practice consists of sitting for three hours twice a-week repeating lotions and mixtures, and attending to ulcerated legs and whitlows in the out-patients' room. Lucky does he think himself when he gets a case of minor Surgical operation which he can take into the theatre. A day or two after our meeting we went to St. Magog's on operating day, attracted by seeing in the diary that Crusher was going to excise a hip-joint, perform lithotomy, and remove a tumour weighing forty pounds. The theatre was crammed to the topmost bench. One by one the patients were brought in, and, amid the silence of the admiring students and the approving whispers of his friends, the great Surgeon performed. When the last suture had been inserted, and the last patient had disappeared under the care of the Hospital porters, Crusher turned to the assembled crowd, and, in his usual deliberate, happy way, began to deliver "a few clinical remarks." The attention was profound. Crusher went on, dwelling with the fondness of a great artist on each point in the operations, illustrating the cases by the accumulated experience of a third of a century—stating the reasons for what had been done—demonstrating the structure of the diseased tissues removed. Considering how valuable his time is, thought we, Crusher's prolixity is certainly most self-sacrificing. His oration, however, seemed absolutely short to the students who listened with rapt attention. The only individual evidently grudging the time was our friend Dryhope. His assistant's duties performed, we watched him narrowly whilst Crusher was haranguing. There he sat restless on the foremost bench, apparently engaged in examining the qualities of a new forceps, but his eye all the while wandering impatiently from speaker to listeners, and his fingers straying mechanically every five minutes to his waistcoat pocket, and more than once diving impulsively for his watch. But at length his trial is over. Crusher stops, and taking with him the calculus he has extracted, gracefully makes his exit. His departure is the signal for a universal round of applause, and then a universal seizure of hats. The theatre in the course of a minute is almost cleared, when Dryhope, in a voice half deprecatory, half reproachful, announces that he is going to remove a piece of necrosed bone from the terminal metacarpal of the middle finger of an out-patient. But the spell is dissolved; the men are gone, with the exception of some half-dozen friends and one or two first-year's men, who gather up and form a thin semicircle round the operator. The sequestrum is neatly removed, and when the finger is bound up, we take our friend's arm, and make our way into the street. "What a selfish fellow Crusher is," are the first words that fall from the assistant. "He knew that I had that operation to perform, that it was the only one I had had for a month, and that the students were all due at the Medi-

cine class in a quarter of an hour, and yet he takes up all the time with his long-winded commonplaces. I wonder whether *my* time will ever come." Just then we are hailed by a Hansom cab on its way to the railway station. Sharp's rubicund visage looks out, and he greets us with "Good bye, old fellows. I have just been telegraphed for. Old Lady Broadacres has tumbled down stairs and broken the neck of her femur, and I have two stone cases at the West Thrington to-morrow." We walked home musing on which was in reality the true path to Surgical honour.

## THE WEEK.

### THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE meeting of the General Council has been marked by several votes, which require special notice from us. As it is more pleasant to award praise than blame, we would, in the first place, congratulate the Council on the vigour they have shown in dealing with certain offenders against Professional morality. The names of the notorious Robert Jacob Jordan, and of the still more notorious Samuel La'Mert, have been erased from the Register which they had disgraced. An application made by Mr. Richard Organ to the Society of Apothecaries, to be admitted to examination, having been referred by the Court of Examiners to the Council, that body were recommended not to examine Mr. Organ, on the ground that he had endeavoured to procure a license from the College of Physicians of Edinburgh by personation. The cases of John Lacey and John Potter Sargeant, persons whose names had been formerly erased from the Register, were also discussed. These cases are still *sub judice*; that of Lacey having been referred to the Branch Council, in order that his statement may be heard, and that of Sargeant to the Executive Committee, who are to require satisfactory evidence of character. The Council refused to comply with the petition of John Kearney, of Clonmany, for re-registration. A thorough desire to do their duty in this department, and to keep the Profession pure from quackery and imposture as far as their powers permit, seems to have animated the Council, and they deserve and will receive the credit which appertains to a just discharge of their functions.

We now turn to matters of a different complexion. In the first place, by the casting vote of the President, reporters for the press are still excluded. This may be a merciful arrangement for us of the fourth estate, considering the amount of *vox et preterea nihil* which characterises the proceedings of certain Medico-political conclaves we wot of; but in this matter we are bound not to consider our own ease, and we object to the policy of the Council as contrary to the spirit of open discussion which is embodied in the institutions of this country, and to the maintenance of a due sense of responsibility amongst the members of the Medical Parliament. A still graver charge against a small majority of the Council is, that they continue to permit the Royal College of Surgeons of England and certain of the Scottish Universities to set at naught their educational recommendations, and to defy their authority. It is true that the Council of the College of Surgeons has condescended to address a letter to the General Council, in which they argue in favour of the course they have adopted. But their argument terminates in the announcement that they "accordingly propose to continue their regulations on the subject" of general and professional education. We do not now discuss the wisdom of the apprenticeship system, nor the precise time at which a preliminary examination ought to be passed. The broad fact lies before us that the recommendations of the General Council of Medical Education of Great Britain have been openly and publicly set aside, that the General Council find themselves incompetent to enforce their own regulations, and that they have quietly submitted to be bearded by a Corporation which the law has placed under

their authority. Such a state of things requires no comment. It is bootless to speak of the injustice dealt out to loyal Corporations—a point which has been fruitlessly urged by the President of the Royal College of Surgeons of Edinburgh. Equally useless is it to descant on the contempt to which a narrow majority has subjected the whole body to which they belong. It is plain that an assembly which does not respect its own acts and powers can command but slight respect out of doors. The motion of Mr. Teale, that a year spent in pupilage to a Practitioner holding the appointment of Surgeon to a Hospital, Dispensary, or Union Workhouse, should be recognised as part of Medical education, provided it be passed after the first year of studentship, agreeing as it does in spirit with the view we have taken on the apprenticeship question, cannot be held to settle the matter. It remains a fact that the recommendations of the General Council are not binding on any Corporation or University, for the Council itself has ratified their disavowal by one of the leading educational bodies of the Medical commonwealth.

---

PARLIAMENTARY.

ON Monday night the House of Commons listened to Mr. J. A. Smith's narration of some extraordinary occurrences which have recently taken place in the girls' school of the Royal Victoria Patriotic Asylum. The explanation afterwards given by Sir John Pakington, one of the Royal Commissioners of the Patriotic Fund, appears to us to have left the main facts alleged untouched. The idea of punishment and of treatment entertained by the officials of Wandsworth is, we trust, peculiar to themselves. Under the category of punishment comes the case of a girl of sixteen who was flogged with a birch rod by order of the chaplain. Under that of treatment, we have an instance of two girls sent by desire of the secretary to town to be mesmerised. With regard to the former, it may be that the punishment was meted out for some flagrant crime, for it was stated that theft was not uncommon in the school. But birching young women of sixteen smacks too much of St. Petersburg to suit our English taste. The result, as might be supposed, was the resignation of a large number of ladies who acted on a committee appointed to investigate the condition of the school. The birch is now said to be discontinued, but the cane is still honoured in the establishment. Mesmerism, we suppose, is also abandoned, as Mr. Corry assured the house that a Medical officer of experience attended the Asylum daily, and no cases were treated except under his direction. A more serious case than either of the preceding was brought forward by Mr. Smith. It appears that a girl named Bennett was subjected to solitary confinement for two days for some act of insubordination by direction of the chaplain. She was locked up during the day, and only released at night to go to bed. At half-past eight on the evening of the second day, when another girl went to visit her, to take her food, and to set her at liberty, she was found burnt to death. She was the daughter of a soldier, but not a pupil. She was too old to be admitted as a pupil, but she was admitted as a servant, for the purpose of instruction in domestic duties, and received no wages. A coroner's inquest was held, and a simple verdict of "Accidental death" returned. The lady superintendent, it is admitted, was absent at the time of the occurrence. But there can be no doubt that the whole circumstances were highly disgraceful to the management of the Asylum.

We are glad to see that on Tuesday night Mr. Fenwick's motion of "An Address to her Majesty to issue a Royal Commission of Inquiry into our Sea Fisheries, with the view of increasing the supply of a favourite and nutritious article of food for the benefit of the public," was carried by a majority of 50 to 27. Mr. Fenwick, after stating the almost incredible numbers of fish consumed in

England, and the enormous amount of the capital embarked in the trade, observed that it was generally acknowledged that the fisheries were falling off year by year, and that, unless something were done to arrest this progressive diminution, the result would be serious. He then pointed out the causes of this reduction in the produce of the fisheries—namely, the waste and destruction of the spawn, the taking of fry and small fish, and the mode of fishing, the causes being similar to those which had destroyed the salmon fisheries. He read various communications and reports in confirmation of his statements, and instanced the success that had attended the appointment of a Commission of Inquiry into the salmon fishery. The increasing population of England can ill afford that any food supply should be diminished, much less one that requires neither land nor labour for its production.

---

THE DEATH OF SIR CULLING EARDLEY.

WE need not repeat what we said last week, to the effect that vaccination is no plaything; nor is there anything surprising in the fact that an agent so potent should occasionally run riot, if the health of the recipient be in an unsatisfactory state. It is most deeply to be regretted that so benevolent a man as Sir Culling Eardley should have fallen a victim to this usually life-preserving and beneficent operation. But as it is, the circumstances are worthy to be put on record, and we willingly insert the following account, for which we have to thank Dr. Tasker Evans, of Hertford. We would also especially call attention to the letter of Dr. Miller, recording cases of small-pox during vaccination in India, published in another part of our columns. Dr. Evans writes:—

"In consequence of one of the lady's-maids having fallen ill at Bedwell Park with small-pox, I was requested by the late Sir Culling Eardley to call and re-vaccinate the whole of the establishment, which I did on the 19th of April. They were all adults, eighteen in number, and the vaccine lymph inserted into Sir Culling's arm was from the same source as that used for the other members of the family, who all did well. When I saw Sir Culling's arm on the 23rd, there was no appearance of the vaccine vesicle, but more inflammation and swelling than I have usually seen after re-vaccination. These symptoms increasing, Dr. Headland met me in consultation, and it was our hope the case would yield to treatment; but, on the 23th the symptoms becoming more unfavourable, Mr. Headland saw him. Yet we still hoped that the case would terminate favourably; but, on the 2nd of May, we feared there were purulent deposits into the cellular tissue of the arm. The following day Mr. Headland came again to Bedwell, accompanied by Mr. Hancock, of the Charing-cross Hospital. The latter gentleman made incisions into the upper and fore-arm, when a good deal of matter oozed out; there were further operations of the kind required afterwards. Sir Culling was relieved by these operations. Suitable nourishment and medicine were administered to support the system, and opiates were given at night. After some days, sloughs separated, and the arm seemed going on tolerably well; but on the 18th there was more constitutional disturbance, giving ground for increased anxiety, and symptoms of pyæmia appeared on the 20th. Death ensued on the following morning."

---

POISONING BY CHLORIDE OF ZINC.

THE following case of accidental poisoning appeared in the *Times* of last week. This is at least the seventh instance of poisoning which has resulted from the reckless obstinacy of the proprietors of Burnett's disinfectant, who persist in selling to the public a corrosive irritant in bottles which closely resemble in shape and general appearance those in which Dinneford's solution of magnesia is supplied:—

"A most distressing case of accidental poisoning occurred a few days ago at the hamlet of Rusthall, near Tunbridge-wells. The deceased, Maria Frances Jane Wood, was the wife of Captain T. P. Wood, late of the 29th Regiment. It appeared by the evidence adduced at the inquest on Tuesday, that the deceased, who had recently been confined, had been

accustomed to take occasional draughts of 'Dinneford's pure fluid magnesia,' a bottle of which was kept upon a shelf in Mrs. Wood's dressing-room, in which her maid and the baby slept. On the morning of the previous Saturday, about five o'clock, the maid, having been requested by her mistress overnight, took down from the shelf what she supposed to be a bottle of magnesia, and, pouring out three-quarters of a wineglassful, took it to her mistress, who drank it. Mrs. Wood felt a burning sensation, and asked her maid to fetch the bottle out of which she had taken the liquid. The maid then discovered that she had administered to her mistress a quantity of 'Sir William Burnett's disinfecting fluid,' which is a well-known active corrosive poison. Mrs. Wood, immediately she ascertained the mistake, took a large dose of castor oil, and Dr. Johnson, who arrived as speedily as possible after he received information of the accident, administered a mixture of milk, oil, and eggs, and afterwards the stomach-pump was used. The unfortunate lady, however, never rallied from the violent shock to her nervous system, and died about midnight on Sunday. It transpired during the inquiry that the bottle of disinfecting fluid had been used by the monthly nurse during the confinement of the deceased, and that she had left it on the same shelf as the fluid magnesia. In the meantime the maid had not administered any medicine to her mistress, and, being unaware that the bottle was on the shelf beside the magnesia, seized it in the hurry of the moment. Glancing at the label, she saw the word 'fluid,' and thought it was a bottle of magnesia which she had used previously to the confinement of her mistress. It was singularly unfortunate that the two bottles were alike in size and form, and in the colour both of the glass and liquid. The label on both was large, and the word 'fluid' was in a prominent line. The bottle of disinfecting fluid, however, was fluted at the back, denoting that it contained poison, though the word 'poison' was not printed upon it. The maid was described as a very kind and attentive servant to her mistress, who fully exonerated her from blame, and expressed a hope, when death was approaching, that she would continue to take charge of the infant, and be as attentive to Captain Wood (who has become totally blind from the effects of an accident sustained in military service) as she had previously been, and Captain Wood expressed himself in similar terms. The jury returned the following verdict:—'That the deceased died from the effects of a dose of Sir William Burnett's disinfecting fluid accidentally given for a dose of Dinneford's fluid magnesia; and the jury cannot separate without expressing their strong disapprobation that a mixture of such a poisonous nature as the former should be sold without the bottle being legibly labelled with the word "Poison," and they request the coroner to communicate with the agents for the fluid accordingly.'

## GENERAL CORRESPONDENCE.

### IS RE-VACCINATION DANGEROUS?

LETTER FROM DR. MILLER.

[To the Editor of the Medical Times and Gazette.]

SIR, — Your remarks on vaccination, and Mr. Wells' letter upon re-vaccination, have recalled to me some facts connected with the subject which came under my immediate observation. I send them to you with the hope that they may call forth others of a similar character, and make Medical men reflect and determine that the little operation is not so trifling or free from serious consequences as many suppose.

In Calcutta, in the year 1850, a severe epidemic of small-pox broke out. Its ravages were most severely felt amongst the natives; the Europeans and Eurasian population suffered also. The *furor* for re-vaccination was great. Two cases, adults, both good-looking women, were re-vaccinated with healthy lymph, selected with great care by the Superintendent of Vaccine; but in both cases, on the eighth day, variola set in, of a confluent form; and though they both narrowly escaped with their lives, the indelible impression of the disease is to be seen on their faces to this day. One of these cases was so bad, that for nine consecutive days she was supported entirely by beef-tea and brandy enemata: the mucous membrane of the mouth was in such a pustular condition she could not swallow, and in the air-passages also I infer, because she had aphonia for six months after her attack.

The most painful case of all was the following:—I vaccinated, in August, 1854, when no epidemic prevailed, a healthy infant, the first child of a mother aged twenty. The vesicle passed through all its stages to maturation. The mother was suffering from "prickly heat," and had abraded the skin on the right fore-arm by scratching it (a common thing in the tropics). In carrying her child the vesicle burst, and the lymph trickled over the abraded surface; in short, she accidentally re-vaccinated herself. On my visit to inspect the child's arm on the eighth day, the mother showed me her own. I treated it with indifference. On the sixth day she was attacked with rigors, followed by fever; on the eighth day a pustular eruption appeared, which proved to be variola of the most confluent form. She soon became the most revolting mass of corruption, and died on the seventeenth day from the date of the accidental re-vaccination. Need I add, that these experiences have impressed themselves on my mind. I am sure other Medical Practitioners in India will corroborate these cases, by offering some of a similar nature for publication.

These occurrences are so rare, that it is difficult to speculate on the causes from whence they arose. They were not dependent on impure lymph, because the utmost care was evinced in selecting it. In the two first the variolous poison was abroad, but the evidence of the last case goes against that, for no epidemic then existed. It may be fairly questioned whether they do not help to confirm the experiments made by Mr. Ceely, that vaccine and variola are one and the same disease, the latter modified by passing through the system of the cow, and whether there are not certain conditions in the human system already vaccinated which would favour the re-conversion of the vaccine lymph into variola, and so render re-vaccination a very questionable proceeding.

I am, &c.

J. W. M. MILLER, M.D.,  
Physician Royal Portsmouth, Portsea, and  
Gosport Hospital.

June 1.

## GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

MINUTES OF MEETING, WEDNESDAY, MAY 27, 1863.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

MR. GREEN, *President*, took the chair at Two o'clock, p.m.

*Present*—

Dr. Burrows.	Dr. Fleming.	Sir Charles Hastings.
Mr. Arnott.	Mr. Syme.	Dr. Sharpey.
Mr. Cooper.	Dr. Thomson.	Mr. Lawrence.
Dr. Bond.	Dr. A. Smith.	Mr. Teale.
Dr. Embleton.	Mr. Hargrave.	Dr. Christison.
Dr. Storrar.	Dr. Leet.	Dr. Stokes.
Dr. Alexander Wood.	Dr. Apjohn.	
Dr. Andrew Wood.	Dr. Corrigan.	

Dr. FRANCIS HAWKINS, *Registrar*.

The Minutes of the last meeting were read and confirmed.

1. Moved by Dr. BOND, seconded by Dr. STOKES—"That a Committee be appointed to take into consideration and to report (during the present meeting) what further steps it is desirable for the General Council to take in reference to the "British Pharmacopœia. The Committee to consist of

Dr. Christison, Chairman.	Dr. Acland.
Dr. Apjohn.	Dr. A. Smith.
Dr. Sharpey.	Mr. Arnott.
Dr. Stokes.	Dr. Storrar."
Dr. Burrows.	

—Agreed to

The Registers of Students for 1862-3, with explanatory letters, were submitted to the Council.

2. Moved by Dr. ANDREW WOOD, seconded by Mr. TEALE—"That the Registers of Students, with explanatory letters, be referred to the Committee on Returns."—Agreed to.

Read the following letter from the Royal College of Surgeons of England:—

"Royal College of Surgeons of England, May 4, 1863.

Sir,—I am desirous to acquaint you, for the information of the General Council of Medical Education and Registration, that the Council of this College, on the 13th of June last, appointed a Committee to consider—

"Whether any, and if so, what alterations it would be proper to make in the Regulations of this Council relating to the education and examination of candidates for the diploma of Member of the College, so as to bring them more in accordance with the recommendations of the General Medical Council in reference to general and professional education."

"That this Committee addressed letters to the Fellows and Members of the College holding appointments in the Hospitals, Infirmaries, and other charitable institutions of England and Wales, and to those engaged in large general practice, in order to ascertain what opportunities are available throughout the country for practical instruction in Medicine and Surgery, and what is their opinion on the best mode of commencing professional education. The whole subject of the College Regulations was examined carefully at repeated meetings of the Committee and of the Council. As the circumstances of those who intend to adopt the Medical

Profession, and the opportunities of instruction within their reach, are extremely various, the Council are of opinion that the course of education cannot be subjected to any absolute and inflexible rule without great disadvantage, and even much unnecessary hardship in particular cases.

"In the opinion of the Council, the leading principle in the education of those whose life will be devoted to the treatment of accidents and diseases should be to make it as practical as possible, especially at its outset. The minor duties of Surgery, especially in the manipulative department, and the usual course of injuries, diseases, and their treatment, can be understood in great measure without previous theoretic training; they are matters of great interest in themselves, calculated to excite and keep up the attention of the student, and to make him feel the advantage, or rather the necessity, of that clearer insight which is to be derived subsequently from scientific teaching in the schools. He thus becomes acquainted with those ordinary duties of his profession with which he will be principally occupied from the very commencement of his active career, although, in plain truth, they cannot be learned in a great school. The Council would think favourably of the arrangement if the early portion of the Medical education could be carried on at home, under the influence of domestic life and associations, or in the house of a competent master, so that the danger of sending an inexperienced youth into the world without guidance, and especially into a great Metropolitan Medical School, should be reduced to the smallest possible amount.

"The Council therefore are of opinion that an option should be left to parents and guardians as to the time and manner in which that portion of study not spent in Medical Schools should be employed, and accordingly propose to continue their Regulations on the subject.

"They have, at the same time, introduced modifications into their rules calculated to provide against irregularities and abuses, and to ensure the continued and efficient prosecution of the studies now required.

"Copies of the Regulations, as thus amended, are herewith enclosed.

"I have the honour to be, Sir, your obedient servant,  
"EDMUND BELFOUR, Secretary."

3. Moved by Dr. STORRAR, seconded by Mr. HARGRAVE—"That the letter of the Royal College of Surgeons of England now read be received, printed in the Minutes, and referred to the Education Committee."—Agreed to.

Read the following letter from the President of the Royal College of Surgeons of Edinburgh:—

"To the President of the General Medical Council.

"The Royal College of Surgeons, Edinburgh, May 19, 1863.

"Sir,—I am directed by the Royal College of Surgeons of Edinburgh, over which I have the honour to preside, to bring under the notice of the General Medical Council, at its ensuing meeting, the position in which the College has been placed by the proceedings of the General Medical Council.

"The College adopted the whole of the Recommendations issued yearly by the General Medical Council. It did so in the trust that other licensing bodies would likewise do so, and in the faith that, if they did not, the General Medical Council would not fail to endeavour to compel them to do so. I refer more especially to two of the most important of the Recommendations issued by the General Council. 1. That after September, 1861, the preliminary examination in general education be passed previous to the commencement of professional study. 2. That the commencement of professional study be understood to be the time of commencing study at a Medical School.

"After due notice given to intending students of the approaching changes, this College acted on these Recommendations, and accordingly no student beginning after September, 1861, was allowed by the College to register as a student of Medicine during Session 1861-2, who had not passed the whole of the preliminary examination in general education. In this course the College had the co-operation of the Royal College of Physicians of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, by both of which bodies the same regulation was announced and carried out. This Recommendation, however, was not adopted or carried out by other bodies conferring qualifications in Scotland (I refer to the Scottish Universities), the Regulations of which require the preliminary examination in general education to be passed before the commencement of professional study only 'as far as possible.' Again, the Recommendation defining the commencement of professional study to be by attendance at a Medical School, has not been adopted by the Royal College of Surgeons of England, which recognises attendance at an Hospital or Dispensary, or pupilage with a Surgeon, as modes of commencing professional study equally with attendance at a Medical School; and the fact of that College having issued such Regulations contrary and subsequent to the Recommendations of the General Medical Council, was prominently brought before the Council at its meeting in May, 1862.

"The General Medical Council, however, took no steps to enforce the adoption of its Recommendations by the bodies whose regulations were not in accordance with them, and even refused to pass a vote of disapproval of the course pursued by a body which had issued regulations contrary to the Recommendations of the General Council. By this course of procedure on the part of the General Medical Council, this College was placed in a very difficult position, and has reason to complain of having been led on by the Council to adopt regulations, in the endeavour to carry out which it has been deserted by the Council itself.

"I need hardly say that it is in vain for one licensing body to endeavour to carry out a regulation requiring the examination in general education to be passed before the commencement of Professional study, if the doors of other bodies are open without such a condition; or for one College of Surgeons to define the commencement of Professional study to be only attendance at a Medical School, so long as another recognises apprenticeship as one of the modes of constituting such commencement. In consequence, therefore, of the failure of the Medical Council to support the College in its endeavour to carry out the recommendations of the Council, the College has been compelled to suspend the operation of the regulations in question. This the College has done by attaching to section 1, chapter iii., to section 2, chapter iv., and to section 3, chapter v., of its printed regulations, issued in August, 1862 (a copy of which is herewith transmitted), a foot-note, intimating that, 'In consequence of the proceedings of the General Medical Council in May, 1862, this regulation will not take effect until further notice.' This course was adopted by the College after a conference with the Royal College of Physicians of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, held to consider the position in which the Colleges and Faculty were placed by the above-mentioned proceedings of the General Medical Council.

"In regard to requiring the examination in general education to be passed before commencing attendance at a Medical School, the College,

without expressing any opinion upon the merits of the question, is ready to enforce such a regulation, in the event of all the Colleges, Universities, and other licensing bodies engaging to do the same, from and after a certain date, and in such a manner as shall leave no room for doubt.

"In regard to Professional study, the College has avoided ambiguity, by simply fixing the number of sessions of attendance at a regularly constituted Medical School, as not less than four Winter Sessions, or the alternative of three Winter and two Summer Sessions; and I have to suggest to you, that, by adopting a similar formula, the General Medical Council would avoid the difficulty which—as experience has shown—arises from the use of a phrase so ambiguous, and so liable to evasion, as that of 'Professional study.'

"I may be permitted to add that the proceedings of the Medical Council above referred to have occasioned not only embarrassment to the College, but disappointment of the hopes entertained in the College of an improvement in Medical education through the influence of the Medical Council. Unless the Council will confine its Recommendations (as distinguished from the mere expression of what it considers desirable) to what it is able to enforce, and will show its intention to enforce them without fail or delay, on any of the bodies which shall have failed to adopt them at the specified time, it is obvious that the influence of the Medical Council for good to the Profession must be seriously impaired.

"I remain, Sir, your obedient servant,  
"P. NEWBIGGING, President."

4. Moved by Dr. STORRAR, seconded by Dr. SHARPEY—"That the letter of the President of the Royal College of Surgeons of Edinburgh now read be received, printed on the Minutes, and referred to the Education Committee."—Agreed to.

Read a letter addressed to Dr. Burrows by the Registrar of the Royal College of Physicians of London:—

"Royal College of Physicians, London, S.W., May 23, 1863.

"Dear Sir,—I am directed to state, for the information of the Medical Council, that this College has passed a bye-law (March, 1863), providing for the appointment of an additional Examiner in Surgery. After June, therefore, the examinations on the subjects of professional education will be conducted by

- Two Examiners in Anatomy and Physiology.
- " " Chemistry, Materia Medica, and Practical Pharmacy.
- " " The Principles and Practice of Medicine.
- " " The Principles and Practice of Surgery.
- " " Midwifery and the Diseases Peculiar to Women.

"I am also further directed to inform you that the College has passed the following Regulations:—

"That the University of Athens be added to the other Universities already qualifying candidates for admission to the examination of this College.

"That the testamur of having passed the Examination in Arts at Codrington College, Barbadoes, be accepted in lieu of the examination on the subjects of general education conducted by the Examiners of this College.

"That the certificate of the second class in literature and science of the Cape of Good Hope should be accepted in lieu of the examination conducted in the College before the admission of students to professional studies."

"I am, dear Sir, yours faithfully,  
"HENRY A. PITMAN, Registrar."

"George Burrows, M.D., etc.,  
Representative of the College in the General Council  
of Medical Education and Registration."

4. Moved by Dr. ANDREW WOOD, seconded by Mr. HARGRAVE—"That the letter from the Registrar of the Royal College of Physicians of London to Dr. Burrows be received, printed on the Minutes, and referred to the Education Committee."—Agreed to.

Read the following letter from the Director-General of the Army Medical Department:—

"Army Medical Department, March 14, 1863."

"Sir,—I have the honour to forward the enclosed correspondence from the College of Surgeons of Ireland, by which it will be seen 'that the Council of this College has granted diplomas to its Fellows and Licentiates, testifying that they are qualified to practise Medicine as well as Surgery,' and to inform you that, having submitted the same to the Right Honourable the Secretary of State for War, together with your reply to my letter of the 12th ult., stating that you have no authority to answer the question as to whether the holder of the licence of the Royal College of Surgeons in Ireland, registered as such, is qualified to practise Medicine as well as Surgery. I have been directed by Sir George Lewis to refer this question to the General Council of Medical Education, and have therefore to request you will be pleased to submit the same to the next meeting of the General Council, and to favour me with their reply.

"I have the honour to be, Sir,  
"Your most obedient humble servant,  
"J. B. GIBSON, Director-General."

"The Registrar, General Council of Medical Education,  
32, Soho-square, W."

5. Moved by Mr. HARGRAVE, seconded by Mr. SYME—"That the Licentiates of the Royal College of Surgeons in Ireland, registered as such, are qualified to practise both Medicine and Surgery, in accordance with the powers of the Medical Act."

The debate on this motion was adjourned.  
Confirmed—JOSEPH HENRY GREEN.

MINUTES OF MEETING, THURSDAY, MAY 28, 1863.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

MR. GREEN, President, took the chair at Two o'clock p.m.

Present—

- |                     |                  |                       |

| Dr. Alexander Wood. | Dr. Apjohn.      |                       |

Dr. FRANCIS HAWKINS, Registrar.

The Minutes of the last meeting were read and confirmed. The adjourned debate was resumed on Mr. HARGRAVE'S motion, viz.—"That the Licentiates of the Royal College of Surgeons in Ireland, registered as such, are qualified to practise both Medicine and Surgery, in accordance with the powers of the Medical Act,"

1. Question put—"That Mr. Syme be allowed to withdraw his name as seconder of the foregoing motion."—Carried.

Mr. HARGRAVE required that the majority and minority be entered on the Minutes.

<i>Majority—</i>	<i>Minority—</i>
Mr. Cooper.	Dr. Burrows.
Dr. Acland.	Dr. A. Smith.
Dr. Bond.	Mr. Hargrave.
Dr. Embleton.	Dr. Apjohn.
Dr. Storrar.	
Dr. Alexander Wood.	
Dr. Andrew Wood.	
Dr. Fleming.	
Mr. Syme.	
Dr. Thomson.	
Dr. Leet.	
Dr. Corrigan.	
Dr. Sharpey.	
Mr. Teale.	
Dr. Christison.	
Dr. Stokes.	

2. Moved by Dr. CORRIGAN, seconded by Dr. SMITH—"That the Registrar be directed to forward the following reply, with the documents referred to, to the Director-General of the Army Medical Department:—

"Sir,—I am directed by the General Council of Medical Education and Registration, in reply to the inquiry in your letter of March 14, 1863, 'whether Licentiates of the Royal College of Surgeons, registered as such, are qualified to practise Medicine as well as Surgery,' to inform you that a similar question has been already before the General Council, having been submitted by the Poor-Law Board of England, in a communication of August 5, 1859, and the reply of the General Medical Council will be found in the Minutes of the meeting of General Council of August 10, 1859, a copy of which is herewith sent.

"The General Council, in explaining in that Minute the nature of the qualifications or licences legally granted by the several licensing bodies, enumerated the Royal College of Surgeons in Ireland among the bodies authorised to grant only a Licence or Diploma in Surgery.

"The Royal College of Surgeons of Ireland raised the question again before the Poor-Law Board of Ireland, in October, 1862.

"The Poor-Law Commissioners of Ireland referred the matter to the law officers of the Crown, the Attorney-General and Solicitor-General for Ireland.

"The following is their opinion:—'After perusing and considering the charters of the College of Surgeons, we are of opinion that it has not the power, and is not competent, to grant a Diploma or Degree in Medicine.'

"A copy of the opinion is herewith sent. The correspondence at length between the Poor-Law Commissioners of Ireland and the Royal College of Surgeons of Ireland will be found in the Annual Report (16th) of the Poor-Law Commissioners for Ireland, dated March 21, 1863.

"If the opinion of the law officers of the Crown in Ireland be correct, the Royal College of Surgeons of Ireland has not power, and is not competent, to grant a Diploma or Degree in Medicine."

Amendment moved by Dr. STORRAR, seconded by Dr. SHARPEY—"That the Director-General of the Army Medical Department be respectfully informed that the question, whether the Licentiates of the Royal College of Surgeons of Ireland are qualified to practise both Medicine and Surgery, is one of legal interpretation, on which the Council declines to pronounce an opinion."

The amendment was put, and negatived.

The original motion was then put, and carried.

Dr. ANDREW WOOD required that the majority and minority on the original motion be entered on the Minutes.

<i>Majority—</i>	<i>Minority—</i>
Dr. Burrows.	Dr. Acland.

Dr. Andrew Wood.	Dr. Sharpey.
Dr. A. Smith.	
Dr. Apjohn.	
Dr. Corrigan.	
Sir Charles Hastings.	
Mr. Teale.	
Dr. Stokes.	

3. Moved by Dr. CORRIGAN, seconded by Dr. A. SMITH—"That the Report of the Committee of the King and Queen's College of Physicians in Ireland, on the recommendation of the General Council relative to Preliminary and Professional Education, be printed in the Minutes."—Agreed to.

#### KING AND QUEEN'S COLLEGE OF PHYSICIANS, IRELAND.

*Report of the Committee on the Communication of the General Council relative to Preliminary and Professional Education.*

The President and Fellows of the King and Queen's College of Physicians in Ireland have had under consideration the Report of the General Medical Council of August 11, 1859, on Preliminary and Professional Education and Examination; and, fully impressed with the great importance of the subject, they desire to submit the following observations:—

They consider that the mere "opinion" or "recommendation" of the General Medical Council as to what should be required in education and examination will be of no avail to insure competent education and efficient examination in the present circumstances of the numerous qualifying or licensing bodies in the United Kingdom; for, as the incomes of many of them are dependent more or less on the fees received for licences and degrees, each licensing body is deterred from raising its standard of education and examination to what it may consider adequate, by the apprehension that, in so doing, such standard may exceed the requirement of some other licensing body, and that thus candidates may desert the body requiring the higher standard to obtain a qualification elsewhere on easier terms. This apprehension has not only prevented improvements in education and examination, but it has led to a downward competition, that has of late years caused a progressive deterioration in the standard of preliminary and professional education and examination.

The College is of opinion that this great fundamental defect can only be met, in the present state of the law, by the General Medical Council laying down a definite scheme of preliminary and professional examination for the several Medical licensing bodies; and in the event of any of those

bodies not adopting such scale, that then the General Council should have recourse to the powers vested in them under clause xx. of the Medical Act, and apply to the Secretary of State to have such college or corporation removed from the list of recognised licensing bodies.

It has become the more imperative to lay down such a scheme since the passing of the Medical Act, as previously to the passing of the said act the degrees and diplomas of the several universities and colleges held different values in public estimation, according to the standard of education and examination demanded by each; but the Legislature having, by the Medical Act, placed all degrees and diplomas in Medicine and Surgery from the several universities and colleges on an equality, it is now incumbent on the General Medical Council to enforce uniformity in education and examination according to the respective qualifications granted.

The College begs to submit the following observations on preliminary education:—

The preliminary education of the Medical student demands the greatest attention. In it is most fully seen the baneful effect of each corporation fearing that its standard may be higher than that of another: and the unfortunate result of preliminary examination not being required previously to entrance on professional education is, that young men enter on the study of the Profession, not only ignorant of Latin and Greek, and of any modern foreign language, but unacquainted with the simplest rules of English composition. As the only occasion of testing preliminary education that presents itself is at the final examination, the consequence is, that if there be then any examination at all in preliminary education, it becomes little more than a mere form, inasmuch as it would be considered harsh to reject a candidate for deficiency in preliminary education after he had spent several years in the study of the Profession.

This great evil can only be obviated by requiring a definite preliminary examination, which the student must pass in whole or in part before commencing his Medical studies.

The College does not approve of the view put forward in the following extracts from the Report of the Medical Council as to the mode of testing preliminary education:—

"That, as far as may be practicable, testimonials of proficiency granted by the national education bodies, according to the following list, be accepted, with such additions as the Medical Council may from time to time think proper to make.

"That the examination on general education be eventually left entirely to the examining boards of national education bodies recognised by the Medical Council."

The following are the reasons on which the College dissent from the foregoing recommendations:—

There never could be any certainty that the "testimonials of proficiency," or "the examination on general education," of the examining boards of "national education bodies" would be, or continue to be, uniform, or such as might be applicable to the Medical Profession. The examinations might frequently vary. They might be from time to time of too high or too low a standard; they might comprise branches of knowledge not requisite as preliminary to a Medical education; or they might be deficient in branches which are essential, and the times of the year at which some of them are held would be inconvenient for Medical students. There would be thus entailed on the General Medical Council the annual task of revising the regulations of all the national education bodies of the United Kingdom; and thence would arise alterations, extensions, or withdrawals of recognition, creating annually perplexity and confusion, which would be still further increased by the changes that are now taking place in progress in some of the universities, by which the undergraduate course is being divided into two departments, one for literature, the other for science.

The General Medical Council would appear to have already in some measure entertained the view here put forward, that a definite code of preliminary education for the Medical Profession should be laid down, for they admit that "a very few, though important branches of knowledge" will require to be specially provided for in the education and mental training of the Medical student. (a)

For the above reasons, the President and Fellows of the King and Queen's College are of opinion that the General Medical Council should originate a scheme of what they consider a sufficient preliminary education and examination for students of their own Profession.

This scheme being thus laid down by the Council, all students who had gone through such examinations in the arts' course of any university as comprised the subjects of such preliminary examination, or who had undergone examination before national education bodies recognised by the General Council, which should in like manner comprise the subjects of preliminary education as laid down by the General Medical Council, should be considered as having passed their preliminary examination. This plan would preserve to the Profession the independence of regulating its own curriculum of preliminary education, and at the same time recognise all arts' courses and examinations of national education bodies which contained the required curriculum.

The President and Fellows are, however, of opinion that the mere matriculation or entrance examination of any university, even though it should ostensibly include all the subjects in the scheme of the Medical Council, should not be received in any case as a sufficient guarantee of the possession of the requisite preliminary education, as the College is aware that many educational authorities are of opinion that matriculation or entrance examinations should be as lenient as possible, in order that students might not be deterred from entering on a university course.

The proposed plan, it is suggested, will preserve a proper control over preliminary education, insure its consonance with the peculiar requirements of the Profession, and tend to enlarge the sphere of the student's general acquirements; for, while any insufficient course of education will be rejected, there will be an encouragement to his entering on an arts' course that may contain more than he requires, and that will exempt him afterwards from any special examination in preliminary education.

The College would suggest the following as the subjects of preliminary or general education and examination, viz.:—

English composition.		
French or German—translated into English.		
Latin,	do.	do.
Greek,	do.	do.
Logic.		

(a) The General Council "believe that, with the exception of a very few though important branches of knowledge, the education and mental training of the students destined for the Medical Profession ought not to differ from those adopted for other professions."—*Vide* Report, p. 1.

Physics, including Elementary Mechanics.  
Optics; Hydrostatics; Pneumatics.  
Mathematics, including Arithmetic to end of Decimal Fractions.  
Algebra, to end of Simple Equations, involving one unknown quantity,  
Euclid, first three Books.

There still remains a class of students, though it is hoped their number will rapidly diminish, who may not have gone through a sufficient portion of an University Arts' Course, or undergone any other examination, for whom it will be necessary to provide a preliminary examination.

With regard to these, the following plans are submitted for consideration:—

I. That examiners, to be appointed by the respective Branch Councils of England, Ireland, and Scotland, which severally represent the licensing bodies of their respective divisions of the United Kingdom, should at certain stated periods forward, with due notice, to an authorised person in the several cities or towns in which recognised Medical schools are established, printed examination papers, under regulations such as are now adopted in examinations in the Civil Service Department; or—

II. That at stated periods the students of this class should attend at London, Dublin, or Edinburgh, to undergo a like examination as in the Civil Service.

The College desires to express its preference for the first of these plans.

Before quitting the subject of preliminary or general education, the College desires to draw the attention of the General Medical Council to an inconsistency in the list of bodies proposed to be recognised in Ireland as competent to grant "testimonials of proficiency," by their ordinary examinations. The matriculation examinations of the three Colleges of the Queen's University, viz., the Queen's Colleges of Belfast, Cork, and Galway, and of the Apothecaries' Hall of Ireland, are excluded, although comparatively extended, and with a very moderate fee annexed; while the entrance examination of the Dublin University is the only testimonial recognised, which is not so extended as the others, and for which the fee is so heavy as almost to amount to a prohibition.(h)

The Apothecaries' Hall of Ireland is protected against competition, and has therefore a power of maintaining the curriculum as above, which the other corporations named in Schedule A of the Medical Act do not possess; for Clause LV. of the Medical Act enacts that "nothing in this Act shall extend or be construed to extend to prejudice or in any way affect the rights, privileges, or employment of duly licensed apothecaries in Ireland, so far as the same extend to selling, compounding, or dispensing medicines;" and by the Apothecaries' Act of Ireland of 1791 (31 Geo. III. c. 34, s. xxvi.) it is enacted that, "if any apothecary shall open shop or warehouse for the retail of medicine, or practise the art and mystery of an apothecary, within the kingdom of Ireland, without such person or persons having obtained the proper certificate for that purpose hereinbefore directed, such person so offending shall for every such offence forfeit the sum of twenty pounds, to be recovered by the Governor and Company of the Apothecaries' Hall of Dublin."

With regard to recommendation No. 8, that no student should be permitted to begin his Professional studies who had not previously passed the requisite preliminary examination, the College is of opinion that it would be more conducive to a sound general education for the student to undergo it in two parts:—the first, comprising English, Latin, Greek, and arithmetic, previously to his beginning any Professional study; the second part, containing a modern language, logic, mathematics, algebra, and

(b) The following are the Curricula of the Matriculation or Entrance Examination of the several bodies above mentioned, with the fees of each, viz:—

Apothecaries' Hall of Ireland.	Queen's College, Belfast.	Queen's College, Cork.	Queen's College, Galway.	Dublin University.
<i>Latin.</i> Sallust. Virgil. <i>Greek.</i> Gospel of St. John; Or Dialogues of Lucian; Or Homer's Iliad, two Books. <i>French.</i> Telemachus. Charles XII. <i>Science.</i> Euclid, two Books. Algebra, including simple Equations. Arithmetic, especially Decimals. <i>Composition.</i> <i>English.</i>	<i>Latin.</i> Horace. Quintus Curtius. Virgil. Livy. Sallust—Caesar. Any two of the above Books which the Candidate may select; with translations from English into Latin. <i>Greek.</i> Homer. Euripides. Xenophon. Lucian. Any two of the above. <i>English Language.</i> English Grammar and Composition <i>History.</i> Roman History. <i>Geography.</i> Ancient and Modern. <i>Mathematics.</i> Euclid. Algebra. Arithmetic.	<i>Latin.</i> Virgil. Re-translation into English from Cæsar. <i>Greek.</i> Xenophon. Grammar. <i>Mathematics.</i> Euclid, Book I. <i>Arithmetic.</i> <i>English.</i> Grammar.	<i>Latin.</i> Any one of the following authors:— Virgil. Horace. Sallust. Cæsar. Re-translation <i>Greek.</i> Any one of the following authors:— Homer. Xenophon. Lucian. <i>Mathematics.</i> Euclid, two Books. <i>Arithmetic.</i> Algebra. <i>English.</i> English Grammar and Composition <i>History.</i> Grecian and Roman. <i>Geography.</i> Ancient and modern.	<i>Latin.</i> Any two of the following:— Virgil. Horace. Sallust. Livy. Terence. <i>Greek.</i> Any two of the following:— Homer. Gospel. Euripides. Sophocles. Plato. Lucian. Xenophon. <i>English.</i> Composition. <i>History.</i> <i>Algebra.</i> <i>Geography.</i> Moderu.
Fee 5s.	Fee 10s.	Fee 10s.	Fee 10s.	Fee 16guineas.

physics at the end of the first and second year's professional study, to be undergone previously to his admission to the first professional examination.  
By thus prolonging the general or preliminary education into the first years of professional study, a better general education would be secured to the student, than by premature and isolated studies of literature and science.

On the second division of the subject of professional education, the College desires to observe that they consider it most desirable that the examination should be divided, as recommended by the Education Committee, into two parts: the first comprising the elementary and collateral branches; the second, the practical department of Medicine, Surgery, and Midwifery.

The College does not think it necessary at present to go into details of courses of lectures or branches of study; these will more properly remain for the consideration of the General Council.

It is, however, equally as incumbent on the General Medical Council to lay down a course of education and examination under the head of Professional education, as under the head of preliminary or general education; and the College only desires at present to suggest that, in the second or final part of the professional examination in Medicine and Surgery, a portion of it should be strictly practical, viz., by examination and diagnosis, and proposed treatment of Hospital cases at the bed-side, carried out under the immediate observation of the examiners; and also, in addition to the *visd voce* examination, that a portion of the examination should be by papers, which would be available for reference, in the event of any inquiry being found necessary as to the efficiency of the examination.

The College attaches much more value to efficient examination than to any code of education or courses of attendance on lectures or Hospital practice; for they believe it will be admitted, that under the present system the required certificates can frequently be obtained without any sufficient evidence of regular attendance on the part of the student, or any proof whatever of his having acquired any Professional knowledge during such attendance.

The College is also of opinion that, in all applications for diplomas in medicine or surgery, the applicant should state whether he has been previously rejected by any of the Universities or Colleges; for it is well known that at present it is frequently the case that a rejected candidate passes in quick succession from one examining body to another, until he meets with an examination sufficiently low to permit him to pass it. It might be advisable to have a regulation, that a candidate rejected by any University or College should not be examined by any other until a period of— months had elapsed.

Should any of the plans here proposed, or any others, which will enforce uniformity and sufficiency of education and examination, be adopted by the General Medical Council, the President and Fellows of the King and Queen's College of Physicians in Ireland will support and carry it out; but they have no confidence in the construction or permanence of any scheme of education or examination which is not rendered compulsory on all; nor do they consider it practicable for any of the several corporations to sustain any improved code of education or examination while it is left optional with other competing licensing bodies to adopt it or depart from it.

P.S.—The question of the fees payable for degrees or diplomas has not been alluded to in the Report; but the College would suggest that the subject is one deserving the consideration of the General Council.

The College is not sufficiently acquainted with all the relations and circumstances of the several licensing bodies of England and Scotland to offer any general observations in reference to the United Kingdom.

They beg to observe, that in Ireland there are at present four public bodies granting degrees or diplomas in medicine and surgery, viz., the University of Dublin, the Queen's University, the King and Queen's College of Physicians, and the Royal College of Surgeons. Of these, the two former, viz., the Dublin University and the Queen's University, are in possession of large endowments granted by the State in former years, or of a large annual Parliamentary grant; while the other two, viz., the King and Queen's College of Physicians and the Royal College of Surgeons, receive no aid from the State, and are wholly dependent on the fees received from candidates for examination.

It appears to the College that a competition as to fees between bodies so differently circumstanced would be most unfair; and the College hopes that, on the subject being brought under the notice of the representatives of the several licensing bodies constituting the General Council, such a scale of fees for degrees and diplomas will be arranged as will be satisfactory and just to all concerned.

Ordered by the College to be printed.

April, 1863.

LOMBE ATTHILL, M.D., Registrar.

Read the following memorial from the Company of the Apothecaries' Hall of Dublin:—

To the General Council of Medical Education and Registration of the United Kingdom.

The Memorial of the Company of the Apothecaries' Hall of Dublin

Sheweth,—That by Royal Warrant for the regulation of Medical Officers of the Army, bearing date October 1, 1858, and issued subsequently to the passing of the "Medical Act," it is required that every candidate for the Army Medical Service, before being allowed to present himself at the Competitors' Examination, should, in addition to a Diploma in Surgery, "produce a Qualification in Medicine, or a Licence to practise it from one of the Colleges or Bodies legally authorised to grant a Certificate to that effect, or that qualifies a Civilian to practise Medicine" in Great Britain or Ireland.

That the late Director-General of the Army Medical Department, and the late Secretary of State for War, signified their intention to recognise the licence of the Company of the Apothecaries' Hall of Dublin, as being one of the bodies enumerated in schedule (A) of the Medical Act, as "a certificate that qualifies a civilian to practise Medicine" referred to in the Warrant.

That the Medical Council, by raising doubts as to the sufficiency of the qualification granted by the Company, have prevented this recognition taking effect, and have thereby entailed obloquy and injury upon the Company and their licentiates.

That the Company have left no means untried to satisfy the Council of the power of the Company to grant a licence, such as entitles its holder to practise Medicine, as well as of their licentiates being both "de facto and de jure" Medical Practitioners; and in evidence thereof the Company have laid before the Council legal opinions by the highest authorities both

in England and Ireland; to wit, the Right Honourable Joseph Napier, late Attorney-General of Ireland, who states: "That, on a full consideration of the statutes and authorities (English and Irish) I am of opinion that the legal rights and privileges of the Irish Apothecary are not inferior to those of the English. That in the course of a considerable experience I have never known these rights or privileges doubted, or made a question in courts: several proceedings have taken place in later years to put down ignorant and unskilful persons who practised *though unlicensed*, but the general rights of the licensed Apothecary have not been, nor, as I conceive, could they have been properly questioned." And the Right Honourable Sir Richard Bethel, late Attorney-General of England, who, with the Irish Apothecaries' Act, the Medical Act, the Royal Warrant, and the objections of the Medical Council before him, states: "I have not the least doubt, therefore, of the Company of Apothecaries in Ireland being a body legally qualified and empowered to grant licences to *practise Medicine*, or of its Licentiates being *regularly qualified Medical Practitioners* within the true meaning and intent of 'the Medical Registration Act.' There can be no doubt of the right of existing and future Licentiates of the Apothecaries' Hall, Dublin, to be registered under that Act, and when registered as such licentiates to *practise Medicine*; the fact of being registered under the Medical Act is such a certificate as justifies a civilian to *practise Medicine*; and every person so registered has a good title to present himself at the competitive examination."

That the Company are induced thus briefly to restate their case, and from it make another appeal to the General Council, with the hope that they will be led to see that it is a matter not of favour, but of simple justice to recognise the licence of the Company as "a qualification in Medicine," and that having accepted the course of study and examination to be gone through in order to obtain this qualification, and having finally admitted the Licentiates of the Apothecaries' Hall of Ireland to the *Medical Register*, the Council cannot judicially deny to them the title which is common to all other persons similarly circumstanced, to present

themselves at the competitive examination for the appointment of Assistant-Surgeon in Her Majesty's service.

Signed, on behalf of the Apothecaries' Company of Dublin,  
JEROME O'FLAHERTY.

Apothecaries' Hall of Dublin, October 25, 1862.

4. Moved by Dr. STORRAR, seconded by Dr. ALEXANDER WOOD—"That the Memorial from the Apothecaries' Company, Dublin, be received and printed in the Minutes."—Agreed to.

5. Moved by Dr. LEET, seconded by Mr. SYME—"That the General Medical Council, having by their resolution of August 9, 1859, declared 'that the Licence of the Apothecaries' Hall of Ireland is not equivalent to a Degree from a University or College authorised to grant such;' and that this resolution being at variance with the provisions of the Medical Act, which does not recognise any difference in the qualifications of registered Practitioners, as regards the right of practice, further than as those qualifications refer to Medicine or Surgery; that this Council now declare that the Licentiates of the Apothecaries' Hall of Ireland are admitted to registration as Practitioners in Medicine."—The debate on this motion was adjourned.

Confirmed—JOSEPH HENRY GREEN.

MINUTES OF MEETING, FRIDAY, MAY 29, 1863.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Mr. GREEN, *President*, took the chair at Two o'clock p.m.

*Present*—As before.

The Minutes of the last meeting were read and confirmed.

Dr. BURROWS laid before the Council the Report of the Finance Committee.

1. Moved by Dr. BURROWS, seconded by Dr. ANDREW WOOD—"That the Report of the Finance Committee be received and entered on the Minutes."—Agreed to.

Report.

The Finance Committee beg leave to present, in the Table subjoined, a statement of the Estimated and Actual Income and Expenditure of the year 1862; also an Estimate of the Income and Expenditure, as far as the Committee are able to judge, for the year 1863.

(a) This includes the sum of £406 7s. for the General Meeting in October.

The Committee also append a statement of the actual and prospective expense of the publication of the Register, under the reduced charge for printing, and the arrangement that 2000 copies in sheets are to be purchased for circulation by Her Majesty's Government.

Statement showing the Actual and Prospective Saving in the Expense of Publishing the Register.

750 Copies of the Medical Register for 1862 cost .. ..	£439 5 7
Total Receipts for Sale of ditto .. ..	85 2 0
Loss in 1862 .. ..	£354 3 7
750 Copies of the Medical Register for 1863, under the new estimate (see General Minutes, No. 38, p. 2, and No. 42, p. 5, and Executive Committee Minutes, No. 37, p. 2), cost .. ..	325 15 10
2000 Copies in sheets to be circulated by Government .. ..	168 0 0
	£493 15 10
Probable Produce by Sale of the Medical Register for 1863, say .. ..	£80 0 0
By Sale of 2000 to the Government .. ..	250 0 0
	330 0 0
Loss in 1863 .. ..	£163 15 10
In future years the cost of 2500 Copies of the Medical Register will be about .. ..	475 0 0
And the Produce of the Sale about .. ..	330 0 0
Leaving a deficiency of about .. ..	£145 0 0

The Finance Committee of 1862 called the attention of the Council to the cost of publishing the monthly lists of new entries on the local Registers (see General Minutes, No. 42, p. 11), and the Council, on the recommenda-

tion of the Committee, directed that henceforth the publication of the lists should be quarterly. The result of this change has been as follows:—

The Monthly Lists for 1861 cost .. ..	£53 17 6
The Quarterly Lists for 1862, as recommended by the Finance Committee of last year, cost .. ..	30 0 0

Being a saving of .. .. £23 17 6

The Finance Committee have also suggested certain modifications in the Annual Statement of Receipts and Expenditure, etc., for the consideration of the Executive Committee.

The Committee have again to report that, with respect to the further demand that may be made on the funds of the Council, on account of the publication of the Pharmacopœia, they can offer no approximate estimate.

The General Secretary of the Pharmacopœia Committee has placed before the Finance Committee a statement of Accounts for the past year, and this is appended to the foregoing Report.

We have examined this account and the vouchers, and find that there is a balance of £110 0s. 10d., as stated.

GEORGE BURROWS, M.D., *Chairman.*

On the motion of Dr. EMBLETON, the Council resolved itself into a Committee on Education.

Dr. EMBLETON laid before the Council a corrected tabular statement, showing the conformity or non-conformity of the Regulations of the Bodies in Schedule (A) with the recommendations of the Medical Council, and the reasons for non-conformity given by the respective bodies.

2. Moved by Dr. EMBLETON, seconded by Dr. STOKES—"That the corrected tabular statement, showing the conformity or non-conformity of the regulations of the Bodies in Schedule (A) with the recommendations of the Medical Council, be received and printed in the Minutes."—Agreed to.

TABLE OF THE REGULATIONS OF THE BODIES MENTIONED IN SCHEDULE (A) TO THE MEDICAL ACT, RELATIVE TO EDUCATION AND EXAMINATIONS, SHOWING THEIR CONFORMITY OR NON-CONFORMITY WITH THE RECOMMENDATIONS OF THE MEDICAL COUNCIL.

	Examination in General Education (including Latin) before Commencement of Professional Studies. (Recommendations 1 & 5.)	Commencement of Professional Studies to be at a Medical School. (Recommendation 2.)	Four Years at least of Professional Studies required. (Recommendation 18.)	Professional Examinations to be divided into at least Two Parts; the First to take place after Two Years, the Second after Four Years of Study. (Recommendation 19.)	Twenty-one to be the earliest Age for a Licence. (Recommendation 17.)	Candidates to sign Statement that they have not been rejected within Three Months. (Recommendation 24.)
Royal College of Physicians, London.	Conformable .. ..	Conformable ..	Conformable.	For Licentiates. First examination after the termination of the 2nd Winter Session of study at a recognised Medical School; the Second after at least 18 months from the first examination. Not conformable as regards Members.	Conformable.	Conformable.
Royal College of Surgeons of England.	Conformable .. ..	Attendance on lectures or hospital practice, or registered pupilage, considered as commencement of professional studies. Not conformable.	Conformable.	First examination after the termination of the 2nd Winter Session of attendance at a recognised School; the Second after the termination of the fourth year of professional education. First examination not conformable.	Conformable.	Not noticed.

King and Queen's College of Physicians in Ireland.	Examination in general education previous to or within the first two years of professional study.	Conformable ..	Conformable.	Students recommended to divide their course of study into two periods of two years each. The examination is divided into two parts. Students may be examined in the subjects of the first part at the termination of the first period of study, or in all the subjects of their education on the completion of their Medical studies.	Conformable.	Not required.
Royal College of Surgeons in Ireland.	Conformable, but Regulation suspended.	Conformable ..	Conformable.	Conformable as to division of the examinations, but first examination after three years, and the second after four years' study.	Conformable.	Conformable.

	Examination in General Education (including Latin) before Commencement of Professional Studies. (Recommendations 1 & 5.)	Commencement of Professional Studies to be at a Medical School. (Recommendation 2.)	Four Years at least of Professional Studies required. (Recommendation 18.)	Professional Examinations to be divided into at least Two Parts; the First to take place after Two Years, the Second after Four Years of Study. (Recommendation 19.)	Twenty-one to be the earliest Age for a Licence. (Recommendation 17.)	Candidates to sign Statement that they have not been rejected within Three Months. (Recommendation 24.)
Apothecaries' Hall, Dublin.	Conformable .. ..	The practice conformable, but the Regulation not explicitly stated.	Conformable.	For Licentiates. The examination divided into two parts. First examination may be at the close of the 2nd Winter Session; the second not before the completion of the 4th Winter Session.	Conformable.	Not required. A question as to this is put verbally to the candidate before examination.
University of Dublin.	Conformable .. ..	Conformable ..	Conformable.	Conformable.	Not stated ..	Not noticed.
Queen's University in Ireland.	Candidates recommended to pass the matriculation examination prior to entering on the second period of professional studies.	Conformable ..	Conformable.	The first examination may be passed at the termination of the 1st period of curriculum, extending over two years, or at any subsequent period, or simultaneously with the degree examination.	Not stated ..	Not required.

Read the letter from the Royal College of Surgeons of England, referred to the Committee by the Council. (Sec Minutes No. 48, p. 2.)

Read a memorial from the Medical Officers of the Devon and Exeter Hospital. Also a memorial from the Medical Officers of the West of England Infirmary for the Cure of Diseases of the Eye.

3. Moved by Mr. ARNOTT, seconded by Dr. ACLAND—"That the memorials from the Medical Officers of the Devon and Exeter Hospital, and from Medical Officers of the West of England Infirmary for the Cure of Diseases of the Eye, be received and entered on the Minutes."—Agreed to.

To the President and General Council of Medical Education and Registration of the United Kingdom.

The Memorial of the Physicians and Surgeons of the Devon and Exeter Hospital,

Sheweth,—That we the undersigned, being Physicians and Surgeons of the Devon and Exeter Hospital, beg most respectfully to represent to the General Council that the Devon and Exeter Hospital was founded, in the year 1741, by the Very Reverend Dr. Clarke, Dean of Exeter, who had previously founded the Hants County Hospital at Winchester.

That the Devon and Exeter Hospital has four Physicians, four Surgeons, and a Resident House Surgeon, Apothecary, besides Consulting Physicians and Surgeons, who were so elected on retiring from the more active duties of Physicians and Surgeons. That it contains 228 beds, and is most liberally furnished with every appliance. That it has a Museum of Natural and Morbid Anatomy, with Lecture and Dissecting Rooms attached. That it has a Medical Library of about 3000 volumes (comprising every branch of Medical literature), derived chiefly from the libraries of Dr. Glasse, Dr. Bartholomew Parr, and the late Samuel Barnes; and that this Library, which is supported by the contributions of the Medical Staff, and most of the Medical Practitioners of Exeter, is open to the students frequenting the said Hospital on the payment of a small annual subscription.

That we further beg leave to state that for more than a century the Devon and Exeter Hospital has been reputed to be an eminent school of clinical instruction. That its apprentices and students have been distinguished in the Metropolitan Schools for their knowledge of Medicine, Surgery, and practical Anatomy as long as Schools of Medicine have existed in the Metropolis.

That notwithstanding that these facts are frankly acknowledged in the chief Metropolitan Schools for Medicine, the number of students, especially of apprentices, has of late so declined, that the General Committee of Governors of the said Devon and Exeter Hospital have passed and sent to us, your memorialists, the following resolution:—"That the Medical officers of the Hospital be desired to consider the great diminution of the number of the pupils that are entered here, and if any, and what remedy can be applied, and report thereon to the weekly board."

To this inquiry we, your memorialists, have replied that the diminished number of pupils has been principally, if not entirely, caused by the gradually prolonged courses of study at Medical Schools enforced on candidates by the various examining and licensing boards, and the consequent neglect of early practical study; and that we are further convinced that the evil will be increased and perpetuated if the General Council, ignoring the valuable means of early education afforded by the Hospitals, Dispensaries, and other Medical Institutions, so numerous in all parts of England, should persevere in their present resolution to confine the commencement and prosecution of Professional study to Medical Schools.

That we further assured the Committee of the Devon and Exeter Hospital, that as the regulations of the General Council diminish the number of pupils throughout the country districts, to the prejudice of Medical education, and serious inconvenience in conducting the business of provincial Hospitals, and other Medical Institutions, we regarded the question as one of importance to the members of the Medical Profession generally, that we therefore should deem ourselves justified in calling attention to this subject, in order that we might take counsel with the Medical officers of other provincial Hospitals in England, which, like our own, though not fully constituted "Schools of Medicine," are recognised as "Clinical Schools" by the Royal Colleges of Physicians and Surgeons.

That we were the more bold in adopting these opinions, and in taking this course, because we believe that the majority of the members of the General Council are by their high position, social and Professional, too far removed from the great body of Medical Practitioners to be intimately acquainted with their habits of life and mode of practice, whilst we, who are largely consulted throughout a very extensive and varied district, presenting every conceivable condition of practice, are intimately acquainted with our Medical brethren at their own homes, and in the houses of our patients.

That we would premise that, in any suggestions we may presume to offer, we do not contemplate the higher rank in Medicine or Surgery, but the great body of general practitioners; the former, after the completion of their collegiate education, can afford for many years to maintain their connexion with Hospitals and other great Medical Institutions, and scarcely commence practice in earnest until they have attained to middle life; whilst the latter, who constitute the more important class of the Medical Profession, enter early upon their full sphere of duty, and must be com-

petent from the outset to act with self-reliance, business habits, and powers of physical endurance.

That the mode of education formerly pursued fulfilled these conditions, it being eminently practical; that it commenced with an apprenticeship nominally of five years, but practically of shorter time, because it usually included the period spent at a Medical School; that it taught from the commencement the daily requirements of the Medical man, trained him to the general duties of private practice, instructed him in Medicine, Surgery, and Pharmacy; and that, where the education was conducted in an Hospital, Anatomy was usually acquired, and the higher doctrines and proceedings of Surgery inculcated under circumstances far more advantageous than they can be in a crowded Hospital attached to a Medical School; that the apprentice then proceeded to a Metropolitan School, where he attended a few short courses of lectures, but was particularly occupied with Dissection and with Hospital Practice, which the knowledge he had already acquired enabled him to comprehend; that, during the summer, he usually returned to his master, and applied in practice the science he had acquired in the school; and thus this practical knowledge, collected day by day, and without exhausting effort, was early associated with a patient self-reliance and self-confidence necessary to its judicious application.

That the system enunciated by the General Council (after some preliminary examination, which implies the possession of a certain amount of general knowledge), begins and ends with lectures in a Medical School, and with Hospital Practice—this occupies nearly four years; that the number of lectures is so considerable, and their topics so varied, that the mind of the student (wholly unfamiliarised, as is assumed, with Medical subjects) is bewildered and exhausted by the continuous strain upon its attention.

That, during this exhausting succession of lectures, Hospital Practice is, indeed, enjoined, but it is performed under all the unfavourable circumstances of a crowd, and that Practical Anatomy is not so diligently cultivated as heretofore.

That this system does not make the practical and ready man, so conspicuously the case in the older plan of a preliminary apprenticeship.

That it provides, by lectures, a full amount of Professional lore, but that it virtually sets aside the practical instruction available throughout the provinces, under the guidance of country Practitioners, and of the Medical officers of provincial Hospitals.

That these important sources of efficient practical instruction, where disease can be calmly studied, and its treatment be understood and appreciated, are now, in a great measure, running to waste; whilst, by returning to the former system of Medical education, they would be utilised for the improvement of Medical education and the public benefit.

That we trust we shall be pardoned if we remind the General Council that there are in England nearly three hundred Provincial Hospitals and Dispensaries, besides clubs and unions, which, however unpretentious, supply a still larger and more important experience in the treatment of acute disorders, all of which are available for clinical instruction, but from which, as we understand, it withholds its sanction.

That, even at the risk of being wearisome, we must again entreat the General Council to be patient and hear us; that, in the former mode of education, a large proportion of young Medical pupils passed their earlier years of study in the country, for the most part under the care of their immediate relations; that the plan of the General Council renders their residence in a large city during the whole period of Medical education obligatory; that this not only injures their morals, but presses heavily on the means of their parents; that it will cast almost insuperable difficulty in the way of Medical Practitioners, country clergymen, and other Professional men, who could formerly educate their sons for the Medical Profession at a moderate expense, and that we conceive the result is already evident.

That we, your memorialists, therefore earnestly entreat that the General Council may have regard to the education of that more numerous and more important class of the Practitioners of Medicine, and no longer seek to compel them to a course of study well suited, indeed, to its own members, and to those whose circumstances justify their aspiring to the exclusive class of Consulting Practitioners, but wholly unsuited to the limited means and toilsome lives of General Practitioners.

ARTHUR KEMPE, F.R.C.S.

W. W. JAMES, F.R.C.S.

JNO. HADDY JAMES, F.R.C.S.

To the General Council of Medical Education and Registration of the United Kingdom.

The respectful Memorial of the Medical Officers of the West of England Infirmary for the Cure of Diseases of the Eye, Sheweth,—That the said Infirmary was founded in Exeter in the year 1808, and is the oldest provincial Eye Infirmary in England.

That as its means have enlarged its benefits have been more widely extended, and that it derives its patients mainly from the four Western Counties,

That it is conducted with the utmost liberality, so as to facilitate as much as possible the admission of all persons requiring its aid. That to this end all Clergymen, whether subscribers or not, are privileged to introduce their own poor parishioners as out-patients. That in practice the recommendation to this charity is a bad eye, and that no introduction is required, except when there are strong grounds to suspect imposition. That for an in-patient the recommendation of a Governor (whose right of recommendation is unlimited) is required, but that such patient is supported free of all expense, whatever length of time he may remain, unless by his own admission he can pay a small sum towards the positive expense of his maintenance.

That it had under care during the last year 1874 patients, of whom 78 were in-patients. That since the opening of the Infirmary there have been admitted 42,641 patients; that of these 612 have been cured of blindness from cataract, and 90 by an operation for artificial pupil.

That the pupils attending this Infirmary rarely exceed five in number; that they are therefore able to inspect, under the supervision of the Surgeon, the patients resorting thereto, and actually and truly to see the operations and other delicate manipulations, which is impossible when many pupils are collected together; that they have ample opportunities of afterwards watching these cases in which operations have been performed, and know exactly the result.

That we, your Memorialists, believe that this genuine practical instruction is the common characteristic of Provincial Medical Charities, we therefore earnestly pray that the General Council may encourage Medical Students to resort to Provincial Schools of Clinical Instruction, and not limit its recognition of "practice" to the crowded Hospitals attached to "Schools of Medicine."

P. C. DE LA GARDE, } Surgeons.  
JOHN EYDE,  
T. SHAPTER, M.D., Physician.

Moved by Dr. ANDREW WOOD, seconded by Mr. SYME,—“That inasmuch as the Regulations of the Royal College of Surgeons of England do not require the commencement of Medical Study to be at a Medical School, they are not in accordance with the recommendations of the Medical Council, and are not such as to secure the possession of the requisite knowledge and skill for the efficient practice of Surgery.”

The debate on this motion was adjourned.

Confirmed—JOSEPH HENRY GREEN.

MINUTES OF MEETING, SATURDAY, MAY 30, 1863.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Mr. GREEN, *President*, took the chair at Two o'clock, p.m.

*Present—*

Dr. Burrows.	Dr. Andrew Wood.	Dr. Corrigan.
Mr. Arnott.	Dr. Fleming.	Sir Charles Hastings.
Mr. Cooper.	Mr. Syme.	Dr. Sharpey.
Dr. Acland.	Dr. Thomson.	Mr. Teale.
Dr. Bond.	Dr. A. Smith.	Dr. Christison.
Dr. Embleton.	Mr. Hargrave.	Dr. Stokes.
Dr. Storrar.	Dr. Leet.	
Dr. Alexander Wood.	Dr. Apjohn.	

Dr. FRANCIS HAWKINS, *Registrar*.

The Minutes of the last meeting were read and confirmed.

1. Moved by Dr. ALEXANDER WOOD, seconded by Dr. FLEMING—“That, whereas the Poor-law Commissioners of Ireland require that every candidate for Medical employment under them shall produce a licence in Midwifery, in addition to licences in Medicine and Surgery, it be remitted to a Committee to consider whether such a requirement is legal, and whether the Council should take any steps in regard to it.

“The Committee to consist of

Dr. Alexander Wood, Chairman.	Dr. A. Thomson.
Mr. Teale.	Dr. Sharpey.
Dr. Leet.	Dr. Fleming.”
Dr. Bond.	

—Agreed to.

On the motion of Dr. EMBLETON, the Council resolved itself into a Committee on Education.

The adjourned debate was resumed on Dr. ANDREW WOOD's motion, viz.:—“That inasmuch as the Regulations of the Royal College of Surgeons of England do not require the commencement of Medical study to be at a Medical School, they are not in accordance with the Recommendations of the Medical Council, and not such as to secure the possession of the requisite knowledge and skill for the efficient practice of Surgery.”

(*First Amendment.*)

Moved by Dr. APJOHN, seconded by Dr. A. SMITH—“That this Council do submit a case to Her Majesty's Attorney-General and Solicitor-General, with the view of ascertaining whether, under the provisions of the Medical Act, this Council possesses the power of issuing Regulations in relation to the general and professional education of Medical students, the enforcement of which will be mandatory upon the different licensing bodies enumerated in Schedule (A) of said Act.”

(*Second Amendment.*)

Moved by Mr. HARGRAVE, seconded by Dr. CORRIGAN—“That the second Recommendation of the Report on Education be re-considered, viz.:—That the time of commencing professional studies shall be understood to be the time of commencing studies at a Medical School, and that no qualifying body be held to have complied with the recommendation of the Council which shall allow the examination in general education to be passed after the commencement of professional study.”

Question put to the vote—“That the original motion be amended.”—Carried.

Dr. ANDREW WOOD required the majority and minority to be entered on Minutes.

<i>Majority—</i>	<i>Minority—</i>
Mr. Arnott.	Dr. Storrar.
Mr. Cooper.	Dr. Alexander Wood.
Dr. Acland.	Dr. Andrew Wood.
Dr. Bond.	Dr. Fleming.
Dr. Embleton.	Mr. Syme.
Dr. A. Smith.	Dr. Thomson.
Mr. Hargrave.	Dr. Leet.
Dr. Apjohn.	Sir C. Hastings.
Dr. Corrigan.	Dr. Sharpey.
Mr. Lawrence.	Dr. Christison.
Mr. Teale.	
Dr. Stokes.	

Second amendment put and negatived.

Dr. ANDREW WOOD required that the majority and minority be entered on the Minutes.

<i>Majority—</i>	<i>Minority—</i>
Dr. Storrar.	Mr. Arnott.
Dr. Alexander Wood.	Mr. Cooper.
Dr. Andrew Wood.	Dr. Acland.
Dr. Fleming.	Dr. Bond.
Mr. Syme.	Dr. Embleton.
Dr. Thomson.	Dr. A. Smith.
Dr. Leet.	Mr. Hargrave.
Dr. Apjohn.	Dr. Corrigan.
Sir Charles Hastings.	Mr. Lawrence.
Dr. Sharpey.	Dr. Christison.
Mr. Teale.	
Dr. Stokes.	

First amendment put and negatived.

Dr. ANDREW WOOD required that the majority and minority be entered on the Minutes.

<i>Majority—</i>	<i>Minority—</i>
Dr. Embleton.	Mr. Arnott.
Dr. Storrar.	Dr. Acland.
Dr. Alexander Wood.	Dr. Bond.
Dr. Andrew Wood.	Dr. A. Smith.
Dr. Fleming.	Dr. Apjohn.
Mr. Syme.	Mr. Lawrence.
Dr. Thomson.	Mr. Teale.
Mr. Hargrave.	Dr. Stokes.
Dr. Leet.	
Dr. Corrigan.	
Sir Charles Hastings.	
Dr. Sharpey.	
Dr. Christison.	

The original motion was then put, and negatived.

Dr. ANDREW WOOD required that the majority and minority be entered on the Minutes.

<i>Majority—</i>	<i>Minority—</i>
Mr. Arnott.	Dr. Storrar.
Mr. Cooper.	Dr. Alexander Wood.
Dr. Acland.	Dr. Andrew Wood.
Dr. Bond.	Dr. Fleming.
Dr. Embleton.	Mr. Syme.
Dr. A. Smith.	Dr. Thomson.
Mr. Hargrave.	Dr. Leet.
Dr. Corrigan.	Sir Charles Hastings.
Mr. Lawrence.	Dr. Sharpey.
Mr. Teale.	Dr. Christison.
Dr. Stokes.	

Moved by Mr. TEALE, seconded by Dr. STOKES—“That the Medical Council, whilst appreciating the great value of the practical opportunities afforded to the student who is a pupil of a regular member of the Profession holding the appointment of Surgeon to a Hospital, General Dispensary, or Union Workhouse; and whilst considering that a year spent in such pupillage might be regarded as one of the four years of Professional study recommended by the Council, is of opinion that such year of pupillage, apart from the practical and systematic study of the elementary and ancillary sciences of Medicine, should not be conducted during the first year, but at some period during the subsequent years of Professional study.”—Agreed to.

Moved by Dr. ANDREW WOOD, seconded by Dr. EMBLETON—“1. That all students pass an examination in general education, if possible, before they commence their Professional studies. 2. That students may in particular cases be registered for the first time who have passed only a part of their examination in general education, but that that examination must in all cases have been completed previously to the commencement of the second Winter session.”—Motion negatived.

Confirmed—JOSEPH HENRY GREEN.

PROVINCIAL CORRESPONDENCE.

EDINBURGH.

THERE was a somewhat exceptional interest towards the latter part of the last meeting of the Medico-Chirurgical Society, as Dr. Ramsbotham, of London, was present, and Professor Simpson gave a long and eloquent commentary upon the late case at Chester, of Bromwich v. Waters. He particularly dwelt upon the *animus* that was exhibited by the plaintiff, and upon Serjeant Shee being specially retained, and taken off his usual beat because his talents for vilification were thought to be superior to those of other men. Then, having shown that the case against Dr. Waters had entirely broken down at an early stage of the proceedings, Dr. Simpson turned his attention to the Medical witnesses, especially Drs. Lee and Ramsbotham, who had, *par nobile fratrum*, come all the way to Chester to give evidence against a Professional brother, and by all accounts it was not their fault that this laudable object was not carried out. Dr. Lee especially seems to have shone on the occasion, and to have had his memory under that complete control which distinguished the witnesses in a once famous court-martial at Windsor. The general reader may, however, be interested to know that Dr. Lee once doctored Prince Woronzoff, and that the effect on his mind of that distinction was such that he now forgets his own age, the contents of his own book, and does not know what superficial ulceration of the os uteri is. Rather hard,

too, on one who never spent an idle hour, and never took a holiday. "All work and no play, made, etc.," eh, Dr. Lee.

Dr. Ramsbotham spoke at some length, and with great good humour, in reply to Dr. Simpson. We were sorry to see that such a celebrated lady's Doctor was so little of the lady's man, as to lay most of the blame on Miss Bromwich, who is the most obstinate old maid, etc., etc., "ever put breath into," (serve her right for being unmarried, and probably healthy). Dr. Ramsbotham went on to inform the Society what his party had said on the subject at luncheon. Heavens, what a feast! It was in a hotel, so probably their bodies were well cared for; but we, indeed, envy any lover of intellectual conversation who may have been admitted to a repast where seduction, uterine disease, pregnancy, and erotomania were discussed by one toxicologist, two accoucheurs, and a brace of females more inquisitive than fascinating. But Dr. Ramsbotham looked at the business with the catholic eyes of true philanthropy. He saw benefit to himself and also to his banker's account. He declared that he went to Chester to give evidence against Dr. Waters and benefit Miss Bromwich; but with such ingenuity was he to do so, that, in reality, he would be of more benefit to Dr. Waters than to Miss Bromwich; in short, owing to the narrowness of the circumstances, he was to deliver himself of his evidence by *turning*, as then in any case he would land feet first, like Irishmen and cats. Dr. Keiller, however, said very plainly that if Dr. Ramsbotham had really intended to benefit Dr. Waters in the witness-box, he had gone a curious way about it, and, to an ordinary mind, his statements seemed unlikely to benefit the Professional brother for whom he expressed such regard, so we will hope that Dr. Ramsbotham really earned conscientiously his fee, and as Dr. Waters has not to pay it, we trust that fee is as large as himself, and his well-earned reputation. His back is broad enough to bear a little badinage, but an eminent Medical man, whose name is familiar to the youngest student, might surely turn that eminence to better account. If men like Serjeant Shee can hire out their fine talents for the use of "the most obstinate old maid who had ever breath in her body," we are sorry, but he cannot help it; in his profession he can no more shrink from such dirt than Dr. Ramsbotham could decline attendance on some London hetaira. But Doctors surely can refuse to be parties to such iniquity, to pander to pruriency, to disseminate through the medium of the newspaper press their ideas on the relative moralities of the various methods of manipulating diseased and disgusting females. If this sort of thing goes on, every boy and girl in the country will be as well acquainted with the signs of virginity—should there be any possessing them left—and the best remedies for hysteria, as the ordinary run of Practitioners in the days of William Hunter or Smellie. Dr. Keith has been doing ovariectomy with success. Dr. Alexander Wood continues his hypodermic injections of sedatives, and I may mention two very interesting cases,—one a severe case of neuralgia of the cord and testicle. The patient, a youth preparing for orders, suffered agony at short intervals, and after one injection has been, it would appear, permanently cured. In the other, a man had ruptured his biceps tendon, and suffered from excruciating cramps. One injection relieved him for some time, and enabled him to work. It is to be hoped that Dr. Wood will furnish the Profession with some more information on this curious but very successful method of subduing pain.

At the last meeting of the Royal Society, Professor Simpson began with a paper on the umbilical cord, and ended with one on a Pictish inscription. As Professor of Antiquities to the Royal Scottish Academy, he refreshes himself now and then with such light reading as is to be found on the monoliths of the east of Scotland.

I am glad to see that Professor Laycock is to resume his classes of practical psychology. It is only such training that will prevent doctors stultifying themselves in the witness-box, signing certificates that have to be repented of and paid for, being useless advisers when for every motive, from friendship to avarice, they would wish their advice to have practical value.

The summer classes in Edinburgh are very pleasant, the weather generally good, the scenery lovely. April showers take the starch out of the collars of academics, and the May sunshine brightens up the wits of even the unhappy enthusiast alluded to by Churchill, who

"by the taper's light,  
Wearing away the watch of night,  
Sat reading, but, with o'ercharged head,  
Remembered nothing that he read."

Lord Palmerston took his degree here some weeks since, and made a speech, and Dr. John Brown found a sensation old servant, who had preserved a box of tools belonging to his lordship for such a length of years,—I think fifty the papers say. The old woman called his Premiership "Maister Harry," so of course the tools are genuine and not the only ones. Dr. John Brown, he who first popularised the not difficult operation of excision of the mammary gland, as performed on the mistress of Rab and his friends, has not the merit of originality here, as Barnum did the Washington's nurse trick years ago.

Our Royal Infirmary has just had a change made in its Surgical staff, owing to the resignation of Dr. Struthers, who purposes devoting himself entirely to anatomical instruction. Dr. P. H. Watson, who lectures on surgery, has succeeded to the vacant wards, and Mr. A. M. Edwards has been elected Assistant-Surgeon.

The St. Andrew's vacant Chair of Anatomy and Medicine is the next Medical election on the *tapis*, caused by the resignation of Dr. Day. The candidates are Dr. Oswald Bell, who has for some time been acting for Dr. Day; Dr. Clelland, Demonstrator of Anatomy in Glasgow University; Dr. Wilson, Demonstrator of Anatomy, University of Edinburgh; and Dr. Glen, Dundee. The first-named gentleman is likely to be the successful candidate, and as he is well known and respected in St. Andrew's, it will be satisfactory in that quarter if he is appointed; but there is nothing to find fault with in any of the candidates, all of whom are up to the work.

The Secretary of the Anderson's University, Glasgow, advertises the Chair of Medical Jurisprudence vacant by the resignation of Dr. J. B. Cowan, who has accepted the Chair of Practice of Medicine. Candidates are requested to lodge their applications before June 12.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MAY 26, 1863.

Mr. PARTRIDGE, President, in the Chair.

Mr. JOHN WOOD read a Paper on a

CASE OF EXTREME DEFORMITY OF THE NECK AND ARMS, TREATED SUCCESSFULLY BY GRADUAL EXTENSION, EXCISION, AND ADJACENT AND REMOTE TRANSPLANTATION.

The subject of the case was a little girl, aged nearly nine years. In consequence of an extensive burn, the chin was drawn down to within an inch of the sternum by a broad and prominent band of hard, tough cicatrix, the mouth distorted, and the head drawn a little towards the left shoulder. The right arm was contracted at the elbow to somewhat more than a right angle. The left wrist was extremely contorted, the hand being turned back upon the fore-arm, so that the fourth and little finger nearly touched its back surface, and the joints of the carpus and metacarpus were inverted by a very prominent, tense, falciform cicatrix, placed opposite the fourth finger, and extending along the lower third of the fore-arm. A large sore still remained at the upper half of the back of the fore-arm; this had been stationary in healing, on account of the great tension of the skin around, which was seamed with cicatrices, and very inelastic. The case was treated by Mr. Wood in King's College Hospital towards the end of the year 1862. The right arm was first extended gradually by the use of a straight splint and graduated pads. On October 4, an operation of transplantation was performed on the neck. A quadrangular flap of skin was taken from the right side of the cicatrix, where the integuments were hollow, loose, and puckered. It was then turned across, and placed in the site of the cicatrix, which had been previously divided by a V-shaped incision, separating the band close to its attachment on the breast-bone. The flap was held in its place by wire sutures. None of the hardened cicatrix was removed by the operation, but was dissected up freely towards the chin, and left to unite to the upper part of the flap. At the lower part of the neck, in the site whence the flap was derived, an open sore remained to heal by granulation. The head was

kept well thrown back, and the wound dressed with water-dressing. By the end of a month the wounds had nearly healed, the chin remaining elevated, and the motions of the head free. The condition of the left fore-arm, the small quantity of healthy skin remaining, the persistent and extensive sore, the extreme contraction of the lunated cicatrix, and the great retroversion of the carpal and metacarpal joints rendering all efforts at extension fruitless, and precluding any attempt at transplantation of adjacent parts, Mr. Wood resolved to attempt the removal and transplantation of a portion of skin from the abdomen to the arm to supply the want of tegumentary tissue. The part of the abdominal surface chosen for the operation was that on the left side of the navel, in the direction of the superficial epigastric vessels. Upon this region the limb could be comfortably placed, and kept immovable for a sufficient length of time to permit of adhesion, the arm and belly rising and falling together in the movements of respiration, so that relative immobility was secured. A cuirass-splint was first moulded in gutta-percha over the chest and upper part of the belly; to its left border was fixed a scroll splint of the same substance, passing round the upper arm. A flat, straight splint for the fore-arm was attached to the lower border of the breast-plate. This was perforated freely with holes, covered by wash-leather, well padded with cotton wool, and worn comfortably by the patient for twenty-four hours before the operation. On the 5th of November, the patient being under the influence of chloroform, the lunated cicatrix was divided transversely opposite the wrist-joint, and freed by extension and dissection from the subjacent fascia and tendinous sheaths, which were found uninjured. A lancet-shape flap, about two inches and three-quarters long and two inches and a-half wide at its base, with its attached margin or base directed towards the groin in the course of the superficial epigastric artery, was then raised from the abdomen with a good portion of subcutaneous fat adherent to it. The edges of the wound left by its separation were brought together by pins and wire sutures, supported by adhesive plaster and thick dressing. The fore-arm was then placed upon it, so that the gaping wound produced by straightening the wrist after the transverse incision, was placed opposite to the lancet-shaped flap, the point of which fitted exactly into the angle of the cross cut. The flap was then secured by wire sutures to the edge of the arm incision. Through the middle of the flap and the upper part of the integuments of the arm were passed two rectangular pins in opposite directions, about an inch apart from each other. The pins were then locked into each other's loops, so as to form a wire parallelogram, the ends of which acted upon the middle of the flap through a pad of lint, thus exercising a lever-like pressure, which could be regulated to the degree of swelling ensuing in the flap. The cuirass-splint was then adjusted and fixed to the body by broad strips of plaster, and to the fore-arm by means of long narrow strips, with a bandage placed over all in such a manner that the wound could be examined without deranging the fastenings. November 6.—The flap was uncovered and found in capital position, with evidences of adhesion at the edge nearest the fingers; the pad of lint under the pins readjusted. 8th.—Three of the wire sutures at the upper margin of the flap removed by the House-Surgeon, who thought that they were dragging somewhat. The flap is firm in its place, and evidently adherent by its deep surface, though it has slightly retracted where the sutures were removed. 10th.—The silk thread removed from the pins; cicatrization completed for about an inch near the fingers. 14th.—The cuirass-splint raised for the first time since the operation for the purpose of examining and cleansing the sore on the body. All the pins and sutures were at the same time carefully removed. The wound was found filled with healthy granulations, no primary adhesions having formed at the edges. Wound dressed with a thick layer of simple dressing; splint readjusted. Two or three fresh points of cicatrization are observed at the upper edge of the flap. 21st.—Since the last report the splint has been lifted, and all the wounds dressed daily; all the sores are cicatrizing rapidly; flap firmly adherent. By the 27th the whole margin of the flap had become cicatrized to the arm, close up to the root. On the 29th, the first step towards the division of the flap from the belly was taken. An incision, about half an inch in extent, was made on each side of the base, in an oblique direction towards the surface of the abdomen, so as to include as much integument as possible on the arm side of the incision, and to indicate the lozenge-shape which the patch was intended

to assume when totally severed from the body. Lint was then placed between the cut edges to prevent re-adhesion to the body. The splint was then altogether removed, and the arm kept in its place (removed a little nearer to the navel than before) by straps and bandage. After three more partial sections of the base of the flap on alternate sides at intervals of a week, during which time the hand had been gradually more and more flexed upon the fore-arm, so as to draw from the abdomen as much skin as possible on to the wrist, and the whole arm also shifted more over towards the median line, so as to leave the sore on the abdomen free from pressure, the flap being found partially sensible to the contact of the point of a pin, and in a satisfactory condition of vascularity, the final severance of its remaining attachment to the body (about half an inch in extent) was accomplished on the 3rd of January, 1863. There was free bleeding from the arm side of the cut surface, showing complete vascularity. At this time the sores on the arm and belly were reduced to small proportions, covered with florid granulations, and cicatrizing nicely. The arm was now placed on a splint with a hand-piece bent almost double, and flexed freely every day to restore the pliability of the tendons and their sheaths, so long bent backwards and contracted. The small sores which remained healed up speedily and without check. In the mean time, that portion of the scar in the neck in which the old contracting cicatrix had been left in the former operation had begun again to contract. An attempt to stretch it gradually resulted in a partial return of the ulceration. On January 31, Mr. Wood removed the whole of this contracting portion of the cicatrix by two vertical incisions, meeting above and below, carried so deep as to include the whole of the contracting substance, and leaving two opposed even surfaces of healthy tissue. These surfaces were then drawn together by three points of quilled suture, composed of wire and two pieces of flexible catheter, the wire being carried deep into the wound and emerging an inch from its margins. The immediate edges of the incision were united by points of interrupted suture of thin silver wire. The whole was supported by long narrow strips of adhesive plaster. Union by adhesion to the extent of two inches was the result, a small sore remaining above and below it. The quilled and other sutures were withdrawn at the end of a week. The sores were dressed with water and simple dressing, and supported by plaster; and a gorget or collar of gutta-percha was worn to support the chin, and to keep off friction from the sores. These soon healed up, leaving a long linear cicatrix of an inverted L shape, which gradually became an equable curve when the chin was raised to its full extent. The case was illustrated by drawings of the neck and arm taken before and during the several stages of the foregoing operations. The little patient also was exhibited to the Fellows of the Society, as a practical illustration of the benefit derived from the treatment, more satisfactory than casts or drawings, however truthful. The present condition of the parts operated on is as follows:—The chin can be thrown backwards quite to the normal extent, and the head bent freely from side to side. The linear cicatrix left by the operations describes a regular curve, rendered more open and a little more prominent by extreme extension. All deformity of the mouth is removed, and when viewed in profile from the side opposite to the cicatrix, the neck and chin have a regular and normal curve. On the left side of the neck and front of the breast-bone the cicatrices resulting from the burn and operations are visible, but not prominent or irregular at the surface. The right arm can be extended to a straight line, without any rising of the cicatrix at the elbow. The left arm presents, on the back surface of the wrist, a lozenge-shaped patch of skin, rather paler, yellower, and more elevated than that of the surrounding parts. The patch is about three inches long, and an inch and three-quarters wide. The cicatrix enclosing it is linear and small. All the sores are completely healed, the arm being covered with cicatrices, except a small portion over the radius. The fingers can be closed upon the palm by the action of the flexor muscles, and the wrist bent well forwards. A little tendency of the third and fourth fingers to spring backwards still exists. The furrows and grooves on the palm and front of the wrist are restored, and the knuckles are normally prominent. The patient can grasp and hold things with great power and facility.

The PRESIDENT said that most surgeons had had experience in cases of severe burn, and hoped that the gentlemen present would give their opinions on the case just read.

Mr. CURLING remarked that Mr. Wood gave the best reply

to the Surgical writer whom he quoted as opposed to all operations for the cure of deformities from burn because they always ended in failures, and as advocating the treatment by extension, in the case which had been related that evening. Complete success had attended well-planned and skilful operative treatment. No doubt much good might be effected by extension, and slight cases of contraction might be remedied by it, for a cicatrix is a yielding material. But we could not by extension get rid of deformity; we might stretch, but we could not remove large projecting flaps in the neck and in the arms. Judging from the drawing of the contraction in the neck of Mr. Wood's patient, arising from a band about an inch in width, Mr. Curling considered it one which could be remedied without much difficulty. The chief interest of the paper consisted in the revival of the Taliacotian operation, and great credit was due to Mr. Wood for the ingenuity with which he had successfully dealt with the contraction at the back of the hand, by transferring a portion of skin from the abdomen to that part. Such an operation, however, was of very limited application. It was well adapted to remedy deformities about the hand, but was quite inapplicable to the more serious and more common contractions met with in the neck. In the worse cases of such contractions, where the lower lip was everted, the lower jaw drawn down and elongated, and the teeth projecting like tusks, owing to extensive destruction of the skin, he believed there was no other mode of completely obviating the frightful deformity but by transplanting portions of skin from the shoulders—the American operation. Mr. Curling briefly alluded to a case which he had successfully treated in this way. He stated that the failure of many of the operations for remedying contractions from burn arose from under-cutting the cicatrices. These parts were lowly organised, and derived their blood-vessels chiefly from the parts beneath, and not from the surrounding healthy skin. By forming flaps of the cicatrices the circulation was cut off, and sloughing ensued.

Mr. HILTON, referring to some observations of Mr. Curling regarding the necessity for transplantation of skin as a means of removing by operation cicatricial contractions in the neck after burns, said that he had succeeded in remedying several instances of extreme and broad contractions by simply dividing transversely the whole of the contracted structures, and dissecting them up sufficiently to enable the deformity to be at once corrected, leaving, of course, a very large raw surface to heal by granulation. All subsequent contractions were prevented by the patient lying continuously flat upon his back, with the nape of the neck resting on a small sand-bag, so as to throw the head backwards, and maintain the wound on the front of the neck in a state of extension. Such an operation brought the patient's state to that which existed at the period when the raw granulating surface followed the burns; and no doubt that was the time when by adopting decided and well-considered means of extension and counteraction the subsequent formidable contractions might be prevented almost with certainty if persevered in. Indeed he had no hesitation in stating his conviction that if this view were appreciated and acted on with the determination on the part of the Surgeon to succeed, and not to allow any difficulties to divert him from his purpose, then these contractions requiring operation for their cure would diminish both in number and severity. It should not be overlooked that time is an important remedial element, necessarily so because in deep burns the skin had to be reproduced by the surrounding margin of healthy skin; and further, when the whole surface of the wound is covered with young skin, it is not perfect or mature skin; it has to undergo a further process of integral organisation, liable to be accompanied and perverted by contraction, which must be guided and controlled by the prolonged use of mechanical appliances capable of defying effectively the tendency to contraction. There were at Guy's Hospital numerous drawings of patients, exemplifying the pertinency of these observations in relation to the treatment of contractions following burns. Admiring the ingenuity of the method of proceeding, and gratified by the success of Mr. Wood's transplantation of skin to fill up the gap upon the patient's arm made by the burns, yet, seeing the small size of the transplanted skin, the small extent of new skin required for the occlusion of the wound, he would offer this interrogatory remark, whether the same amount of good might not have been obtained by proceeding on the plan just referred to; in other words, after the cicatrix had been extensively and carefully dissected from the subjacent tendons,

so as to displace or destroy all deformity, whether, had a splint been applied to the hand and fore-arm in order to anticipate and prevent contraction, nature, young and energetic, with wonderful reproductive powers at the age of this patient, would not have succeeded in filling up the gap without the aid of the skin from the abdominal walls? He was disposed to think that the result might have been as successful as that which had been seen that night from the hands of the Author.

The PRESIDENT said, in reference to the contraction following burns, that it occurred often after the completion of the cicatrization. When at Birmingham he had seen many cases of very severe burn, and could bear testimony to the great advantage of continued and slow extension. The natural position of the limb should be maintained for some time after cicatrization.

Mr. FERGUSSON regretted that the author of the paper had treated of two subjects together—one of very common, the other of very uncommon occurrence. It was desirable in the discussion not to lose sight of the really important point in Mr. Wood's case—the successful performance of a Taliacotian operation. Some doubt had been thrown upon the operation of Taliacotius—that is, the successful removal of a portion of the body to supply a deficiency in a distant part. But here was an instance in which a portion of the integuments of the abdomen were successfully transferred to the wrist. This was the really important feature in Mr. Wood's case.

Mr. Wood said that he considered himself fortunate in having been able to elicit the opinions of gentlemen whose eminence entitled them to much consideration, and for whose judgment he entertained so much respect, upon the case he had brought forward. He, however, felt bound to say that he differed from Mr. Hilton in the opinion that the cicatrix could in any sense be considered as healthy. Containing no sebaceous or sweat glands—structures which conduce to the softness, elasticity, and extensibility of true skin—and having an inevitable tendency to contract indefinitely, he could not conceive how the production of a new cicatrix by incision only could guarantee the case from a return of deformity, so effectually as the interposition of a sufficient portion of true skin by transplantation. The great obstacle to slow extension met with in the case was the speedy recurrence of ulceration in the cicatrix under tension. In the arm, the presence of a large and persistent sore in the line of extension rendered such treatment impossible, and necessitated the adoption of the method of transplantation from a remote part, which constituted the chief and novel feature of the treatment. He should also mention that much good had resulted from freely lubricating the cicatrices with oil during the progress of the treatment. The oil he conceived to supply in some measure the want of the sebaceous secretion in the cicatrix, and rendered it more pliant and tractable. He thanked the President and Fellows of the Society for the favourable manner in which his paper had been received, and for the flattering remarks made upon the case.

## OBITUARY.

### DEATH OF MR. F. WAKEFIELD SKEY, M.R.C.S.

(From a Correspondent.)

It is with great regret we record the death of this estimable member of the Profession, who expired on Friday week, under the following melancholy circumstances:—The deceased had long suffered from a severe neuralgic affection, from which he was only able to obtain relief by constant recourse to chloroform; and to so great an extent did he sometimes carry it, that on more than one occasion he has been found insensible. When filling the office of House-Surgeon to St. Bartholomew's Hospital, he had carried the anæsthesia so far that considerable difficulty was experienced in recovering him, notwithstanding the use of galvanism, artificial respiration, etc., and on this occasion he faithfully promised his afflicted parents never to have recourse to it without advice. He religiously kept his promise until the afternoon of Friday week, when an unusually severe paroxysm came on; and, having an important engagement, he had recourse to his old, and, on this occasion, fatal remedy. How long he had succumbed to the active and subtle agent is not known, but

he was found in his chamber kneeling at a chair with a handkerchief to his face which had contained the chloroform. He immediately received every attention, but too late; the vital spark could not again be recalled. The deceased, who received his elementary education at the Charterhouse School, and his Professional at St. Bartholomew's Hospital, was only 31 years of age, and, as Honorary Surgeon to the Royal Artillery Company, his loss is severely felt by the members of that ancient corps, as a most generous comrade, one who, like Sheridan, "could keep the midnight table in a roar." Mr. Skey was an accomplished musician, an excellent poet, painter, and well-educated and high-toned gentleman. The Profession deeply sympathises with his grief-stricken and honoured father.

M. RENAULT, the celebrated veterinarian, formerly Professor and Director of the Veterinary School at Alfort, and, at the time of his death, General Inspector of Veterinary Schools, has just died, at the age of 58. He had been dispatched by the Government to investigate the peripneumonia now raging amongst the cattle in the Pontine Marshes, and was recently reported to be suffering from pernicious fever at Bologna. It is now, however, stated that his fatal illness has been due to contagion of the peripneumonic disease raging amongst the cattle.

### MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members of the College, having undergone the necessary Examinations, were admitted Licentiates in Midwifery at a Meeting of the Board on the 27th inst. :—

Robert Johnson, Bellaghey, Co. Derry, diploma of Membership dated June 28, 1833; Frederick George Lawrence, Malmsbury, Wilts, April 30, 1861; Bartholomew Lumley, Corbridge, Northumberland, June 4, 1861; John Ellerton, M.D. St. Andrew's, and L.R.C.P., Wakefield, Yorkshire, January 28, 1862; James Tily, Hitchin, Herts, April 25, 1862; Henry Seekamp Ward, L.S.A., Horncastle, Lincolnshire, July 31, 1862; Thomas Moore, Wilmslow, near Manchester, November 18, 1862; Robert Lloyd Jordison, L.S.A., South Ockendon, Essex, November 18, 1862; John Reynolds, L.R.C.P., Truro, Cornwall, April 21, 1863; John New Moore, Moreton-in-the-Marsh, April 22, 1863; Hugh Richard Duncan Mackintosh, L.R.C.P. Cheltenham, April 22, 1863; Fitzherbert Dermott, Melbourne, Australia, April 24, 1863; Adolphus Burnell Great Rex, M.D. St. Andrew's, L.R.C.P., Holborn-hill, April 24, 1863; William John Alkin, Denton, near Manchester, May 6, 1863; William Adolphus Frederick Bateman, Richmond, Surrey, May 8, 1863; Cornelius Benjamin Fox, Truro, Cornwall, May 7, 1863; Arthur John Watts, Harrow-road, November 18, 1862.

The names of the Members of the College who underwent the Examinations on Tuesday, Wednesday, and Thursday last for the Fellowship will not be published until the same shall have been confirmed by the Council.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, May 28, 1863 :—

James Harmer, Somerville, Bloxwich, Staffordshire; Edward Cooke Houseman, Clint, Ripley, Yorkshire; Thomas Pigg, Newcastle-on-Tyne; Bartholomew Lumley, Corbridge, Northumberland.

### APPOINTMENTS.

\* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

BEALES, ROBERT, M.D. St. And., has been appointed Justice of the Peace for the Borough of Congleton, Cheshire.

BOULTON, A. E., L.S.A., has been appointed House Physician to King's College Hospital.

BOWRING, G., M.R.C.S. Eng., has been elected Medical Officer to the Workhouses of the Manchester Township.

EVANS, GEORGE F., M.D. Cantab., has been appointed Hon. Physician to the Magdalen Asylum, Edgbaston, Birmingham.

FLEMING, JOHN GIBSON, M.D. Glasg., has been elected Representative of the Faculty of Physicians and Surgeons, Glasgow, in the General Council of Medical Education and Registration.

GIBB, Dr., has been elected Assistant-Physician to the Westminster Hospital.

ROKITANSKY, Professor. This distinguished man has just been appointed Referee for Medical and University Education to the Austrian Ministry.

SCANZONI, Professor. The celebrated Würzburg accoucheur has received a "call" to Baden-Baden, where he will early next year assume the direction of an obstetrical establishment to be founded there.

TOLLER, EBENEZER, M.R.C.S., of St. Luke's Hospital, has just been elected Medical Superintendent of the Gloucester County Asylum.

YEO, J. B., M.R.C.S. Eng., has been appointed House-Surgeon and Secretary to the Hants County Hospital, Winchester.

### DEATHS.

ANGUS, ALEXANDER, of 66, Frith-street, Soho, W., at Huntingdon, on May 31, aged 58.

BARNETT, LYSANDER HOOKER, L.S.A., at 72, Fore-street, Limehouse, on May 30, aged 35.

BERESFORD, CHARLES, M.R.C.S. Eng., at Langharne, Carmarthenshire, on May 25, aged 32.

BRACKEN, ISAAC, F.R.C.S.I., at Ballymahon, Co. Longford, Ireland, on May 24.

BROWN, Rev. WILLIAM, M.D., Secretary of the Scottish Missionary Society, on May 15, aged 79.

BUDD, JAMES HERBERT, M.R.C.S. Eng., at Wickham Market, Suffolk, on May 29, aged 39.

CASSON, EDWIN, L.R.C.P. Edin., at Pannal, near Harrogate, on May 23.

DARLEY, HENRY, M.D., at No. 7, Kildare-street, Dublin, on May 30.

DUNCAN, WM. HENRY, M.D. Edin., at West Park, Elgin, N.B., on May 23, Medical Officer of Health for the Borough of Liverpool.

KELLY, EDWARD, M.D. Edin., at Castle-street, Ballyshannon, Ireland, on May 22.

LESTER, JAMES P. P., L.F.P.S. Glasg., at Kirkpatrick, Durham, Kirkcudbrightshire, on May 16, aged 39, formerly of St. John's, New Brunswick.

LEVER, JOHN G., M.R.C.S. Eng., at Culworth, Banbury, Oxon, on May 9, aged 70.

OLIVER, RICHARD, M.R.C.P. Lond., at Bicton Heath, Shrewsbury, on May 26, aged 63.

SKAY, FRANCIS W., M.R.C.S. Eng., at Coleman-street, London, E.C., on May 29, aged 31.

THE COLLEGE LECTURES.—Professor Gulliver, F.R.S., resumed his course of lectures on Tuesday last, and will deliver six discourses on the Blood, Chyle, and Lymph, and will be followed, on the 16th inst., by Professor Solly, F.R.S., who will also deliver six lectures on the Brain and Spinal Cord, and some of their Diseases.

THE CASE OF ALLEGED POISONING AT BALLYMENA.—Dr. Courtenay, the Medical man who was acquitted of the charge of having administered poison to a young lady, has obtained leave to file a criminal information against Mr. Hunt, the resident or stipendiary magistrate at Ballymena.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the College, held on the 1st inst., the following gentlemen were elected officers for the ensuing year, viz. :—William Colles, *President*; Josiah Smyly, *Vice-President*; Edward Hutton, *Secretary*. *Council*—Arthur Jacob, William Hargrave, Robert Adams, James Barker, Hans Irvine, Edward Hutton, Robert Pentland, Richard G. H. Butcher, Samuel G. Wilmot, Awly P. Banon, Peter Shannon, Rawdon Macnamara, Hamilton Labatt, Benjamin M'Dowel, Edward Ledwich, William Jameson, Alexander Carte, William Healy, and James H. Wharton.

ANTHROPOLOGICAL SOCIETY OF LONDON.—May 26.—Sir Charles Nicholson, Bart., V.P., LL.D., D.C.L., in the chair. A paper was read by Professor G. Busk, F.R.S., on "Human Remains from so-called Brick Earth near Chatham." The remains were, Professor Busk demonstrated, not derived from the brick earth, but merely from surface soil, and showed evidence of having been killed by sabre-cuts. Professor Busk entered into the general question of the prehistoric crania of the British Islands, and was inclined to divide them into three categories, the characters of which he gave in detail. He also entered into many interesting particulars respecting the chemical characters of fossil bones. A long discussion took place respecting the authenticity of the human jaw from Moulin-Quignon, which was joined in by Professor Busk, Mr. Carter Blake, Mr. Charlesworth, Mr. Hogg, and the President.

THE Lord Chancellor has confirmed the appointment by Dr. Lankester of Dr. William Hardwicke to be his Deputy as Coroner for the County of Middlesex.

ACADEMY OF SCIENCES, PARIS.—In the Section of Physics, in the room of the late M. Despretz, M. Edmund Becquerel, son of the celebrated *savant* of that name, has been elected by forty-two out of fifty-five votes. M. Leon Foucault, whose name is European in connexion with the pendulum demonstration, and other scientific investigations, received nine votes. This *savant*, to whom the doors of the Academy have been so long and so unaccountably closed, declined on this occasion becoming a candidate, and the nine votes were therefore merely complimentary.

ACADEMY OF MEDICINE, PARIS.—Professor Rokitansky has been elected a Foreign Associate by forty-two out of fifty-three voters present. The other candidates were Virchow, Frerichs, and Magnus Huss.

GEOLOGICAL SOCIETY.—Perhaps the most crowded meeting of this Society which has taken place for many years was that of Wednesday, the 3rd inst., when a paper was read by Joseph Prestwich, Esq., F.R.S., on the "Section at Moulin-Quignon." An animated discussion ensued thereon between Dr. Falconer, Messrs. John Evans, Busk, Godwin-Austen, Brady, Charlesworth, Huxley, Tyndall, and Prof. Ramsay (President). The result of the opinion of the meeting, so far as it could be ascertained, at the late hour at which it terminated, being to affirm that the majority of the flint implements found in the "black band" at Moulin-Quignon were spurious, and to assign to the "black band" an antiquity coeval with that of the deposition of the "high-level gravels."

ST. THOMAS'S HOSPITAL.—The Governors of St. Thomas's do not appear to be a bit nearer than ever obtaining a site for their new Hospital. The Governors of Bethlehem are quite impracticable. £150,000 have been offered by the former to build a new Bethlehem, and contemptuously rejected by the latter, who require a *carte blanche* to buy an estate and plunge into bricks and mortar to any tune they may think proper. Meanwhile, there has been a public meeting at Southwark to bring pressure to bear on the governors of St. Thomas's, and to demand that the Hospital be rebuilt as near as possible to its old site, certainly not farther from it than Bethlehem Hospital, the site near Newington Church, or the Surrey Gardens. Lastly, the Physicians and Surgeons of St. Thomas's have held a meeting in consequence of a communication from the Treasurer, in which they adhere to the principle expressed in their memorial that the Hospital should be as near as possible to the centre of the Metropolis, and state their opinion that the usefulness of the Hospital has been greatly diminished by its temporary establishment at the Surrey Gardens. If ever there were an illustration of the vulgar adage of "too many cooks," etc., we have it in the fortunes of St. Thomas's.

QUININE IN INDIA.—The experimental cultivation of Chinchona plants in India has met with a success which has exceeded the most sanguine expectations. Specimens of bark grown in India have been received in England, and are now undergoing analysis by Mr. Howard, the eminent quinine manufacturer. He has obtained a first and second crystallisation of very white sulphate of quinine from bark of only two years' growth, besides chinchonine and chinchonidine. Meanwhile the plants are multiplying rapidly; five Government plantations are established in the Neilgherry hills, and natives, as well as Europeans, are undertaking the cultivation in all parts of the hill districts of India.

A FORMIDABLE OPERATION.—According to the *Gazette Médicale de Strasbourg*, Dr. Kœberlé has just performed one of the most extraordinary operations ever undertaken in Surgery. While removing through an opening made in the abdomen a fibrous tumour of the uterus of a considerable size, he determined, in consequence of the changes which the uterus and ovaries had undergone, to extirpate the whole of these organs, leaving only the vaginal portion of the cervix uteri. The operation was performed on April 20, and the patient suffered from no untoward consequence, being five weeks after the operation quite convalescent.

THE GORILLA.—The suggestion which was thrown out by an eminent zoologist about two years ago that we should have gorilla skins speedily a drug in the market, has not yet been realised. A magnificent skin of an old male gorilla, with the skull, has, however, been brought from the Gaboon by Mr. Winwood Reade, the adventurous explorer, who has followed in the footsteps of Du Chaillu, and has by him been deposited in the museum of the Anthropological Society of London during the past week. The specimen has been placed in the hands of the taxidermist, and will, most probably, when stuffed, equal in dimensions the old male gorilla in the British Museum. Although the epidermis has peeled in patches from parts of the breast, one of the arms, and the back and crown of the head, those who are aware of the condition in which the Museum specimens were put into the stuffer's hands, will have no fear but that Mr. Winwood Reade's specimen will equal them in faithfully reproducing, so far as possible, the contour, colour, and size of the great ape.

FOOD AND MEDICAL COMFORTS FOR PAUPERS.—Dr. Cameron, "Public Analyst" to the city of Dublin, having been employed by the South Dublin Board of Guardians to examine the brandy and sugar supplied to the workhouse, has sent in a startling report. The so-called French brandy he found to be a spurious article, consisting of spirits of wine, flavoured with some such fruit as prunes, and coloured with burnt sugar. The sugar he found extremely damp, containing a very large proportion of treacle, and a considerable amount of such impurities as sporules of fungus, particles of cane, albumen, and starch granules. It contained also in great abundance a species of acarus, or mite, closely resembling in appearance and nature the insect which, by burrowing in the skin, produces itch. "It is no exaggeration," says Dr. Cameron, "to affirm that there cannot be less than 100,000 of these insects in every pound of sugar. In ten grains weight I estimated 500, most of which were so large as to be distinctly visible to the naked eye." Such sugar is not only detrimental to health, but the least economical kind that can be employed, from its defective sweetening power. On the motion of Alderman Bonsell, seconded by Mr. Caldbeck, it was unanimously resolved that the contractors should be prosecuted.—*Dublin Correspondent of Times*.

COLLEGIATE ELECTIONS.—The annual nomination of Fellows of the Royal College of Surgeons of England for seats in the Council of that body will take place at the College on Thursday, July 2, when three vacancies will be declared, caused by Mr. Cæsar Henry Hawkins and Mr. Thomas Tatum going out in rotation, and by the resignation of Mr. William Coulson. The two first named gentlemen will, it is stated, offer themselves for re-election; the Fellows will therefore have to appoint a successor to the last-named gentlemen; and perhaps it will be necessary to inform the electors that the names of eligible candidates on the prescribed official forms must be sent into the Secretary's office within ten days from the publication of the announcement in the *London Gazette*, and as the advertisement appeared on Tuesday, the 26th ult., it is apparent that the said notice must be lodged on or before Wednesday next. The following are the terms and conditions of the nomination, viz.:—"2. Every Fellow desirous of a seat in the Council shall, within ten days from the publication of the *London Gazette*, in which the day of meeting for the election shall be announced, transmit or deliver to the Secretary of the College, or person acting for him, a notice and declaration signed by himself in the following terms:—I, A. B., of C., Fellow of the Royal College of Surgeons of England, do hereby declare that I am a Candidate for a seat in the Council of the said College; that I am in the *bonâ fide* practice of the Profession of a Surgeon, and that I do not practise as an Apothecary. Together with a nomination signed by six Fellows of the College in the following terms, viz.:—We, the undersigned Fellows of the Royal College of Surgeons of England, do hereby certify that A. B., of C., is in our estimation a fit and proper person to be a member of the Council of the said College: and we do hereby nominate him a Candidate for a seat in the said Council. And also a certificate, signed by three Fellows, in the following terms, viz.:—We, the undersigned Fellows of the Royal College of Surgeons of England, do hereby certify, on our own personal knowledge, that A. B., of C., is in the *bonâ fide* practice of the Profession of a Surgeon, and that he does not practise as an Apothecary." The following are the names of the Fellows who have been mentioned as coming forward:—

Mr. Bishop, F.R.S., ex-member of the Council.

Mr. Turner, of Manchester.

Mr. Lane, of St. Mary's Hospital.

Mr. Curling, of the London Hospital.

Mr. Hancock, of the Charing Cross Hospital.

IRISH MEDICAL ASSOCIATION.—The tenth annual meeting of this body was held on Monday, June 1, in the College of Surgeons, Dublin; Dr. Jacob in the chair. The annual report, which was read by Dr. Quinan, alluded to the proceedings of the Association with respect to a number of legislative measures affecting the Profession. The exertions of Dr. Mackesy, in reference to the Registration Bill, were thankfully acknowledged. The appointment of Dispensary Medical officers under that Bill had, it was stated, been secured; the fee for the registration of each case had been doubled, and an objectionable penal clause, for compelling certificates of the cause of death, had been abandoned. On the motion of Dr. Harvey, of Cork, seconded by Dr. Darby, of Bray, a

resolution was passed declaring that the minimum salaries of Poor-law and Dispensary Medical officers should be £100 a year. Resolutions were also carried respecting the remuneration of Medical witnesses in courts of law, retiring allowances to Poor-law Medical officers, Parliamentary representation of the Medical Profession, &c.

**MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.**—The annual meeting of this Society was held on Monday, the 1st inst., in the Royal College of Surgeons, Dublin, when the chair was taken by Dr. Mackesy, of Waterford, President of the College. The chairman, in the course of an eloquent speech, stated that the members of the Society, desirous to perpetuate the memory of its benevolent founder, had very generally subscribed for the purpose of having two portraits of the late Dr. Kingsley, painted by the eminent artist, Mr. Catterson Smith, and that it was arranged that one of these portraits should be placed in the College of Physicians, the other in the College of Surgeons. Dr. Mackesy added that he considered himself fortunate that it had fallen to his lot to preside at the meeting at which one of these memorials was to be inaugurated. The annual report was read by Dr. Wharton, Honorary Secretary. Dr. Benson, in moving the adoption of the report, complained of the apathy of many members of the Profession in not supporting the Society. Nevertheless, he considered that the Society was making progress; they had £6000 in the funds, and they expected in a short time to receive an additional sum of £4500.

NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

Vincit qui se Vincit.—Not according to the Medical Act.

The following Papers are in the hands of the printer:—Dr. W. S. Kirkes, "On Chorea, its Relation to Valvular Disease of the Heart, and its Treatment;" "Surgical Inquiries (No. I.," by J. Ferneux Jordan, M.R.C.S., etc.; "On Latent Syphilis, etc.," by Langston Parker, F.R.C.S.; "Clinical Midwifery," by Dr. Ramsbotham.

VACCINO-SYPHILITIC INOCULATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your last number contained a letter from my friend Mr. Hine, of Nottingham, on the subject of the case I lately reported in your columns. He gives expression to facts so clearly stated by Mr. Hutchinson, and so universally known, that my respect for your space prevented me, in my report, from answering his objections by anticipation. I hoped your readers would give me credit for not overlooking considerations so entirely obvious.

My own experience, and, as far as I can learn, that of other observers, furnish no instances of inherited disease as severe as that which I described and yet as late in its appearance, even in the eldest child, especially when the mother has had no abortions, and no symptoms of syphilis even in her pregnancy, and when the father and the remaining children are absolutely free from any trace of the disease. In cases much less severe, I have usually found an earlier manifestation of the cachexia, and the second child, if born after only a short interval, always more or less affected.

Of course there are several possible explanations. The child may be the fruit of pre-nuptial intercourse with an infected person. As I have said, a single case proves nothing, but I think my explanation the most probable among those that occur to me; and the question it raises is certainly too important to be hastily disposed of.

Stroud, Gloucestershire. I am, &c. ROBERT B. CARTER.

FOREIGNERS IN THE ARMY MEDICAL SERVICE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you do me the favour to inform me whether it is possible for a foreigner (young Prussian military Physician) to enter the Medical service of the English army? I am, etc.

London, June 1. M.D. Berlin.

[The law forbids it, unless the applicant be naturalized.—Ed.]

THE THREE PHYSICIANS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have heard the old comic song of the "Three Physicians" sung many and many a time in my youth, but never saw it in print until last week in your journal. Perhaps you will let me supply a missing verse, which is essential to connect the substitutions of the chambermaid with the complaints subsequently made by the Doctors.

"Soon a dame, grown with plethora red in the face,  
Called these three Doctors in to consult on her case;  
They retired with much pomp, saying 'Hang it, let's cup her,  
But what news since we last met at Newark at supper?'  
Derry down, etc."

The version I have heard of the two last stanzas is as follows:—

"Says Isaac, 'My friends, pray don't say dis is sham,  
For you see, my dear broders, how dirty I am.  
I don't know vat it ish, but I can't pash a shlongh,  
But I roll myself in it, just like an old show.'  
Derry down, etc."

"Now here's to the learned of famed Warwick-lane,  
Let them ne'er think their trade by our verse we profane.  
Doctors' great eyes aud hands are good emblems well taken,  
And hog's liver aud crow, you know, oft save our bacon.  
Derry down, etc."

I am, &c.

THE DISCOVERY OF THE PROPERTIES OF THE CALABAR BEAN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have read with pleasure the very interesting papers which have been recently communicated to the various Medical journals, on the myositic action of the Calabar bean, proving the interest taken in the subject by eminent men in various quarters. My satisfaction has, however, been slightly shaded with a degree of disappointment that the circumstance of my having had the fortune to discover this action has received an extremely meagre and doubtful acknowledgment.

I have to regret that the investigation on the Calabar bean, which formed the subject of my inaugural thesis, publicly defended on July 31, 1862, has been delayed in its publication, in a printed form, for so long a time. In the meantime, however, I had informed an enthusiastic Ophthalmic Physician, Dr. D. Argyll Robertson, of the discovery, forgetting that by so doing I incurred the risk of losing the advantage of being the first to announce what was my proper discovery.

My letter is not written for the purpose of claiming any disputed honour. My right is distinctly admitted by Dr. Robertson, in the introductory remarks to his first paper, read before the Medico-Chirurgical Society of Edinburgh, and afterwards published in the *Edinburgh Medical Journal* for March, 1863; and Professor Balfour, in the discussion at the Society, which followed the reading of Dr. Robertson's communication, said he was anxious that Dr. Fraser "should have the credit of having first discovered its action on the pupil" (*Edinburgh Medical Journal*, March, p. 861). The reality of this claim will be more fully shown by the publication of my thesis, which will be commenced in the *Edinburgh Medical Journal* for July.

A young writer will be excused, in the meantime, for expressing his chagrin to find paper after paper written on the ophthalmic applications of the ordeal bean, in only the first of which allusion is made to the discoverer, while in all the others he is ignored. I am, &c.

THOMAS R. FRASER, M.D. Edin.

Materia Medica Laboratory, University of Edinburgh, May 26.

THE TREATMENT OF PSORIASIS INVETERATA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As the few remarks I made on this disease in the *Medical Times and Gazette* of January 24, have been so favourably noticed, I am (on account of the apparent interest attached to this class of case) induced to give a short reply to the letters of Drs. Gaskoin and Sadler.

Dr. Gaskoin has misunderstood my statement regarding the treatment I adopted. I never intended to intimate that Fowler's solution and quinine would prove effectual in all cases. I found those drugs useful in my own practice, and have no doubt but many others found them useful in similar cases. I agree with Dr. Gaskoin in thinking that this disease is not apparently confined to any particular kind of constitution; yet, on investigation, I believe we will be able to find some trace of a scrofulous constitution, either "hereditary" or "acquired." When this does not exist, we must then adopt a different treatment from that which may be dogmatically stated to be useful. In that type which is the result of syphilitic impregnation, mercury must first of all be given, and finally Fowler's solution, the use of which has been found to be more beneficial than any of the other compounds of arsenic. I have every reason to believe that quinine will be found a useful adjuvant in every case, especially if any dyspeptic symptoms exist.

Although the remarks on the use or introduction of the liquor arsenici

chloridi are intended for me, I may yet be permitted to offer a few words of remark on its use, and to state that I neither know nor heard of any Practitioner who has ordered this preparation, which at best is of doubtful utility. Some of the oldest and ablest Practitioners, both here and in other places, state to me that their experience is in accordance with my observations. This compound has been omitted from most of our Pharmacopœias, and Mr. Beasley, in his book of prescriptions, merely mentions the dose of this preparation. We may add that most of the compounds of the chlorides are in disuse, and I expect they will, later on, form some of the fashionable remedies of Veterinary Surgeons.

I have here with grateful feelings to thank Dr. Sadler for his kindness in sending me all the published accounts of the Purton Spa. I have no doubt but its use may be beneficial. Together with being sceptical regarding the virtues of spas in general, I must remark that all that has been said in praise of this water cure, its wonder-working good, and indiscriminate use, seems to border on a kind of puff. That class of lepra and psoriasis, the result of syphilitic impregnation, is, as far as I have observed, produced by the repeated application of caustics to the chancres, while no internal remedies had been administered. I will reserve for another time any remarks I may make on the mercurial and non-mercurial treatment of syphilis.

Limerick, May 10.

T. B. MORIARTY, A.B., M.D., &amp;c.

## POOR-LAW MEDICAL RELIEF.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR.—Permit me again to trespass on the pages of your Journal to inform the Poor-law Medical officers that since my last communication with them I have employed much time in superintending and directing the preparation of an extensive series of tables, placing side by side the number of parishes, area in statute acres, population, number of Medical officers, and their salaries at different periods, also the amount of extra Medical fees, and in a final column the total Medical expenditure, the dates commencing in the year 1842, and terminating in 1861; the evidence accompanying this will, I trust, convince the most sceptical of the justice of our complaints, and the incorrectness of some of the material points in Mr. Cane's statements last session. This evidence I intend to lay before the Select Committee as soon as it shall be reappointed. I have, however, been informed, through the medium of a member of parliament, "that the delay in the reappointment of the Committee arises from pressure of business at the board, owing to distress in the north, and that a continuance bill for the year is likely to be brought in." In this I trust my informant may be mistaken, as it is not long since I had a letter, in reply to one I addressed to the Right Hon. C. P. Villiers, promising me "a communication as soon as the appointment is made," which leads me to believe that it was then at least intended to move the reappointment of the Committee; but as it is possible, that even when they meet, it may only be for the purpose of drawing up a report, and not to receive further evidence, I think it most desirable to be prepared for that event, and put into print a part at least of the evidence I have drawn up, in order that the Committee may be in possession of certain facts, and come prepared to recommend to Parliament resolutions which will tend to improve the system of Medical relief to the poor.

The great drawback in placing my evidence in the printer's hands is the want of money, having already expended about £25 more than I have received; it must therefore now rest with the Poor-law Medical officers themselves whether I am to proceed or stand still. I believe we have arrived very near the termination of our up-hill labours; I therefore advise we should go on a little further and crown the summit of the hill; the old adage, "faint heart never won fair lady," is not inapplicable to our case.

No great cause has ever been carried in the House of Commons without much trouble and some expense; and as ours is a great cause, involving annually the welfare of one million and a quarter of the sick poor of this kingdom, I do trust my Medical friends will not shrink from a little further exertion.

I am aware it is considered by many a hopeless task to fight against a public board, but I feel convinced that we have only to prove the soundness of the views we advocate to insure the present President of the Poor-law board following in the footsteps of the Right Hon. J. Sotherton Estcourt, and aiding us in the reform so much needed. Since the commencement of the present year I have received but £19 10s., and part of this is from gentlemen unconnected with union practice—a sum but little over the cost of the postage of the last issue of circulars sent to the 3073 Poor-law Medical officers. I trust I have but to name the circumstance of the want of money to arouse my friends to the very little exertion required to place a few shillings' worth of postage stamps in a letter and forwarding them to me.

Whilst addressing the Poor-law Medical officers on a public question, permit me a little further space to say a few words on a subject personally affecting myself. The facts are briefly these:—Many years since an orphan in very delicate health was placed under my care, the general opinion being that he would never attain his majority; he, however, not only accomplished this, but afterwards proceeded on a tour to Australia, America, and India, and died at Futteghur in March last, leaving all his property to me, subject to certain annuities, which will absorb the greater part of the present income. There is, however, a small estate in Chancery which he was trying for at the time of his death, and if I can establish his legal claim to it, that property will be mine; but, in order to do this, I must prove that he was the heir-at-law, and for this purpose I require the date of the birth of his father, Charles Henry Miller Lolley, and his uncle, John Hopkinson Lolley, sons of William Martin Lolley by his first wife, Ann Swaine, to whom he was married in Liverpool in 1802, and from whom he was divorced in Scotland in 1812. Search has already been made to discover their place of birth, but in vain; I have therefore thought it just possible some one of my Medical friends who possess Medical ledgers for the years 1800 to 1813 might by simply turning to the index of their books, and running down the letter L, by chance discover the name of Lolley, and thus give me a clue to the dates of these births, and assist a brother in either obtaining a few hundred pounds, or in preventing him needlessly expending money in a Chancery suit. The births most probably took place either in or near Liverpool, the father having been a wine and spirit merchant there. In Wales also they had relatives, as the property in Chancery belonged to a Mrs. Allen, of the Glen, near Langillew, Denbigh, but as the divorce took place in Scotland, the births might possibly have been there. This, it will be said, is rather a wide field, but as your Journal is read in all those places, it is not improbable some one of your readers may be found who can assist me.

I am, &amp;c.

12. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

ORIGINAL LECTURES.

PROFESSOR HUXLEY'S LECTURES  
AT THE  
ROYAL COLLEGE OF SURGEONS.

THE LECTURES ON THE VERTEBRATE SKULL.

[The account of the structure and development of the vertebrate skeleton, which was announced as the subject of the latter part of Professor Huxley's course, resolved itself, practically, into a discussion of so much of that subject only, as is involved in the study of the structure, development, and morphological relations of the skull. Partly on this ground, partly because the exigencies of an oral demonstration demand a method and style of exposition which are not those best fitted for descriptive writing, the Lecturer has determined on preserving only the substance of his discourses, and the general arrangement of the matter which he adopted. Henceforward, therefore, the lectures will not be numbered, but the subject matter will appear in successive sections.]

I.—The Structure of the Human Skull.

The human skull is by no means one of the simplest examples of a vertebrate cranium which can be studied, nor is the comprehension of its structure easy; but, as all vertebrate anatomy has started from the investigation of human organisation, and the terms osteologists use are derived from those which were originally applied to definite parts of the organism of man, a careful investigation of the fundamental structure of the human skull becomes an indispensable preliminary to the establishment of anything like a sound comparative nomenclature, or general theory, of the vertebrate skull.

Viewed from without (Fig. 1), the human cranium exhibits a multiplicity of bones, united together, partly by sutures, partly by ankylosis, partly by moveable joints, and partly by ligaments; and the study of the boundaries and connexions of these bones, apart from any reference to the plan discover-

FIG. 2.

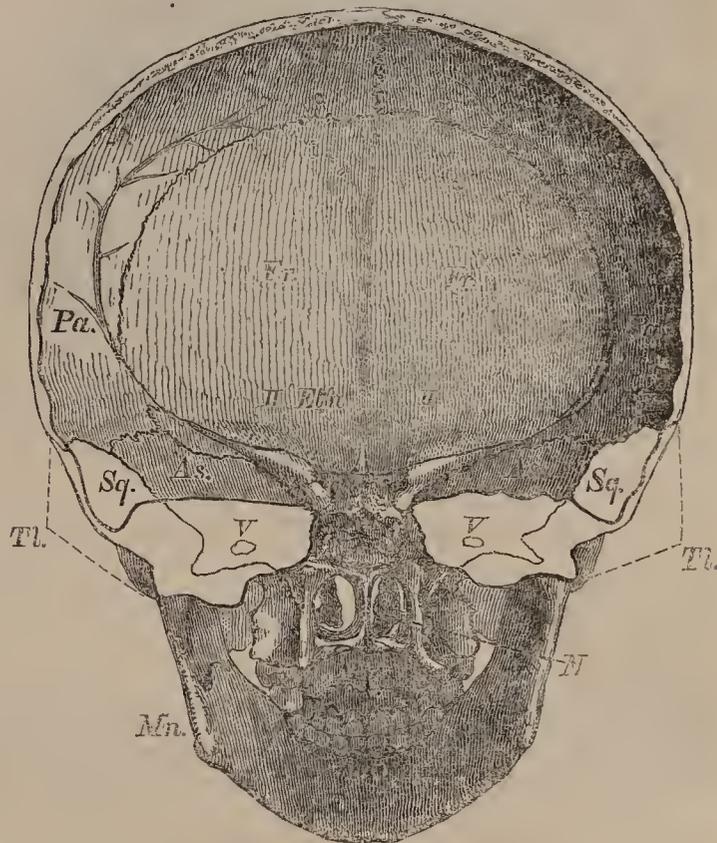

FIG. 2.—Anterior half of the skull of a young person (six or seven years of age) transversely bisected. The temporal bone (Tl) on each side is left in outline, and the contour of the alisphenoid is supposed to be seen through it. II, optic foramina between the roots of the orbitsphenoids; V, foramen ovale for the third division of the trigeminal; N indicates the nasal chamber; Mx is placed in the buccal chamber.

able in the whole construction, is the subject of the topographical anatomist, to whom one constantly observed fact of structure is as valuable as another. The morphologist, on the other hand, without casting the slightest slur upon the valuable labours of the topographer, endeavours to seek out those connexions and arrangements of the bony elements of the complex whole which are fundamental, and underlie all the rest, and which are to the craniologist that which physical geography is to the student of geographical science.

Perhaps no method of investigating the structure of the skull conduces so much towards the attainment of a clear understanding of this sort of architectural anatomy, as the study of sections, made along planes which have a definite relation to the principal axes of the skull.

If a vertical and transverse section be taken through the skull, in such a manner, that the plane of the section shall traverse both external auditory meatuses, the skull will be divided into two unequal portions—an anterior, larger, and a posterior, smaller. The former, if viewed from behind, will present the appearance represented in Fig. 2.

A stout median floor (BS) whence lateral continuations (AS) are prolonged to meet an arched roof (Pa), divides a capacious upper chamber, which, during life, lodged a part of the brain, from a lower chamber, formed by the bones of the face. This lower chamber itself is again separable into two parts, an upper, divided into two by a median septum (Vo)—the nasal passages; and a lower, the oral cavity.

The posterior portion of the bisected skull (Fig. 3) presents, in like manner, a strong floor (BO) and a large upper chamber for the lodgment of parts of the brain; but the lower chamber seems at first to be absent in the skeleton, being represented, in fact, only by the styloid processes (Sty) the so-called stylo-hyoid

ligaments, and the hyoidcan bone (*Hy*) which is suspended by these ligaments to the skull.

FIG. 3.

FIG. 5.

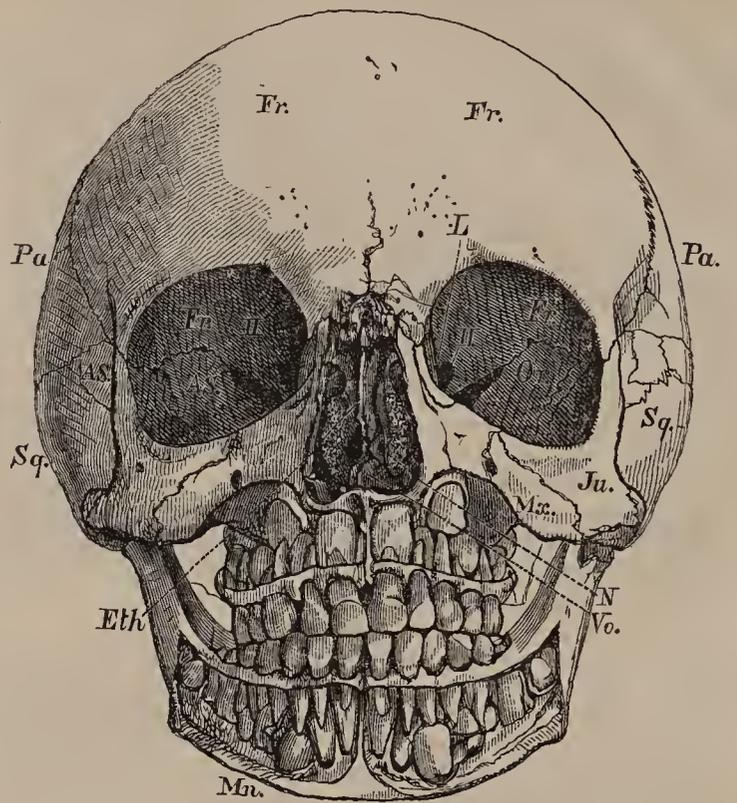

FIG. 5.—Front view of the skull, the halves of which are shown in Figs. 2 and 3. *N.*, nasal chamber; *Or.*, orbit. The nasal bones are removed, and so much of the upper and lower jaws as is necessary to show the permanent teeth.

A longitudinal and vertical section of the skull (Fig. 4) enables us to observe the same relations of the parts from another point of view. The central bones (*BO*, *BS*, *PS*, *Eth.*, *Vo.*), which lie between the arches of the brain-case above and the arches of the face below, are, in such a section, found to constitute a continuous series, from the occipital foramen to the anterior extremity of the nasal passage, which, as it forms the common centre or axis, not only for the bones of the brain-case or cranium proper, but also for those of the face, may be termed the *Cranio-facial axis*.

It will be useful to divide this axis into two portions,—a posterior *basi-cranial* (*BO*, *BS*, *PS*), which forms the centre of the floor of the proper cranial cavity; and an anterior, *basi-facial* (*Eth.*, *Vo.*), which constitutes the axis of the front part of the face.

Three pairs of chambers, destined for the lodgment of the organs of the higher senses, are placed symmetrically upon each side of the double bony box thus described. Of these, two pair are best seen in a front view of the skull (Fig. 5), the inner pair being the *olfactory*, or *nasal chambers* (*N*), the outer pair, the *orbits* (*Or*). The other pair are better displayed in the transverse sections, Figs. 2 and 3, and are formed by the temporal bones of anatomists (*T*), and especially by the petrous and mastoid portions of those bones.

There is an obvious difference between the relations of these sensory chambers to the contained sensory organ, in two of these chambers as compared with the third. The sensory apparatuses of the nose and of the ear are firmly fixed to, or within, the bony chambers in which they are lodged. That of the eye, on the other hand, is freely moveable within the orbit.

An axis, upper and lower arches, chambers for the sensory organs,—such are, speaking generally, the components of the skull. The special study of these components may be best commenced from the cranio-facial axis. Viewed either from above (Fig. 6) or from below (Fig. 7) the cranio-facial axis is seen to be depressed, or flattened from above downwards, behind, and thick and nearly quadrate in the middle; while, in front, it is so much compressed, or flattened from side to side, that it takes the shape of a thin vertical plate. In such a young skull as that from which the Figures 7 and 8 are taken, the depressed hindermost division of the axis is united with the rest, and with the bones *EO*, *EO*, only by sychondroses and is readily separable, in the dry

skull, as a distinct bone, which is termed the *basi-occipital* (*BO*). The basi-occipital furnishes the front boundary of the occipital foramen, and its postero-lateral parts, where they abut against the bones *EO*, contribute, to a small extent, to the formation of the two occipital condyles. In the adult skull the *basi-occipital* anchyloses completely with the ex-occipital on the one hand, and with the next bone of the basi-cranial axis on the other, so that the saw must be called to our aid in order to demonstrate the bone.

FIG. 6.

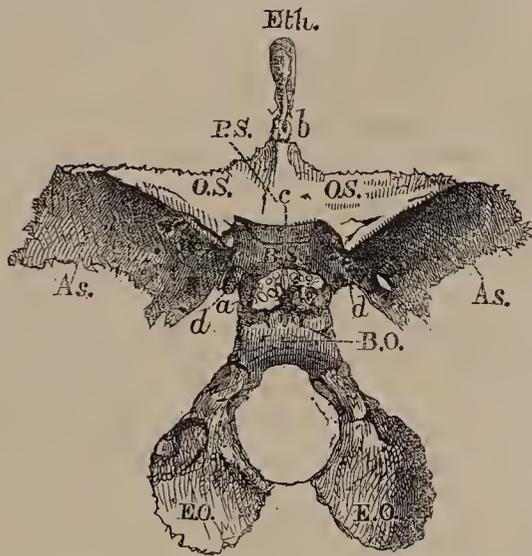

FIG. 6.—Cranio-facial axis and lateral elements of the superior arches of a human skull viewed from above. *a*, the speno-occipital synchondrosis; *b*, the ethmo-sphenoid synchondrosis; *c*, the *tuberculum sellæ*, indicating the line of demarcation between the basi-sphenoid and the presphenoid; *d*, the *lingule sphenoidales*.

FIG. 7.

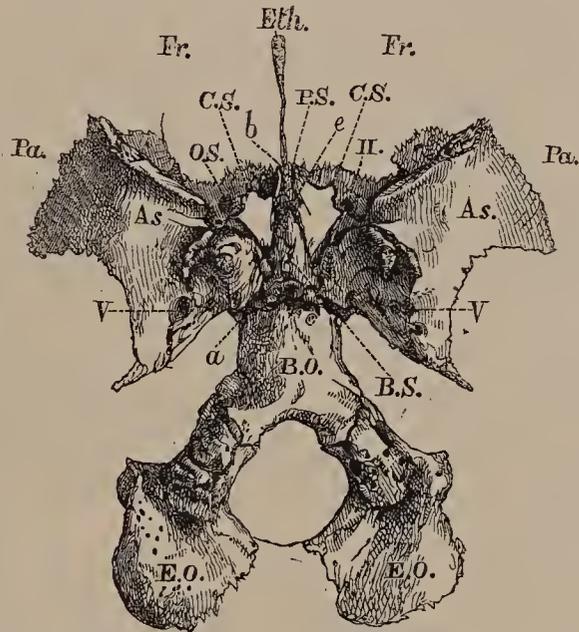

FIG. 7.—Cranio-facial axis and lateral elements of the superior arches (as in Fig. 6), with the pterygoid bones, and without the vomer, viewed from below. *e*, junction of the basi-sphenoid and presphenoid with the internasal cartilage; *C.S.*, *cornua sphenoidalia*, or bones of Bertin.

From the synchondrosis *a* to the point *b*, in even so young a skull as that here represented, the basi-cranial axis is formed by one continuous ossification, excavated superiorly (Figs. 4 and 6) by a saddle-shaped cavity, the *sella turcica*, which lodges the pituitary body,—an organ of no great physiological moment, so far as we know, but of first-rate morphological significance.

On each side of the hinder part of the *sella turcica*, the basi-sphenoid presents a groove for the internal carotid artery, and this groove is completed in front and externally, by an osseous mass, tapering from behind forwards, the *lingula sphenoidalis*, which lies between the basi-sphenoid and ali-sphenoid. At the front part of the *sella*, separating it from the depression for the optic commissure, there is a transverse ridge, the *tuberculum sellæ*. (*a*) The region between the synchondrosis and the

*tuberculum* is the upper surface of the *basi-sphenoid*. Its under surface (Fig. 7) exhibits a median wedge-shaped portion, terminating abruptly at the point *e*, on each side of which are stuck on, as it were, two delicate bones, shaped somewhat like sugar bags, with their wide and open ends directed forwards and their apices backwards. These are the bones of *Bertin*, or *cornua sphenoidalia*, which do not properly belong to the basi-sphenoid, but coalesce with it in the course of growth.

From the *tuberculum sellæ* (*c*) to the point (*b*) in the upper view (Fig. 6), and from the point *e* to *b* of the lower view (Fig. 7), the middle region of the cranio-facial axis belongs to a third bone, the *presphenoid* (*PS*) which terminates the basi-cranial axis.

I say *terminates* the basi-cranial axis, because the appearance of a continuation forwards of that axis by the *crista galli*, or upper margin of the *lamina perpendicularis* of the ethmoid, is altogether fallacious, depending, as it does, upon a special peculiarity of the highest Mammalian skulls, which arises from the vast development of the cerebral hemispheres. In the great majority of *Mammalia* below the Apes, in fact, the free edge of the *lamina perpendicularis* is not horizontal, but greatly inclined, or even vertical; and in these cases the whole *lamina* plainly appears to be, what it really always is, beyond, or anterior to, the floor of the brain-case; while the true basi-cranial bones are parts of the floor of the brain-case.

During foetal life, the basi-sphenoid and presphenoid are united only by synchondrosis, traces of which may even be discovered (as Virchow has shown) as late as the thirteenth year, or later. Even before birth the two bones become anchylosed superiorly, their junction being marked by the *tuberculum sellæ*, and the remains of the synchondrosis extend obliquely from this spot downwards and forwards to the point *e'* on the under surface of the axis, where its cartilage becomes continuous with the osseo-cartilaginous internasal septum.

It is this osseo-cartilaginous septum between the two nasal cavities, the upper free edge of which constitutes the *crista galli*, while the lower free edge supports the *septum narium*, which constitutes the *basi-facial axis*.

All the upper and middle part of this septum is formed by a thin osseous plate, the *lamina perpendicularis* of human anatomy, or true *Ethmoid* (*Eth.*), which abuts, in front, upon the frontal and nasal bones; behind, upon the presphenoid; and below, upon a rod-like mass of cartilage, which becomes connected with the *septum narium* and the premaxillary bones anteriorly and inferiorly, and is obliterated with age.

The inferior and posterior part of the septum is constituted by a bone with a gutter-like upper and anterior boundary, which embraces the whole rounded inferior and posterior edge of the cartilage in question, and thus extends from the under surface of the basi-sphenoid, posteriorly and superiorly, to the middle of the roof of the bony palate anteriorly and inferiorly. This bone is the *Vomer* (*Vo.*).

Thus there are three bones in the *basi cranial axis*,—the basi-occipital, basi-sphenoid, and presphenoid; and there are two bones in the *basi-facial axis*,—the ethmoid and the vomer; and the essential difference between these two sets of bones is, that the former constitute the middle part of the floor of the brain-case, while the latter are altogether excluded therefrom.

We may now turn to the upper arches of the skull, or those bones which form the walls and roof of the brain-case. In the young skull from which the figures 6 and 7 are taken, the postero-lateral margins of the basi-occipital are united only by synchondrosis with the rest of the occipital bone. The parts of the latter which are thus united with the basi-occipital, and which limit the sides of the great occipital foramen, are primitively distinct bones,—the *Exoccipitals* (*EO.*); while the squamous part which bounds the posterior segment of the foramen is known as the *Supra-occipital* (*So, So'*). All these bones, eventually becoming anchylosed together, form the occipital bone of the human anatomist; or what we may term the first, posterior, or *Occipital segment* of the skull.

From the sides of the *basi-sphenoid*, external to the *lingule*, two wide processes, well known as the "greater wings of the sphenoid" or *Alisphenoids* (*AS*) spring, and unite sutureally with the great expanded parietal bones (*Pa*), which form the dome-like crown of the skull, and unite in the middle line in the sagittal suture. In this way a second, middle, or *Parietal segment* of the skull is distinguishable.

In like manner, the presphenoid passes, on each side, into

(a) Where the terms employed in our ordinary handbooks of Human Anatomy do not suffice for my purpose, I employ those used by Henle in his classical "Handbuch der Systematischen Anatomie des Menschen," now in course of publication.

the smaller processes, the "lesser wings of the sphenoid," *ala minores*, or wings of Ingrassias; which, on account of their relations to the orbits, have been well named the *orbito-sphenoids* (O S). And these, externally and anteriorly, unite by suture with the arched and expanded frontal bones (*Fr*), originally double, and separated by a median frontal suture, which ordinarily early disappears. These bones not only meet in front, but send in processes which roof over the orbits and unite with the free anterior edges of the orbito-sphenoids, thus leaving only a long and narrow vacuity on each side of the *crista galli*, and in front of the presphenoid.

The presphenoid, the orbito-sphenoid, and the frontals are the constituents of the third, anterior, or *Frontal segment* of the skull.

It will be observed, however, that this enumeration of the bones of the three great segments of the skull does not account for all the distinct osseous elements which enter directly and indirectly into its boundaries. If all the bones mentioned are put together there still remain four considerable vacuities, two small, already mentioned, in the proper front wall of the skull, on each side of the *crista galli*; and one on each side, posteriorly, between the occipital and parietal segments, of very much larger size, and extremely irregular form. The anterior vacuities are filled up by those spongy osseous masses, united with the *lamina perpendicularis* in the adult skull, which are called "lateral masses of the Ethmoid," or "superior and middle spongy bones," and more immediately by the perforated cribriform plate, which allows of the passage of the filaments of the olfactory nerve, and connects these lateral masses with the *lamina perpendicularis*, or proper ethmoid. Looking at the bones which form the immediate walls of the upper and middle part of the nasal chambers, with reference only to the olfactory organs, we might say, in fact, that the anterior vacuity of the cranium proper is stopped by the ossified walls of the olfactory sacs, consisting of the ethmoid and vomer in the middle line, of the superior and middle spongy bones (or so-called lateral masses of the ethmoid) supero-laterally, of the inferior turbinal bones infero-laterally. And to these ossifications must be added, as members of the olfactory group, the bones of Bertin posteriorly and superiorly, and the nasal bones anteriorly and superiorly.

The great posterior vacuity on each side is filled up by the *Temporal bone*, which consists of a very considerable number of distinct elements, only distinguishable by dissection and by the study of development in Man, but which remain permanently distinct, and undergo very strange metamorphoses in many of the lower vertebrates. Some of these constituents of the temporal bone, such as the squamous portion or *squamosal* (*Sq.*), and the *malleus*, *incus*, and *stapes*, are discriminated by the student of ordinary human anatomy; but there are many others which he is not in the habit of regarding as distinct osseous elements. Thus the bony "external auditory meatus" is primitively a distinct bone, termed *Tympanic* (*Ty.*) on account of its affording the frame in which almost the whole of the tympanic membrane is set. The *styloid process* (*Sty.*) is originally a distinct bone. And, lastly, the *pars petrosa* and *pars mastoidea* of human anatomy are, in reality, made up of three distinct ossifications, of which I shall have to say more presently, but which I shall speak of for the present under the collective name of the *periotic* bones, because they immediately surround the organ of hearing.

Not merely the periotic, but also the squamosal and tympanic bones are so closely related to the auditory organ, that the postero-lateral apertures of the cranium may be said to be stopped by the osseous chambers of the auditory organ in the same way as the anterior apertures are closed by the osseous chambers of the olfactory organs. As the eye is contained only in a mobile fibrous capsule, the sclerotic, the apertures which lead to the orbit—the sphenoidal fissures and the optic foramina—are not closed by any special bones pertaining to the sensory organ lodged therein.

Thus the brain-case may be said to be composed of three superior arches connected respectively with the three divisions of the basi-cranial axis, and of two pair—an anterior and a posterior—of bony sense capsules interposed between these arches. A middle, third pair of sense capsules is not represented by bone in the cranial walls.

At the Thames Police Court, last week, two persons were fined for neglecting to have their children vaccinated. In both cases the children had contracted small-pox.

## LECTURES ON ECZEMA,

(INCLUDING ITS IMPETIGINOUS, LICHENOUS, AND PRURIGINOUS VARIETIES,)

DELIVERED AT THE

Dispensary for Skin Diseases, Glasgow.

By T. McCALL ANDERSON, M.D., F.F.P.S.

Physician to the Dispensary for Skin Diseases; Physician to the Deaf and Dumb Institution, etc., Glasgow.

### LECTURE II. (a)

(Continued from page 557.)

*Ætiology.*—Eczema attacks by preference those of the lymphatic temperament, the scrofulous, and the debilitated, these states of system constituting some of the predisposing causes, the exciting being usually some external nor internal irritant. The disease, however, often attacks persons in the most robust health, in whom neither external nor internal irritation is apparent. These cases must be referred to some idiosyncrasy,—the "Dartous diathesis," as the French call it, which is certainly a convenient word to cloak our own ignorance of its nature. Improper, insufficient, or bad food is very apt to call it forth. The most familiar illustration of this is to be met with in infants whose mothers have a deficient or unhealthy secretion of milk, or who insist upon nursing their children for eighteen months or even two or three years. On the other hand, though not nearly to the same extent, a too liberal diet, and too stimulating food and drink, predispose to, but rarely are the exciting causes of, eczema. Mental excitement seems to operate somewhat in the same way as excessive quantities of nutriment.

Eczema is apparently an hereditary disease, as there are numerous instances of parents and their offspring being affected, several of which are at present under my observation. Devergie says, and very likely correctly, that eczema is probably not, strictly speaking, hereditary, but only the constitution which favours the development of an eczema. This is, however, a distinction without much difference.

Infants and females seem, *ceteris paribus*, to be more liable to it than males, being more excitable and their skins more sensitive. In the former, deficient lactation, as above mentioned, gastro-intestinal disturbance, and dentition; in the latter, derangement of the uterine organs operate frequently as exciting causes.

Atmospheric vicissitudes may give rise to an eruption of eczema, as alternations of heat and cold, a moist atmosphere, a variable climate, etc. The eruption makes its appearance much more commonly in summer and winter than in spring or autumn. Thus Devergie's statistics show that of 384 cases, 60 commenced in spring, 127 in summer, 28 in autumn, and 169 in winter; that is to say, 296 in summer and winter, and only 88 in spring and autumn.

A varicose condition of the veins, keeping up a constant hyperæmia of the parts, as we meet with most frequently on the legs and about the anus, is a powerful predisposing cause; so also are tumours pressing upon the trunks of veins, and producing congestion of these parts from which the ramifications of the trunk are derived. It is in this way that uterine tumours, masses of impacted fæces, etc., predispose to eczema of the genital organs and anus.

While females are more liable to be attacked by eczema than males, the latter are more exposed from the nature of their occupations to the exciting causes. Those whose calling exposes their skin to the action of acrid substances or great heat, are often attacked, *e.g.*, cooks, grocers (hence the term "grocer's itch," the hands being the parts affected), bakers, smiths, bricklayers, etc. The heat of the sun sometimes produces eczema on the exposed parts of the skin (hence the term "eczema solare"). The use of hot and mineral baths, though often beneficial, sometimes calls out or aggravates an existing attack of the disease. Its occurrence is also favoured by working so as to heat the body much and produce perspiration, especially on those parts which are in contact with one another, also by exposure to cold and by the use of cold water in the form of baths, or cloths wrung out of cold

(a) These Lectures have been carefully revised, and many alterations and additions made.

water. Other irritants may likewise produce it, *e.g.*, the friction of thick flannel underclothing, the friction of opposed surfaces of skin, aided by the habitual moisture of the parts in some persons as we meet with between the hips, in the axillæ, on the flexor surfaces of many of the joints, etc.

The application of stimulating liniments may call it forth, as croton oil liniment; likewise ointments, as antimonial ointment, blisters, the preparations of mercury (hence the term "eczema mercuriale"), sulphur, and iodine, alkalies, acids, parasitic fungi, and animal parasites, *e.g.*, lice, fleas, bugs, and lastly, and most important of all, the itch-insect; for almost all aggravated cases of scabies are complicated more or less with eczematous eruptions. This is owing to the scratching which the irritation of these parasites induces.

The irritation of the razor, especially when blunt, and irritating discharges from the nostrils, meatus, mouth, anus, and genital organs are fruitful sources of eczema.

I have known patients affected by sleeping with those who were labouring under the disease, and I quite agree with Wilson in the opinion that this is often owing to the discharge from the eczematous eruptions acting as an irritant to the skin of the healthy person, though not always, for the cause is to be looked for, not unfrequently, in their being exposed to the same predisposing and exciting causes, as bad food, unwholesome dwellings, pediculi, etc.

Internal irritation may give rise to eczema, as that from teething, disordered stomach and bowels, ascarides, tapeworm, fistula, hæmorrhoids, stricture of the urethra, etc. Certain internal medicines may call it forth, *e.g.*, copaiva and turpentine, producing an erythema, which, by scratching, may advance to eczema. The internal administration of arsenic sometimes causes intolerable itching, and the scratching thus occasioned may call forth an eczematous eruption.

The *diagnosis* of most cases of eczema is by no means difficult, if you bear in mind those symptoms which I have endeavoured to impress upon you as being the most prominent and least variable. The itching, the infiltration, the exudation on the surface of the skin, the formation of crusts, and the punctated appearance of the exuding surface, are features which, though not invariably present, should be always kept in view when examining a supposed eczematous eruption with a view to its diagnosis. You must also remember what I have, I hope, convinced you of, that vesicles are by no means essential to the eruption, but that the principal elementary lesion may be either an erythematous state of the skin, a vesicle, a pustule, a papule, or a fissure, and that there is often a mixture of several or of all of these lesions on an eczematous surface. It will be apparent, from what has been said with regard to the causes of eczema, that the state of the system generally, however much it may guide us in treatment, affords a very small clue indeed to the diagnosis of the disease, and we must consequently rely almost solely upon its local manifestations.

*Erythema* can never be mistaken for eczema, if you understand what is meant by the word, and keep in view the fact that it is merely the first stage of an eczema, particularly of that form of it which I have described to you as eczema erythematodes, and that most eczematous eruptions terminate in an erythema. You must therefore be prepared to find patches of erythema mingled with patches of typical eczema in cases of this disease.

Erythema is distinguished from eczema by exhibiting itself in the form of simple redness of the skin, accompanied in the second stage by exfoliation of the epidermis (pityriasis), by the itching being usually more moderate, by the absence of any appreciable infiltration, by the total absence of exudation on the surface of the skin, of vesicles, pustules, fissures, and crusts.

I have known cases of eczema mistaken for *erysipelas*, an error which should rarely be committed, as they differ from one another in very many important respects. Thus, in *erysipelas* the disease tends to creep over the skin and continuously to invade new surfaces; the face and the lower extremities are the parts usually attacked; the redness of the skin is uniform, not punctated as in eczema; the edge of the eruption is abrupt, and the swelling often great. Again, while bullæ occasionally form on the *erysipelatosus* ground, neither vesicles, papules, nor pustules are to be seen; there is no exudation on the surface of the skin (except from the rupture of bullæ), and burning heat, pain, and tension are invariably complained of in the advancing stages, rather than itching, which is only felt in the stage of desquamation.

Lastly, *erysipelas* is usually an acute affection, which runs its course in a week or two, being preceded and accompanied by feverish symptoms of a low type.

Some of the varieties of *herpes* (I do not allude to *herpes zoster*, which can never be taken for it) may be mistaken for the vesicular form of eczema; but in the former the vesicles, which are arranged in clusters, are much larger, remain intact much longer, run their course in a few days, are not replaced by fresh crops, are not accompanied by infiltration of the skin to any extent, and itching is almost completely absent, being replaced by a sensation of burning heat.

The affection which is most liable to be mistaken for eczema is *Scabies*,—the disease due to the presence of the *Acarus Scabiei*; not a recent case, however, but a chronic one which, owing to the long continued and severe scratching, is complicated with eczematous eruptions. If the case is one of scabies, you will usually have a history of the disease being communicated by contagion, and, as far as my experience goes, persons sleeping in the same bed with the patient for any length of time are sure to be affected likewise. Then you will find in most cases, in different parts of the skin, but most readily about the hands or wrists, the little canals which the itch-insects form in the skin, the recent ones containing the acarus and its eggs in various stages of development. On scraping the garments which the patient wears next the skin, and placing the matter on a glass slide, you may sometimes detect the *débris* of acari and their eggs with the microscope. The above symptoms, when present, are conclusive as to the case being one of scabies. But the seat and character of the eruptions in scabies sometimes serve of themselves to clear up the diagnosis. Eczematous eruptions on the nipples of the female, or the penis of the male, or about the hands or umbilicus, are always very suspicious, and so are pruriginous eruptions, which are most abundant on the lower part of the abdomen, the inner aspect of the thighs, and the front of the fore-arms. If eczematous pustules on the hands, feet, and hips be superadded, the case is almost certainly one of scabies. But be careful not to let yourselves be led into error by looking upon patches of eczema of the hands as proof positive of the presence of the itch-insect, unless several of the above symptoms are present also, as simple eczema often attacks, and is limited to, these parts. In doubtful cases, we should treat the patient as if he were labouring under scabies at first (d), when the itching will be at once moderated if it is a case of scabies, but only slightly ameliorated if one of eczema. It must, however, be borne in mind that, although the itching does not entirely disappear under the use of sulphur, we must not conclude too quickly that it is not a case of scabies, for the treatment may not have been efficiently carried out, and even if it has been, the eczematous eruptions which have been called forth by the scratching in a case of scabies, may be a source of itching long after the acari have been killed. Cases, therefore, of scabies complicated with eczematous eruptions, are very liable to be mistaken for eczema; but if we are on our guard, the error is not likely to occur, unless there is no history of contagion, and unless we fail to detect the furrows of the acarus and the insect itself.

A typical case of *psoriasis* can never be mistaken for a typical case of eczema, but when patches of the former have lost their characteristic silvery scales, and when itching is complained of, as sometimes happens, they may be mistaken for eczema. But, in *psoriasis*, the patient's account of the appearance of the eruption at an earlier stage, the more dusky colour of the inflamed parts, the absence of that punctated appearance of the surface so often met with in cases of eczema, and of all moisture, the occurrence of characteristic patches of the disease on other parts of the body, the detection of the eruption on the elbows or knees, and the history of the case in general, should prevent error. And this leads me to state that very many cases are diagnosed incorrectly from confining the examination to one or two patches of eruption, when, by exposing a larger surface and more patches, quite a different picture of the disease is obtained. I think it of great importance, in the diagnosis of all skin diseases, to see the whole, or as much as possible of the skin, even although the patient says that there is no eruption, except where he has indicated, as I have often found such statements to be either knowingly or unwittingly wrong.

*Pemphigus foliaceus* may be mistaken for eczema, and, indeed, some dermatologists hold that it is not a variety of

(d) For the treatment of scabies, see my work on the "Parasitic Affections of the Skin," p. 140. London: Churchill, 1861.

pemphigus at all, but of eczema, an opinion in which I cannot coincide. In pemphigus foliaceus the eruption usually commences on the front of the chest; when fully developed it covers the whole body, without leaving intervals of sound skin; it is almost always fatal; bullæ are usually to be detected at some period of the disease; the infiltration of the skin is not great; itching not usually excessive; the scales and crusts are very large. In eczema, on the other hand, the eruption has no particular tendency to commence in the front of the chest; it never covers the whole body without leaving intervals of sound skin; it is never fatal; bullæ are not to be detected except in a few cases, and then on the soles and palms only, owing to the thick cuticle preventing the bursting of the vesicles; the infiltration of the skin is often great, the itching excessive, and the scales and crusts are not so large as in pemphigus foliaceus.

The disease first described by Devergie as *Pityriasis rubra*, (e) and later by Hebra (f) may be taken for eczema; and, like pemphigus foliaceus, is regarded by some as a variety of that disease. I have seen three or four cases of this rare affection, one of which is carefully recorded by my lamented friend, Dr. McGhie, (g) and the points which are most characteristic of it, in my opinion, as distinguishing it from eczema, are the uniform redness of the eruption terminating abruptly at the edges, but gradually extending till the entire cutaneous envelope is evolved; the exfoliation of epidermic scales, which are easily detached, the masses separated being very large (often several inches in diameter), and so numerous that a basket full may often be removed in the morning; the burning heat; the very slight itching; the absence of infiltration and exudation to any extent, and the complete absence of that punctated appearance of the skin so often met with in eczema, and of vesicles, pustules, or papules.

That rare form of skin disease described by Hebra (h) under the name of *Lichen ruber*, and not referred to, as far as I am aware, by any other author, presents many symptoms in common with eczema. In lichen ruber, however, the eruption consists of papulæ only, and in no case do we meet with either vesicles or pustules. Then, again, when the eruption becomes confluent, while there is redness and infiltration of the skin and epithelial desquamation, as in cases of eczema, there is no exudation whatever, nor formation of crusts, and the itching is only slight. And, lastly, when fully developed, the eruption covers the whole body, without leaving the smallest interval of sound skin, and it is almost invariably fatal in the long run, being preceded by marasmus. These are quite unknown occurrences in cases of true eczema.

Some forms of *syphilitic eruption*, and more especially eczema syphiliticum, may be mistaken for non-syphilitic eczema. But, in the diagnosis of the syphilitic affection, we are assisted by the history of the case, by the occurrence of the eruption after the contraction of a hard chancre, which was accompanied by induration of the glands in the neighbourhood; by its coincidence with other manifestations of syphilis, as engorgement of the posterior cervical glands, syphilitic headache, and rheumatism, burning heat of skin at night, ulceration of the mucous membrane of the mouth, tongue, and fauces, and falling out of the hair. In addition to this, you will often notice several forms of eruption in the skin at one time in the syphilitic disease, as eczema, roseola, condylomata, etc.

But you may have all these symptoms, and yet the eczematous eruption may be non-syphilitic, for there is no reason why a syphilitic patient may not be affected with non-syphilitic eczema. You will be prevented from falling into error, however, by finding out whether or not the eczema appeared simultaneously with other syphilitic manifestations, and by carefully examining the eruption itself. If it is syphilitic, it is most apt to occur near the orifices of the body (about the nose, mouth, etc.), though it is by no means confined to these parts. It has a great tendency to assume the circular form, and to exhibit a coppery tint. Its edge is usually elevated. The ulcers, when present, are larger, deeper, more unhealthy-looking, and have perpendicular edges, and itching is not usually complained of.

(f) "Handbuch der Speciellen Pathologie und Therapie. Dritter Band. Acute Exantheme und Hautkrankheiten," von Hebra. Zweites Heft, p. 321. Erlangen, 1862.

(g) *Glasgow Medical Journal*, January, 1858, p. 421.

(h) For a detailed description of lichen ruber, see "Handbuch der Speciellen Pathologie und Therapie. Dritter Band. Acute Exantheme und Hautkrankheiten." Zweites Heft, p. 315. Erlangen, 1862.

There is just one other caution which I must give you, and it is this, that non-syphilitic eczema occurring on the legs has a tendency to exhibit a decidedly coppery tint and large ulcers with perpendicular edges and unhealthy bases. This is owing to the continued congestion to which these parts are subjected, owing to their distance from the centre of the circulation, to their dependent position, and to their being frequently the seat of a varicose condition of the veins.

If you are still in doubt, treat the eruption by means of localised mercurial vapour baths, when, if it is syphilitic, it is sure to vanish.

There are several other forms of skin disease which you may mistake for eczema, but I prefer alluding to them when I bring under your notice the local varieties of eczema, in which place their diagnosis can be studied to better advantage.

## ORIGINAL COMMUNICATIONS.

### SURGICAL INQUIRIES.—No. I.

#### ON LIGATURE OF THE COMMON CAROTID ARTERY AS A REMEDY FOR PROGRESSING COMPRESSION OF THE BRAIN CAUSED BY EXTRAVASATION OF BLOOD FROM INJURY TO THE HEAD.

By FURNEAUX JORDAN,

Professor of Descriptive and Surgical Anatomy at Queen's College; Assistant-Surgeon to the Queen's Hospital; Senior Surgeon to the Eye and Ear Hospital, Birmingham.

THE varieties of compression of the brain resulting from injury are few and well marked. The symptoms of compression from depressed bone (or foreign bodies) occur instantaneously, and continue without increase or diminution. In compression from extravasated blood, the most valuable indication is gradual increase of the severity of the symptoms. Occasionally the symptoms of compression are deferred for a short time—it may be minutes or hours. Compression of the brain from the presence within the skull of the products of inflammation cannot, of course, occur before the development of the inflammatory process.

Intra-cranial extravasation of blood may occur external to the dura mater, within the arachnoid, under the pia mater, and into the cerebral substance or ventricles. External to the dura mater the hæmorrhage is almost invariably from the large middle meningeal artery, its trunk, or main branches. Within the arachnoid and in the other localities enumerated the hæmorrhage usually takes place from some branch of the internal carotid.

As a general rule, it cannot be doubted that compression from extravasated blood admits of diagnosis from concussion. The present state of our knowledge, however, compels the admission that a small class of cases exists in which the various forms of pressure from effused blood cannot be diagnosed from concussion or from each other. It may be in such cases that pressure is inconsiderable, and that concussion is severe and complicated.

To say that in all cases of concussion there is a physical change, is simply a corollary to the indisputable conclusion of modern science that there is no functional disease. In all cases, except the most slight and transient, there is structural lesion, contusion, laceration, or cerebral hæmorrhage. Such lesion may be apprehended when the symptoms of concussion are protracted, or of a mixed, or of an apparently irregular ("apparently," for in science nothing is irregular), character. The very existence of doubt between concussion and compression should be regarded, I think as diagnostically in favour of concussion complicated with obvious or makroscopic injury. In the slighter cases the injury is subtler—microscopic, hyper-microscopic, or dynamic.

The incontrovertible fact remains, that, of injuries of the head, one of the most common and the most fatal is extravasation of blood from rupture of the large meningeal artery. Of the various kinds of compression from extravasated blood it is undoubtedly the most severe, the most extensive, the most fatal, and the most easily recognised. Its historical landmarks are not readily to be mistaken. Typical cases are numerous, and every Surgeon has seen them. An injury is inflicted on the head by a fall or a blow, which may or may not be followed by concussion; if there is concussion, it is

usually transient. After a longer or shorter interval of consciousness, symptoms of coma appear, which, although slight at first, gradually and surely advance to the common termination—death.

It is necessary that I should examine somewhat closely the phenomena which ensue upon rupture of the large meningeal artery. I shall first describe those symptoms which indicate the earlier stages of compression.

Commencing, partial, and progressing compression from blood which is being poured out from the large meningeal artery, may be recognised by the following symptoms:—After a severe injury to the head, as has already been stated, there may or may not be concussion. If symptoms of concussion are present, they either disappear quickly, or they diminish in intensity. (Should they remain unchanged, there is probably marked cerebral lesion). In either case there shortly ensue very different and very peculiar symptoms. Of these the most conclusive is partial paralysis, showing itself in the side opposite to the injury; in the iris it appears as diminished sensibility, with a tendency to dilatation; in the soft palate it gives rise to slight stertor. The breathing and the pulse become slow and regular. If there has been an interval of consciousness, incoherence of speech and drowsiness, which together frequently resemble intoxication, will usher in the symptoms just recounted. The face is also flushed, and the skin warm—conditions of importance, as showing that reaction has set in; for it is only when reaction from the shock of the injury occurs, that the circulation in the meningeal artery acquires sufficient vigour (as Mr. Fergusson well puts it) to separate the dura mater from the skull and thrust it inwards upon the brain.

It cannot be too strongly insisted upon that the slight coma, slight hemiplegia, slight stertor, and the other symptoms referred to, gradually increase in intensity, and we have, after hours of constant bleeding from the large meningeal artery, all the phenomena of

*Complete compression*, namely, complete hemiplegia, intensely loud stertor, "whiffing" at the corner of the mouth, a largely dilated and quite insensible pupil. Paralysis of the rectum and bladder, as evinced by the spontaneous evacuation of fæces, and retention of urine (a) is also present. The spontaneous escape of fæces, however, when the rectum is loaded, is a sequence of other states of the nerve centres, attended by temporary muscular depression, apart from that of physical compression. Unconsciousness is also a condition by no means peculiar to compression of the brain; but, allied with other symptoms, it has at least a negative value, and when it comes on gradually, after partial or complete recovery from concussion, it is justly attributed to extravasation of blood. An excellent observer, Mr. Bryant, records a singular case, which he entitles "relapsing concussion." I cannot but think that the relapsing unconsciousness was due to a slight cerebral hæmorrhage, occurring with reaction—a condition frequently recovered from. Mr. John Adams appears to agree with Abernethy, Brodie, and Guthrie in attaching great importance to slowness of the pulse (36 to 40 in adults, 50 in children) as an indication of compression.

Hæmorrhage from any source, except the large meningeal artery, in sufficient quantity to produce compression, is exceedingly rare. The effusion of blood in small quantities, as one of our best observers in this province of Surgery, Mr. Prescott Hewett, has fully shown, is not infrequent. When compression does occur, as indicated by its characteristic signs, the hæmorrhage is usually from one of the larger branches of the internal carotid, and is seated opposite the middle fossa of the base of the skull, where, from obvious anatomical conformations, the severest cerebral lacerations take place. Anatomical peculiarities also prevent, as a rule, laceration of the cerebellum or posterior lobe of the cerebrum, hence the extreme infrequency of hæmorrhage from the

branches of the vertebral artery. Effusion of blood from a sinus is a still more exceptional circumstance. Mr. Adams, an eminent authority, apparently regards it as highly improbable. That the passively flowing venous blood in a canal separated from the bone by a wall of dura mater is capable, when that wall is ruptured, of separating the dura mater from the bone and driving it into the brain, seems almost incredible, when a comparatively large, strong, and vigorous artery like the middle meningeal takes hours, occasionally very many hours, to tear the dura mater from its firm osseous attachment—an attachment, too, which becomes more intimate the closer we approach the base of the skull, as in the locality of the lateral sinus. It is much more probable that a rupture being produced in that layer of the dura mater which forms the inner wall of the sinus, copious hæmorrhage should occur into the arachnoid. A case, however, is recorded by Mr. Prescott Hewett, where extravasation, with compression, occurred from the lateral sinus. Mr. Hewett also considers that in such cases concussion merges into an immediate and severe compression. Thus, according to this able observer, the extremely infrequent accident in question differs materially in locality, in history, and in symptoms, from rupture of the large meningeal artery.

I have now given a brief summary of our knowledge of compression of the brain from sanguineous effusion. The propositions I have made, while they certainly represent my own experience, accord also, I believe, in the main with the views of our best and most modern observers—Prescott Hewett, John Adams, Bryant, Fergusson, Erichsen, and Syme.

Having shown that among injuries to the head one of the most common, severe, fatal, and, in its several stages, the most easily recognised lesion is rupture of the large meningeal artery, I now propose a remedy that shall arrest the hæmorrhage in its earlier stages, and consequently save both brain and life. The remedy alluded to is the application of a ligature to the common carotid artery. Bearing in mind the known effects of the operation, and the nature of the changes it is proposed to arrest, such a proceeding is at once suggested by the facts of anatomy, the laws of physiology, and the principles of surgery.

Commencing and progressing compression from rupture of the large meningeal artery can, in a certain number of cases, as every authority admits, be undoubtedly recognised. If, then, at the commencement of the hæmorrhage, a ligature be placed on the common carotid artery of the same side (and opposite to the hemiplegia), the flow of blood will as certainly be stopped as when a ligature is applied to the carotid for a wound of the tonsillitic artery, or a wound of the internal carotid in the pharynx, or for an aneurism in the orbit.

In such an accident as hæmorrhage from the meningeal artery, the most delicate organisation in the body and life itself are at stake. For this very injury, however—the most terrible and fatal in surgery—there is practically no treatment.

The views of modern authors on the use of the trephine in compression from extravasated blood are so generally unfavourable that I do not misrepresent them at the same time that I express my own opinion when I say that the trephine is practically useless in the injury under consideration.

The most that can be said for the operation of trephining is that it is a little less severe and a little less fatal than some of the accidents in which its use is resorted to. The following statement will approximate sufficiently near to the truth (and probably it favours the trephine) to afford a conception of the relative gravity of the operations of trephining and deligation of the common carotid artery. In ten adults to whom the trephine is applied, nine die from the operation; in ten cases of ligature to the common carotid, one dies from the operation. The objections to the trephine in compression of the brain from extravasated blood are so overwhelming that, not only is it rarely resorted to, but it is everywhere taught that its use should be avoided until death itself is close at hand. In all cases the removal of the clot is extremely difficult, and, in most, impossible. In a large number of cases the coagulum is formed at the floor of the cranial cavity, in all other cases the blood descends towards the base, and in most instances it reaches it. At the same time the clot is very widely diffused, is very hard, and is remarkably adherent to the dura mater. If very diffused, the trephine is utterly inadequate to its removal; if not diffused, its locality is variable, and can rarely even be guessed at (for in most cases of rupture of the meningeal artery the fracture is simply a crack or fissure, and

(a) Very conflicting views are taught in explanation of the circumstance that in paralysis affecting both rectum and bladder the contents in the one viscus escape, and in the other are retained. I submit that clinical experience, physiology, and the anatomical disposition of the organs in question point to the following interpretation:—The rectum discharges its contents only when loaded. Now, when the rectum is loaded, more muscular force is required to retain than to expel the fæcal accumulation. In the bladder an opposite condition prevails; here more force is needed to expel than to retain the fluid contents. When the bladder is distended to the utmost degree which its physical strength permits, the urethra becomes distended also, and the bladder runs over. There is no incontinence. When the healthy bladder is distended, discomfort arises from prolonged efforts to refrain from expulsive action. When the healthy rectum is distended, discomfort arises from the endeavour to maintain contraction of the sphincter.

affords no external indication of its locality, and, in extremely rare cases, rupture of the large meningeal artery may occur without fracture), hence in a few cases the trephine has been applied at one spot, and the coagulum has been elsewhere.

If the objection be made that the diagnosis of the source of hæmorrhage cannot be so accurately established as to justify the application of a ligature to the common carotid, I reply, that while the objection militates powerfully against the use of the trephine, the presumed uncertainty illustrates the advantage of the proposed remedy, for if in the hours which succeed to a serious injury to the head there appear symptoms of pressure on the brain, in ninety-nine cases in a hundred blood is being poured out of some branch of the external or internal carotid arteries.

As compression occurs with or follows reaction and vascular activity, there is not only no danger of syncope—which in the uncompressed brain occasionally follows the application of a ligature to the common carotid—but a prospect of actual relief from the compression, apart from the great object of the proceeding, namely, the prevention of further hæmorrhage. To diminish the aggregate quantity of blood circulating in a compressed cerebral hemisphere must certainly diminish the compression. Physical laws and logical deduction alike necessitate the conclusion that, to diminish the bulk of the compressed body is to diminish, possibly to remove, the compression. In this way may be explained the apparent and temporary benefit which has been occasionally observed after a justly discarded proceeding—venesection—in the various forms of compression.

Cases of compression from extravasated blood are frequently under supervision from first to last, and consequently great facility is presented for the adoption of the treatment now put forward. Unfortunately, however, no remedial measure has ever been proposed for any human ailment which is not too frequently powerless, because the appropriate cases come too late.

The advance of physiological science will every day enable us to diagnose with increasing certainty the various lesions to which the encephalon is subject. Moreover, if the remedy which I submit to the impartial consideration of Surgeons be regarded as one offering a means of prolonging life, it will tend to stimulate to closer observation and improved diagnosis of cranial injury.

The progress of pathology already suggests a means of increasing the safety of the operation of applying a ligature to the common carotid artery. The occurrence of embolism best explains almost all the more serious evils (cerebral inflammation and softening, and pulmonary affections) which occasionally follow deligation of the common carotid. As the dislodgment of coagula giving rise to this condition is greatly influenced by motion, I should, for several days after the operation, immovably fix the head, neck, thorax, and shoulders by appropriate apparatus.

Whether, in consequence of the degenerative changes in the cerebral vessels, deligation of the common carotid could secure any advantages in apoplexy is for Physicians to determine. Such determination will be influenced by certain questions: Is there any form of apoplexy in which sanguineous effusion admits of accurate diagnosis? Are the seats of extravasation regular or ascertainable? In a given case are the causes exceptionally severe or unlikely to recur?

I have already so closely condensed the conclusions put forward in this paper, that they do not admit of a shorter recapitulation. I would, however, earnestly draw the attention of the reader to the following reiterations:—1. That compression of the brain from extravasated blood is a common and a very fatal form of injury. 2. That in a large number of cases it is recognisable in all its stages. 3. That hitherto no treatment has afforded relief. 4. That in the earlier stages (not necessarily the earliest) brain and life may be saved by the application of a ligature to the common carotid artery.

A BON-MOT.—A lady applied to one of the most celebrated Parisian Surgeons, complaining of a severe pain in the region of the rectum, requesting him to fix a time to come and visit her at home. Having done so, he inquired her address, which she gave as “*Avenue du Cocyte*.” “*Avenue du Cocyte*,” replied our surprised confrère; “but where in the world is that?” “Leading out of the *Rue St. Lazare*.” “Oh, I understand now, *Avenue du Coq*, No. 6.”

## Medical Times and Gazette.

SATURDAY, JUNE 13.

### THE PROCEEDINGS OF THE MEDICAL COUNCIL.

OUR Medical Parliament has met, held its session, and prorogued itself till next year; it sat nine days, or rather afternoons, and, judging from the length of the printed minutes, got through a considerable quantity of work; indeed, the matters discussed, and the motions made, with or without one or more amendments, were so numerous that we do not wonder that the Council felt a generous pity towards its clerks, and voted them each a gratuity of ten guineas “for their extraordinary labours.” The number of speeches made, their average length, the prevailing style of oratory, who are the Gladstones, the Palmerstons, the Whallys, of our little senate, whether or no it contain a Rupert of debate, all these things are hidden from us by the vote which still refuses a reporters’ gallery; a refusal to ourselves “in mercy sent” we think; but, whether it be so or not, we are not likely to enjoy it long. The system of “*Annuals*,” so successfully cultivated in “another place,” has taken root in our Council chamber also; and, as the motion for the admission of the press, which last year counted only six supporters, was this session lost by only the casting vote of the President, we may be certain of its reappearance next year with increased probability of success. But though we cannot have the pleasure of reading the eloquent speeches by which, no doubt, the requirements of the times, the feelings of the Profession, etc., were enforced, we have the satisfaction of criticising the individual voters. Any member can require that the names of the majority and minority of any division be hung up for public inspection,—a gibbeting privilege, which accordingly one member did exercise on this, and, indeed, on many other occasions; and it is somewhat curious to observe that on this question the majority is nearly entirely composed of the English representatives, the Scotch and Irish members almost exclusively forming the minority. Shall we confess that, thinking sadly of debates in “another place,” this fact by no means tends to lessen our respect for the astute *amour propre* of the majority.

We have been careful to mention the quantity of work the Council has apparently achieved, because we are anxious to give it all possible praise, and it evidently places a high value on mere quantity. We must, on this account, regret that we cannot follow the example of its Pharmacopœia Committee, and give numerical details of work done. Would that we could do justice to the members, by recording the exact number of attendances—the daily and total number of hours and minutes spent in the Council chamber—the total and individual number of speeches made, and votes given, and so on; but we must content ourselves with a general acknowledgment of the severe industry of the Council, and proceed to consider the quality of its work. In our last number we noticed the

praiseworthy vigour shown by the Council in casting out from the Register the black sheep of the Profession, but we gave them more credit than they deserve. We stated that they had erased Robert Jacob Jordan's name from the Register; this was a mistake; they only erased "his qualification as a member of the College of Surgeons of England." We are forced to suppose that they did not consider the pandering to the public taste for erotic anatomy amounted to "infamous conduct in a Professional respect," or why did they not mete out to him the same measure of punishment as to Samuel La'Mert? We are curious to know how the representatives of the College advised in Council on this subject; the College can rule the Council in other matters, why not have incited it to more vigorous and courageous action here? or does that which is "flat blasphemy" in Lincoln's-Inn-Fields wear a lighter hue in Pall-Mall?

The Council of the College of Surgeons has written a letter to the General Council, containing some touching and very original remarks on the blessings of domestic life and associations, and the dangers of exposing ingenuous youths to the temptations of the Medical Schools, and stating that they mean to continue to do what they like, and are not going to be fettered by the recommendations of the General Council. We know that there are those who have looked with fear and trembling at the Ajax of the examining boards defying the lightning of the Council, and who have innocently believed that the latter body would exercise its power by reporting to the Privy Council that "the regulations of the College of Surgeons of England are not in accordance with the recommendations of the Medical Council, and not such as to secure the requisite knowledge and skill for the efficient practice of Surgery;" that, consequently, the examining halls of the College would become a howling desert, and the palace in Lincoln's-Inn-Fields be reduced to a library and a show-shop for Hibernian giants and the products of natural selection. Nothing of the sort occurred. The College knew what hands held the bolts, and complacently felt secure. The Council is content to record that many of the examining boards are very fairly good and obedient, and that in their "opinion" it would be nice if all were as pretty-behaved; and there the matter rests,—a very encouraging result for the restive boards, and one likely to bring forth much fruit. The College of Surgeons of Edinburgh, fearing for its fees, has already suspended one of its regulations, made in accordance with the recommendations of the Council, and so has lowered itself again to the level of the English College, and we may expect to see other bodies follow its example. Lacking confidence in the wisdom of its own recommendations, or lacking courage to attempt to enforce them, the Council proposes to throw on the Privy Council the responsibility of making "regulations respecting the education and examination of Practitioners in Medicine, Surgery, and Pharmacy." The Medical Council will, indeed, venture to draw up regulations, but they are not to be obligatory till they have been endorsed by the Privy Council. This happy device for increasing the dignity and usefulness of the Medical Council is to be contained in an amended Act, which may perhaps be obtained some day. Meanwhile, the Council will exercise and train its talents in drawing up regulations, which the Universities, Colleges, etc., will adopt or not, just as they please.

As the suggestions for amendments of the Medical Act are not to be considered in Council until next year, it is not worth while our discussing them now. The new Section—LVII.—will certainly never be carried; it would seriously lessen, if not entirely destroy, the Government trade in patent Medicines, and is therefore a hopeless suggestion.

We are glad to see that the Council propose to take steps providing for the education and examination of all chemists and druggists; but any measures for this purpose will require great care and consideration, or they will only serve to confuse the public and foster the druggist's counter practice.

If a chemist can announce that he is a "certificated compounder of Medicine of the Apothecaries' Company, or the Pharmaceutical Society according to the Medical Act," how are the public to distinguish between him and the Licentiate in Medicine of the former body? The Council passed the motion that "the Licentiates of the Apothecaries' Company in Dublin are, as Apothecaries, entitled to practise Medicine in Great Britain and Ireland."

In reply to an inquiry from the Army Medical Department, the Council, in accordance with the decision of the law officers of the Crown, confirmed their previous decision, that the College of Surgeons of Ireland has not the power to grant a licence in Medicine.

No decision, however, was come to about registering licences in midwifery; we are naïvely informed that the Executive Committee had refused to register certain licences in midwifery conferred by the Colleges of Physicians and Surgeons in Ireland; but that a solicitor's letter, "couched in peremptory terms," made them at once draw in their horns, and yield the request; and, with an acknowledgment that the present state of things regarding these licences is very inconvenient and unjust, all further consideration of the matter is deferred to the next meeting of the Council.

The opinion of the Chief Justice of the Common Pleas in the case of *Turner v. Raynell* does not appear to have been noticed by the Council. According to that decision it would seem that a Medical firm can recover for services rendered by any of its members, so long as any one of them is registered. Any one may therefore evade payment of the registration fee by entering into partnership with a registered Practitioner. This is certainly entirely contrary to the spirit of the Medical Act, and is, we should have thought, in both a legal and a financial point of view, eminently worthy of the consideration of the Council.

The Council adopted a simplified form of registration of Students—a form which appears to us scarcely capable of further pruning; but, with the want of confidence in themselves which characterises all their acts, they afterwards passed a motion to refer "to the branch Councils to report to the next meeting of the General Medical Council as to the simplest mode of registering Medical students."

The Council actually had the courage to enunciate the proposition "that the overloading of the curriculum of education, whether as to the number of courses, or of lectures in particular courses, must be followed by results injurious to the students," a self-evident proposition, some may think; but let us be thankful for any real decision by our Parliament. We are happy to say they also expressed a positive opinion "that the number of courses of lectures required to be attended" by the several licensing bodies "might be reduced with advantage, so as to give the student a larger amount of time for self-education;" and they resolved to "take into consideration, at the next meeting, the propriety of recommending a reduction in the number of courses of lectures," so that any student Utopian enough to imagine that the licensing boards will meekly follow any of the recommendations of the Council, may indulge in dreams of "a good time coming." We defer our consideration of the proceedings relative to the new Pharmacopœia to a future occasion.

## THE WEEK.

### ERUPTIVE FEVERS DURING PREGNANCY.

The *Edinburgh Medical Journal* for June contains an amusing account of Arab Surgery by Mr. P. K. Varban, L.R.C.S. Edin., who is settled at Nazareth; it likewise gives an account of an interesting discussion on eruptive fevers in pregnant and parturient women. Dr. Simpson laid down what we believe to be the law, that they may attack pregnant women who may recover; not so parturient women. It will be interesting if an account can be taken of the pregnant women who

suffer from small-pox during the present epidemic in London, and of the results.

#### EFFECTS OF MERCURY ON SHEEP.

PROFESSOR JOHN GAMGEE, in the June No. of the *Edinburgh Veterinary Review* draws attention to the mischiefs arising from the reckless use of mercurial ointment as a dressing for scabby sheep. Sheep, he says, and ruminants are more readily poisoned by mercury than any other domestic animal; and in some instances, mercury appears to be the cause of death *directly*, by its effects on the blood; in others it seems to kill by the varnish with which it covers the skin, which hinders the exhalations from that organ, and engorges the lungs; in others, again, it seems to produce an enfeebling of the digestive powers, so that a change to a better diet proves fatal. Severe salivation and loosening of the teeth are common occurrences.

#### RABIES IN SHEEP.

THE same Review gives an extract from the *Albany Country Gentleman* of a series of cases of rabies in pregnant ewes, which were bitten by a mad dog, December 24, 1862. The wounds healed rapidly. The disease was noticed on January 12, 1863. The number of cases was seven; the period of incubation varied from nineteen to twenty-six days; the average duration eight days. All fatal. The first symptom was extraordinary and unnatural salacity, in which the manner, and gestures, and sounds of the *male* were closely imitated; followed by unhealthy appetite, swallowing wood, straw, dung, etc.; no thirst, and no dread of water; intense pugnacity and frenzy; *reopening of the wound*; debility and prostration; neither stupor, paralysis, nor convulsions.

#### PARLIAMENTARY.

THE Vaccination Bill (Ireland) was read a second time in the House of Lords on Friday, June 5.

On the same evening, the case of Sergeant-Major Lilley, a non-commissioned officer of the 6th Dragoons, serving in India, whose death was caused by illegal confinement, was brought before the House of Commons by Mr. D. Fortescue. We need not allude to the circumstances under which Lilley was ordered under arrest by the officer commanding his regiment, Colonel Crawley. It is sufficient that the Judge-Advocate pronounced them entirely condemned by law, and the Commander-in-Chief in his memorandum, and speaker after speaker in the House proclaimed their cruel injustice. No Medical man will doubt that Lilley's death was as directly caused by his imprisonment as those of the prisoners in the Black Hole of Calcutta. Himself, his wife—dying of phthisis complicated by diarrhoea—and two other sergeant-majors, were closely confined during several weeks in a single room in a bomb-proof building, formerly used as cavalry stables, which has since been pulled down as unfit for occupation. The room was literally an oven, for its roof could not get cool,—the fall of temperature at night not being sufficient to carry off the heat collected during the day. A sentinel was placed over the sergeant-major, with injunctions to keep him constantly in sight, and not to permit him to receive any communications from without. In consequence of a sergeant's wife having attempted to communicate with the sick woman Lilley, Colonel Crawley ordered the sentry to be stationed inside the room, and there, in the presence of strange men, renewed from day to day, and posted three feet from her bed, all the functions of nature had to be performed by this dying woman. After four weeks' imprisonment, Sergeant-Major Lilley died. No inquest or committee of inquiry, which would be in India equivalent to an inquest, was held, but a *post-mortem* examination was made by the regimental Surgeon, who certified that the cause of death was apoplexy, brought

on by his sedentary life, and the peculiar circumstances in which he was placed. One of the other sergeant-majors confined was on his release found to be delirious, and was immediately conveyed to the Hospital, where he was discovered to be suffering from brain fever. An attempt was made after Lilley's death to prove that it had been caused by excessive drinking, and a sutler's bill for wine and spirits, supplied under Medical orders to the sick wife, was offered as evidence. Sergeant-Major Lilley's character has been, however, completely cleared from this allegation,—a fact which has been acknowledged in the Memorandum of the Commander-in-Chief. Notwithstanding the atrocity of the case, the authorities at the War Office have determined to retain Colonel Crawley in his command. The Commander-in-Chief has contented himself with reprimanding him in company with two or three other officers of the regiment, amongst whom is the Surgeon—the last on the ground that he had shown some disapprobation of his commanding officer before a younger member of the corps! Discipline, no doubt, is the first necessity of existence in an army, but it is certainly an estimate of guilt peculiar to the Horse Guards to punish a man for a deed of tyranny which produced the death of an innocent and meritorious soldier, and another for expressing disapprobation of the former's conduct by reprimands, if not verbally identical, yet written in the same official tone, and contained in the same Circular. From the speech of the Marquis of Hartington, it appears that Colonel Crawley had obtained the sanction of his two commanding officers, Generals Sir W. Mansfield and Farrell, for placing Lilley under close arrest. It is clear, however, from the expression of opinion in the House, that this horrible tragedy must be submitted to further investigation.

On Monday, Mr. Gregory's resolution that the Royal Botanical Gardens of Edinburgh should be open to the public after the hours of Divine service on Sundays, as is the case of other botanical gardens supported by Parliamentary grants, was negatived by a narrow majority of sixteen, in deference, it would appear, to the strong views on the subject held in Scotland, and expressed by the Lord Advocate, Mr. Mure, and Major Hamilton.

In the House of Lords on Tuesday, the Security from Violence Bill was read a second time without a division.

In the House of Commons, Mr. Ferrand gave notice that he would, on Thursday next, ask the Secretary of the Home Department whether it was his intention to introduce a Bill this Session to limit the hours of labour for children in potteries and paper-tube factories.

#### MEDICAL BOOKS AND THEIR TITLES.

THE propositions that a title which merely expresses the subject of the work is no more matter of property than the subject itself, and that in a general subject there can be no copyright, seem to be of such an obvious and elementary nature, that our readers will probably be surprised at our deeming it necessary to draw attention to them. It is the undoubted privilege of every man to publish a book upon any subject he pleases; and, having done so, most authors would not have much hesitation in calling the publication by its right name, without troubling themselves to ascertain the titles of previous works treating on the same matter. Suppose the laws or ethics of literature to have enforced the observance of a contrary rule, and then imagine the position of an author who should be enterprising enough to add one to the number of existing English dictionaries. Those already published would of necessity have been called by different names, and "Dictionary," "Vocabulary," "Lexicon," "Thesaurus," "Alveary," Word-book, every available Latin, Greek, and Anglo-Saxon derivative having been exhausted, human ingenuity must fail inventing a new name which would indicate the nature of the work. The author would be compelled by the operation of such a law either to suppress

his book, or to give it to the world destitute of a title. Lord Macaulay, in publishing his "History of England," would have been involved in still greater difficulties by the application of so rigorous a code of literary morality. The rule that we are deprecating has lately been impliedly enunciated to its fullest extent by two members of the Medical Profession, the referees in the questions between Dr. Mayne and Dr. Fowler, as to their works respectively published under the title "Medical Vocabulary." These gentlemen, while wholly acquitting Dr. Fowler of the charge of plagiarism, expressed an opinion that the title of his work was derived from Dr. Mayne's, and that the appropriation was not justified so long as the copyright of the "original" work existed. It is almost needless to state that in the reports of legal decisions on matters of copyright no case can be found in which mere identity of title proceeding from the common adoption of a general subject has been even alleged to involve an infringement of copyright. The marginal note to the report of one case decided by Lord Eldon is to the effect that copyright exists in an individual work, but not in a general subject, though from its nature the consequence may be close resemblance and considerable interference. That to another case determined by Lord Erskine contains these words, "Though copyright cannot exist in an East India calendar as a general subject, any more than in a map, chart, series of chronology, etc., it may in the individual work." However, in neither of these cases had the doctrine in question been alleged by either side to be law. In fact, the referees, Dr. Peacock and Dr. Meadows, would appear to be the originators of the idea of property in such a title as the one they speak of; and a moment's reflection will convince our readers that no such principle is acted on or recognised in the literary world, in reference to Medical or any other works.

## LOCAL REPORTS ON SMALL-POX.

(Continued from page 567.)

### XX. *Small-Pox and Vaccination in Putney and Roehampton.* By Dr. HARLAND WHITEMAN, Medical Officer of Health for Putney.

UNTIL December of last year small-pox had for a long series of years been absent from this parish and adjoining hamlet. The first of about a dozen cases noted between the latter part of 1862 and the present time, occurred to an unvaccinated labouring man, who had just before removed into the parish. This case proved fatal in the Small-Pox Hospital, to which institution the patient was removed shortly after the appearance of the disease, and the death was, of course, registered there. The remains of the poor man, however, were brought from the Hospital to be buried in this neighbourhood. A brother of the deceased living in Putney attended the funeral, and contracted the disease; but having accidentally heard that this man was also unvaccinated, I persuaded him, although symptoms of the malady were then plainly visible, to submit himself at once to the operation, and a more decided proof of its protective power I could not have received. The two diseases—the vaccine and the varioloid—went through their course together, and presented all the characteristic phenomena of each, but the one so modified the other, that the patient recovered without a bad symptom.

The only other fatal case of which I am cognisant occurred to an unvaccinated nurse-child, nine months old, who it appears was not born in the parish, and whose unprotected condition was therefore unknown and unsuspected until too late to remedy the evil. Two other persons residing in the same house in which this infant died, viz., a boy of 12 and a girl of 16, shortly afterwards took the disease. Whilst attending the infant, I noticed this boy and girl looking very ill, and, suspecting the cause, I urged the performance of vaccination on them both. The boy submitted, being then unprotected, and he had the varioloid disease very slightly, and made a good and speedy recovery. Not so, however, the girl, who, relying on the efficiency of her vaccination in infancy, (though I had great doubts whether the operation had ever been performed,) was greatly opposed to its performance, and

the consequence has been she has experienced a prolonged and painful convalescence, and will, doubtless, carry about with her to her latest hour the most unmistakable facial indications of the virulence of the malady from which she has suffered.

I could cite many cases of a like kind from the records of a practice of nearly thirty years, during the greater part of which time I have performed the functions of a public vaccinator, but the above are referred to as having recently afforded to my own mind strong evidence that vaccination, submitted to even at the eleventh hour, does largely protect against the virulence and fatality of small-pox, if it accomplishes nothing more. My own experience is that, when properly performed, carefully inspected on the eighth day, and pronounced by a skilled operator to have put on all the characteristic appearances of the true vaccine vesicle, as described by Jenner, it may be relied on as a perfect protection through life, in a large majority of cases; but since there are so many exceptions, and as it is an undoubted fact that many persons do take small-pox, though the most efficient vaccination has been accomplished in infancy, the question of re-vaccination becomes one of serious import to Medical men, to whom the public are just now looking for advice and direction upon so debatable a point.

The absolute infallibility of primary vaccination few practical men of the present day will be found to maintain, any more than they will the uniform action of the best established remedial agents. Persons of particular habits or idiosyncrasies there always will be in whom the most careful administration of well-known drugs will be followed by the most extraordinary and unlooked-for results, and it is not likely that cow-pock inoculation will be found uniformly exempt from all departures from its ordinary issues.

Whenever appealed to by the sceptical or the hesitating as to the desirability of re-vaccination, my reply is, that as the occasional introduction of genuine and well-selected vaccine lymph into the arms of young persons and adults is, with very few exceptions, attended by no other inconvenience than a slight and bearable irritation, and the most trifling constitutional disturbance, most Medical men are disposed to look upon it as a very simple, but at the same time very valuable test of the efficiency, or otherwise, of previous vaccinations; for should such re-vaccination fail to produce a perfect vesicle, what, I usually ask, can be more satisfactory than to feel assured that the protection afforded by the operation in infancy remains, in all probability, unimpaired? On the contrary, should it result in the production of the perfect vesicle, is it not something to feel more secure than before against the virulence of the disease, and the fatality so frequently attending it when occurring in the unprotected? This kind of reasoning I generally find suffices to remove the scruples of those of my patients who are really capable of being reasoned with on such a subject. The unreasonable, the ignorant, and the prejudiced are, I think, much better left to be persuaded or frightened, as the case may be, out of their scepticism by the cautionary handbills and other notices that have been very judiciously issued by both the Board of Works and the Board of Guardians of the district in which this parish is situated. I am pleased to add that the latter authority appears to be fully alive to the necessity of adopting measures for the isolation of the poor suffering from small-pox, and that the fact of suitable conveyances being placed at the disposal of the public, to secure the easy and speedy removal of all sufferers desiring such isolation, has been extensively advertised throughout the district.

By such measures, and by persevering exertions in the prosecution of vaccination, I indulge the hope of soon seeing the dreaded enemy, with which we have for some months past been doing battle, driven from its strongholds in this locality.

### XXI. *Report on the Small-Pox Epidemic in the Hackney District.* By J. W. TRIPE, M.D., Medical Officer of Health.

THE present epidemic differs from the outbreaks in 1855 and 1856 by being more general and more fatal. In the outbreaks of 1855 and 1856, I was able to trace it to an importation of the disease from other parts of London, but in this I have failed in doing so. The district has, during my appointment, been unusually free from the disease, as the table appended shows, which I attribute to the comparative sparseness of the population (about 88,000 in 3949 acres), the absence of over-

crowding, except in a few portions of the district, and the satisfactory manner in which vaccination is generally performed. Some time since I made a personal inspection of the children attending, not only the parochial, but all the large schools, and was surprised to find so large a number presenting good marks. The present epidemic has been far more fatal than any other, as 22 deaths have been registered this year, against 16 in the year 1855, and 13 in the year 1856. I have made inquiries at each house in which a fatal case occurred, and, so far as I could learn, no child had died who had been vaccinated; but, as the parents in some instances had moved out of the house directly after the funeral, I could not ascertain this for certain. In some houses I was informed that every inhabitant had taken the disease, in others that one only had had it. This I attribute to want of care, or want of room to properly isolate the patient, for in my own practice I have rarely had more than one case in a house; in the first place, because I always re-vaccinate all above twelve years of age, and secondly, because I advise good ventilation, isolation of the patient, and the wearing of washing dresses by all the females who enter the apartment. Of course with poor persons these precautions cannot be carried out, and in these cases removal should be strictly enforced, if practicable.

I am glad to say that the Guardians have erected in their grounds a small iron Hospital for small-pox and fever cases, so as to be independent of the special Hospitals, and have also provided a carriage for the conveyance by any parishioner of patients suffering from infectious diseases.

## GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

### MINUTES OF MEETING, MONDAY, JUNE 1, 1863.

#### ROYAL COLLEGE OF PHYSICIANS, LONDON.

MR. GREEN, *President*, took the chair at Two o'clock, p.m.

#### Present—

Dr. Burrows.	Dr. Andrew Wood.	Dr. Corrigan.
Mr. Arnott.	Dr. Fleming.	Sir Charles Hastings.
Mr. Cooper.	Mr. Syme.	Dr. Sharpey.
Dr. Acland.	Dr. Thomson.	Mr. Lawrence.
Dr. Bond.	Dr. A. Smith.	Mr. Teale.
Dr. Embleton.	Mr. Hargrave.	Dr. Christison.
Dr. Storrar.	Dr. Lect.	Dr. Stokes.
Dr. Alexander Wood.	Dr. Apjohn	

Dr. FRANCIS HAWKINS, *Registrar*.

The Minutes of the last meeting were read and confirmed.

Dr. AQUILLA SMITH presented the Report on the publication and distribution of the Register.

#### Report.

The Committee appointed to consider and report on the publication and distribution of the Register, and also on the expediency of accepting a proposal for the insertion of advertisements in the Register, with a view to diminish the expense of publication, beg leave to report as follows:—

1. Considering that advertisements are inserted in publications more or less analogous in nature and purpose to the *Medical Register*, and issued under the authority of public departments, it does not appear to the Committee that there would be any impropriety in the admission of advertisements, under proper restriction, to be bound up with the *Medical Register*. Considering, however, the practical difficulties that would probably occur in exercising a censorship on advertisements which might be offered for insertion, even were they restricted to advertisements of books, and the risk of offence from what might be deemed undue admission or unfair exclusion in particular cases, the Committee do not think that it would be expedient to accept the proposal. The Committee feel the more confident in arriving at this conclusion as the loss incurred in the publication of the Register is now much reduced; and as the inducement to select the Register as a medium of advertising would probably be lessened by the consideration that the Council could not guarantee that advertisements would be bound up with the copies supplied in sheets to the Stationery Office.

2. Respecting the recommendation to be made as to the distribution of the copies to be supplied to the Government, the Committee submit the following list of public offices and functionaries among which the 2000 copies supplied may be advantageously allotted. It will be observed that Registrars of Births and Deaths are not included, and simply because their number in Great Britain amounts to 3206.

#### List of Distribution.

England and Wales:	
County Courts ..	500
Coroners ..	353
Law Courts (various) ..	149

1948

AQUILLA SMITH, *Chairman*.

1. Moved by Dr. SHARPEY, seconded by Dr. STORRAR—"That the Report on the Publication and Distribution of the Register be received and entered on the Minutes, and that the recommendations therein made be adopted by the Council."—Agreed to.

2. Moved by Dr. ACLAND, seconded by Dr. A. SMITH—"That the Executive Committee be directed to print annually in the Register a statement of the distribution of the copies of the Register as approved by the Government."—Agreed to.

Dr. CORRIGAN presented the Report of the Committee on Amendments of the Medical Act.

#### Report.

The course the Committee have adopted is to go through the sections of the Medical Act *seriatim*, and to append to each section such proposed amendments as seemed fit to be submitted for consideration.

The Committee do not propose that the General Council should at present express an opinion on the proposed amendments, nor are the Committee unanimous in some of the amendments suggested.

The Committee suggest that the present course might properly be, that the General Council, without expressing any opinion on the proposed amendments, should give instructions to the Executive Committee to have a Bill drawn up, embodying the proposed amendments; that the Bill thus drawn up should be transmitted to the several licensing bodies mentioned in Schedule (A) for their consideration, and that the amended Bill, with any alteration suggested by the several licensing bodies, should be submitted for consideration at the next annual meeting of the General Council.

There remains one point on which the Committee have not been able to suggest a satisfactory amendment—the licence in midwifery. The difficulty has arisen from the charters of the several Colleges differing in power in regard to this licence. The College of Physicians of London, the Colleges of Physicians and Surgeons of Edinburgh are not authorised to issue separate licences in midwifery, while the College of Physicians in Ireland and the Colleges of Surgeons of England and Ireland are empowered to issue such separate licences. This appears to maintain an inequality of privilege that ought to be removed.

#### THE MEDICAL ACT.

ANNO VICESIMO PRIMO ET VICESIMO SECUNDO VICTORIÆ REGINÆ, CAP. XC.

#### ORIGINAL ACT.

#### PROPOSED AMENDMENTS.

<i>Title</i>	
An Act to Regulate the Qualifications of Practitioners in Medicine and Surgery.	A Bill to Amend the Medical Acts.

#### Preamble.

Whereas it is expedient that persons requiring Medical aid should be enabled to distinguish qualified from unqualified Practitioners. Be it therefore enacted by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in the present Parliament assembled, and by the authority of the same as follows:—

Whereas it is expedient that persons requiring Medical aid should be enabled to distinguish qualified from unqualified Practitioners; and whereas it is moreover necessary for the safety and protection of the public towards securing adequately educated Practitioners in the several departments of Medicine, Surgery, and Pharmacy: be it therefore enacted, etc., etc.

#### SECTION 5.

X. The General Council shall appoint a Registrar, who shall act as secretary of the General Council, For Sect. X.—Substitute the following:—  
The General Council shall appoint

and who may also act as Treasurer, unless the Council shall appoint another person or other persons as Treasurer or Treasurers; and the person or persons so appointed shall likewise act as Registrar for England; and as Secretary and Treasurer or Treasurers, as the case may be, for the Branch Council for England; the General Council and Branch Council for England shall also appoint so many clerks and servants as shall be necessary for the purposes of this Act; and every person so appointed by any Council shall be removable at the pleasure of that Council, and shall be paid such salary as the Council by which he was appointed shall think fit.

XIII. All moneys payable to the respective Councils shall be paid to the Treasurers of such Councils respectively, and shall be applied to defray the expenses of carrying this Act into execution in manner following; that is to say, separate accounts shall be kept of the expenses of the General Council, and of those of the Branch Councils; and the expenses of the General Council, including those of keeping, printing, and publishing the Register for the United Kingdom, shall be defrayed, under the direction of the General Council, by means of an equal percentage rate upon all moneys received by the several Branch Councils; returns shall be made by the Treasurers of the respective Branch Councils, at such times as the General Council shall direct, of all moneys received by them; and the necessary percentage having been computed by the General Council, the respective contributions shall be paid by the Treasurers of such Branch Councils to the Treasurer or Treasurers of the General Council; and the expenses of the Branch Councils shall be defrayed, under the direction of those Councils respectively, out of the residue of the moneys so received as aforesaid.

XIV. It shall be the duty of the Registrars to keep their respective Registers correct in accordance with the provisions of this Act, and the Orders and Regulations of the General Council, and to erase the names of all registered persons who shall have died, and shall from time to time make the necessary alterations in the addresses or qualifications of the persons registered under this Act; and to enable the respective Registrars duly to fulfil the duties imposed upon them, it shall be lawful for the Registrar to write a letter to any registered person, addressed to him according to his address on the Register, to inquire whether he has ceased to practise, or has changed his residence, and if no answer shall be returned to such letter within the period of six months from the sending of the letter, it shall be lawful to erase the name of such person from the Register; provided always, that the same may be restored by direction of the General Council, should they think fit to make an order to that effect.

XX. In case it appear to the General Council that the course of study and examinations to be gone through in order to obtain any such qualification from any such College or body are not such as to secure the possession by persons obtaining such qualification of the requisite knowledge and skill for the efficient practice of their Profession, it shall be lawful for such General Council to represent the same to Her Majesty's Most Honourable Privy Council.

XXI. It shall be lawful for the Privy Council, upon any such representation as aforesaid, if it see fit, to order that any qualification granted by such College or body, after such time as may be mentioned in the

a Registrar, who shall act as Secretary of the General Council, and may act as Treasurer, unless the Council shall appoint another person or other persons as Treasurer or Treasurers. The General Council shall also appoint so many clerks and servants as shall be necessary for the purposes of this Act; and every person so appointed shall be removable at the pleasure of the Council, and shall be paid such salary as the Council shall think fit.

Clause XIII. and proposed amendments, with observations of Scotch Branch Council of No. 27, 7th Feb., 1863, to be referred back to solicitor for observations.

For Sect. XIII. — Substitute a Section to the following effect:—

Separate accounts shall be kept of the expenses of the General Council, and those of the Branch Councils. The expenses of the Branch Councils shall be defrayed, under the direction of those Councils respectively, out of the moneys received by them. Returns shall be annually made by the Treasurers of the respective Branch Councils of all moneys so received and expended by them; and the said Treasurers shall, as soon as possible, transmit the balance remaining in their hands to the Treasurer of the General Council; and the expenses of the General Council, including those of keeping, printing, and publishing the Register of the United Kingdom, shall be defrayed, under direction of the General Council, out of the fund arising from the contributions of the Branch Councils, as well as from all other sources, to be called the General Council Fund.

Sect. XIV.—Insert the following after the words "his residence:—"

And if any person registered shall notify to the Registrar that he has ceased to practise, and wishes to withdraw his name from the Register, the Registrar shall have power to erase his name.

For Sect. XV.—Substitute a Section to the following effect:—

It shall be lawful for the General Council to lay down such regulations respecting the education and examination of Practitioners in Medicine, Surgery, and Pharmacy, as may appear to them fitted to insure adequate knowledge and skill in the several departments of the Profession; and the said General Council shall then submit said regulations to Her Majesty's Most Honourable Privy Council; and the said regulations, if sanctioned by the said Privy Council, shall then be obligatory upon all Universities, Colleges, and other bodies enumerated in Schedule (A) to this Act.

For Sect. XXI.—Substitute the following:—

And it shall be lawful for the Privy Council, upon its being represented to them that any University, College, or other body enumerated in

order, shall not confer any right to be registered under this Act: provided always, that it shall be lawful for Her Majesty, with the advice of her Privy Council, when it is made to appear to her, upon further representation from the General Council or otherwise, that such College or body has made effectual provision, to the satisfaction of such General Council, for the improvement of such course of study or examinations, or the mode of conducting such examinations, to revoke any such order.

XXVII. The Registrar of the General Council shall in every year cause to be printed, published, and sold, under the direction of such Council, a correct register of the names in alphabetical order according to the surnames, with the respective residences, in the form set forth in schedule (D) to this Act, or to the like effect, and Medical titles, diplomas, and qualifications conferred by any Corporation or University, or by Doctorate of the Archbishop of Canterbury, with the dates thereof, of all persons appearing on the General Register as existing on first day of January in every year; and such register shall be called "The Medical Register;" and a copy of the Medical Register for the time being, purporting to be so printed and published as aforesaid, shall be evidence in all courts and before all Justices of the Peace and others that the persons therein specified are registered according to the provisions of this Act; and the absence of the name of any person from such copy shall be evidence, until the contrary be made to appear, that such person is not registered according to the provisions of this Act; provided always, that in the case of any person whose name does not appear in such copy, a certified copy, under the hand of the Registrar of the General Council, or of any branch Council, of the entry of the name of such person on the general or local register, shall be evidence that such person is registered under the provisions of this Act.

XXIX. If any registered Medical Practitioner shall be convicted in England or Ireland of any felony or misdemeanour, or in Scotland of any crime or offence, or shall after due inquiry be judged by the General Council to have been guilty of infamous conduct in any Professional respect, the General Council may, if they see fit, direct the Registrar to erase the name of such Medical Practitioner from the register.

XXXI. Every person registered under this Act shall be entitled, according to his qualification or qualifications, to practise Medicine or Surgery, or Medicine and Surgery, as the case may be, in any part of her Majesty's dominions, and to demand and recover in any court of law, with full costs of suit, reasonable charges for Professional aid, advice, and visits, and the cost of any medicines or other Medical or Surgical appliances rendered or supplied by him to his patients: provided always, that it shall be lawful for any College of Physicians to pass a byelaw to the effect that no one of their Fellows or Members shall be entitled to sue in manner aforesaid in any court of law, and thereupon such byelaw may be pleaded in bar to any action for the purposes aforesaid commenced by any Fellow or Member of such College.

XXXIV. After the first day of January, one thousand eight hundred and fifty-nine, the word "legally qualified Medical Practitioner," or "duly qualified Medical Practitioner," or any words importing a person recognised by law as a Medi-

Schedule (A) does not comply with such regulations, to declare that any qualification granted by such University, College, or body, shall not confer any right to be registered under this Act. Provided always, etc.

To Sect. XXVII.—After the words "provisions of this Act," add the words as proposed in the Tabular Statement, viz:—

"And that he is not possessed of any qualification which would entitle him to be registered in accordance with the provisions of this Act."

For Sect. XXIX.—The clause, as suggested by Mr. Ouvry, and printed in the Tabular Statement approved of, viz:—

The Council may refuse to register any person who may have been convicted, in England or Ireland, of any felony or misdemeanour, or in Scotland of any crime or offence; and if any registered person shall be so convicted, or shall, after due inquiry, be judged by the General Council to have been guilty of infamous conduct in a Professional respect, whether before or after registration, the General Council may, if they see fit, direct the Registrar to erase the name of such person from the register.

Sect. XXXI.—Every person registered under this Act shall be entitled, according to his qualification or qualifications, to practise Medicine, or Surgery, or Pharmacy: or Medicine, and Surgery, and Pharmacy, as the case may be, etc.

To Sect. XXXIV.—The following words to be added:—"According to his qualification or qualifications."

cal Practitioner or Member of the Medical Profession, when used in any Act of Parliament, shall be construed to mean a person registered under this Act.

XXXVI. After the first day of January, one thousand eight hundred and fifty-nine, no person shall hold any appointment as a Physician, Surgeon, or other Medical officer, either in the Military or Naval Service, or in emigrant or other vessels, or in any Hospital, Infirmary, Dispensary, or Lying-in Hospital, not supported wholly by voluntary contributions, or in any Lunatic Asylum, Gaol, Penitentiary, House of Correction, House of Industry, Parochial or Union Workhouse or Poorhouse, Parish Union, or other public Establishment, Body, or Institution, or to any Friendly or other Society for affording mutual relief in sickness, infirmity, or old age, or as a Medical Officer of Health, unless he be registered under this Act: provided always, that nothing in this Act contained shall extend to repeal or alter any of the provisions of the Passengers Act, 1855.

XXXVII. After the first day of January, one thousand eight hundred and fifty-nine, no certificate required by any Act now in force, or that may hereafter be passed, from any Physician, Surgeon, or other Medical Practitioner, shall be valid unless the person signing the same be registered under this Act.

XL. Any person who shall wilfully and falsely pretend to be, or take or use the name or title of a Physician, Doctor of Medicine, Licentiate in Medicine and Surgery, Bachelor of Medicine, Surgeon, General Practitioner, or Apothecary, or any name, title, addition, or Description implying that he is registered under this Act, or that he is recognised by law as a Physician, or Surgeon, or Licentiate in Medicine and Surgery, or a Practitioner in Medicine, or an Apothecary, shall, upon a summary conviction for any such offence, pay a sum not exceeding twenty pounds.

XLVIII. It shall, notwithstanding anything herein contained, be lawful for Her Majesty, by Charter, to grant to the Royal College of Surgeons of England power to institute and hold examinations for the purpose of testing the fitness of persons to practise as Dentists who may be desirous of being so examined, and to grant certificates of such fitness.

LV. Nothing in this Act contained shall extend or be construed to extend to prejudice, or in any way to affect, the lawful occupation, trade, or business of Chemists and Druggists and Dentists, or the rights, privileges, or employment of duly licensed Apothecaries in Ireland, so far as the same extend to selling, compounding, or dispensing medicines.

Sect. XXXVI.—The word "Apothecary" to be inserted after "Surgeon" in fifth line.

For Sect. XXXVII.—Substitute the following:—

After the first day of January, one thousand eight hundred and fifty-nine, no certificate required by any Act now in force, or that may hereafter be passed, from any Physician, Surgeon, or Apothecary, or other Medical Practitioner, shall be valid, unless the person signing the same be registered under this Act.

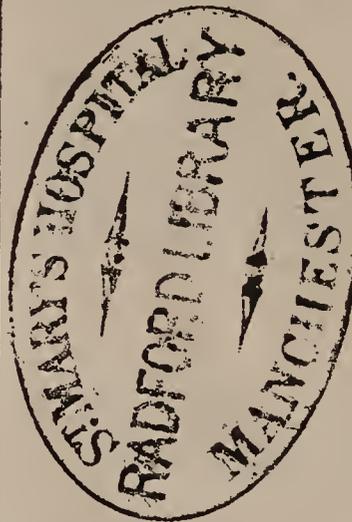

On and after the day of 1863, it shall not be lawful for any person, unless registered under this Act, to pretend to be, or take or use the name or title of Physician, Doctor of Medicine, Licentiate in Medicine or Surgery, Master in Surgery, Bachelor of Medicine, Doctor, Surgeon, Medical or General Practitioner, or Surgeon Apothecary or Accoucheur, or Licentiate or Practitioner in Midwifery, or any other Medical or Surgical name or title, and any unregistered person so offending shall forfeit and pay a sum of not exceeding £20, to be recovered in a summary way before the Justices of the Peace.

Sect. XLVIII.—Amend by introducing the words, "Ireland and the Faculty of Physicians and Surgeons," after "England."

Sect. LV.—Omit the words, "Chemists, Druggists, and."

A section to the following effect to be added:—

Sect. LVI. It shall not be lawful for any person to keep open shop for the compounding of Physicians' and Surgeons' prescriptions, unless he be a Licentiate of the Apothecaries' Hall of England or Ireland, or shall have received a certificate of competency to compound medicine, from either of the above bodies, or from the Pharmaceutical Society, or from some other body duly authorised in England, Ireland, or Scotland, by the General Medical Council, to institute the necessary examination, and to grant such certificate, and at such rate of fee as the General Medical Council, with the approval of the Privy Council, may sanction; and any person keeping open shop for the compounding of medicine, unless qualified as aforesaid, shall, upon a summary conviction for any such offence, before any Justice of the Peace, pay a sum not exceeding £20; and, for the better protection of the public, and to ensure the

May 29, 1863.

3. Moved by Dr. CORRIGAN, seconded by Dr. BURROWS—"That the Report be received and entered on the Minutes."—Agreed to.

Dr. CHRISTISON presented the Report of the special Pharmacopœia Committee.

*Report of the Special Committee appointed by the General Council on May 27, 1863, relative to the Pharmacopœia.*

The Committee appointed "to take into consideration, and to report what further steps it is desirable for the General Council to take in reference to the Pharmacopœia," have carefully considered various matters which have been put before them and the Council by the Chairman of the Pharmacopœia Committee. They have to report that several of these matters are of great importance, and require the attention of the Council before its present meetings come to an end; and they recommend that these be all settled now, so that as little as possible of the business connected with the Pharmacopœia shall be left over to another Session of the Council.

I.—The first subject to which the Committee have turned their attention is the expense attending the preparation and publication of the Pharmacopœia, and the mode and terms of payment.

Every member of Council was, or might have been, aware that a Pharmacopœia, which was to be an amalgamation of three national Pharmacopœias, could not be prepared without a large expenditure. During the first Session of the Council there seems to have been a general understanding that, unless for the services of Professional Chemists and others, to whom the several branches of the Pharmacopœia Committee might find it necessary to entrust a part of their duty, the Council would escape any outlay on account of those engaged in preparing the work. The labour required of the Sub-Committees, however, soon proved to be so great in prospect, that it was impossible to expect that so many Professional men should surrender their time without some compensation. Accordingly it was stated by the Chairman of the Pharmacopœia Committee, at the Session of Council in 1859, that provision would have to be made for a charge on this account. No idea could be formed at that period, however, of the probable charge, under any possible arrangement, which the Pharmacopœia Committee or the Council could then have proposed.

This Committee are confident, that no one conversant with the practical difficulties which surrounded the task committed to the Pharmacopœia Committee will suppose that any part of the work they have gone through was superfluous, or has been the cause either of delay or of expense which might have been avoided. It may be added, that the extra expenditure occasioned by the delay which originated in the question settled by the Council last October, relative to weights and measures, has been inconsiderable.

The mode of payment of all charges on account of the Pharmacopœia has been clearly understood by its Committee; but little appears on the subject in the Minutes of the Council, which can serve as a guide to the present Committee. The understanding was, that the Council should advance from the registration fund such money as might be required for current expenses, the payment of which could not be justly postponed; that these advances should be repaid from the proceeds of the sale of the Pharmacopœia; and that the other charges, including especially compensation to members of the Sub-Committees for their time and services at Sub-Committee meetings, must depend on the amount of these proceeds. Accordingly, the advances made by the Council, on account of the Pharmacopœia, were applied to remuneration for much chemical, botanical, and pharmaceutical advice and experiment; for the attendance of nine members at two delegations, one in London and another in Edinburgh; and for lesser current expenses. But the remaining charge, which relates to the services of secretaries and editors, to certain extensive chemical investigations, and to attendance on Sub-Committee meetings, is still open for consideration; and this Committee are of opinion that all these charges ought to be settled, as far as possible, by the Council, before its present meetings terminate.

The Committee of Council beg here to observe, that the Council, in advancing at different periods sums from the registration fund, for the current expenses of the Pharmacopœia Committee, does not appear to have given any special authority, or instructions, as to the particular items of current expense which should be paid from these advances. The chairman of the Pharmacopœia Committee made certain statements on that head to the Council from time to time; and he considered himself entitled to endorse, and the treasurer of the Pharmacopœia Committee to pay the charges mentioned above, as in conformity with the statements made in Council. It might have been better had the instructions of the Council been more specific. But this Committee submit that the attempt

carrying out of the provisions as aforesaid, it is hereby enacted that the Medical Council may appoint from time to time one inspector for England, one for Ireland, and one for Scotland, whose duties it shall be to inspect, as often as may be required, all shops where medicines are compounded, and to carry into effect the provisions of this Act in regard to such shops; and that such inspectors be paid such salaries out of the Consolidated Fund as the General Council, with the approval of the Lords Commissioners of Her Majesty's Treasury, may from time to time determine.

A Section also to be added as follows:—

Sect. LVII.—No patent quack or other medicine shall be sold unless a sworn certificate of its composition be lodged with the Registrar of the General Council, and a copy thereof be open for inspection in the shop or place in which such medicine is sold; and any person or proprietor of a shop selling any secret remedy shall, on summary conviction, for each such offence, be liable to a penalty not exceeding £20.

D. L. CORRIGAN, Chairman.

to make them so would probably have involved frequent delays, on account of the necessity, under such instructions, of references from the Pharmacopœia Committee to the General Council at times when the Council might not be sitting.

The Council should keep in view, before providing for the payment of attendance on Sub-Committee meetings, that a large proportion of the fund accruing from the sale of the Pharmacopœia will be required to replace what has been advanced from the registration fund, and to defray the cost of printing and publishing the work, and remuneration still due for chemical investigations, and to secretaries and editors.

The terms on which the charges thus remaining due should be paid, have received the most earnest attention of this Committee.

Two distinguished chemists were requested jointly to undertake together extensive investigations essential for the chemistry of the Pharmacopœia. These gentlemen devoted their whole time for many days to these investigations, and one of them had to leave his professional duties at Edinburgh in order to meet the other at Dublin. The chairman of the Pharmacopœia Committee informs us that these labours were undertaken on the footing that, in all probability, those who conducted them would be paid by the Council an allowance at the same rate as members of the General Council for attending its meetings; and that this allowance would be very much under the usual fees received by chemists in the like circumstances.

The duties of the secretaries being over, or very nearly so, the Committee are able to come to an opinion under that head of expenditure; and they recommend that the sum of £100 be paid to each of the secretaries of the Edinburgh and Dublin Sub-Committees; and the sum of £150 to the secretary of the London Sub-Committee, who has acted also as general secretary of the whole Committee.

The duty of the editors has only now begun. The Committee have been informed that this duty will last four months; and as two of the editors reside at a distance, one in Edinburgh and the other in Dublin, the labour of all three must be considerable. The Council should also be informed that it has no claim on these gentlemen, originating in membership of the Council; for none of them is a member of this body. The Committee are therefore of opinion that the Edinburgh and Dublin editors ought to be awarded for their trouble a sum of £50 each, and the principal editor in London a sum of £75.

The payment to Members of the Sub-Committees is a different question. If the Committee look only to the Professional position of most of the gentlemen who compose the Pharmacopœia Sub-Committees, and to the time and knowledge which they have given to the duty undertaken by them at request of the Council, this Committee could scarcely hope to compensate them for their services by an adequate remuneration. The Committee therefore recommend that £500 should be voted as an Honorarium to each Sub-Committee. The sum of all the Sub-Committee meetings has been during four years 407; and the sum of attendances of all the Members has been 1851. But even these numerous attendances give no idea of the amount of labour of the Sub-Committees, not a few of whose Members have given much of their private and individual leisure to the business of the Pharmacopœia.

II.—The next subject brought before the Committee relates to the form or forms in which the Pharmacopœia ought to be published. After the statements put before the Council at the meeting of Council on the 26th instant, it is merely necessary for this Committee to report their opinion, that on the whole it is advisable that two editions be published contemporaneously, an octavo and a duodecimo edition, as proposed by the Executive Committee of the Council. The Committee find that the duodecimo edition may be sold at the low price of 5s. a copy, and the octavo at 7s. 6d., without involving the Council in any eventual loss, although a portion of the advances made by the Council may be for some time undischarged.

The Council will recollect that the price of the work must receive the sanction of the Lords of her Majesty's Treasury.

III.—The third question submitted to the Committee is, whether it may not be advisable that the publication of the Pharmacopœia be preceded by some explanation of its composition, the principles of its construction, the changes introduced, and the necessity under which the Members of the several branches of the Medical Profession will lie of making themselves acquainted with the British Pharmacopœia, and of discarding all those which it is to supersede. The Committee are of opinion that a measure of this kind may prove not only acceptable to the Medical Profession at large, but likewise very serviceable for preventing inconvenient and even dangerous errors. The Committee do not think it necessary that the General Council should themselves prepare and authorise a publication of this nature. But the Chairman of the Pharmacopœia Committee has expressed his readiness to publish such a document, if agreeable to the Council.

IV.—The next subject for the Committee's consideration regards the means which may be taken by the present Council for supplying their Members with the experience which the Council has gained as to the most suitable machinery for preparing future editions of the Pharmacopœia, and publishing them with the least possible delay and expense.

It appears to have been thought by some Members of the Council, that the number of persons who have been engaged in preparing the British Pharmacopœia, and consequently the expense, might have safely been less than on the present occasion. The Pharmacopœia Committee might indeed have consisted of a smaller number of Members, had the Council not had to reconcile three Pharmacopœias, and the members of the Medical Profession in the three divisions of the kingdom, who have been long accustomed to use them. Without a large representation in Committee from the several bodies concerned in those works, serious jealousies and obstacles would have arisen, which it would have been highly undesirable to provoke. But the Council is now the sole authority, and alone incurs public responsibility, in regard to the Pharmacopœia. It may henceforth adopt without reserve the measures which seem most suitable for subsequent editions.

The Committee, on considering what measures may be now recommended to the Council, have been impressed with the recommendation of the Chairman of the Pharmacopœia Committee, that the improvements in Medicine and Pharmacy ought not to be allowed to accumulate long without being introduced by authority to the Medical Profession at large; and that therefore either a supplement, or new edition, of the Pharmacopœia, ought to be brought out every five years on an average; and that, for this purpose, a charge should be given by the Council to one or more competent persons to keep up the necessary information for the Pharmacopœia on a level with advancing knowledge from month to month; so that the requisite changes might be supplied to the Council within a very short period after demand.

To this end the Committee advise that—

1. In each capital of the three divisions of the kingdom respectively the Branch Council should appoint a person to undertake this duty who is a Medical Practitioner, acquainted with the natural history and chemistry of Pharmacy.

2. That it should be an instruction to these gentlemen to invite information as to improvements in the Pharmacopœia from the Medical, Surgical, and Pharmaceutical bodies of the several divisions of the country.

3. That, under the sanction of the Executive Committee, the treasurer be empowered to pay to each of these gentlemen a sum not exceeding £20 annually for charges for scientific and practical inquiries.

4. That they should intercommunicate their results half-yearly.

5. That they should be ready every five years to give, at the request of the General Council, their conjoint opinion as to the changes they consider advisable for a new edition, or a supplement, of the Pharmacopœia.

6. That the Executive Committee should have charge of editing and publishing such new edition or supplement, after approval by the General Council.

V.—The last subject to be referred to by this Committee is the recent introduction of a bill into the House of Commons, for altering the weights and measures of the kingdom to the metrical decimal system of France and many other countries. The bill contemplates that, if passed, the Act shall be permissive for three years, and then compulsory. Pharmacy is expressly included. The House of Commons takes up the second reading of the bill on July 1.

The Council will observe that it is quite otherwise circumstanced in respect to this bill, than when it came to a decision last October on the question whether the French metrical system of weights and measures should be adopted at that time as the system of Pharmacy in this country. The Committee, therefore, beg to call the attention of the Council to the approaching proceedings in Parliament. But they leave it to the Council itself to decide whether any, and what steps should be taken by the Council in the present position of this important question.

R. CHRISTISON, *Chairman.*

4. Moved by Dr. CHRISTISON, seconded by Dr. ANDREW WOOD,—“That the Report of the Special Pharmacopœia Committee be received, and printed in the Minutes.”—Agreed to.

Dr. ALEXANDER WOOD presented the Report of the Committee appointed to consider the recognition of Foreign or Colonial Degrees or Examinations.

#### Report.

The applications are three in number.

1st.—One from McGill University of Montreal, dated 22nd August, 1862, and craving to have its degree recognised for Registration.

The Committee submit the correspondence between the Dean of the Medical Faculty of McGill University and their Registrar, feeling that they cannot add anything to the excellent letter of the latter, which fully explains the position of the Council.

“McGill University, Montreal,  
“22nd August, 1862.

“Sir,—I beg leave to make application, through you, to the General Council of Medical Education on behalf of the Medical Faculty of McGill University, to have its degree recognised for registration.

“McGill University, as will be seen from the calendar herewith sent, holds a Royal Charter, and is in full operation in all its Faculties. The Medical Faculty more especially, has been very successful, 159 students having attended its lectures during last Session.

“From its commencement as a Faculty, it has required a high standard of excellence in its Professional Examinations.

“It has also earnestly endeavoured to elevate the Preliminary Examination to as high a standard as the educational institutes of the country would permit.

“As will be seen in the printed Abstract of its Regulations, a competent knowledge of Latin, and of either English or French composition, is required, and after the 1st of May, 1863, a Students' Medical Education will be held, to commence from the date of his passing this Preliminary Examination.

“By referring to the Regulations of the College of Surgeons of England, it will be found that the Council of the College has recognised our Preliminary Examination, and accepts certificates of attendance upon our Courses of Lectures and Hospital.

“This question has been recently brought before our Faculty by Dr. Elkington, one of the Assistant-Surgeons of the Grenadier Guards, who recently applied to the Medical Registration Office to have his McGill degree registered; this was refused, in conformity with Rule II. Section (A) of the printed Regulations of the Council.

“Several Army Surgeons, after attending lectures, obtained degrees in course of May last from this University, and as the Director-General of the Medical Department of the Army will not recognise any Professional title until registered, our Faculty has instructed me, as its Dean, to make this application for recognition to the Council of Medical Education and Registration.

“I have the honour to be, Sir,

“Your most obedient servant,

“GEO. W. CAMPBELL, A.M., M.D.,

“Dean of the Medical Faculty of McGill University, Montreal.

“To Dr. Francis Hawkins, Registrar, Medical Council.”

“General Council of Medical Education and Registration  
of the United Kingdom,

“32, Soho-square, London, W. September 3, 1862.

“Sir,—I have had the honour to receive your letter, dated 22nd ult., and shall take the earliest opportunity of laying it before the General Medical Council.

“In the meantime, I beg to refer you to the Medical Act, 1858 (a copy of which is bound up with every copy of the Medical Register), from which you will perceive that the Medical Council has no power to order the Registration of any Foreign or Colonial degree, unless it were obtained after regular examination, and before the passing of the Medical Act. The truth is, that the Medical Act was not intended to legalise Foreign, or even Colonial degrees, within the United Kingdom, except so far as was necessary to prevent the Act from having a retrospective effect on persons already practising on such degrees within the United Kingdom.

“The right of registration was to be given by the Act only to the degrees and diplomas of the Universities and Colleges of the United

Kingdom, which are enumerated in Schedule (A) to the Act, and over which bodies the Medical Council can exercise, under the Act, certain visitatorial powers.

"But it is clear that the Act could not give such powers to the Council, or, at least, that the Council could not exercise them over Foreign or even Colonial Universities and Colleges.

"It is open, however, to those Universities and Colleges to make arrangements for the recognition of their degrees and diplomas with the bodies mentioned in the Schedule (A) above referred to.

"These bodies may be considered as the portals to the Medical Register.

"For the attainment, therefore, of the object for which your letter of the 22nd of August appears to have been written, I would venture to refer you to the Universities, and the Colleges of Physicians and Surgeons of the United Kingdom.

"I have the honour to be, Sir, your most obedient Servant,

"FRANCIS HAWKINS, Registrar of the General Medical Council.

"GEO. W. CAMPBELL, Esq., A.M., M.D., Dean of the Medical

"Faculty of McGill University, Montreal."

The Committee recommend that the Council intimate that they have no power to grant the application.

2ndly.—An application from Codrington College, Barbadoes, to have the "Testamur" granted by that College received among those regarded as a sufficient equivalent for the preliminary examination of the licensing bodies.

The Committee are satisfied that the qualifications required by that College are amply sufficient to warrant the Council to grant to it the privilege which is sought.

3rdly.—A request from the Tasmanian Council of Education, that the "Degree of Associate of Arts," granted by that body, be inserted among the educational qualifications mentioned in the third section of the Report of the General Committee on Education, adopted by the Council on the 6th July, 1861.

The requirements for this degree are very high, comprising an examination on the following ten subjects:—

1. English.
2. Latin.
3. Greek.
4. French Grammar, or Italian.
5. Pure Mathematics.
6. The Elementary Principles of Hydrostatics and Mechanics.
7. The Elements of Chemistry.
8. Zoology and Botany.
9. Drawing and Architecture.
10. Geology.

The candidate is required to satisfy the examiners that he possesses a competent knowledge of four of these at least, of which Latin or pure mathematics must be one.

It thus appears that the regulations do not render both Latin and mathematics imperative, and the Committee cannot recommend the Council to sanction any certificate which does not bear that the holder has passed a satisfactory examination in Latin as well as in mathematics. As, however, many students will probably pass in both these branches, their degree might be accepted, if accompanied by a certificate that the examiners were satisfied with the knowledge of the applicant in these two departments in each particular case.

ALEXANDER WOOD, *Chairman.*

5. Moved by Dr. ALEXANDER WOOD, seconded by Dr. ARJOHN—"That the Report on the recognition of Foreign or Colonial degrees or examinations be received and entered on the Minutes."—Agreed to.

Dr. ALEXANDER WOOD presented the Report of the Committee on Special Claims for Registration.

*Report.*

Only two special claims have been presented:—

1st.—Application from George Frederick Collier to have his Degree of M.D. conferred by the University of Leyden, on 15th December, 1828, registered.

The application is accompanied by a Certificate from the Dean of the Medical Faculty of the University of Leyden, certifying that the Degree was conferred after regular examination.

The Committee recommend the Council to grant the application.

2ndly.—Application from Dr. Peter Smith to have his Degree of M.D. from the University of Pennsylvania, conferred 4th April, 1845, registered.

The Committee have satisfied themselves that Dr. Smith was in practice in the United Kingdom prior to the passing of the Medical Act; and under very peculiar circumstances they recommend the Council to sanction the registration of his qualification.

ALEXANDER WOOD, *Chairman.*

6. Moved by Dr. ALEXANDER WOOD, and seconded by Dr. ARJOHN—"That the Report on Special Claims for Registration be received and entered on the Minutes."

Dr. EMBLETON presented the Report of the Committee on Returns from the Licensing Bodies.

*Report.*

Your Committee, in presenting the Report on Returns from Bodies in Schedule (A), in compliance with the 16th and 23rd Recommendations of the Report of the General Council on Education (1861) beg to state:

1. That the returns, in compliance with Recommendation 16th, have, since the Report of last year, been received by the Registrar from all the bodies named in Schedule (A), and have been sent by him to each Member of the General Council.

These Returns contain, as was recommended by your Committee last year, the latest regulations of the bodies named in Schedule (A), as regards both Preliminary and Professional Education and Examination; and the degree of their conformity or non-conformity with the Recommendations of the Report of the General Council on Education (1861), is shown in the table already laid before the Council, and which, in a corrected form, is appended to this Report.

By this table, in which are incorporated some remarks by members of the Council, it will be observed that the amount of conformity in the printed Regulations is considerable; and your Committee are glad to be enabled to state that several of the seeming non-conformities only faintly exist in practice, and that there is a general belief pervading the bodies in Schedule (A) as ascertained from their representatives, that a still nearer approach to conformity is attainable.

2. That Returns, in compliance with the 23rd Recommendation, have been received from all the bodies in Schedule (A). The result of these returns may be seen in the accompanying table, which shows the number of students examined and the number rejected by each of the Licensing bodies.

TABLE OF RETURNS UNDER RECOMMENDATION 23.

Licensing Bodies.	Passed.		Rejected.	
	First Examination.	Second Examin.	First Examination. Number.	Second Examin. Number.
Roy. Coll. Phys. England ..	60	65	5	22
Roy. Coll. Phys. Edinburgh..	75	81	10	10

Queen's Univ. in Ireland ..	36	34	6	5
Totals .. .. .	1425	2151	343	295

3. The registers of students, with explanatory letters, having been referred to them (No. 48, Minutes of General Council), your Committee, further present the subjoined Table of the numbers of students registered according to Recommendations 8 and 9, during the winter of 1862, by each of the bodies in schedule (A), that keeps a Register of Students, showing the numbers registered before and after the expiration of the fifteen days recommended by the Council to be allowed for registration. From this Table it will be seen that the numbers registered after the expiration of the fifteen days are comparatively few, satisfactory letters explanatory of the reasons for such delays have been sent in from the various Bodies in whose registrations those delays have occurred, and doubtless next year this Table will be still more in accordance with your recommendation.

REGISTER OF STUDENTS, 1862.

*Under Recommendations 8 and 9.*

Licensing Bodies.	Before the 15 days.	After the 15 days.	Total.

\* 1, Examined by an American University.

On the whole, your Committee regard as satisfactory the results brought out in these tables, so far as they go, and feel confident that under a simpler mode of registration, and with a little more attention, these results will in future be found more completely in conformity with the recommendations of the Council.

D. EMBLETON, *Chairman.*

7. Moved by Dr. STORRAR, seconded by Dr. SHARPEY—"That the Report of the Committee on Returns from the Licensing Bodies be received, and referred to the Education Committee."—Agreed to.

The Council resolved itself into a Committee on Education.

1. Moved by Dr. ANDREW WOOD, seconded by Dr. THOMSON—"That four years of Professional study, embracing at least four Winter Sessions, or three Winter and two Summer Sessions, at a Medical School be required, dating from the first registration."

Dr. ANDREW WOOD, by permission of the Council, withdrew his motion for the present Session.

2. Moved by Mr. TEALE, seconded by Dr. EMBLETON—"That the following more simple form of registration of students be adopted in the place of that which stands in the Education Report of 1861":—

No.	Name.	Date of Registration.	Place of Study.	Arts Examination, and Date.

—Agreed to.

3. Moved by Dr. ACLAND, seconded by Dr. ANDREW WOOD—"That the words 'Medical School' in the Recommendations of the Medical Council shall be held to mean any institution where courses of lectures are delivered, or systematic practical instruction given in departments of Practical Medicine, or of the sciences accessory to it, such institution being recognised by any of the bodies named in Schedule (A)."

Amendment moved by Mr. HARGRAVE, seconded by Dr. STOKES—"That the consideration of this motion be postponed to the next Session of the Council."

Amendment carried.

The Council having resumed—

The adjourned debate was resumed upon Dr. LEET's motion (see Minutes, No. 49, Sect. 5), which, by permission of the Council, was amended as follows:—"That this Council is of opinion that Registered Licentiatees of the Apothecaries' Company of Dublin are, as apothecaries, entitled to practise Medicine in Great Britain and Ireland."

Amendment moved by Dr. AQUILLA SMITH, seconded by Dr. CORRIGAN—"That the General Medical Council having already had before them the question referred to in the memorial from the Apothecaries' Hall of Ireland on the several occasions, viz., August 9, 1859; June 19, 1860; July 4, 1861; and May 19, 1862, do not consider it expedient on their part to re-open the question. That conflicting legal opinions on the question have at various times come before the Council, and that the Registrar be directed to forward to the Director-General of the Army, for his information, the memorial of the Company of the Apothecaries' Hall of Dublin, with the legal opinions of the Right Hon. Joseph Napier, Attorney-General for Ireland, March 27, 1845; the Right Hon. Sir Richard Bethel, Attorney-General for England, February 15, 1860; Mr. William Smith, June 25, 1861; the Right Hon. Thomas O'Hagan, Attorney-General for Ireland, and James A. Lawson, Solicitor-General for Ireland, February 11, 1863."

On the motion of Dr. CORRIGAN, the debate was adjourned.

*Confirmed*—JOSEPH HENRY GREEN.

MINUTES OF MEETING, TUESDAY, JUNE 2, 1863.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Mr. GREEN, *President*, took the chair at Two o'clock, p.m.

*Present*—As before.

The Minutes of the last meeting were read and confirmed.

1. The adjourned debate was resumed, on the motion of Dr. LEET, seconded by Mr. SYME, viz.—"That this Council is of opinion that registered Licentiatees of the Apothecaries' Company of Dublin are, as Apothecaries, entitled to practise Medicine in Great Britain and Ireland;"

And on the Amendment, moved by Dr. AQUILLA SMITH, seconded by Dr. CORRIGAN, viz.—"That the General Medical Council, having already had before them the question referred to in the Memorial from the Apothecaries' Hall of Ireland on the several occasions, viz., August 9, 1859; June 19, 1860; July 4, 1861; and May 19, 1862, do not consider it expedient on their part to re-open the question.—That conflicting legal opinions on the question have, at various times, come before the Council, and that the Registrar be directed to forward to the Director-General of the Army, for his information, the Memorial of the Company of the Apothecaries' Hall of Dublin, with the legal opinions of the Right Hon. Joseph Napier, Attorney-General for Ireland, March 27, 1845; the Right Hon. Sir Richard Bethel, Attorney-General for England, February 15, 1860; Mr. William Smith, June 25, 1861; the Right Hon. Thomas O'Hagan, Attorney-General for Ireland, and James A. Lawson, Solicitor-General for Ireland, February 11, 1863."—Amendment put and negatived.

Dr. A. SMITH required the names of the majority and minority to be entered on the Minutes.

*Majority*—

- Dr. Burrows.
- Mr. Cooper.
- Dr. Bond.
- Dr. Embleton.
- Dr. Storrar.
- Dr. Alexander Wood.
- Dr. Fleming.
- Mr. Syme.

- Dr. Stokes.

Dr. ALEXANDER WOOD presented the Report of the Committee appointed to consider the requirement, on the part of the Poor-law Commissioners of Ireland, of a Licence in Midwifery from candidates for employment under them.

*The Committee on the Requirements of the Commissioners for Administering the Laws for Relief of the Poor in Ireland have to Report—*

That by the General Orders of that Body, no person can be appointed as a Medical Officer of a Dispensary or Workhouse under their control, without possessing a Degree or Licence to practise Medicine, a Diploma or Licence to practise Surgery, "and also a Certificate from some Board or Court of Examiners, or other Body duly authorised to grant the same, of his possessing a competent knowledge of Midwifery." A case was brought under the notice of the Committee of a gentleman who had obtained a Licence in Medicine from the Royal College of Physicians of Edinburgh, and a Licence in Surgery from the Royal College of Surgeons of England. This gentleman's qualifications were considered by the Irish Poor-law Commissioners to be incomplete, "inasmuch as he does not possess a Certificate from some Board or Court of Examiners, or other Body duly authorised to grant the same, of his possessing a competent knowledge of Midwifery." It will be seen in Schedule (A) to the Medical Act that the only Body therein empowered to have a Licence in Midwifery granted by them entered on the Register, is the Royal College of Surgeons of England: so that, practically, every applicant for employment under the Poor-law Board in the land would, if the order above quoted were duly enforced, have to repair to London for this extra qualification.

Your Committee are indeed aware that an application was made to the Executive Committee by the Colleges of Physicians and Surgeons in Ireland, to have certain Licences in Midwifery conferred by them entered on the Register, which the Executive Committee, on March 7, 1859, refused to do. This decision appears on the Minutes of the Executive Committee in the following terms:—

"The Executive Committee gave direction that in the *General Register* no licence in midwifery should be entered except that conferred by the Royal College of Surgeons of England, because they are unable to find authority in the Medical Act for the registration of any other midwifery licence."

Subsequently, however, on the 31st May, 1859, on receipt of a letter from a solicitor employed by the College of Physicians and Surgeons of Ireland couched in peremptory terms, the Executive Committee yielded, and directed these qualifications to be entered in the Register.

The Executive Committee appears to have consented to yield to the pressure thus applied, in consequence of a legal opinion obtained by them from Sir Hugh Cairns and Mr. Arthur Hobhouse, from which the following is an extract:—

"1. Whether the licentiatees in midwifery of the King's and Queen's College of Physicians in Ireland, and of the Royal College of Surgeons in Ireland, can lawfully be entered on the Register?"

"2. Whether the General Council can exercise towards these licentiatees any power of dispensing with the provisions of the Act?"

"1. It appears to us that no question of this kind can arise with respect to the Royal College of Surgeons in Ireland; for by the extracts from the charters which have been furnished to us, it would seem that this body does not grant any licences in midwifery except to persons already being fellows or associates of the body, so that all their licentiatees in midwifery must possess a previous and higher title to be registered. The case is different with the College of Physicians, who have power to examine and license all midwives. The question must turn on the meaning to be ascribed to the word 'licentiate,' in clause 3 of Schedule (A).

"We are of opinion that the sounder construction of the Act is to give to the term its literal and full meaning, unless there is something to forbid it, either in the general scope of the Act, or in its terminology.

"The general scope of the Act militates rather in favour of, than against the extended construction of the term; for it seems not to be the intention to disqualify any duly qualified Practitioner, but to give to every one licensed by a duly authorised body, a recognised position in that calling to which he is licensed.

"There is very little in the Act to throw light on the particular term used. The only instance in which it is used in connection with midwifery is in clause 4 of Schedule (A); and as we are given to understand that the general licentiatees of the English College of Surgeons are, and are styled, Fellows or Members, and that it has no licentiatees so styled, except its licentiatees in midwifery, we do not see that any argument in favour of restricting the use of the term in clause 3 can be drawn from its use in clause 4.

"In each case the terms used are sufficient to describe all the Practitioners acting under the authority of the body which is spoken of.

"The result is, that we are of opinion that every person who has received a licence is, for the purposes of this Act, a licentiate in that art to which his licence applies.

"2. The answer to this question depends upon the construction of Schedule (A), and is governed by the same considerations as the answer to question 1."

This opinion seems to be not very decided; and your Committee are of opinion that, unless compelled by law to insert these qualifications, the General Council should refuse to do so, as they are certainly injurious to the interests of other bodies, and not calculated to elevate the character of the Profession.

In conclusion, your Committee would recommend—

1. That the President be requested to correspond with the Home Secre-

tary, in order to have the order of the Irish Poor-law Commissioners rescinded.

2. That the Bodies at present granting Licences in Midwifery should be requested to surrender this privilege, in the event of a new Medical Act being obtained.

3. That should this be found impracticable, the amended Medical Act should be so framed as to confer the power of granting Certificates in Midwifery on all Bodies which duly examine in that department of medicine.

4. That the Executive Committee be instructed to take the opinion of counsel unconnected with Ireland, on the propriety of continuing to register those qualifications in midwifery which do not appear in Schedule (A) to the Medical Act.

ALEXANDER WOOD, *Chairman*.

2. Moved by Dr. ALEXANDER WOOD, seconded by Dr. LEET—"That the Report of the Committee on the requirements of the Commissioners for administering the Laws for the Relief of the Poor in Ireland, be received and entered in the Minutes."—Agreed to.

The Report of the Special Committee appointed by the General Council on May 27, 1863, relative to the Pharmacopœia (see Minutes, No. 52, p. 14), was taken into consideration.

3. Moved by Dr. CHRISTISON, seconded by Dr. SHARPEY—"That the sum of £94 10s. be voted to Dr. Apjohn for chemical investigations connected with the Pharmacopœia."—Agreed to.

4. Moved by Dr. CHRISTISON, seconded by Dr. SHARPEY—"That the sum of £154 7s. be voted to Dr. Douglas MacLagan, for chemical investigations connected with the Pharmacopœia."—Agreed to.

5. Moved by Dr. CHRISTISON, seconded by Sir CHARLES HASTINGS—"That £150 be voted to Dr. Garrod, as General Secretary of the Pharmacopœia Committee, and Secretary to the London Sub-Committee; £100 to Dr. Charles Wilson, and £100 to Dr. Aquilla Smith, as Secretaries respectively of the Edinburgh and Dublin Sub-Committees."—Agreed to.

6. Moved by Dr. CHRISTISON, seconded by Dr. ACLAND—"That to the principal Editor in London, Dr. Farre, £75 be voted, to be received when the Pharmacopœia is published; and that to each of the Edinburgh and Dublin Editors, Dr. MacLagan and Dr. Neligan, £50 be voted, to be received when the Pharmacopœia is published."—Agreed to.

7. Moved by Mr. SYME, seconded by Mr. HARGRAVE—"That £500 be voted to each of the Sub-Committees, for preparing the Pharmacopœia, as a honorarium for their time and services, the Sub-Committees being respectively,"—

*London Pharmaceutical Sub-Committee.*

Dr. Watson.	Mr. Green.
Sir James Clark.	Mr. Nussey.
Dr. Farre.	Mr. Squire.
Dr. Garrod.	

*Edinburgh Pharmaceutical Sub-Committee.*

Dr. Christison.	Dr. MacLagan.
Dr. Begbie.	Dr. Andrew Wood.
Dr. Sellar.	Mr. Syme.
Dr. Wilson.	Mr. Macfarlane,
Dr. Sanders.	Afterwards, on his death, Mr. Gardner.
	Mr. Robertson.

*Dublin Pharmaceutical Sub-Committee.*

Dr. Apjohn.	Dr. Neligan.
Dr. A. Smith.	Dr. Barker.
Dr. Williams.	Dr. Leet.

Amendment moved by Dr. ANDREW WOOD, seconded by Dr. LEET—"That payments to the Sub-Committees on account of the Pharmacopœia be delayed till next Session of the Council, when the Pharmacopœia shall have been published, and the Council shall be enabled to form a correct judgment as to the money they may be able to vote as a honorarium to them."

The amendment was put and negatived.

Dr. ANDREW WOOD required that the names of the majority and minority be entered on the Minutes.

*Majority—*

Confirmed—JOSEPH HENRY GREEN.

MINUTES OF MEETING, WEDNESDAY, JUNE 3, 1863.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Mr. GREEN, *President*, took the chair at Two o'clock p.m.

*Present—*

Dr. Burrows.	Dr. Andrew Wood.	Sir Charles Hastings.
Mr. Arnott.	Dr. Fleming.	Dr. Sharpey.
Mr. Cooper.	Mr. Syme.	Mr. Lawrence.
Dr. Acland.	Dr. Thomson.	Mr. Teale.
Dr. Bond.	Dr. A. Smith.	Dr. Christison.
Dr. Embleton.	Mr. Hargrave.	Dr. Stokes.
Dr. Storrar.	Dr. Leet.	
Dr. Alexander Wood.	Dr. Corrigan.	

Dr. FRANCIS HAWKINS, *Registrar*.

The Minutes of the last meeting were read and confirmed.

The consideration of the Report of the Special Pharmacopœia Committee was resumed.

1. Moved by Dr. CHRISTISON, seconded by Dr. ANDREW WOOD—"That the proposed price of the Pharmacopœia—viz., 7s. 6d. for the large, and 5s. for the small edition—be submitted, according to the provisions of the Act of Parliament, to the Commissioners of the Treasury."—Agreed to.

2. Moved by Mr. SYME, seconded by Dr. ANDREW WOOD—"That the several sums voted for the publication of the Pharmacopœia shall be paid at the end of six months from the time of its publication."

Amendment, moved by Mr. ARNOTT, seconded by Dr. ACLAND—"That the Treasurers be authorised, under the direction and sanction of the Executive Committee, to advance such sums of money as may be necessary to discharge the expenses incurred in preparing, printing, and publishing the Pharmacopœia."

Amendment put and carried.

3. Moved by Mr. TEALE, seconded by Dr. SMITH—"That Dr. Christison be requested to prepare and publish an explanatory statement of the forthcoming Pharmacopœia, showing its composition, the principles of its construction, the changes introduced, and the necessity under which the members of the several branches of the Medical Profession will lie of making themselves acquainted with the British Pharmacopœia, in place of the Pharmacopœias which it is to supersede."—Agreed to.

4. Moved by Dr. CHRISTISON, seconded by Mr. HARGRAVE—"That the Council adopt the recommendations of the Special Pharmacopœia Committee, which provide for the preparation and publication of the new editions of the Pharmacopœia."—Agreed to.

5. Moved by Dr. SHARPEY, seconded by Dr. CHRISTISON—"That it be an instruction to the Executive Committee to watch the progress of the Bill on Weights and Measures, now before Parliament, and, in the event of its passing the second reading, to take such steps, by petition in the name of the Council, or otherwise, as may seem to them best calculated to prevent the enactment of any statutory restriction or obligation affecting the use of weights and measures in pharmacy, unless with such provisions as shall obviate the risk of its inconvenient or premature enforcement."—Agreed to.

6. Moved by Dr. BURROWS, seconded by Sir CHARLES HASTINGS—"That the Report of the Finance Committee be adopted."—Agreed to.

7. Moved by Dr. ALEXANDER WOOD, seconded by Mr. HARGRAVE—"That the Standing Orders in regard to the 'Order of Business,' regulating the manner of taking the votes be amended as follows:—

"1. That if there be but one amendment, the vote shall be first taken upon it; and if it is negatived, then on the original motion.

"2. That if there be more than one amendment, the amendment last moved shall be first put to the vote; and in the event of its being negatived, then the amendments shall be put in the inverse order to that in which they have been proposed. If all the amendments are negatived, the vote shall then be taken on the original motion."—Agreed to.

8. Moved by Dr. ALEXANDER WOOD, seconded by Dr. LEET—"That the Registrar be directed to send annually, within one month after the Meeting of Council, to the various bodies in Schedule (A), the names of those who, during the meeting of the Council, have been struck off the Register by order of the Council, and to request the attention of each Body to Regulation 7, Chapter VIII., of the Standing Orders, which shall be altered as follows:—

"That the Council recommend that any person whose name has been once removed from the Register shall not be admitted to Examination for any new Qualification, without the consent of the General Medical Council."—Agreed to.

9. Moved by Mr. TEALE, seconded by Mr. HARGRAVE—"That the Report of the Committee on Recognition of Colonial and Foreign Universities be adopted."—Agreed to.

10. Moved by Dr. CORRIGAN, seconded by Dr. A. SMITH—"That the Registrar be requested to apply to the several Licensing bodies mentioned in Schedule (A) to the Medical Act for copies of the Charters or Acts of Parliament under which those Licensing Bodies issue Degrees or Licences, and possess or exercise any other powers in reference to Medicine, Surgery, Midwifery, or Pharmacy."—Agreed to.

11. Moved by Dr. CORRIGAN, seconded by Mr. A. SMITH—"That it be an instruction to the Executive Committee to obtain returns of the regulations relative to education and examination from the several licensing bodies mentioned in Schedule (A); to ascertain in what particulars the regulations of any of those bodies may differ from the recommendations of the General Medical Council; to request from those corporate bodies, whose regulations so differ, such observations or explanations as they may deem fit to offer; and to submit the correspondence, with their report thereon, to the next meeting of the General Council."—Agreed to.

12. Moved by Dr. STOKES, seconded by Mr. SYME—"That, looking at the various curricula of professional education enforced by the licensing bodies enumerated in Schedule (A) to the Medical Act, the Council are of opinion that the number of courses of lectures required to be attended might be reduced with advantage, so as to give the student a larger amount of time for self-education. That the overloading of the curriculum of education—whether as to the number of courses, or of lectures in particular courses, must be followed by results injurious to the student."—Agreed to.

Mr. LAWRENCE required that the names of the majority and minority be entered on the Minutes.

*Majority—*

Mr. Arnott.  
Mr. Cooper.  
Dr. Acland.

*Minority—*

Dr. Andrew Wood.  
Dr. Thomson.  
Mr. Hargrave.

Majority—

Dr. Bond.  
Dr. Embleton.  
Mr. Syme.  
Dr. A. Smith.  
Dr. Leet.  
Dr. Corrigan.  
Sir Charles Hastings.  
Mr. Lawrence.  
Mr. Teale.  
Dr. Stokes.

Minority—

Dr. Christison.

13. Moved by Mr. SYME, seconded by Dr. CHRISTISON—"That the Medical Council resolve to take into consideration, at the next meeting, the propriety of recommending a reduction in the number of courses of lectures which the regulations of the various licensing boards at present render obligatory. That, with the view of facilitating the consideration of this subject, the General Council request to be favoured with the opinion of the bodies in Schedule (A), on the possibility and propriety of this, before next meeting."—Agreed to.

14. Moved by Dr. ACLAND, seconded by Mr. HARGRAVE—"That the various resolutions and recommendations of the Council, affecting directly the subject of Medical education, be separately printed; that a copy be furnished to the several bodies named in Schedule (A), to the members of the General Council, and other persons named by the President; and that written communications be invited concerning them from those to whom they may be sent."—Agreed to.

15. Moved by Mr. TEALE, seconded by Mr. HARGRAVE—"That the Council recommend to the various Licensing Bodies, named in Schedule (A) of the Medical Act, the consideration of the *ad-eundem* principle in the granting of degrees and licences, with a view to the reduction of the number of examinations on the same subject, which the student is now frequently obliged to undergo, in order to obtain a plurality of qualifications."—Agreed to.

16. Moved by Dr. ANDREW WOOD, seconded by Mr. TEALE—"That the Medical Council, having by the Act of Incorporation a corporate seal, the following bye-laws in reference to it, which have been prepared by the Solicitor be adopted by the Council, and that it be remitted to the Executive Committee to carry them out:—

1. The corporate seal shall be kept in a box having two different locks. The key of one lock shall be in the custody of the President; that of the other in the custody of the Registrar.

2. The seal shall only be affixed by order of the General Council, or, when the General Council is not sitting, by order of the Executive Committee of the General Council, its use by such Committee being limited to such Acts as may be necessary to effectuate the powers delegated to it by the General Council.

3. Any order for affixing the seal, shall state the object of its use, and shall be entered on the Minutes of the General Council, or of the Executive Committee, as the case may be.

—Agreed to.

17. Moved by Dr. EMBLETON, seconded by Dr. THOMSON—"That it be referred to the Branch Councils to report to the next meeting of the General Medical Council, as to the simplest mode of registering Medical students."—Agreed to.

18. Moved by Dr. ANDREW WOOD, seconded by Dr. CHRISTISON—"That the standing order which provides for the rising of the Council at six o'clock be suspended for this day."—Agreed to.

19. Moved by Dr. CORRIGAN, seconded by Dr. A. SMITH—"That the Executive Committee be requested, in accordance with the recommendation of the report of the Medical Acts' Amendments Committee (see Minutes, June 1, 1861), to have a Bill drafted embodying the amendments prepared; that copies of such Bill be forwarded to the Branch Councils, for their observations thereon; that the Executive Committee cause to be prepared, for the next annual meeting of the General Council, interleaved copies of such Bill, with all suggested amendments; and that the General Council, at the same time, desire it to be understood that they refrain at present from expressing any opinion on the amendments now proposed."

(First Amendment.)

Moved by Dr. CHRISTISON, seconded by Mr. SYME—"That the Report of the Medical Acts' Amended Committee be re-committed."

(Second Amendment.)

Moved by Dr. FLEMING, seconded by Dr. THOMSON—"That the Report of the Medical Acts' Amendments Committee be forwarded to the branch Councils, for their observations thereon."

Second amendment put to the vote, and carried.

20. Moved by Dr. ANDREW WOOD, seconded by Mr. ARNOTT—"That the Report of the Committee on appointments of members of the Council be received, entered on the Minutes, and adopted by the Council."—Agreed to.

Report.

The Committee appointed by the General Council to consider and report whether any, and what steps should be taken by the Council in relation to the retirement and election of its members, in view of the expiration of the term of five years from its constitution, beg to make the following Report:—

The documents in the possession of the Registrar do not form a complete record of all appointments which have taken place; but from those which the Registrar has, it appears that some members were appointed generally, without specifying any term; others were appointed specifically for five years; while others who were originally appointed without any specification of term have received subsequent appointments, making their tenure of office one year only.

It appears to the Committee that in each case the period of office, whether for five or any other number of years, must be calculated from the day of appointment, and that steps should be taken to ascertain correctly the date of appointment of each of the present members of the Council.

As regards members appointed in the place of others, it appears to the Committee that their tenure of office must be regulated by the instrument appointing them, without reference to the period of appointment of the persons in whose place they have been substituted.

Your Committee have had under their consideration the tenure of office by the President. On his election he became a member of the Council; and though the 8th Section of the Act seems to draw a distinction between the President and the other members of the Council, yet, on the whole, your Committee is of opinion that the President is subject to the same rules as to tenure of office as the other members of the Council.

Your Committee recommend that a book should be kept, containing the

names of the members of the Council, the bodies they represent, the date of appointment of each member, the term for which he was appointed, and the date of the death or retirement of each member, such book to be regularly kept up, so as at once to show the period at which each of the bodies having power to appoint should proceed to a new appointment; also the same particulars with regard to members appointed by the Crown.

Your Committee also recommend that a form for appointing members should be prepared, and sent by the Registrar to the Secretary of State, and to each body having power to appoint, two months before the expiration of the term of the existing appointment, so that the new appointment may be made to take effect from the day on which the old appointing shall expire.

Your Committee submit a form of such appointment:—

WE, the \_\_\_\_\_, in pursuance of the power given to us by the Medical Act, do hereby appoint \_\_\_\_\_

to be a member of the General Council of Medical Education and Registration of the United Kingdom, for the term of \_\_\_\_\_ year \_\_\_\_\_ from the \_\_\_\_\_ day of \_\_\_\_\_ 186\_\_\_\_\_

With reference to the fact that the term of office of members constituting the Executive Committee may expire while the General Council is not sitting, your Committee suggest that in appointing the Executive Committee the General Council should delegate power to supply vacancies amongst the members of that Committee.

Your Committee, in conclusion, think it right to state that this Report has been drawn up under the guidance of the Solicitor of the Medical Council.

JOHN STORRAR, Chairman.

21. Moved by Dr. ANDREW WOOD, seconded by Mr. HARGRAVE—"That the case prepared at the meeting of the General Council in 1862, relative to the educational sections of the Medical Act, with the opinion of counsel thereon, be received, and printed in the Minutes."—Agreed to.

Case for the Opinion of Counsel.

The Medical Council is desirous of being advised as to the true construction of the Medical Act (1858), so far as relates to the educational sections.

By the Medical Act a General Council of Medical Education and Registration of the United Kingdom is constituted.

Counsel will no doubt have in view the entire scope of the Act, but the sections which especially refer to the powers of the General Council as to education are the 18th (and the Schedule (A) therein referred to), the 20th, 21st, 22nd, and 24th.

By the 18th Section, "The several Colleges and bodies in the United Kingdom mentioned in Schedule (A) to this Act shall from time to time, when required by the General Council, furnish such Council with such information as they may require as to the courses of study and examinations to be gone through in order to obtain the respective qualifications mentioned in Schedule (A) to this Act, and the ages at which such courses of study and examination are required to be gone through, and such qualifications are conferred, and generally as to the requisites for obtaining such qualifications."

The 20th Section provides, that "in case it appear to the General Council that the course of study and examinations to be gone through in order to obtain any such qualification from any such College or body are not such as to secure the possession by persons obtaining such qualification of the requisite knowledge and skill for the efficient practice of their Profession, it shall be lawful for such General Council to represent the same to Her Majesty's Most Honourable Privy Council."

Sections 21, 22, and 24 state the action to be taken by the Privy Council on such representations being made.

The question on which the Medical Council is desirous of obtaining information may be stated generally as follows:—

"Whether the General Medical Council, in considering the returns made to it by the several Colleges and bodies in the United Kingdom in accordance with Section XVIII. of the Medical Act, is entitled to have respect to the supposed value of different degrees or licences, or whether the Medical Council is limited by Clause XX. to laying down a minimum standard sufficient in its opinion to secure the requisite knowledge and skill for the efficient practice of their profession by the holders thereof, although in the opinion of the General Council the standard may not be that which should be demanded for the higher qualifications."

For the better understanding of the question intended to be raised, it will be necessary to state the action which the General Medical Council has taken with reference to general and professional education.

In the year 1859, the General Medical Council came to the conclusion, that, as they were authorised by the Medical Act to represent to the Privy Council whatever defects of study or examination they might consider to exist on the part of bodies granting qualifications to practise, it would be expedient for them to publish their views on the subject of education and examination, so that every body which was entitled to grant qualifications to practise might be informed beforehand what standard of proficiency would be required by the Council.

The General Medical Council have accordingly issued three reports on education and examination, dated respectively 1859, 1860, and 1861. Copies of these reports accompany the case.

The Report of 1859 is preceded by some general remarks, pointing out the views of the Council as to the nature and importance of the preliminary examination in general knowledge which should be required.

The subject of education is divided by the General Council into three heads:—

1. Preliminary General Education.
2. Professional Education.
3. Professional Examinations and the conditions on which the higher qualifications in Medicine and Surgery should be granted. (*Vide* the Report of the Committee on Education, 1861.)

The General Medical Council report with some fulness on the first head, and issue "Recommendations" as regards the Preliminary Examinations in General Education which should be required of all students seeking any kind of Professional qualification whatever.

They also make some "Recommendations" on the subject of Professional Examination (Head 3), but these "Recommendations" are of a general character, and apply alike, without distinction, to all Professional Examinations.

In the Report of 1860, an opinion is recorded which, in the Report of 1861, is extended to Surgery:—

"That it is not desirable that any University of the United Kingdom should confer any Degree in Medicine or Surgery—whether that of Bachelor, Doctor, or Master—upon candidates who have not graduated in Arts, or passed all the Examinations required for the Bachelorship in Arts, or the Examinations equivalent to those required for a Degree in Arts."

It may be now stated, as a result of the steps taken by the General Medical Council, that an Examination in General Education is required by all Bodies who confer Degrees or grant Diplomas or Licences, and that in most cases the Examination in General Education has been further made preliminary in conformity with the wish of the Council.

But there has not been an equal concurrence of opinion on the part of all the Bodies mentioned in Schedule (A) with the resolutions of the General Medical Council of 1860 and 1861 (Head 3), relating to the General Education of persons obtaining higher qualifications in Medicine or Surgery; nor can it be said that the General Medical Council are unanimous in the opinion that they have authority under the Medical Act to require a higher standard of proficiency for candidates for higher qualifications than for persons only obtaining a Diploma or Licence to practise.

The Regulations of some of the Bodies named in Schedule (A) were already in accordance with the recommendations of the Medical Council; of those which were not in accordance, some have conformed with the recommendations, and others have questioned the power of the Council to require any regulations beyond such as are essential for securing the requisite knowledge and skill for the efficient practice of their Profession.

Up to this present time, it must be remarked that the authority of the General Medical Council to issue "Recommendations," or to make representations to the Privy Council in regard to the insufficiency of study and examination for higher qualifications as distinguished from the sufficiency of study and examination required for a Diploma or Licence, has only been disputed as respects preliminary General Education; because, in fact, the General Medical Council have not as yet taken any step in regard to the Professional Education for University Medical or Surgical Degrees; neither have they considered the expediency or otherwise of fixing a higher standard for those higher qualifications conferred by Medical Bodies beyond the Diploma or Licence to practise; but it will be evident, that should the General Medical Council take up these points at a future meeting, the same conflict of opinion, as to the extent of their authority, is likely to arise, and in a more extended form.

Let attention now be drawn to Schedule (A). In this Schedule are enumerated all the titles or qualifications derivable from Universities or Medical Bodies which may be recorded in the Medical Register. These titles or qualifications not only represent to the mind of the Profession, and to the mind of the public, variety in degree of proficiency in Medical and Surgical Science, but also variety in nature, at least to some extent, *e.g.*, Medicine and Surgery.

Difference of opinion has existed as to the word Profession, as used in Section 20, it being contended, on the one hand, that it must be applied to the entire Schedule, and that the authority of the General Medical Council is restricted to the requirement of a minimum standard common to all qualifications; while the opposite view is, that the word Profession is to be taken in its distributive sense, and applied to each title or qualification separately, so that the General Medical Council would be authorised to estimate the extent of proficiency and variety of attainment which should correspond with each title or qualification in the Schedule, and make representations accordingly, if need be, to the Privy Council.

The questions for your consideration are:—

1. Is the General Medical Council, in making representations to the Privy Council, restricted to representing such cases (should they exist) in which the course of study and examination, whether in general knowledge or in strictly Professional studies, is inadequate to secure the possession of the requisite knowledge and skill for the efficient practice of any grade whatever of the Medical Profession?

2. Is the General Medical Council authorised to represent to the Privy Council that a course of study and examination, whether in general knowledge or strictly Professional studies, though adequate to secure the requisite knowledge and skill for the efficient practice of the Profession under one grade or qualification, is not adequate for the efficient practice of it under another grade or qualification?

3. Is the General Medical Council authorised to represent to the Privy Council that a course of Professional Study and Examination, though adequate as to kind, to secure the requisite knowledge and skill for the efficient practice of one department of the Profession, say Medicine, is not such, as to kind, as ought to be required in order to secure the requisite knowledge and skill for the efficient practice of another department of the Profession, say Surgery?

#### Opinion.

We have considered the questions submitted to us, and are of opinion as follows:—

1. We think that the General Medical Council, in making representations to the Privy Council, is not restricted to representing cases in which the course of study and examination, whether in general knowledge or in strictly Professional studies, is inadequate to secure the possession of the requisite knowledge and skill for the efficient practice of any grade whatever of the Medical Profession generally. We think that the Medical Council, having regard to the 31st section of the Medical Act, is entitled to discriminate between qualifications for the practice of Medicine and qualifications for the practice of Surgery; and that the Medical Council may represent to the Privy Council cases in which the course of study and examination to be gone through in order to obtain a qualification for the practice of Medicine, is inadequate, in any respect, to secure the requisite knowledge and skill for the efficient practice of Medicine, though adequate, it may be, in that respect, for the efficient practice of Surgery, and *vice versa*. To this extent, but only to this extent, we think that the Medical Council is not restricted to the requirement of a standard common to all qualifications.

2. Except in reference to the distinction we have mentioned between qualifications for the practice of Medicine and qualifications for the practice of Surgery, we do not think that the General Medical Council is authorised to represent to the Privy Council that a course of study and examinations, whether in general knowledge or in strictly Professional studies, though adequate to secure the requisite knowledge and skill for the efficient practice of the Profession, under one grade or qualification, is not adequate for the efficient practice of it under another grade or qualification. We do not think that it is within the functions of the Medical Council, acting under the 20th section of the Medical Act, to make representations to the Privy Council with regard to the insufficiency of study and examination for higher degrees or qualifications, as distinguished from the sufficiency of study and examination required for a diploma or licence to practise. We do not think that the Medical Council is authorised, for example, to demand a higher standard of proficiency for the degree of Doctor of Medicine than for that of Bachelor; nor to demand higher standard of general or Professional education from graduates of

Universities qualified to practise Medicine, or to practise Surgery, as the case may be, than from licentiates of corporations similarly qualified.

3. We think, as a ready mentioned, that the General Medical Council is authorised to represent to the Privy Council that a course of Professional Study and Examination, though adequate as to kind, to secure the requisite knowledge and skill for the practice of the Medical Profession in the department of Medicine, is not such, as to kind, as ought to be required, in order to secure the requisite knowledge and skill for the efficient practice of the Profession in the department of Surgery, and *vice versa*. But the Medical Profession must, in our opinion, be considered as, for this purpose, divided only into the two departments mentioned, *viz.*, those of Medicine and Surgery.

ROUNDELL PALMER,  
C. J. SELWYN,  
F. VAUGHAN HAWKINS.

22. Moved by Dr. ALEXANDER WOOD, seconded by Mr. SYME—"That the Council is of opinion that the matter referred to in a memorial presented by Dr. Edwards Crisp, respecting the Carnichael Prizes, is not within the powers of the Council, as limited by the Medical Acts, and the Council therefore decline to enter on its consideration."—Agreed to.

23. Moved by Dr. ALEXANDER WOOD, seconded by Mr. SYME—"That the Council is of opinion that the matter referred to in a memorial presented by Henry Holmes, M.D., M.R.C.S., of Bridgenorth, respecting the conduct of the Salopian Medico-Ethical Society, is not within the powers of the Council, as limited by the Medical Acts; and the Council therefore decline to enter on its consideration."—Agreed to.

24. Moved by Dr. ANDREW WOOD, seconded by Dr. EMBLETON—"That it be remitted to Dr. Embleton, in conjunction with the Registrar, to prepare and print an Index of all the Minutes, as well of the General Council and Executive Committee as of the Branch Councils."—Agreed to.

25. Moved by Dr. ANDREW WOOD, seconded by Dr. THOMSON—"That £200 of the General Registrar's salary of £500 be charged against the funds of the Branch Council for England."—Agreed to.

26. Moved by Dr. CHRISTISON, seconded by Dr. ANDREW WOOD—"That the consideration of the Report of the Committee on the requirements of the Commissioners for Administering the Laws for Relief of the Poor in Ireland, be deferred till the next meeting of the General Council."—Agreed to.

27. Moved by Dr. A. SMITH, seconded by Dr. CORRIGAN—"That the Executive Committee be authorised to protect the copyright of the *British Pharmacopœia*, which is vested in the General Council."—Agreed to.

28. Moved by Dr. CORRIGAN, seconded by Mr. SYME—"That the Executive Committee be requested to direct their attention, and take such steps as may appear advisable to them, towards obtaining from Government a suitable place of meeting for the General Council."—Agreed to.

29. Moved by Dr. ANDREW WOOD, seconded by Mr. TEALE—"That the Executive Committee consist of—

"The President. "Mr. Arnott.  
"Dr. Burrows. "Dr. Acland.  
"Dr. Sharpey."

—Agreed to.

30. Moved by Dr. A. SMITH, seconded by Dr. ANDREW WOOD—"That the powers and duties delegated to the Executive Committee, in accordance with the ninth section of the 'Medical Act,' shall be vested in the Committee until the next meeting of the General Medical Council."—Agreed to.

31. Moved by Mr. TEALE, seconded by Mr. HARGRAVE—"That the thanks of this Council are eminently due, and are hereby offered, to the Royal College of Physicians, London, for their obliging and courteous accommodation during the present session of the Medical Council."—Agreed to.

32. Moved by Dr. ANDREW WOOD, seconded by Mr. HARGRAVE—"That a gratuity of ten guineas be given to the servants of the Royal College of Physicians of London."—Agreed to.

33. Moved by Dr. A. SMITH, seconded by Mr. HARGRAVE—"That a gratuity of ten guineas be given to Mr. Bell, and the same to Mr. Roope, the clerks, for their extraordinary labours in attendance on the Council."—Agreed to.

34. Moved by Dr. EMBLETON, seconded by Mr. HARGRAVE—"That the thanks of this Council are due, and are hereby tendered to the Treasurers of the Council, Dr. Burrows and Dr. Sharpey, for their important services."—Agreed to.

35. Moved by Dr. CORRIGAN, seconded by Dr. ALEXANDER WOOD—"That the grateful thanks of the Council be, and are hereby given, to the President, for his continued zeal, kindness, and attention, in discharging his duties this session."—Carried by acclamation.

#### MINUTES OF ADJOURNED MEETING, WEDNESDAY, JUNE 3, 1863.

ROYAL COLLEGE OF PHYSICIANS, LONDON.

Mr. GREEN, *President*, in the chair.

#### Present—

Mr. Cooper.	Dr. Fleming.	Dr. Corrigan.
Dr. Embleton.	Dr. A. Smith.	Mr. Arnott.
Dr. Alexander Wood.	Mr. Hargrave.	Mr. Teale.
Dr. Andrew Wood.		

Dr. FRANCIS HAWKINS, *Registrar*.

The Minutes of the last meeting were read and confirmed.

#### REVIEWS.

*A Clinical Memoir on Certain Diseases of the Eye and Ear, consequent on Inherited Syphilis; with an Appended Chapter of Commentaries on the Transmission of Syphilis from Parent to Offspring, and its more Remote Consequences.* By JONATHAN HUTCHINSON, F.R.C.S., Senior Assistant-Surgeon and Lecturer on Surgery at the London Hospital; Assistant-Surgeon to the London Ophthalmic Hospital, etc. London: Churchill and Sons. 1863. Pp. 269.

THIS is a book upon a difficult subject. We have to show where the great difficulty lies, and how Mr. Hutchinson

meets it. Given certain diseased conditions of the eye and ear in young persons, the author undertakes to prove by clinical evidence that they derive their origin from inherited syphilis. For the most part, the patients themselves can give no assistance in tracing them to the supposed cause, and considerations of moral obligation or motives of kindness preclude the Surgeon from pursuing his investigation by direct questioning. He is thus driven to indirect methods of arriving at his object. In some instances, indeed, this is not the case, as one or both parents may either exhibit unmistakable marks of syphilis, or may confess to its occurrence, or may detail enough of the previous Medical history of the child to supply full conviction to the mind of the Surgeon. But, in the majority of cases of suspicious disease, it is not so, and the difficulty to be met is to fix upon some unmistakable tokens or objective signs of the hereditary syphilitic diathesis,—such as shall declare to all who observe them that the person exhibiting the marks is hereditarily infected. Taking these signs as positive indications, corroborative evidence may be sought to strengthen the case in the eyes of the less believing. Now, Mr. Hutchinson considers that he is in possession of such objective tokens, at all events in persons whose age has advanced to the period of second dentition. We are not about to discuss the accuracy of this test; it is sufficient for us here to say that he quotes Mr. Dixon and Mr. Paget as satisfied with its value. To those persons who are disposed to accept the test, this work will be conclusive in its reasoning; to those who do not accept it, the conclusions of the author will not be satisfactory. Such persons must withhold their judgment until they have tested by their own experience the test itself. The test of hereditary syphilis, in the difficult cases alluded to, mainly lies in the exhibition of certain developmental peculiarities especially obvious in the state of the permanent teeth, but also in other marks, respecting all which we shall allow our author to speak for himself. “*The central upper incisors of the second set are the test teeth*, and the Surgeon not thoroughly conversant with the various and very common forms of dental malformation will avoid much risk of error if he restrict his attention to this pair. In syphilitic patients, these teeth are usually short and narrow, with a broad vertical notch in their edges, and their corners rounded off. Horizontal notches or furrows are often seen, but they, as a rule, have nothing to do with syphilis.”—P. 204. A plate, illustrative of typical syphilitic teeth, is given. “Next in value to the malformations of the teeth are the state of the patient’s skin, the formation of the nose, and the contour of his forehead. The skin is almost always thick, pasty, and opaque. It also often shows little pits and scars, the relics of a former eruption, and at the angles of the mouth are radiating linear scars running out into the cheeks. The bridge of the nose is almost always broader than usual and low; often it is remarkably sunk and expanded. The forehead is usually large and protuberant in the regions of the frontal eminences; often there is a well-marked broad depression a little above the eyebrows. The hair is usually dry and thin, and now and then (but only rarely) the nails are broken and splitting into layers.”—P. 205. And then follow some signs which we must pass over, referable to former syphilitic attacks of inflammation of the eyes. All these signs together Mr. Hutchinson calls the “syphilitic physiognomy.”

The diseases of young subjects, about which Mr. Hutchinson is most certain that he is correct in referring them to hereditary syphilis, are acute iritis, chronic interstitial keratitis, and inflammation of the choroid and retina. About other diseases of the eye treated of in his book he appears less certain. We will therefore confine our attention here to the diseases we have mentioned, leaving our readers to make their own acquaintance, as we think they ought to do, with the whole subject as placed before them by this experienced observer.

Twenty-three cases of acute iritis in young infants, the oldest aged sixteen months, are related, in most of which there was a history of syphilis in the parents, or the association with the iritis of indubitable syphilitic maladies in the child. A very few of the cases, although strongly suspicious, are not such as to carry full conviction to our mind. We will quote our author’s brief summary respecting this disease:—“1. The subjects of infantile iritis are much more frequently of the female than the male sex. 2. The age of five months is the period of life at or about which syphilitic infants are most liable to suffer from iritis. 3. Syphilitic iritis in infants is often symmetrical, but quite as frequently not so. 4. Iritis, as it occurs in infants, is seldom complicated, and is attended

by but few of the more severe symptoms which characterise the disease in the adult. 5. Notwithstanding the ill-characterised phenomena of acute inflammation, the effusion of lymph is usually very free, and the danger of occlusion of the pupil great. 6. Mercurial treatment is most singularly efficacious in curing the disease, and, if recent, in procuring the complete absorption of the effused lymph. 7. Mercurial treatment previously adopted does not prevent the occurrence of this form of iritis. 8. The subjects of infantile iritis, though often puny and cachectic, are also often apparently in good condition. 9. Infants suffering from iritis almost always show one or other of the well-recognised symptoms of hereditary taint. 10. Most of those who suffer from syphilitic iritis are infants born within a short period of the date of the primary disease in the parents.”—P. 26. To this series of aphorisms is appended a note which we also quote:—“In many of the cases the patients had previously been treated by mercury for other symptoms of hereditary syphilis. In one instance the second eye was attacked while the patient was taking mercury for the cure of iritis in that first affected. This I have known occur more than once in adults. In the latter, in five instances I have seen acute syphilitic iritis set in during actual ptyalism.” We can match the observation by another. We have seen rheumatic pericarditis not only set in during mercurial treatment of the original articular rheumatism several times, but once after ptyalism had commenced. Others must have met with a similar phenomenon. Although the drug does not prevent the occurrence of a disease, it is still believed to modify its progress.

Nearly half the book is occupied in the discussion of the syphilitic origin of chronic interstitial keratitis, respecting which the author says that its occurrence is not only now considered by several high authorities as pathognomonic of inherited taint, but that “it is almost invariably coincident with the syphilitic type of teeth, and, when these two conditions are found together in the same individual, I should certainly feel that the diagnosis was beyond doubt.”—P. 205. This being the importance attached by Mr. Hutchinson to the matter, one cannot be astonished at his devoting so much space to the subject. Indeed, he tells us at starting that the heredito-syphilitic origin of this disease, and of the dental peculiarities mentioned, are the principal assertions met with in the pages of his book. It is a disease which, under the name of “scrofulous corneitis,” has frequently been described by authors on ophthalmology. The following are the chief reasons which have induced Mr. Hutchinson to regard it as a direct result of inherited syphilis:—“1. From its being a very well marked and peculiar form of ophthalmia, it is *a priori* probable that it acknowledges some single and definite cause. 2. Its subjects are almost invariably of a very peculiar physiognomy, and usually bear the most marked similarity to one another. 3. Its subjects almost invariably have their upper central incisor teeth of the permanent set dwarfed and notched in a peculiar and characteristic manner. 4. In most cases the features alluded to under the last two heads bear no resemblance whatever to those of struma properly so-called. On the contrary, the subjects of tuberculous struma usually have large white teeth, and are often of a florid complexion. 5. I have not yet seen a single case in which the patient was the subject of phthisis, and but very few in which suppuration of the glands of the neck had occurred. 6. It affects by preference the eldest living child of the family, a circumstance to be expected under the syphilitic hypothesis, but wholly inexplicable under that of struma. 7. It affects female children in preference to males, and usually occurs in families in which a large infantile mortality has taken place. 8. It occurs in all classes of the community, the well-fed and under-fed, the residents of the most healthy situations (sea-coast, etc.), as well as those of crowded cities. 9. In a large proportion of those cases in which I thought it right to make direct inquiries on the subject, I obtained a confession that one or other parent had suffered from constitutional syphilis prior to the birth of the patient. 10. In a very large majority of those cases in which I obtained information as to the health of the patient during early childhood, a clear history of the usual symptoms of infantile syphilis was given. 11. In many instances there was a clear history of symptoms of infantile syphilis having been observed in brothers or sisters of the patient. 12. Whilst, as above observed, enlargements of the lymphatic glands are unusual, other affections far more closely connected with syphilis than with true struma, such as nodes, ulceration of the palate, and erosive lupus, are not

infrequent in subjects of this disease." — P. 124. Mr. Hutchinson's conclusions are derived from 102 cases, which are detailed and tabulated in his book. He tells us that the prognosis is favourable just in proportion as the intolerance of light is slight, and that even in the most severe cases a certain amount of clearing may be anticipated. The treatment he prefers is the use of mercurial ointment behind the ears, in the neck, and under the axillæ every night, and of a mixture containing iodide of potassium, iodide of iron, and tincture of nux vomica.

The chapter on inflammations of the choroid and retina, as dependent upon inherited syphilis, is much more brief, only fourteen cases being recorded. Mr. Hutchinson expresses a belief that, were it not that these deeper lesions generally occur with or after an attack of keratitis, they would be more frequently noticed; as it is, the haziness of the cornea prevents the ophthalmoscopic inspection by which the disease is recognised.

The Seventh Chapter is a brief one, and the only one devoted to consideration of diseases of the ear. It is entitled "On Deafness in connexion with Inherited Syphilis." Twenty-one cases are noted, fifteen of which were previously detailed in the chapters relating to disease of the eyes. All had suffered from keratitis. In this form of deafness the function seems to fail without any external disease; it is usually symmetrical, and its stages are often so rapidly passed through, that a patient who six months ago could hear almost perfectly, becomes, without otorrhœa, or any marked degree of pain, utterly deaf. The author believes the deafness due either to disease in the nerves, or to some changes in the non-accessible parts of the auditory apparatus.

The book concludes with a series of aphorisms respecting constitutional syphilis, and its transmission from parent to offspring, which we must needs pass over now; nevertheless, they will be read with interest. The whole book is the work of a man whose careful and extended observation will ensure for him an attentive hearing by every class of Practitioner.

## FOREIGN CORRESPONDENCE.

### GERMANY.

BERLIN, May 12.

It is a curious fact that until now the state of animal heat during and after parturition has scarcely at all been investigated, although we possess many valuable observations on the temperature of the living body in its normal physiological condition and in febrile diseases. It is therefore a great merit on the part of Dr. Winckel, Assistant-Physician to the Lying-in-Institution connected with this University, to have taken up this subject; and as he has arrived at many valuable results, I shall to-day communicate to you the most salient points of his experiments.

From various reasons he always determined the state of the temperature in the vagina before, during, and after birth. A sensitive thermometer was placed into the vagina, so that the globe was from two to four inches from the introitus, and was kept in its position by the thighs, which were pressed against one another. To measure the temperature in the arm-pit during birth is not only troublesome and tedious to the Physician, but also nearly intolerable to most parturient women, on account of the uncomfortable position of the arm. In the arm-pit it is necessary that the thermometer should remain at least twenty-five minutes, while in the vagina on the average nine minutes are sufficient for the thermometer to reach its highest standard; moreover, the instrument does not give any inconvenience to the women, whether they lie on the back or on the side. The question would then arise whether the canal of the vagina might not be too wide during birth for an accurate determination of the temperature to be made, and whether the local hyperæmia of the vagina would allow of conclusions to be drawn therefrom as to the temperature of the body altogether. It therefore became necessary to make comparative observations on the temperature in the arm-pit and the vagina. These gave the result—1st, that if all other circumstances, such as clothing, air, food, etc., remained the same, the difference in the temperature of the arm-pit and the vagina was nearly constant, that of the latter being 0.1 to 0.4° C. higher than that of the former; 2ndly, that if variations were observed in this difference, these were always caused

by a higher temperature of the skin; and 3rdly, that even if there were considerable morbid conditions of the vagina and uterus (which was generally the case only after, but not during birth), there was always the greatest similarity as regards the temperature of both places, so that it became evident that we might, during and after parturition, draw just as certain conclusions with regard to the temperature of the blood from the heat of the vagina as from that of the arm-pit.

In a hundred experiments made in women who were in the last two months of pregnancy, Dr. Winckel found the temperature of the vagina, between 9 and 10 a.m., on the average to be 100°.67 F.; between 5 and 7 p.m. it was on the average 100°.79. This remained the same during the whole of the last two months, and did not even increase within the last few hours before birth; in one case only was there an inconsiderable augmentation of temperature in the evenings of the last four days before birth. The hope therefore that we might perhaps be able to determine, by means of the thermometer, whether labour was impending, was not fulfilled.

It is not difficult to ascertain the temperature of the vagina in the first period of birth; during the second, if the head descends rapidly, the thermometer is sometimes expelled; but where the head comes down slowly, or where it remains fixed for some time, we may even during the second period determine the heat of the vagina without much inconvenience. Care must be taken to introduce the globe in an oblique direction below the lower labium of the os uteri, lest the membranes might be prematurely ruptured. In drawing our conclusions from the facts observed, we must take into account the ordinary daily variations of temperature. Animal heat increases under ordinary circumstances from 2 to 10 a.m., and decreases from 10 a.m. till 2 p.m.; it then again rises from 2 till 6 p.m., and is diminished from 6 p.m. till 2 a.m. Muscular exertion is always apt to give rise to an increase of heat; and it might therefore be expected that, as there is much muscular action in parturient women, even during the first period, and which continually increases as labour is progressing, we should find an augmentation of heat, more especially in primiparæ. But there are other circumstances which regulate and rather tend to diminish the temperature. Most parturient women do not partake of food during labour; they generally feel a great desire for cooling beverages, by which animal heat is diminished. Moreover, respiration is generally short, rapid, and superficial, while expiration is prolonged and intensified (screaming, moaning, etc.). Less oxygen is therefore carried to the blood, and, at the same time, the evaporation from the lungs is increased, whereby cold is produced. Heat is also lost by evaporation from the skin, the more so as the women are generally only lightly covered up.

Experiments made in forty parturient women, with regard to the circumstances just mentioned, have shown that the mercury always rose much faster during pains than before or after them. Heat is slightly increased during every labour. (0°.34 to 0°.40 F.) It does not rise continually and in proportion to the progress of labour, but the ordinary daily variations of temperature still go on undisturbed. The temperature is slightly higher in the second than in the first period. Early rupture of the membranes has generally no influence upon the heat. In premature births heat is much the same as in ordinary ones. Immediately after birth, it amounts to 101°.05. Compared with the temperature of the second period, it was higher than this, if birth took place between 2 and 10 a.m., and between 2 and 7 p.m., but lower if it was between 10 and 1 in the morning, and between 7 p.m. and 2 a.m. Within the next twelve hours, the heat rises about 1°, and only falls within the second twelve hours after birth. With regard to anomalous pains, it was found that if any inflammation was present, the temperature increased continuously even during the intervals between the pains, and that after birth it suddenly fell again considerably.

I now proceed to give some remarks which lately came from Professor Traube with regard to pneumothorax and the metallic sounds perceived in that affection. The best way to hear these sounds is to percuss a considerable surface of the thorax by means of a plessimètre. In many cases the metallic sounds could not be heard during life, but very distinctly after the death of the patient. The mixture of gases contained in the thorax has a certain tension, which may be much larger than that of the atmosphere. By the refrigeration of these gases after death the tension is diminished, and thus the perception of the sound facilitated. If the tension is exceedingly high, no

sound is produced. In several cases where the tension had been very considerable during life, Professor Traube, at the autopsy, first opened the abdomen. The metallic sounds, which had been very distinct before, disappeared if the diaphragm was slowly pushed upwards, whereby the tension in the sac of the pleura was of course increased. In one case only this experiment did not succeed, but here there was a considerable fistula, and the air escaped through the windpipe in proportion as the pressure was augmented.

To show the presence of pneumothorax after death, three methods may be employed—(a) The body is shaken before the autopsy is commenced. If there is pneumothorax, the gases mix with the effusion, and froth is produced. (b) The soft parts are so prepared that they form a sort of pouch with the chest; this is filled with water, and the thorax is then punctured below the water. (c) The abdomen is in a similar manner filled with water, and the diaphragm then punctured. In the two latter cases the air visibly escapes to the surface of the water.

An impediment to the exchange of gases within the bronchial tubes may cause death in two different ways: (a) amidst symptoms of dyspnoea, or (b) amidst symptoms of paralysis of the heart. Dyspnoea is considerable if, by the impediment to respiration, not only the absorption of oxygen is diminished, but also a considerable accumulation of carbonic acid in the blood is caused. Death may ensue without dyspnoea if there are only few red corpuscles in the blood, so that the formation of carbonic acid in the system is altogether diminished, and in consequence of a weakened heart's action, the transverse section and the rapidity of the current of blood is so much decreased, that only a trifling amount of carbonic acid can be carried to the medulla oblongata. Thus, Professor Traube has seen cases of pneumothorax with scarcely any dyspnoea, where the patients had been greatly weakened by phthisis. In the same manner bleeding will relieve dyspnoea, but this remedy is a double-edged knife. If a patient dies of an acute affection of the respiratory organs, at a time when his blood still contained a normal amount of red corpuscles, death is produced in a rather complicated manner. The carbonic acid, an excess of which is accumulated in the blood, excites not merely the nerves of respiration, but also both nervous systems of the heart to increased activity. By the augmented action of both the muscles of inspiration and the heart, the consumption of oxygen is considerably increased, while a lesser quantity of this gas is carried to the blood. The consequence of this is, that the blood becomes at last so poor in oxygen, that the excitability of the nervous centres is reduced to zero; that is, that they cannot even be excited by the maximum amount of carbonic acid carried to them. That the action of the nerves of inspiration is extinguished before that of the nerves of the heart, may be explained by the different length of the nervous courses. Those fibres which conduct the impulse of the medulla oblongata to the muscles of inspiration are far longer than the fibres which pass from the ganglia of the heart to the muscular substance of this organ; and this is the reason why the heart's action always lasts longer than that of the inspiratory apparatus, that is, why breathing ceases before the pulse disappears. The case is quite different if anæmic persons die from an affection of the respiratory organs. In such patients less oxygen is carried to the centres of life, and therefore the excitability of these latter is far less in them than in persons who were in good health. At the same time the quantity of the stimulus is less considerable; and thus the excitation is so feeble that no dyspnoea is produced. Nevertheless, death will ensue here as well as in the former case, because, owing to the impediment to respiration, at last a minimum amount of oxygen is carried to the blood, so that the excitability of the nervous centres is likewise reduced to zero.

## OBITUARY.

### DEATH OF DR. PHILIP BURNARD AYRES, M.R.C.S.

THE readers of the *Medical Times*, with which journal he was so long and so intimately connected, and also an offshoot, the *Pharmaceutical Times*, of which he was the editor, will regret to learn that this accomplished Physician died on Thursday, April 30, at his residence in the Champ de Mars, Port Louis, Mauritius, after an illness of about ten days. The first symptoms were those of a bilious remittent fever, rife at that

period; but as he felt little or no pain, he neglected to pay that attention to himself which he would have done to a patient. On the Tuesday week preceding his decease he went to bed in his usual good spirits, but awoke in the middle of the night with an excruciating pain in his abdomen. From the intensity of his sufferings it was evident to the Medical men in attendance that some lesion of a grave nature had taken place. The most energetic treatment was resorted to, but without success, and, notwithstanding all efforts, he gradually sank. The post-mortem examination confirmed the diagnosis which had been formed during life, and disclosed a perforation of the small intestine about an inch and a-half from the ilco-cæcal valve, with the concomitant appearances of intense peritonitis. Thus one of the rarest, and, at the same time, most unexpected, complications in a disease of comparatively little danger became the ultimate cause of the death of one of the most distinguished Physicians that ever visited the Mauritius.

Dr. Ayres was born at Thame, in Oxfordshire, on December 12, 1813, and from his earliest youth gave indications of a strong predilection for the natural sciences, and so decided was his taste for, and so complete his devotedness to his studies, that his parents resolved that he should embrace the Medical Profession as the best adapted to satisfy his longings for science. In 1836, he became a Licentiate of the Society of Apothecaries; on April 25 in the same year a member of the Royal College of Surgeons; and on December 9, 1841, a Doctor of Medicine of the London University, from which learned institution he carried off seven medals. He then entered on the active duties of his Profession, and, engaged almost night and day in providing for his young family, he yet found time for his favourite studies—botany and natural history. In physiological chemistry and hygiene, by long research and unrelenting industry, he brought out new facts which elicited the attention of the scientific men of his time, in the glorious array of whom he soon obtained a distinguished place for himself. Having been introduced by his friend Mr. Stone to Professor Quekett, a warm friendship sprang up between these men of congenial tastes, and, being an elegant writer, he edited the greatest part of that celebrated histologist's lectures, and assisted greatly in the histological catalogue of the Hunterian Museum. As a lecturer at the Charing-cross Hospital on chemistry he drew a large and attentive class. In 1851, he was appointed Physician to the Islington Dispensary; and in 1855, through the interest of his attached friend, the late lamented James Robinson, the well known Dentist, of Gower-street, the Secretary of State offered him the post of Superintendent of Quarantine at the Mauritius, which he at once accepted, and arrived on the scene of his future labours on January 5, 1856. In an elaborate notice of the death of Dr. Ayres, which appears in the *Overland Commercial Gazette*, it is stated that those who knew the state of matters at that time can fully appreciate what Dr. Ayres did in his new appointment. The misery he endured, his separation from his family, his trials, his excessive labours, were nothing for him; always calm and cheerful, he looked to the end—the completion of his task, and the improvements of the quarantine system. The excellent accommodation for the Indians at the Lazits of Flat Island, if not mainly due to him, at least was established by his earnest representations. Several of his reports, especially those of the Medical Charity Commission, and those on Quarantine and Sanitary Reform, bear the stamp of a masterly mind. His various communications to the Royal Society of Arts and Sciences, on the Geology of Flat Island, on the Diseases of Mauritius, and the Utility of Vaccination, are the results of careful observation and deep study. In every one of them are to be seen the same luminous train of reasoning—the suggestion of measures hitherto unheard of in this colony, conducive alike to the health of its inhabitants, and abounding with conclusions of the most practical value. Appointed Surgeon in charge of the Civil Hospital a little after the retirement of the late Dr. Montgomery, he soon placed that establishment upon a footing which gave universal satisfaction. Whilst discharging his official duties, he did not, however, neglect his scientific pursuits. Intent upon writing a Flora of Mauritius, each moment he could snatch from busy labour was spent in his botanising walks, but death snatched him away ere his work was finished, and the Flora of Mauritius remains uncompleted!—a work which, had his life been spared, would have placed him on a level with the first botanists of the day.

In private life he won the esteem of all those who knew him. Kind-hearted, generous, sympathising, he was always to be found foremost wherever any good was to be done, displaying on all occasions the benevolence and integrity of the true Christian, the courtesy of the gentleman, the kindness of the friend. To the disconsolate widow and the fatherless children the loss is irreparable, more especially as they have been left, it is greatly feared, in straitened circumstances. His eldest son, a most accomplished artist, is at present pursuing his Medical studies with great success in Edinburgh.

#### EDMUND BELFOUR.

THE members of the Profession will sympathise with the worthy and time-honoured Secretary to the Royal College of Surgeons in the lamentable death by drowning of his only son. On the 4th inst. Mr. E. Belfour left his residence, Grove House, Putney, soon after six o'clock for his usual early pull on the river Thames. As he did not return, some uneasiness was felt, and inquiries were made, the result of which was that his boat, one of those dangerous out-riggers, was discovered drifting without him. Search was immediately commenced, and a large number of boats were employed in dragging that part of the river over which he was supposed to have passed, but no trace of the body could be found until Saturday morning, when it was discovered at Hammersmith. An inquest was held on the remains the following Monday at the Boileau Arms, and adjourned until the following day, when a verdict of "found drowned" was returned. This terrible catastrophe has not only plunged the family and friends of the deceased into deep grief, but is keenly felt by all who enjoyed the privilege of his acquaintance. This was shown at his funeral, which took place on Wednesday last, and was attended by a large number of the most distinguished inhabitants of the neighbourhood, including the members of the London Rowing Club, of which the deceased was a Vice-President.

#### LEGAL INTELLIGENCE.

##### COURT OF QUEEN'S BENCH.—JUNE 4.

(Sittings in Banco.)

EX PARTE SERGEANT v. THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

This was an application by a Medical man under the Medical Council Act of 1858, which provides for a general registration of Medical men, and enacts that only those who are registered shall be entitled to sue for their fees. The Council had sent a circular letter to all Medical men, desiring to know if they had ceased to practise, but through his absence from home he did not receive the letter, and did not hear of it until December, 1861. He had since then repeatedly applied to the Council to register him, but his applications had not been acceded to. He now desired a *mandamus* to compel them to register him, and he made an affidavit to the effect that he was duly qualified, and that his right to be registered was not disputed.

Mr. Henry James now moved on his behalf for a *mandamus* to the Council to register him.

The Court granted a rule.

#### MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen passed the First Part of the Professional Examination for the License of the College on June 5, 1863:—

Charles William Ellis Foster, Leeds School of Medicine; George Lamb, 162, Caledonian-road, Islington; Richard John Lupton, School of Medicine, Liverpool; William Vacy Lyle, St. Mary's Hospital; Jesse Wheelock Thibou, St. Bartholomew's Hospital; Henry George Walker, University College; and Walter Thomas Priccaux Wolston, King's College.

APOTHECARIES' HALL.—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, June 4, 1863:—

Francis Henry Burdett, Birmingham; Wm. Hy. Hayward, Church-street, Oldbury; John Douglas Lawrie, Bradford, Yorkshire; Chis. Mont.

Davenport Davidson, Springfield, Wandsworth-road; Jas Acworth Angus, Newcastle-on-Tyne; Thos. Jewison Jefferson, Market Weighton, Yorkshire; Wm. Llewellyn Nash, Cheltenham; John Crump Lindop, St. Bartholomew's Hospital; John Sebastian Wesley, 38, Southampton-row; Thomas Henry Barnes, Clare, Suffolk.

The following gentlemen also on the same day passed their First Examination:—

Richard John Lupton, Liverpool, and Robert Harrison, Nether Sevens, Milnthorpe.

#### APPOINTMENTS.

\* \* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

ALLINGHAM, WILLIAM, F.R.C.S. Eng., has been elected Surgeon to the Great Northern Hospital.

BAYLEY, JOSEPH, M.R.C.S. Eng., has been elected Medical Superintendent of the Salop and Montgomery Lunatic Asylum, Bicton, near Shrewsbury.

COLLES, WILLIAM, F.R.C.S.I., has been elected President of the Royal College of Surgeons, Ireland.

CULLINAN, PATRICK M., M.B., T.C. Dub., has been appointed Justice of the Peace for the County of Clare.

EARLE, EDWARD S., F.R.C.S. Eng., has been elected Honorary Surgeon to the Western General Dispensary.

GANDY, W., M.R.C.S. Eng., has been appointed House-Physician to the Westminster Hospital.

HORRIDGE, A. C., M.R.C.S. Eng., has been appointed House-Surgeon to the Westminster Hospital.

MOORE, WILLIAM W., M.D. Edin., has been elected one of the Honorary Physicians to the Brighton and Hove Dispensary.

MURRAY, GUSTAVUS C. P., M.D. Edin., has been elected Physician-Accoucheur to the Great Northern Hospital.

MURRAY, WILLIAM, M.D. Durham, has been appointed Physician to the Dispensary, Newcastle-on-Tyne.

PARKER, W., L.F.P.S. Glasg., has been appointed Medical Officer of Health for Bermondsey.

SMYLY, JOSIAH, F.R.C.S.I., has been elected Vice-President of the Royal College of Surgeons of Ireland.

SWALLOW, JAMES DODD, M.D. Univ. St. And., has been appointed Surgeon to the Royal South London Dispensary.

THOMAS, L., L.R.C.P.L., has been elected Assistant Medical Superintendent of the Devon County Lunatic Asylum, Axminster.

WATERS, WILLIAM, L.K.Q.C.P.I., has been elected Medical Officer to the Carbury Dispensary.

WILLIAMS, WILLIAM W., M.D. St. And., has been appointed Consulting Physician to the Gloucester County Lunatic Asylum.

#### DEATHS.

BARRY, WILLIAM, M.D., at 7, Burlington-street, Bath, on June 2, aged 80, late Deputy-Inspector-General of Hospitals.

BEERE, WILLIAM HENRY, M.R.C.S. Eng., at Banbury, Oxon, on May 21, aged 32.

BIGNELL, JOHN BEAVIS, M.D. St. And., at Barnstaple, Devon, on May 14, aged 77.

BURROWES, PHILIP, M.R.C.S. Eng., at 88, Gloucester-crescent, Hyde-park, on June 6, aged 47.

DALRYMPLE, ARCHIBALD, late of Norwich, on May 28, aged 53.

DYKE, GEORGE W., M.D. Edin., at Chippenham, Wilts, on May 27.

FOX, THOMAS JAMES, L.R.C.S.I., at Cottage-park, Kilgobbin, County Dublin, on June 2.

HUNT, ROBERT, M.R.C.S. Eng., at Terrington St. Clement's, King's Lynn, on May 28, aged 53.

KINGDOM, EDWARD W. C., M.D. Edin., at North Fort, Liverpool, on May 6, Staff Surgeon Army.

WHITE, Dr. T. A., at Galway, Ireland, on May 27.

THE LEVÉE.—The following presentations to the Prince of Wales, on behalf of the Queen, took place at St. James's, on Monday, the 8th inst., the names having been previously left at the Lord Chamberlain's Office, and submitted for her Majesty's approval, viz.:—Staff-Surgeon P. J. Clarke, by the Adjutant-General; Assistant-Surgeon M. W. Cowan, M.D., by Major-General A. B. Stransham; Dr. S. J. Goodfellow, by Lord Leigh; Assistant-Surgeon Dr. Hodgson, by Colonel C. Bingham; Dr. E. Lankester, Coroner for Middlesex, by the Right Hon. C. P. Villiers, M.P.; Deputy Inspector-General of Hospitals J. Lovell, by Sir C. Wood; Inspector-General Dr. Macpherson, on appointment of Honorary Physician to Her Majesty, by Sir C. Wood; Staff Assistant-Surgeon E. L. McSheehy, by the Adjutant-General; Dr. George Moore, R.N., by the Duke of Somerset; Surgeon G. Pain, on re-appointment to the Royal Artillery, by Colonel C. Bingham; Assistant-Surgeon T. Tarrant, M.D., by Colonel C. Bingham. The following gentlemen attended the Levée, viz.:—Doctors Minter, F.R.C.S.; James McCann; —McCann; Edward Smith, F.R.S.; and Royston Piggott. Messieurs G. B. Childs, F.R.C.S.; John Simon,

F.R.S.; Howel Morgan, F.R.C.S.; and Haynes Walton, F.R.C.S.

**THE HEALTH OF THE KING OF PRUSSIA.**—The King of Prussia has been ordered by his Physicians, Messrs. Grimm, Böger, and Lauer, to Carlsbad, to take a course of the waters there. He is said to be suffering from renal calculus.

**THE CAMEL IN EUROPE.**—The directors of the Garden of Acclimatization, in the Bois de Boulogne, have admitted camels among the animals to which they have directed their attention. Two of these animals are to be seen there at this moment, of the species called *Camelus Bactrianus*.

**CAMBRIDGE UNIVERSITY.**—The fees for the degree of Master in Surgery have been fixed as follows:—For those who have not taken any degree previously, £18; for those who have taken the degree of B.A. or M.B., £12; for those who have taken the degree of B.A. and M.B., £6; for those who have taken the degree of M.A., £1.

**ENFORCING VACCINATION.**—There is before the House of Commons a Government Bill extending only to Scotland, proposing that after February next a schoolmaster or schoolmistress shall be liable to a penalty for receiving into a school a child under fourteen without a Medical certificate of its having been vaccinated. There is to be a penalty also upon any one who shall receive into his or her employment or service a young person under eighteen without such a certificate. Every prisoner and every person admitted to parochial relief is to be vaccinated as soon as possible after admission to such relief or imprisonment, unless the Surgeon is satisfied that such person has been vaccinated or has had small-pox.

**ROYAL COLLEGE OF SURGEONS.**—The readers of this Journal will be surprised to learn that, notwithstanding the number and importance of the subjects for collegial prizes annually offered by the Council of the College of Surgeons for competition among its members, that few, if any, attempt to carry them off; no award has yet been made for the subjects of the past year, and now there are the six following prizes open for the present and ensuing year, viz:—The Collegial Triennial Anatomical Prize of Fifty Guineas. The subject of this prize is: "The Structural Anatomy and Physiology of the Lymphatic Vessels and Glands (the anatomical distribution not being required); the communications (if any) between the Lymphatics and the Blood-vessels to be demonstrated; and the influence (if any) which the Lymphatic Vessels or Glands exercise on the fluid they transmit to be elucidated. The dissertation to be illustrated by preparations and drawings." There are two Jacksonian Prizes of Twenty Guineas for the present year, 1863, the subjects of which are: "The Pathology and Treatment of Diseases of the Larynx; the diagnostic indications to include the appearances as seen in the living person. The dissertation to be illustrated by drawings and preparations;" and "The Normal and Pathological Anatomy of the various Synovial Bursæ connected with the Muscles and Tendons of the Upper Extremity, and the treatment of their Diseases. The dissertation to be illustrated by preparations and drawings." There are also three subjects for prizes for the ensuing year, 1864, namely: "Club Foot; its Causes, Pathology, and Treatment." "The Diseases of the Ankle-joint, and of the Joints and Bones of the Tarsus, requiring Surgical Treatment; and stating the Treatment, including Operative, most suitable in each case, with the results thereof;" and "The Malformation, Diseases, and Injuries of the Fingers and Toes, with their Surgical Treatment. The dissertation to be illustrated by preparations and drawings."

**THE NATIONAL MEDICAL REGISTRATION ASSOCIATION.**—This Association, it will be remembered, was established by some leading members of the Profession immediately after the passing of the Medical Act in 1858, to secure, as far as possible, the efficient operation of these clauses which it was expected would confer so much benefit upon the public and Profession, by affording them protection against the unqualified and dishonest pretender. That this Association has rendered the Profession important services there can be no question, and if it has not attained to all that was hoped and expected, it has been due to the utter failure of a certain clause of the Act referred to, and the means at its disposal, rather than to a want of effort on its part. The activity of the Vigilance Committee, and the terror it excited in the minds of evildoers at that time, cannot be forgotten. Prosecution after prosecution was undertaken, and manfully fought to the death, nor did they desist until they had demonstrated but too clearly the worthlessness of the 40th clause in par-

teular. The Committee then memorialized the Medical Council to obtain from Parliament an amendment of this clause, but at present to no purpose. Until, however, this clause is altered, the Association, as a prosecuting body, is powerless. But we regret to learn that, owing to the members' subscriptions being very much in arrear, a debt of nearly 200*l.* properly incurred is pressing very heavily on the Committee, and that their respected treasurer, J. Lavies, Esq., is really subject to personal annoyance on account of it. This ought not to be, and we wish to call the attention of all our readers to the fact. All members of the Association are beyond doubt legally liable for the debts of their Committee. There is, however, a higher feeling, and one that we feel sure will actuate them and the Profession generally, and they will feel in honour bound to protect the pockets of those who have so generously bestowed their time and energies, as well as their money, in this service. Some members of the original Committee have determined to relieve their treasurer of the annoyance to which he is subject, and at a meeting held on Monday evening the following subscriptions were announced:—William Fergusson, Esq., £2 2*s.*; Dr. George Webster, £2 2*s.*; John Erichsen, Esq., £2 2*s.*; John Propert, Esq., £2 2*s.*; the proprietors of the *Lancet*, £5 5*s.*; Ernest Hart, Esq., £2 2*s.*; J. F. Clarke, Esq., £2 2*s.*; Dr. E. Kirby, Esq., £2 2*s.*; Dr. Hillier, £1 1*s.*; Jabez Hogg, Esq., £2 2*s.*; Dr. H. G. Wright, £2 2*s.*; Dr. Bradford, £2 2*s.*; William Adams, Esq., £2 2*s.*; N. H. Clifton, Esq., £2 2*s.*; Dr. Thane, £1 10*s.*; W. A. N. Cattlin, Esq., £2 2*s.*; Dr. J. B. Williams, £2 2*s.*; Sir J. Ranald Martin, K.C.B., £2 2*s.*; Dr. Theodore E. Ladd, £2 2*s.*; Dr. G. Pearse, £2 2*s.*; Charles Tunaley, Esq., £2 2*s.*; Dr. Thomas Ansell, £2 2*s.*; J. Mann, Esq., Charter House, £1 1*s.*; Dr. Grasmann, 10*s.* 6*d.*; Dr. Hensley, 5*s.*

ON Saturday, the 20th, a short paper will be read by Dr. Druitt before the Metropolitan Association of Medical Officers of Health, at their evening meeting, at 8, Richmond-terrace, Whitehall, S.W., at half-past Seven; Subject: "Impediments to Successful Vaccination." The attendance of vaccinators is desired.

**DESGENELTES.**—Some amusing anecdotes are told in the *Union Médicale* of this celebrated Army-Surgeon while officiating as Examiner at the Faculty. He was the very providence of the weak and feeble. His questions were of interminable length, and when the candidate sometimes attempted to put in a few words, he would exclaim, "Now, silence, will you! Your interruption is neither polite or politic. It is not polite, for no man should be interrupted while speaking; and it is not politic, for while I am talking you are committing no errors, and the time is running out." An affirmative vote was the inevitable result of these interrogatories. On one occasion, however, he had to examine Kerrouman, a famous pharmacien of encyclopædial knowledge and lively wit, who wished to become a Doctor. Broussais first examined him, and the replies were solid and brilliant. When Desgeneltes' turn came, he said, "I have to examine you in Hygiene, which embraces Medical Police. You may be called upon to exercise municipal functions, as I have been (Desgeneltes was mayor of his *arrondissement*), and you ought to be acquainted with the laws and regulations which govern Medical Police. Now, what would you do supposing, as happened to me yesterday, you arrived home at ten o'clock at night, and found a man easing himself at your door?" Those present burst out laughing, and Broussais touched his elbow, as if to say, do now be more serious. Kerrouman, swift as an arrow, and with indescribable irony, replied, "Sir, the case you put would appear to me of so serious a nature that I should call you into consultation." Again bursts of laughter followed; but, strange to say, Desgeneltes, who usually so keenly relished a witty reply, became much ruffled, and voted against the candidate. The matter, without the interference of Broussais, would have been brought before the Council of the Faculty.

## BOOKS RECEIVED.

- Outlines of Surgery. By F. Le Gros Clark, F.R.C.S. London: John Churchill and Sons. 1863.  
The Nullity of Metaphysics as a Science among the Sciences. London: Longman and Co. 1863.  
The Connection between Tuberculosis and Insanity. By T. S. Clouston, M.D. 1863.  
The American Journal of the Medical Sciences, April, 1863. Philadelphia: Blanchard and Lea.

## NOTES, QUERIES, AND REPLIES.

*He that questioneth much shall learn much.—Bacon.*

In consequence of the publication in this Journal of a *verbatim* copy of the Minutes of the General Council of Medical Education and Registration, we were compelled to omit last week all Reviews of Books, and in our present Number the Hospital Reports.

*M.R.C.S.*—We believe not.

*M.R.C.S.E., Ramsgate*—Such an advertisement is, as our correspondent says, "most unprofessional." The offender would be best dealt with by the local Medico-Ethical Association.

*Mr. Wyld's Map of Africa*, showing the source of the Nile, should be consulted by all who desire to know the facts of that great discovery.

*Pray don't pump upon this fellow!*—If any one heard this said in a public row he would know what it meant. Equally do we know what is meant by those disgusting advertisements in the American newspapers, cautioning women against using such and such a quack pill when pregnant, "lest they might bring on miscarriage."

*Dudley*.—If a representation were made to Dr. F. Hawkins, Secretary to the Medical Council, showing that an M.D., L.R.C.P. and S. of Glasgow, and L.M., circulated handbills like those of the meanest tradesman, promising all sorts of impossible cures, and puffing a secret remedy and system of treatment, the Council must take some notice of the matter.

*Public Vaccinators* are placed in an awkward position. They must keep up their stock of lymph by keeping up a weekly roll of vaccine patients, and they are bound to promote vaccination generally. Whatever may be the duties which a gentleman has to perform, he will always perform them as a gentleman. He may send and warn small tradespeople of the necessity of vaccination, and yet neither in form nor substance be a mere "toutter," or interfere with the practice of other Medical men.

*Inoculation*.—The following appeared in the *Oxford Journal* of February 3, 1758; we copy the same, *verbatim et literatim*, for the edification of our readers:—

"I George Ridler near Stroud in the County of Gloucester Brand cloth Waver at the desire of people hereabout do gee nautis that I have inockilated these two zeazons past between two and dree hundred vor the smeal pox and but two or dree of um died—A many people be av-card o the theng but evaith tis no more than scratten a bit of a haul in their yarm and pushing in a piece of scraped rag diped in some of the pocky matter of a child under the distemper—That everybody in the nashion may be sarved I wool God willing undertake to inockilate them with the peviser they wool teak two purges before hand and louze a leetle blood away vor half a crown a yeard; and I will be bould to say noo body goes beyond me. N.B.—Poor volk at a shilling a yeard but all must pay vor the purging."

## THE MYOSITIC ACTION OF THE CALABAR BEAN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In reference to a letter from Dr. Thomas R. Fraser, inserted in the *Medical Times and Gazette* of this date, I desire to state that I do not claim, and have never, either directly or indirectly, claimed, the credit of having discovered the property possessed by the Calabar bean of contracting the pupil; on the contrary, I have from the first acknowledged that that discovery was Dr. Fraser's. What I have done is, to examine carefully all the effects produced by this agent on the eye, and to point out its importance and some of its practical applications. I am, &c.

4, Maitland-street, Edinburgh, June 6.

D. ARGYLL ROBERTSON.

## THE CASE OF SIR CULLING EARDLEY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The Profession is indebted to Dr. Evans for detailing the symptoms and progress of the late Sir Culling Eardley's case. The obligation would be much increased if he could publish the history of the vaccine-lymph that was used, giving its source, time and mode of keeping, together with the manner of performing the operation, whether by scarification or lancet; if by the latter, was the same instrument used as for any other member of the household. Without this knowledge, the experiment, as regards the important question of re-vaccination, is a "blind" one. As many Practitioners of great experience object to re-vaccination, it is desirable that every case attended with untoward symptoms should be fully investigated. If the able Practitioners who were called to treat this unfortunate case would give us their several or joint opinion as to the cause, whether accidental or constitutional, of the fatal complication, it would be of lasting value to the Profession.

I have heard of severe inflammation after re-vaccination being attributed to the poisonous action of the colouring matter used to dye a black stuff dress. It is worth while to bear this in mind, as a possible source of cutaneous poisoning, at the present day, when under-clothing is worn of the most decided and often brilliant colours. I am, &c.

3, Finsbury-square, E.C., June 8. SEPTIMUS GIBBON, M.B. Cantab.

## A BREAST-TOURNIQUET AND A CATARACT KNIFE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you kindly permit me to bring under the notice of the Profession two Surgical Instruments which may possibly prove useful?

(1.) A tourniquet for controlling hæmorrhage in the removal of tumours of the breast. This consists in a stout steel ring (of variable size), with an upright at the two opposite ends of one of its diameters. To the top of each upright a strap is attached. The edge of the ring, compressing the tissues between it and the wall of the thorax by the pressure of the straps which buckle round the chest, controls the surrounding circulation.

(2.) A knife for making the section of the cornea in cataract operations with one single puncture. This instrument is nothing but an enlarged triangular revatome, such as is used in the operation of iridectomy, but

is intended to avoid the necessity of two punctures in making the corneal flap.

On the advantages of either instrument (a) I am not yet in a position to speak from experience, but in the meantime should be glad to hear that other Practitioners had tried them, and with what results.

I am, &amp;c.

## APPOINTMENTS FOR THE WEEK.

June 13. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m.; Charing-cross, 1 p.m.; Lock Hospital, Dean-street, Soho, 1 p.m. Royal Free Hospital, 1½ p.m.

15. Monday.

Operations at the Metropolitan Free Hospital, 2 p.m.; St. Mark's Hospital, 1¼ p.m.; Samaritan Hospital, 2½ p.m.

16. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m. ETHNOLOGICAL SOCIETY, 8 p.m. John Crawford, Esq., "On the so-called Celtic Languages and Races."

17. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m. Middlesex, 1 p.m.

18. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2 p.m.; Surgical Home, 2 p.m.; Royal Orthopædic Hospital, 2 p.m.; Royal Free Hospital, 1½ p.m.

19. Friday.

Operations, Westminster Ophthalmic, 1¼ p.m.

(a) They may be had of Mr. Coxeter, of Grafton-street.

ORIGINAL LECTURES.

PROFESSOR HUXLEY'S LECTURES

AT THE

ROYAL COLLEGE OF SURGEONS.

THE LECTURES ON THE VERTEBRATE SKULL.

(Continued from page 610.)

In like manner, the face may be resolved into a series of bones, occurring in pairs from before backwards, and forming more or less well-defined lower arches, some of which embrace the nasal cavity, being placed in front of, or above, the oral aperture, while others enclose the buccal chamber, and are situated behind and below the oral aperture. Of the former, *pre-oral* bones, there are four pairs—the *premaxillæ* (*Pmx.*), the *maxillæ* (*Max.*), the *palatines* (*Pl.*), and the *pterygoids* (*Pt.*)

The *premaxillary* bones, which lodge the upper incisor teeth, so early lose their distinctness in man, by becoming ankylosed with the maxillary bones, at any rate externally and anteriorly, that they are rarely recognised as distinct parts. Nevertheless, a suture extending upon the bony palate from the posterior margin of the alveolus of the outer incisors to the incisive foramen, very commonly persists, as an indication of the primitive distinctness of these bones. The most important character of the premaxillæ, regarded morphologically, is, that they are connected, superiorly, with the anterior termination of the cranio-facial axis, and that this connexion is a primary one. Each premaxilla passes from its inner end, which is united with the axis, outwards and backwards. Two of the other three pair of pre-oral bones have similar relations to the cranio-facial axis. The anterior of these are the *Palatine* bones; the inner, or sphenoidal, processes of which are connected with the basi-sphenoid and with the vomer; while the outer, or orbital, processes articulate with the so-called lateral masses of the ethmoid and with the maxilla; so that the upper part of each palatine bone is directed, from the cranio-facial axis, with which its inner end is connected, outwards and forwards (Fig. 8). The third pair of bones, the *Pterygoids*, are the internal pterygoid processes,—bones which are originally quite distinct from the sphenoid, while the external pterygoid processes are of a very different character, being mere outgrowths of the alisphenoids. These are connected with the basi-sphenoid (or rather with the *lingule sphenoidales*), above, and, in front, with the palatines, while their planes are directed backwards and somewhat outwards. The fourth pair of pre-oral bones—the *Maxillæ*—are connected in front and internally with the premaxillæ, and behind and internally with the palatines, but they nowhere come into direct contact with the cranio-facial axis, at least primarily.

I make the latter qualification because the vomer articulates with the superior surface of the palatine plates of the maxillæ, and it may be said that, in this way, the maxillæ do unite with the cranio-facial axis. This articulation, however, has nothing to do with the primitive connexions of the bones, but depends upon a modification of the maxillæ peculiar to the higher vertebrata. The bony apertures—called “posterior nares”—in Man, for example, are structures of a totally different character from, and superadded to, what are called the posterior nares in a frog, or ordinary lizard, or bird. In these lower vertebrates, the posterior nares are apertures, bounded on the inner side, by the vomer, on the outer side and behind, by the palatine bones, in front, by the premaxillæ and maxillæ. In Man, on the other hand, the apertures so called are bounded, it is true, on the inner side by the vomer, and on the outer side by the palatine bones; but they are also bounded below and in front by the palatine bones, and the premaxillæ and maxillæ have nothing to do with them. On looking closely into the matter, however, it will be found that that region of the palatine which forms the outer and inferior boundary of the posterior nares of Man is a something which has no representative in the lower vertebrate.

But if, with a fine saw, the greater part of the perpendicular plate of the palatines, and the corresponding part of the maxillaries, and, with these, their palatine plates, be cut away, leaving only the premaxillæ, vomer, and upper parts of the maxillary and palatine bones; it will be found that hinder

nares are left, which entirely correspond with the “posterior nares” of a bird or of an amphibian; that is to say, they are passages between the vomer in the middle line, the premaxillæ and maxillæ in front and externally, and the palatines externally and behind.

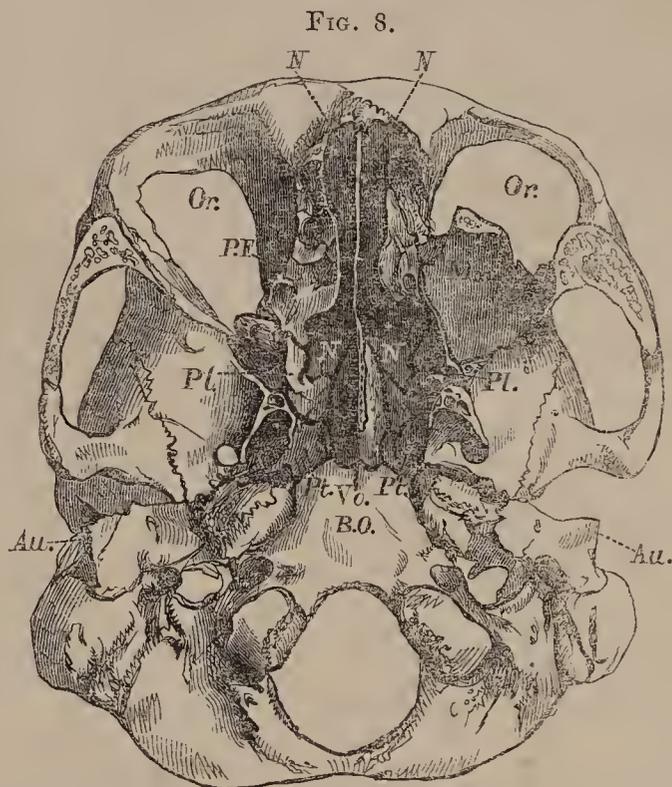

FIG. 8.—The base of a human skull—the nasal, ethmoid, vomerine, maxillary, palatine, and pterygoid bones being cut through horizontally, and their lower portions removed. The entire right maxilla is taken away. The posterior pair of letters, *N N*, are situated in the median nares, which are incomplete in front in consequence of the removal of the premaxillæ.

In fact, the apertures of the nasal chamber into the mouth, thus artificially exposed, are those which originally exist in Man and the higher *Vertebrata*; but the downward growth of the maxilla into its alveolar process, and of the palatine bone into its perpendicular plate, and the production inwards of the palatine plates of these bones, which eventually unite with the vomer, give rise to the apertures, which are ordinarily called posterior nares. So that in Man, for example, there are three pairs of “nares:”—the *external*, situated between the anterior end of the internasal septum, the nasal bones, and the premaxillæ, as in the lower vertebrates; the *median*, between the vomer, the palatines, and the premaxillæ, which correspond with the posterior nares of the lower vertebrates; and the *posterior*, between the vomer, internally, and the palatines above, at the sides, and below, which are peculiar to the higher vertebrates.

And, to return to the maxilla, we find that it really differs altogether from the other pre-oral bones, and is, as it were, fastened on to the outer sides of the premaxillary and palatine bones, without having any primary direct connexion with the cranio-facial axis.

The *post oral* bones surround the buccal cavity, and form two distinct arches—the *mandibular* and the *hyoidean*. Neither of these arches is directly connected with the cranio-facial axis, nor with the segments of the brain-case, but both are suspended to different parts of the temporal bone, which is so singularly intercalated between the middle and posterior of those segments.

The *mandible* (*Mn*) consists of two rami, ankylosed at the symphysis, and each consisting of a single piece, the condyle of which articulates with the squamosal.

The *hyoid* bone (*Hy*), composed of its body and two pairs of cornua, does not articulate directly with the temporal bone, but a ligament connects it with the styloid process, and this last bone unites with the posterior part of the petiotic capsule.

Thus, the natural connexions of the bones by no means allow of the separation of the walls of the lower chambers of the skull into a series of arches springing from, and corresponding with, the axial parts, as we found to be the case with the walls of the upper chambers.

If the temporal bone be detached, the hyoidean and mandibular arches come with it, and exhibit no connexion with the occipital or the parietal segments. Indeed, the latter is

pre-occupied by the pterygoid and the palatine, both of which are connected with the basi-sphenoid (at least with the *lingula*), while the anterior part of the palatine is also connected, in the adult state, with the presphenoid, by the inter-mediation of the *cornua sphenoidalia*.

Two bones yet remain to be mentioned which come neither into the category of axial bones, nor of superior or inferior arch bones, nor, strictly speaking, of sense-capsule bones. These are the *Lachrymal (L)*, intercalated between the nasal, maxillary, and lateral mass of the ethmoid, and serving to lodge the conduit which places the orbit and the nasal cavity in communication; and the *Jugal or Malar (Ju)*, which connects the bones of the orbital chamber with the squamosal element of the temporal bone.

The skull thus composed serves as a protection to the organs which are lodged within it, and which are of as great importance in their morphological, as in their physiological, aspect.

The cerebral hemispheres and cerebellum, with their dependent parts, fill the cranial cavity, the lower lateral margin of the posterior cerebral lobes corresponding with the *torcular Herophili* and the lateral sinuses, on the inner surface of the occipital bone; or, in other words, with the line of attachment of the tentorium. Certain axial parts of the brain have definite relations to the axial parts of the cranium. Thus, the medulla oblongata lies upon the basi-occipital. The pituitary body rests upon the upper surface of the basi-sphenoid, this bone constituting the chief part of the front as well as of the hinder wall of the *sella turcica*. The *chiasma* of the optic nerves rests upon the hinder portion of the upper face of the presphenoid, and the peduncles of the olfactory nerves upon the front portion of that face. The termination of the axial parts of the brain in the beak of the corpus callosum corresponds with the termination of the basi-cranial axis in the anterior extremity of the presphenoid.

Not less important are the relations of many of the cerebral nerves to the lateral elements of the arches of the brain-case.

The filaments of the olfactory nerves pass out through the cribriform plates, leaving the ethmoid proper, or *lamina perpendicularis*, upon their inner side, and the lateral masses of the ethmoid, or superior and middle spongy bones, upon their outer sides.

The optic nerves pass out through the optic foramina, situated between the roots of the orbito-sphenoids, from the *chiasma*, which rests, as has just been stated, upon the posterior and upper part of the presphenoid. Hence it follows that the presphenoid lies in front of, and between, the optic nerves, which embrace it, as in a fork, from behind.

The third and fourth pairs are not of so much morphological importance that I need dwell upon them, but the trigeminal affords first-rate cranial landmarks by its nasal branch and its whole third division. The nasal nerve enters the orbit by the *foramen lacerum anterius*, passes to the inner side of the eye, and then, traversing the anterior of the two ethmoidal foramina, perforates the "lateral mass of the ethmoid," and entering the cavity of the bony cranium, though it always lies beneath the dura mater, skirts the olfactory aperture, and passes out into the nasal cavity, by an aperture in the front part of the cribriform plate. We shall find this irregular perforation of the "lateral mass of the ethmoid," by the nasal division of the fifth nerve, to be an excellent guide to the determination of the homologue of the bone in the lower *Vertebrata*.

The third division of the trigeminal traverses the *foramen ovale* in the posterior part of the ali-sphenoid, so that it makes its exit behind the greater part of that bone, and altogether in front of the periotic bones.

The *portio dura* enters the internal auditory foramen in the periotic mass, runs along its canal, situated above the *fenestra ovalis*, and eventually passes out by the stylo-mastoid foramen. It therefore perforates the fore part of the periotic capsule, passing in front of the membranous labyrinth. The *portio mollis* also entering the periotic mass, by the internal auditory foramen, terminates in the membranous labyrinth.

The eighth pair passes out through the *foramen lacerum posterius* completely behind the periotic capsule (which thus lies between the exits of the fifth and of the eighth pairs), and in front of the exoccipitals.

The ninth pair perforates the exoccipitals in front of the condyles.

With regard to the relations of the nerves to the inferior arches of the skull, only one circumstance calls for particular notice,—this is the distribution of the terminal divisions of

the *portio dura*. This nerve divides, as it is about to leave the temporal bone, into two portions, the larger of which passes out by the stylo-mastoid foramen, and, besides giving off many other branches, supplies certain muscles of the hyoidean apparatus.

The smaller division of the nerve, of comparatively insignificant size—the *chorda tympani*—returns to the tympanic cavity, crosses it, and leaving it by an aperture internal to, and above the tympanic element, runs down upon the inner side of the lower jaw. In Man the great development of the facial muscles gives a predominance to the branches of the *portio dura* which supply them; but in the lower vertebrates the nerve becomes more and more completely represented by simple mandibular and hyoidean divisions, corresponding respectively with the *chorda tympani* and the branches distributed to the stylo-hyoid and digastric.

In the preceding description of the architecture of the human skull, I have, as far as possible, avoided complicating the general view of its structure which I have desired to give, by entering into any details which were not strictly necessary; but there remains one part of the cranium—the temporal bone—the structure of which must be carefully and thoroughly investigated, if we desire to understand the modifications undergone by the bones which correspond with its constituent elements in other *Vertebrata*.

FIG. 9.

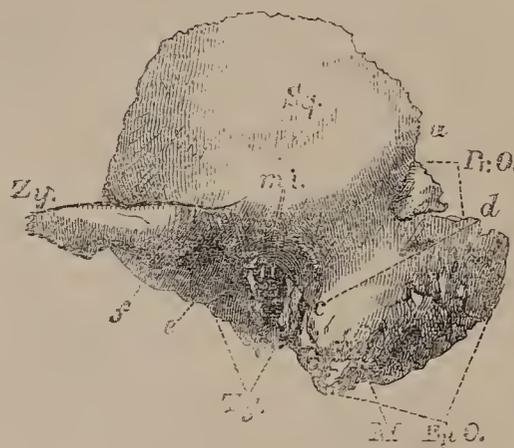

FIG. 9.—Left temporal bone, half n.s. *a b*, posterior root of the zygomatic process; *e*, middle root; *f*, anterior root; *b*, post-auricular fossa; *m i.*, long processes of the malleus and of the incus.

Viewed from without, the temporal bone presents the well-known *pars squamosa (Sq.)* and *pars mastoidea (M.)*, in the re-entering angle between which, the tympanic element (*Ty.*) is fixed.

No suture separates the *pars squamosa* from the *pars mastoidea*, but the posterior limits of the former are indicated, in the first place, by the curved ascending portion of the posterior root of the zygoma (*a b*), which bounds the attachment of the temporal muscle; and secondly, by a curved ridge, convex backwards, differently defined in different subjects, the *margo tympanicus* of Henle, which passes downwards, behind the auditory meatus, until it cuts the contour of the tympanic bone. Near the upper end of this ridge is an elongated "post-auricular fossa" (*b*), more marked in old than in young subjects.

The portion of the squamosal element, the free edge of which terminates in this ridge, forms an arch, the posterior pillar of which constitutes the posterior and upper wall of the auditory meatus, while the anterior pillar constitutes the front boundary of the glenoid cavity. The centre of the arch is interrupted by the middle root of the zygoma (*e*), or post-glenoidal process of the squamosal, which runs as a wedge-shaped ridge transversely to the span of the arch.

The upper edge of the anterior wall of the gutter-shaped tympanic bone (which forms the hinder boundary of the glenoid cavity), unites with this ridge, crossing its direction obliquely inwards and forwards. Beyond the ridge it is no longer united with the squamosal, but, keeping its oblique direction, crosses rather to the inner side of the lower edge of that bone, and leaves the Glaserian fissure between the squamosal and itself.

A section taken through both the external and the internal auditory meatuses (Fig. 10) shows that this arched plate of the squamosal is interposed between the upper half of the tympanic and the upper parts of the *pars petr. sa* and *pars*

*mastoidea*, the depth of the interposed squamosal being greatest posteriorly, while it diminishes to nothing anteriorly.

The upper region of the *pars petrosa*, however, does not directly abut, by its thick mass, against the squamosal, but by a thin horizontal plate which roofs over the tympanum, the Eustachian tube, and the *antrum mastoideum*, and is the *tegmen tympani*.

The lower region of the *pars petrosa* in like manner gives off a thicker and shorter plate, which forms the floor of the Eustachian tube and the outer or inferior boundary of the carotid canal, in front; the floor of the tympanum, in the middle; and then, becoming gradually thicker, constitutes the lower boundary of the *antrum mastoideum*. It is with the outer edge of this inferior, or floor-plate of the tympanum that the lower portion of tympanic bone becomes ankylosed. The inner wall is of course constituted by the outer surface of the more massive part of the *pars petrosa*. Thus, the roof and floor of the tympanum are formed by the superior and inferior prolongations of the *pars petrosa*, while the outer wall of the tympanum is formed above by the squamosal, and below by the tympanic. A section taken vertically and transversely

bony elements, and we shall by-and-by see reason to believe that it is even more complex still, inasmuch as the so-called *pars petrosa* will prove to be composed of two distinct elements, an inferior *opisthotic* bone, containing the lower part of the cochlea, and a superior *pro-otic* sheltering the greater part of the vestibule, the upper part of the cochlea, the anterior vertical semicircular canal, part of the posterior vertical canal, and the external semicircular canal.

Behind the posterior boundary of the squamosal, constituted by the two diverging lines above described, lies all that portion of the temporal bone which is known as the *pars mastoidea*. But as I shall have occasion to demonstrate when explaining the mode of development of the temporal bone, this *pars mastoidea* is, in reality, made up of extensions of two of the primitive constituents of the *pars petrosa*, and of a third element, the *epiotic*. The posterior margin of the squamosal, as above described, may be said roughly to form two sides of a parallelogram. The third side is the thick part of the upper edge of the *pars mastoidea*, corresponding with the termination of the upper and anterior surface of the *pars petrosa* on the inner side of the bone. If a fourth side is made by an imaginary line connecting the ends of the others, the bony surface which lies above and in front of the line will as nearly as possible belong to the *pro-otic* element, while that which lies below and behind it, including the mastoid process, belongs to the *epiotic*. On the other hand, a certain amount of the *pars mastoidea* internal to the digastric groove belongs to the *opisthotic*.

Fig. 10.

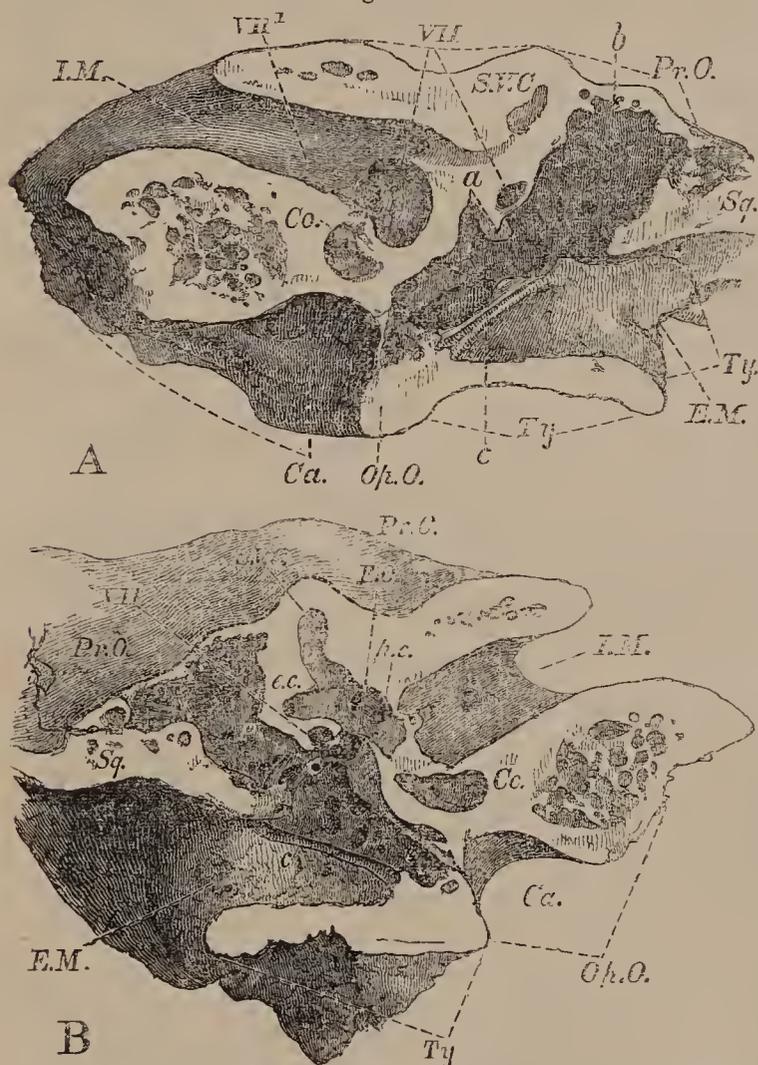

FIG. 10.—Views of the petrous and tympanic portions of a right temporal bone of the skull represented in Figs. 2 and 3, magnified two diameters. A, the anterior half of the bone; B, its posterior half; I.M., internal meatus; E.M., external meatus; a, processus cochleariformis; b, chamber in which the heads of the malleus and incus lie; c, groove for the tympanic membrane; S.V.C., superior vertical semicircular canal; e.c., external semicircular canal; p.c., posterior vertical semicircular canal; Co, cochlea; P, pyramid; F.O., fenestra ovalis; VII, canal for portio dura; VII<sup>1</sup>, for portio mollis.

to the axis of the skull through the middle of the *fenestra ovalis*, in the way described above, shows that the squamosal bounds, externally, an upper chamber of the tympanum, which is nearly as deep as, and is wider than, the lower division, bounded externally by the tympanic membrane (Fig. 10). It is in this upper chamber that the heads of the malleus and incus are lodged, the handle of the one and the long process of the other, only, depending into the proper tympanic cavity. Hence, in looking into the tympanum from without (Fig. 9) when the ear-bones are *in situ*, only these processes are seen, the heads of both malleus and incus being hidden by the arched plate of the squamosal. Thus, the tympanum is formed by a very complicated adjustment of

ORIGINAL COMMUNICATIONS.

AN ACCOUNT OF THE  
PHYSIOLOGICAL RESEARCHES OF  
THE REV. PROFESSOR HAUGHTON, M.D.,  
TRINITY COLLEGE, DUBLIN.

(Continued from page 396.)

DIABETES MELLITUS.

No disease can offer a more spacious field for the exercise of scientific ingenuity than Diabetes Mellitus. Slowly and at long intervals have the leading points in its chemical history been arrived at, and, till the most recent times, its pathology threatened to keep itself a secret. Aretæus, the Cappadocian, included dropsy of various kinds under the title of diabetes, which he gave to the class of diseases in which diuresis was a prominent symptom, either constant or occasional. It was for Dr. Thomas Willis, of Christchurch, Oxford, to discover that diabetic urine "quasi melle aut saccharo imbuta, miro dulcescebat." Cowley, in 1778, isolated the saccharine principle. The sugar having been now discovered to be present in the urine of these patients, the question of its origin came to be discussed, and may be said to be even at the present moment *sub judice*. Till the time of Mead, Physician to George the Second, the kidneys were regarded as the seat of the disease, and their altered condition was viewed as the anatomical expression of the phenomena, but his dissections led him to suspect the liver was the organ at fault. Rollo and Macgregor found out that sugar was formed in the stomach, and considered it to be due to imperfect digestion, as it was not then known that the saccharisation of starch was the natural and physiological action of saliva.

An important advance in the history of diabetes was made by Sir Robert Kane in 1832; he controverted the erroneous idea that the sugar was formed at the expense of urea, by publishing cases to prove that the urea and sugar in this disease were not complementary.

Bernard's discovery (1848) and isolation (1857) of the glycogenic matter of the liver, a substance allied to sugar, reconvertible into sugar, and a product of the sugar and starch used as food, gave birth to his theory of diabetes mellitus, that either sugar was excessively formed in the liver, or there was a defective destruction of it in the lungs. Pavy considers that there is a defective assimilation of sugar in the liver, that the product of the starch and sugar of the food instead of being converted into amyloid substance in the liver, is allowed to filter through, and enter the circulation unchanged.

Notwithstanding these advances in our knowledge of the disease, there are many points connected with it buried in the

deepest obscurity. It has been often remarked in the treatment of diabetes, that no matter how strictly the patient has been confined to an animal diet, no matter how scrupulously sugar-producing food has been excluded from his "carte," still evidences of saccharine impregnation were found in the urine. It is known that the blood of the lower cava between the liver and heart contains sugar in animals which have been exclusively fed on flesh food; its existence under these circumstances led to the enunciation of the glycogenic function of the liver, though there are supporters of the view that it is from the flesh of the vegetable feeders on which the carnivora live that the sugar is derived. Analysis of the urine made by Brücke, and confirmed by Dr. Bence Jones, have led them to believe that sugar is a constituent of healthy urine.

However, his own investigations have led the Rev. Prof. Haughton to consider that sugar does not normally occur in healthy urine,—a result which has been confirmed by experiments made by Professor Jellett, with his new and highly sensitive saccharometer. Professor Haughton specially studied six out of several cases of diabetes mellitus—four of these are tabularly stated below—with regard to the ingestion and excretion of sugar and urea. The food used by these patients was accurately estimated in sugar and urea equivalents, and great care was taken to avoid any irregularities of diet. The quantity of glucose sugar producible from the various kinds of food used was thus estimated:—

*Brown Wheaten Bread.*—1. According to Peligot's researches it appears that in whole wheaten meal, on the average, the proportion of proteinic to starch compounds is as 14 per cent. to 68 per cent. 2. The proteinic compounds are to urea as 3 to 1. 3. Starch will produce glucose in the proportion of 81 to 99.

From these data the subjoined chain follows:—

	1 lb. of brown bread.
1	267 grs. urea.
1	3 grs. proteinic compounds.
14	68 grs. starch.
81	99 grs. glucose.
	4755 grs. glucose.

Hence 2lbs. of this bread are equivalent to 9510 grains of glucose. The chain rule, which is admirably adapted for these calculations, may be stated as follows:—

1. Write down the term of demand, as head of the column of consequents; a little to the left, and in a line under it, write the term which is of the same kind, as head of the column of antecedents.

2. In the same line with this, and under the term of demand, write a second consequent, the quantity which is of equal value.

3. As second antecedent write down the quantity which is of the same kind as the second consequent; and as third consequent the quantity which is of equal value with second antecedent.

4. Proceed in this way, making each antecedent of the same kind as the last consequent, and each consequent of the same value as the last antecedent, until we arrive at the last consequent, which will be the odd term.

5. Divide the product of the consequents by the product of the antecedents.

The quotient is the value of the term of demand expressed as required.

For example, it is required to know what is the sugar equivalent of 1 lb. of rice. Rice, according to Boussingault, contains 83 portions of starch to 7.5 of azotised matter; 1 lb. of rice is known by experiment to be equivalent to 245 grains urea.

<i>Antecedents.</i>	<i>Consequents.</i>
	1 lb. rice (term of demand).
1 lb. rice.	= 245 grains of urea.
1 grain urea	= 3 grains azotised matter.
7.5 grains azotised matter or ( 75 ).	= 83 grains starch or ( 830 ).
81 grains starch	= 99 grains glucose.
	9942 grains glucose.

In this example, 1 lb. of rice, the term of demand, is made the first consequent, and the quantity which is of the same kind the first antecedent; this is followed by 245 grains of

urea as second consequent, because it is of the same value, and so on.

The product of the consequents divided by the product of the antecedents is the value of the term of demand expressed as required. Hence, 2 oz. of rice are equivalent to 1243 grains of glucose.

In this manner the sugar and urea ingested in the four cases here given were calculated and compared with the quantities excreted, the results being shown in the tables.

This scheme contrasts favourably with the elaborate table published by Dr. Pavy, of investigations on the excretion of sugar alone, conducted several times every day, and involving an amount of labour very inadequately repaid by the results arrived at.

(To be continued.)

## ON CHOREA: ITS RELATION TO VALVULAR DISEASE OF THE HEART, AND ITS TREATMENT.

By W. S. KIRKES, M.D.,  
Assistant-Physician and Lecturer on Medicine at St. Bartholomew's Hospital.

Few forms of disease are so distressing to witness, and so perplexing to treat, as those of aggravated chorea; not unfre-

quently, indeed, such cases terminate fatally. The circumstances under which these urgent forms of the disease occur are so various, that we need not feel surprised at there being no very decided rules for treatment laid down, even in the best standard works. The treatment of ordinary chorea is well enough defined, and, as is well known, the disorder, in this its simple form, usually disappears in time, be the direct treatment what it may—even if there be none at all. It is not in such forms of the disease, therefore, that anxiety is felt, and the skill of the Physician severely taxed, but in those violent and furious examples in which, but for speedy help, death from exhaustion seems inevitable. Ordinary chorea, as is well known, usually occurs in weakly, irritable children, in whom at the same time there is occasionally associated some temporary disorder, such as constipated bowels, worms, irregular dentition, the irritation connected with approaching puberty, and, later on, the evils of disordered menstruation.

Omitting, for the present, any further allusion to these occasional attendants on chorea, the influence of which has probably been much over-estimated, I wish specially to draw attention here to three other conditions with which chorea is not unfrequently associated,—namely, rheumatism, disease of the heart, and pregnancy.

1. It is now well known that chorea is one of the evils to which the subjects of acute rheumatism, or of the rheumatic diathesis, are liable. This association of disease has been observed much more frequently in this country and in France than in Germany, the pathologists of which latter country, indeed, are disposed to doubt its occurrence. (See, for example, Hasse, in Virchow's "Handbuch der Pathol. und Therapie." Bd. 4, p. 164.) Sometimes the chorea is developed during the progress, or towards the subsidence of the rheumatic attack; occasionally, though rarely, it precedes the development of the rheumatism; very frequently it occurs some weeks or even months after the rheumatic affection of the joints has disappeared. The nature of the relation between the two forms of disease has been the subject of much discussion. Formerly, when our knowledge about chorea was much more limited than it now is, the development of the choreic and other nervous phenomena in the course of rheumatism was attributed by some to simultaneous inflammatory mischief in the membranes of the brain or spinal chord, by others to sympathy of the nervous centres with coincident pericarditis. (a) But the fact since ascertained, that rheumatic chorea may occur and prove fatal without leaving any trace of inflammation about either the cerebro-spinal centres or the pericardium, shows that some other explanation is requisite. Dr. Begbie, who has written so well on the subject, advanced the opinion that the same diathesis or morbid condition of the blood which gives rise to rheumatism, may give rise also to chorea; the irregular muscular movements, as well as the affection of the joints and of the heart being, in his opinion, the results of the rheumatic diathesis. (*Monthly Journ. of Med.*, 1847; also his lately published "Contributions to Practical Medicine.") With this opinion the observations of Dr. Watson and Dr. Todd in the main agree. M. Sée also took the same general view, and even inclined to the belief that the rheumatic diathesis is the real cause of nearly all cases of chorea, whether any affection of the joints be established or not. He believed, however, that it is mainly through the medium of an inflammatory affection of some one or more of the serous membranes, especially the pericardium, that the rheumatic diathesis brings about the nervous affection. (*Mémoires de l'Acad. de Méd.* Paris, vol. xv., 1850.) Cases, however, not unfrequently occur, and prove fatal, without exhibiting any signs of serous inflammation; hence such explanation cannot always hold good. In a paper published in the *Medical Gazette* in 1850, I endeavoured to show that one of the most common attendants on fatal cases of chorea is an inflammatory affection of the cardiac valves, and that probably such valvular affection has an important share in the production of the nervous symptoms. Subsequent observation has confirmed me in that view, and I now believe that whenever chorea occurs in association with acute rheumatism, the valves of the left side of the heart are inflamed, and that therefore the association is not between chorea and rheumatism, as usually believed, but between chorea and valvular disease of the heart, excited by rheumatism. According to this view chorea occurs in rheumatism, not simply because of the rheumatism

itself, but because the rheumatism is so apt to excite endocarditis, on which I believe the chorea mainly to depend.

The principal grounds for this opinion are, first, the frequency, if not invariableness of an endocardial murmur in cases of chorea associated with rheumatism; secondly, the fact that in all the fatal cases of rheumatic chorea examined by myself after death, the valves of the left side of the heart have presented unmistakable proofs of recent inflammation, and, thirdly, that evidence of like inflammation is furnished by the records of nearly every fatal case published, whenever the state of the valves of the heart is mentioned.

2. Cases of chorea not unfrequently occur in which no other attendant morbid condition can be found than that of valvular disease of the heart. Sometimes such cases happen in individuals belonging to a rheumatic family, and in whom therefore the rheumatic diathesis may be assumed to be in some degree operative; sometimes they happen in association with some of the trivial temporary disorders, such as worms and the like, which have been mentioned as occasional attendants on chorea. Very often, however, I have failed to detect in such cases any evidence of rheumatic tendency to account for the cardiac disease, and any proof of the existence of any other ailment likely to explain the chorea. Whatever be the circumstances under which these cases of chorea occur, the evidence of valvular disease is usually clear, and is furnished by endocardial murmurs during life, and, when they prove fatal, by structural changes observed after death. The existence of an endocardial murmur in many cases of simple chorea was long ago pointed out by Dr. Addison, and the observation has since been abundantly confirmed by Dr. Todd and others. When at the base of the heart, and attended by general signs of anæmia, it is of course open to doubt whether organic disease has any share in its production, or whether it be not entirely functional. When at the apex, however, where, indeed, it is most commonly perceived, and where anæmic murmurs are rarely heard, its origin in mitral imperfection is nearly certain. It has been suggested that such apex murmurs may occasionally be due to irregular choreic contraction of the *museuli papillares* of the heart, whereby valvular imperfection and regurgitation may be temporarily induced. Be this explanation true or not, and I doubt its correctness, for there is no good proof that involuntary muscular organs participate in the choreic disorder, it can only explain a temporary or momentary murmur, not a permanent one, such as commonly exists in chorea. Moreover, it is by no means clear, as Dr. Todd long ago pointed out (*Medical Gazette*, 1849, p. 664) that closure of the auriculo-ventricular valves would be in any degree affected by irregular action of the papillary muscles. One important point in connection with these choreic murmurs requires to be especially noted, namely, that absence of a murmur is no proof of the absence of even serious organic disease of the valves of the heart. I have repeatedly observed cases in which the most careful examination failed to detect a murmur, even up to the last day of life, yet in which after death there were unmistakable signs of recent acute mischief about the valves. The fact is important, because it warrants us in assuming the existence of valvular disease in suspected cases, even although no murmur be heard. The explanation of the fact is very simple; the thickening, swelling, and other changes in the mitral valve, including fibrinous depositions, were, in the cases to which I allude, and probably therefore in others similar to them, observed principally, if not exclusively, on the auricular surface of the valve, above the free margin, which was thus uninterfered with in its power of closing and preventing regurgitation. The proofs of inflammatory mischief in the valves disclosed after death are usually quite plain, and consist of swelling, alone or combined with evident vascularity, softening and loosening of texture, a rough, granulated, occasionally abraded surface, and often the presence of separable fibrinous concretions. The change in many cases, however, is so very slight, and requires such careful examination for its detection, that I am persuaded it has frequently been overlooked, and therefore has not been described as often as it really exists. The granules, too, are frequently so minute as to be readily lost sight of, unless specially sought for. Often, too, they adhere so loosely to the surface of the valve that they may be readily brushed off in the ordinary examination of the interior of the heart, and thus not be taken into account. Although the mischief found may thus be slight, and the granular deposits few and small, yet these changes by no means represent the amount of inflammation

(a) For a full account of these views, see the valuable work of Dr. Burrows, "On Disorders of the Cerebral Circulation."

which may have been going on during life. They represent it, indeed, no more than do the granulations on a wound after death represent the amount of discharge from the wound during life. Much evil may have resulted from continued valvular inflammation, which leaves but little sign in the degree of structural change disclosed after death.

3. Several recorded cases by Ingleby (*Lancet*, 1840), Lever ("Guy's Hosp. Rep." 2nd ser. Vol. V. and VI.), Romberg ("Manual of Nervous Diseases"), and others, leave no doubt of the occasional occurrence of chorea during the pregnant state. Some of the worst, most furious, and fatal cases of this disorder have indeed occurred during pregnancy. The relation which the pregnant state bears to the chorea has not been clearly determined. Certain points of interest, however, are presented by the recorded cases, as analysed by Sée (*loc. cit.*), Romberg, and others. (b) The chorea, for example, seldom occurs before the second month of gestation, or after the fourth; in one of two instances observed by myself, however, it commenced in the fifth month, and in the other at the end of gestation. Similar instances of its late occurrence have been recorded by Ingleby and others. Sometimes, on the other hand, it begins soon after conception. From the third to the fifth month, however, appears to be the average period for its commencement (Sée). It is more common in primipara than in those who have already borne children. Also, it is more common in those who fall pregnant in early life than in those who do not become pregnant till later. From nineteen to twenty-four is the average period of life at which it occurs, according to M. Sée. In one case it occurred at sixteen, and in several others at ages between sixteen and twenty. It may occur in those who have not, as well as in those who have, suffered from the disease on a former occasion. Its occurrence in one pregnancy does not necessarily entail its repetition on the patient becoming pregnant again, though occasionally the same patient has chorea in two or three successive pregnancies (Lever and Romberg). It appears to occur independently of anything unusual or abnormal in the pregnant state, and of any attendant disease detectable during life. Once developed, it usually continues until delivery, whether this be premature, as often happens, or at the end of the natural term; it generally ceases then, but sometimes continues longer.

Such are some of the main points noticed about chorea in pregnancy. There is, however, nothing in them to explain the connection. Accordingly, one is led to the belief that in this, as probably in most other forms of chorea, more is due to the peculiar nervous temperament of the pregnant person, and perhaps to some attendant condition, than to the mere pregnancy itself. Naturally the pregnant state is one which is attended by much nervous excitement, especially when it occurs for the first time, and in young subjects, and especially, too, when it occurs under circumstances occasioning much mental distress or disgrace. This was well shown in one of Dr. Levick's cases (*American Journal of Medical Science*, January, 1862), that of a young girl who had been seduced at the age of 16. She suffered much from the consequent shame and disgrace on becoming pregnant, and soon after was seized with chorea, which killed her. The natural state of nervous susceptibility during pregnancy in young persons renders them also specially liable to be over-impressed by all causes of mental disturbance. Levick mentions one case in which the death of a friend seemed to be largely concerned in the production of the chorea; and another in which a sudden fright developed the attack. But together with these general and special circumstances producing an undue state of nervous excitement, and rendering the subjects unusually susceptible of any additional cause of irritation, physical or moral, there probably is associated in most cases of chorea in pregnancy a peculiar predisposing tendency to nervous affections. This is shown in the fact that in many of the recorded cases there had been chorea on a former occasion; also that on the occasion of subsequent and quite natural pregnancies chorea recurred in several of them. It may be assumed therefore that the choreic tendency had all along existed in those attacked, but that it required the peculiar circumstances connected with pregnancy specially to predispose to it, and, in addition, perhaps some direct exciting condition, like a mental shock, or some associated state to develop it.

Fortunately, fatal cases of chorea in pregnancy are rare; but unfortunately such cases when they have occurred have rarely been examined thoroughly after death; hence we are deprived of much that might help to an interpretation of the association in question. The number of cases which I have found recorded being so few, I venture to append the two following to the list already published, especially since I believe they furnish some clue to the pathology of puerperal chorea, as well as of chorea in general:—

*Case 1.*—A young married woman, aged 20, was admitted into St. Bartholomew's Hospital in January, 1852, being five months pregnant with her second child, and suffering from violent general chorea of about three weeks' duration. The attack had been gradually coming on for several weeks before it assumed the severity by which it was characterised on the patient's admission. She had had no similar attack in her former pregnancy, or at any other time, and had no rheumatic history. For two days the violent choreic movements continued without any mitigation, except while the patient was under the influence of chloroform, and on the morning of the third day she miscarried, lost a large quantity of blood, and almost immediately died. The points of chief interest disclosed on the post-mortem examination were the following:—The substance of the spinal cord and of the brain, especially the cerebellum, was remarkably soft, inelastic, and pale. The membranes of the brain were healthy; those of the spinal cord were congested, and in the loose tissue immediately outside the theca were numerous large ecchymose-looking spots, consisting apparently of recently-extravasated blood. Similar apparent ecchymoses were found among the deep muscles of the back, on the outer surface of the heart, in the muscular tissue of the left ventricle, amid the loose tissue connecting together the great vessels at the base of the heart, along the costal pleura, and, in the greatest abundance, in the tissue of the omentum, mesentery, and other folds of the peritoneum. On more closely examining these spots, especially those in the loose tissue about the base of the heart, it was found that they were not real ecchymoses, or extravasations of blood, but masses of small tortuous vessels gorged with dark, stagnant blood, which was variegated by pale, buff-coloured streaks, apparently of separated fibrin. So closely identical in appearance were the spots met with in the various parts, that there seemed no doubt of their being all of the same nature, namely, portions of extreme capillary engorgement, resulting probably from some cause of obstruction to the circulation therein.

The heart was small, flaccid, and empty. The right valves were healthy. The mitral and aortic valves, near their borders, were studded with pale, soft, loosely-adhering granules. The lungs, and the various abdominal organs, including the recently-emptied uterus and its appendages, were healthy. On various parts of the trunk and limbs were numerous large pustules, somewhat like ordinary boils. There were also several suppurating lymphatic glands in the neck, and the right mammary gland was enlarged, hard, unduly vascular, and many of the lactiferous tubes yielded a puriform fluid on section and pressure.

The pathological appearances in this case resolved themselves, therefore, into a pale, soft state of the nervous centres, as commonly found in chorea; soft, easily-separable vegetations on the left valves of the heart; numerous patches of intense capillary congestion, resembling ecchymoses, in various loose textures of the body; pustules in the skin, and suppurating lymphatic and mammary glands. Nearly all these conditions were indicative of a contaminated state of the blood. The cause of this contamination at first seemed doubtful. The patient, just before the development of the urgent choreic symptoms, had, it was subsequently learnt, cut her thumb deeply; the wound suppurated, the hand became much swollen, and at the time of her death the wound was still gaping and unhealthy-looking. Had this been the source of introduction of morbid material into the blood? Possibly it had, although against it there is the fact that the lungs were healthy, and it is rarely, if ever, that these organs escape when the venous blood is contaminated by the products of phlebitis, or other similar noxious matters introduced. Another suggestion was furnished by the deposits on the valves of the heart; these afforded indications of an inflammatory state of the endocardium, which was probably sufficient to have contaminated the arterial blood, and to have brought about local obstruction in the capillaries, and thus occasioned the ecchymose-looking spots. The presence of these patches of capillary engorgement about the theca of the spinal cord may

(b) For a good discussion of the subject, consult Dr. Tanner in his "Signs and Diseases of Pregnancy;" see also, for references to most of the published cases, Dr. Charles Reeve's book on "Diseases of the Spinal Cord."

have contributed materially to keep up the irritation in the nervous centres to which the chorea was due. Without, however, commenting further on this case at present, let me narrate the other:—

*Case 2.*—In December, 1859, a healthy woman, aged 25, who had borne one child previously and miscarried twice, was taken in labour at her own home, and sent to St. Bartholomew's Hospital for assistance. The gentleman who attended her from the Hospital found her in a state of violent chorea. She was delivered of a full-grown living child in a few hours, and the movements then partially ceased, but soon afterwards recurred with increased severity. The patient was brought to the Hospital, and died in four days, exhausted by the violence of the choreic agitation. It was ascertained that the chorea had commenced only three or four days before parturition; also that the woman had suffered from chorea when fourteen years old, the attack at that time appearing to have been in connexion with rheumatism. The body, examined after death, appeared well nourished. The brain and its membranes were congested; the cerebral substance tolerably firm. The spinal cord was not examined. The lungs and abdominal viscera appeared healthy. The left ventricle of the heart was a little hypertrophied; all the valves were healthy, except the mitral, which presented signs of old mischief, in thickening and shortening of the tendinous cords, and of recent mischief, in a row of small warty vegetations along the auricular surface, just above the free margin. The uterine organs presented the appearance proper to them a week after delivery.

In this, as in the previous case, there were thus signs of recent mischief in the mitral valve. It is on this account chiefly that the case is worthy of notice. The valvular affection becomes especially significant when taken in conjunction with the fact that a similar condition of the valves existed (whenever the heart was specially mentioned) in every one of the fatal cases of puerperal chorea which I have found recorded.

REPORTS OF HOSPITAL PRACTICE  
IN  
MEDICINE AND SURGERY.

THE EDINBURGH ROYAL INFIRMARY.

CASE OF AMPUTATION OF THE THIGH—  
ACUPRESSURE—REMOVAL OF NEEDLES  
TWENTY-ONE HOURS AFTER THE OPERATION.

(Under the care of Mr. EDWARDS.)

[Reported by R. L. TAIT.]

J. S., age 7½, had been suffering from disease of the left knee-joint when I saw him first, in December, 1862.

There were several openings on either side of the joint, and one in the popliteal space. A large abscess extended along the whole front of the thigh. As the abscess was evidently induced by the irritation of the diseased ends of the bones, it was determined to remove them at the same time that it was evacuated. Amputation was quite inadmissible, not only on account of the feeble, hectic condition of the patient, but also the extent of the abscess. The patient's father was told that the operation was merely to be a preliminary in all probability to amputation, as complete recovery of the limb was not to be expected. After the sources of irritation were removed, the abscess became greatly diminished in size, and the boy's health steadily improved for four months, when Mr. Edwards, in presence of Professor Simpson, Dr. Bean, R.N., and others, removed the limb close to the trochanters by the lateral flap operation. All the large vessels, including the superficial and deep femoral arteries, were in the internal flap; they, along with three smaller branches, were secured by short sewing needles, and loops of wire placed across the axis of the arteries, and therefore with their ends towards the cleft between the flaps when the latter were adjusted. A deep obturator branch retracted so as to give trouble in securing, and was controlled by a long needle, passed by Professor Simpson through the skin.

Twenty-one hours after the operation all the needles were removed, and there was no subsequent hæmorrhage, except a slight trickling of venous blood from the orifice left by the

long needle in the skin, but this stopped in a few minutes, and did not recur.

April 28.—Flaps have adhered, and the stump is nearly healed. There is a small quantity of discharge from the upper part.

The recovery was complete before the fourth week, which must be considered as tolerably rapid, considering the prolonged illness and greatly wasted condition of the patient. It may be considered that the treatment in this case was too severe, but I do not see what other course I could have pursued under the circumstances. Had I been satisfied in the first instance with merely opening the abscess in the thigh, the downward course of the patient's strength would not have been arrested. Had I, on the other hand, amputated, I must have done so through an abscess and through tissues in an acutely inflamed condition, but by removing the ends of the bones, and hence the cause of all the disturbance in the soft parts, I obtained time to rally the patient's almost exhausted energies, and allow the excitement in the neighbourhood to subside. When performed rapidly (and even the most ingenious lingerer over an operation can scarcely occupy more than three or five minutes), and when for chronic disease the shock to the system seems scarcely more from excision of the knee than excision of the elbow-joint. Of course, long exposure of the raw surface, necessarily of large extent, alters the circumstances.

As to the method of arresting the arterial bleeding, nothing can be more satisfactory than acupressure, and, although I cannot pretend to apply the needle so quickly as ligatures could be applied, yet expertness in their application may surely be acquired, and it is, it must be an advantage, under ordinary circumstances to have foreign materials out of the wound at an early period. It does seem somewhat contradictory to introduce wire sutures, and say you do so because they produce less irritation than thread, and yet to leave a number of threads in the wound, and as many Surgeons have declared, believe they not only produce no irritation, but do positive good.

Mr. Dix, of Hull, has favoured me with two communications on the subject of his paper read before the Medico-Chirurgical Society. His method of crossing the vessel with a loop or staple I have never tried; this plan, which reminds one of the directions given in a fragment of Archigenes, preserved by Oribasius, that the vessels bringing blood to the part are to be sewn together (*διαβράπτω* to sew through or between). Cocchius rendering them "consuenda vasa sunt." Ambrose Paré applied "this strong twisted thread" . . . "through the skin making your stitch over the said vessels by piercing through the raw flesh and skin. Then make your ligature on the fold of a rag, thus you bind the artery and vein (see Wiseman)." If for "thread" you read "wire" and for "rag" "cork," you have a tolerably correct description of Mr. Dix's method.

THE LONDON HOSPITAL.

SYME'S AMPUTATION AT THE ANKLE—RECOVERY—PATIENT ABLE TO WALK ON THE STUMP DURING TWO YEARS—AMPUTATION OF THE LIMB ON ACCOUNT OF DISEASE OF THE KNEE AFTER THE LAPSE OF ELEVEN YEARS—DISSECTION.

(Case under the care of Mr. CURLING.)

T. C., at the age of 7, was brought into the London Hospital on April 15, 1852, in consequence of the fore part of his right foot having been crushed by the wheel of a dray passing over it. Mr. Curling at once amputated the foot at the ankle-joint, and removed the malleoli. The part healed favourably, and a shoe made by Gray, of Cork-street, was afterwards worn. For two years the boy was able to walk and jump as well almost as before the accident. The head of the tibia and knee-joint then became diseased, and contraction took place, so that he was no longer able to bear on the stump.

About a year and a-half ago an attempt was made to straighten the limb by forcible extension. This was followed by suppuration in the thigh, when all extension was discontinued.

In May, 1863, at the age of 18, he applied to Mr. Curling to amputate the limb.

The leg was acutely flexed on the thigh, and admitted of no extension. There were sinuses leading to diseased bone at the head of the tibia. He has reddish hair, and is of strumous

appearance. There is shortening of the index finger, and a large cicatrix resulting from necrosis and removal of the metacarpal bone.

On May 7, Mr. Curling amputated the thigh by Teale's method, which was most convenient, in consequence of the flexed condition of the limb.

*Dissection of the Amputated Limb by Mr. Couper, Assistant-Surgeon to the Hospital.*—The knee admits of very little extension, and is kept flexed by the hamstring muscles together with the condensed and shrunken tissues with which their tendons are matted in the popliteal space. There is more lateral gliding of the tibia on the femur than is normal, but the movement is unaccompanied by grating, although much rough and denuded bone is felt within the joint when a probe enters it by any of the sinuses. Thus, when introduced by either of two sinuses whose orifices on the front of the leg are three inches below the head of the tibia at the outer side, a probe encounters rough open cancelli within the head of the tibia, in which there is a large cavity moistened with pus. In some places the bone crumbles too easily under the impact of the probe. Carried further, the instrument enters the joint, and again, on the patella, encounters a carious surface. The patella is not ankylosed. A third sinus at the upper limit of the ham space conducts to rough bone on the back of the outer condyle of the femur. The skin is natural over the knee, and is nowhere glued to the subjacent bone. The muscles of the thigh and leg are much atrophied, and the condyles of the tibia and femur are thus by comparison, although not actually, enlarged. On the other hand, these bony prominences maintain a natural external form. The head of the tibia still touches the back of the condyles of the femur, and although the leg is flexed so that, before amputation, the heel all but touched the buttock, the axis of the tibia preserves its right relation to that of the femur.

A vertical section is made from before backward through the knee-joint in the mesial line. In the vicinity of the section, the articular surfaces of the patella, femur, and tibia are loosely connected by watery, areolar tissue, which resolves itself under the microscope into exceedingly fine, single filaments, irregularly interlacing in wide meshes. Nowhere are wavy, fibrillated bands of normal binding tissue visible; there is, however, an abundant intermixture of fat. On destroying these loose adhesions in the outer half of the dissection, the femoral condyle is found without cartilage, except in the middle, where a circular, cartilaginous island, an inch in diameter, remains, and shelves off posteriorly into rough, open cancelli, and in front into a portion of the articular surface, whose cartilage is wholly replaced by soft, gelatinous, and very vascular granulations, and by the watery, areolar tissue just mentioned. Through these the point of the knife is easily sunk into the open subjacent cancelli. The articular surface of the patella retains only a central islet of cartilage in apposition with that on the outer femoral condyle. Its edge is thinned, and around it the articular surface is carious, or is covered by soft, vascular granulations. The outer part of the head of the tibia is excavated, and its cancelli are bathed in pus. This portion of the joint contains no vestige of sound synovial membrane. Neither in the inner half of the joint, with an exception to be mentioned, is any free or healthy synovial surface present, although the inner is less disorganised than the outer half. A small piece of cartilage on the patella has a smooth, glistening, and free surface, but elsewhere the synovial surfaces are adherent, and converted either into loose, filamentous tissue, or into tissue more condensed, firm, and vascular. Cartilage still covers most of the inner condyle of the femur and of the corresponding surface of the head of the tibia, but these surfaces are only exposed by breaking down the close fibrous adhesions by which the synovial membrane is replaced. The edges of both cartilages are thinned and encroached upon by soft granulations bathed in pus. The semilunar cartilages have disappeared, but crucial ligaments are still traced, although much altered. It is impossible to ascertain how far the cancelli of the tibia are infiltrated with pus, seeing that the saw must have carried that fluid beyond the diseased tissues. The section is continued vertically through the tibia and through the stump at the ankle in a direction from before backward and a little outward. The bellies of the gastrocnemius and soleus are wholly converted into fat. The lesser muscles of the leg are less completely fatty, and contain, here and there, pale, tawny, muscular fasciculi. The tendo-Achillis is much thinner than is usual at the age of eighteen. Traced into the stump, it ends in a patella-like disk of

bone, which, fixed below, glides freely by means of a bursal surface against the blunt and rounded posterior edge of the lower end of the tibia and fibula. This bone has the following dimensions:—Length,  $1\frac{1}{4}$  inch; breadth,  $\frac{3}{4}$  inch; thickness at the centre,  $\frac{1}{2}$  inch. It is composed of cancellous bone, bounded by a very thin laminar surface. Its long axis is horizontal, its back strongly convex, its anterior surface concave, both in the horizontal and in the vertical direction, the latter curve being the stronger. It thus accurately fits against the edge of the tibia, on which it plays. The fibres of the Achillis tendon spread out a little as they approach this bone, and then invest it on all sides, becoming incorporated with its periosteum. From the lateral and from the lower edge of the bone there is continued a membraniform ligament, which, together with some thinner fibrous bands coming from its upper border, where the tendo-Achillis joins it, loosely unites this sesamoid bone, after the manner of a capsular ligament, to the lower extremities of the tibia and fibula. The fibres coming from the lower edge are thickest and most numerous of any, and, although much less bulky than the tendo-Achillis, are formed by the re-union of its fibres after they have spread and enveloped the bone. They run forward to insert themselves over the anterior third of the lower surface of the end of the tibia. The lateral fibres run to either edge of this surface, and the thin bands from the upper edge of the sesamoid bone terminate upon the back of the tibia immediately above the posterior rounded edge of its lower extremity. The interior of the capsular ligament, as well as the bony surfaces which it bounds, are smooth, like the interior of a bursa, but are not lined with epithelial particles. They are moistened, however, with glairy, synovial fluid. The lower fibres constitute the ultimate insertion of the tendo-Achillis, just as the patellar ligament gives insertion to the rectus femoris, and the osseous disk has much resemblance to a sesamoid bone developed within the substance of the tendo-Achillis. Yet, whatever may have been its function during life, its formation must be attributed to a pure accident.

In dissecting the tendo-Achillis from the tuberosity of the os calcis, during the operation of 1852, Mr. Curling doubtless raised with it a portion of periosteum, which afterwards became a transplanted centre of ossification.

The thick skin and granular fat investing the stump are identical with those of the natural heel.

The length of the tibia, measured from the inter-articular spine to the centre of the lower extremity, is  $13\frac{1}{2}$  inches; that of an adult tibia (period of development not precisely known, but with furrows denoting the recent adhesion of epiphyses—possibly belonging to a female), between the same points, is 14 inches; that of an old male tibia, well marked in all respects, is  $15\frac{1}{2}$  inches between the same points.

## CHELTENHAM GENERAL HOSPITAL.

### CASE OF TUMOUR OF THE PHARYNX—LARYNGOTOMY—TUBE WORN FOR MORE THAN TWO YEARS—DEATH—AUTOPSY.

(Referred to in the Medical Times and Gazette of June 8, 1861.)

[Reported by Mr. DAVID HARTLEY, House-Surgeon.]

GEORGE J. H., about two years of age, was brought to the Hospital as an out-patient in 1859, having a swelling under the angle of the lower jaw on the left side, apparently an enlarged gland, which his mother said was first observed when he was three months old. It was not painful, and the child appeared in good health. Various means were used, but it did not get less, and in a few weeks, his mother said, he made a noise in breathing, particularly when asleep, and he had some difficulty in swallowing. The uvula was larger than usual, and relaxed. To this various applications were used, and the swelling in the neck left to itself. In this state he remained without much alteration till September 5, 1860, when he was taken to the Hospital almost suffocated, and breathing with great difficulty. Mr. Bubb, who, during my absence, was acting as House-Surgeon, perceived, on looking into the throat, a large tumour behind the velum, more especially on the left side. On pressing back this tumour, the breathing was temporarily relieved; in twelve hours after admission, during which time several means had been resorted to without benefit, the child was in so much danger that Dr. Eves performed laryngotomy. An elastic tube was introduced, with instant relief to the breathing, and the child went

to sleep quietly, and the next day was able to take wine and fluid food. Several attempts were made by Dr. Eves to remove the tumour, but unsuccessfully, portions only being cut off.

On September 20, a double silver tracheotomy-tube was substituted for the elastic one, and worn constantly as long as the child lived. He could swallow his food very well, walked about the house, and, in fine weather, the garden, without any inconvenience. He played about and enjoyed himself like other children. His voice was entirely lost, although he could occasionally blow a child's whistle. The tumour continued to increase, notwithstanding it had been several times cut away as far as could be reached.

Dr. Eves, after consultation, gave up all idea of effectually removing it, and with his consent, in April, 1861, I took the child to King's College Hospital, when Mr. Fergusson kindly examined the case, but did not give any favourable prognosis for further operation. I therefore brought the boy back to Cheltenham.

The tumour in the mouth and the swelling of the neck both steadily increased. In March, 1862, by the resignation of Dr. Eves, the child became a patient of Mr. Hawkins, who several times cut off portions of the tumour (which was neither sensitive nor vascular), as it interfered with mastication. A few months ago an abscess formed in the neck on the left side, which was opened near the orifice where the tube was inserted, and very offensive matter discharged. Similar abscesses continued forming till his death. He had occasionally severe attacks of dyspnœa when he used to call the nurse to clean the tube. On one of these attacks the nurse brought him to me apparently dead, but a change in the position of his head appeared to remove some obstruction, and in a few minutes he was as well as usual. On May 17 last, I opened a large abscess near the trachea with the usual relief. On the following morning he was dressed and had his breakfast, when he asked the nurse to clean his tube. This she did, but as his face became turgid, she removed the tube and ran with him into my room. He was slightly convulsed. I passed a long elastic tube down the trachea, but found no obstruction; he was dead.

*Autopsy, May 19, Twenty-six Hours after Death.*—The body was much emaciated. The neck was greatly swollen. On making an incision from the chin to the sternum, and reflecting the integuments and muscles, the tumour was exposed. It occupied the whole of the mouth and fauces, and extended into the right posterior nares and lay on the glottis; there were no adhesions to the bones of the cranium or the cervical vertebræ. There was caries of the left ramus of the lower jaw, and also of one of the transverse processes of the cervical vertebræ. The tumour had its origin under the left angle of the lower jaw, from which it had been developed towards the pharynx, and was, in all probability, congenital. The diameter of the carotid artery, just below the bifurcation, was one-third of an inch. The weight of the tumour was one pound one ounce and a quarter avoirdupois; the circumference being eleven inches and a-half, the widest surface measuring six inches. On cutting through the tumour it was found to consist of fibroid tissue, the capsule being the mucous membrane of the fauces.

LIVERPOOL SOUTHERN HOSPITAL.

EXTIRPATION OF THE WHOLE OF THE TONGUE FOR CANCER—SECTION OF LOWER JAW—RECOVERY.

(Under the care of Dr. NOTTINGHAM.)

[Reported by Dr. GULSTON WOLLASTON, Senior House Surgeon.

J. McD., formerly a soldier in the East India Company's service, aged 44, was admitted into the Liverpool Southern Hospital on March 4, 1863.

There is extensive malignant disease on the left side of the tongue, extending far back, and nearly half way across the organ. He has always lived a steady life, but has been a great smoker. No very distinct history as to the duration of the existence of the disease can be obtained, but he believes it to be about two years, although the progress has been very slow to within a few weeks of admission.

Under the use of several local remedies, everything went on smoothly for some days, but on the night of March 15 a smart gush of arterial hæmorrhage took place, which was restrained by styptics with much difficulty. From this date he became rapidly worse; scarcely a day passed without an

attack of bleeding, often to a large amount; the disease extended rapidly; the pain was constant and most acute; in fact, the patient was going down hill very fast. All applications failed to stop the hæmorrhage—strong nitric acid, tincture of iron, Pagliari's styptic, the actual cautery, etc., etc. being used without the least benefit. Plugging the mouth with a large sponge was the only thing that afforded temporary relief.

At a consultation held on April 14, it was determined to remove the tongue, as being the only chance of prolonging the man's life, and this was accordingly done the same day.

Chloroform having been administered, the patient sitting in a chair, an incision was carried over the chin in the median line, to a little above the level of the hyoid bone. A small labial artery had to be tied, and this was the only vessel requiring ligature in the whole operation. The lower jaw was divided by two lines of section, meeting at an angle, so that the juxtaposition of the two pieces, one entering, as it were, within the grasp of the other, was afterwards more easily maintained. Each half of the divided jaw was now seized and drawn forcibly apart, and the inferior and lateral attachments of the tongue separated. The chain of the écraseur was then passed over the base of the organ, immediately in front of the epiglottis, and retained in this position by the finger during the operation of the instrument. The tongue was separated in about eight minutes, without the least hæmorrhage. A hole was bored on either side of the section in the jaw, and the extremities of the bone brought together with a piece of strong iron wire, the soft parts being kept in apposition by means of hare-lip pins. Primary union took place; deglutition could not be performed for three weeks, the patient had therefore to be supported solely by beef-tea and brandy enemata.

On May 14, the man was discharged, to all appearances quite well; the union in the divided jaw was not very firm, but still there was union; deglutition was perfect; articulation astonishingly distinct; in fact, those accustomed to him could distinguish most of what he said.

The question arises will the disease return? Probably it will; time alone will prove this. The operation was performed to save the man from dying from hæmorrhage, in which particular it has, undoubtedly, been completely successful; independently of which, the removal of the disease will no doubt prolong the man's life for a longer or shorter period as the case may be.

Medical Times and Gazette.

SATURDAY, JUNE 20.

THE GENERAL COUNCIL AND THE PHARMACOPŒIA.

THE fifty-fourth section of the Medical Act of 1858 required that the Medical Council "shall cause to be published under their direction a book. . . . to be called the British Pharmacopœia," and, in order to fulfil this, among other ends of their being, the Council during their first Session, in November, 1858, appointed a committee "to prepare and publish the National Pharmacopœia with all convenient speed;" the result of which is, that during the last Session of the Council, in this present year of grace 1863, the above-

mentioned Committee "can confidently predict that the National Pharmacopœia will be published not later than October next." We remember to have heard that a young and enthusiastic connoisseur once found himself in a picture gallery with the late Mr. Ernest Hartzen, and, to evince his knowledge of art, began to point out some faults in a picture of Etty's, when Mr. Hartzen, one of the most learned and profound art-critics of the day, interrupted him with "Will you pardon me if I give you some advice: when you look at any work of art, first seek for its beauties, and not for its defects; you will have so much more pleasure." Believing that this critical canon is as just as it is generous and pleasant, and that it has a far wider application than to the fine arts only, we hasten to congratulate the Medical Council on the near completion of the new Pharmacopœia. It has long been felt to be a very great and serious inconvenience that the Colleges of Physicians of London, Edinburgh, and Dublin should publish separate Pharmacopœias, in which the catalogues of the drugs employed in medicine and the pharmaceutical compounds differed in arrangement, strength, mode of preparation, and nomenclature—that the prescriber should have to consider in what division of the empire his prescription would probably be dispensed, and the chemist the Pharmacopœia according to which it had most likely been written. The scandal to British Medical science, and the not slight danger arising from this unseemly state of things, had long been freely acknowledged; but no power had been able to overcome the petty jealousies of the three Colleges so far as to induce them to unite in the publication of a national Pharmacopœia; it was felt therefore that the production of such a work was by no means one of the smallest benefits expected to flow from the General Medical Council; its advent has been eagerly looked for, and the announcement of its near approach hailed with universal satisfaction. No one of course expects that it will meet with unmingled approval; but, be its merits or defects what they may, the fact that its existence will be a material, tangible proof of the usefulness of our Medical Parliament will not a little conduce towards securing it a favourable reception.

Of the book itself we as yet know very little, beyond the facts that it is "to be published in the English language, with the lists of the *Materia Medica* and compounds in the Latin language;" and that two editions, in duodecimo and in octavo, are to be published contemporaneously, at the prices of five shillings and seven-and-sixpence respectively, from which we draw the happy inference that it will not be very voluminous.

A forerunner, or detached *envoi*, containing "an explanatory statement of the forthcoming Pharmacopœia," is to come from the practised and honoured pen of Dr. Christison. It is to "show the composition of the work, the principles of its construction, the changes introduced, and the necessity under which the members of the several branches of the Medical Profession will lie of making themselves acquainted with the British Pharmacopœia, in place of the Pharmacopœias which it is to supersede." No better choice of an exponent could possibly have been made.

We fear that we have now come to the end of the pleasant part of our work. We must indeed acknowledge that the Pharmacopœia Committee have not been idle; for, as they are themselves careful to inform us, the three branch committees into which they divided held 407 meetings, and the number of attendances of the members was 1851; and they further held two conferences of delegates in London and Edinburgh; but as there may be a "busy idleness," so there may be also an "idle industry;" and it does not seem possible to praise very highly the kind of industry which required five years to amalgamate three pre-existing Pharmacopœias, though we do not forget that the Committee consisted of eminent members of a busy Profession; and we may suppose that the original

instruction to the Committee to prepare the Pharmacopœia "with all convenient speed" referred to the convenience of the Committee rather than to that of the Profession at large. It is true that considerable delay was caused last year by the necessity of obtaining an Act of Parliament vesting the copyright of the Pharmacopœia in the Council, and by the agitation and controversy aroused by the Committee's new fancy grain; but that the need of Parliamentary powers was not discovered till so late certainly was not very creditable to either Council or Committee; and the battle of the grains was the result of a weak compromise between the Avoirdupois and the Troy champions in the Committee.

The "special Pharmacopœia Committee" appointed this Session observe that "it appears to have been thought by some members of the Council that the numbers of persons who have been engaged in preparing the British Pharmacopœia, and consequently the expense, might safely have been less." We venture to predict that the opinion of "some members of the Council" will be very generally the opinion of the Profession, who will further be apt to wonder why the said opinion of "some members" has been so sterile. The Medical Council voted away for Pharmacopœia expenses above £2000 during this Session, and they had previously advanced at least £1600, and no part of these sums goes to defray costs of printing and publishing. These are very large sums, and we believe that the heavy expense of the new Pharmacopœia and the lengthened delay in its preparation are alike due to the unnecessarily large number of persons engaged on it. The Committee originally appointed by the Council consisted of ten members, and they were given powers "to add to their numbers," "to beg of the three Colleges of Physicians to appoint Fellows to be associated with them," "to communicate with the Pharmaceutical Society for the same purpose," and "to appoint a chemist or chemists to assist them;" the result was the formation of a Sub-Committee in London consisting of seven members, in Edinburgh of ten, and in Dublin of six. Who, remembering the shrewd saying of an experienced old committee man, that "the best possible number for a working committee is three, of whom two never attend," would not feel that the constitution of the Pharmacopœia Committee was only too sure to infect it with the spirit of hesitation, compromise, and postponement of difficulties that has so often marred the labours of the General Council? Perhaps no severer comment can be offered on the unbusiness-like character of the whole arrangements than the remarks in the report of the Special Pharmacopœia Committee of 1863:—"There seems to have been a general understanding [in the Council] that, unless for the services of professional chemists and others, the Council would escape any outlay on account of those engaged in preparing the work. The labour required of the Sub-Committees, however, soon proved to be so great in prospect that it was impossible to expect that so many professional men should surrender their time without some compensation." Who outside the Council would ever have expected it? or, when enlightened, would have left the arrangement of the compensation till the work was done?

However, if the Profession obtain a good Pharmacopœia for five shillings per duodecimo copy, it will, we doubt not, be ready to condone any shortcomings of the Council in preparing it; and, with regard to future editions or supplements, the Council have made arrangements which certainly do not err on the side of extravagance. Each of the Branch Councils is to appoint a "Medical Practitioner acquainted with the natural history and chemistry of pharmacy," who is to keep "the necessary information for the Pharmacopœia" posted up from month to month to "a level with advancing knowledge," and "to invite information as to improvements in the Pharmacopœia from the Medical, Surgical, and Pharmaceutical bodies" of his division of the Kingdom; the three gentlemen so appointed are "to intercommunicate their

results half-yearly," and they are to be ready every five years to give to the General Council "their conjoint opinion as to the changes they consider advisable for a new edition, or a supplement, of the Pharmacopœia." And these gentlemen are to do all this for £20 a-year each! This arrangement exhibits, both as to the number of agents employed, and the definite settlement of their remuneration, a most laudable disposition on the part of the Council to profit by past experience.

We omitted last week to point out that the Minutes of the General Council contained a case prepared relative to the educational sections of the Medical Act, "with the opinion of counsel thereon." It appears to be counsel's opinion that the General Medical Council can, through the Privy Council, require "that the course of study and examination, whether in general knowledge or in strictly Professional studies," be adequate "to secure the possession of the requisite knowledge and skill for the efficient practice" of the lowest grade of the Medical Profession; and that they can represent to the Privy Council that any such course while adequate, as to kind, to secure the requisite knowledge and skill for the efficient practice of Medicine, is not such, as to kind, as ought to be required for the practice of Surgery, and *vice versa*; but that they cannot demand different standards of proficiency for the different Professional grades or degrees.

### THE WEEK.

#### MEDICAL MEN WANTED IN SOUTH AUSTRALIA.

A CORRESPONDENT of the *Guardian* newspaper, writing from Adelaide, South Australia, March, 1863, says:—

"Frequent advertisements evince that Medical men are wanted just now in several places here, where they would soon make satisfactory incomes if they could tide over the difficulty of supporting themselves for the first few months; and I think that in some districts a sufficient number of people could be induced to guarantee to a qualified man a certain remuneration for Medical attendance during the first year."

He also says:—

"The journal published by Mr. Waterhouse, who accompanied Mr. Stuart in the capacity of naturalist, has caused great disappointment on account of its meagre nature. The interior of the country is level and monotonous, with little timber, and that chiefly the universal gum-tree. Great part of it is stony. Other extensive districts are scantily clothed with spinife, or porcupine grass, a plant so sharp and prickly that the cattle cannot eat any part of it but the flower stalk. Water is very scarce, bad, and undrinkable. There is no disguising the fact that great part of the interior of this continent, if not a desert, is exceedingly barren, and capable of supporting only a small number of cattle on a very great extent of country."

#### THE COLLEGE ELECTIONS.

In another page will be found the latest news about the approaching elections. Really there seems some fear of a return to the old title of College of Surgeons of *London*, so little do the country Surgeons seem inclined to contest the privilege of belonging to the governing body of their College. If the times of meeting of the Council do not suit country Surgeons, they ought to demand such an alteration as may enable them to be present without too great a sacrifice. Petty details and routine work might be transacted by a London Committee; but, for the discussion of really great questions, the meetings ought to be so arranged that country Surgeons could take a part in them. At all events, the number of important questions which are astir; the vast advances made by Surgery; the daily increasing "points of contact between science and art," and the increasing number of men devoted to pure Surgery, point to one grand principle in this and all future elections. We want *fresh blood*. We want men who can look at medico-political and educational questions with fresh and independent eyes. And we claim

a seat at the Council, not as the perpetual privilege of a few, but as an honour to be enjoyed in turn by all men, whose age, character, and position entitle them to claim it. Foremost amongst the new candidates stands Samuel Armstrong Lane. For many years a most popular teacher of anatomy, a veteran Hospital Surgeon, the editor of "Cooper's Dictionary," of unimpeachable character as a gentleman and man of honour, his claims are paramount for a vacant seat. As regards the other two seats, we should be sorry not to see Mr. Cæsar Hawkins and Mr. Tatum re-elected; but then, if it should please the Fellows to give them a temporary holiday, and to elect two of the other candidates *pro hac vice*, we will undertake to say that no one would bear the thing with greater equanimity, or rejoice more heartily that two of their *confrères* should enjoy a taste of senatorial dignity, than would Mr. Hawkins and Mr. Tatum. Every fair and manly English maxim, sentiment, and, if you please, prejudice, favours this policy. "Fresh blood," "fair play," "every man in his turn," "room for all,"—such are the sentiments which we believe will animate the electors as they go down to the ballot-boxes.

#### SUCCESSFUL PROSECUTION OF AN UNQUALIFIED PRACTITIONER AT LIVERPOOL.

ON June 9, the Liverpool magistrates fined a man named Robert Fell £5, with costs, for practising as a Doctor of Medicine contrary to the Medical Act. It appeared that five years ago Fell had endeavoured to elude the penalties of the Act by removing the word Surgeon from his door. It was, nevertheless, proved that he had visited, prescribed, and sent medicines in several recent cases. His treatment appears to have been routine, and his scale of fees limited. The application of whisky and water to the head, and of mustard and water to the feet, seems to have been his stock practice, whilst his charges varied from 1s. to 1s. 6d. There was some evidence that he had been in the habit of giving certificates of death, but the absence of a principal witness prevented the magistrates investigating this part of the charge. In defence, it was pleaded that Fell had done "no more than almost every clergyman in country districts did every day;" but as clergymen do not extract small coin from the pockets of their parishioners for advising cold lotions to the head and mustard baths, the plea was not allowed. The fact that three children had died under Fell's care seems to have steered the hearts of the bench even to the plea that Mrs. Fell's ministrations to the poor were highly esteemed by the clergy of the district. It is to be noticed in this case that the magistrates convicted on the ground that Fell wilfully and falsely pretended to be a Practitioner of Medicine, he having practised as one, and not on the ground that he had taken or used either of the names or titles specified in the Medical Act.

#### LIFE ASSURANCE FOR WORKING MEN.

A CIRENCESTER paper contains an account of an insurance office called the "General Provident Assurance Company," the ostensible object of which is charitably to provide for the working classes the benefits of life assurance. The capital of the company is stated at £50,000, with power to increase it to £1,000,000. The prospectus informs the artisan that "weekly, monthly, and quarterly payments—a few shillings per annum will provide for a family, and save from want the wife and little ones." Persons insuring for sums under £50 are not subjected to Medical examination, but in the case of larger amounts, a Medical opinion is required, and Dr. Hodges, of Cirencester, has been appointed Medical referee. In course of time, the company doing a considerable business in the counties of Gloucestershire, Wiltshire, and Monmouthshire, Dr. Hodges' fees amounted to £5 15s. 6d., for which he very naturally applied. Applica-

tion after application, however, proving fruitless, although numerous letters from the Secretary, printed in the journal from which we quote, acknowledge the debt, Dr. Hodges placed the matter in the hands of his attorney. A writ was served on the secretary, who, instead of remitting the money, had recourse to what is technically known as "putting in an appearance," a proceeding by which time is gained. In the course of communication, however, between Dr. Hodges and the secretary, it came out that the district agent received 50 per cent. on the premiums, and yet had managed to get into the company's debt. This seems to have been a reason assigned for non-payment. An office with a capital of £50,000 sued for an acknowledged debt of £5 15s. 6d. is a curious phenomenon. No doubt it may be explicable by circumstances with which we are not acquainted. But, at all events, the managers do not display that appreciation of the value of appearances which was established as a ruling principle in the conduct of insurance companies by the sagacity of the late Tigg Montague, Esq., of "Anglo-Bengalee" memory.

#### PROTECTION FOR COURTS OF EXAMINERS.

ALL "examiners" lose their temper at times. It is impossible that it should be otherwise. If there be forty-nine well-informed, free-speaking, honest examinees,—young fellows who can look you full in the face, give a plain answer to a plain question, and not be afraid to say "I don't know," when that happens to be the case—there is sure to come a fiftieth—some crafty, idle fellow, with a hangdown look, who fences and hedges with every question, never can be got to say plain "no" or "yes," or "black" or "white," but continues to give some shifty, evasive, equivocating answer, which shall just cloak his ignorance. Now, with such an examinee, an examiner must get a little vexed, and perhaps may show it; most probably he does;—and small blame to him. Such things can't be helped. There used to be, in bygone days, both at Hall and College, a few testy and irritable men, who were the terror of all candidates, and were surly to all alike. But times are now altered for the better. Such things ought not to be, and not only so, but there should be no possibility of such things being dreamed of, or said in joke, or told, whether maliciously or falsely, or the reverse. Inoffensive young men, coming up for a great and anxious trial, ought to be protected from the rudeness and annoyance to which it is notorious they were occasionally exposed of yore; and examiners, like Cæsar's wife, should be exempt from even a breath of scandal. The remedies are simple. The first is a little publicity. The presence of some independent and competent witnesses, such as a deputation from the Medical Council, would act as a restraint on any ill-tempered examiner, and secure the condemnation of any ill-informed student. The second is "fresh blood." If there are any such offenders in a Court of Examiners, they are often amongst the oldest,—the men who look on their office as a fee simple, not to be disturbed, and to whom the duties are a mere routine. There is no Court of Examiners which is not improved by regular and frequent changes.

#### COUNTRY SCHOOLS OF MEDICINE.

At page 598 of the *Medical Times and Gazette* for June 6, 1863, will be found a memorial to the General Council from the Medical Officers of the Devon and Exeter Hospital and of the West of England Infirmary for Diseases of the Eye; and at page 599 will be found a resolution, moved by Mr. Teale, seconded by Dr. Stokes, and agreed to by the Council. The memorialists demanded justly that men of education, activity, and experience in the country should have a fair share in the education of their successors. They point out the abundant means of practical education which the three hundred County Hospitals and Dispensaries in England afford. They show that in the country pupils can easily see everything necessary

for instruction in the practical part of their Profession, and can do with their own hands as learners what they will hereafter have to do under their own responsibility. They contrast with these facilities the scenes presented by the wards of London Hospitals, where the beds are surrounded by crowds, and where but few of the surgical pupils are really *dressers*; that is to say, that although all must pay, and that heavily, to see and hear, only the privileged few, who pay more heavily still, have the power of exercising their fingers. They therefore claim, reasonably, that a part of the Medical student's four years' pupilage should be spent in the country; and this part of their demand was granted by the above-named resolution of the Council. One of the four years may be spent with a "regular member of the Profession holding the appointment of Surgeon to an Hospital, Dispensary, or Union Workhouse." The rest of the request was waisted to the winds. The Council happily will not allow that the year so spent shall be the *first*, though it may be any subsequent year. Thus the student, who we hope will be kept at a good school and well grounded in languages and mathematics till past seventeen, will not be turned loose into a surgery, but will begin, as common sense dictates, by studying chemistry, natural philosophy and anatomy,—the alphabet of his Medical studies. Then he may go to a country Surgeon, with advantage to both parties. He may be of real use to his master, and he will be prepared to understand what he sees. Afterwards he can return to a Medical School, and will be ready for minute anatomy and physiology, and the nicer study of diagnosis. We would venture to suggest to our country brethren that they ought to set their faces against the monopoly which has been conferred by the College of Surgeons on "Medical Schools." It is perfectly unnecessary for the young student to have an elaborate museum, or a series of minute experiments in physiology. Can Exeter supply a young man with the means of studying the elements of natural philosophy, besides chemistry practically, and anatomy by means of bones and of bodies from the workhouse for dissection? If so, the first two years may well be spent in such a school instead of one subsequent one. But if not, we hope that the Council will resolutely oppose any return to the old vicious system of apprenticeship, in which one, two, three, or more of a youth's best years were spent, not only in not learning anything, but in losing the power of learning.

#### PARLIAMENTARY.

On Thursday, the 11th, in the House of Commons, the Attorney-General, in answer to a question put by Sir A. Agnew, said, that in his opinion the officials of railway and steam-boat companies were not justified by the common law in removing from carriages or vessels under their supervision persons obviously labouring under small-pox. Neither was he aware of any Act of Parliament which rendered persons who spread small-pox by wilfully travelling in public conveyances when suffering from the disease liable to penalty.

On the same evening, in Committee of Supply, on the vote of £122,881 for the Science and Art Department, the debate principally turned on the architectural exploits of Captain Fowke, which were severely criticised in reference to the ornamentation of the new buildings at Kensington. Mr. Smith's motion for the reduction of the vote by £10,000 was negatived by a majority of ninety-eight.

On Friday, the 12th, Lord Palmerston announced, in reference to a notice given by Mr. Coningham, that H.R.H. the Commander-in-Chief had determined that circumstances connected with the imprisonment of Sergeant-Major Lilley justified the subjecting the conduct of Colonel Crawley to an inquiry by a court martial. The speech of Mr. Coningham, which was characterised by indiscriminate invective, not only against the generals commanding in India, but against H.R.H. the Commander-in-Chief, was severely censured by the Marquis of

Hartington and Lord Palmerston. Their censure seems to have been justified by the subsequent explanation of his conduct given by the Duke of Cambridge in the House of Lords on Monday night.

The vote for the purchase of the land on which the Exhibition building stands was carried on Monday by a majority of 267 to 135. The vote for the purchase of the building itself was not taken. The sum to be given for the land is £120,000; £80,000 is to be paid for the building, and £284,000 for renovations and improvements, making a total of £484,000. The covered area thus obtained it is proposed to devote to the reception of the Natural History Department of the British Museum, of the Museum of Patents, and of the National Portrait Gallery. Of the seventeen acres, Professor Owen is to have five, and, as a consequence, the National Museum in Bloomsbury is to be shorn of its greatest attraction. It would be foreign to our pages to discuss the merits of the Exhibition building. As the House has agreed to buy the land, there can be little doubt but that the other purchase will follow. We all know that the building is the ugliest in Europe, that a large portion of it is dark, that it is badly drained, badly floored, and that it is not water-tight; but it may be that these defects admit of remedy. Neither do we enter on the question of whether the Commissioners and contractors are animated by the most high-souled self-sacrificing patriotism, or whether the whole thing be not one of the grossest jobs to which a Government has ever lent countenance. These matters we leave to non-professional disputants. But we do protest against depriving eight-tenths of the metropolis of their principal means of scientific education, by banishing the Natural History collections to a distant suburb. When the question of removal was before Parliament last year, we stated at length our reasons for objecting to it. The success which has attended the proposal of this year has not convinced us. For the scientific workers of the eastern and central districts, and for the great mass of the artisan and middle classes, the Natural History Museum will, from the time of its exportation to Kensington Gore, be utterly and hopelessly useless.

From a notice given by Lord Enfield on Tuesday night, it would appear that a rumour has got abroad that a report has been lately sent to the Treasury in which the value of the Exhibition building is estimated at £30,000 less the cost of pulling it down. Lord Enfield gave notice that it was his intention to ask if such report has been received, and whether there would be any objection to lay it on the table previous to the vote of £80,000 for the purchase being proposed.

A bad site and a bad building are dear at any price; but it is rather too much to be forced, for reasons of economy, to pay for the latter three times more than it is worth.

On Wednesday, Lord Raynham obtained leave to bring in a Bill for the protection of young persons under the age of sixteen years engaged as domestic servants and apprentices; also a bill to regulate corporal punishment in schools and elsewhere. The Bills were brought in and read the first time.

#### M. DEMARQUAY ON ENGLISH SURGERY.

M. DEMARQUAY has recently published in the *Union Medicale* (No. 70) some of the impressions he derived concerning English Surgery during his visit to London as a juror of the Exhibition. Upon the whole, we do not complain of the estimate formed by our *confrère*, who sees that there is something at least to be learned from our Hospitals and our practice; but one or two statements may be noticed. He seems to think that we administer chloroform in a far too free manner,—an observation to be expected from a Surgeon of the Paris Hospitals, in which this assuager of suffering is often very imperfectly employed. The reason M. Demarquay assigns for such imperfect administration is of that idealistical kind we have become in the habit of regarding as peculiarly French. He says that when the English patient

is brought completely under the influence of chloroform, "a painful feeling is produced when we behold placed upon the operating-table a human mass brought there solely to undergo the operations indicated by art. As chloroformisation is continued during the entire period of the operation, and the patient is carried away while still under the influence of the anæsthetic, there results a complete isolation of the patient and the Surgeon, which is truly painful. The man is effaced by such a mode of procedure, the operator becoming a mere instrument, and the patient mere matter for operation. Those moral sympathetic ties, which become established between the operator and the operated prior to the operation, and at the moment when the patient returns to his senses, have no place in the English Hospitals, where this mode of procedure prevails. In this point of view ours is the better practice." Aye, in this point of view; but what is it in the patient's point of view? Freedom from pain, rather than a "moral sympathetic tie," is, we take it, the grand point with him.

The construction and convenience of our operating-theatres, their admirable illumination, the mode of transporting the patients to and fro, and the mode of dressing, receive great praise at the hands of M. Demarquay, contrasted as they are with what prevails in France. In comparing the results obtained in the two countries, he observes that we must bear in mind that the London patients can bear operations much better than the Parisians, who are of a far more nervous and impressionable temperament, whatever this may be due to, whether difference in race, in habits, or in manner of living. With respect to the diagnosis, he considers that French Surgery is more minute, precise, and affirmative, while in indications of treatment English Surgery is more bold and more hasty. Thus, in respect to the numerous and remarkable examples of excision met with in the London Hospitals, there has not first taken place in these cases that series of local and general treatment which would have been put into force in Paris. While English Surgery is so proud of the results of these operations, French Surgery is better pleased with avoiding such operations by medico-chirurgical treatment, and thus preserving the limbs in their entirety. In calculating the statistics, we may expect a greater proportion of favourable results from the English resections than from the French, as these latter are not resorted to until the last extremity, when all other means have been exhausted. The true object of inquiry should be the diseases of the joints themselves; are they best treated by these more prompt and hasty operations, or by more varied and more expectant therapeutical agencies? But M. Demarquay finds that if, in some respects, London Surgery is bolder than French, in others it is more timid. Thus, delicate operations for the removal of malignant tumours are much rarer in London than in Paris. This, he conjectures, may be due to the fact of such cases being treated at special Hospitals, and should be borne in mind in estimating the relative mortality of the general Hospitals of the two countries. We believe that this class of operations is of more common occurrence in our Hospitals than M. Demarquay supposes, and that their greater rarity, compared with what prevails in Paris, is not due to any predominance of special Hospitals, but to the increasing want of confidence entertained in their efficacy by our Surgeons.

#### THE MEDICAL PROFESSION IN AMERICA—ABOLITION OF THE USE OF CALOMEL AND TARTAR EMETIC BY AUTHORITY.

THE deplorable political convulsion which is now agitating the States of North America, and every day shaking them further and more completely asunder, has not failed to be reflected in the mirror of Medical journalism. War is the great and absorbing subject which now occupies the thoughts of American citizens, whatever their business or profession, whatever the station in society that they may hold, whether lawyers, surgeons, or merchants, citizens, or aliens. War infl-

trates everything. The doings of the army, and the state of the army, are the almost sole topics which find place even in the Medical Journals. Everything smacks of war. We have now before us several numbers of the *American Medical Times*, published in New York. They contain, as might be expected, a distinct department for Army Medical Intelligence; but this is not all, for nearly every article relates to some question of Military Surgery, is a report of some military Hospital; tells a tale of fever, hospital gangrene, or erysipelas—those scourges of close and crowded wards; or, at any rate, proceeds from the pen of a military Surgeon. Well! foreign war is an evil, war at home a greater evil, and civil war the greatest evil of all; but out of even the last of these some good may be anticipated. America may be expected to gain what she has long needed—an indigenous and independent school of Surgery and Medicine. True, its first lessons will be learned amid the noise and slaughter of the battle-field. But this is just where British and French Surgeons first threw aside their leading-strings, and acquired the practice of independent thought, a reverence for the teachings of actual observation. Well will it be, too, if the fiery ordeal which it is now passing through acts also in the purification of the Profession from all that is gross in ignorance and whatever is unseemly in morality and behaviour.

It may be thought that we are using some harsh expressions when hinting thus at a need for improvement among our Professional brethren in the American States. We certainly should not do so without good reason; and, harsh as our words may appear, they are not nearly so condemnatory as the language of their own journalists, or the simple facts recorded in some recent numbers of the periodical we have mentioned. We mentioned some time ago the difficulty which was experienced at the outbreak of the war in obtaining a sufficiency of Surgeons, and the imperfect character of the qualifications of those whom the authorities were under the necessity of appointing to the charge of the sick and wounded. It was stated that new regulations were about to be put in force in this matter, that more strict examinations were to be instituted, and so on. But what a tale is unfolded by memoranda just recently issued from the Washington War-office! How do they warrant harsher language still than that which we have used! Here are some extracts. After naming three Surgeons dismissed the service "for absence without proper authority," they having failed to make a satisfactory defence before the military commissions, we meet the following:—

"Assistant-Surgeon J. P. Alcorn, 126th Ohio Volunteers, for accepting bribes for procuring discharge of soldiers. Assistant-Surgeon R. S. McGee, 100th Regt. Indiana Volunteers, is hereby dismissed the service of the United States, he having been a convict in the Illinois State Prison on the charge of robbery and counterfeiting."

If anything will show the straits to which the authorities are reduced, the possibility of such persons ever obtaining a Surgical appointment at all would suffice to do so. Such a thing degrades every Army Surgeon, however fit himself to associate with "officers and gentlemen." We are told in one page of the journal we have been quoting that the Medical Hospital stores embrace "a more liberal supply of articles and drugs than is furnished to any army in the world," but in another there appears an order issued from the office of the Surgeon-General, which could not possibly be the result of parsimony, since the drugs referred to are among the cheapest that could be prescribed. We can only infer that, as a body, the Army Surgeons of the States are not sufficiently careful or sufficiently instructed to be trusted with such dangerous weapons. In contemplating the following remarkable order we cannot avoid thinking,—

"Quid leges sine moribus,  
Vanæ proficiunt?"

It runs as follows:—

"Surgeon-General's Office, Washington,  
May 4, 1863.

"1. From the reports of the Medical inspectors and the

sanitary reports to this office, it appears that the administration of calomel has so frequently been pushed to excess by Military Surgeons as to call for prompt steps by this office to correct this abuse; an abuse, the melancholy effects of which, as officially reported, have exhibited themselves not only in innumerable cases of profuse salivation, but in the not infrequent occurrence of mercurial gangrene. It seeming impossible in any other manner to properly restrict the use of this powerful agent, it is directed that it be struck from the Supply Table, and that no further requisitions for this medicine be approved by the Medical directors. This is done with the more confidence, as modern pathology has proved the impropriety of the use of mercury in very many of those diseases in which it was formerly unfailingly administered. 2. The records of this office having conclusively proved that disease prevalent in the army may be treated as efficiently without tartar emetic as therewith, and the fact of its remaining upon the Supply Table being a tacit invitation to its use, tartar emetic is also struck from the Supply Table of the Army. No doubt can exist that more harm has resulted from the misuse of both these agents in the treatment of disease than benefit from their proper administration.

(Signed) "W. A. HAMMOND, Surgeon-General."

There are other edged tools in the Surgeon's hand which are rather awkward playthings. We wonder what the next order will be, probably this:—"It having been conclusively proved by official records that numerous unnecessary amputations have been performed by the Army Surgeons, and that thus many officers and men have been rendered incapable of further service in the army of the United States, the Medical directors are required to approve no further requisitions for amputating instruments, and to see that those now in use be returned to store. This is done with the more confidence, as modern Surgical experience has proved that wounded limbs may often be restored under judicious treatment without having recourse to their entire removal. No doubt can exist that more harm has resulted from the misuse of these instruments than benefit from their proper use."

Ἰητροὺς γὰρ ἀνὴρ πολλῶν ἀντάξις ἄλλων.  
Ἰούς τ' ἐκτάμνειν ἐπὶ τ' ἥπια φάρμακα πάσσειν.

## REVIEWS.

*A System of Surgery: in Treatises by Various Authors.* Edited by T. HOLMES. Vol. III. 1862. Pp. 916.

THIS third volume of Holmes's comprehensive work, embracing the subjects of Operative Surgery, the Diseases of the Organs of Special Sense (the ear and nose), of the Air-Passages, and of the Organs of Circulation, Locomotion, and Innervation, is in no respect inferior to the two preceding. Like them, it includes Essays of widely dissimilar value and literary ability. Some few of these Essays, it must be confessed, are scarcely worthy of their company; but others—and we are glad to say the majority—may fairly challenge comparison with any of their kind in the English language.

Among the former we must, we fear, place the first article of this volume, that by Mr. Smith, on Minor Surgery. Crude and insufficient throughout, it is scarcely redeemed from insignificance even by its series of neat diagrams. For we cannot regard illustrations of bandaging, and of such matters as are familiar to the student from the earliest period of his career, as of any great value.

Far more useful would it have been if the artist's skill had been transferred to the succeeding article, by Mr. Lister, on Amputation. Here, in a greater degree, perhaps, than in any other part of this otherwise admirable book, is felt the great want of illustrations. It is, indeed, scarcely possible without their aid to make an account of an operation clear, or even intelligible. Setting aside this drawback, which we hope to see remedied in future editions of the work, Mr. Lister's essay is in the highest degree able and instructive. In a clear and concise history of the operation, he compares the various methods that have been, or are still in vogue. He gives full credit to Mr. Teale for his method of carrying out the important principle of removing the cicatrix from the points of subsequent pressure on the limb, but enforces the undoubted objection to the operation in very muscular subjects, viz., the extreme length of anterior flap which it requires. He directs

attention to Mr. Spence's modification of the operation as partly remedying this objection, and suggests the advantage of a still further curtailment of the anterior flap, eking it out by a small posterior one. Mr. Lister's remarks on the after-treatment are equally sound and judicious. Adopting the same line of argument as before, viz., that drawn from the history of the operation, he points out how, from the earliest times, the success of the operator has been strictly proportionate to the simplicity of his after-treatment.

Equally able, and still more original, is the same writer's essay on Anæsthetics. We regret that we have not space to give a full analysis of this important Essay. Mr. Lister's observations have led him to form decided opinions on many points connected with the administration and mode of operation of chloroform widely different from those usually held in the Profession. He points out that chloroform, by its primary action on the cerebro-spinal centre, is the great antagonist to shock. He therefore believes, and advances strong reasons for the belief, that many deaths which have happened suddenly at the commencement of operation have been improperly set down as deaths from chloroform, and might, on the contrary, have been prevented by the full action of this powerful narcotic. While admitting that some few deaths may have been due to fear of the chloroform itself, (which, indeed, it would be difficult to doubt,) he ascribes the great majority to an overdose of the anæsthetic from careless administration. He also proves, by some well-contrived experiments, that there is no better mode of giving it than on a folded cloth; having ascertained that "so far from the amount of chloroform given off from the cloth being in dangerous proportion to the air inhaled, the whole quantity which evaporates from the under surface, even when the rate is most rapid, viz., just after the liquid has been poured upon it, is below Dr. Snow's limit of perfect security against primary failure of the heart."

In threatened death from asphyxia (the usual cause), he lays great stress on the efficacy of drawing the tongue forcibly forwards by a pair of forceps, the good effect of which he believes to be due to a reflex stimulation. There is much that is new, we might almost say startling, in this article; quite enough to show that there is still much to be learned on the subject. Doubtless, in the investigation now in the hands of a committee of the Medico-Chirurgical Society, the opinions of so able and trustworthy an observer will be subjected to a fair scrutiny.

The next Essay, on Plastic Surgery, by Mr. Holmes Coote, is, like the contributions of the same author in former volumes of this work, scarcely worthy of his reputation, and far below the level of his earlier writings. Careless and superficial, it takes but little cognisance of the labours of others in this field. This is the more to be regretted, in that the subject is one of such vast and increasing importance. We question, moreover, how far Mr. Coote's teaching can be accepted as in accordance with the present condition of Surgery. When he lays it down as a rule, almost without exception, *that a cicatrix should never be touched with the knife*, we can scarcely believe that he is expressing, as he says, the opinion of most Surgeons of experience of the present day, or that so sweeping a condemnation of this class of operations is justified by statistics.

We pass rapidly over the four next articles, which, though leaving little to be desired, offer no special points for remark. Mr. Hinton treats us to an admirable *resumé* of the vast store of knowledge which has been accumulated, chiefly in our own times, concerning diseases of the Ear. Mr. Ure revels in the uninviting subject of Diseases of the Nose, which appears to have been his first Professional love, and of which he certainly makes the most. And the late Henry Gray has left us a sufficiently comprehensive account of the Surgical Diseases of the Larynx, though unfortunately marred by his literary deficiencies. The description of the laryngoscope and its uses, left unfinished by Mr. Gray, forms a separate article, or rather sketch, susceptible of improvement, by Mr. Durham.

Then follow the Essays on the Circulating System. Mr. Moore describes Diseases of the Absorbents, which are among the most interesting, and, at the same time, the most puzzling, affections to which the animal body is liable. The peculiar physiological questions to which they give rise are not overlooked by Mr. Moore; but it will be long, we fear, before a sufficient explanation can be given of such an apparently simple phenomenon as the arrest of the inflammation by the

intervention of a gland. Mr. Moore treats with equal ability and completeness the Diseases of the Arteries.

Scarcely inferior in interest to Diseases of the Absorbents are those of the Veins, which receive full justice from Mr. Callender. He introduces some original experiments, tending to support the doctrine of those pathologists who deny the occurrence of inflammation of the lining membrane of veins; and his creed on this point necessarily affects his description of phlebitis. The whole subject of this disease must indeed be considered as still *sub judice*.

We come now to what must be regarded as the gem of the volume, if not of the whole work—the Essay, viz., On Aneurism, the joint production of Mr. Holmes himself and Mr. Hart. Of this masterly Essay it is not too much to say that it is the most complete, the most talented, and original work on the subject in any language. It will well repay the attentive study of any Surgeon. To attempt even an outline of its leading features would be but to mar its fair proportions. But the subject of the treatment of aneurism has in modern days received so large a share of attention, that a rapid glance at this portion of the Essay will not be out of place. The authors (for Mr. Hart is entitled, we believe, to a full share of the credit of the article) do not absolutely reject the old method of operating (recently revived by Mr. Syme) in certain cases to which no other known treatment is altogether applicable, as in axillary and gluteal aneurism, and traumatic aneurism at the bend of the elbow. In describing the Hunterian operation, we are glad to see that they take occasion to vindicate in an eloquent protest the fame of our great Surgeon from the senseless vanity of the French writers, who, by ignoring the essential distinction between it and Anel's operation, would claim the merit of its invention. Almost all French writers speak of it as the "methode d'Anel." It is, therefore, a timely protest, especially as, in Mr. Holmes's words, "the operation still is, and probably will long remain, the last resource of Surgeons in the graver cases of aneurism." Other methods of treatment of more modern date, some of which, indeed, may be considered as still on their preferment, are thoroughly analysed. There is the fashionable compression, the exact value of which has yet to be determined; the treatment by flexion, the chief merit of whose introduction belongs to Mr. Hart himself, and which appears destined to meet with great success; and other minor methods of treatment, the applicability of which is, to say the least, very limited; viz., by manipulation (the idea of Mr. Ferguson), by galvano-puncture, and by injections.

Mr. Holmes writes two other articles in this volume, those, viz., on Diseases of the Bones and on Excision. In both he shows the same knowledge and mastery of his subject which render him a good and safe guide to the student. This is especially the case in the latter of these two articles (which, in conformity with the arrangement of the book, should, we think, have been classed among the articles on operations). Mr. Holmes is himself no mean authority on the subject of excisions; and, after the keen controversies of late years, the opinions of so temperate and sound an advocate will be received with respect.

Diseases of the Muscular System are, for the most part, so obscure and so little understood, that Mr. Tatum's Essay may well be accepted as a good *resumé* of what little is known on the subject. He especially insists on a form of circumscribed inflammation found to occur in the course of tertiary syphilis in women, some cases of which were described by him in 1845; but the nature of the affection is obscure and doubtful.

Dr. Little's paper on Orthopædic Surgery is a full and admirable exposition of his well-known views on the pathology of deformities, and their treatment. That the whole subject of their pathology is, however, still in an unsettled condition is evidenced by the recent publication of Mr. Barwell's views on the subject, which threaten to revolutionise this department of Surgery.

The Essay on Diseases of the Joints, by Mr. Athol Johnson, is the work of a Surgeon whom we would rather accept as a guide in the treatment of these affections than in their pathology. How wide are the gaps in our knowledge of this latter is indeed conspicuous, from the uncertain manner in which Mr. Johnson speaks of the various forms and results of inflammation in its different stages.

Of the remaining Essays by Mr. Shaw, on Diseases of the Spine, and by Dr. Brown-Séquard, on Diseases of the Nerves, it will suffice to say that the names of their authors are a

guarantee of their excellence. Mr. Shaw's is, as it were, the complement of his equally admirable Essay, in Vol. II., on Injuries of the Back. And no one, we presume, has greater claim to speak, *ex cathedra*, on diseases of the nerves than Dr. Brown-Séguard.

The volume finishes with the article on Diseases of the Tongue, by Mr. H. Coote, which is dissociated from the remaining Essays on the Organs of Digestion, we presume, because it happened to be ready for publication. The whole volume fully maintains the high character of the work, and amply justifies the promises of its able editor.

## FOREIGN AND PROVINCIAL CORRESPONDENCE.

### AMERICA.

NEAR FALMOUTH, VIRGINIA, May 25.

A LONG time has now elapsed since I last wrote to you, and that simply because nothing particularly interesting to the Profession had, until lately, occurred—a dearth of news was the cause of my silence. Now, however, the late battle at Chancellorsville gives me occasion to pen you a few lines.

During the months of March and April, as indeed during the whole of the time we have spent in our present camp before Fredericksburg, the health of the army has been such as armies are seldom blessed with. Acute cases of disease have been rare, and such chronic cases as have not recovered or died, have been discharged the service. Free issues of fresh bread, potatoes, and onions have completely rooted out all traces of the scorbutic taint, which the hardships of the Peninsular campaign had implanted in many of the men; and at the same time cases of rheumatic pains which had obstinately resisted every mode of treatment the Surgeon could devise, succumbed to the dietetic change. The end of April thus found the army in fine condition, the few cases that were on the sick reports of the different regiments were sent off to Hospitals lying along the line of the Fredericksburg and Aquia Creek Railroad, and we commenced the campaign from which we have but now returned.

For some two or three weeks previous to the commencement of active operations the ambulance corps of the army, lately reorganised, and considerably augmented, was daily drilled under the superintendence of the Medical officers, so that during and after the battle, the care and expedition with which it performed its duty rendered its services of infinite value.

About the same time, too, corps and division badges were distributed to all the troops; these badges, consisting of pieces of cloth worn upon the cap, indicate, by their form, the army corps; the division by their colour; thus the first corps wears a circular piece of about one inch in diameter, and the colour red, white, or blue, tells whether the soldier belongs to the first, second, or third divisions of that portion of the army. The second corps is known by a club, the third by a diamond, and so on. The stretchers, ambulances, supply wagons, all bear upon them their distinctive mark, and on the battle-field, in front of each division hospital, a flag or placard, displaying on it the badge, directed the wounded soldier to the Surgeons of his own command.

Most of your readers know the history of the action at Chancellorsville, that the fighting continued more or less for five days, but that the battle itself took place on the latter part of Saturday, May 2, and on the Sunday from 5 a.m. to shortly after midday—how on the one day we lost ground, *faute de* Sigel's corps, or rather the corps that was once Sigel's—the eleventh—and on the other, although we had to draw in our lines, the ground we yielded up was inch by inch contested and thickly strewn with the fallen of both parties.

Of the wounded in the Saturday fight many of the severe cases fell into the hands of the enemy, and, along with a few Surgeons that were likewise captured, were removed to the rear of the Confederate lines, while all those who could walk and those whom our stretcher carriers conveyed from the field, were lodged in their respective Hospitals. Upwards of 300 wounded men, some fifty of whom were Confederate soldiers were sheltered in the large brick-house, which, known as the Chancellor-house, gives a name to the fight which then raged around it. This building, unfortunately in the course of the

evening caught fire, probably from some random shell. The flames spread rapidly, and although every exertion was made to have the wounded removed in time, a few, it is said, certainly not many—but in the confusion who can tell—perished.

On the following morning, shortly after the renewal of the battle, your correspondent had occasion to ride to the front, and for some distance along the rear of the fighting line. What a scene of apparent confusion was there! yet it, when less superficially noted, resolved itself into perfect order. In front, the fighting line of infantry, with, on every eminence around, the field-pieces hurling grape and canister on the advancing foe; the regimental Surgeons but a few yards in rear of this line, and their only shelter from the hot-bed of death in front of them a tree, or, if peculiarly favoured by fortune, a small but valuable rising ground. Two hundred yards still farther in the rear the hospitals of divisions, and between these various points the stretcher carriers actively engaged, with measured pace proceeding to the rear with their burden, or at double-quick to the front for a fresh one. The Hospitals were but rude affairs, consisting of uprights supporting a roof of blankets, branches, anything, in fact, that would shelter the wounded from the scorching rays of the sun. The quiet and calmness prevailing beneath these shades contrasted strongly with the din of battle reigning in the outer world. Although the roll of musketry was unbroken, except when drowned by the roar of the artillery, though the air was laden with the hoarse cooing of the shell and shot, with the wild cheers of the combatants, and the nervous neighing of horses excited by their surroundings, yet here so deep the silence seemed that the ravings of a semi-chloroformed patient, or the rasping of the amputating saw as it cut its way through the bone, sounded harshly on the ear. Moving about, deaf to every external impression, calm and self-possessed, the Surgeons, the presiding genii of the temple, in the discharge of their all-important duties, imparted a false sense of security to their patients, who, on their first entrance, were clamorous to be taken farther to the rear, so as to be completely out of range.

About ten o'clock, while on one table chloroform was being administered, while at another the Surgeon had just transfixed the limb, a shell pierced the frail roof of one of the Hospitals, and, bursting, killed two stretcher carriers and wounded some of those already lying wounded. The shock this intruder had occasioned to the nervous systems of every one present was barely recovered from, when a second cooed over our heads, and burst beyond. The enemy were, unawares, shelling our Hospitals, the woody nature of the country preventing them from seeing our flags. This was a trying time for the Surgeons unprotected to operate when every man capable of moving had ensconced himself behind the trunk of the largest tree he could find, and when those whose wounds rendered that impossible with anxious looks grovelled still closer to the earth; yet nobly did they do their duty.

During the afternoon of Sunday advantage was taken of the comparative cessation of hostilities which then occurred to remove the Hospital still further to the rear. On Monday long trains of ambulances carried the wounded across the river to the neighbourhood of Potomac Creek; but whether this was preparatory to a retreat, or to an expected general engagement on the following day, we could not then determine. Retreat, however, was the order, and on the Tuesday evening the operating staffs of the division Hospitals were dismissed to join their various regiments, then moving towards the pontoon bridges, knee-deep in mud, and drenched by the rain, which in torrents accompanied the thunderstorm which favoured the movement. Shortly before sundown of the next day most of the troops, wearied, footsore, and feverish, had joyfully hailed the sight of the ground they had occupied during the winter.

Arrived at Potomac Creek, after a short delay for rest and refreshments, those of the wounded that could bear further transportation were despatched to Washington, while the others, the more severe cases, were carefully attended to in the canvas city formed by the field Hospitals established in the neighbourhood of the Creek. Leaving these now as comfortable as they could be made, let me refer to those, less fortunate, left upon the battle-field, and now prisoners in the hands of the enemy.

On Saturday, May 9, a flag of truce was permitted to cross into the Confederate lines, accompanied by a few Surgeons, to assist those who had been captured in the discharge of the

heavy duties which fell to their lot. Some wagon-loads of supplies were also sent across the river at the same time. Your correspondent accompanied the white flag, and can speak from personal observation of the state of the twelve hundred men that Hooker left in the wilderness around Chancellorsville. These men had all been severely hurt. Struck down, and unable to accompany their retreating comrades, they had lain on the field, while the tide of battle swept over them, the bullets of friend and foe proving alike dangerous. Many while thus exposed were killed, and others a second, even a third time hit. The majority of them were gunshot fractures of the bones of the leg or thigh, penetrating wounds of the cavities, or extensive shell wounds. There, where they had fallen they lay for one, two, some for three days, suffering the agony of thirst under a burning sun, and subsequently exposed to the chilliness of the night succeeding the thunder-storm; some fearful, others hoping that a renewal of the struggle might send a random shot to end their misery. The woods, fired in several places during the heat of the battle, added the fear of a horrible death to their other sufferings; but, so far as I could ascertain, and I paid attention to the subject, none were injured from this cause. They were then collected into five groups, and the Surgeons—one to every hundred men—divided themselves accordingly; but what could they do?—so few among so many, when every one required particular attention, and when no instruments, lint, bandages, etc., were attainable; for, these being Government property, had been confiscated by the Confederates. Even the food which was at their command was hard bread and coffee found in the knapsacks which strewed the battle-field. This state of matters having been represented to General Coultsen, who was then in command, he caused instruments, however, (for he had no lint) and morphia to be placed at their disposal, and what his commissary had he freely gave, viz., flour, sugar, bacon, and hard bread, permitting at the same time a few of the Union prisoners he had in charge to act as nurses. The Surgeons now laboured assiduously at the operating table; yet, active though they were, numberless cases in which operation was indicated remained untouched.

On Sunday, seven days after the fight, the Surgeons and supplies sent by the Union Government reached the field. Supplies in plenty there were, but certainly a larger posse of Surgeons might have been detailed. Half-a-dozen crossed at Bank's Ford to reach the wounded of Sedgwick's army, and a like number at United States' Ford for those that had fallen under Hooker. This reinforcement, small though it was, infused fresh vigour into the hearts of the worn-out Medical men, who had been on the field since the battle, and much good was done. The wounded, likewise, were cheered by the arrival of the flag of truce; for, in addition to the so-much required supplies, a prospect of at some early date being transported to the North bank was opened to them. They were overjoyed at the idea of leaving the place where they had suffered so much from wounds, from exposure, from want of food, of drink, of Surgical assistance, while the sickening odour wafted by every breath of air from the carcases of the horses which in hundreds lay around; and that, scarcely less noisome, emanating from the unhealthy discharges of their own uncleansed wounds, seemed sufficient to wound, and that mortally, the health of the strongest. Diarrhœa was common among them, and in many instances formed a most distressing addition to their afflictions; for, from the lack of sufficient attendants and the nature of their wounds—fractures—the unwilling patient was often obliged to let nature have her course as he lay.

The ambulance train did not disappoint them. On Wednesday morning it appeared, and was greeted by the patients with a feeble cheer. On that day 250 were ferried across on a raft formed of two pontoon boats and some planking; but as this was very slow work, on Thursday a bridge was thrown across, with the consent of the rebels, and 600 were removed, —Friday, at noon, finding every Union man on the north bank.

About half a mile from the river side the Sanitary Commission had established themselves in a house, and here each train on its way to Potomac Creek rested for a time to allow of the distribution of food and stimulants.

If my letter had not already assumed such proportions, I should have found much pleasure in dilating on the care and attention the wounded now receive in the Creek Hospital, and on the cleanliness and air of comfort that now surrounds them; but, instead, I must think of drawing to a conclusion.

It may be interesting to mention that in the battle of Chancellorsville one Surgeon was killed, and three wounded, one of whom has since died.

I may observe, in conclusion, that, since the army has returned to its old quarters, it has been gradually moving,—one division one day, another the next,—from the grounds occupied during the winter to new and previously uncamped-upon soil, while the provost guards are consuming the *débris* left about the old quarters. The warm—nay, hot weather, to which we are now exposed here, renders this sanitary measure one of necessity.

## LIVERPOOL.

JUNE 8.

SINCE my last letter, Liverpool has lost one of her truest benefactors—Dr. Duncan, the Medical Officer of Health for this borough. Those who look into the history of the improvements which have raised the sanitary condition of this town from that in which it was an opprobrium to the civilisation of this country, to its present state—which will bear comparison with the best districts of the country—will find that no individual took a more efficient part in the efforts which have brought about this result than the late Dr. Duncan. It was mainly owing to his investigations and reports that the municipal authorities were stimulated to bring before Parliament and carry, in spite of much local opposition, the Sanitary Act of 1846. Many good men and true had attempted the same end long before, but had failed. So long ago as 1788, the Physicians of the town brought its abominably unhealthy state under the notice of the authorities, and in 1802 the Corporation went to Parliament with an Act based upon the recommendations of the celebrated Dr. Currie, and other Medical men, which, had it become law, would have anticipated many of the improvements which resulted from the Act which came into force more than forty years after; but the influence of those whose property was said to be menaced sufficed to secure the rejection of the bill, and to prolong the *régime* of dirt and disease; while, as a sort of salve for the official conscience, “a Fever Hospital was erected to mitigate the scourge, and a new cemetery bought to hide its victims.”(a)

In July, 1846, the Liverpool Act, the first sanitary act in the kingdom, received the Royal assent, and early in 1847 the sanitary staff was appointed. Dr. Duncan, whose previous course had marked him out as the fittest man for the post of Medical Officer of Health, was requested to undertake its duties. At first it was proposed that he should retain his appointment as Physician to the Infirmary and his private practice, and should receive a salary of £300 per annum. To this arrangement the Home Secretary very properly demurred, believing it to be most important that the health officer should be entirely independent of the influences to which any one in practice must be exposed, and he insisted that the whole time of the Medical officer should be devoted to his duties. This arrangement was therefore made, and Dr. Duncan resigned his office as Physician, and took the appointment, which he held till his death.

One of the first and most important measures under the new act was the clearing out of cellars used as habitations. More than fourteen thousand were found to be thus used, and from these in the four years from 1847 to 1851 more than twenty-two thousand persons were removed. The time which was allowed for this wholesale and wholesome eviction prevented any harm, as the demand for more decent habitations very soon produced an adequate supply of them. The sewerage also was so vigorously attended to, that, in about ten years from the passing of the act, a hundred and forty-six miles of sewers and drains were constructed, at an average cost of 17s. per yard. Proper arrangements were made for emptying ash-pits; the smoke nuisance was abated; and slaughter-houses and knackers'-yards were put under proper control. The result of these efforts amply justified the labour and expense which they entailed, since the proportion of deaths to population soon began to decline, and continued to do so with such rapidity, that by 1850 Dr. Duncan was able to report a saving of life at the rate of 800 a-year, and in 1857 of more than 3000 a-year. It is easy

(a) “Liverpool Past and Present in Relation to Sanitary Operations.”  
By Jas. Newlands, Borough Engineer, of Liverpool.

to compute how many lives have been prolonged, how much disease has been prevented; but it is impossible for any human intelligence to know, it is difficult even to imagine, how much suffering has been spared, how much happiness has been bestowed, how much of the highest moral and social good have gone hand-in-hand with these sanitary improvements. I hope, for the sake of the credit of Liverpool, that the memory of such a man may not be left without some public and permanent recognition of the honour which it deserves. We ought to be proud of having had here the first Medical Officer of Health appointed in the kingdom. We ought to be ashamed of ourselves if we do not fittingly perpetuate the acknowledgment of the gratitude which Liverpool owes to him "*ob cives servatos.*"

The first annual meeting of the Liverpool Auxiliary to the Edinburgh Medical Missionary Society was held this week. Some notice of it may be interesting, especially just now that the subject of Medical missions seems to be attracting a good deal of notice in the Profession as well as out of it. The chair was worthily occupied by one of our oldest and most respected Professional brethren, Mr. Batty, Lecturer on Midwifery in the School of Medicine. The Society has as yet simply aided the funds of the parent Society; but it is hoped that some more proper missionary work may be effected by its agency. It has been most favourably received by the clergy, and ministers, and laymen of all denominations. At the meeting the most important speech was that of Mr. Thompson, the Superintendent of the Mission Dispensary in Edinburgh. The accounts which he gave of the proceedings at that Institution were most interesting in themselves, and most valuable as a proof of the efficiency of Medical missionary effort; for, as he said, if there be such success attending the work of such an institution in Edinburgh, where Medical aid is so easily accessible by the poor, what must it be in a city where the Medical missionary is the only one from whom such help can be obtained? The number of cases relieved annually, Mr. T. stated, had risen from three thousand in the first year of their operations, to about eight thousand in this, the fourth. It was at first supposed that, if the poor looked on the mission dispensary as an institution, the first object of which was to benefit their souls, and that the Medical help offered was regarded as a means to this end, they would avoid it; but such is not the case. The managers are careful that their purpose shall be unmistakably avowed. The doors are opened at 1.30, and from that time till 2, while the patients are assembling, a lady reads the Bible to them. At 2 the doors are closed, an address is then given by the superintendent, after which the patients are attended to as in any other dispensary. Those who require home visitation are seen by the resident Medical officer and by the students who attend the dispensary for the purpose of obtaining practical training in Medical mission work. The population of the Cowgate, where the dispensary is situated includes no small amount of "home heathenism," among whom many are found as ignorant of Christianity and as hostile to it as any Mahomedan or Hindoo. Yet among "the *élite* of the ragamuffinism of Edinburgh"—among the outcasts and infidels who crowd the rooms of the Dispensary, many are to be found who not only come and hear, who not only allow the Dispensary Doctors to tell them the good news of salvation which their obstinate prejudices would not let them hear from the lips of any minister of religion, but in whose changed character and conduct there is the evidence that the truths taught them have become the germs of a new and higher life.

To turn, now, to more purely Professional matters, I am glad to have to record a successful case of the treatment of aneurism on the plan re-introduced by Mr. Syme. A man, aged 42 years, was admitted to Mr. Bickersteth's Ward, in the Royal Infirmary, on account of a large aneurism occupying the left axilla. It had existed for four or five months, and the day before his admission had suddenly become much enlarged. It was evident that the aneurism had ruptured, and it was resolved to lay it open and tie the ends of the vessel implicated. An incision was made, through which the subclavian artery could be compressed against the first rib, and the circulation was controlled by the finger of an assistant, kept upon the vessel in this spot. The aneurism was exposed and then freely opened. It was found that nearly the whole of the axillary artery was converted into a fusiform aneurism, the vessels given off from it partaking in the dilatation of their parent trunk. This gave rise to considerable difficulty; a

large vessel was tied, which appeared to be the artery itself; but on the pressure being for an instant relaxed, a gush of blood from another orifice showed that the one just tied was not the upper end of the vessel. The real vessel being now evident was secured. The lower end of the artery, and the dilated origins of some of its branches were tied. Very little blood was lost in the operation. The patient is doing well, but unfortunately there has been gangrene of the hand and a portion of the fore-arm. The ligatures all came away between the twelfth and fifteenth days, so that the success of the operation may be regarded as secured. I hope that a fuller account of this most important case will be published hereafter.

## GENERAL CORRESPONDENCE.

### TRAUMATIC TRISMUS TREATED BY INDIAN HEMP AND CHLOROFORM.

LETTER FROM DR. FRANCIS H. PARSONS.

[To the Editor of the Medical Times and Gazette.]

SIR,—Having read with great interest the report of a case of trismus algidus treated by Indian hemp, by Dr. Fraser, in the *Medical Times* of February 7, I am induced to send you the following case of traumatic trismus, treated in a similar manner, and with a like favourable result. Perhaps you may not think it unworthy of a place in your valuable journal.

#### CASE OF TRISMUS TRAUMATICUS TREATED BY INDIAN HEMP AND CHLOROFORM.

Rosario G., aged 38, a native Hindoo, employed on board ship, applied to me on April 11, 1863, complaining of pain and stiffness of the muscles of mastication, with inability to open his mouth. He stated that about a fortnight previous he had received a blow on the side of the head, which caused considerable pain, followed by slight bleeding from the left ear. His previous health had been good. For some days he had been unable to open his mouth to the full extent. His jaw had now become firmly fixed, and, having taken no food during the last twenty-four hours, he felt faint and hungry. I placed him under the influence of chloroform for upwards of an hour. This caused a sufficient relaxation of the spasm to enable me to insert a cork between the teeth on the right side. The left temporal and masseter muscles were more tense than the right. Fluid nourishment was now given.

April 12.—The bowels being constipated,  $\text{mij.}$  of croton oil were administered on sugar; this was followed by free evacuation of the bowels. He now complained of difficulty in swallowing, pain in the sternum, and a sense of suffocation; he was seized with severe spasms, affecting not only the neck, but the extremities, causing him to fall to the ground. The jaw was almost as firmly fixed as on the previous day. I again placed him under the influence of chloroform. Ordered Ext. Cannabis Indicæ, gr.  $\frac{1}{4}$ ; chloroform,  $\text{m. v.}$ , dissolved in tinct. card. co.,  $\text{ʒi.}$ , to be given every two hours.

14th.—The mouth remained open to a slight extent; he could bring the lower jaw forward so as to make the lower incisors project beyond the upper ones; there was also free lateral motion in the jaw. He could not masticate, but was able to swallow beef tea without pain; the pain in the sternum was less severe, and respiration more easy; the spasms were now very slight.

18th.—The mouth could be opened to the extent of an inch; the spasms had subsided; pain in the sternum gone; respiration easy. The bowels being again costive, ordered another dose of croton oil. The medicine to be given every three hours.

By the 22nd he could eat meat; was free from pain, and able to walk; treatment was discontinued.

P.S.—As regards the small doses of Indian hemp administered, it must be borne in mind that the extract prepared in India direct from the "*Gangah*" is much more active than that made in England. I have seen gr.  $\frac{1}{2}$  administered to a European followed by complete loss of muscular power, sound sleep, and delirium. A period of two hours is generally essential to obtain the full action of the medicine.

I am, &c.

FRANCIS H. PARSONS, C.M., M.D.,  
Surgeon P. and O. Company's Steam-ship Jeddo.  
Bombay, May 14.

## REPORTS OF SOCIETIES.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 9, 1863.

Mr. PARTRIDGE, President, in the Chair.

A PAPER by GEORGE HARLEY, M.D., was read on  
THE ORDEAL BEAN OF OLD CALABAR; ITS ACTION ON THE  
ANIMAL BODY COMPARED WITH THAT OF WOORARA AND CONIA.

The author began his communication by a brief account of the literary history of the ordeal bean. He next alluded to the botanical characters of the plant. It is a long twining shrub, with papilionaceous flowers and leguminous fruit, the kernels of which, both in taste and appearance, resemble the common white haricot bean. The natives call the plant *Eséré*, and it was by the missionaries named the ordeal bean, in consequence of its being given to persons suspected of witchcraft, with the view of discovering their innocence or guilt. The paper was illustrated by diagrams of the plant, specimens of the bean and its preparations; and its effects on the pupil of a human being and of a cat were shown by Dr. Harley. The conclusions drawn by the author are as follows:—1. The ordeal bean may cause contraction of the pupil when taken internally as well as when applied locally. 2. That atropine and the Calabar bean are physiologically antagonistic. 3. That the ordeal bean paralyses the motor nerves, and leaves the intelligence and muscular irritability unimpaired. 4. That it excites the salivary and lachrymal secretions. 5. That it destroys life by paralysing the nerves supplying the respiratory muscles—being, in fact, a respiratory poison. 6. Although it may weaken the heart's power, it neither stops the circulation nor arrests the heart's action. It is not, in fact, a cardiac poison. 7. It is closely allied in its effects to woorara and conia, most closely, perhaps, to the latter; but it differs from both in its tendency to produce muscular twitchings, and in its power of inducing contraction of the pupil. Neither woorara nor conia exert generally or locally any such effect on the iris. 8. The ordeal bean will prove a most valuable addition to the Pharmacopœia, by not only giving us a useful myopic, but also a powerful anodyne, capable of soothing nerve-irritation without either destroying intelligence or endangering life by arresting the heart's action.

Mr. SOELBERG WELLS was somewhat surprised that, in enumerating the peculiar properties of the Calabar bean, Dr. Harley had not called more attention to its singular power of causing contraction of the ciliary muscle, and thus affecting the accommodation of the eye, as this was of far greater importance than its action upon the pupil. The impairment of vision which follows the application of atropine is not due to the dilatation of the pupil, but to the paralysis of the accommodation. This is proved by the fact that if we employ a sufficiently weak solution of atropine, so that the constrictor pupillæ alone, and not the ciliary muscle also, is paralysed, vision will be but very slightly impaired. Now the Calabar bean possesses the peculiar power of not only causing contraction of the pupil, but also of the ciliary muscle, thus changing the normal into a short-sighted eye. It also counteracts the paralysing effects of atropine upon these muscular structures. In a case of rheumatic paralysis of the constrictor pupillæ and of the accommodation (ciliary muscle) of the eye, which he (Mr. Wells) published in the *Medical Times and Gazette* a few weeks ago, the action of the Calabar bean was fully illustrated, and its power of causing contraction of the paralysed parts traced step by step. With reference to this case he might state that it was now all but cured, the pupil having almost regained its normal size, and vision being nearly perfect. He would not, however, attribute too much of this good result to the effect of the Calabar bean, as it was well known that such cases of paralysis of the pupil and the accommodation, more particularly when they occurred after severe illness, often got well of themselves when the patient's health improved. He, however, believed that in this case the Calabar bean considerably accelerated the cure. With respect to the local action of the bean he might remark, that Professor Czermak and he had been trying its effect upon

the eyes of rabbits, directly after decapitation, and that they had found that it produced marked contraction of the pupil within about twenty minutes of its application. He was, however, still engaged upon these experiments, and had hoped to have concluded them before the reading of Dr. Harley's paper before this Society, which he had not expected until the next meeting.

Mr. J. W. HULKE communicated briefly the results of three experiments which had been made with the alcoholic extract of the bean on patients under his care at the Royal London Ophthalmic Hospital, by Mr. Workman, the House-Surgeon. The first patient, a sailor, had paralysis of both third (cranial) nerves, and mydriasis from syphilitic periorbitis. Two hours after the application of the extract to the right eye, the nearest point of distinct vision was sixteen and a-half inches, and the diameter of the pupil was one line, the proximate point having been previously twenty-six inches, and the pupil two and a-half lines broad. In the same time the near point of the left eye had become twelve and a-half instead of twenty inches, and the pupil one line instead of three lines across. The second patient had paralysis of the left third cranial nerve, with mydriasis, of four years' duration, the consequence of traumatic periorbitis with abscess. In one hour the proximate point had become six instead of eight and a-half inches, and the pupil had contracted from three to three-quarters of a line. In the other unaffected eye the application of the extract effected in the same time an alteration of the proximate point from eight and a-half to four inches, and reduced the pupil from one and a-half to three-quarters of a line. The third was a case of paralysis of the left third cranial nerve, with mydriasis from periorbitis, possibly rheumatic, which had been twice previously cured with iodide of potassium. In an hour the proximate point of distinct vision was brought from ten to five inches, and the pupil changed from three to three-quarters of a line in diameter. Mr. Hulke thought these cases confirmed generally the statement of Dr. Robertson, who was entitled to great credit from his practical inquiry into the physiological action of the bean on the eye.

Mr. SPENCER WELLS gave an account of

A PATIENT UPON WHOM OVARIOTOMY WAS PERFORMED TWICE—  
WITH REMARKS.

The author believed that this case was unprecedented, but he has lately learned that Dr. Attee, of Philadelphia, has performed ovariectomy successfully upon a patient from whom Dr. Clay, of Manchester, had removed an ovarian tumour sixteen years before. The patient whose case, before, during, and after operation, is now narrated to the Society, was forty-two years of age. One ovarian tumour was removed in May, 1862; another in January, 1863. The propositions the author believes to be established by the case are—That ovariectomy may be performed twice on the same patient without unusual difficulty. That it may be advisable to make the incision, in the second operation, at some distance from the cicatrix left after the first operation. That whenever one ovary is removed the opposite ovary should be carefully examined; and that in all penetrating wounds of the abdomen the divided edges of peritoneum should be brought accurately and closely together.

Mr. BAKER BROWN said that as he was the Surgeon who had done the first operation, he would make a few observations on the case, which was one of great interest. The patient had been sent to him for operation by Sir Charles Locock. She recovered quickly, and left the house quite well. A few weeks later he again saw her. She had then pain in the other side of the abdomen, and a tumour the size of a fist, and this in a few weeks became larger and more distinct. He (Mr. Brown) recommended that a second operation should be performed. About this time he was ill, and his son saw the patient. The tumour had then increased very much. He afterwards heard that the operation had been performed by Mr. Wells, and that the patient had died. As he had stated, he had himself recommended the operation, and thus agreed with Mr. Wells in his practice. He could, however, scarcely expect that three months after so serious an operation as ovariectomy the patient could undergo a similar one with success. Yet there was no other alternative, as the disease was increasing very rapidly. It was his invariable practice to examine the other ovary, and both he and Mr. Wells had cut open little cysts in the comparatively healthy ovary, and the patients had done well. As to the method of uniting the

wound, there was a considerable difference of opinion. Dr. Clay, who had had a very great experience in this operation, did not think it of great consequence. He (Mr. Brown) did not think it mattered much. Sometimes he included the peritoneum, and sometimes he did not.

A paper, by Dr. ROBERT LEE, was read on

THE INDUCTION OF PREMATURE LABOUR IN CASES OF PREGNANCY COMPLICATED WITH ALBUMINOUS URINE, DROPSY, AND AMAUROSIS.

Dr. Lee related the case of a lady, whom he saw in consultation with Mr. Bowman and Dr. Ferguson, suffering from disease of the retina and albuminuria. From having previously seen a case in St. George's Hospital, in which albuminuria and dropsy, occurring in a pregnant female, had disappeared on the spontaneous expulsion of a dead foetus, Dr. Lee advised the induction of premature labour. This was not at once carried out, but after some delay some convulsion occurred, and it was then determined not to wait any longer. At this time there was amaurosis, albuminuria, and oedema of the face. The membranes having been punctured, labour ensued, and a dead foetus of four months was expelled. After this the albumen gradually diminished, and the vision improved. In a postscript, Dr. Lee reported the particulars of an analogous case, for which he was indebted to Mr. Bowman.

Mr. W. R. BEAUMONT, F.R.C.S.E., Senior and Consulting Surgeon to the Toronto General Hospital, Canada West, gave a description of a

NEW IRIS-FORCEPS.

The instrument consists, like Langenbeck's and Graefe's, of a fixed and a sliding blade, but differs from theirs inasmuch as the point of the hook is not only more concealed, but its concavity is quite filled by the end of the sliding blade when the blades are closed, so that the whole of the piece of the iris taken up by the hook is securely held. The form of the hook is less curved, and rather larger. The author commented on the disadvantages of the instruments used by Langenbeck and Graefe, and stated his belief that the instrument he had invented was free from these. The mode in which his forceps are used was next described; and the paper concluded by the relation of some cases of operation in which the forceps was successfully employed. The newly-invented instrument was exhibited at the meeting.

WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, MAY 1.

Dr. BARCLAY, President, in the Chair.

THE Seventeenth Annual Meeting of this Society was held at their rooms in Sloane-street. The meeting was well attended by members and several visitors. The Report of the Council and Auditors having been read, the following officers were elected for the ensuing year:—*President*—Dr. Barclay; *Vice-Presidents*—Mr. Cumberbatch, Dr. Baines, Mr. J. Lane, Mr. Prescott Hewett; *Treasurer*—Dr. Baines; *Hon. Secretaries*—Mr. W. Milner and Mr. C. Hunter; *Hon. Librarian*—Mr. Thomas Dickenson; *Members of Council*—Dr. Cahill, Dr. Anstie, Mr. Bannister, Dr. Godwin, Mr. Pollock, Mr. Keen, Dr. Fuller, Mr. Rouse, Dr. Martyn, Mr. Brodhurst, Mr. Vasey, Dr. Way; *Auditors*—Dr. Mareet and Mr. Whitmore. The rest of the evening was devoted to the detail of cases and exhibition of specimens.

Dr. MARTYN related a case of

EMPHYEMA, WITH PARACENTESIS—DEATH.

The patient was a boy, six years old, who had been subject to cough from his infancy. The present illness commenced with feverish symptoms, of a typhoid character, nor were there any chest symptoms, except slight cough, till about the fourteenth day, when he had pain in the chest for the first time, and quick breathing. The chest now showed signs of much effusion in the left pleura, there being complete dulness over the greater part of this side, and vocal resonance was entirely absent. The left side now measured half an inch more than the other. There was, however, no bulging between the ribs. On March 16, no improvement resulting from a blister and diuretic medicines, the breathing becoming more rapid and

difficult, with orthopnoea, and Mr. Pollock concurring, the trocar was inserted a hand's breadth below the axilla, a tea-cupful of thick matter escaped, and the breathing was the next day better. Two days after a larger trocar gave vent to about twelve ounces of matter, and again temporarily relieved the symptoms till the 24th, when more fever set in, and the matter on that day had become more offensive. The patient died on the 26th. No post mortem could be obtained.

Dr. MARTYN then mentioned a case of

PERFORATION OF THE STOMACH AND SUDDEN DEATH.

This was in a young female, aged 19, who suddenly, at her tea, was seized with pains in the stomach and attempts to vomit. Half an hour afterwards the pulse was rapid, the face flushed, the belly excessively tender, and there was great pain all over the abdomen. She died in thirteen hours. The stomach, which was exhibited, had a large rounded opening in its posterior wall, near the lesser border; the mucous coat was elsewhere inflamed and thickened. This patient had been treated by Dr. Martyn for ulcerated stomach during some months.

Dr. MARTYN also exhibited the

STOMACH OF A CASE OF OXALIC ACID POISONING.

The patient, a female, aged 44, had been addicted to spirits, and had taken the poison in solution. The stomach had the usual black appearance, and the duodenum was highly inflamed.

Dr. WAY mentioned a case of

PTYALISM FROM THE USE OF TOYS COLOURED WITH RED PIGMENT.

A small unglazed eup, coloured with red paint, was exhibited by Dr. Way, from the use of which a child, 18 months old, had suffered with profuse salivation, with enlargement of the sub-maxillary glands, sponginess of the gums, fissured tongue, and ulcers with herpetic patches on the external surface of the cheek. A sister of the patient suffered in the same way, but to a less extent. The red paint on the cup gave, when examined, evidence of mercury.

Dr. WAY also gave the details of

A CASE OF SUPPRESSED SMALL-POX,

and showed a kidney and portion of the mesentery from the patient, a child two years old, who died from the undeveloped variola. There was great engorgement of the kidneys and of the mesenteric glands. The other viscera were healthy. Four days before death the patient was in good health; symptoms of fever were followed by minute florid papules on the face, limbs, and trunk; these still existed on the third day without a tendency to become vesicles or pustules. Death, apparently from exhaustion, was preceded by petechiæ and bleeding from the ears, but by no convulsion or coma. Two children of the same family were simultaneously attacked with variola, which ran the ordinary course. All the children had been vaccinated in infancy.

LEGAL INTELLIGENCE.

COURT OF QUEEN'S BENCH.—JUNE 12.

(Sittings in Banco; before the LORD CHIEF JUSTICE Mr. Justice WIGHTMAN, Mr. Justice CROMPTON, and Mr. Justice BLACKBURN.)

THE QUEEN V. THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THIS case raised a question of great importance to the Medical Profession (and also to the public, on account of the deep interest they have in the character of that Profession), under the important Act of 1858, "passed to regulate the qualifications of Practitioners in Medicine and Surgery." The question was as to the functions of the Council in regard to registration of Medical Practitioners. The Act imposes on the Council the duty of keeping such registry; and the 14th section provides as follows:—

"It shall be the duty of the registrars to keep their respective registers correct, in accordance with the Act, and to erase the names of all registered persons who shall have died, and shall from time to time make the necessary alterations in the addresses or qualifications of the persons registered under the Act; and it shall be lawful for the registrar to write a letter to any registered person, addressed to him according to his address

on the register, to inquire whether he has changed his residence or has ceased to practise, and, if no answer shall be returned within six months, to erase the name of such person from the register, provided that the same may be restored by direction of the General Council, should they think fit to make an order to that effect."

Another section (28) provides that for certain causes names may be struck off the list. In the present case the applicant, a Mr. Sergeant, was a Member of the College of Surgeons, and had been upon the registry. The registrar sent the usual letter in 1860, and, owing to the applicant's absence, he did not get it, and in April, 1861, the six months having elapsed without an answer, they struck his name off. He did not hear of it until December, 1861, and in November, 1862, he applied to the Council to restore his name. This was not done, and a correspondence ensued, and in the result, in March, 1863, the Secretary intimated that it would be referred to the General Council, which only met once a year. They met on May 26 last, and referred the matter to the Executive Committee, who were ready to consider the application on being satisfied as to character and qualification. The real question was whether the Council had any authority to entertain this question, or were under an absolute duty to restore the name.

Mr. Henry James had, on the part of the applicant, obtained a rule for a *mandamus* to the Council to register his name, or to hear and determine the matter.

Mr. M. Smith, Q.C., and Mr. Horace Lloyd, appeared on the part of the Medical Council to show cause. The Council, they said, were under this difficulty, that by the Act they could only meet once a year, and had now referred the matter to the Executive Committee. This was done at the next annual meeting after the application.

The Lord Chief Justice said he thought it could not be contended for a moment that the Council could arbitrarily refuse to re-enter the name of a Practitioner merely on account of the miscarriage of a letter through his accidental absence; and it was not reasonable that the question of a re-entry of his name should be hung up for nearly a year. Surely, the Council should meet oftener for such purposes.

Mr. M. Smith said they had now delegated such matters to the executive committee, which sat permanently; and were now ready to hear and determine the matter.

Mr. Henry James, on the part of the applicant, said he insisted that the Council had no right, in such a case of a mere accidental omission from the registry, to enter into any inquiry into character, but were bound absolutely to re-enter the name; but

Mr. Justice Wightman pointed out that there could be no *mandamus* to the Council to register, because the duty of registry was on the registrar. The duty of the Council was to hear and determine the matter.

Mr. Horace Lloyd referred to the case of Mr. Bell against the Pharmaceutical Society, in which it had been so held.

Mr. James still urged that the Council in such a case had no right to enter into any inquiry as to character, etc.; but

The Lord Chief Justice pointed out that the words of the Act were "if they shall think fit," and thus implied that they were to exercise some judgment.

Mr. Justice Crompton said it could not be contended that the Council could not consider under what circumstances the applicant in such a case had been absent or abroad, as they might have been disgraceful, though it might not be so in this case; yet they could not be precluded from inquiry into that matter.

The Court said the applicant could not possibly be entitled to more at present than a *mandamus* to the Council to hear and determine the matter, and that they were ready to do, it appeared, without a *mandamus*. If, indeed, they decided against him on a wrong ground, there might be a ground for a *mandamus* to register; but it could not be anticipated that they would decide wrongly, and therefore, though the rule for a *mandamus* might be made absolute, the writ need not issue unless the decision should be adverse to the applicant, and he should desire to have the ground of the decision considered.

**VIENNA UNIVERSITY.**—It is intended, in the year 1865, to have a grand celebration of the 500th anniversary of the Vienna University, at the same time that the International Exhibition is held in that capital. Invitations are to be addressed to all the Universities and scientific institutions of Europe.

## MEDICAL NEWS.

**ROYAL COLLEGE OF PHYSICIANS OF LONDON.**—At a general meeting of the Fellows, held on Saturday, June 13, the following gentlemen, having undergone the necessary examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—

Edward Sutcliff, 1, Champion-grove, Camberwell; William Henry Fleetwood Buckle, Royal Mint; James Davy Rendle, M.D. St. Andrews, Brixton-hill; William Henry Embling, 30, Oakley-square, Regent's-park; Keith Norman Macdonald, Bath; William John Hunt, Hathersage, near Sheffield; and Alfred Rickards, Armley, near Leeds.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following Members of the College, having undergone the necessary Examinations for the Fellowship on the 26th, 27th, and 28th ultimo, were reported to have done so to the satisfaction of the Court of Examiners, and at a Meeting of the Council on the 12th inst. were admitted Fellows:—

John Thompson, Bideford, Devon, Diploma of Membership dated November 4, 1842; Frederick James Brown, Rochester, November 1, 1844; Edward Lund, Manchester, April 9, 1847; Victor de Meric, Brook-street, Grosvenor-square, June 11, 1847; James Rouse, Coleshill-street, April 11, 1851; John Edward Tuson, H.M. Indian Army, April 25, 1851; William Carr, Gomersal, October 26, 1855; George Frederick Helm, Cambridge, January 14, 1859; Frederick Marsdin, Staniforth, March 2, 1859; Walter Rivington, Upper Holloway, March 18, 1859; William Fairlie Clarke, Cuzon-street, May-fair, January 30, 1862.

At the same Meeting of the Council, the following Members of the College, who had been elected Fellows at previous Meetings of the Council, were admitted as such:—

Thomas Spry Byass, Cuckfield, Sussex, Diploma of Membership dated August 7, 1829; Thomas Edward Eden, Brighton, March 27, 1835; John Henry Hutchins, Rochester, September 2, 1831; George Lowe, Burton-on-Trent, May 5, 1837; Charles Edmunds Thomson, Ross, June 13, 1828.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, June 11, 1863:—

John Harman, Canterbury; Thomas Evans, Llandrussyl, Cardiganshire; William Laidlow, Newcastle-on-Tyne; Thomas Creswick Jackson, 24, Wimpole-street.

As an Assistant:—

John Kilshaw Kenyon, Liverpool.

**PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.**—The following Candidates passed the Major Examination as Pharmaceutical Chemists on June 17:—

Christopher Alcock, Nottingham; John Bourdas, London; Samuel R. Broughton, Wrexham; Marcel A. Gras, Mauritius; Thomas Grundy, London; Louis E. Guiot, Mauritius; Etienne N. Merle, Mauritius; William Thos. Trollope, Yarmouth.

### APPOINTMENTS.

\* \* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

CHRISTIE, JOHN, M.D. Aberd., has been elected Medical Officer to the Aberdeen Dispensary.

JORDAN, MYLES J., L.K.Q.C.P.L., has been elected Medical Officer to the Union Workhouse, Castlebar, County Mayo.

LAKIN, JAMES H., M.B. Lond., has been appointed Surgeon to the Lying-in Charity, Sutton Coldfield.

LITTLE, D., M.D., has been appointed House-Surgeon and Secretary to the Eye Hospital, Manchester.

ROUSE, T. M., has been elected Junior House-Surgeon to the West London Hospital.

WOLFE, JOHN R., M.D. Glasg., has been elected Surgeon to the Aberdeen Ophthalmic Institution for Diseases of the Eye.

### DEATHS.

COATES, JOHN, at South Yarra, New South Wales, on March 15, aged 51.

HODGES, THOMAS, M.R.C.S.E., at 104, Guildford-street, Russell-square, on June 11, formerly of the H.E.I.C.S.

JOHNSON, W. H., M.R.C.S. Eng., at Clarendon-street, Dublin, on June 2.

NEWTON, WILLIAM, M.R.C.S. Eng., at Newcastle-on-Tyne, on May 30, aged 44.

PEARSON, JOHN ARMITAGE, F.R.C.S. Eng., at Buxton, Derbyshire, on June 6.

RHIND, R., Assistant-Surgeon Bengal Army, at Fort William, Calcutta, on May 4.

**THE LONDON HOSPITAL.**—Mr. Hutchinson has been unanimously elected Surgeon to this Hospital, a vacancy having been caused by the resignation of Mr. Critchett. Mr. Hutchinson's promotion will make a vacancy in the staff of Assistant-Surgeons, and we understand that Mr. Walter Rivington is a candidate for the latter appointment.

**HEALTH OF THE KING OF THE BELGIANS.**—Nous tenons d'une source certaine que la santé du Roi a éprouvé dans ces derniers temps une amélioration notable. Les dernières opérations ont été exécutées par M. Henri Thompson, Chirurgien de l'Hôpital de l'Université de Londres, et qui a été recommandé au Roi par S. M. la Reine Victoria.—*L'Indépendance Belge*, June 14.

**SIR CHARLES LOCOCK.**—On Tuesday morning Sir Charles Locock sustained a serious accident by a fall from his horse. It appears that he rode on horseback in Rotten-row during the morning, and on his return to his residence at the corner of Hertford-street, Park-lane, his horse suddenly stumbled, and threw him with some violence, and then rolled upon him. Assistance was promptly rendered, and Sir Charles was extricated as soon as possible, and taken into his residence. Upon examination, it was discovered that the injuries consisted of a fracture of the right arm just above the elbow, and much straining of the muscles of one of his legs. We are happy to say that the result of inquiries at the house last evening was that Sir Charles was in no danger, and progressing very favourably.

**HOSPITAL FOR SICK CHILDREN.**—The eleventh anniversary festival of this institution was celebrated on Tuesday, the 9th inst., at the Albion Tavern, Aldersgate-street, the Right Hon. the Earl of Shaftesbury, K.G., in the chair. The subscriptions and donations announced amounted to upwards of £1000, of which 40 guineas were new annual subscribers.

**SPECIALTIES IN GENERAL HOSPITALS.**—The Medical Board of the Bellevue Hospital, New York (one of the largest in the world), has recommended that wards should be opened for the following specialties:—Diseases of the eye and ear, skin, nervous system, and orthopædia. Two Physicians and Surgeons are to be appointed for each division.

**FARRELL v. POUND.**—The widow of the man Farrell, who, it will be recollected, was killed by oxalic acid sold in mistake for Epsom salts at the shop of Mr. Pound, druggist, in Leather-lane, Holborn, has, in an action brought against Pound, at Westminster, on June 13, recovered damages of £100 in compensation for the loss of her husband.

**THE MEDICAL AND CHIRURGICAL SOCIETY.**—The Fellows of this Society have been summoned to attend a special general meeting on Tuesday next, for the purpose of removing Evan Thomas, of Manchester, from the Fellowship of the Society. It will be recollected that this person was convicted of perjury at the last assizes, and sentenced to imprisonment.

**THE Croonian Lecture on the Coagulation of the Blood** was delivered before the Fellows of the Royal Society by Professor Lister, F.R.C.S. Eng., of Glasgow, on the 11th inst.

**CAPTAINS SPEKE AND GRANT** arrived at Southampton on Wednesday, the 17th inst.

**AN extra evening meeting of the Royal Geographical Society** will be held at Burlington House on Monday, the 22nd inst., at nine p.m., to receive Captains Speke and Grant on their return from Africa.

**PRESENTATION OF A TESTIMONIAL TO MR. GRAINGER.**—A meeting of the subscribers to the Grainger Testimonial took place at the London-bridge Terminus Hotel on the 4th instant, at 4 p.m., to present an address to Mr. Grainger commemorative of his disinterested liberality in founding the Grainger Prize for Physiology at St. Thomas's Hospital. Dr. J. R. Bennet occupied the chair, and delivered a glowing eulogy on the veteran teacher, and Medical and sanitary reformer. Mr. Grainger acknowledged the honour done him in an eloquent speech. A vote of thanks to the chairman was proposed by Mr. F. Le Gros Clark, and seconded by Mr. T. Carr Jackson.

**ALLEGED NEGLIGENCE OF A MEDICAL OFFICER.**—Under this title there appeared in the *Evening Standard* of June 12 an account of an inquest held by the Deputy-Coroner for Middlesex, on the body of a man named George Knowles. Deceased was a drayman, and on Whit-Monday last received

an injury to his leg by slipping off his dray. He kept his bed until Wednesday, the 3rd, when his wife came home and found him much worse. She, with a lodger, went to the workhouse, and they were referred to Mr. Bletchley, the parish Surgeon. They went to Mr. Bletchley's, who refused to go at that time, on the ground that they had brought no order. It appeared from the evidence that it was late at night, that Mr. Bletchley was much engaged at the time, and that he was not bound to attend without a written or printed order. The women were very abusive. The man died shortly after without Medical attendance. The verdict of the jury was simply one of accidental death. Ten of their number, however, wished a censure to be passed on the Surgeon, but to this there were two dissentients. A censure would have been most certainly unjust. Mr. Bletchley was clearly not under legal obligation to go. At the same time, we may repeat what we have often said before, that if our Medical brethren value their own peace of mind and good names they cannot safely refuse their services under any circumstances short of those which produce utter inability.

**COLLEGIATE ELECTIONS.**—(From a Correspondent.)—The forthcoming elections of Fellows into the Council of the Royal College of Surgeons promises to be a spirited one, as there are six candidates for the three vacant chairs caused by the resignation of Mr. Coulson and the retirement in the prescribed order of Messrs. Hawkins and Tatum, who, however, offer themselves for re-election. The following is a copy of the particulars supplied to each Fellow of the College, from which he will have to make his selection:—Mr. Samuel Armstrong Lane, of Grosvenor-place, nominated by Messrs. W. White Cooper, Edward Cutler, Alexander Ure, Henry Lee, George Pollock, and H. Spencer Smith. Mr. George Busk, of Harley-street, nominated by Messrs. John Simon, Prescott Hewett, Charles Hawkins, James Paget, James Dickson, and George Pollock. Mr. Thomas Blizard Curling, of Grosvenor-street, nominated by Messrs. James Paget, Prescott Hewett, George Critchett, Jonathan Hutchinson, T. P. Teale, and J. E. Erichsen. Mr. Henry Hancock, of Harley-street, nominated by Messrs. Francis Hird, Edwin Canton, Henry Smith, Richard Barwell, Henry Power, and Sir J. W. Fisher. These gentlemen are all Hospital Surgeons and good men, and it remains to be seen which has the greatest interest to displace Messrs. Hawkins and Tatum, and to secure the chair vacated by Mr. Coulson. His Hospital colleague, Mr. Lane, appears to be a great favourite, and is receiving the support of two of our contemporaries. It would appear to be the opinion of several distinguished Fellows that new blood should be occasionally infused into the Council, judging from the list of those nominating candidates, more especially with reference to Messrs. Paget, Hewett, and Pollock, who each nominate two new candidates, and as the two first-named are ex-professors of the college, it is rather significant. The Fellows will no doubt admire the independence of these gentlemen. But what are the provincial voters about? It was generally expected that Mr. Turner, of Manchester, would have come forward. Where is Mr. Teale, of Leeds, Mr. Wiblin, of Southampton, who have made reputations beyond their own localities,—are deservedly well known in this metropolis, and in these days of railways and telegrams—annihilators alike of time and space—they would be placed on nearly an equal footing with the London councillors. So little interest do the provincial fellows appear to take in these elections, that, with the exception of Mr. Teale, not one has even signed a nomination paper. With regard to the approaching election it will be more difficult than usual to diagnose the result; some of the knowing ones state that a coalition is formed of the friends of the first three candidates, viz., Messrs. Hawkins, Tatum, and Lane, to bring in these gentlemen, and as all three are or were connected with St. George's Hospital, there is no doubt but that they will receive considerable support. The more scientific portion of the Fellows will support Mr. Ex-Professor Busk, and although Mr. Hancock appears last in chronological order, he appears a decided favourite, and is coming, if a sporting phrase may be allowed, well into the betting. The election will take on Thursday, the 2nd proximo, and in the evening the Fellows will dine together at the Albion Tavern, under the presidency of Mr. Turner, of Manchester, when, judging from the unusually large number of stewards, the party will be a very large one.

**DU CHAILLŪ'S COLLECTION.**—The Museum of this indefatigable explorer has just been dispersed by auction, and one of the most valuable lots, viz., 93—described as a magni-

ificent series of gorillas, male, female, and young, in fine condition, the two adults having been beautifully prepared by Mr. Wilson, the eminent taxidermist—was knocked down to a private member of our Profession, Dr. Edwards Crisp, M.R.C.S., for the large sum of £110, being much below its real value. Mr. Flower, the Conservator of the Hunterian Museum, and Professor Clark, of the University of Cambridge, made judicious purchases for their respective collections; several specimens also went to the University of Oxford.

**SUDDEN DEATH OF JOHN ARMITAGE PEARSON, ESQ., F.R.C.S.**—On Saturday, the 6th inst., the above-named gentleman appeared in his usual health and spirits, and in the afternoon went to dine with his friends, Dr. Sheridan Muspratt and Mr. J. L. Hutton, of Liverpool, at St. Ann's Hotel. At dinner, Mr. Pearson was about to take a glass of wine, when he could not grasp it—he stretched forth his other hand with a like result, and immediately became insensible. Dr. Robertson and Mr. Shipton were instantly sent for, but in a few minutes he ceased to breathe, death being caused by apoplexy. This sudden and melancholy end of one so well known created a deep sensation, and cast a gloom over the whole town, being a great shock to all who witnessed it. Mr. Pearson, formerly of Woolton, near Liverpool, had resided and practised in Buxton during the last eight years. He was one of the Medical staff of the Devonshire Hospital, and was twice elected a member of the Buxton Local Board. His remains were interred at St. John's Church, on Thursday.—*Buxton Advertiser*, June 13.

**TESTIMONIAL TO DR. CHADWICK, OF BOLTON.**—We have great pleasure in announcing that the articles forming the testimonials to Dr. and Mrs. Chadwick are now complete, and for several days have been on view to the subscribers, at Mr. Monk's, jeweller, Deansgate. The testimonials consist of a beautiful silver candelabrum, a splendid silver salver, and a handsome dressing-case, with toilet service complete. The candelabrum is for three lights, and is richly embellished with ornamental foliage. The base of the stand is round, and in the main part its dimensions are thirteen inches diameter. The stand is neatly engraved, and has a plateau richly chased. In the front the following inscription, commemorative and explanatory of the purpose of the testimonial, is engraved in ornamental letters, with flourishes:—"Presented (with other plate) to Samuel Taylor Chadwick, Esq., M.D. Edinburgh, F.R.C.S. England, J.P., etc., in testimony of the grateful appreciation of the inhabitants of Bolton and the neighbourhood, of his long-continued and valuable services as a learned Physician and skilful Surgeon, and of his gratuitous devotion of time and ability to the poor of Bolton. May 13, 1863."—*Bolton Guardian*, June 13.

**A SHAM "DR."**—At the Hartlepool Police-court, on Tuesday, Thomas Hetherington was summoned, at the instance of the Secretary to the Hartlepool Medical Registration Association, for using the title of "Dr.," thereby implying that he was recognised by law. It was stated that defendant had a large brass plate on his door with "Dr. Hetherington's Private Dispensary" thereon; that he circulated bills under the same title; that he had no qualification for such title, and was not in the Medical Registry. Mr. Marshall, for the defence, said the prosecutor had not proved whether his client was in practice as a Surgeon before 1815; that he was not the holder of a diploma from any foreign body or otherwise; and that "Dr." did imply doctor of medicine. He read some cases which had been heard before the Queen's Bench, in which parties had been convicted by magistrates for adding Surgeon to their names, and that such appeals had been decided in their favour.—The Bench said they were of opinion that "Dr." had been evidently used to imply he was a Doctor of Medicine, and not having his name registered as such, they fined him £5 and costs, or two months' imprisonment.—Mr. Marshall applied for leave to state a case at Queen's Bench, which was acceded to.—*Leeds Mercury*.

**ON RE-VACCINATION.**—M. Vleminckx, the distinguished Medical Director of the Belgian army, has been for some years past engaged in investigating the subject of re-vaccination, and the following are the conclusions he has arrived at, based upon 2000 re-vaccinations performed with the greatest care:—1. The re-vaccination of well vaccinated subjects generally produces but very slight useful effect. 2. Re-vaccination is much more called for in the case of persons who have had the small-pox than in those who have been vac-

inated. 3. Re-vaccination is more successful in proportion to the length of time that has elapsed from the period of the first vaccination or an attack of variola. 4. Prior to the age of 25 re-vaccination is generally useless. 5. From that age until the 35th year, it gives rise to useful results in a certain number of individuals, but still in an exceedingly limited number, so that, without proscribing it, it should not be very strongly recommended. 6. After the age of 35 it becomes truly a preservative, and consequently necessary. 7. When it gives rise to no result on a first occasion, this is no reason why it should not be resorted to at another epoch, there being no proof that the receptivity may not have become developed in the period between the two operations. 8. The re-vaccination of pupils of schools and seminaries is useless. 9. The same may be said respecting the soldiers of the Belgian army. These conclusions were arrived at by M. Vleminckx in 1858, and none of them were shaken by the results of other investigations conducted on a large scale in 1861-62; and an epidemic of variola which broke out in East Flanders in 1862 has still farther confirmed their accuracy.

**TRANSMISSION OF SYPHILIS BY VACCINATION.**—An able writer in the *Presse Méd. Belge* (No. 25) strongly protests against the fashion, which now seems to be prevailing, of adopting every case, however defective in its particularisation, brought forward in proof that syphilis can be propagated by vaccination. A careful examination of these cases fails to exhibit a single instance in which the syphilitic infection, if syphilitic it be, which in many cases is doubtful, may not have been conveyed by other means. Dr. Max thinks he has clearly shown that the famous Rivalta cases were quite destitute of satisfactory proof of their syphilitic nature; and his objections have been supported by observers of the highest authority, as Sperino, Cullerier, and Ricord himself. In Belgium, at all events, these Rivalta cases had been buried in well-deserved oblivion, the faith in the efficacy and safety of vaccination being in no wise shaken, when the Profession was startled by the announcement that Ricord had become converted into a believer in the reality of vaccino-syphilitic inoculation by a case brought before the Academy of Medicine by Devergie. This is preposterous, for the case is acknowledged by its own relater as devoid of all particulars requisite to ensure its accuracy, and has been referred back in order that such may be sought for. That an observer of thirty years' experience, and so incisive a critic as M. Ricord should, upon such slight grounds, abandon his views—so recently announced—is indeed incomprehensible, and is much regretted by reason of the temporary triumph thus given to erroneous conclusions. Vaccinal syphilis has been hastily admitted as an acquired certainty, long experience, common sense, and the absence of well authenticated facts notwithstanding.

**BARBER-SURGEONS AND THEIR HALL.**—The pole, which even now, in country places, projects over the shaver's shop door, indicated at first that persons might be bled there, as the patient, when phlebotomy was performed, grasped a tall rod, to keep the arm steady. Of course clever men soon appeared amongst the barbers, and in no long time began to practise as Medical men—on the whole, no doubt, with advantage to the humbler classes; their right to do so was quickly recognised by custom, and Henry VIII. granted them a charter of incorporation, which for several centuries was the sole document which made their occupation legal. On entering from Monkwell Street, the building shows signs of neglect and disrepair, and first you come into a rather spacious hall, which is not often used, and, though elegant in its proportions, is bare and dirty. Quitting this, you enter an inner hall, probably sixty feet long by thirty wide, full of objects of the highest interest. There are several windows at the back, but the light is principally derived from a circular lantern in the centre, and this is a singularly beautiful specimen of the architect's talent. It is very lofty, and is encrusted at every point with exquisitely delicate carvings of fruit and flowers in every possible variety, "not done in plaster," said our cicerone, "but cut out of the solid wood." The walls are covered with extremely fine original paintings, and they look wonderfully fresh and well preserved, scarcely any of them showing the slightest appearance of decay.—*London Scenes and London People*.

**SUPERNUMERARY FINGERS.**—M. Gaillard, Surgeon to the Hôtel Dieu, Poitiers, states that he has met with three varieties of this deformity. 1. The finger is only bifid, articulating with the metacarpus by a single head. 2. Two

fingers are placed in juxtaposition, being articulated side by side, only one articular capsule surrounding the head of the metacarpal bone. The author met with the case of a young child which exhibited four thumbs and four toes (all the children of the family having this deformity). Two thumbs were removed, leaving *in situ* the articular apophysis of the supernumerary thumbs. 3. The supernumerary finger is entirely isolated and implanted on a special articular surface of the metacarpus, the superfluous part almost always being a thumb or great toe. This is the rarest variety, and M. Gaillard relates an example occurring in the person of a tailor, who wished the thumb to be removed in consequence of the obstruction it caused him in his occupation. The synovial membrane of the additional thumb had no communication with that of the normal one. Disarticulation was performed, and although the healing of the wounded surfaces was tedious, the case did very well, the man being well contented to get rid of his incumbrance.—*Gazette Med.*, 1862. No. 43.

## BOOKS RECEIVED.

On the Occurrence of the Malignant Pustule in England. By Wm. Budd, M.D. London: Richards. 1863.

\*.\* A curious and valuable collection of facts. We have several times called the attention of our readers to the significance of flies, *i.e.*, the presence of these pests is proof that there must be some organic matter at hand on which they fed whilst in the shape of maggots, and in which the larvae were undisturbed. Still more does Dr. W. Budd show the manner in which they may be considered as propagators of disease.

Parturition without Pain or Loss of Consciousness. By James Townley, M.R.C.P. Ed. London: J. W. Davies. 1863.

\*.\* The substance of this book is alleged to be a reprint from the *Lancet*. It is perfectly worthless in itself, and is garnished with a series of puffing testimonials from women, which (if genuine) do little credit to the writers, and less to the author, contrivers, and publisher of this not first-class book.

The Third Annual Report of the Acclimatisation Society of Great Britain, Ireland, and the Colonies. 1863.

\*.\* This Society is doing well. It has a good balance at its banker's, and its members are now fairly working out the difficulties of the problems before them. Difficulties there must be, and some failures. The Chinese sheep possess wonderful fecundity, even when crossed, and are described as good sucklers; but they require to be very well fed. Of course they do, for *ex nihilo nihil fit*. They also have very tender feet, a malady which the lambs show at a month old, and which Lord Powerscourt's steward cannot cure even "by dressing with the most approved compositions." If we had to treat such a malady in the human subject, we should prescribe greater variety or quantity of food, or both. Some kinds of deer, and the Moufflon, or Sardinian sheep, thrive at Powerscourt; not so the Eland. "The climate of Ireland," says his lordship, "is, I think, too damp for the Antelope tribe, as I had two pairs of Nylghaie, all of which died sudden deaths, the animal being apparently healthy in the evening, and found dead next morning. These Nylghaies were all examined after death, and the only verdict given by a Medical man was slight congestion of the lungs, and death from the excessive wet. My experience is, that many of these animals will bear a very great amount of dry cold without harm, but wet, *continual* wet, as is proverbially the case in Ireland, makes it an unfavourable climate for experiments with tropical animals. It stands to reason, as far as I see, that the Eland, an animal inhabiting, in his native country, dry, sandy deserts, and able to live without water for days and weeks, and having a capacity of containing his supply of water like the camel, is an animal difficult to accustom to a climate where it rains four days in the week!" Mr. Grantley Berkeley speaks hopefully of the Prairie Grouse, Brazilian Geese, and Pintailed Duck. But besides birds fit for the table, we are promised some which will be of singular use—the Trumpeter Bird, from Central America. "These fine birds, which are expected to breed well in this country, are easily domesticated, and become attached to the human race in a most extraordinary manner. In their own country they will trustily watch a house, like a dog, and they give warning of danger by an arrangement in the windpipe which enables them to give forth a trumpet-like sound—whence the name. The Trumpeter Bird may also, it is said, be trained to watch a flock of poultry, and even to shepherd a flock of sheep. It possesses great courage, and is beautiful in form and colour." Of fish there is nothing to add to our report of Mr. Buckland's late lecture. The prosperity of the Ailanthus silkworm seems to promise that ladies shall, in time, grow their silk dresses in their own gardens. Amongst vegetables, the Chinese Yam seems to require a good deal more study and experiment; the arrowroot and certain pease do not promise much, but the Bunch Grass, an importation from the Mormon district of North America, may probably prove to be a capital crop for sandy and desolate pastures at home. We strongly advise our country friends who have gardens to join the Acclimatisation Society.

The Aural Surgery of the Present Day. By Dr. W. Kramer. Translated by Henry Power, M.B. Lond. London: New Sydenham Society. 1863.

A Year Book of Medicine, Surgery, and their Allied Sciences, for 1862. London: New Sydenham Society. 1863.

Atlas of Portraits of Diseases of the Skin. Fasciculus Third. New Sydenham Society. 1863.

## NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—*Bacon*.

Dr. J. Henderson, Shanghai.—*Cyropædia*, undoubtedly.

Dr. Gervis.—We should have been happy to have inserted the Report, but it is dated June 4, and, in this busy age, things are soon forgotten.

"Constitutional Tendency."—Captain R—, a naval officer of high character, was compelled, by painful indications of nephritic disease, to call one morning on an eminent Physician. Sir Henry listened with deep concern to the captain's symptoms, looked at his tongue, and felt his pulse, but drew his conclusions chiefly from the captain's rubicund nose. "For the next two or three months," said Sir Henry, "I must beg you to abstain entirely from wine, and from all spirituous and fermented liquors." "From beer and spirits, if you like," said the captain; "but after dinner I must have my glass of wine. I can't do without my glass of wine." "You really must do without it," replied Sir Henry, "if you wish to get well." "Get well, Sir Henry?" answered the captain. "Why, I came to you, expecting you would give me something to make me well. I can't do without my glass of wine." (N.B.—The glass of wine, without which the captain could not do, was a glass out of the second bottle.) Sir Henry, finding remonstrance vain, gave a general turn to the conversation, and presently the captain rose to take leave. Sir Henry, with extraordinary courtesy, attended him towards the front door. While they were passing through the hall, Sir Henry, as if struck by a sudden thought, paused opposite the door of his front parlour. "By the by, Captain R—," said he, "this is my museum. Perhaps you would like to walk in and take a look. There are some curious things." They entered. The museum consisted entirely of anatomical preparations, made by Sir Henry himself. The captain looked first at one, then at another, with interest, but also with awe, such as others have felt under similar circumstances. "Now this," said Sir Henry, taking down a bottle which contained something preserved in spirits, and placing it in the captain's hands, "is the kidney in its healthy state." The captain surveyed it with much gravity. "This," said Sir Henry, taking down another bottle, "is a kidney in that state of incipient disease in which yours is at the present time." The captain viewed it with comical concern. "This," continued Sir Henry, taking down a third bottle, "is what your kidney will be a few months hence." The captain stood aghast. "And this," added Sir Henry, taking down a fourth bottle, "is what your kidney will become in its last and fatal state." The captain bolted! However, the captain gave up his glass of wine, which he couldn't do without, and, thanks to Sir Henry's original mode of dealing with a refractory patient, recovered his health. Nevertheless, the captain used always to maintain that he had a "constitutional tendency" to nephritic malady; in support of which thesis he was accustomed to state that his father the admiral had a tendency to the same form of disease. I can just remember the admiral, and of one thing I have a perfect recollection—the admiral, like his son, had a very red nose.—*Blackwood's Magazine*.

### BETHLEHEM AND ST. THOMAS'S HOSPITALS.

A deity in the shape of Sir George Grey, with Lord Shaftesbury and the Commissioners of Lunacy in his train, has at last interposed to expedite the negotiations between the Governors of Bethlehem and St. Thomas's. Whatever be the logic of establishing one Hospital on the site of another, which has just been pronounced by the Home Secretary unfit for its purpose, it is something to know that at least there is a probability that this lunatic Hospital will be erected in pure air away from the din and excitement of the city. The authorities of St. Thomas's, however, are by no means unanimous in desiring the site of Bethlehem. The Medical staff are said to be in favour of a piece of ground, to be reclaimed from the river, opposite to the new Palace of Westminster; and a deputation from the Grand Committee of St. Thomas's had, on Wednesday, the 17th, an interview with the Thames Embankment Committee for the purpose of discussing the subject. The following are the official letters on the subject of the removal of Bethlehem:—

"The Royal Hospitals of Bridewell and Bethlehem.

Whitehall, June 9.

"Sir,—I am directed by Secretary Sir George Grey to transmit to you, herewith, a copy of a letter which has been received from the Commissioners in Lunacy, stating their views in reference to the question of the purchase of Bethlehem Hospital by the Governors of St. Thomas's Hospital, and the removal of the former institution to a healthy and suitable locality in the neighbourhood of London: and I am to request that you will submit the same to the Governors of Bethlehem Hospital, with the expression of Sir George Grey's concurrence in the views of the Commissioners in Lunacy, and of his hope that the Governors will carefully consider the subject of the unfitness of the present site and buildings of Bethlehem Hospital for the purposes of the institution, and not allow the opportunity now offered of removing the Hospital to a suitable locality to escape.

"I have the honour to be, Sir, your obedient servant,

"H. WADDINGTON."

"The President of Bethlehem Hospital, &c."

"Office of Commissioners in Lunacy,

"19, Whitehall-place, June 3.

"Sir,—The Commissioners in Lunacy have watched with much interest the proceedings and discussions which have for some time past been before the public in reference to the question of the purchase of Bethlehem Hospital by the Governors of St. Thomas's, and the removal of the first-named institution to a healthy and suitable locality in the neighbourhood of London. It was the earnest hope of the Commissioners that the pro-

tacted negotiations which have so long occupied the attention of the promoters and well-wishers of both those important and wealthy charities would ere this have eventuated in an arrangement so desirable, and recommended by such obvious considerations of the great benefits which would thence be derived by the unfortunate objects of the respective institutions.

"It is, however, with Bethlehem Hospital and its insane inmates that the Commissioners are specially concerned, and it is with the view, ere it be too late, of urging upon the Governors the expediency and duty of availing themselves of the present favourable opportunity to give the insane the advantages of pure air and cheerful scenery, so essential to health, mental and bodily, that the Commissioners are induced to address to Secretary Sir George Grey the present communication.

"It has for many years been the opinion of the Board that the site of Bethlehem Hospital, as respects its limited extent and situation, in the centre of a dense and rapidly increasing population, is most unsuited to the due Medical care and treatment of the insane, for whose sole benefit the administration of its ample property and income is intrusted to the Governors. Outdoor exercise and recreation, and freedom from disturbance and observation, so indispensable to the proper treatment of insanity, especially in its earlier stages, require an ample extent of grounds and gardens within the boundaries of the institution. In all these respects Bethlehem Hospital is essentially defective, and the Commissioners are unwilling to believe that the Governors can have finally closed the door against the offer of an eligible site in the country, and within a convenient distance of London, of which they have it in their power now to avail themselves.

"The views above expressed have always been entertained by the Commissioners, and were embodied in a communication to Mr. Secretary Walpole as far back as November, 1858; wherein, with reference to a collateral question, the Commissioners adverted to the consistency of the opinion conveyed with the reasons they had given for suggesting the removal of Bethlehem Hospital from its present populous locality into the country."

"The observations above made have been confined to the question of the site; a most important objection to Bethlehem Hospital, as a place for the treatment and cure of insanity, remains to be noticed, viz., the unfitness, according to modern opinions, of the building in respect to its construction and arrangements. The general aspect of the Hospital, externally and internally, notwithstanding the efforts made within the last few years to enliven the long corridors and day-rooms, cannot but exercise a depressing influence upon the inmates, whose means of out-door exercise are so limited and inadequate. The Commissioners, in the case of asylums for pauper lunatics, would never sanction plans upon the principle of Bethlehem Hospital.

"The new Hospital, which the Commissioners still trust will be built in the country, will of course be constructed upon a plan embodying all the improvements suggested by modern experience and the advanced state of science.

"The large funds at the disposal of the Governors confer upon them almost unprecedented means of improving the care and treatment of the insane, and, consequently, impose upon them, in an especial manner, the duty and responsibility of applying those funds in the manner best calculated to promote and extend the objects and benefits of the institution, which cannot be done upon the present site. The opportunity now offered to remove the Hospital to a suitable rural locality may never occur again.

"It will be for Sir George Grey to consider in what way effect can be best given to the views which the Commissioners have thus endeavoured to bring under especial notice, and in the greatness and importance of which they doubt not he will concur. I am, &c.

"W. C. SPRING RICE, Secretary.

"H. Waddington, Esq., Home-office."

THE VALUE OF THE ST. ANDREWS DEGREE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you have the kindness to answer the following question, whether, in the appointment of a Physician to an Infirmary, an M.D. of St. Andrews, taken under the new regulations this year, is not equal, so far as Medical qualifications go, to the same degree taken at London or any other University. I am, &c.

M.D. ST. AND.

[\* \* \* Yes. —ED.]

THE PERMANGANATE OF POTASH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I shall be greatly obliged if some one of your chemical readers will enlighten me in your pages on the value and mode of use of the permanganate of potash. 1. As a disinfectant; naming the colour change in the solution. 2. As a test for the existence of organic impurities in water. And further, as an individual pestered beyond measure by beetles and crickets, I should like to know some agent for their destruction. I am, &c.

HABITANS IN FANO.

SMALL-POX IN PREGNANT AND IN PARTURIENT WOMEN.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—My experience during the present epidemic of small-pox tends so far as it goes to favour the idea that in this disease an exception must be made to the rule laid down by Dr. Simpson and others regarding the eruptive fevers in the puerperal state.

During the last few months I have met with three cases of small-pox in my own practice where the eruption appeared from two to five days after confinement, and I have been informed by Medical men here of three others which have occurred to them. All these were mild cases, and made good recoveries. Another case, however, which probably ought to come under this head, proved fatal. The patient was first seen by a Medical man on the fifth day after delivery; the eruption then appeared to be four or five days old, but the friends had not noticed it until the day before she was visited.

On the other hand, I have had one case where the eruption appeared during the fifth month of pregnancy, and have been informed of two others where it appeared during the third and ninth months respectively. In each case the disease assumed a severe form, labour came on, and the patients died a few hours after delivery.

All the patients were reported to have been vaccinated when children. These numbers are of course too few to admit of a positive conclusion being drawn from them, but perhaps others may be induced to add to them. I am, &c.

Barnsley, June 15.

MICHAEL T. SADLER, M.D. Lond., &c.

ADVERTISEMENT FOR A MEDICAL SERVANT-OF-ALL-WORK.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg to forward to you another specimen of "Board of Guardians" work. The wording of this advertisement, taken from the *Times*, is in itself a curiosity. I thought when I began reading it the Union was advertising for a cook, "duly qualified." I pity the poor fellow who undertakes this appointment, if all we hear by the papers of the character of the population of Aldershot be correct; but, to be sure, "the Board" offer a liberal salary for so small a population, and so circumscribed an area. I fear there will be a severe contest for the post. I am, &c.

CIVIS.

"Farnham Union, Surrey.—Wanted, a duly qualified Practitioner, as one of the Medical Officers of this Union. His district will be the parish of Aldershot, the area of which is about 4144 acres, and the population 4957. His salary £30 per annum, and he will be required to reside at Aldershot. Testimonials to be sent to the Guardians, at the Board-room, Farnham Workhouse, by ten o'clock in the morning of the 18th inst., when the appointment is intended to be made.—Wm. Hollest, Clerk to the Union. Farnham, June 4, 1863."

ASTIGMATISM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In speaking of the word *astigmatism* as having been "lately introduced," I meant that it had lately been brought into common use, and I ought so to have expressed myself. I was quite aware that the word, as Mr. Carter remarks, had been used by Mackenzie; indeed, it was from his treatise that I learned the fact of the peculiarity of vision thus designated having been described by Young and Airy. But I confess to have read Mackenzie's notice carelessly, and thus to have overlooked the statement as to the word *astigmatism* having been suggested by so great an authority as Professor Whewell. I quoted Snellen, because he is one of the latest writers on the subject.

It seems very presumptuous to question the accuracy of Professor Whewell's nomenclature, and I wish to do so with due deference, inasmuch as I am not well acquainted with the terms which the Greeks employed to express optical phenomena.

Is *στειρα* the true Greek equivalent of *focus*? If so, *astigmatism* would seem to imply the absence of any focal point. But this is not the condition of an eye said to be the subject of *astigmatism*. In such an organ rays parallel to its vertical meridian and those parallel to its horizontal meridian have different foci, but still both these foci exist within the eye. It seems to me, therefore, that if *stigma* be the equivalent of *focus*—and on this point I seek information—an eye with the optical peculiarity just noted should be described as being the subject of *Distigmatism*, not of *Astigmatism*. I am, &c.

QUÆRENS.

BITARTRATE OF POTASH IN SMALL-POX.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The subjoined details of three recent cases of variola, treated with the bitartrate of potash with remarkable success may prove interesting:—

On the 9th ult., a girl in her seventh year, daughter of a basket-maker, who had just become convalescent after a severe attack of small-pox, was seized with the usual premonitory symptoms of variola. On the 12th an eruption appeared, and on the evening of that day assumed a pustular form. At 8 p.m. a 22-gr. dose of the bitartrate was administered, and in three hours after an 11-gr. dose. The latter dose was continuously repeated at the same interval. A diminution of the fever was apparent after the third dose. The eruption on the following morning was more copious, but a very remarkable change was perceptible in that appearing after the fourth dose. The modified eruption was of a vesicular character. On the 13th both the primary and modified eruption were evidently yielding to the action of the medicine. Within a week the latter had completely disappeared, and the former was fast fading.

It is worthy of note that a mistake was made by the attendant in diminishing the quantity of the second and subsequent doses. The modified character of the secondary eruption, and its disappearance before the primary, palpably show, however, the effect of the medicine. The girl had been vaccinated in infancy.

A boy of ten years, a member of the same family, was attacked on the 17th ult. On the following morning febrile symptoms were apparent. A 45-gr. dose of the bitartrate was administered at 9 a.m. The fever abated in two hours. The same dose was repeated in six hours after the first, and shortly after its administration the febrile symptoms had entirely left the patient. The bitartrate in this case was administered before the appearance of an eruption. Three spots of a papular nature were afterwards visible, but these faded in two days, and in a week afterwards not the slightest trace of them remained.

A girl in her sixth year, sister to the other patients, failed on the same day as her brother. A 22-gr. dose of the bitartrate was administered at 4 p.m., and the dose repeated in six hours. The fever had quite left the patient on the third day. The eruption in this case was of the same character as in the preceding one, but more copious. In a week it had entirely disappeared. I am, &c.

June 10.

C. R.

SYNOPSIS OF A CASE OF PURPURA COMBINED WITH TYPHOID FEVER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg to forward for publication the following case of purpura and typhoid fever:—Robert M., aged 26, farm servant, married, the father of three children. First seen on the evening of February 26, 1863. *Symptoms*.—Patient had been ailing for ten days or more. Gums bleed freely when pressed; raised or nodulated pink or purplish spots, from the size of the point of the little finger to that of a shilling, observed on both legs; patient observed them several days ago; has passed very little urine for two days, evidently from a congested state of the kidneys. On the fourth day from the first day I saw him, a distinct eruption of typhoid spots is observed over the body. A day or two after this, considerable head symptoms during the night, somewhat drowsy during the day, and complaints of headache; pulse 108; tongue coated with a dark brown fur; considerable thirst; appetite not quite gone. On the tenth day is seemingly better. Tongue clearer, and pulse not so frequent; this favourable change lasted little more than a day, the patient gradually returning to his former state, and on the fourteenth day is markedly worse, breathing is more frequent, and he seems also to breathe with difficulty. Was exposed to a current of very cold air yesterday. Fine crepitus is heard at the inferior half lower lobes of both lungs; two days after this,

bronchial ronchi heard higher up. Hepatization inferior front of right lung; great debility; bed sores; diarrhoea about the 24th day. Crisis from 23 to 30 days.

*Treatment.*—For the nephritic symptoms. First evening (26th).—Dover's powder, warm gruel, mustard poultice to loins.

27th.—No improvement. Venesection to 16 oz. A dose of ol. ricini, liquor. ammon. acet. every four hours in warm gruel. A large linseed meal poultice to region of kidneys. Made urine rather freer after the bleeding, but did not make it very free for more than a week.

*Cephalic Symptoms.*—A vinegar and spirit lotion to the shaven head; a few small doses of calomel; not much relieved by these means. Leeches to the temples; marked benefit from them.

*Pneumonic Symptoms.*—Hydrarg. sub. mur., with pulv. ipecacuanha, and blisters to the chest. For the fever itself he took nitro-muriatic acid in a small quantity of compound infusion of gentian. The bed sores were painted with a solution of gutta-percha in chloroform, as recommended by Dr. Corrigan, of Dublin. Sheet gutta-percha, 3ss.; chloroform ʒj., solve. The diarrhoea was controlled by ipecacuanha combined with chalk. The strength was supported with beef-tea, wine, chicken-soup, etc., etc. No solid food was allowed for upwards of seven weeks.

*Remarks.*—As purpura combined with typhoid fever is a rare disease, it may be thought there has been a mistake in the diagnosis. Now, what are the facts? We have then an eruption of purplish spots on the legs; these are large, and do not disappear on pressure, and the gums bleed freely when pressed. Eight days or more after the appearance of the purple spots we have a second eruption of small spots (over the body), with a red zone and elevated centre, which disappear on pressure; after these have made their appearance the whole train of symptoms point to typhoid fever.

I am, &c.

THOMAS DOWNIE, M.D. St. And., L.R.C.P. Edin.

Blantyre, June 10.

DR. G JOHNSON ON THE USE OF THE LARYNGOSCOPE.  
TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—The admirable paper "On the Use of the Laryngoscope," by Dr. George Johnson, which recently appeared in your Journal, is calculated to draw forth some remarks on the optical bearings of the question, especially in relation to the frontal reflector, which he so strongly recommends; and before proceeding to the scientific part of the subject, its historical aspect may perhaps be allowed to claim our attention.

Though it is well known that Garcia's observations were not credited till verified and extended by Czermak, all honour is claimed for the former; whilst the latter, who, in point of fact, created the art of laryngoscopy, is described as "a diffuser of it throughout the civilised world." If Garcia's paper was "the fountain-head of our knowledge," it would certainly have remained buried in the depths of the *Proceedings of the Royal Society*, had not Czermak, with truly Artesian genius, succeeded in boring through the intervening crust of apathy and incredulity, and reaching its source. This is not a mere form of speech, for those who are acquainted with the literature of the subject must well know that Czermak's paper (March, 1858) was really the first publication which gave an impetus to laryngoscopy.

Had not the necessary limits of Dr. Johnson's article prevented him from going too minutely into details, after stating "that Dr. Türck lent his mirrors to Dr. Czermak," he would doubtless have added, that "for some months, Türck had entirely given up his fruitless attempts to use the laryngeal mirror." This occurred in November, 1857,—not "in the early part of the year 1858;" and though this slight inaccuracy may appear scarcely worth mentioning, it has a certain importance when considered in relation to Professor Czermak's article, already alluded to.

To discuss now the practical part of the question.

1. That it is not absolutely necessary to look through the centre of the reflector was pointed out by me more than a year ago (*Medical Times and Gazette*, April 19, 1862). Indeed, on the ground of its "diminishing the difficulty of managing the reflected light," the plan of not looking through the hole "is strongly recommended to the beginner." On the other hand, the inconvenience of looking through the hole in the mirror is experienced only by the beginner, and a very little perseverance soon overcomes it.

2. When the reflector is perforated, there is no inequality of focal distance; and when the glass is left in the centre (but not silvered), the inequality, is not perceptible for it must be remembered that the reflector is only very slightly concave, and that both its surfaces are parallel.

3. With regard to the eyes being shaded from the direct rays of the lamp, it is to be observed that this is effected by Tobold's condensing illuminator (a), which is infinitely the best lamp that can be used.

4. The more free movement which the frontal reflector allows, though it may be of use for the method of auto-laryngoscopy, recommended by Dr. Johnson, is of no use in examining patients.

5. "The dark spot in the centre of the luminous disc" can only be discovered when a very feeble light is used. With an ordinary Argand gas-burner, it can be seen at a distance of three inches from the reflector, but at five inches it completely disappears. Of course, the reflector is still further from the patient in ordinary laryngoscopy. With an inferior oil-lamp, the dark spot disappears near the focus (of the luminous cone), which ought to be thrown on the laryngeal mirror, whilst with a strong light, such as that of Tobold, there is no dark spot at all.

6. Dr. Johnson asks, "Are there advantages in looking through the centre of the reflector?" The answer to this question is, that where the larynx is large, the frontal reflector can be used, because then the rays, proceeding both from the reflector and the eye, may be able to impinge on the laryngeal mirror, so as to be reflected into the larynx. The advantage, therefore, of looking through the centre of the reflector consists in the rays both from the reflector and the eye proceeding from the same spot; so that if the light is thrown on the laryngeal mirror (properly introduced), the observer cannot fail to see. On the other hand, should the patient be unable to open the mouth widely, or should the opening into the larynx be at all small, the laryngoscopist who uses the frontal reflector will find that both rays (*viz.*, that proceeding from the eye and that from the reflector) cannot strike the laryngeal mirror so as to fall within the larynx.

In conclusion, it is to be observed, that though "we do not look down the tube of the trachea," the same optical laws are in force as if we did. I need hardly say, that "in these days of stereoscopes," everybody knows that reflected images appear behind the surface of the mirror exactly as if they were the real objects (not as though they were drawn on a flat surface).

(a) This lamp can be obtained from Mr. Krohnl, 241, Whitechapel-road.

These observations do not at all detract from the general value of Dr. Johnson's interesting paper, which I have no doubt was read by others with as much pleasure as it was by Yours, etc.

## ORIGINAL LECTURES.

## LECTURES

ON

## ECZEMA,

(INCLUDING ITS IMPETIGINOUS, LICHENOUS, AND PRURIGINOUS VARIETIES,)

DELIVERED AT THE

Dispensary for Skin Diseases, Glasgow.

By T. McCALL ANDERSON, M.D., F.F.P.S.

Physician to the Dispensary for Skin Diseases; Physician to the Deaf and Dumb Institution, etc., Glasgow.

## LECTURE III. (a)

GENTLEMEN,—At our last meeting, I referred to some of the varieties of eczema, to the causes which predispose to, or occasion an attack, and to the diseases for which it may be mistaken. We are now prepared to form an estimate of the gravity of the affection.

The *prognosis* is rarely serious, for, while the eruption causes great irritation and disfigurement while present, it is almost invariably curable. The most serious cases are those in which the eruption covers the greater portion of the cutaneous envelope, especially when they occur in very young infants or in old or infirm persons. In these instances, the natural functions of the skin are interrupted, and the itching may give rise to serious symptoms, such as convulsions, fever, exhaustion from anorexia, loss of sleep, etc. It is a very rare circumstance, however, for eczema to terminate fatally.

It is curious and interesting to watch the effect of inter-current inflammations or fevers upon eczematous eruptions, a very good illustration of which occurred the other day in my practice. I was attending two children for very severe attacks of eczema erythematodes affecting the greater portion of the skin. One of them took measles, and two or three days thereafter the eczematous eruption had almost disappeared. The eruption on the other child continued to flourish for a few days longer, when she likewise was seized with measles, and in her case, too, the eczematous eruption vanished. There could be no doubt that these children were affected with measles, for, while it was difficult to make out the rubeolar eruption on their skins, owing to the existing eczema, their younger brother presented about the same time all the characteristic symptoms of measles. When the rubeola had run its course in the cases of the two first-named children, the eczematous eruption gradually but perseveringly returned—a circumstance which unfortunately happens in most instances, and which must therefore be borne in mind with reference to the prognosis.

A great deal of nonsense has been written about the danger of suddenly “driving-in” (as the expression goes) a severe or chronic eruption, such as eczema. For, while I have treated hundreds of cases of eczema, many of them covering the greater portion of the skin, I have rarely witnessed any bad effect even from the rapid removal of the disease. That deleterious effects are occasionally witnessed, however, I am quite prepared to allow. I call to my recollection just now, for instance, the case of a gentleman, almost the whole of whose body was covered with an eczematous eruption. This I succeeded in removing in a few weeks, and, as it went away, he began to pass some blood by his bowels; but, as he himself wrote, he was “not conscious of any uneasiness in the region of the rectum, as if it arose from piles.” The same symptoms, he informed me, appeared during his recovery from a previous attack, for which he had been treated by Mr. Startin. In both instances it was slight, and soon passed away without producing any injurious effects; indeed, I have never observed any enduring bad results follow upon the removal of an eczematous eruption where proper precautions were taken, no matter how quickly it was accomplished. To this I shall again refer when discussing the treatment.

Attacks of eczema vary much in their duration, according to the constitution of the patient, the site, extent, and severity of the eruption, and the course of treatment pursued. Some cases get well without treatment in a few weeks; others last

for months, or even years. Some would never disappear entirely at all without treatment; but the natural tendency of the disease is to diminish now and then, the change for the better being dependent upon the seasons, atmospheric influences, changes of diet, improvement of the general health, etc.

Relapses are very much to be feared, more especially in the case of those who are apparently in very good health, and in whom the occurrence of the eruption seems to be connected with some unknown peculiarity of the system. They are much less common in those who have suffered from the disease from the use of bad food and the like, for we have here tangible causes, by removing which the eruption is less apt to recur.

Now, supposing that we have a case of eczema under our observation, how do we know that the eruption is on the decline? What, in fact, are the *symptoms of amendment*? It is a good sign when the disease does not tend to spread by the extension of old patches or the formation of new ones, and when no new crops of eruption make their appearance upon the old patches. It is always a favourable occurrence when the infiltration, exudation, and itching diminish. When these symptoms are nearly gone, erythematous and scaly patches are usually left; but, if the disease is progressing towards a cure, the redness gradually subsides, the scales disappear, and the skin resumes its healthy appearance and feeling. It requires, however, to be mentioned, to avoid disappointment, that, when the eruption appears to be rapidly declining, sometimes for some obvious reason, oftener without any assignable cause, the improvement suddenly ceases, a retrograde movement takes place, and, in a few days, the cure is as far off as ever.

When the disease has disappeared, there is usually no trace left of the previous eruption, unless ulceration has occurred, and even then the surface usually resumes its healthy appearance, as the ulcers are for the most part superficial, and do not destroy the deeper tissues of the skin. When they are deep, however, as happens sometimes on the legs, cicatrices are of course left, which vary in size and appearance in proportion to the size, depth, and site of the previous ulceration. Cicatrices likewise follow the application of escharotics, which, though powerful agents for good, are too often injudiciously used in the treatment of eczema. It need hardly be mentioned, however, that any caustic which has been used so freely as to destroy the deeper structures of the skin, and to leave permanent cicatrices, has been employed by an unskilful hand.

Sometimes, after the cure of an eczema, the skin, which had previously been affected, is much darker in colour than natural, owing to the previous determination of blood to the part, and the increased deposit of pigment thereby induced. This appearance is oftenest observed, and lasts longest upon the legs, for the reasons before alluded to as predisposing to the occurrence of ulcers. It is identical with the coloration which so often follows the application of a blister, instances of which are daily met with in practice; but, in both cases, the colour generally fades and finally disappears, and the skin resumes its healthy hue.

Having now discussed the symptoms of eczema in its various forms, the causes which are fruitful in calling it forth, the diseases with which it may be confounded, and its results as far as they are indicated by the features of individual cases, we are prepared to enter upon the object of our previous investigations, the *treatment* of the affection.

It appears to me that no treatment can be more routine and ineffectual than that frequently adopted in this country for the cure of eczema, and cases of this disease are often allowed to go on for months and years, when judiciously selected applications could have removed it in the majority of instances in as many weeks; for there are few diseases more curable than even severe forms of eczema. The means of cure, which we may divide into the constitutional and the local, must vary, however, according to the age, existing state of health and constitution of the patient, and the seat, extent, and severity of the eruption.

Let me, first of all, direct your attention to the *constitutional treatment*:—

It is necessary in this, as in all other diseases, to make a careful examination of the internal organs, and to rectify, as far as it is within the scope of medicine, any deviation from the normal standard which you may detect, and which may be keeping up or aggravating the skin affection. You will be aided in this investigation by calling to mind what I said

(a) These Lectures have been carefully revised, and many alterations and additions made.

with regard to the causes of eczema, and with regard to those states of the system which are most likely to produce, or to intensify the severity of, the eruption. In fulfilling this indication, you must be guided by broad general principles, with which, I take it for granted, you are already familiar. But I must say a few words with regard to derangements of the digestive organs, and more especially to the regulation of the bowels.

*Purgatives* are very useful in cases of eczema, though, with few exceptions, they must be looked upon merely in the light of adjuvants to, or forerunners of, other treatment, and the medicine which is selected will depend upon the inclination of the Practitioner, and the features which each case presents. If the tongue is loaded, the appetite bad, the liver torpid, as indicated by the light colour of the evacuations, and the bowels costive; and if, in addition, the patient is not very strong, small doses of grey powder, in combination with rhubarb and salicine or quinine, may be administered with excellent effect. (b)

If the digestive organs are in the state just mentioned, and the patient robust, and especially if fulness in the hepatic region is complained of, occasional doses of calomel, alone or in combination with scammony, may be resorted to with advantage, as they have the effect not only of correcting the torpidity of the digestive organs, but also of "cooling the blood," as the saying is, and of diminishing the cutaneous inflammation. (c) They may therefore be given with the latter end in view, although the liver and bowels are not in a torpid condition. A calomel purge may likewise be prescribed occasionally, if the eruption is extensive, causing much irritation, and exuding copiously; and if you fear the occurrence of any untoward symptoms from its too rapid removal, by other, and more especially by local, means. (See Prognosis.)

With the same object in view, and much more universally employed than calomel, though, on the whole, not so useful, small doses of sulphur, in combination with magnesia or bitartrate of potash, may be taken every evening, and as good a preparation as any is the sulphur confection (*Confectio Sulphuris*) of the Dublin Pharmacopœia, of which about a teaspoonful may be prescribed. Besides being less effectual, in my opinion, than calomel, it has this additional drawback, that the sulphur is converted into sulphuretted hydrogen, and the secretions have accordingly a very unpleasant odour. It has this advantage over calomel, however, that it is in part eliminated by the skin, and acts beneficially upon that structure, so that it possesses alterative as well as purgative properties. A more pleasant and more elegant preparation is a solution of three or four drachms of sulphate of magnesia in water, with the addition of two scruples of bicarbonate of soda, and made to effervesce by the addition of half a drachm of tartaric acid. (d) This may be repeated every second night. If the patient is of a full habit of body, and if, in addition, he lives too freely, and cannot be prevailed upon to live sparingly, a smaller dose of sulphate of magnesia (say  $\mathfrak{z}$  to  $\mathfrak{z}\text{ii}$ ) may be administered twice daily, from a sixth to half a grain of tartar emetic being added to each dose, so as to deprive him in great part of his appetite for a time. In this case the solution should not be administered in effervescence, else the nauseating action of the tartar emetic may be counteracted.

The doses which I have recommended are for adults, and are merely approximative, for of course some constitutions

(b) ℞ Sulphatis Quinæ, gr. xij.  
Pulv. Rhei, gr. xxxvj.  
Hydr. c. Cretâ, gr. xxx.  
Sacchari Albi, ℥j.

Divide in Pulv. xij.

*Sig.* Two daily. (For an adult.) The dose to be so regulated that the patient has at least one full natural evacuation per day.

(c) ℞ Protochloridi Hydrargyri, ℥j.  
Pulv. Scammonii co., gr. xl. M.

Divide in Pulv. iv.

*Sig.* One every week. (Dose for an adult.) Or,  
℞ Protochloridi Hydrargyri, gr. iv.  
Mas. Pil. Coloc. Co. gr. v.  
Extr. Belladonnæ, gr. j. M.

Divide in pil. ij.

*Sig.* One at bedtime, and a seidlitz powder in the morning. (Dose for an adult.)

(d) ℞ Sulphatis Magnesiae, ℥ijj.  
Bicarbonatis Sodæ, ℥ij.  
Aquæ, ℥ij. M.  
℞ Sacchari Albi,  
Acidi Tartarici, āā ℥ss.  
Syrupi Limonum, ℥ss.  
Aquæ, ℥iv. M.

*Sig.* Mix the two solutions in a large tumbler, and drink during effervescence. (Dose for an adult.)

are more susceptible of the action of purgatives than others, and care must be taken to avoid the administration of mercurials as much as possible in the case of those with whom they disagree. Not long ago, for instance, I gave a couple of grains of calomel and three of grey powder to a little girl, which gave rise to the most profuse salivation, ulceration of the mouth, and swelling of the gums and submaxillary glands. Now, this is far more remarkable than the production of similar symptoms in the adult, even with the same dose, for, as a general rule, as most of you are aware, it is much easier to salivate an adult than a child.

Having attended to the condition of the internal organs in general, and of the digestive organs in particular, the internal treatment now radiates in two directions, according as the eruption occurs in the case of those who are apparently in the most robust health, in whom the eczematous rash is called forth in virtue of some peculiar idiosyncrasy (see the causes of eczema) or of those who are scrofulous or debilitated from insufficient or unwholesome food, or from previous disease.

In the latter, nourishing food, tonics, especially those containing iron and cod-liver oil, are our sheet-anchors, and I have repeatedly cured very severe cases of eczema by the systematic administration, for a couple of months, of cod-liver oil and syrup of the iodide of iron, all other treatment of importance having been omitted. The following is a case in point, and you will probably remember that I purposely refrained from additional means of cure, in order that you might see the charming effect of the oil and iron alone:—

Lawrence D., aged about fifteen months, was brought by his mother to the Dispensary, on October 9, 1862, affected with eczema impetiginodes. The eruption covered almost the whole body, with the exception of the fingers and feet, was very itchy, constantly exuding, and studded with crusts. The child was dreadfully emaciated, "just skin and bone," as the mother remarked. It could neither sleep nor eat, and was so weak that it had to be brought upon a pillow. The case looked hopeless, and, indeed, the child had been given up by the previous attendant; but acting upon what I have observed in similar cases, twenty drops of syrup of the iodide of iron in a teaspoonful of cod-liver oil were prescribed, to be repeated thrice daily, and the dose of the oil to be gradually increased up to a tablespoonful.

On October 16 the child was better. The skin being still itchy, however, a lotion of dilute hydrocyanic acid (*Ed. Ph.*), containing twenty minims to the ounce of water, was ordered, to be used thrice daily. The oil was omitted for a week, as it produced purging. With this exception, the oil and iron were continued uninterruptedly till November 17, about five weeks after the commencement of the treatment, when the mother brought the child out of gratitude to show how well it was. There was hardly a vestige of the previous eruption, with the exception of a few dry crusts and discoloured spots on the buttocks, which were rapidly disappearing. The child appeared to be in robust health; it was quite plump, and its cheeks rosy; its skin soft and white; its appetite very good; and its sleep sound and refreshing. The medicine was to be continued for another month.

Here, then, is an instance of an infant cured of a frightful eczematous eruption, and rescued from the jaws of death by the internal administration of cod-liver oil and iron alone. In severe cases such as this, you will sometimes find it of advantage to rub the oil into the skin of the whole body two or three times a day in addition to its administration internally. Cod-liver oil is sure to do good in these cases if the stomach bears it, and especially if it is taken greedily and with relish by the patient. This is oftenest observed in children whose mother's milk is below par. When this is detected, the mother should no longer give her child the breast, and, amongst the higher classes, who can afford to have a wet nurse, a good one should at once be procured. Amongst the lower orders the child should be fed, in great part, "upon the bottle," a mode of nourishment which, though inferior to the employment of a good wet nurse, is much more desirable than the exclusive use of the deteriorated milk of the mother. Those children whose health has been deteriorated by imbibing their mother's milk too long—and instances are often met with, especially amongst the poor, of children being fed upon the breast, not for months, but for years—should be weaned without delay, and appropriate nourishing food substituted.

These children often suffer from diarrhœa, but while special remedies, guided by general principles, may be cautiously employed towards its removal, you must bear in mind that it

is often the result of debility, in which case you may expect it to disappear spontaneously when the diet is altered and the general health improved.

In adults under similar circumstances, cod-liver oil and iron are almost equally serviceable, and in them, and likewise in the case of children, small quantities of stimulants may in some cases be superadded, though it is generally advisable to use them with caution.

Some patients, and adults oftener than infants—for the latter rarely refuse it if the system really requires it—cannot take cod-liver oil, in which case cream may be substituted, though it is not so beneficial; and, while taken with relish at first, it is more like to derange the stomach in the long run. So that if the case is undoubtedly one which calls for the use of the oil, do not let the patient put it aside lightly, but make repeated trials of it in varying doses, and always let the bowels be carefully regulated before administering it. Sometimes it is tolerated better by swallowing a small pinch of magnesia about half an hour after the oil is taken, as was recommended lately in some of the Medical journals.

When the appetite is very deficient, a pure tonic may be substituted for a ferruginous one with advantage, such as small doses of quinine and sulphuric acid in a bitter infusion; (e) or, if the stomach is too weak even for this, you may try a little dilute sulphuric acid, which should be given in half-drachm doses twice daily in a wine-glassful of cold water, and which is usually well borne.

But, let us now take the opposite class of cases—and very common they are—in which the patients are neither ill-fed, scrofulous, nor debilitated; but, on the contrary, appear, with the exception of the eruption, to be in a good state of health. In such instances, then, what means, operating upon the system at large, are we justified in having recourse to?

Some recommend the abstraction of blood by means of the lancet, but this is hardly ever necessary; indeed, I have neither had recourse to it myself, nor seen it employed by others; for, while many severe and extensive eruptions in plethoric persons have come under my observation, I have found purgatives—especially those containing calomel—answer all the ends in view. The local abstraction of blood by leeches, cupping-glasses, or scarifications, may sometimes be resorted to with advantage, if the patches of eruption are much inflamed, and especially if the lower extremities are affected, as these parts, for reasons formerly mentioned, are more liable than others to congestion and its results. Even local bleeding may, however, be dispensed with in the majority of cases, although I am aware that this opinion will be regarded in the light of a heresy by some.

The diet must be very carefully regulated, and the patient warned to eat very moderately and slowly, and to masticate his food well. A simple mixed animal and vegetable diet may be recommended, dressed dishes, pastry, pickles, spices, strong tea, and coffee, being particularly avoided. The use of wine, spirits, and malt liquors must, in general, be suspended for a time at least, though in some instances they may be taken sparingly. But you must be cautious, in the case of those who have previously been in the habit of taking them in excess, of discontinuing them all at once, and you must remember, in reference to prognosis, that the cure of an eczema is much more difficult when the patient has been much addicted to the use of stimulants.

In some cases you will find it of advantage to prescribe milk diet for a time, all animal food being avoided.

In the cases which we are now considering, and applicable, to a certain extent, to the class previously alluded to, in conjunction with the means then recommended, there are three classes of internal medicines upon which I place considerable reliance, but especially upon the first, for the removal of the eczematous eruption. These are the preparations of arsenic and sulphur and alkalies.

Of the arsenical preparations, the one which I am most in the habit of employing is Fowler's solution (Liquor Arsenicalis, Ed. Ph.), although any of the others may be selected, according to the taste of the Practitioner. I think it better, however, that the Physician should limit himself as much as possible to one preparation of arsenic, for he thus becomes

Inf. Cascariillæ, ad. ʒviiij. M., et cola per chartam.

ʒiq. A tablespoonful thrice daily, half-an-hour before food. (Dose for an adult.)

more familiar with its exact mode of operation, and with the probable dose for different constitutions. An adult may commence with five minims thrice daily, and at the end of a week or so, if it agrees, the dose should be increased by a drop every second or third day, till the disease begins to yield or the medicine disagrees. I do not think it necessary to stop it if slight irritation of the eyes or puffiness of the face is induced; but if these symptoms are at all aggravated, and especially if they are accompanied by pains in the stomach and head, anorexia, and nausea, the dose should be diminished, or in some cases omitted for a few days. You must on no account stop its administration altogether, however, because these physiological effects are produced, and I thoroughly endorse the statement of Dr. Begbie, that, "in order to secure its virtues as an alterative, it will be necessary to push the medicine to the full development of the phenomena which first indicate its peculiar action on the system. Arsenic, as a remedy, is too often suspended, or altogether abandoned, at the very moment its curative powers are coming into play. The earliest manifestation of its physiological action is looked upon as its poisonous operation; the patient declares that the medicine has disagreed with him; forthwith the Physician shares his fears; the prescription is changed, and another case is added to the many in which arsenic is said to have failed after a fair trial of its efficacy." (f) It is necessary to observe, however, that the appropriate dose of Fowler's solution varies in different individuals, and that, while five minims thrice daily soon disagree with some, ten, fifteen, twenty, or even thirty may be taken by others with impunity and with benefit.

To prevent the medicine from deranging the stomach, it should always be given *immediately after* food, and in persons whose digestive organs are weak, a tonic infusion, such as the infusion of cascarrilla or gentian, forms a very good vehicle for its administration, and in some cases even a few drops of morphia may be superadded (g) if the stomach is very easily deranged.

As the disease yields, the dose may be gradually diminished, but in no case should its use be suspended till some time after the complete removal of the eruption.

In the case of infants at the breast, it is advisable to administer the arsenic to the mother, whose milk thus furnishes not only nourishment to her babe, but likewise an antidote to its complaint. In children of one or two years one minim may be given twice daily, and the dose gradually increased.

In some cases you may think it advisable to combine arsenic with mercury, as in Donovan's solution (solution of the hydriodate of arsenic and mercury) of which ten minims may be administered thrice daily, the dose being gradually increased. Each drachm of the solution contains about  $\frac{1}{2}$ th of a grain of oxide of arsenic,  $\frac{1}{4}$ th of a grain of oxide of mercury, and  $\frac{5}{8}$ ths of a grain of iodine in the state of hydriodic acid in chemical combination. (h)

And sometimes you may find it beneficial to prescribe arsenic along with iodine, and without mercury, in which case you will find Neligan's prescription, which he names the ioduretted solution of the iodide of potassium and arsenic (i) a very good one indeed, and one which is much used.

I very frequently make use of a private mark, known to two or three Apothecaries, in prescribing arsenic, and I think with good reason. For instance, I know of a lady for whom Fowler's solution was prescribed, who, finding that she was improving under its use, increased the dose of her own accord, and thereby induced poisonous symptoms. Some time after this, she consulted Cazenave, and on her return from the Continent she came to her family Physician, and informed him that she had never been able to take arsenic since she had administered to herself the overdose. The

Doctor, on looking at Cazenave's note, found that she was at that very time taking arsenic without knowing it, under his orders, and with good effect. Then again, some people who consult me have already taken arsenic without benefit, and either refuse to take it again, or are so sceptical of its efficacy, that they take it with great irregularity, and are convinced in their own minds they are to derive no benefit from it—conditions which are very prejudicial to the due operation of any drug.

Very often, in these cases, the previous arsenical course had been improperly carried out, or not continued sufficiently long, and we are thus compelled either to give it in a concealed form, or to dispense with the use of a most powerful therapeutic agent.

## ORIGINAL COMMUNICATIONS.

### ON CHOREA: ITS RELATION TO VALVULAR DISEASE OF THE HEART, AND ITS TREATMENT.

By W. S. KIRKES, M.D.,

Assistant-Physician and Lecturer on Medicine at St. Bartholomew's Hospital.

(Continued from page 639.)

II. From all that has so far been said, then, one fact seems to be prominent, namely, that under whatever circumstances chorea may arise,—whether in association with rheumatism, with pregnancy, with disordered uterine function, worms, constipation, irregular dentition, or any other supposed determining cause, or even without any special attendant circumstance,—an inflammatory affection of the left valves of the heart, indicated by morbid sounds or excited action during life, or proved by structural changes after death, is a very frequent, if not invariable accompaniment of the nervous affection. This fact naturally suggests the belief that the affection of the valves plays an important part in the chorea. Then arise three questions—Does the chorea produce the affection of the valves? or does the latter lead to the former? or, again, are they both the result of some one common cause?

Dr. Branson, who many years ago drew attention to the fact of the cardiac valves being often affected in chorea, was of opinion that the state of the nervous centres producing the chorea occasioned the endocarditis also. It is difficult, however, to understand how this can be, and Dr. Branson does not offer any satisfactory explanation of it. Again, it has been suggested that perhaps the fibrinous concretions found on the cardiac valves in cases of fatal chorea result, not from valvular inflammation, but from simple coagulation of blood retarded in the cavities of the heart during the violence of the choreic movements. There are many objections to this view; among others a very weighty one, namely, that, if it were true, such concretions ought to be found in cases of cardiac obstruction in general, which is certainly not the case. Very often, moreover, the chorea is too slight to occasion any such obstruction to the circulation. An instance of this was furnished to me lately by a mild case of chorea, which terminated fatally from typhoid fever, and in which the mitral valve was freely studded with granular vegetations, although there had been no signs of obstructed circulation during life.

Moreover, the fibrinous concretions in fatal chorea are often found accompanied by other and unmistakable signs of inflammation. It may be concluded therefore that there is no sufficient reason for believing the nervous affection to be the cause of the valvular disease. Before endeavouring to answer the inquiry whether the valvular affection can be regarded as explaining the chorea, let us look at the third question, namely, whether the nervous and cardiac affections may not both be due to a common cause. This is the view which Begbie, Todd, Sée, and others seem to favour. As already observed, they ascribe the choreic symptoms, the valvular inflammation, and the affection of the joints when it exists, to a rheumatic state of the blood. No doubt all these phenomena may, in predisposed persons, be developed by the rheumatic diathesis, when it really exists. Yet, since there are many cases of associated chorea and valvular disease, without the slightest evidence of a rheumatic tendency—as in at least half of the fatal cases of chorea that I have witnessed—I believe we are justified in looking for some other

explanation of the chorea than that afforded by the above hypothesis. Then, too, against the view that the rheumatic diathesis is sufficient to explain the chorea, stands the fact that the choreic symptoms usually occur, not during the intensity of the rheumatic attack, when the diathesis may be supposed to be most concentrated and operative, but after the rheumatism has continued for some time, and expended its violence, or on its subsidence, often indeed some weeks or even months after its disappearance, and after the patients have been regarded as convalescent, and when the poison therefore may be supposed to have been thoroughly eliminated. Out of forty-eight cases of chorea associated with acute rheumatism analysed by M. Sée the chorea was preceded by the rheumatism in no less than forty-one. It is indeed very common, especially in Hospital out-patient practice, to meet with cases of chorea, in which, on inquiry, the nervous attack is found to have succeeded a rheumatic attack suffered some weeks or months previously.

In such cases there is usually evidence of cardiac disease still existing, and it is surely more natural to ascribe to this attendant mischief in the heart some share in the production of the chorea, than to refer the complaint to the bygone rheumatism.

These points bring us then to the other query, whether the valvular disease can of itself, in any measure, help to occasion the chorea in already predisposed subjects. There are various reasons, in addition to what has just been said, for believing that this may be so. It is quite intelligible, for example, that the valvular inflammation may account for many secondary evils in the nervous system and elsewhere, and this without ascribing anything to supposed sympathy of the nervous centres with the cardiac mischief. We can readily understand that the blood in such cases, often previously unhealthy from rheumatic poison, and now rendered still more impure by the introduction of inflammatory products and fibrinous particles from the diseased valves, is calculated to disturb very materially the functions of the various organs through which it circulates. To such influence may probably be ascribed much of the restlessness, nervous excitement, choreic agitation, or even delirium, in those persons who by age, sex, hereditary predisposition, or some attendant condition, such as exhaustion from prolonged pain and sleeplessness, occasioned by a rheumatic attack, are peculiarly disposed to disturbances of the nervous system. We can thus understand also the singular fact, already mentioned, of chorea often occurring several months after the subsidence of rheumatism, and during the continuance of valvular mischief only—whether this mischief be still of an inflammatory kind, or consist merely in the formation, softening, decay, and separation of fibrinous concretions on thickened, abraded, and still unhealed surfaces of the valves. So, also, we can understand the occurrence, in predisposed persons, of chorea in pregnancy, or during any temporary functional derangement of important organs, provided there be, as there so often is, attendant valvular disease. In all these instances, the cardiac affection, and not the mere pregnancy or functional disorder, is probably the medium through which the nervous phenomena are developed in those who by hereditary or acquired tendency are specially predisposed thereto. Partly by the mere circulation of morbid blood through the nervous centres, partly, also, perhaps, by temporary obstruction in the minute capillaries occasioned by fibrinous particles arrested therein (see *Case 1* of puerperal chorea), the irritation leading to the development of the choreic or other analogous phenomena may be accounted for.

The cause of the endocarditis in those cases in which there are no signs of the rheumatic diathesis to explain it, is not very clear. There evidently are such cases; the occasional occurrence, for example, of valvular inflammation in the course of pyæmia, of the exanthemata, of pregnancy, and in other conditions wherein rheumatism appears to play no part, is strong evidence for the belief that endocarditis is not always of rheumatic origin. The view which would explain inflammation of the cardiac valves by referring it always to a rheumatic state of the blood, whether a rheumatic affection of the joints occurs or not, can scarcely be regarded as more than an assumption founded on our ignorance respecting the other conditions which may give rise to this affection of the heart. The object at present in view, however, is not so much to explain the endocarditis as to show that chorea, whether it occurs in rheumatism, in pregnancy, or in any other attendant condition, is intimately associated with the results of an

inflammatory affection of the valves of the left side of the heart, however this inflammatory affection be brought about. The frequency with which I have met with this association, and the number of recorded cases in proof of it, convince me that future observation will still more positively demonstrate that an affection of the left valves of the heart, with the presence of granular vegetations upon them, is an almost invariable attendant upon chorea, under whatever circumstances the chorea may be developed. There may, however, be some rare cases in which chorea may originate independently of endocarditis. Chorea in itself is essentially 'a nervous affection, just like epilepsy or hysteria, and, like them, it may be called into existence by any direct shock or other cause of great disturbance to the nerve centres in those who, by hereditary or acquired tendency, are specially predisposed to nervous disorders, and this quite independently of any cardiac or other organic lesion. Such, however, appear to be exceptional cases. In the great majority, especially of the severe and fatal instances of chorea, and probably in all those associated with the rheumatic diathesis, an inflammatory affection of the cardiac valves appears to be an essential link in the chain of phenomena, and probably plays an important part in the production or aggravation of the nervous disorder.

III. With regard to the treatment of chorea, especially in its acute and serious forms, where help is so urgently called for, we are aided largely by our experience as to the class of persons in whom the disease usually occurs. Such persons almost always exhibit in a more or less marked degree two main peculiarities. 1. They are of an unduly excitable and irritable nervous system. 2. They are weakly, feeble, often anæmic, and their tissues imperfectly nourished. A few remarks on each of these two points may be of service in guiding to the right plan of treatment:—

1. That chorea is very intimately associated with an unusually excitable and irritable state of the nervous system is an idea which has been maintained by many pathologists. (a) The view is supported by the following well-known circumstances:—

(a.) The subjects of chorea are commonly those who possess in a marked degree what is called the nervous temperament. As children they are restless and fidgety, excitable, and easily alarmed. As they become older and approach puberty the peculiar nervous susceptibility and sensitiveness become even more marked. (b.) The disease is most common at the age when the nervous system is most impressible, namely, in early childhood, and about the age of puberty. (c.) It is much more common in the more excitable female sex than in the male. (d.) In females, too, it is especially liable to occur at those times, when, from sympathy with ovarian and uterine irritation, the nervous system is peculiarly susceptible of impressions; for example, about the first establishment of the catamenia, during disordered menstruation, and in early pregnancy, especially when contracted under circumstances entailing shame or mental excitement of any kind. (e.) It is often preceded by circumstances of prolonged mental depression, anxiety, or distress, and is often called into existence by some shock to the nervous system, such as fright.

2. That the subjects of chorea are of feeble frame and imperfectly nourished, is usually very evident. Generally they are thin, with small weak muscles; are soon fatigued; they often possess the signs of general anæmia, with pallid features and dilated pupils; their circulation is feeble, and although the heart's action may be, and occasionally is, unduly rapid from nervous excitement or valvular disease, yet the skin is often below the natural temperature, the hands and feet often remarkably cold, in spite of choreic movements. Most of the bodily functions, too, are imperfectly performed, and the secretions deficient, as in ordinary anæmia. Hence in great measure the constipated bowels so common in chorea.

It is probably owing to this feeble and imperfectly nourished state of the various tissues of the body that the badly-fed and badly-clothed children of the London poor are so especially liable to chorea,—the liability being increased, too, by the depressing conditions, physical and moral, under which they but too commonly live. Participation of the nervous system in this state of imperfect nutrition would help to explain much of this tendency to chorea, for it is well known that imperfectly nourished or exhausted organs are much more readily excited to morbid action than organs in a state

of perfect nutrition. The nervous system especially illustrates this: witness the convulsions so readily excited in children exhausted by diarrhoea, or by insufficient or inappropriate food; the convulsions and delirium of puerperal women after great hæmorrhage, and of others similarly weakened by great loss of blood; the great nervous excitement so common in very anæmic persons; the delirium tremens of the drunkard, and of others whose nervous system has been exhausted by any great drain or trial; and some forms of temporary mania directly resulting from the nervous exhaustion consequent on deep sorrow, anxiety, or severe mental strain.

That the nervous system in choreic subjects does participate in this imperfect state of nutrition in general is in itself very probable. The view is supported by the fact that such subjects, although occasionally quick and precocious, are usually incapable of much mental or bodily exertion; their volition and self-control is generally small, and they are speedily fatigued by muscular efforts. Often the chorea is attended by an almost paralytic state of the affected muscles, voluntary power over them being greatly diminished. This is especially observed on the subsidence of the involuntary movements, the limbs being then often left remarkably weak, almost powerless. Not unfrequently, too, a state of partial hemiplegia accompanies, or succeeds, or, in some rare cases, according to Dr. Todd (*loc. cit.*, p. 171), even precedes the choreic movements, and thus indicates the participation of part of the brain in the atomic state of other portions of the nervous system.

A state of imbecility, too, is not an unfrequent result of prolonged chorea, and equally indicates the lowered tone and enfeebled nutrition of the nervous centres. Then there is the evidence furnished by the great advantage often derived from such treatment of chorea as is directed to give tone to the nervous and general system, and to check, by means of sedatives, the waste of nervous and muscular force and tissue produced by the violent and prolonged involuntary movements. Lastly, there is the evidence afforded by post-mortem examination of fatal cases. On this latter point it may be well to offer a few further remarks. The morbid appearances after death from chorea have not been satisfactorily determined. The records of post-mortem examinations of fatal cases of this disease are often very incomplete. It is seldom that all parts of the body have been examined, or, if examined, that their state has been mentioned; often the spinal cord has been neglected; still more often has the heart been overlooked. According to Hasse, one of the most recent writers on the general pathology of chorea (Virchow's "Handbuch der Pathologie und Therapie") changes have been most frequently found in the membranes of the brain, consisting of exudations, chiefly serous. Such effusion, however, he properly ascribes to the mode of death. Seldom have traces of inflammatory action in the membranes of the spinal cord been discovered. Congestion of the brain and cord has been several times observed; but this hyperæmia, like the serous effusion, is no doubt, as Ingleby long ago pointed out (*Lancet*, 1840, vol. i., p. 783), the result of the convulsive mode of death. Softening of the brain and cord, as Hasse observes, has also been many times found, though no satisfactory explanation of this, he says, can be given. M. Sée's elaborate analysis of eighty-four autopsies of chorea cases (*loc. cit.*) does not throw much additional light on the subject.

The softened state of the nervous centres deserves especial attention. It appears to be always the pale kind of softening. This condition was observed in all the fatal cases of chorea examined by myself, and in a large number of those recorded by others. Sometimes the spinal cord alone, sometimes the brain alone, or parts of it, sometimes both these nervous centres, are mentioned as the seat of such softening. If in so many cases the brain and spinal cord, together or separately, have, when examined, presented unmistakable signs of pale softening, it is reasonable to infer that a like state may have existed in many of the other cases in which the nervous centres were not examined. Also, it is reasonable to believe that some close relation exists between the softening and the chorea. Respecting the probable cause of such softening, several circumstances perhaps concur to produce it. In the first place, it may be assumed that the nervous centres, naturally deficient in tone in persons possessing the choreic tendency, participate in the imperfect nutrition occasioned in all parts by the feeble circulation and impoverished state of blood so commonly present in such persons. This impaired state of nutrition may explain much of the want of tone and stability of the nervous centres

(a) See among others Todd (l. c.), Lever (l. c.), Bond (*British and Foreign Medical-Chirurgical Review*, 1860), Levick (l. c.), Handfield Jones (*British Medical Journal*, January 5, 1861.)

and the want of right control over their functions possessed by choreic subjects; it may also explain their peculiar proneness to be unduly excited and disturbed in their functions by ordinary impressions. Then, in addition to this naturally defective state, the nutrition of the nervous centres will probably be still more impaired by the unhealthy state of blood which commonly precedes and attends the development of the chorea. The rheumatic diathesis alone may in some cases account for this unhealthy state of the blood, though probably in the majority of cases it is mainly due to the associated valvular disease. Respecting the probable relation between the softening of the nervous centres and the chorea, it may be believed that their imperfectly nourished condition renders these centres unduly excitable by even ordinary impressions, and that, thus predisposed, they are subjected to the additional disturbing influence of blood vitiated and rendered peculiarly irritating by the attendant rheumatic or valvular disease, which thus becomes mainly instrumental in developing the nervous disorder.

Since, then, there are strong grounds for believing that in chorea the nervous system is, from hereditary tendency or acquired predisposition, in an unduly susceptible state, also that this state of morbid irritability is connected with imperfect nutrition of the nervous centres, and lastly, since the choreic phenomena resulting from such nervous irritability appear to be often developed by, or at any rate closely associated with certain other functional or organic disorders, such as mental shocks, disturbed digestive or uterine functions, rheumatism, but, above all, with affections of the cardiac valves, the indications for treatment become plain.

These are, first, to remove, if possible, and guard against the recurrence of, such of the just-named sources of additional irritation as may be detected, be they of nervous, digestive, uterine, cardiac, or any other kind of origin. In case of distinct evidence, or even a suspicion of a rheumatic diathesis, explaining the attendant valvular disease, the alkaline treatment of rheumatism may be safely employed in conjunction with other measures. Secondly, to give tone to the debilitated nervous system by promoting its more perfect nutrition. Hence the great good of generous diet, cod-liver oil, special neurine tonics, such as quinine, iron, zinc, and arsenic, in most forms of ordinary chorea. Hence, too, the great use of out-door exercise, gymnastics, and other methods of promoting nervous and muscular activity, for by thus increasing the healthy discharge of normal function, healthy nutrition is best maintained and increased. These, and other general measures of a like kind, such as cold sponging, or the shower-bath—provided it be borne well, and does not overshock and frighten, as it very often does—are applicable to nearly all forms of chorea, and are often sufficient to promote their cure. But when we have to deal with the acute and violent forms of this disorder, additional means have commonly to be adopted. The chief object, then, must be to put a stop as speedily as possible to the violent involuntary movements, and to the attendant sleeplessness, for if these continue long they tend almost certainly to kill by exhaustion, hence the indication, thirdly, to tranquillise the highly excited nervous system, and procure sleep. Nothing appears to accomplish this so readily as the use of opiates, combined with diffusible stimulants. Opium, morphia, or henbane, with ether or ammonia, in doses proportioned to the age of the patient, the degree of effect they produce, and the violence of the symptoms, and repeated at regular intervals, will often in a few hours mitigate the violence of the choreic movements, and in a few days lead to their almost complete removal. In the more furious examples, however, injections of laudanum into the bowels, repeated inhalations of chloroform, or the subcutaneous introduction of a solution of morphia, may be advantageously substituted for, or adopted in conjunction with, the preceding. In addition to these sedative measures, the employment of wine, or, in the more urgent cases, even brandy, often seems to be remarkably productive of good. The benefit resulting from this combined opiate and stimulating plan seems to prove, as before remarked, that the nervous excitement on which the choreic movements depend is in great measure the result of exhaustion; the opiates allay the excitement, and the stimulants counteract the exhaustion and retard tissue change, while, at the same time, the rapid waste of nervous energy occasioned by the involuntary movements and prolonged sleeplessness is greatly reduced thereby. Meanwhile, measures for repairing this waste and restoring the nutrition of the nervous

centres can also be employed. Good nourishing food, with a liberal allowance of meat, eggs, and milk, should be given. Quinine, iron, zinc, or arsenic may also be administered simultaneously with the opiates and stimulants. A review of the treatment of the most violent forms of chorea recorded by others or treated by myself, has convinced me that the most successful and most speedily cured cases are those which have been treated on such a plan as that just advocated. Details of cases, and references to confirmatory facts and examples recorded by others are omitted here, in order to avoid lengthening still further a communication already too long.

Lower Seymour-street.

AN ACCOUNT OF THE  
PHYSIOLOGICAL RESEARCHES OF  
THE REV. PROFESSOR HAUGHTON, M.D.,  
TRINITY COLLEGE, DUBLIN.

DIABETES MELLITUS.

(Continued from page 396.)

The first point to which the Professor invites attention is the excessive excretion of urea, and he is sanguine that this phenomenon will throw much light upon the disease in question. In diabetes mellitus there is almost always a canine appetite, a relish for food, and an apparent assimilation of an amount of food from twice to thrice that which satisfies ordinary appetites, at the same time there is notoriously no work done by this food. Before offering an explanation of this physiological paradox, he makes the following calculation:—Assuming the following compositions for proteine, glucose, and urea:

Proteine	. $C_{36}H_{27}N_4O_{12}$	. 393	atomic weight.
Glucose	. $C_{12}H_{14}O_{14}$	. 198	„ „
Urea	. $C_2H_4N_2O_2$	. 60	„ „

The following relation is evident:—

$$(1) \text{ Proteine} + (23) \text{ water} + (3) \text{ oxygen} + (4) \text{ carbonic acid} = \\ (3) \text{ glucose} + (2) \text{ urea.}$$

This relation shows the possibility, at least, of proteinic compounds, by the addition of small quantities of water, oxygen, and carbonic acid (which all exist in abundance in the blood), becoming converted into glucose and urea; and an examination of the atomic weights will show that such a reaction would produce very nearly five grains of glucose for every grain of urea. We have now two sources for urea and two for sugar, as excreted by a diabetic patient. Some of the urea he ate and drank as food, or took in medicine, the rest was formed in his body by a perverted decomposition of nitrogenous tissues; similarly part of the sugar he excretes was derived from external sources, being formed from the starch contained in the food by the well-known reaction:—

$$(1) \text{ Starch} + (4) \text{ water} = (1) \text{ glucose.}$$

and the other part originated in the same decomposition of proteinic structure which gave rise to an excess of urea—a destructive process which requires the system to be renovated by large quantities of nitrogenous food. In the case of Owen Murphy, the food ingested was, on the average, capable of producing 9321 grs. of glucose per day, and did actually produce, on the average, 9773 grs. These quantities, though practically equal, are not related to each other as cause and effect; the excreted sugar is divisible into two portions—

1. Sugar resulting directly from starch food . 4803 grs.
2. Sugar resulting from decomposition of proteinic compounds . . . . . 4970 „

Total . . . . . 9773 grs.

The differences between 4803 grs. and the total sugar equivalent ingested, 9321 grs., not being employed in the manufacture of urea or of glucose, must theoretically have gone to produce carbonic acid and water. This difference amounted to 4518 grs. Glucose is converted into water and carbonic acid by the addition of oxygen, according to the following reaction:—

(1) Glucose + (24) oxygen = (12) water + (12) carbonic acid. Reference to the atomic weight of these compounds shows that glucose produces carbonic acid in the proportion of 198 to 264, or exactly 3·4. Hence the 4518 grains of glucose, which was the difference between the total sugar ingested and

the sugar directly formed from starch food, will be converted into carbonic acid and discharged by the lungs.

The most accurate determination of the daily excretion of carbonic acid by the lungs of a person in a state of quietude flows from the observations of Dr. Edward Smith, and gives 71.622 grains of carbonic acid per pound of body weight per day. Applying this to Owen Murphy's case, since his weight was 93.56 lbs., we find the carbonic acid to be excreted by him in a state of quietude to be 6701 grains; when this is compared with the result due to the oxidation of the glucose, the correspondence is too strikingly similar to be attributed to chance.

The minimum excretion of urea of a person in health, consuming the smallest amount of food consistent with bare existence, and observing a state of quietude of mind and body, is 2 grains of urea per lb. of body weight; this quantity representing the expenditure of work which every pound weight of living man requires per day to keep it alive, and prevent it from becoming subject to the ordinary chemical laws of inert matter. In the case of Owen Murphy, supposing him to be in health, but in the minimum condition of quietude of body and mind, the urea due to *opus vitale* (taking his weight at 94 lbs.) would amount to 188 grains, and this converted into work done—according to the rule alluded to in a former paper, viz., 39 grains of urea are equivalent to 100 tons lifted one foot—gives 482 tons lifted one foot. The minimum excretion of carbonic acid of the same person, weighing 94 lbs., at 72 grains of carbonic acid per lb., would amount to 6768 grains. From this, which is the total carbonic acid exhaled from the lungs, is to be subtracted a certain amount of carbonic acid, which is always formed in the healthy production of urea from proteinic compounds, in order to obtain the effective work due to the carbonic acid; and this amount which is to be deducted is found from the equation,—

$$(1) \text{ Proteine} + (75) \text{ oxygen} = (2) \text{ urea} + (32) \text{ carbonic acid} + (19) \text{ water,}$$

in which the urea being to the carbonic acid as 120 : 704, it follows that 188 grains of urea correspond to 1103 grains of carbonic acid, so that in the case of Owen Murphy, the

$$(1) \text{ Minimum excretion of urea was } \dots \dots \dots 188 \text{ grains.}$$

[94 lbs. body-weight at 2 grs. urea per lb. (*opus vitale*)]

$$(2) \text{ Minimum excretion of carbonic acid } \dots \dots \dots 6768 \text{ ,,}$$

[94 lbs. body-weight, at 72 grs. carbonic acid per lb.]

$$(3) \text{ Carbonic acid due to production of 188 grs. of urea } \dots \dots \dots 1103 \text{ ,,}$$

5665 grains.

To convert carbonic acid into work done, the Professor assumes, from Favre and Sillerman's experiments, that one grain of carbon will, by its combustion into carbonic acid, raise 8000 grains of water from 32° F. to 33° F.; and also from Joule's experiments, that the heat requisite to raise one pound avoirdupois of water from 32° F. to 33° F. would lift 772 lbs. through one foot. Hence it follows that the combustion of 100 grains of carbon is equivalent to 39.39 lbs. lifted one foot, the inference from which is that, if Murphy had been in health, the result in work done of the minimum excretion of urea and carbonic acid, consistent with health, in a state of quietude of mind and body, would have been,—

$$(1) \text{ 188 grains urea equivalent to 482 tons lifted one foot.}$$

$$(2) \text{ 5665 ,, carb. acid ,, } \quad \underline{\quad 618 \quad} \text{ ,, } \quad \text{ ,, }$$

Total work done . . . . . 1100 tons

We must now contrast this amount of work with that which would result if the common theory were true, that the urea is produced as usual from the oxidation of proteinic compounds according to the formula—(1) *proteine* + (75) oxygen = (2) urea + (32) carbonic acid + 19 water; for in this case it should be accompanied by its usual and healthy equivalent of work done, viz., 100 tons per 39 grains urea, and the calculation would stand thus:—Murphy in diabetes excreted 1182 grains urea, equivalent to 3031 tons lifted one foot. But this is nearly three times the minimum amount necessary to have kept the patient alive, for the *opus vitale* of such diabetic patient is represented by 1100 tons, so that by the common theory we have a large surplus of work unaccounted for; it cannot be due to *opera mechanica* or *mentalia*, for in those prostrated by this disease there is the greatest incapacity for mechanical exercise, and peculiar aversion to mental exertion;

the unhappy patient himself, by his vacillating and feeble mind and helpless body, is a living contradiction to the idea that the whole of the excessive excretion of urea is derived from the ordinary sources.

Calculated according to the Professor's theory, the amount of work done by an individual in the condition of Owen Murphy is exceedingly close to that which has been shown to be the minimum consistent with life.

Murphy (*Diabetes*).

(1) Urea of min. op. vitale, 188 grs.,	
equivalent to . . . . .	482 tons
(2) Carbonic acid excreted, due to	
the combustion of 4518 grs. of	
glucose = 6024 grs., equivalent to	657 tons
	<hr/>
	1139 tons
Deduct 79.5 tons equivalent to	
729 grs. of carbonic acid, retained	
by the diseased production of	
994 grs. of urea . . . . .	79 tons

Total work done . . . . . 1060 tons lifted one foot.

The Professor assigns a double origin to the urea excreted in diabetes; one is a healthy action, a true combustion, and equivalent to work done; it is represented by the relation—

$$(1) \text{ Proteine} + (75) \text{ oxygen} = (22) \text{ urea} + (32) \text{ carbonic acid} + (19) \text{ water;}$$

the other is a decomposition, and he considers that in the diseased condition the proteinic compounds resolve themselves, without giving out work, into glucose and urea, which decomposition is represented by the relation—

$$(1) \text{ Proteine} + (23) \text{ water} + (3) \text{ oxygen} + (4) \text{ carbonic acid} = (3) \text{ glucose} + (2) \text{ urea.}$$

The two theories of diabetes mellitus he thus compares:—

One theory assumes the sugar to be formed exclusively from starch food; the other assumes it to have a double origin, partly from starch food, and partly from proteinic compounds; these two origins giving about equal quantities of sugar. The first theory fails in two ways; it does not account for the presence of excreted sugar, when all starch food is carefully excluded; and it fails completely to explain the large excretion of urea, which, on this theory, ought to be accompanied by an amount of work done that is nowhere discoverable. The second theory explains the presence of sugar in the excretions on almost any description of food; and also gives a rational explanation of the large excretion of urea, by attributing it to a decomposition not attended by the development of work done.

On both theories a large proportion of the food consumed is wasted in the production of sugar. In the first theory this waste of food occurs in the conversion of starch into glucose, which is excreted as such, without giving out work; in the second theory a similar waste occurs in the spontaneous decomposition of proteinic into glucose and urea, which is supposed not to be attended with the giving out of work; but the essential difference between the two theories is that while they both offer an explanation of the excretion of glucose, the first theory fails to explain the corresponding and equally remarkable excretion of urea, a phenomenon which is satisfactorily accounted for by the second theory.

**PARTIAL INSANITY.**—It has seemed to the Commissioners in Lunacy that it would be very desirable if arrangements were made for the reception in the lunatic Hospitals of persons of whom (say the Commissioners) "we have reason to know that there are many," not insane, but who, being conscious of a want of power of self-control, or of addiction to intemperate habits, or fearing an attack, or a recurrence of mental malady, but being in all respects free agents, may be desirous of residing as voluntary boarders in an institution for the care and treatment of persons of unsound mind, submitting to a modified control, and conforming to the general regulations of the Hospital. These Hospitals are in most cases mainly supported by endowments or annual subscriptions; a few are in a great measure self-supporting. The Commissioners have just taken the opinion of Mr. Welsby upon the subject. He states that he does not find in the statutes for the regulation of registered Hospitals any prohibition on such persons being admitted as inmates on the terms above suggested, and he is of opinion that they may be received accordingly, contracting alone, or jointly with others, to conform to certain regulations expressed or referred to.

REPORTS OF HOSPITAL PRACTICE  
IN  
MEDICINE AND SURGERY.

WESTMINSTER HOSPITAL.

RUPTURED POPLITEAL ANEURISM—LIGATURE  
OF THE FEMORAL ARTERY—SUPPURATION OF  
THE SAC AND SECONDARY HÆMORRHAGE  
MORE THAN TWO MONTHS AFTERWARDS—  
AMPUTATION—RECOVERY.

(Under the care of Mr. HOLTHOUSE.)

ELIZABETH L., aged 29, married, pale, and cachectic-looking, and a hard spirit-drinker, was admitted into the above Hospital, under the care of Mr. Holthouse, on December 2, 1862, with a large painful fluctuating swelling of the right ham and upper third of the leg. The patient says her attention was first attracted to it about eighteen months ago, in consequence of suffering from cramps in that leg, when she perceived a small swelling about the size of a nut at the lower part of the ham, and it has continued to increase gradually to the present time. She can assign no cause for it.

*Examination of the Limb.*—The knee is kept a little bent, and a small quantity of fluid occupies its synovial sac. A tape carried over the joint, and around the most prominent part of the tumour, gives fifteen and a-half inches as its circumference while the circumference of the corresponding part of the opposite limb, bent at the same angle, is only eleven and a-half inches. The skin over the upper and outer part of the tumour is of a dusky red colour, and deep fluctuation is felt over every part, but it is more evident opposite this discolouration of the surface. A feeble impulse, synchronous with the heart's beat, is communicated to the hand placed on the tumour, and a very decided, though not a loud, bruit is heard over every part of it. Pressure on the femoral artery in the groin arrests the impulse and bruit, but produces no effect on the size of the tumour, neither can its size be diminished by any amount of pressure which the patient is able to bear. The pulsation of the posterior tibial artery behind the inner malleolus is less distinct than on the sound side; the superficial veins of the leg are slightly enlarged and distended, there is no œdema of the ankle or foot, and the temperature of both feet is equal and natural.

As the swelling was very painful, a large warm linseed-meal poultice was applied, which gave great relief, and on the 4th the whole tumour felt more solid and less painful.

December 10.—Is exceedingly irritable and impatient, and could not bear the flexion treatment, which was tried for forty-eight hours. The consistency of the tumour remains the same, but it has been less painful ever since the application of the poultice; it now measures sixteen and a-half inches in circumference. The treatment with the ring tourniquet was now tried, two being applied over the femoral artery at a short distance from each other. At her urgent request four ounces of gin were ordered.

11th.—As irritable and impatient as ever; has removed both the compressors, the limb was therefore put up on a McIntyre splint with a broad thigh-piece, and outside and around this an ordinary tourniquet was placed, having its pad on the femoral artery, and the thigh protected from the pressure of the band by the thigh-piece of the splint. Mr. Holthouse hoped, by treating her as if she had a fracture, to compel quietness, and thus more effectually control the patient's restlessness, and also the circulation of the limb; but two days afterwards she had loosened all the bandages and removed the tourniquet, which she declared she was unable to bear. She had very little sleep, although an opiate was taken every night, and she complained of having constant pain in the leg and foot. The circumference of the limb around the tumour was now seventeen inches. As it was obviously useless to persist in further attempts at treatment by compression, the patient was placed under chloroform on the 16th, and the femoral artery tied in the lower part of Scarpa's triangle, the tumour now measuring seventeen and a-half inches in circumference. After the closure of the wound the limb was rolled in a flannel bandage over a worsted stocking, and the foot and ankle enveloped in wool.

17th.—Has not slept well since the operation, but feels very

comfortable and free from pain. The right foot is quite warm, though the wool has been removed, as she felt it too warm, and the heat excited formication. All excitement has disappeared, and the patient now is calm and rational, and expresses herself as feeling very comfortable and grateful.

21st.—Countenance has quite lost the expression of suffering it had, and is cheerful and healthful-looking. Has had scarcely any pain in the limb since the operation, but the foot continues quite numb, though warm.

22nd.—Removed the bandage and stocking to examine the foot, which is warm and of natural colour, though numb.

24th.—Continues improving in looks and cheerfulness, and has now a good appetite. For the first time says the foot is beginning to throb. Full diet. Porter, Oss.; gin,  $\bar{z}$ iv.

January 3.—The ligature has not yet come away, but she continues in a satisfactory state. No pulsation or bruit can be detected in the tumour, which, however, is not smaller, and the skin over the most depending part of the ham is more livid and thinner, fluctuation being evident. The temperature and sensation of the foot good.

5th.—The ligature came away this morning without hæmorrhage.

12th.—Looks and feels well. Got up yesterday, and experienced only weakness of the limb, which she could not stand on. Appearance and size of the tumour have undergone no change: it is still livid, soft, and fluctuating.

31st.—Goes out with crutches nearly every day; her foot suspended in a sling; appearance and feel of tumour the same, but circumference less (sixteen and a-half inches).

February 14.—Went out a few days ago, and came back intoxicated; she has not been well since; tongue foul; appetite bad; look depressed.

21st.—Continues poorly, and without appetite; appearance of tumour the same, but feel very different,—quite soft, and fluctuating everywhere, and tender on pressure; foot also painful.

24th.—Whole leg hot, painful, and inflamed, and foot œdematous; skin over the most prominent part of the tumour thinner, the whole contents evidently fluid. Mr. Holthouse made an incision one inch and a-half in length, and gave exit to about sixteen ounces of bloody pus with a few soft coagula. A bandage was afterwards applied from the foot to above the knee, a large wet compress being applied to the wound.

25th.—At 7.30 p.m. yesterday evening a large gush of arterial blood took place, which was arrested by the tourniquet, and on Mr. Holthouse's arrival she was pallid, covered with a cold perspiration, and almost pulseless. Having cleared away the blood, and made her comfortable, a ring tourniquet was substituted; but on coughing another slight gush took place, which was immediately checked by tightening the instrument. She rallied under stimulants, and passed a good night, and up to this time, 3 p.m., had had no return of the hæmorrhage. She was taken to the theatre, and the wound enlarged, with the view of securing the bleeding vessel; but, not finding it, the limb was removed at the lower third of the thigh by the flap operation.

26th.—Is very comfortable, free from pain, and has a good pulse.

March 8.—The ligature on the femoral came away to-day, the other having separated previously. Has not had an unfavourable symptom, and most of the wound has healed without suppuration.

14th.—The whole of the incision has healed, though not cicatrised, the only dressing required being a strip of dry lint over the granulations.

April 4.—Has been up and about since last note, but is very pale and feeble. Goes to Walton this afternoon.

*Examination of Limb.*—The sac of the false aneurism, which afterwards suppurated, extended from the upper part of the popliteal space to about the junction of the middle with the lower one-third of the leg, and contained a few loose coagula and a little bloody pus; its walls were constituted by the boundaries of the popliteal space above, and by the condensed and infiltrated skin and the gastrocnemius muscle below, between which the cavity existed. On washing this well out, the true aneurismal tumour was seen, with the popliteal nerve flattened out over it, the popliteal artery also somewhat flattened, and apparently enlarged before it expanded into a fusiform aneurism, from two to three inches in length, about one and a-half in breadth, open in its whole length towards the cavity of the abscess, and containing a firm solid clot. The artery leading to the aneurism was

pervious from the point of section, and apparently healthy. The posterior tibial was small; one of the articular arteries very large.

THE ROYAL LONDON OPHTHALMIC HOSPITAL.

A CASE OF ENTROPIUM, PROBABLY SPASMODIC IN ORIGIN, SUCCESSFULLY TREATED BY THE REPEATED APPLICATION OF COLLODION.

Communicated by Mr. SPENCER WATSON.)

ANN S., aged 59 years, an unmarried woman of spare habit, came under treatment with severe purulent ophthalmia of the left eye on August 20, 1862.

22nd.—The cornea sloughed, and the lens escaped.

Since that date there has been great irritation going on, and the lower lid has become inverted, from irregular action of the orbicularis and tensor tarsi muscles.

On September 20 the corneal wound had cicatrised, and she now came under Mr. Hulke's care, and under my observation as clinical assistant.

On the 27th collodion was applied to the lower lid.

This was repeated twice a week until December 27, when the entropium was entirely overcome, and the irritation caused by it entirely ceased.

On March 21, 1863, she again presented herself. Since the last note she has had an attack of iritis in the right eye, from which she has made a good recovery. The lid of the left eye is still in good position.

This case is instructive, as illustrating the benefit of the persevering application of simple remedies, and, at the same time, the necessity of great patience during a somewhat tedious course of treatment.

The entropium in this patient was probably first induced by swelling of the lid during the attack of purulent ophthalmia. This swelling happening to affect the lower part of the lid more than its upper border, and the dermal rather than the conjunctival surface, the marginal fibres of the orbicularis were thrown into such a position that their contraction, during the continuous blepharospasmus accompanying the disease, caused the inversion of the ciliary margin. This tendency would be increased after the slough of the cornea and the escape of the lens, for the lids would then have lost the support usually given them by a full and healthy eyeball. Probably the looseness and flaccidity of the skin in this patient contributed to the result. It is well known to Surgeons that ectropium is a more common accident of severe purulent ophthalmia than entropium; this, therefore, may be looked upon as an exceptional case.

The collodion here used was rather less fluid than that usually employed, and it was brought to the necessary consistence by evaporation previous to each application. It was found that by this means a firm film could be applied, and would dry on so rapidly that the flow of tears, which was occasionally very copious, had not time to pass over the part and prevent adhesion. It was of the greatest importance to dry the surface thoroughly before applying the collodion, and it acted most efficiently when a portion of the film was attached to the upper part of the cheek.

It gave complete relief to the patient after each application, and the pellicle often remained attached for three or four days, so that the relief was thus made continuous. This plan had to be persevered in for three months.

UNIVERSITY OF DUBLIN.—At the Summer Commencements, held in the Examination Hall of Trinity College, on Wednesday, June 24, the following degrees in Medicine and Surgery were conferred:—*Licentiatii in Medicinâ*.—David Gulielmus Telford, Edvardus Thomas French, and Jacobus Robertus White. *Baccalauri in Medicinâ*.—Laurentius Edv. Desmond, Carolus Fleetwood Churchill, Giraldus E. Barron, Alexander Preston, Isaacus Waugh, Gulielmus F. Smith, Johannes M. Purser, Josephus Henry, Henricus F. E. Phillips, Robertus Morton, Carolus Baker Stoney, and Gul. Peirce. *Magistri in Chirurgiâ*.—Isaacus Waugh, Gulielmus Fawcett Smith, and Carolus Baker Stoney. *Doctor in Medicinâ*.—Laurentius E. Desmond.

Medical Times and Gazette.

SATURDAY, JUNE 27.

THE NEW CIRCULAR FOR THE ARMY MEDICAL DEPARTMENT.

IF anything were wanted to indicate the uncertain and vacillating course upon which Her Majesty's advisers have entered, the publication of two Circulars by two separate Ministers for War, within almost as many months, would declare it.

We make no apology for recurring to the present deplorable state of the Army Medical Department, for it is as much our duty as journalists to speak out freely as it is the duty of the Profession generally, and of our younger Surgeons in particular, to indicate plainly their opinions—so plainly, that "he who runs may read," although the runner be a Horse Guard's official.

If ever we are to hold our proper position as a Profession—if ever we are to enlarge our sphere of usefulness—it is essential that the acts of governing bodies should not be registered and passed over in silence.

We find this new Circular or Warrant, No. 825—for it will be soon as important for the War Minister to number effusions as for a journalist to distinguish his serials, if these official documents are to follow one another so rapidly—is to be substituted for that of March last (No. 808).

The present one is the same as the last—neither better nor worse! After enumerating that "relative rank shall carry with it all precedence and advantages attaching to the military rank with which it corresponds, and shall regulate the rates of lodging money, number of servants, rations of fuel and light, or allowances in their stead;" it goes on to add "except for officers and others to whom special rates have been assigned."

What this means exactly, or why these few words needed a new Circular, we do not know. We are contented to believe that it is one of those things "which no feolah can understand;" but we can hardly imagine any one so sanguine as to deem the "exceptions" will be in favour of the Army Medical officer!

It is quite possible—nay, quite in keeping with the past history and present conduct of those who sit in high places—that "special rates" may be assigned below those to which an Army Medical officer's relative rank would entitle him.

When we happen to know—for we have heard it stated by them—that the best class of men in Her Majesty's army would resign the service if they had the power now to enter upon a new field, we ask ourselves—What do the younger men expect from it?

Time and space would prevent our going through all the causes of discontent; suffice it that there is a spirit of antagonism to the Army Medical Department in everything emanating from the Horse Guards, and—what is quite as bad, if not worse—there is no evidence that the present administration of the Department is conducted in the way that it might be.

We should like to know why an Inspector-General of

Hospitals should have to serve *three years* in that grade before he ranks as a Major-General, when an Inspector-General of Musketry, a Chaplain-General, and a Commissary-General takes that position at once on their appointment to their respective ranks?

The Commander-in-Chief, we take it, when he has to pour out "the vials of his wrath" upon a Colonel—Crawley, for example—and upon a member of the Medical Department, uses vials of very different capacities!

Let us take the Department from any point of view, and what do we find? There is a great reduction in the numbers of the higher ranks; there are vacancies in abundance that have not been—nor are they likely to be—filled up; there is, consequently, no leave of absence for Medical officers, and there is so little chance of promotion for any new Assistant-Surgeon, that one grows grey in the calculation of the probabilities as to the time!

That portion of the Medical Department serving in India are even worse off than their brethren at home!

Look at the Department socially! What is the position of a Medical officer at mess? Now we do not want to see Military Surgeons transformed into *officers* only,—we are *utterly opposed* to a man's endeavouring to appear as if his *relative* were an *absolute* rank. Nothing can be more ridiculous or reprehensible than this; but we do think that it is unjust to place the Surgeon-Major of a regiment, who pays more to the mess in subscriptions than the colonel, and whose relative rank is next to that officer's, in a lower position, at his own mess-table, than the youngest subaltern present, as is now done, if, as is said to be the case, the mess dinner is a "military parade," which, if he be an unmarried officer, he must, by the regulations of the service, attend daily.

If we turn to the internal working of the Department we find it no better.

There never was a period when men were subjected to such rigorous laws; there never was a period when men were so arbitrarily mulcted of money for expenses connected with rejected recruits or unregistered diets! The Army Medical officer is as much fenced and hemmed in by bands of red-tape as ever, and his hands are still more engaged with the pen and ink-bottle than the stethoscope or his patients. Medical officers are called upon to obtain the instruments for marking the letters D. and B.C., and they have to superintend and instruct the Hospital sergeants in the infliction of a punishment. As well might a Surgeon be called upon to supply the cat, and instruct the drummer in using it as to do these things!

The honest exercise of some discretionary power by a Medical officer never entailed so large a number of "reasons in writing" as now. The execution, too, of the so-called sanitary duties will soon render the post of Quarter-Master unnecessary, and we venture to suggest that a considerable saving might be effected if Medical officers had to superintend and instruct in barrack cooking! By some curious oversight on the part of the authorities, this has not yet been made the subject of any War-office or Departmental order!

We must not forget that the privileges—and they were but few—enjoyed by the Surgeons of Regiments in India have been ignored; for instance, the Surgeon has been denied the *privilege* of exchanging, which every other officer enjoys as a matter of *right*, and the whole patronage of Indian appointments is circumscribed within the limits of "Whitehall-yard."

But enough! We had hoped that with the late Sir George C. Lewis's eulogium upon the then forthcoming Warrant something would have been done effectually. We trusted that after the occupancy of Whitehall-yard by a man like Alexander there would have been a new era in the Medical Department. It is unnecessary to add a word about our disappointment!

In conclusion, one word. In August, the Army will advertise its vacancies, and we venture to predict—shall we

add hope—that the daily papers will have to repeat their remarks how these vacancies were "plugged up" by the "sweepings of the schools," and how *Punch's* advertisement for "Medical snobs" met with numerous applicants.

## THE WEEK.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—EXPULSION OF MR. EVAN THOMAS.

ON the evening of Tuesday last, after the ordinary meeting of the Society, a special meeting was held in order to determine whether the name of Mr. Evan Thomas should be removed from the list of Fellows. He had in March last been sentenced to three months' imprisonment for perjury, and consequently his name had been removed from the roll of the College of Surgeons and from the Medical Register. According to a by-law of the Society it was necessary that four-fifths of the members present should vote for expulsion. Of thirty-six, thirty-four voted for it, and two against it. The President therefore erased the name from the list.

THE ELECTIONS AT THE COLLEGE OF SURGEONS.—VOTE FOR LANE AND BUSK.

THE elections to the College Council continue to excite much interest, and various are the speculations as to the successful candidates. The feeling in favour of Lane continues steady; his claims cannot be set aside. Next to Lane comes Mr. Busk; and we say without hesitation to the country Fellows, that, if they do not support him, they will deserve ever hereafter to be snubbed themselves. Mr. Busk is an experienced and distinguished Hospital Surgeon,—a man of science *par excellence*. He is just the man whose opinion would be of service in the Council, and, if promoted to the Court of Examiners, as he ought to be, he would enable that body really to test the proficiency of students in physiological science. At present the complaint is, that students examined at the College are afraid to profess the most recent scientific doctrines, lest they should be reprimanded. With Mr. Lane and Mr. Busk, the opinion of most Fellows inclines in favour of returning one of the elder candidates, Mr. Hawkins or Mr. Tatum. After Lane and Busk comes the name of Mr. Curling. From the earliest point of his Professional life, when he published his standard work on "Tetanus," based on the Jacksonian Prize Essay, his career has been one of solid unobtrusive work. He is said to have been unwilling to come forward, lest by so doing he should interfere with the just claims of Mr. Busk; but of course his friends would be much to blame if they allowed him to be thrust aside, in order that a younger man, with certainly fewer titles to distinction, should be placed over his head.

THE SITE OF ST. THOMAS'S.

THE Medical officers of St. Thomas's Hospital have made one more move, and a very significant one. It is well known that there are diverse interests at stake in the new site. The interests of the patients, of course, demand a pure air, an elevated site, and such space as can only be got a little way out of town. If there were one or two receiving houses in Southwark or Lambeth for such cases as really cannot travel further, it would suffice: but as for the majority of the sick and injured—a man who has to be removed at all, may as well be removed three miles into pure air as into foul. With railway accommodation, it would be easy to send 95 per cent. of the patients at once to a country Hospital. But the interests of the Medical officers point to a Hospital within an easy drive of Park-lane. Private practice and a flourishing Medical school—two objects which surely were "never contemplated by the founder"—give these gentlemen a leaning towards a conspicuous town site as near Belgravia as possible. Accordingly, "the intentions of the

founder, for the benefit of the Southwark poor," are now found to be quite compatible with the planting the Hospital westward, opposite the new Houses of Parliament. The site, it is true, has yet to be created, over the mud of the Thames; but then, the Medical officers flatter themselves that a good time is coming when the Thames shall no longer stink, when fog shall be unknown, and when the natural laws which connect miasm with low muddy sites shall be suspended, in order that the Southwark poor may have "the priceless benefit of a Medical School." We happen to know that a leading Medical officer so far forgot himself, that he congratulated the Treasurer of St. Thomas's on his improved health since living out of town; possibly we shall hear of people being recommended to go to Bankside for change of air.

PARLIAMENTARY.

IN the House of Lords, on Thursday, June 18, after a conversation in reference to the purchase of the Exhibition building, when the dissentients were represented by the Duke of Rutland and Lord Hardwicke, the subject of vaccination was introduced by Lord Lyttleton, who quoted the suggestions of the Council of the Epidemiological Society for an alteration of the law on the subject. These suggestions were:—1. The making provision for the systematic local supervision of vaccination. 2. The providing more effectual means whereby the local authority or appointed superintendents might ascertain who were and who were not vaccinated. 3. An extension of the age within which vaccination must be performed in those districts in which, from the limited population, etc., vaccination from the arm could only be maintained periodically. And, 4. An extension of the powers of the Privy Council over local arrangements for vaccination, so far as was necessary to secure the more effectual maintenance of local supplies of fresh lymph. Lord Lyttleton wished to know whether it was the intention of the Government to introduce a bill for an amendment of the law in this or the next session of Parliament.

Earl Granville said that the Government were fully alive to the necessity of something being done, and were considering the best means of effecting an improvement in the law.

In the House of Commons, the most important event was the second reading of the Public Works (Manufacturing Districts) Bill. This measure is intended to provide for the unemployed in the factory districts, by engaging them in works wherein a certain amount of unskilled labour may be employed as supplementary to skilled. Such works are sanitary improvements, making drains and sewers, levelling waste lands, forming parks and recreation grounds, cleansing and improving rivers, forming reservoirs, etc. The million and a half to be lent to the local authorities for these purposes—£431,756 only of which is to be allotted to the payment of unskilled labour—however inadequate as a means of relief for the entire population of the factory districts, is still an instalment of good. If a better sanitary condition in our industrial towns be the result deduced from the cotton distress, that calamity, like the Fire of London, may come to be hereafter regarded as a national benefit.

On Friday, June 19, the House of Commons went into committee on the Alkali Works Regulation Bill, sent down by the Lords, one great provision of which is to enforce the condensation of the muriatic acid gas evolved in the manufacture. The influence of the gas on vegetable and animal life was illustrated by Mr. Bruce, who said that in the neighbourhood of St. Helens and other towns trees and vegetation were injured and occasionally destroyed, residences were rendered uninhabitable, and cattle suffered so that the quality of their milk was affected, and they cast their young.

The various clauses of the bill were discussed, and most of them agreed to.

The Chancellor of the Exchequer, in answer to Lord

Enfield's question as to the report said to have been received by Government assigning £30,000 as the value of the Exhibition building, said that no official report had been sent to the Treasury. It was true that Mr. Bowring, the Secretary of the Commissioners of 1851, had drawn up a statement in which he placed the minimum value of the materials at £30,000, but the maximum value at £200,000. No positive standard could be named, as the value depended on the nearness or distance of the market. It would appear, therefore, that the country is to pay a price out of all proportion to the intrinsic value of the materials, simply because it has bought the ground on which they stand.

From a question asked by Sir J. C. Jervoise, it appears that the sum of £434 10s. is to be expended in investigating the effect of vaccination on sheep and in the examination of sheep arriving at Irish ports, for the purpose of preventing the spread of small-pox amongst them. Sir G. Grey said that the experiments were not yet completed, but when they were there would be no objection to laying the results before Parliament.

On Monday, June 22, in answer to a question by Mr. Coningham, the Marquis of Hartington said that it had been decided that Colonel Crawley should be recalled to this country, where the court-martial in reference to his conduct in the case of Sergeant-Major Lilley will therefore take place.

The debate on the purchase of the Exhibition building is postponed until Thursday in next week.

On Tuesday, June 23, in the House of Lords, Lord Shaftesbury drew the attention of the House to the recent melancholy death of the unfortunate seamstress (the report of the inquest on whom will be found in another part of this Journal) alleged to have been caused by overwork and unfit sleeping apartments. He asked whether the Government were prepared to introduce a measure for the ventilation and sanitary regulation of the workrooms in which seamstresses were employed.

Lord Granville was not prepared to state that the Government intended to introduce any bill on the subject; but if Lord Shaftesbury himself would bring in a bill, it would meet with full consideration.

A similar question was asked in the House of Commons by Mr. Bagwell, and received a similar answer from Sir George Grey. The truth is, that, deplorable as the state of things revealed by this case is, interference on the part of the Government would be surrounded with difficulties. Many of the workrooms, as Sir George Grey said, form parts of private houses, and if they, with the sleeping apartments, are to be subjected to inspection by Government officials, the same surveillance might, with equal justice, be extended to the bedrooms of domestic servants, and the underground closets where butlers sleep. The only principle which can be safely asserted is that if any class are dependent, or, if sick, are likely to be dependent on public money, the health and wellbeing of that special class then becomes justly the public care. In the case of other classes no interference on the part of Government with habits of living can take place without trenching on the prerogatives of freedom of action and of choice. We know that this principle has been departed from in the case of the bakers, but it is one to which it would be dangerous to sanction many exceptions.

The House of Commons went into committee on the Vaccination (Scotland) Bill. The only amendment moved, and we regret to say carried, was one by Mr. Blackburn:—that the fee for the public vaccinator be 1s. 6d. within two miles, instead of 2s. 6d., and beyond that distance 2s. 6d., instead of 3s. 6d. Such is the idea held by the House of Commons of Professional remuneration—1s. 6d. for performing an operation requiring skill and care, whose importance cannot be overrated, at a distance of two miles from the operator's house—sixpence more than the law allows to a London cabman as his fare!

CONDITION OF THE MILITARY HOSPITALS OF THE UNITED STATES—USE OF BROMINE IN PYÆMIC DISEASE.

TYPHUS, erysipelas, and Hospital gangrene, appear to have been very prevalent in many of the military Hospitals of the Northern States of America, those of Annapolis, Louisville, Nashville, and Meerfreesboro having especially suffered. At Louisville the disease occurred almost always in patients who had been wounded at the battle of Meerfreesboro, and who had been retained in crowded Hospitals for some time previous to their transportation to Louisville. The Medical director of the Nashville Hospitals asserts that no one upon whom the gangrene had already appeared was ever sent from Nashville, and yet many were so infected when admitted to the Louisville Hospitals. The development of the disease on the route seems to have been owing to the fact that the transportation of the wounded was effected by means of crowded and ill-ventilated boats, and that the trip by the Cumberland and Ohio rivers frequently occupied several days. During this time these patients, who had already undergone much suffering, were exposed to all the influences most apt to engender this disease. In contrast with this fact it was found that as soon as the Louisville and Nashville railroad was opened, so that the wounded could be conveyed from city to city in one day, all importation of gangrenous sores into Louisville ceased. A similar cause seems to have been operative in introducing Hospital gangrene into the Annapolis general Hospital. Erysipelas also was very rife in the Nashville Hospitals after the battle of Meerfreesboro, and both here and at Louisville special Hospitals were set apart for the reception of such cases. The treatment almost universally adopted in the Louisville Hospitals is that originated and introduced by Surgeon Goldsmith, U.S.V. It consists in the direct local application of bromine, either pure or in solution, to the surfaces of the sloughing sore. Due care is always taken first to remove as thoroughly as possible the sloughs, so that the agent may act on the living tissues, and permeate them to some extent. In cases in which the burrowing is so extensive and deep-seated as to render the application of the bromine difficult or incomplete, Dr. Goldsmith resorts to hypodermic injection of bromine at the circumference of the sore. The punctures with the point of the syringe are made at intervals of from one-half to three-fourths of an inch, and one drop of pure bromine is thrown into the tissues at each application. Dr. Goldsmith states that in forty-eight hours the specific character of any such sore can be destroyed. The arrest of the virulent process is at once evinced by the absence of the peculiar odour and by the marked change for the better which immediately ensues in the constitutional symptoms. Two methods are employed in the application of bromine to the treatment of erysipelas. In the first, the vapour is employed: the part affected is enveloped in dry lint, a cloth saturated with pure bromine is applied over this, and the whole dressing covered with a piece of oiled silk. The only objection to this method is the tendency of the bromine to soak through and produce blistering. The other method is to apply directly to the part a solution of bromine and bromide of potassium of the strength of fifteen to forty drops of the former to an ounce of water. It appears from a letter by Dr. Woodward, of the Park Barracks, Louisville, that he has been using bromine also as a remedy in diphtheria. For the treatment of this disease he says he has found no means so effective as inhalation of the vapour of bromine, and the exhibition of from half a drop to a drop in glycerine every four, five, or six hours. The same writer says that he is using bromine also in both primary and secondary syphilis with marked success. The vapour of bromine is also being used in the wards as a prophylactic against erysipelas. Before using it in the crowded wards, Dr. Woodward states that they used to get from five to eight cases of erysipelas per week, but since its use not one case has originated in the wards. He says that so well is its power established to prevent the spread

of erysipelas, that even the ward masters and nurses, who used to dread the effects of being in the wards with erysipelas patients, no longer fear it in the least, for they see there is perfect immunity from danger. It is said that it is equally preventive of Hospital gangrene. Notwithstanding that the isolation of the gangrenous patients had not been enforced at Louisville, an Inspecting Surgeon sent from Washington reports the little tendency of the disease to spread from bed to bed. He regards the absence of this tendency to infection as telling strongly against the supposed virulence of the affection, and thinks that it should even throw doubts upon its true nature. At any rate, he thus sums up the impression left on his mind by what he saw there and at other Hospitals where bromine is used. 1. That the external employment of bromine in the treatment of Hospital gangrene has been attended in Louisville with the most marked and beneficial results. 2. That he has not observed any injurious consequences whatever to have resulted from its application, but the contrary. 3. That all the Medical officers with whom he had conversed in Louisville, Nashville, and Meerfreesboro unite in testimony as to the valuable therapeutic powers of bromine in the treatment of erysipelas, and that his own observation fully confirms their views. 4. That as a disinfectant the use of bromine in Hospital wards, and especially in Hospitals intended for the reception of infectious diseases, is to be recommended, and is eminently deserving of further trial. Dr. Woodward, we may add, thus sums up the physiological action of medicinal doses:—"Bromine has a directly stimulant and tonic action, as well as antiseptic. Under its use the volume of the pulse is increased, but not its frequency. The skin becomes warm, the secretions from the kidneys increased, and the deposits of the urine are largely increased."

REVIEWS.

*Observations on Diseases of the Rectum.* With Wood Engravings. By T. B. CURLING, F.R.S., Surgeon to the London Hospital, Examiner in Surgery to the University of London, etc. Third Edition, Revised and Enlarged. London. 1863.

MR. CURLING is no mere specialist, but a Hospital Surgeon, whose life has afforded him the broadest possible means of observation and experience over the whole of the art. His book therefore may be consulted with the full conviction that it will not merely contain those petty minutiae which may be learned by treating the common maladies of large numbers of wretches in the out-patients' room, but that it will embrace whatever subjects show the connection between maladies of the rectum and the whole of surgery in the broadest sense.

The present edition contains eight new chapters,—on Nervous Affections of the Rectum; the Villous Tumour; Epithelial Cancer; Atony of the Rectum; Organic Contractions; Obstructions, and the Operations required for their Relief; Congenital Imperfections; and Colotomy in Cases of Imperforation. The last subjects have received special attention, and we may say that a careful perusal of them, showing the number of various complications which Surgical industry and ingenuity has collected and classified, and the results, gives us a most hopeful view of the increasing benefits which Surgery is destined to bestow on suffering humanity.

Mr. Curling's work is written in a good, clear, unaffected style, like the work of a man who has plenty of stuff, and does not want to eke it out unnecessarily. It is evidently written for the Profession; and we can promise any of our brethren who desire to add a new book on the subject to their shelves, that they will be well satisfied with Mr. Curling's.

CHANGES AT THE LOCK HOSPITAL.—The office of Surgeon to the Lock Hospital has become vacant by the resignation of Mr. Henry Lee, whose other Professional avocations prevent his being able any longer to hold the office. Mr. Gascoyen will now become Surgeon to the in-patients, and the office of Surgeon to the out-patients will be open for competition.

## PROVINCIAL CORRESPONDENCE.

## EDINBURGH.

June.

No wonder that some of us cannot walk erect, for Dame Nature has not weighted us with our viscera in equal proportions, as was shown by Dr. Struthers in an elaborate paper read the other evening before the Medico-Chirurgical Society. He had carefully weighed the viscera of numerous subjects, and found that the right half of the body had the preponderance, which accounts, in his estimation, for us using the right arm, and resting on the right leg more than on the opposite limb. So it would appear that those are fortunate who happen to have an enlargement of a viscus on the left side, thereby tending (like John Gilpin's bottles) to keep a proper balance.

Dr. Struthers is at present investigating cases of supernumerary toes and fingers. However, he does not confine himself to open-handed mortals, but has recently gone the whole hog, and written a pamphlet on the solid-hoofed pig. Talking about viscera, Dr. Warburton Begbie exhibited to the Society a spleen which weighed close upon eleven pounds. The blood of the patient examined during life contained considerable quantities of white corpuscles. Dr. Begbie has some interesting cases in his wards in the Infirmary, and he has promised to read us a paper at no distant date, and, as he is an enthusiast in his Profession, and no mean observer, we may anticipate something worthy. I consider that the Medical School here is fortunate in having such a man as Dr. Begbie—one who can impart instruction so well, and elucidate the subject he takes in hand. Dr. P. H. Watson showed a very small probe-pointed steel catheter, No. 1, made of tempered steel, to be used in cases of stricture. It can be passed into the bladder much more easily than the No. 1 silver, as not being so liable to bend. Dr. M. Duncan has recently had a case of extra-uterine pregnancy. The fœtus was discharged per anum, and presented a breech presentation, and although the sphincter ani was dilated so considerably both by the passage of the fœtus and by the necessary introduction of the hand of the Accoucheur, it recovered its normal proportions in a few days, and in the meanwhile the patient had no difficulty about retaining the fœces.

The Edinburgh Artillery Militia are at present up for training and exercise, and are a fine body of men, none being enlisted under five feet six inches. The Government make a great mistake in serving out leather stocks to soldiers; they are a source of great discomfort, and, after our Crimean experience, I wonder that the men's tunics and jackets are not made with "tabs" inside the collar, similar to the officers'; it would be a great pecuniary saving, and avoid the chance of sore necks and threatened apoplexy. In the new artillery carbine exercise, I notice that in the "prepare to charge,"—and I would draw the attention of the Director-General Army Medical Department to this,—the rear rank comes to the "support," bringing the stock across the left thigh, the barrel slanting towards the right shoulder, and the sword right in front of the face of the right hand file, so that if the men advance at the double, there is every chance that some one or other gets a gash across the face, or an eye poked out, the more especially if the ground happen to be uneven. The old style of "support" was much more safe and effective, viz., the butt to the front, the barrel in the bend of the elbow, and the sword behind the head of the right hand man.

The other night I was called to a case of suicide by hanging, but which presented such very suspicious appearances that I warned the police, and desired that their Surgeon should be sent for; he consequently attended, and examined the body, coming to the conclusion that it was a case of self-destruction, and his report to the Procurator Fiscal was to that effect, and there ended the affair, my suspicions turning out, as it happened, to be groundless, the public prosecutor (so called, I presume, because he very seldom prosecutes, and that in private) being quite satisfied. Now, I hold that such a state of matters is not as it should be, and a public investigation should take place on all cases of sudden death. Our present police Surgeon happens to be a highly-accomplished and well-educated gentleman, a good toxicologist, and eminently well fitted for the post he holds; but supposing that a Surgeon not so well qualified or conscientious as Dr.

Littlejohn occupies the situation, is the report by that single individual to influence the Fiscal as to the investigation of suspicious cases? and even then that functionary may be unwilling to prosecute inquiries, in order to save himself any trouble and annoyance. I have frequently heard it remarked that nowhere can a murder be committed with such secrecy as in Scotland, and although there may be disadvantages connected with "crown's quests," still, on the whole, there is less chance of the escape of the guilty. Here the forensic duties of the police Surgeon are under the direction of the police authorities of the district, and it seems to me that the Procurator Fiscal is under the direction of the Surgeon of police. Mr. Spence has had two cases of tracheotomy for croup, one in the Royal Infirmary and one in private; both have done well. He has also had two cases of excision of the knee-joint. One of them primary, on a patient who was rash enough to leap from a railway-carriage while it was in motion. He uses two saws in the performance of the operation; a large one for the femur, and a small one, without a back, for the tibia. Almost all Surgeons have their fancy and pet instruments, which they consider to be the proper things for the several operations, and, although some cavil at it, there is no harm; for, after all, if the object in view is successfully obtained, little recks it whether it be attained by means of a fancy or orthodox tool.

Professor Simpson has had several new cases of vesico-vaginal fistula, in which he has had his usual success, using merely a vulsellum, knife, and a threaded needle. There are few operations for which the Medical man gets such grateful thanks as for this apparently a simple one, but in reality difficult of performance, giving such relief and comfort to the truly unhappy patient. Dr. Simpson has had also a case of clitorotomy, performed on account of that distressing malady, nymphomania, where the poor sufferer is banished equally from public and private society,—a martyr to circumstances over which she has truly "no control."

Mr. Edwards has been using acupressure in lieu of the ligature, and with success. I wonder that it is not more frequently tried in the Profession, but there is, has been, and ever will be, an indisposition to generalise any new system. We like the good old beaten path, and hesitate to tread those by-roads, lead they ever so much to honour and renown.

## GENERAL CORRESPONDENCE.

## A NOTE ON SMALL-POX.

LETTER FROM DR. JOHN MACDONOGH.

[To the Editor of the Medical Times and Gazette.]

SIR,—Harriet B., aged 19 years, residing in St. Paul's-place. She and her elder sister stated that the said Harriet B. was duly vaccinated when an infant (a good cicatrix, etc.). In a few months after vaccination she was exposed to the contagion of small-pox. She took it, had it very full, and was marked by it.

On June 15 she died of confluent small-pox. Ill eleven days.

I am, &amp;c.

JOHN MACDONOGH, M.O., and M.O.H.

Clapham, June 17.

## BOOKS RECEIVED.

Clinical Researches on the Auscultation of the Head. By M. H. Roger, M.D. Translated from the French by Alfred Meadows, M.D., M.R.C.P. London: Renshaw. 1863. Pamphlet.

\* \* \* About twenty years ago, a kind of hoax was perpetrated on the Medical Profession by two American Physicians—Drs. Fisher and Whitney—who pretended that they had discovered a series of morbid sounds by auscultation of the head of children and adults, and promised that the ear should be as available for detecting disease in the brain as it is in the chest. The universal experience of Physicians soon showed that all this was futile. Nevertheless, Dr. Henri Roger has submitted the whole question to a fresh series of experiments, and his principal results are as follows:—A bellows sound, synchronous with the systole, can be heard in some children whilst the fontanelle is open, not after. It is not characteristic of any diseased condition, inflammatory or otherwise; it may be present or absent in diseased or in healthy children alike. As for the cerebral *agophony* described by Dr. Whitney, it existed only in the imagination. The one practical fact which Dr. Henri Roger has sifted out is, that when the blood is so poor as to cause a *souffle* in the arteries, then sometimes that sound may be detected over the fontanelle. Hence Dr. Roger claims for it a certain diagnostic value in the early stage of rickets and anæmia. The pamphlet is well worth reading as a record of patient investigation, and cool sarcastic analysis. *Materiam superat opus* a long way.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their Examination in the Science and Practice of Medicine, and received certificates to Practise, on Thursday, June 18, 1863:—

John Brown Oliver, High Wycombe; Joseph Willes, Brighton; John Chas. Geo. Robertson, Edinburgh; George King, Leckford, Hants; Geo. Septimus Thompson, Newcastle-on-Tyne; William Johnson Smith, King's College Hospital.

The following gentlemen also on the same day passed their First Examination:—

John Hargreave Wraith, Manchester; Chas. Humphrey Weld, Middlesex Hospital; Henry Wilson, Charing-cross Hospital.

### APPOINTMENTS.

\* \* \* The Editor will thank gentlemen to forward to the Publishing-office, as early as possible, information as to any new Appointments that take place.

**BROADBENT, WILLIAM H., M.D.** Lond., has been elected Physician to the Western General Dispensary, Marylebone-road.

**COLQUHOUN, ALEXANDER E., M.D.** Glasg., has been appointed House-Surgeon to the Lancaster Infirmary and General Dispensary.

**COULSON, WILLIAM, F.R.C.S. Eng.**, has been appointed Honorary Consulting Surgeon to St. Mary's Hospital.

**COUPER, JOHN, F.R.C.S.**, Assistant-Surgeon to the London Hospital, has been elected Lecturer on Physiology at the London Hospital Medical College.

**HARPER, PHILIP N., F.R.C.S. Eng.**, has been elected Surgeon to the London Surgical Home.

**HUNT, A., L.R.C.S.I.**, has been appointed Medical Officer for the Infirmary and Fever Hospital, Dungarvan, Co. Waterford.

**JACKSON, J. HUGHLINGS, M.D., M.R.C.P.**, Physician to the Metropolitan Free Hospital, and Assistant-Physician to the Hospital for Epilepsy and Paralysis, has been elected Lecturer on Physiology at the London Hospital Medical College.

**JEAFFRESON, H., M.B.**, has been elected Resident Medical Officer to the London Fever Hospital, Liverpool-road.

**SHILLTOE, BUXTON, F.R.C.S. Eng.**, has been appointed Surgeon to the Great Northern Hospital, King's-cross.

**WORTHINGTON, FRANCIS S., L.R.C.P. Lond.**, has been appointed Assistant-Surgeon to the Mutford and Lotherland Dispensary and Infirmary.

### DEATHS.

**ARTHUR, THOMAS NORWAY, L.S.A.**, at Prees, Shropshire, on May 22, aged 52.

**BEST, DE HORNE**, second years' student at the London Hospital, and son of H. W. Best, M.R.C.S., Thetford, Norfolk, in London, on June 19, aged 20.

**BODDINGTON, ROBERT, M.R.C.S. Eng.**, at Ditchling, Sussex, aged 69.

**FENTON, JOHN, L.R.C.S. Edin.**, at Edinburgh, on June 11, aged 43, late of Newcastle-under-Lyme.

**GOLDING, BENJAMIN, M.R.C.P. Lond.**, at Boltons, West Brompton, on June 21, aged 69.

**JOHNSTON, JOHN ARMSTRONG, L.K.Q.C.P.I.**, at Bailieborough, Co. Cavan, on June 7, aged 33.

**MORRISON, T. COUTTS**, late Surgeon-Major, Army, at Rockhampton, Queensland, on March 24, formerly of Edinburgh.

**MUNCE, Dr.**, at Drumbo, on June 6, aged 71.

**O'HERLEHY, DANIEL POWER, M.D.**, at Madeira, on May 20, aged 38.

**OWEN, WILLIAM, M.R.C.S. Eng.**, at Machynlleth, Montgomeryshire, on June 10, aged 36.

THE King of the Belgians, we are happy to announce, has been considerably relieved by the attendance of our countryman, Mr. Thompson, who has now returned home, but who will probably renew his visit in a short time.

**TESTIMONIAL TO MR. MASON, OF BURTON-ON-TRENT.**—We have great pleasure in recording that the inhabitants of Burton have presented to Mr. W. Mason, the highly-esteemed Surgeon of that town, a valuable testimonial of their gratitude and respect in the shape of a handsome brougham, horse, set of silver-plated harness, and a silver salver. A numerous attended meeting was held in the Town-hall on Tuesday, the 16th inst., for the purpose of presenting the testimonial. J. Nunneley, Esq., occupied the chair. The salver bears the following inscription:—"This salver, with a brougham, horse, and harness, were presented to William Mason, Esq., of Burton-upon Trent, on the occasion of his sixtieth birth-day, by his patients and friends, in token of their high esteem for his Professional skill, and his unremitting kindness and attention, and especially for his self-denying services to the poor in times of sickness, through upwards of thirty years in Medical practice.—Burton-on-Trent, June, 1863."

THE gold medal of the Odontological Society of Great Britain for the best essay on the "Pathology of Dental Caries" has just been awarded to W. K. Bridgman, Esq., L.D.S., R.C.S., of Norwich.

**UNIVERSITY INTELLIGENCE.**—OXFORD, JUNE 18.—In a Congregation holden this morning the following degrees were conferred:—Bachelors of Medicine—Frederick Luxmore Heaton, Jesus College; Edward Leeds, Wadham College.—Cambridge, June 18.—A Congregation was held to-day at 12 o'clock, when the following degrees were conferred:—Doctor of Medicine—Reginald Thompson, Trinity. Bachelors of Medicine—Alfred G. P. Wilks, Trinity; Frederic Bagshawe, St. John's; Thomas Davies Welch, Caius.

**ANTHROPOLOGICAL SOCIETY OF LONDON, JUNE 23.**—Dr. James Hunt, F.S.A., President, in the chair. W. Winwood Reade, Esq., F.R.G.S., read a paper on the "Bush Tribes of Equatorial Africa." His residence at the Gaboon, and occasional journeys into the interior, enabled him to afford reliable information on the subject. The Mpongwe, who inhabit the mouth of the Gaboon, have become tolerably civilised by their contact with white men. The constitution of the tribes of the interior is that of the Veddahs of Ceylon. They live in families or clans, over which a headman or patriarch presides. This headman has influence, but no authority. He is usually the oldest man of the clan. The women, of course, do all the hard work, excepting that which is beyond their strength, as cutting down trees to clear a plantation, or which, like hunting or fishing, is beyond their skill. They worship wood spirits, lake spirits, mountain spirits, and they invoke the shades of their ancestors. Mr. W. Reade had not the slightest doubt of the existence of cannibalism amongst the Fans, or more correctly, *Bafanh*. Man's flesh was, like monkey's, very good; but only the old men had the privilege of eating it, the head falling to the chief or patriarch. The natives of Equatorial Africa were not aborigines, and showed traces of a bygone higher civilisation. The meeting adjourned after a vote of thanks to Mr. Reade and some discussion.

**ST. THOMAS'S HOSPITAL.**—A meeting of the governors of Bethlehem Hospital was held at Bridewell Hospital on Monday, June 22, to consider the letters from the Secretary of State for the Home Department and the Commissioners of Lunacy, which we have already published. The treasurer of Bethlehem read a letter in answer, which he described as "courteous, yet dignified, and uncompromising." To this he proposed to append two letters from Drs. Hood and Lawrence in opposition to that of the Commissioners. The treasurer's letter not meeting with the general approval of the meeting, the consideration of the reply to the Home Secretary was postponed, and, on the motion of Alderman Phillips, it was resolved that the president, treasurer, and five of the governors of Bethlehem and St. Thomas's Hospital should meet in the meantime for a preliminary discussion. On Tuesday, a General Court of the Governors of St. Thomas's Hospital was held at the London-bridge Railways Terminus Hotel. It was agreed, on the motion of Mr. Tite, that the General Court request a deputation of their body to meet a similar deputation from Bethlehem as soon as possible, with a view to ascertain whether it is probable that an arrangement can be made for obtaining the Bethlehem site on terms mutually advantageous; and in the event of the Grand Committee not being satisfied that such an arrangement can be made within a reasonable period, that they be authorised and requested to continue their negotiation with the Metropolitan Board of Works for the purchase of the site on the proposed south embankment of the river.

**COLLEGIATE ELECTION.**—A circumstance has just occurred which increases the interest taken in this election of Fellows into the Council of the College of Surgeons to an extent hitherto quite unknown in the annals of collegiate elections. On perusing the Bye-Laws it appears that Mr. Coulson, whose turn it would have been to vacate his chair next year, but who is resigning it this year, will be succeeded by that one of the three successful candidates who may obtain the least number of votes, and who consequently will have to resign the chair in July, 1864,—subject, of course to re-election. The bye-law on the subject is very distinct. It states that "when there shall be any vacancy in the Council, by the death or resignation of an elective member, the Fellow of those elected, who shall have been so elected by the smallest number of votes, shall be the substitute member of Council in

the room of such elective member; and when more than one such vacancy shall be required to be so filled up, the Fellow elected by the smallest number of votes, shall be the substitute in the room of that member whose period of office would have first terminated, and so in regard to each of such vacancies respectively." This reading of the Bye-laws is stimulating the friends of the candidates to fresh exertions to return their respective favourites at the head of the poll. The election will be by ballot, and in the following manner; papers with the names of the six candidates in chronological order, thus:—Cæsar H. Hawkins, Thomas Tatum, Samuel A. Lanc, George Busk, T. Blizzard Curling, Henry Hancock, will be ready for the electors, who must draw their pens through the names of those for whom they do not vote, taking care not to leave more than three names in such list, less if they like, even to plumping for any one gentleman; on another paper they will sign their names and addresses, to enable the Secretary to see that none but Fellows vote; the first paper is to be deposited in a box in front of Mr. President Luke, who, at the termination of the proceedings, will declare the numbers polled by each candidate. After which, the candidates will dine together at the Albion Tavern, when Mr. Turner, of Manchester, will occupy the chair.

**THE DISCOVERERS OF THE NILE.**—A crowded meeting of the Royal Geographical Society was held on Monday, June 22, at Burlington-house for the purpose of welcoming back Captains Speke and Grant. The reception of the successful explorers was, we need scarcely say, enthusiastic. Captain Speke read a paper entitled "The Nile and its Tributaries Compared." Each of the travellers was accompanied by a black boy from the most intelligent of the Equatorial tribes discovered. The little fellow accompanying Captain Speke is described as a fine boy, about 14, is an excellent specimen of the intellectual black type, his nose being as straight and his forehead as high as those of an European, although his woolly head and dark skin were thoroughly characteristic of his African blood. He seemed in no way disconcerted at his reception, and was as cool and collected as if he had attended the meetings of the Society all his life. Captain Speke gave a long and interesting account of the people of the countries through which he passed, and detailed the reception he met with from various kings and chiefs. The people of these countries—Unyoro, Uganda, and Karagwe—are most intellectual, but have a great distrust of the white men, owing to the enormities committed by the slave traders. The difficulties of travelling through these countries are almost insuperable, from numberless causes. The native kings are continually at war with each other, which causes wholesale desertion among the men forming the expeditions. The natives, however, with whom he had had amicable relations, were most friendly and honest, not only helping him themselves with presents, but sending men with him into other friendly nations as safeguards. He considers that the race is the same as the Abyssinian, and derived from a commixture of the race of Shem with that of Ham. They are mostly tall, well-made men, with straight noses and curly hair. They have no religion, and do not believe in a soul. The people of Karagwe he praises most highly. The king and princes are in every respect worthy of the epithet "gentlemen." The people are scrupulous in their dress, and shake hands when they meet. The following evening, June 23, Captain Speke delivered a lecture at the Royal Institution. H.R.H. the Prince of Wales, attended by a numerous suite, honoured the lecturer by his presence. In the course of his lecture, Captain Speke gave a number of curious particulars of the remarkable people whom he had discovered.

**DEATH IN THE WORKROOM.**—The circumstances of the following deplorable case require no comment in a Medical journal. An inquest was held at the St. James's Workhouse, on Thursday, June 18, before the Deputy-Coroner for Mr. Bedford, relative to the death of Mary Ann Walkley, aged 20, who at the time of her decease was in the employ of Madame Elise, Court dressmaker, 170, Regent-street. The case had already excited considerable attention, in consequence of a letter which appeared in the *Times* of Wednesday, 17th inst. It appeared from the evidence that the deceased, who was of a somewhat delicate constitution, and who worked in a room with nearly thirty others, was taken ill on Friday, and on Sunday night became much worse, when Medical assistance was called in. Remedies

having been administered, she appeared to fall asleep, and her bed-fellow, Miss Santrey (who was examined as a witness), retired to rest with her, but on awakening in the morning was shocked to find her companion dead by her side. A post-mortem examination was made by Mr. Keys, of Warwick-street, who deposed that death resulted from apoplexy, and stated, in answer to the coroner, that long hours of work in a crowded apartment, and sleeping in a close, badly-ventilated room, would have a great tendency to produce the symptoms which he described. Mr. Clarke, Surgeon, of Gerrard-street, concurred in the evidence of Mr. Keys. He described the bedrooms, which were divided by partitions into compartments just large enough to contain two beds placed end to end. If, as had been stated, there were two young women in each bed, he considered they were decidedly unfit places for any one to sleep in, and more particularly in the state of health in which the deceased had been. Mr. Bush, who had attended the deceased during the unavoidable absence of his principal, Mr. Keys, expressed his opinion that the rooms in which the deceased died were overcrowded and badly ventilated. The jury returned the following verdict:—That the deceased died of apoplexy; but there is too much reason to fear that her death was greatly accelerated by working long hours in a crowded workroom, and sleeping in a close, badly ventilated bedroom. The husband of Madame Elise said he did all he could for the comfort and health of his young people, and if the jury would tell him what he ought to do, he should be most happy to listen to their suggestions. The coroner replied that that was a question for a surveyor. The inquiry then terminated.

**ADULTERATION OF GERMAN YEAST.**—At a late meeting of the City Commissioners of Sewers, Dr. Letheby directed attention to the fact that a large quantity of adulterated German yeast was being imported into London from Schiedam. The samples which he had examined contained from a third to half their weight of pipe-clay, and as this yeast is used in the preparation of fancy bread, he stated that the presence of the alumina of the pipe-clay might, from its great quantity, lead to a charge against the baker for adulterating his bread with alum. But besides that, as the pipe-clay enabled the dealers to send putrid yeast into the market, the bread was in most cases very unwholesome. He advised the Committee that as this yeast came through the custom-houses of London and Hull, the authorities should be advised of the matter. A letter was read from Mr. Blackburn, a chemist, in Old Elvet, Durham, confirming by his own experience the report of Dr. Letheby in that respect, which he had read in a newspaper. About twelve months ago he said he weighed an ounce of yeast, put it in a tumbler, and mixed it with water, and after carefully washing it at least a dozen times he was unable to dissolve any more of it. He allowed the material to dry, and again weighed it, when, to his surprise, he found exactly three drachms of pipe-clay remaining. He sincerely hoped the commission would endeavour to put a stop to such shameful adulteration.

## NOTES, QUERIES, AND REPLIES.

He that questioneth much shall learn much.—Bacon.

*J. G. L.*—8, Russell-place, Fitzroy-square.

*M. R. C. S. Eng., late Army.*—We have no official information on the subject, but there is little doubt that a Member of the College might obtain an appointment. Write to the Embassy.

*Corrigendum.*—Mr. A. M. Edwards' case of amputation of the thigh, which we inserted last week under the head of Hospital Reports, was inserted by mistake in that section of the journal; the case was treated in private, and not at the Royal Infirmary.

*The Amenities of Colonial Journalism.*—We have lately received a number of the *Yeoman and Australian Acclimatiser*, a paper the chief end of whose being seems the reproduction of scraps from the *London Field*, and the publication of long articles in abuse of two Medical periodicals—the *Australian Medical Journal* and the *Medical and Surgical Review*. Here is a specimen of its criticism on a paper published in the latter:—"It is a mere raw bush production, and has no style, no intelligence, no English, and no grammar." We should advise our Professional brethren Melbourne do not care much for his Bœotian assailant. But it seems to us that if the *Yeoman and Australian Acclimatiser* be a fair specimen of Australian periodical literature, it would well repay the colonists to start a society for the purpose of acclimating editorial courtesy and its kindred virtues.

HEALTH INSURANCE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Is there any "insurance office" who allow a weekly allowance in case of sickness, on the principle of "clubs;" and what is the scale of the monthly or yearly payment to insure an allowance in illness?

I am, &c. CORRESPONDENT.

THE DOSE OF ATROPINE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I think Dr. Brown-Séguard stated some few weeks since, in the *Medical Times and Gazette*, that it was dangerous to give more than one-sixtieth of a grain of atropine (except in combination) for a dose. I have given for nearly two years past, to one patient, from a fifth to a sixth of a grain of Morson and Son's sulphate of atropine daily, simply dissolved in water, and in one dose.

June 23. ISHMAEL.

THE ARMY MEDICAL DEPARTMENT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In reply to your correspondent's question—in how many years will a man now entering the Medical Department of the Army get his promotion?—I beg to inform him, and all others, in about nineteen and a-half to twenty years; besides which, the grievances, with one exception, remain unredressed. The Duke of Cambridge is unaltered towards the department. The Horse Guards continue to snub; and, in fact, whoever enters will regret it ultimately. Let not the Irish schools be deceived.

I am, &c. OBSERVER.

POOR-LAW MEDICAL REFORM.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Permit me space to inform the Poor-law Medical Officers that the Select Committee on poor relief has again been nominated, and it consists of the same members as last year. I have forwarded to the House of Commons a statement in reference to the evidence delivered by Mr. Cano last session, and I feel convinced that after its perusal the most sceptical must admit there is great need of considerable changes being made in the Medical relief of the poor. Since my last letter, nine Poor-law Medical Officers have sent subscriptions, and I hope, now that the Committee has been re-appointed, a little more life will be infused into our proceedings, and that I shall be placed in a position to call a public meeting at any moment, should it be deemed necessary; but with a debt of about £25, I do not feel justified in incurring further personal liability, and therefore the responsibility of further active measures must depend upon the liberality of the Poor-law Medical Officers themselves.

I am, &c. RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, June 23.

RUSSELL'S HOSPITAL BED APPLIANCE AND HOSPITAL STRETCHER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your *Medical Times and Gazette* of November 8 last, I perceive a very gratifying notice of the few simple appliances shown by me in the late Exhibition. I would draw attention to two of these articles, viz., the Hospital bed appliance and improved Hospital stretcher.

In consequence of their beneficial and gratifying use wherever placed, and being introduced into Her Majesty's service, I published some pamphlets for distribution, in order, by giving them to the public, to extend their general utility, until something simpler and more effective be found out. In passing under notice of a jury of such experience and scientific attainments, the public would naturally be influenced by their expressed opinion in award. But an omission, one article only having been numbered, led to the error of that one only being mentioned in the published award. Thus my trouble and efforts were almost rendered nugatory. For the sake of these two articles I feel it a duty to mention that I have received an official communication, by direction of Lord Granville:—

"That, on reference to the jury records, the Honourable Mention awarded to you in Class 17 was intended to extend to all the articles exhibited by you in that class, enumerated in the Illustrated Catalogue, No. 3579."

They are there enumerated, beginning with improved Hospital bed appliance and improved Hospital stretcher. I should feel obliged by your insertion of the fact in any way you may consider most advisable, my object being to engage the attention of Medical gentlemen and Hospital authorities, so as to give confidence in their trial. The appliance is easily fitted to any Hospital bedstead, and I shall be happy to give any assistance and information I can.

Shrewsbury, June 22. I am, &c. G. RUSSELL.

THE EXAMINATION OF ASSISTANT-SURGEONS IN THE ARMY FOR THE RANK OF SURGEONS.—EXAMINATION PAPERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Enclosed you have an exact copy (which you may publish if you consider them of sufficient interest) of the questions given to Assistant-Surgeons (at the last examination) qualifying for promotion to rank of Surgeons.

I am, &c. CHIRURO.

EXAMINATION FOR ASSISTANT-SURGEON PREVIOUS TO PROMOTION.

First Day.—Pathology.

1. Describe the events, and their pathology, which may be expected to follow the inoculation of the syphilitic virus.  
2. Enumerate the points you have been in the habit of investigating, and which it is necessary to investigate and describe in all cases of venereal ulceration.

3. Describe the pathology and the course of encephaloid or medullary malignant tumours, situated, say, in the region of the shoulder, as contrasted with an enchondroma similarly situated.

Second Day.—Military Surgery and Surgical Anatomy.

1. Name the principal varieties of dislocations to which the hip-joint is subject, state what the distinguishing signs of them are, and explain them anatomically.

2. Name the several species of iritis, and their distinguishing symptoms. Describe the treatment appropriate to each variety. Soldiers are not infrequently unfit for service after iritis, from occlusion of the pupil or extensive synechia, what means would you adopt to prevent such consequences?

3. Enumerate anatomically the structures displaced in disqualifying flatness of the soles of the feet. What are the remote and proximate causes of this deformity? Name the external signs which distinguish "broad feet" from "flat feet."

4. Give a sketch of the regulated system adopted for discharging disabled soldiers; enumerate and explain the several prescribed documents which are ordered to be furnished in case of a disabled soldier sent home from a foreign station with a view to his being discharged from further service. Particularise the nature of the documentary evidence which is specially required by the principal Medical officer of the Invalid General Hospital to enable the Commissioner of Chelsea Hospital eventually to decide upon a disabled soldier's claims for pension.

Third Day.—Hygiene.

1. Enter fully into the question of the best means of preventing the following diseases, or of arresting their spread when present:—Typhoid Fever, Cholera, Malarious Diseases.

2. What has your experience led you to believe to be the proper arrangement of barracks for infantry and cavalry soldiers on home service? State fully your views as to the size and position of rooms and arrangement for ablutions, latrines, &c. What are the rules on the subject in the Queen's and Hospital Regulations?

Fourth Day.—Medicine.

1. Explain the action of malaria on the fluids and solids of the human body, and its influence in modifying the course and phenomena of tropical diseases.

2. Give the signs, physical and general, of cardiac dilatations, and direct physical signs of aortic obstructions.

3. What do you understand by the term "insolation?" Give the best account you can of this affection. Lay down clearly the general principle of treatment, best means of preventing on the line of march and in barracks in hot climates.

END OF VOLUME I. 1863.

LONDON :

PRINTED BY BENJAMIN PARDON, LOVELL'S-COURT, PATERNOSTER-RROW

**CHLORODYNE**  
 WAS DISCOVERED AND INVENTED IN THE YEAR 1848 BY  
**DR. J. COLLIS BROWNE, M.R.C.S.L. EX. ARMY-MED. STAFF.**  
 AND IN 1856 HE CONFIDED  
**THE ORIGINAL AND ONLY FORMULA**  
 FOR ITS MANUFACTURE  
 SOLELY TO **J. T. DAVENPORT, PHARMACEUTIST,**  
 33, GREAT RUSSELL ST. BLOOMSBURY SQUARE, LONDON.  
 REGISTERED, 1856.

**NOTIFICATION.**

THE attention of Medical Men is directed to the Piratical application, by some parties in the Trade, of the term "Chlorodyne" to various mixtures compounded of Chloric Æther, Opium, Indian Hemp, and Peppermint, in Imitation of the ONLY Genuine preparation of this name.

The dangerous expedient of encouraging or advocating the assumption of a name specifically indicating a particular property or remedy—such as *Chlorodyne* is to spurious imitations and substitutions—ON THE GROUND OF CHEAPNESS, is a subject of surprise and grave reproach, supremely so, when the adulteration, sophistication, and tampering with Drugs, becomes so serious and important a consideration in the successful practice of Medicine.

The fact of these Piracies must fully convince the Profession of the extraordinary efficacy of the Genuine Chlorodyne; whereas the sad results and disappointment arising from the use of spurious compounds cannot be expressed.

Each Genuine Bottle bears a Red Stamp, with the words, "Dr. J. COLLIS BROWNE'S CHLORODYNE," in White Letters.

**REDUCTION OF PRICE.**—In Bottles, 1oz., 3s.; 2oz., 5s.; 4oz., 8s.; 10oz., 15s.

To Hospitals and Charities in large quantity, a Liberal Discount.

**TOWLE'S CHLORODYNE.**

Medicinal Properties :—  
 Anodyne, Diaphoretic, Sedative, Astringent, and Anti-Spasmodic.

**CAUTION.**—For the convenience and safety of prescribing Chlorodyne, in combination with other ingredients, so as to avoid decomposition (a result known to have taken place) through the use of SECRET COMPOUNDS, Mr. TOWLE begs to call the attention of the Profession to the following component parts in his Preparation :—

CHLOROFORMYL  
 ÆTHER.

OL. MENTH. PIP.  
 ACID. PERCHLOR.

TINCT. CANNABIS INDICÆ.  
 ACID. HYDROCYAN.

TINCT. CAPSICI  
 MORPHIA & THERIACA.

The proportion of Morphia— $\frac{3}{4}$  gr. inf. 3j. Dose—Five to Twenty Drops.

Letter from ALFRED ASPLAND, Esq., F.R.C.S. Eng., J.P. Chester and Lancaster, Surgeon 4th Cheshire Batt. V.R., Surgeon to the Ashton Infirmary.—"After an extensive trial of your Chlorodyne in Hospital, Infirmary, and Private Practice, I am able to state that it is a valuable medicine. I have found its action peculiarly serviceable in Bronchial, Spasmodic, and Neuralgic Affections. I have never found it produce headache or feverish disturbance, results which not unfrequently occur from other forms of Chlorodyne. As a sedative to allay excitement arising from the abuse of intoxicating drinks, so commonly witnessed in our Barrack Hospital, I have been perfectly satisfied with it. Its known composition will doubtless prove an additional recommendation to the Profession."

Sold by Wholesale Houses in bottles, 1 oz., 1s. 6d.; 2 oz., 2s. 6d.; and 4 oz. to 20 oz., 1s. per fluid oz.

Sole Manufacturer—A. P. TOWLE, CHEMIST, &c., 99, STOCKPORT-ROAD, MANCHESTER.

**CHLORODYNE.**

"INVENTED AND DISCOVERED, IN 1844, BY RICHARD FREEMAN."

(Extract from Affidavit made before S. C. WARD, Esq., Chancery Record Office, Chancery-lane, London, June 16th, 1862.)

The Inventor begs to thank the Medical Profession for the liberal support he receives from them, and to assure those who have not yet tried his Chlorodyne that it is superior to any other maker's, being more certain and more lasting in its effects; and the low price which he charges for it allows the poorest sufferer to enjoy its extraordinary beneficial influence. The immense demand for it by the Profession is a convincing proof that they find it a most valuable therapeutical agent. The following are a few out of many voluntary Medical Testimonials :—

From W. VESALIUS PETTIGREW, M.D., Hon. F.R.C.S. Eng., formerly Lecturer upon Anatomy and Physiology at the St. George's School of Medicine.

"I have had the opportunity of trying the effects of Mr. Freeman's Chlorodyne, and find it an excellent Anodyne and Antispasmodic medicine."

From H. J. O'DONNELL, M.R.C.S.E. and L.M., &c., &c., Albert-terrace, London-road, S.

"I can with much confidence bear testimony to the efficacy of Mr. Freeman's Chlorodyne as a Sedative and Antispasmodic, having used it for some years in Colic, Neuralgia, Phthisis, and Asthma. I daily administer it in after-pains, and in all cases find it infallible. It is the most valuable medicine we have in Labour cases. I find, since I have used it, the pains

seldom or ever exceed the third day, while with the former remedies my patients suffered eight or nine days. In fact, I cannot speak too highly of it."

From F. W. HOOPER, M.D., M.R.C.S. Eng., &c., &c., Medical Officer, Christ Church District, Camberwell.

"I have much pleasure in stating that, after a sufficient trial of Mr. Freeman's Chlorodyne, I am fully persuaded that it is superior to any preparation of the kind, and, from its moderate price, is a great boon to the suffering poor, who daily acknowledge its salutary benefit."

From W. G. KING, M.D., M.R.C.S. Eng., Hackney.

"I have used your Chlorodyne for some time, and can bear testimony to its efficacy and value in all cases in which a Sedative has been indicated."

Manufactured by RICHARD FREEMAN, Pharmaceutist, Kennington-road, London, S.;

And Sold by all Wholesale Houses, in bottles, 1 oz., 1s. 6d.; 4 oz., 5s.; and 8 oz., 10s. each.

**IMPROVEMENTS IN SHIRTS.**

- RODGERS'S IMPROVED CORAZZA, six for 31s. 6d., and six for 42s.
- RODGERS'S IMPROVED COLOURED, six for 26s., and six for 31s. 6d.
