

[Supplement to *The Builder*, July 31, 1890.]

AN

✦ ILLUSTRATED ✦ WEEKLY ✦ MAGAZINE ✦

FOR THE

ARCHITECT, ENGINEER, ARCHÆOLOGIST, CONSTRUCTOR,
SANITARY REFORMER, AND ART-LOVER.

CONDUCTED BY

H. H. STATHAM,

FELLOW OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

"Every man's proper mansion-house, and home, being the theater of his hospitality, the seat of self-fruition, the comfortablest part of his own life, the noblest of his sonne's inheritance, a kinde of private princedome, nay, to the possessors thereof, an epitome of the whole world, may well deserve, by these attributes, according to the degree of the master, to be decently and delightfully adorned."

"Architecture can want no commendation, where there are noble men, or noble mindes."—SIR HENRY WOTTON.

"Our English word TO BUILD is the Anglo-Saxon Bylðan, to confirm, to establish, to make firm and sure and fast, to consolidate, to strengthen; and is applicable to all other things as well as to dwelling-places."—DIVERSIONS OF PURLEY.

"Always be ready to speak your mind, and a base man will avoid you."—WILLIAM BLAKE.

VOLUME LVIII.—JANUARY TO JUNE, 1890.

OFFICE: No. 46, CATHERINE STREET, COVENT GARDEN, LONDON, W.C.

INDEX TO VOLUME LVIII.

JANUARY TO JUNE, 1890.

Superintendence.

the erection of a large building the direct duties of superintendence devolve upon the clerk of works, but it is even in that case incumbent upon the architect to visit the building with tolerable frequency, for his drawings and specifications will not always be accurately interpreted, even by a clerk of works who has been under him for years. It is possible, too, that clerks of works may not be always worthy of that implicit confidence which architects, sometimes to their own loss and discredit, are only too willing to place in them. Moreover, clients consider their architect's repeated presence on the building a necessity; they have often a blind belief in his omniscience and omnipotence, and cannot think that all will be well if the master-mind be not there to oversee.

But it is not always that an architect has the pleasure of carrying out large buildings, and of being relieved of much of the irksomeness of superintendence by an efficient clerk of works. In every practice there are many buildings which are too small to warrant the employment of a clerk of works, and it is in supervising the erection of these that an architect needs all the care, watchfulness, honesty, and decision which he can command. If, again, the work be let in trades to different contractors, the architect's difficulty reaches its maximum. The proprietor, however, expects everything to be done according to drawings and specifications, and really be-

lieves that his architect will see to it that such is the case. Wightwick, in his "Hints to Young Architects," says, "a gentleman . . . will . . . be inclined to visit upon his architect those failures in particular construction which only good workmen can insure, under the direction of the contracting builder, and the supervision of an ever-watchful clerk of works, exclusively occupied on one job. It will be well, therefore, for the architect at once to undeceive his employer in this last particular." And, again—"when an employer will not take upon himself the responsibility of trusting to the efficiency of the contractor and his men, the architect is bound to insist on the engagement of a well-tried clerk of the works. The author of these 'Hints' has suffered so much from a too-ready desire to save his employer the charge of a constant supervisor, that he cannot too strongly urge upon those whom he now addresses the advisability of having a clear understanding with their patrons on this point." We wonder if an employer ever did arrive at any clear understanding on the point, other than this, that the architect is responsible from beginning to end. The claim of the architect to the possession of all drawings and specifications is supported by the argument that the client required a building, not paper; that the latter represents but a means to an end, and is as much the property of the architect as the chisel is of the mason or the plane of the joiner; and this argument,—not altogether flawless, let us say,—acknowledges the architect's responsibility for the proper erection of a building in accordance with his client's requirements. We do not see that an architect can rightly claim possession of the drawings, and at the same time disclaim respon-

sibility for the work. However, disclaimer or no disclaimer, it will always be found that, whether a clerk of works be employed or not, clients unhesitatingly consider that architects have neglected their duties if buildings exhibit faults of construction, however minute, and are not erected strictly in accordance with the original drawings and specifications, or such modifications thereof as the clients themselves have approved. A recent resolution of the London School Board, "calling on their former architect, Mr. Robson, to make good the loss arising from defective foundations in the Broad-street Schools," shows this very plainly. Taking into consideration the somewhat peculiar nature of Mr. Robson's appointment, this resolution was a mistaken one, but the fact remains that a majority of the Board declared their conviction of the architect's responsibility for bad workmanship and deficient materials. It was stated in the *Builder* at the time (July 21, 1888), that "if the case had been that of an architect in ordinary practice on his own account, it might reasonably be said that he ought to have given personal inspection to so important a matter as foundations; every architect in ordinary practice ought to do that."

This unchangeable and, to our mind, quite unblamable, determination of clients respecting an architect's responsibility, is almost, if not altogether, universal. It is vain for an architect to contend against it; on the contrary, he ought to accept the position fearlessly, and do his utmost to ensure the proper realisation of his schemes. It will be better for his own future practice; for, be a house never so picturesque, if the drains smell it will be an abomination to its owner, and the latter will become a thorn in the architect's side. Architects lose more clients through

carelessness of superintendence than from any other cause.

There is another reason why architects, especially in country towns, can ill afford to neglect the arduous duties of superintendence. We refer to the existence of that great army of men, chiefly, we believe, joiners, who, on the strength of their "practical knowledge" of the building trades, "creep and intrude and climb into the fold." The artistic faculty is in most of them wofully lacking, but, despite the ugliness of their productions, they prosper, and one reason of their success is this: the belief which men have that their "practical knowledge" (magical words!) will ensure more searching superintendence of work; on the principle, doubtless, of setting a thief to catch a thief.

The architect will do well also to remember that additions to his works by brother-practitioners at some future time will make known his shortcomings. But we do not wish to insist upon the necessity for close supervision merely because that would be to the architect's pecuniary interest; there is a higher motive than that. It is in truth a question not so much of self-interest as of duty; the architect is engaged to superintend the erection of a building as well as to design it, and if he neglect the former he is, like an idle servant, dealing unjustly with his employer, receiving wages for work which he does not perform. If the architect recognise this truth and act up to it, it will be well with him; if not—with all sorrow be it said—he scamps his work no less than does the dishonest builder, and is not acting for the honour and best interests of his great profession.

The necessity for effectual superintendence having now been stated, the question remains for our determination,—how can an architect with least possible annoyance to proprietor, contractor, and himself, ensure the careful and honest erection of buildings without the constant supervision of a clerk of works?

In February last Mr. T. M. Rickman read a paper at the Institute on "Writing a Specification," and the speech of Mr. Arthur Cates in the discussion which followed, is thus reported:—"From the paper they gathered that Mr. Rickman considered that the first qualification of an architect was to possess patience, and after that the most essential quality was decision, and in the latter quality *he feared architects were often wanting, especially in insisting that the work should be executed as specified.*" Let us take these italicised words as a sort of text, calling attention first, however, to the further qualification, which Prof. Roger Smith pointed out to be still more important, to wit, knowledge.

Every architect learns by experience,—more or less bitter,—the difficulties of superintendence, and as the years pass discovers how prolific of such difficulties are the unconsidered clauses of a specification. It is a golden rule for all students that, when drawing a ground-floor plan, every line must be studied in its relation not only to the remaining portions of that plan, but also to all other plans up to the roof-plan, and to all elevations. A similar rule would be this,—in writing a specification every word must be studied not only in its relation to other words and to the drawings, but also in its relation to the building and the superintendence of its erection. All words such as "proper," "sufficient," "strong," "good," and the like, which convey no definite meaning, must be avoided, and strict definitions must be given of terms, which are variously interpreted by different architects and builders,—"prime cost," "best," "perfect," "complete." In specifying that wood shall be "free from sap," the architect is demanding something of which the getting will cause him endless trouble; when he says that it must be "without large dead knots" he binds himself to pass small dead knots, and also large knots which are not dead, although such is probably not his intention. We often see in specifications of woodwork that "all measurements refer to finished sizes," and in many cases it is absolutely impossible to obtain material of the

specified scantling without an unwarrantable waste of a client's or a builder's money. A cut of an ordinary circular saw wastes, roughly speaking, $\frac{1}{2}$ in. of wood; thus, a plank 11 in. by 3 in. will cut into four pieces 3 in. by about $2\frac{1}{2}$ in., and the size of such a piece when planed on all sides will be probably less than $2\frac{1}{2}$ in. by $2\frac{1}{2}$ in. For an architect to write such a clause, and then specify a piece of planed deal 3 in. thick betrays great thoughtlessness, and if he obstinately adheres to the letter of the specification, the builder will have to pay heavily in a large contract for the architect's original blunder. The thicknesses of floorboards and doors may prove a bone of contention if the architect has specified them to be 1 in., $1\frac{1}{2}$ in., $1\frac{1}{2}$ in., and so on; it is better to ask for $\frac{3}{4}$ in., $1\frac{1}{4}$ in., $1\frac{3}{4}$ in., and so on. It is foreign, however, to our purpose to enter into the hundred and one details that must be considered in writing specifications; but the broad fact must be stated that the most exasperating difficulties of superintendence are those which arise from the vagueness, inaccuracy, or incompleteness of the specification, for these faults come home to roost with the architect himself. If the writing of the specification be scamped, depend upon it, the work itself will be scamped. Do not specify "best red deal," and be content with "fourths" and "fifths"; but be very careful to specify exactly what you require, and see that you get it.

In the retirement of the "private office" it is comparatively easy to decide upon the merits of rival materials; to determine the quality of each according to the character of the building, so that everything shall be quite good enough for its purpose, but not extravagantly so; to say that this method of construction will be better than that; and to demand the special fittings of one firm in preference to all others. The architect sitting in his own little court is not wearied by the cries of an irate plaintiff or an exasperated defendant, but calmly judges each question of material and construction as it arises. He is unhissed, comparatively unfurried, and deliberately, to the best of his knowledge and judgment, specifies whatever is most adapted to the special needs of the building which he is about to erect. It is this coolness, this freedom from disturbing influences, upon which we wish to lay particular stress. It is true that it is at times necessary to deviate from a specification, however carefully it may have been written, but it is equally true that at the time of writing a specification the experienced architect is, on the whole, more able to see clearly and without prejudice what is best for his client than at any subsequent time. His thoughts are concentrated on the work then in a manner they will not be again. Soon other buildings thrust themselves upon his attention, and in a very few weeks he forgets the motives which induced him to write this clause or that clause, and would forget a great part of those decisions which had cost him so much thought, if the specification were not before him in black and white. Again, when the building is being erected, the architect is, to some extent, however unconsciously, under the influence of the contractor; and the latter, by plausible pretexts and persistent attempts, is often able to obtain the architect's sanction to variations of the work which are probably to the contractor's benefit, and possibly to the proprietor's loss. During the preparation of the drawings and specifications the client's influence is paramount, but after the contract is signed it usually happens that the contractor is seen a dozen times while the client is seen once,—this is especially true in reference to works carried out for bodies of men,—and, unless the architect be very wary, the contractor's influence waxes while the client's wanes. The fact, too, that for one building transaction with any one client the architect may have half a score with a successful contractor tends to the same result.

These three reasons—the unbiassed deliberation with which a specification is (or ought to be) written, the absorption of thought by new

work at a later time, and the subtle influence of the contractor—seem to us so cogent that we recommend the architect never to alter a specification except after the very gravest consideration. Moreover, when an architect prepares a specification, he does it as agent for his client; he provides for his requirements as well as and as economically as he can, and translates these requirements into technical language; but as soon as the specification is accepted by proprietor and builder as the basis of a contract the architect's position changes; his specification becomes a legal document, and he the person appointed to see that the work is carried out in accordance therewith, and also (often enough) in case of dispute to act as arbiter between the two contracting parties. The duty he owes to his client compels him to insist that every detail be completed as well as specified; his duty as an upright man pre-emptorily declares that he shall not attempt, to the contractor's loss, to read into a vague specification a meaning which the words will not rightly bear. There are cases where an architect has laid the punishment for his own carelessness upon the back of a poor contractor, or has even connived at inferior work in order that the builder should not claim an extra for additional labour caused by constructional errors, for which the architect was responsible. In the former case the architect is grossly unjust; in the latter, fear of a client's displeasure makes him disingenuous, and causes him to sacrifice his employer's interests to hide his own mistakes; he loses his integrity, and with it the contractor's good opinion, for he has joined with him in doing an underhand action.

To young architects we would say, let your drawings be accurate and complete; let your specifications be written carefully and deliberately; let them contain, as clearly and simply as your knowledge of the English language will permit, all the information which is necessary for the thorough conveyance of your ideas on every detail of the projected work; and then, having done all this, make up your mind to adhere to the drawings and specifications unless absolutely compelled by uncontrollable circumstances or by increase of knowledge, to alter them. If you do this, superintendence will be rid of some, at any rate, of its difficulties.

We have more to say on the subject in a subsequent article.

SCHOOL-PLANNING OF SECONDARY SCHOOLS FOR DAY BOYS.

BY A HEAD MASTER.

THE following paper is an attempt to describe the requirements of the schoolmasters who have to use Secondary, or what are sometimes called High schools. Mr. Robson has written a book mainly on the planning of elementary schools; and Mr. Robins mainly on technical schools; but I do not know of any attempt to deal with higher schools specially. As to my own qualifications, I may say that I am myself head master of a large higher school, and that I have visited most of the high schools in Paris, and here and there in Belgium, Germany, and Scandinavia. I am inclined to think that, of all the day schools, those in Stockholm and Gothenburg are the most perfect and complete in plan; while, of the boarding schools, the Ecole Monge, in Paris, is by far the most perfect in arrangement. It is worth mentioning that the head master of the latter school had a very large influence in settling the plans.

School arrangements may be looked at from three points of view, according as they facilitate the work of the head master, teachers, or pupils. Now the most important work of the head master is supervision. Indeed, in most Continental schools he does not teach at all; in English schools he teaches too much. Shut up in his sixth form room he may be giving a good lesson, while, perhaps, ten or twenty assistants may be giving bad ones. He ought, indeed, to teach the sixth form boys to such an extent as to keep thoroughly in touch

with them; but his main task is, or should be, supervision. He is better employed in teaching his assistant-masters than in teaching his boys. But supervision means much more than this. He has to supervise not only all the teaching, but much of the discipline of the school. So long, indeed, as the boys are shut up in their respective class-rooms, the assistant-masters are mainly responsible for discipline. But when the school is assembled together, *e.g.*, at prayers, or when all the boys are entering the building or leaving it, then the head master is mainly responsible. Also when the classes are redistributed at the change of lessons, when boys are passing about for various reasons, it is the head master, with his porter or discipline master, who is responsible. If you wish to make his task of supervision difficult, then build all the class-rooms in a line, as in Reading School, so that the boys may have far to go in changing classes; and you may connect the line of class-rooms with a long echoing corridor,—convenient for a stampee, for hustling, for running races. Narrow corridors especially facilitate hustling. Also sharp turns in a corridor will bring classes into sudden collision and riot at change of lessons. Nor will it be possible to detect the ringleaders if the corridor is dark. Moreover, a good deal of quiet bullying may be done in a dark corridor. While the head master is in one corridor the riot can be started in another. Also, if the head master's private room is properly sequestered, the boys can be noisy with safety.

I may as well make a list of a head master's chief foes as regards discipline. They are (1) disorder and noise; (2) bullying; (3) petty larceny; (4) indecent writing. In coping with all these the architect can greatly aid him, or can render good discipline almost impossible. I have said enough to show that to cope with disorder or bullying, the fewer corridors we have the better. But it should be remembered that horse-play, practical joking, and bullying occur in the playground and outbuildings also. Every corner, therefore, of the playground should be visible from the head master's room and from some of the class-rooms. Disorder, too, is very likely to occur at the entrances and exits of the school; these, therefore, should be commanded from the head master's room. It follows, then, that the administrative block should be so placed that it commands a view of the main entrances to the school, the playground, the hall, and the corridors. By the administrative block I mean the four rooms which are assigned (1) to the head master for interviews with parents, teachers, and pupils; (2) to the secretary, with shelving for school stationery, &c.; (3) to the assistant-masters, with room for their hats and coats, and for the school library; (4) for the porter or discipline master, with space for maps, tools, stores, &c. We may say that the porter, the secretary, and the head master form the special disciplinary staff. They must, therefore, be housed centrally, and their rooms must not be far away from one another, as the head master will be continually requiring to communicate with the porter and the secretary. The porter, like the head master, should be so placed as to be able to keep an eye on every boy who attempts to enter or leave the school, who is loafing in a corridor, or is outside of his class-room on any pretext. It is especially important that the porter should have a view from his room of the latrines and urinals, and of every one who enters or leaves them.

Now I come to the third offence, not very common, and happily confined as a rule to small deer,—I mean petty larceny. This takes place mainly in the central cloak-room. There is nothing more difficult to stop than this petty larceny; and it occurs because it is impossible to supervise the cloak-room adequately. The porter's other duties make it impossible for him to be always on guard in the cloak-room. In addition to this trouble, much disorder and confusion arises on a wet day, before several hundred boys can find their own overcoats and umbrellas,

many of them being much alike. The remedy is to abolish the central cloak-room altogether; and instead of it, to attach a separate cloak-room to each class-room, and put it in charge of the master who teaches in that room. It should be about 6 ft. wide, and should run the whole length of the class-room. It may be 9 ft. high, or it may be carried up to the same height as the class-room. It should be separated from the class-room by a wooden screen, pierced with a continuous window; and the master should be so seated that he can command every part of it. It should be thoroughly well lighted by an external window, and be heated by hot-water pipes, so that wet coats may be dried. There should be two doors, both leading back into the class-room, and not into a corridor or the hall. Thus this annoying school offence may be made almost impossible. In this, as in all matters of discipline, prevention is better than cure.

The fourth trouble that a head master has to face is that, whatever pains he takes to get a good tone among his lads, some time or other he will admit a black sheep, and he will have indecent scribbling on the walls, or indecent writing passed about. The latter process is greatly facilitated by building plenty of corridors. To prevent the former,—scribbling on the walls,—all the internal walls of class-rooms, corridors, halls, &c., and, in particular, the slabs of the urinals and the closets should be lined with glazed bricks to the height of 7 ft. Moreover, the porter's room must be placed near enough to the urinals for him easily to make frequent visits. And I should like these offices to have only low walls, so that they may be completely open to the view of each master who has a first-floor room on that side of the building on which these offices are situated. They need not be placed close to the main block, but they should be placed near enough to facilitate supervision as much as possible.

So much for difficulties of discipline. Now as to the health and efficiency of masters and pupils. If unhealthy arrangements prevail, and I find them almost universally unhealthy, not only in the English public schools, but even in the model schools of Germany, Scandinavia, and France (here also the *Ecole Monge* is a brilliant exception), the efficiency of the school goes down to an enormous degree. I have hardly seen more than one or two schools where the boys do not look jaded and listless, pale or flushed, as the case may be, and restless and cross at the end of afternoon school; and the masters also, only more so. Again, my boys come back to school with clear skin, bright eyes, cheerful, full of work; the masters also; and for a time all goes merrily as a marriage bell. Then the health standard declines, industry declines, friction increases, the teacher ceases to be bright and cheerful himself, the boys do not learn well, and the teacher does not teach well. We systematically lower the health of teachers and boys all round. At last the boy leaves school, and probably recovers. It is usually surprising to see what a splendid fellow, physically, your boy soon is when he has left school. The masters do not leave, and often become nervous, querulous dyspeptics. Now architects can raise the efficiency of our teachers at least 25 per cent., and the happiness and cheerfulness of masters and boys at least 50 per cent., if they will exterminate four evils. These are noise, gas fumes, dust, and foul air.

Of noise, one of the causes is my *bête-noire*, the corridor. Another is the planked floors. Wood blocks are much less noisy and more durable. But I should like to see some kind of noiseless asphalt laid down, not only in the corridors, but in the class-rooms and hall. It need not be cold to the feet, for to each desk would be fixed a foot-rail, so that the feet of each boy would be removed from the floor. The noisiest of all corridors is that paved with flags or stone; the tramp of feet along such a floor echoes all over a building.

Till we get the electric light, it is inexcusable for architects to poison us by inserting gaseliers which do not carry off fumes.

But a much worse enemy is dust. The way to introduce plenty of it is to build projecting mouldings and wide window-sills in the class-rooms; secondly, to have cupboards with a well at the top to hold dust; thirdly, to have a wooden floor, which can only be brushed, and may not be washed except when the vacations begin; fourthly, ceiling and walls, if whitewashed, will hold some dust; these, also, cannot be washed; lastly, the desks of boys and master may be so designed that the sweeping-brush cannot get beneath them; thus nest-eggs of dust are left. The ideal class-room would have an asphalt floor, with a rise in the centre, and gutters all round; there would be glazed bricks for the walls, at any rate half-way up; and the ceiling also would be distempred or so constructed as to wash. In the corner should be a hydrant, and floor, walls, and ceiling should be sluiced, not once in three months, as at present, but every night, in a third of the time that it takes to sweep the room. The extra cost of the water-pipes would be saved in the lessened daily cost of cleaning, to say nothing of the additional security against fire. I remember seeing the great dining-hall at the *Ecole Monge*; it had just been vacated; the boys ate at little marble tables; a relay of servants carried off plates and dishes; the windows were thrown wide open; a mighty hydrant was opened, and a deluge was sent flying over tables, floor, and walls; and in a moment crusts, crumbs, smells, and foul air disappeared in one gush. The windows were closed, heat turned on, and soon the hall was ready for another batch of diners. No trouble is too much to take if only we can banish this great foe—dust.

But the worst of all these evils is foul air. This, more than anything else, ruins health and shortens lives. I never entered a school yet which was thoroughly well ventilated as well as warmed. The first thing to notice is that the problem of ventilation in summer is quite different from that of ventilation in winter; also that the problem is a much more difficult one if the rooms are not warmed by fires in open grates, but in some more artificial way that is less expensive in coal and labour. As to ventilation in summer, the extracting process differs little from that used in winter; except that in summer the outflow of vitiated air can only be assisted by heating with gas jets a main extractor flue of metal; whereas in winter we can accelerate it by using the waste heat of the chimney leading up from the fires and furnaces used to warm the building, as well as the gas fumes led up from the gaseliers in each room. In summer the real difficulty is not so much with the exits as with the inlets of fresh air. In the winter the difference of temperature between the air of the rooms and the outside air is usually considerable, and the air generally rushes up the "Tobin" tubes readily. But in summer the two temperatures differ much less, and much less air comes up the tubes. The only remedy I know is to have good cross-draughts, which, however, must be kept high up above the boys' heads. For this purpose, a large part of the head of each window should be made to open; and large shutters should be placed in the opposite wall at the top of it, swinging on a horizontal pin running through the centre of each. If both the shutters and the upper sashes of the windows are open, a good current of air can generally be produced into the corridor. It is, of course, essential the corridor itself shall have a good current of air passing through it.

In winter, the extracting-flues and the Tobin tubes usually work fairly well, when the tubes are properly constructed. Usually the external opening of the tube is masked by an ornamental grating, which diminishes the current of air by at least one-half. Why cannot this grating be omitted altogether? Secondly, in many tubes I have found valves inserted. These are often jammed by rubbish which has fallen into the tube, and which cannot be cleaned out. There should be no valve at all, but just an ordinary box-lid at

* Because rubbish will be put down the tubes: see next sentence.—Ed.

the top of the tube, which can be so made as to close either partially or wholly. It should be possible to clean out a Tobin tube as easily as one cleans one's pipe. Nor should cotton-wool or the like be placed in the tube to act as a dust-filter; it is soon stuffed up with dust, and no one remembers to remove it. It may be news to some that no air at all will pass through a Tobin tube if wire netting with fine meshes be placed over the top. I found six new tubes the other day all in this state: not a whiff of air passed up. The bappy owner had been deluding himself for three months with the idea that his rooms were being ventilated. As soon as I put my fist through the wire gauze, a strong draught rushed up. For school purposes, a Tobin tube should be open to its full width at both ends, but may have a lid at the top.

Connected with ventilation is the subject of heating. Under no circumstances should the temperature of a class-room be allowed to rise above 60 deg., nor should it fall below 55 deg. The two systems of heating of which I have heard good accounts are Mr. Cunningham's mechanical or positive system, by which warm or cold air is driven by a machine in the basement through tubes to each room at any rate and any temperature desired. This would seem to solve the whole problem of ventilation as well as of heating, if extracting flues be added. But I have no information as to the initial cost and daily cost of such a system, or of its success. I believe that it was adopted at the High School, Dundee. The system I have to deal with is that of Perkins' hot-water pipes, in which an alkaline solution should be put to prevent freezing in the Christmas vacation. I am told that they ought to have been placed in coils inside the Tobin tubes. But if my Tobin tubes acted as exits instead of inlets, as they do sometimes, all the heat would pass into the open air instead of into the class-room. Perhaps this would not occur if we had extracting flues, which we have not. Another difficulty that occurs to me is that the current up the Tobin tubes varies greatly in strength. If it were freezing outside, and I had the lid of the tube wide open, the air would rush up the tube so fast that it would be heated but little in passing among the hot-water pipes coiled in the tube. On the other hand, if I partly closed the lid, little air would pass up into the room. In the former case I should have plenty of air entering into the class-room; but it would be air almost cold. In the latter case the air entering the room might be warm enough, but there would be little of it. Can any of your readers tell me of any school where the difficulties of ventilation and heating have been met successfully?

So much for the buildings from the point of view of health. I have spoken, too, from the point of view of the head-master. Now, what do the assistant masters want? In the first place, architects should remember that nowadays no school, even in England, uses the hall for teaching purposes, except under compulsion, and because there are not enough class-rooms. Doncaster and Bristol Grammar Schools are, I hope, the last schools that will be designed in England for the classes to be taught in one big hall, each interfering with the other. On the Continent, one often meets with schools, even of the first magnitude, without a hall at all. I would not go so far as that. Without a common place of assembly a school would seem rather a collection of separate schools than one corporate entity. And that is what the Continental gymnasiums and the rest really are. We want a hall in an English school, but as we do not want it for teaching, or even for examinations, it must be regarded, in comparison with the class-rooms, where the main work of the school goes on, as being an article *de luxe*. What money there is to spare, then, should be spent on the class-rooms, and not on the hall. The uses of the hall are, or might be, these—(1) for prayers; (2) for the head-master to address a levy of the whole school on matters affecting the school as a whole. These two are the only two objects for which

the hall is essential; all the rest are subsidiary. (3) It may be used as a play-room in bad weather; but covered sheds in the fresh air of the playground are better. (4) It may be used as a gymnasium, one half being reserved for classes with dumb-bells and Indian clubs, the other covered with gymnastic apparatus. If so, the latter should be so constructed that part of it, *e.g.*, ropes and poles, can be raised overhead when not in use, as in the Central Gymnasium, Stockholm, while the rest, such as the bars, should sink beneath the floor, as in some other of the Stockholm schools. But gymnastics kick up a great dust, and moreover ought to be performed in fresh air, therefore it is better to have a separate gymnasium in the playground. However, if one has no gymnasium, but a large hall, it is well to turn the hall to account for gymnastics. (5) A great hall is not necessary for prize days. The hall need not be constructed so vast as to accommodate a crowd of outsiders who only come once or twice a year, perhaps. It is really too great a waste of capital. Much better to have the prize distribution and speech-day in the Town-hall, connecting the school, as it should be, more closely with municipal life. Therefore, the hall need not be larger than will accommodate the pupils, with perhaps a margin for 200 spectators at some school theatricals or bouse-concert. (6) Nor is the hall indispensable for examinations. It is better to have two or three sets of double class-rooms for this purpose, so arranged that each pair can be thrown into one. Supervision also is easier in such a room; and there is greater quiet than in a large hall. (7) The last use of a hall, and a very good use it is in my opinion, is to use it as a passage-room for all the class-rooms. But the class-rooms should open direct into it, and not into intervening corridors. I can conceive of no greater happiness for a disciplinarian, than to be able, from his own room, to see every boy who enters or leaves a class-room. That is what the central hall comes to. There should be a continuous window, about 5 ft. from the ground, running along the side of the class-room which is next to the hall, so that the head-master, as he goes round, can see the state of discipline in each room, without entering the room and disturbing the class in its work. Not that he wants to play the spy on his staff, but that he may see easily what are the classes where his assistance and presence is required by a weak disciplinarian or by some master newly appointed and in need of help. If the school is very large, the hall will need galleries, and may be surrounded by class-rooms, two stories high on all four sides. Or the class-rooms may be placed on three sides only, and on the fourth side may be placed rooms, of one story only, for the head-master, secretary, &c.; what I have called above the administrative block. A space may be reserved in the centre of the hall for assembly of the whole school at daily prayers, &c.; this may be marked off by wooden removable screens. These should be about 4 ft. high; thus, boys when seated in this central area would be unable to see any boys passing from room to room; in this way the central space might be utilised for examinations, if thought necessary. On the other hand, these low screens would not hinder the head-master or discipline-master from having an uninterrupted view of every part of the hall up to the class-room doors. I suppose that the stairs also leading to the gallery might descend into the hall, so as to be well in view.

To return to the assistant-masters and their class-rooms. There may be two or three small rooms, and certainly two pairs of double class-rooms, not only in order that these latter, when thrown together, may be used for examinations, but that every master, while new to the school, may be put at one end of a double room of which the discipline may be at first entrusted to an older and more experienced member of the staff at the other end. When the new man has got his footing the movable partition may be closed, and he may be left to his independence. Double rooms are also useful for choir-work

and art teaching, and a pair of class-rooms in the upper story should be specially designed and lighted for the latter purpose. Also two or three sound-proof piano-boxes or piano-rooms are usually necessary; they are better outside the building. The ordinary class-room should be at least 30 ft. long, 20 ft. broad, 16 ft. high. Three of my own class-rooms are 40 ft. long for classes of thirty boys, and we find it an enormous advantage to have the desks at one end of these oblong rooms and an open space at the other end; at this latter we seat the boys whenever any lesson is given where pens and ink are not required. At this end of the room we can have place taking, which greatly enlivens the work of a class of small boys. Moreover, the boys get change of position. I pitied the German boys, chained to one desk all day. And ventilation is aided greatly; *e.g.*, in summer, when the class is seated at the desks, the windows at the other end of the room are always open, and *vice versa*. If the desks are arranged in this fashion, and if dual desks are employed, 20 ft. is not quite sufficient breadth for the room. All cupboards should be carried up to the ceiling, so as not to bold dust. In every school I have seen abroad lately, the light is made to fall from behind over the boys' left shoulders; cross-lighting also is avoided. If the annual fee for tuition exceeds 10*l.*, there should not be more than thirty boys in each class; if the fee is lower, not more than forty. The windows should be carried high up, the panes should be of clear glass, and the amount of window-space should be large. There should be one main entrance to the room, besides two doors into the cloak-room attached to it.

I have spoken above of the floors, ceiling and walls. There should be a blackboard on wheels, even if a continuous blackboard runs all round the four walls. I think that the assistant-master would now be a happy man. I should add that it is most important to provide abundance of urinals and closets, far better to have too many than too few, scarcity of accommodation leads to the most serious trouble if boys are waiting about for their turn and conversing. It is as well to speak plainly about these things. It is also desirable to provide kitchens and a dining-hall in a large day-school. Many pupils may come from a distant part of the town, and a large number may come in by train from the surrounding towns and villages. Nothing can be worse for the morals of the school than for these boys to frequent public-houses for a sausage and glass of beer at 3*d.*, as they often will, in order to have some dinner-money left to be spent on other purposes. Nor is it advisable to let them loaf about in the streets and add to their education there.

Of the schools of the type which I incline to, those with the hall-passage, the following is a list more or less correct. I hope that any errors in the list may be corrected, and additions made to it. Mr. Robson's Board school at Haverstock-hill, and the Blackheath school for girls; Mr. T. Roger Smith's Board school in Johnson-street, Stepney; Mr. Robins's school in Camden-town; Mr. Clutton's day-school in Liverpool; St. Francis Xavier's College; Lancing College; the Salt schools at Saitaire; a new Board school at Leeds; and the École Monge, Paris. Useful remarks upon the hall-passage plan, as well as articles on ventilation and heating, will be found in Sonnenschein's new "Cyclopedia of Education."

I will conclude with a few particulars about the best day-school I have seen,—the new "Real-schule" at Gothenburg, built for 700 day-boys, and already nearly full. The town contains only 90,000 people, and there are actually two more high schools for boys, each of them with 700 boys. What a contrast to England! The total cost of the "Real-schule" comes out at 40*l.* per head. This includes the buildings, heating and ventilating apparatus, desks and fittings, and gas, water, and electric fittings. Externally, like all the Swedish high schools, the building is plain, but it is imposing from its height and mass, and it has the merit of telling its story,—you see at once that it is a school. It con-

sists of three stories above a basement. The reason why it comes out so expensive is,—first, the vast corridors; second, the immense hall at the back, a much finer room than many town halls; thirdly, the great number of rooms in excess of those used for the actual task of teaching. Out of forty-seven rooms only twenty-two are class-rooms, the remaining twenty-five being devoted to such purposes as laboratory work, lecture theatres, store-rooms, &c. In Stockholm also great high schools are being built at even greater cost, varying from 55*l.* to 65*l.* per head. Each has a large separate gymnasium. I found the cost of installing a large gymnasium for 600 boys to be about 275*l.* Gymnasiums seemed to be elaborated in Sweden more than anywhere else. F. B.

P.S.—Since this paper was written I have obtained a pamphlet by Sir Henry Roscoe, published by Danks, in which he demonstrates the astonishing foulness of the air of schools, and gives his preference to a mechanical system of ventilation, with particulars as to its initial and daily cost.*

NOTES.

THE course of Mr. Lambert's examination before the Board of Trade a few days ago, the Great Western Manager alluded to the constantly-increasing expense incurred by the Company in fulfilling the requirements of the Board in order to secure greater safety in the working. It is undeniable that a large expenditure is due to this cause, and not to any increase of traffic; and quite as true that such expenditure does not enable railway companies to work the traffic more economically or with greater speed. But the additional increase of safety brings with it a corresponding reduction in the amount paid by way of compensation for injury to life and property, and Mr. Courtenay Boyle promptly directed attention to this view of the matter. The measures of precaution which the Board have insisted upon have been called for by frequently-recurring disasters, and the adoption of such measures brings its own reward. An allusion was also made to the Railway Bills of 1885, which, it will be recollected, were petitioned against by all sections of the community, and ultimately abandoned. Mr. Lambert's explanation of this is that the Bills were not supported by the Board of Trade as the companies were led to believe they would have been. This is instructive, for the attitude of the Department,—and, indeed, of the Government,—towards these much-abused measures was the subject of a considerable amount of speculation at the time. The selecting of stations for working out the terminal expenses seems to grow more and more complicated. The London and North-Western Company, as we have already remarked, submitted sixteen, the associated companies are prepared with details of a further 101, while the traders have put in a list of forty-four more places with regard to which similar information is demanded. It is to be hoped that this part of the case will be narrowed down very considerably before the inquiry is re-opened next week. The able Secretary of the Railway Companies' Association (Mr. Oakley, of the Great Northern Railway) will probably be the next witness.

THE promoters of the Central London Railway Bill have issued a statement for the popular mind, to do away with the misapprehension which they say exists on the part of the public in regard to this scheme; and certainly if it is true that a leading London paper described it as a scheme for running an electric railway along the surface of the most crowded streets, the promoters have some

* There can be no kind of question that mechanical ventilation, when it can be afforded, is the most efficient and the most certain in all seasons, for schools and other public buildings; an opinion we have frequently expressed.—Ed.

reason to complain of "misapprehension." The following are the main points of the statement:—

"The Central London Railway is proposed to start at Queen's-road, Baywater, to pass under Baywater-road, Oxford-street, Holborn, Newgate-street, Cheap-side, and King William-street, and to terminate near the eastern end of King William-street by a junction with the recently-constructed City and Southwark Subway. . . . The mode of construction proposed to be adopted in the case of this railway (except as regards the stations) is practically the same as that used in the City and Southwark Subway. There will be two iron tubes, or tunnels, of about 11 ft. internal diameter. One will be used for the up traffic, the other for the down traffic. A steel shield with a cutting edge will be forced by powerful hydraulic pressure into the clay in advance of the excavation, so as to obviate the slightest risk of movement in the ground over or near to the tunnels. The iron tunnel as it is placed in position will be grouted with blue las line in a semi-liquid state, which, when it sets, becomes virtually stone, and the result is an iron tunnel encased in stone, the strength and durability of which will be enormous. The same system of construction will be adopted for the stations, which will be of iron, instead of brickwork as in the City and Southwark Subway. In order to drive these tunnels the sites of the proposed stations will be first acquired, and shafts will be sunk on the private property so acquired, and not in the streets. The spoil will be brought to the surface by these shafts, and the material for constructing the railway will be passed down through them. The work can be carried on simultaneously in both directions from all the station sites. In the construction of the railway there will be no interference with the surface of the streets, and consequently no stoppage of the traffic."

This seems to render it evident that the railway can be constructed without material interference with street traffic. Whether the game is worth the candle, and whether the proposed means of transit will be as popular as the promoters profess to believe, is another question. Travelling in a tube 50 feet under the ground is not an attractive idea; and while the pamphlet states that "perfect ventilation will be maintained" it does not go into any particulars as to the means to be adopted to ensure this. An extract fan would be necessary for each section of the line between stations, unquestionably.

WE learn that out of the first competition for New York Cathedral the designs of four architects or architectural firms have been selected, the authors of which are to compete a second time. They are Messrs. Potter & Robertson, Mr. W. Halsey Wood, Messrs. Heins & La Farge, and Mr. G. Martin Huss. The first-named architects are well known for good Romanesque work; and it is also known that Mr. Potter is the bishop's brother. The other three are not well known in regard to church architecture, and some of those who had considerable reputation in this respect, names certainly much better known on this side of the water, have been left outside. Nothing can however be done for a long time, as the 1892 Exhibition is to be held on the site ultimately to be appropriated to the cathedral.

THE *Berliner Philologische Wochenschrift* for December 21 gives a good summary of the most important of the archeological discoveries of 1889, among which, the discovery of the temple of Despoina, in Arcadia, to which we drew attention some weeks ago, naturally holds the first place. The temple, it will be remembered, was found on the north side of the ridge known as *Trophi*, about 100 metres to the west of the ruins of a chapel of S. Athanasios. The ground-plan has been clearly made out, and proves to be that of a Doric hexastyle prostyle temple. The orientation of the building is east and west. It is twenty metres long by ten broad, the cella is thirteen metres long. The portico, which fronts the entrance, is of marble; the walls of the cella have their lower courses of masonry of local stone, the upper of unburnt brick. The portico appears to have been crowded with votive offerings, of which the bases are fortunately still extant. Dedications to Despoina are frequent, and some of the tiles are inscribed *Δεσποινῆς*, "of Despoina." Happily, therefore, there is no

shadow of a doubt as to the name of the temple. Near to the back wall of the cella is a large base, shaped  Here

it is supposed stood the four figures by Damophon, which Pausanias describes (viii. 37, 3), and to which we have already called attention. The actual sculptural fragments discovered, which Mr. Kabbadias conjectures (and the conjecture amounts almost to certainty), belong to this group, are as follows:—A colossal female torso, three colossal female heads, various other fragments, among them a hand with the stump of a torch, another with a lamp, a third holding a piece of a snake; fragments of the feet of a marble chair, four female figures, the lower parts of which branch out into two snake-tails. These last are all the same height (0.23 m), and stand in the same attitude, with one hand raised; they each hold a round object, on which something else, presumably the side supports of a chair, rested. We can only repeat that, as these are the first and only fragments we possess from the hand of the famous Damophon, they are of signal importance, and we hope their publication may not be long delayed.

IN building the new railway-station of Trastevere, at Rome, some ancient Roman tufa quarries, with long and wide galleries, have been discovered in the east side of the hill of Monteverde, and in cutting through the rock a new road leading to the railway-station, a quadrangular niche was found in the tufa; this niche has a pediment, on which is sculptured in bas-relief a club between two vases. In the cornice the following inscription is cut:—

L' DOMITIUS' PERMISSVS.
FECIT

The bottom of the niche having been carefully cleared of earth, sculptures and other objects were found, which showed it to be a little shrine sacred to Hercules. The excavations were continued to a depth of 5 metres, when the altar was found in its place, standing on two steps built of brick, and before it were two pedestals, 0.75 m. high and 0.50 m. wide, each of which bore the following inscription:—

IMPERIO
HERCVLI SACRVM
L' DOMITIVS
PERMISSVS

On the front part of the altar traces of stucco bas-reliefs are to be seen, but as a great part of the stucco has fallen off, they can hardly be made out; they apparently represented a dance. The inside of the niche is covered with red plaster, and various ornaments, such as birds and flowers, are painted on a yellow field. The objects found in the shrine are four tufa statuettes, representing Hercules, a marble head of Bacchus, another of Jupiter, a bust of Minerva, and other fragments of marble and tufa statues. The excavations were continued around the shrine, and resulted in the discovery of various marble slabs, used for paving the temple or for covering its walls, and of the following pieces of sculpture:—Bust of a bearded adult; bust of a young man, with a light beard and thick hair; bust of a beardless youth, very well preserved; bust of a man strikingly resembling to the Emperor Trajan. These busts were placed on a base of variegated marble. Two fragments of Ionic capitals, a few terra-cotta lamps, and a great many bronze coins of Augustus and of Antoninus Pius, were also found.

IN the Prati dei Castelli of Rome, where the Palace of Justice is now being built, two large sarcophagi of marble have been dug out. One of these is 2 metres in length, and 0.65 metres in breadth. It is ornamented with two bas-reliefs representing winged *genii* occupied in picking grapes. On the front part of the sarcophagus is the bust of the defunct, who holds a book in her left hand. The sculpture and the manner in which the hair is arranged lead to the belief that the sarcophagus belongs to the second

half of the third century after Christ. Under the bust two masks of Bacchus are sculptured. On all the front part of the sarcophagus traces are still to be seen of ancient gilding. The style belongs to the epoch of decline in art. The other sarcophagus, of great size, is entirely made of unpolished marble, and its lid is a slab of marble which had already been used for some other purpose.

ON the Capitoline Hill, where important works for the erection of a monument to Victor Emanuel are going on, part of the fortifications belonging to the Arx or citadel have been discovered a few metres from the spot where the other ruins had already been found. (See *Builder*, 1889.) The newly discovered remains comprise four rows of large tufa blocks, perfectly square. Near this ancient building, in a subterranean chamber above which Paul III.'s (1534-1549) tower, demolished two years ago, originally rose, the skeleton of a man has been found on the bare earth, with two great medieval swords crossed on his breast.

EXCAVATIONS are now in progress in the area occupied in ancient times by the Imperial villa built by Nero (see *Builder*, July 13, 1889, pp. 21-23). Some rooms built of large bricks, covered with stucco of excellent workmanship, and with pavements of mosaic representing ornaments and different animals, have been found. In one room a fine statue of Venus of white marble was still preserved in its place. Of this we will give an illustration shortly.

THE City of Chicago seems to have been holding high festival over the opening of a music hall and theatre (or "theater," as they call it in the new American language) of no ordinary splendour and proportions. To judge from the language of the Chicago newspapers, indeed, one would think that Paradise had been opened to the citizens, but the illustrated supplement of the *Daily Inter-Ocean*, published in honour of the event, shows that a rather remarkable building has been erected, as far at least as its interior arrangement and design are concerned. Externally the building has the likeness of a monster hotel of rather heavy and ungainly design, and with nothing in its architectural treatment to indicate the nature of the interior which is enclosed behind this outer mask of hotel rooms. The paper above referred to publishes a section, which enables us to see how the large theatre is arranged within this outer rampart of chambers, which rises all round high above the roof of the theatre. The section as published does not, however, indicate how the interior is lighted. The property-rooms appear to form a solid block over the greater part of the auditorium, an arrangement which would not be approved of in this country. The arrangement of the seating as shown in the section ought to be very good for enabling a large number to see and hear well. There is an immense pit or "parquette" extending in a very gradual rise from the orchestra bar to the back of the house. The orchestra is sunk, on the principle which Wagner was mainly instrumental in starting, between the audience and the stage, in a gallery with a concave floor, we presume for the purpose of reinforcing the sound. One of the special constructive features is that a coved ceiling to the upper circle, having the cove facing towards the audience, is capable of being turned round on its lower edge and dropped to form a cove towards the house and shutting out the upper circle, thus rendering the house smaller if desired: the cove is designed, we are informed, so as to fit into the architectural design in either situation. This is a new idea worth noting. From some sketches of bits of the interior given in the *Inter-Ocean* it would appear that the architects (Messrs. Adler and Sullivan) have developed a certain amount of originality in the treatment of detail. An organ is placed adjoining the proscenium arch, and flanking the end of the orchestra chamber; but

apparently masked behind a decorative screen. It furnished an important addition to the opening proceedings, however, the ceremony being opened by a Triumphant Fantasia for organ and orchestra composed for the occasion by M. Dubois, a French organist and composer. The building is intended, we gather, for either musical or dramatic performances as desired. No scale is appended to the section, but taking the general heights of boxes, &c., as affording a rough scale, it would seem that the house must be too large for anything but spectacular drama. However, it is evidently a building worth attention, though we wish the exterior architecture had more to recommend it. "The Auditorium" is the name by which the building will be known.

A PROTEST has just been made by a number of Stockholm architects against recent jury decisions, the step being due chiefly to the result of the recent competition in respect of the new Houses of Parliament and Treasury Buildings to be built in Stockholm, to which we have referred on several occasions, and which caused a keen competition, some 120 designs having been sent in. Two of the competitors, Messrs. Ulrich and Melander, some time back lodged a protest on their own behalf against the decision, but no steps were taken by the authorities in the matter. Now, however, a protest has been drawn up, signed by fourteen leading Stockholm architects, in which the step taken by their two colleagues is fully approved, the chief ground of complaint being that the juries in architectural competitions, when judging the plans sent for competition, do not adhere to the principal conditions laid down in the programme, whereby those competitors suffer who have followed these conditions most strictly. The protesting architects, therefore, demand a strict adherence to the conditions of the programme in architectural competitions. This protest is signed by such leading Swedish architects as Messrs. Clason (designer of the new National Museum), Ekholm, Holmgren (architect of the new Upsala Museum), Lindgren, &c.

THE Secretary of the London Electric Supply Corporation publishes a significant letter in the *Times* of Thursday containing a quotation from Mr. Musgrave Heaphy's report on the causes of the fire at 8, Grosvenor-square, which arose from the electric lighting installation. Mr. Heaphy's report said:—

"I have made an examination of this installation of Mr. Amherst, at 8, Grosvenor-square, as far as it was possible under the circumstances. I found the work in the house was certainly not in accordance with any fire-insurance rules with which I am acquainted, nor with the specification of the London Electric Supply Corporation. The conductors were in contact under the floors, they were unencased, and fastened by metal staples. Among the few places that I was able to examine, I found that a staple had cut into the insulation. The conductors in another place were in contact with the bell wires."

It was at a date subsequent to this evidently most careless piece of work that the Electric Supply Corporation very rightly determined to refuse to supply their current into any buildings until, by inspection, they had first satisfied themselves that the work had been properly done and in accordance with their specification. They added that had they known of the facts now brought out by Mr. Heaphy's inspection, they would never have connected the installation at 8, Grosvenor-square to their mains, as with work done in the way that was, "a fire sooner or later was inevitable." This is an important lesson to private owners to be very careful whom they employ to fit up electric lighting in their houses. If all the companies which have concessions to supply London districts adopt the same course which the Electric Supply Corporation have taken, and refuse to connect with any residence until a competent electrical engineer has made a satisfactory report upon the fittings, the danger to private owners from their own carelessness will at all events be minimised.

THE serious accident on the Chesapeake and Ohio Railway, near White Sulphur Springs, is said to have been occasioned by "the spreading of the rails" while a train was going at high speed to make up for lost time. This, we presume, is one of the results of the American expeditious system of laying down railways in an incredibly short space of time, of which we hear every now and then. It is not an accomplishment to be very proud of. English railways occupy more time in construction, but the rails do not burst open under high speeds when they are once down.

SHORTLY after the death of Dr. William Chambers, the restorer of St. Giles's Cathedral, Edinburgh, it was resolved to erect a monument to his honour. The question was raised as to the shape which the memorial should take. One proposal was that a built-up chapel, to the east of the north transept, which had been used as the Session-house of the High Church, should be thrown open, put in proper order, and a monument with a recumbent figure of the deceased placed therein; another proposal was that a bronze portrait statue should be placed upon a suitable pedestal in an appropriate site in the open-air. The latter course was adopted, and Mr. Birnie Rhind, sculptor, was entrusted with the commission; the site fixed upon being in Chambers-street, immediately opposite the Museum of Science and Art. The question as to restoring the closed-up chapel has again cropped up, and it has been resolved that it should be converted into a memorial chapel to Dr. Chambers, with a stained-glass memorial-window therein. There will thus be five chapels attached to the cathedral, two on the south side and three on the north. The two former, comprising the Moray chapel and the Montrose chapel, are sufficiently supplied with appropriate monuments, but the three latter are empty. It would greatly add to the attraction of the cathedral, and give it an air of greater completeness, were these chapels furnished with canopied tombs; and there seems no reason why the appropriation of one of them as a memorial to Dr. Chambers should exclude from it any appropriate memorial to another. The walls of the aisles have, since the restoration, received numerous memorial-tablets, principally brasses, and care seems to have been taken that these should not be incongruous with the surroundings, and one of the best of these has been placed in the Montrose chapel beside the fine monument recently placed there, which was designed by Dr. Rowand Anderson.

THE Tudor Exhibition at the New Gallery has a higher interest than the Stuart Exhibition of last year, inasmuch as one of the principal figures among the Tudor Sovereigns, Henry VIII., as well as a good many of his subjects, had the good fortune to be painted by a great artist, whose works are now, by the irony of fate, more valuable for his own name attached to them than for the names of the eminent persons of the day whose portraits he painted. The Holbein portraits of Henry VIII. are numerous in the West Gallery; none perhaps so interesting and characteristic as the unfinished cartoon (42) representing Henry VIII. standing with his legs apart and with that kind of general look of a bully which was an essential part of his character. Among other Holbeins may be especially mentioned the portrait of himself (52), the "portrait of a man" (67), belonging to Sir John Millais, and before seen in the Burlington House loan exhibitions, the magnificent full-length of the "Duchess of Milan" (92), one of the finest female portraits ever painted; and the "Sir John Moore" (100). These, and the artist's small studies of heads and figures, are alone worth a visit to the exhibition. The Queen Elizabeth set of pictures in the North Gallery are of less interest, because Queen Elizabeth had no Holbein, nothing better than Zuccherro, to paint her. The portraits of her very very much in physiognomy, and only one or two make her

really handsome; but the horribly-constructed ladies' dress of the period was enough to destroy any degree of natural charm. There is a fine collection of armour in the hall, and the cases in the rooms contain some objects of decorative art of great beauty and interest, in particular some of the cups in the case in the centre of the West Room. The cup belonging to Corpus Christi College (812), and that given by Henry VIII. to the "Barber-Surgeons" Company (814) are beautiful work. Some of the decorative work and armour we shall give illustrations of shortly.

PAPERS have been read at the recent meetings of the Northern Architectural Association at Newcastle by Mr. W. H. Dunn and Mr. J. H. Morton, on the subject of "Architects as Scientists," the latter gentleman's paper being apparently a reply to the former one, in which Mr. Dunn urged that the scientific and technical side of architectural practice should be more developed and attended to by the architect, who should be the chief workman. "The chisel, the hammer, and the plane would have to enter largely into the work of their young men if they were to keep the position of the architects in the nineteenth century." So far as this is possible it is no doubt advisable; but one man and one lifetime are not sufficient for everything, and we fear the fumes of chemistry may have a tendency to clog the brain of the designer. Architecture has been too much mere design, or even mere drawing; now there is evidence of a reaction in which design in the proper sense may be snuffed out. The practical reactionists are in danger of forgetting that, after all, the intellectual interest of the architecture of the past is mainly in its design; in its outside quality. Turn over such a *résumé* of the subject as is given in Fergusson's history, and it must be evident that what makes the subject worth a great book on it, with hundreds of illustrations, is the various forms of architectural design and expression employed in different times and in different countries. The practical construction employed, though indissolubly connected with the subject of design, is not that side of architecture which has rendered the subject perennially interesting to educated minds of all times. It is the design and artistic element of the architectural monuments of Athens and Rome, Florence and Venice, that renders them sacred shrines; it is not the construction which draws us to look at them, interesting though this is as the basis of the design. The *Newcastle Daily Chronicle*, in a generally sensibly-written leader on the subject of the two papers, unconsciously points to one of the most apt illustrations of the danger to architecture from the artisan side of the study being developed at the expense of the architectural, viz.: the Scott Monument of Edinburgh. This is an old example often quoted before, of what the studious artisan can accomplish. It is so in more senses than many people are aware of: it is a very clever and ambitious design, as a whole, for a self-trained artisan to have produced; but the detail is coarse and bad to a degree, and has been a source of annoyance to thousands of those whose eyes are trained to know what good detail means. It is in detail that the hand of the really cultured and artistic architect, and the difference between him and the artisan, is especially shown. Many people could rough out a general sketch of a powerful design, who would ruin their own work when they came to detail it: and they will never learn refinement in detail from practising with "chisel and plane" and "the fumes of chemistry."

The Potsdam Mausoleum.—The work on the mausoleum now being built at Potsdam, which is to contain the remains of the late Emperor Frederick, is actively progressing, and it will be finished in the Spring. The interior of the cupola is to be lined with Italian mosaic, manufactured in Venice.

LETTER FROM PARIS.

FOR some days the world of art in Paris has been disturbed over a conflict that has arisen within the Société des Artistes Français, and which may lead to serious results in regard to the future existence of that body. This is no less than a proposition for the formation of a new society apart from the existing Society, and having its own annual exhibition, and admitting into its regulations neither "exemptions" nor rewards. If this movement is accomplished,—and latest advices speak of it as certain,—the new Salon will have at its head, besides M. Meissonier, all the masters of the younger school, MM. Puvis de Chavannes, Roll, Gerxev, Carolus Duran, Dagnan-Bonveret, and Besnard, among painters, M. Dalon among sculptors, and among engravers MM. Bracquamand, Walter and Pannemaker. This will be a very dangerous rival to the old society, which has been led by MM. Bouguereau and Tony Robert-Fleury on a course that seems very ill-advised and impolitic.

What has happened is this. In regard to the recompenses decreed by the International Jury of the Exhibition, a certain number of artists, discontented no doubt with the results of the awards, proposed that they should be disregarded and should not figure in the book of the annual Salon. Naturally, M. Meissonier, in his position as President of the Jury of Fine Arts, energetically combated this proposition, which is absolutely contrary to established usage. It may be as well to add that M. Bouguereau figures in all the Salon books with the detailed list of honours he has received in the previous universal exhibitions of 1855, 1867, and 1878. M. Meissonier, at a very stormy meeting, endeavoured to convince the artists that they could not now take a step that would diminish the value of the awards given in the most recent of these exhibitions. His efforts were in vain, the coeteries of the ateliers prevailed over his reasoning, and M. Bouguereau's proposition was adopted by a large majority of votes. M. Meissonier has accordingly withdrawn from the Société, followed in his retreat by a great number of artists, who have signed a strong protest against what they consider as an absolute want of courtesy not only towards the French Government but towards foreign artists. What will be the precise result, and whether the new society will endeavour to retain a hold on the Palais d'Industrie, or seek a footing in M. Formigé's new building on the Champ de Mars, cannot be predicted at the moment. Possibly the State, which has been directly insulted by the existing Société, will feel itself at liberty to withdraw the use of the Palais d'Industrie, and hand it over to the recalcitrants. Whatever the result, the action of the existing Société is in very bad taste, and much to be regretted.

While there is this dissension among the artists of the sterner sex, it is a curious coincidence that the society of lady artists, "Union des Femmes Peintres et Sculpteurs," seems in a way to be more prosperous than it has previously been. It is directed by a very able sculptor, Madame Léon Bertaux, and does not quarrel about awards, but is devoting itself seriously to the artistic education of women; and in consequence of its efforts there is talk of creating presently at the École des Beaux-Arts a special course of sculpture and painting for women, and admitting them to compete for the Prix de Rome, &c. This feminine emancipation in art has already produced appreciable results, for in the Universal Exhibition the Fine-Art Section counted ninety-two lady artists who received medals, among whom fifty-one were Frenchwomen. Twenty-three members of the "Union des Femmes" were among the awarded, of whom seventeen were French and six foreigners; and of the four gold medals awarded to lady artists, two were given to members of the "Union," Mmes. Demont-Breton and Léon Bertaux.

Nothing has yet been positively decided as to the treatment of the various exhibition buildings, though it is high time it were, if the Champ de Mars is to be got into order within a reasonable period. Its present aspect, in the dull December weather, with its half-dismantled porticoes and galleries, is melancholy in the extreme.

The two large palaces of Beaux-Arts and Arts Libéraux are now nearly empty, and the Cairo street is dismantled. Here and there heavily-laden waggons circulate amid the mass

of débris. All the buildings on the quays are gone, but on the Esplanade des Invalides most of the structures are still standing. The foot-bridges which connected the various parts of the Exhibition have been removed; that over the end of the Pont d'Alma, which formed a kind of triumphal arch over that approach to the Exhibition, is to be re-erected at Calais, at the new central station of the Chemin de Fer du Nord.

Various new monuments or works of art have been inaugurated during the past month. The first to be noted is that of the two decorative groups in bronze placed at the entry of the abattoirs of La Villette. These groups, which during the Exhibition were erected on the Champ de Mars, opposite the Ville de Paris pavilions, represent the one "Fâturage," and the other "Abatage des Bestiaux," and are the work of M. Albert Lefevre and M. Lefevre Dostonchamps. Then came the opening of the new Mairie of Suresnes, designed by M. Bréasson, who has done well with the conditions and the site assigned to him. The new building has a façade towards the Seine with a large central pavilion, containing the Salle des Fêtes, flanked to right and left by the lower pavilions, containing respectively the Salle du Mariage and that of the Conseil Municipal. Internally a large vestibule paved with mosaic and decorated with marble columns gives access to the rooms of the principal story, by a fine double staircase with a wrought-iron balustrade. On the ground-floor a circular gallery communicates with all the administrative offices.

On the hill of Montmartre there has also been opened the large reservoir intended to supply the higher grounds on the right bank. This reservoir, which is to contain 6,200 cubic metres of spring water, and of Engineer-in-Chief Seine water, is the work of Engineer-in-Chief Beehmann. The façade has been built after the designs of the architect M. Diet, adjoining the Church of the Sacré Cœur. Speaking of this church, we may observe that M. Abadie's fine building is now freed from its exterior scaffolding. The work of the vaulting is now being actively carried on, and the church will probably be covered in by the end of this year. The formal opening of the building is fixed for the end of the year. The mass of the building has now a very striking effect at the crown of the hill on which it stands. The cost up to the present date has been 22 million francs.

Various new monuments are in course of execution. M. Dalon has completed the model of the statue to be erected, by public subscription, to the memory of Victor Noir, the young journalist who was killed in 1870 in a duel with Prince Pierre Bonaparte, and whose death was the beginning of the public excitement that led to the fall of the Empire. The statue, of life size, will be executed in bronze by the *cire perdue* process. The artist has represented Victor Noir at the moment when he was about to fall from his mortal wound. The head is very expressive, and the attitude natural. The work, when completed, will be placed in one of the Parisian cemeteries, either Montmartre or Père Lachaise.

M. Crank, on his part, has commenced for the town of Lille the monument to be raised there, also by public subscription, to her great citizen General Faiderbe. The close of the year is announced for the inauguration of this monument, which is surmounted by a figure of Faiderbe and flanked at the four corners by figures representing the constituent elements of the old "Armée du Nord,"—an infantry soldier, a sailor, a dragoon, and a member of the national "Garde Mobilisée."

Lastly, M. Tony Noël has completed for the town of Versailles a very fine statue of the sculptor Hodon, who was born in that town in 1741. The pedestal for the statue is the design of M. Favier, architect.

M. Louis Dumoulin, a young artist who became known some years ago for a series of pretty views of Paris, is exhibiting at the Galeries George's Petit a hundred pictures and studies brought from Japan and China, where he was sent by M. Castagnary, then director of Fine Arts. The exhibition is the result of a two years' sojourn in the far east, scenes from which are illustrated with evident attention to nature and not in the spirit of conventional illustration. Nevertheless, the artist's earlier manner was better on the whole, and perhaps he will return to it now that he has come back to his native country.

The Société Centrale des Architectes has just constituted its new Council as follows: M.

Charles Garnier, president; MM. Alfred Normand and E. de Joly, vice-presidents; M. Loviot and M. Rons, principal secretaries; M. Boileau, editing secretary; M. Harel, archivist; M. Bartaumeux, treasurer; MM. Bailly, Hermant, and Danmet, "censors."

At the Ecole des Beaux-Arts the awards have been given for the exercises in the History of Architecture executed by the pupils of the second class. Medals have been awarded to M. Guimard, pupil of MM. Raulin and Genyus; M. Labouret and Perkins, pupils of MM. Danmet and Girault; MM. Beauvois and Francon, pupils of M. André; M. Debat, pupil of M. Pascal; and M. Parize, pupil of M. Gimain. Twenty-nine "mentions" were awarded.

The French architects who are competing for the Achilles Leclère prize, which is to be decided on March 1, have been given as a subject, "An arena for bull-fights." In a programme chosen by the French Academy for French artists, a "plaza de toros" was certainly unexpected. It seems to be a last reminiscence of the exhibition time, when a futile attempt was made to introduce into Paris this pastime, little in accordance with French taste and feeling.

The epidemic of influenza which has for two or three weeks caused us much anxiety has been the cause among other things of the death of the painter Jules Garnier, an artist of much talent, of a peculiarly Parisian cast. In his short career he unfortunately wanted fine talents and a great facility in composition on subjects of a more than doubtful taste, which brought him a popular renown through the reproduction of photographs and engravings of such works as the "Droit du Seigneur," "Borgia S'Amuse," &c. He was also the author of a well-known picture entitled "Le Libérateur du Territoire," representing Thiers amid the acclamations of the Assembly of Versailles. He produced also the drawings for a series of engravings for an edition of the "Contes de la Reine de Navarre," and some very clever illustrations to a book which appeared lately under the title of "Jeux de Cirque." Few painters had a better knowledge of the types and costumes of the sixteenth century, and he had composed a series of 160 illustrations for the "L'ite of Rabelais," which are now to be seen in the galleries of the Boulevard de Madeleine.

Another artist, William Wyld, who had a certain degree of celebrity under the Second Empire, died a few days since, aged eighty, at his atelier in the Rue Blanche. Wyld was born in London, but had passed more than fifty years of his life in France. He obtained a troisième médaille in 1839, and a deuxième in 1841, and the cross of the Legion of Honour at the Exhibition of 1855. He had been a pupil and intimate friend of Bonington; later he became the travelling companion of Horace Vernet, with whom he went to Rome and to Algiers. He was mainly instrumental in introducing into France the taste for water-colour painting. The Luxembourg Museum possesses two of his pictures, one of them a very fine view of Mont St. Michel from Avranches.

THE ENGLISH IRON TRADE IN 1889.

It would be difficult to point to any year in which the conditions of improved trading were of such a generally satisfactory nature, both to manufacturers and their workmen, as during the twelve months which we have just left behind us. For 1889 will long continue to be remembered as the year which, opening under the most favourable auspices and full of promise, has by far exceeded the expectations formed at its beginning. This is true of trade in general, but more particularly so with regard to the iron industry of this country. It does not matter from which point of view we look upon things as they presented themselves in 1889. The production of iron and steel was larger than during any previous year. The export trade was excellent, and to say that the home demand was full but feebly describes the state of trade. But what is by far the most satisfactory feature of the year's trading is that prices rose irresistibly, yet steadily, in sympathy with the growing requirements both of crude and finished material from beginning to end, the only exception being that fit of speculation which set in towards the end of October, lasted throughout November, but died out again in December. Trade was too sound to be upset by this spell of feverish buying, which only tended to inflate prices for a time, but soon gave place to the more rational conditions with which the year closed. It was stated in these

columns a twelvemonth ago that a flood-tide set in in the third quarter of 1888 which would carry the iron trade well on into the year 1889. How this has been verified has just been briefly indicated, and will be somewhat more fully described in the review of the year which follows.

The figures of the total production of iron and steel in the British Isles in 1889 will not be known for some time to come; but the returns for the first six months of the year show a very respectable increase over the corresponding half of 1888, in which year, it will be remembered, the output exceeded any previous year. As being the most complete returns, we merely quote the figures given for pig-iron, of which 4,083,597 tons were produced in 1889, against 3,902,804 tons in 1888. As the activity of the iron trade was greatest in the second half of last year, it may be assumed that the whole year will show a large excess of production. That this surplus of output, and more, was all utilised is demonstrated by the stocks of pig-iron at the end of the year being considerably reduced. The decrease of stocks in Scotland alone amounts to 208,593 tons, as compared with the stocks at the end of 1888. While the Scotch output of pig-iron decreased 28,846 tons, the local consumption increased by 173,636 tons, and the shipments by about 22,000 tons. In the North of England the reduction of stocks is estimated at 250,000 tons, the same increasing by about 152,000 tons. Although the production of pig-iron in the North-West has been greatly increased by the lighting of furnaces which had long been idle, the consumption and shipments have quite overtaken the output, stocks showing a decrease of about 52,000 tons. In other districts the decrease has been correspondingly large, while in some localities stocks have almost entirely disappeared. In this respect, 1889 compares most favourably with 1888, at the end of which year heavy stocks still exerted a depressing influence upon the market. The monthly returns published by the Board of Trade present an equally satisfactory picture. According to the returns for the eleven months ending November 30 last, we exported iron and steel of the value of 26,945,374, compared with 24,946,089, and 22,808,857, in the corresponding eleven months of 1888 and 1887 respectively. The improvements in the last two years, and in 1889 more particularly, has consequently been steady, indicating a healthy state of trade. It has already been shown that the consumption of crude iron for manufacture into finished products was all that could be desired.

But the best criterion of the prosperity of the iron trade in 1889 is the great advance in the Scotch pig-iron warrants were quoted in January at 42s., and they closed the year at 62s. 6d., or just 50 per cent. higher. Scotch makers' iron advanced more than 30s. per ton on the year. No. 3 G.M.B. Cleveland iron was quoted 34s. at the beginning of the year, and at its close 60s. 6d. for prompt and 62s. to 63s. for forward delivery. The increase in this class of pig-iron was consequently nearly 75 per cent. The most remarkable circumstance in connexion with the Scotch and Cleveland pig-iron trade occurred at the end of October and the beginning of November, the period of the greatest inflation, caused by speculation, when warrants of Cleveland iron rose to 68s. and even 69s., an increase of 100 per cent., and Scotch warrants to only 64s. (the highest of the year), or 50 per cent. Bessemer iron sold in the North-West in January at 45s. to 45s. 6d., and on November 19 it was worth 78s., reaching subsequently to 77s. 6d., but it closes the year at 79s. to 80s. for mixed numbers of Bessemer. It need only be added that in Lincolnshire pig-iron advanced 35s. per ton, in Lancashire and Derbyshire 30s., in Staffordshire 27s. 6d., and in South Wales about 18s. a ton, in order to show to what an extent prices were sent up by a healthy and growing demand and consequent scarcity, speculative influences causing an abnormal rise only during a very brief period.

There was a very large production of a very heavy consumption of manufactured iron. In the North of England alone the output was 425,000 tons, or 35,000 tons more than in 1888, which was far larger than was expected. Prices in that important centre experienced a very substantial improvement, the average advance being about 2l. 10s. a ton. Common bars rose in the North from 5l. 2s. 6d. to 8l. plates and angles rising in a corresponding degree; in Scotland, from 5l. 7s. 6d. to 8l. 7s. 6d.; in Lancashire, from 6l. 10s. to 8l. 5s., and black

sheets from 7l. 5s. to 9l. 15s. In Staffordshire, marked bars were sold in January at from 7l. to 7l. 10s., while in December they fetched 9l. 10s. An advance in marked bars of 10s., or, perhaps, 12s. a ton is fully expected in January. Welsh bars have risen 2l. 10s. per ton on the year, their present prices ranging from 7l. 10s. to 7l. 15s., compared with 4l. 17s. 6d. to 5l. in January last. With the advance in iron, finished hardware has begun an upward movement at first slowly, owing to stronger competition, but in the latter half of the year more in keeping with the higher prices of iron. At the present time manufacturers of hardware are able to obtain full rates, and are provided with an abundance of work, which augurs well for the future. The tinplate trade has not been as prosperous as other branches of the iron industry. Although the output is estimated to have been larger than in any preceding year, and there was, consequently, full employment, while exports were more than ever before, manufacturers of tinplate have begun a great difficulty in obtaining prices more in accordance with the advanced cost of the raw material. The advance for some descriptions of tinplates has been no more than 1s. 6d. per box, while for other brands it has reached 3s. per box.

Owing to an exceedingly bountiful foreign demand from all quarters excepting the United States, which have almost ceased to buy steel in our market, but no less to home requirements which could only with difficulty be met, the steel trade of the country has passed through a year unequalled in prosperity. The output has been large, beyond any previous record. The export trade chiefly included rails, while the home demand came, first and principally, from shipbuilders, but also from railways, the engineering and other auxiliary branches of trade. In this respect the past year resembles its predecessor, for in 1888 the principal run was also upon shipbuilding material for use at home and rails for export. So well are steelmakers booked with orders that the majority of them have at the present time twelve months' work in hand, and this has been secured at prices which cannot be described as otherwise than remunerative, notwithstanding the increased cost of the raw material and fuel. At the same time, it is not at all unlikely that rates for steel will go on improving for some time yet. The advances in the value of steel products have been quite as pronounced as those of finished iron. In the north-west of England, the great steel centre of this country, the increase has been about 65 per cent. Steel rails, which were 4l. in January last, are now not obtainable under 7l. There has been a large output of shipbuilding material, quite a new industry in the district, and, along with a heavy production, there has been a substantial increase in price. The advance has ranged from 6l. to 10l., ship angles from 5l. 5s. to 8l. 15s., and boiler plates from 8l. to 11l. The other manufacturers of the district have participated in the rise; a staple product, tinplate bars, having gone up from 3l. 17s. 6d. to 6l. In South Wales steel rails are now sold at 7l. to 7l. 10s., against 4l. 10s. at the commencement of the year, while tinplate bars fetch 7l. 7s. 6d. to 7l. 10s., compared with 4l. 15s. in January. In the North of England, steel rails, which were worth only 3l. 17s. 6d. to 4l. a twelvemonth ago, now realise 6l. 17s. 6d. and 7l., while steel ship plates cannot be obtained at under 8l. 15s., against 6l. 15s. at the beginning of 1889. In Scotland, ship plates have gained as much as 3l. 10s., having reached 10l., compared with 6l. 10s.

We have already referred to the large consumption of iron and steel by shipbuilders, and we now know that the out-turn of new tonnage has been simply immense. The production of our shipyards in 1889 amounts to the colossal total of 1,270,000 tons of new shipping, which is by 20,000 tons larger than the best shipbuilding record previously, — viz., in 1883, when the tonnage launched was 1,250,000. In 1888 the tonnage of new ships amounted to 994,000, so that last year the improvement over 1888 was 366,000 tons. The chief centres of shipbuilding contributed to the 1889 total as follows:—Clyde, 335,301 tons; Tynes, 281,710 tons; Wear, 217,336 tons; Tees, 110,436 tons; the Hartlepool, 84,109 tons; Belfast, 80,000 tons; Marsey, 35,000 tons. There is every prospect that 1890 will be as good a year for shipbuilders as its immediate predecessor, especially as large contracts have been placed by the Admiralty, most of which will be completed

THE MONTROSE MONUMENT; S

DR. ROWAND ANDERSON, ARCHITE

ST. GILES'S CATHEDRAL, EDINBURGH.

DESIGNED BY MESSRS. J. & W. B. RHIND, SCULPTORS.

THE BUILDER, JANUARY 4, 1890.

year, while good bookings have been made for the next few months for the mercantile marine. The engineering trades of the country have been as prosperous this year as at any previous year, marine engineers, of course, taking their share; but other departments of engineering have also secured good portions of orders offering both on home and foreign account. It is a highly satisfactory sign of the times that the recent reports of the trade union committees on the state of trade reveal the fact that not more than one per cent. of its members are present out of work—a residuum which will never disappear, even if trade were more prosperous than it is now. It is only natural that workmen should have shared to some extent in the prosperity of trade, and it is gratifying to be enabled to place it on record that, so far, no serious troubles have arisen, and that wages having in most cases been judiciously arranged. But it cannot be doubted that should the present condition of trade continue, there will arise differences as to remuneration which will require much mutual forbearance to smooth over.

Having arrived at the conclusion of what has proved a more satisfactory task than it has been on several previous occasions, a few words may be added as to the future of the iron trade. It is that future is bright cannot be denied by impartial observers, the elements of prosperity being still in evidence. There is at present no lack of money, and to whichever quarter of the globe we look, there are signs that it will be forthcoming to assist in those developments of industry which are the helpmates of civilisation. It is well known that in opening up new countries the iron trade and its related industries play a great part, and from this section, at any rate, benefits to the world will result. As has been pointed out, the year upon which we have just entered will provide ample work for shipbuilders, and these in their turn will make large demands for material. Another fact, and an important one, should not be overlooked. The prosperity of the iron trade of this country is participated in, to a greater or less degree, by the iron industries of foreign countries, and bears the same promise of permanency. Under these conditions, the prediction may be ventured that 1890 will not be far behind 1889, if it does not feel one of the most prosperous years of the present decade.

OLD TABLET IN PRINCES-STREET, WESTMINSTER.

We give this as an addition to the illustrations list of old street tablets in London, of

Old Tablet in Princes Street, Westminster.

which several sketches were published in the *Builder* for December 14 of last year.

Society of Arts.—The meetings of the Applied Art Section of the Society of Arts will commence on January 28, when Mr. Edward C. Robins, F.S.A., will read a paper on "The Relation of the Fine Arts to the Applied Arts." At subsequent meetings papers will be read on "Cast Iron and its Treatment for Artistic Purposes," on March 3, by Mr. James Orrock, R.I., on "The Claims of the British School of Painting to a thorough representation in the National Gallery," when pictures by illustrious English masters whose works are not included in the National Gallery will be exhibited by the reader of the paper; on March 25, by Mr. H. Arthur Kennedy, on "Glass Painting"; on April 15, by Mr. C. Purdon Clarke, C.I.E., on "Modern Indian Art"; and on May 13, by Professor W. C. Roberts-Austen, F.R.S., on "The Use of Alloys in Art Metal-work."

Illustrations.

VIEW OF SELBY ABBEY.

SELBY Abbey was referred to by Sir Gilbert Scott as the only one of the Yorkshire Abbeys not wholly or partially in ruins. The restoration carried out under Sir Gilbert Scott's direction left the nave in a safe state for many years to come; but the choir is now in so dilapidated a state that it has been thought necessary for safety to remove the services into the nave, and the expenditure of a few thousand pounds will be necessary merely to put the choir into a state of security against downfall.

The following quotations are taken from a recent report on the state of the building by Mr. J. Oldrid Scott:—

"It is more than two years since I drew up a specification, at the request of the churchwardens, for the restoration of the north transept; its condition at that time was very serious, but it was found impossible to undertake the work at once, and in the meantime the mischief has increased. Cement tests, which were then placed across the cracks, have given way, showing that there is a movement towards the north actually going on.

The walls are bulged to a very dangerous extent, and the condition of the great window is such that a calamity may occur at any time.

I therefore venture to urge on the inhabitants of Selby, as well as on others interested in the Abbey, the absolute necessity and duty of taking prompt measures to arrest the evil which is at work, and to place the transept in a condition of safety.

The plans I have already prepared include the restoration of the gables and pinnacles, as well as the addition of an outer roof of higher pitch, such as the transept once had. I fear it may not be possible to raise the funds now for this part of the work, and although it is most desirable that it should be carried out before long, yet it may be postponed for a time, and the restoration limited to the essential works of underpinning the foundations, rebuilding the window, and securing the walls, roof, and ceiling.

Until this has been done, the Abbey cannot be looked upon as secure, and a very heavy responsibility must rest on those charged with its maintenance.

Besides this work of repair, there are various other parts of the Abbey which call for attention. Among these the choir certainly takes the first place. It is of the finest possible design, its scale is magnificent, and the beauty and richness of its details almost unequalled, and yet owing to the

injuries it has received and to the accumulation of whitewash and dirt, it has an air of neglect which is very depressing. It suffered considerably from the fall of the tower in the seventeenth century, one bay of its groining being destroyed, and the western part of the south aisle, as well as the cloisters, being ruined. It was this that led to the insertion of the very hideous windows which are such a serious blot on the beauty of the choir. Whether it will be possible to remedy all these defects now I do not know, but I understand that the cleaning and repair of the stonework of the choir will be taken in hand at once, and I would strongly plead that at least the reinstatement of the missing part of the groining and the restoration of the south-west cloister window should be done at the same time. . . .

It is earnestly to be hoped that a vigorous effort may at once be made to place the north transept in a secure condition, and also to deal with the choir. The one work will make but little difference in the appearance of the Abbey, but it is absolutely necessary and will carry great and lasting satisfaction with it. The other, on the contrary, will have a most striking effect on the whole interior, bringing out the great beauties of the building, and removing for ever that heavy cloud of neglect which for the last three centuries has shrouded one of the finest of all the Yorkshire Abbeys."

In a further report, dated Nov. 9, 1889, Mr. Scott says—

"In my report dated Sept. 17 last, my remarks are confined to such works of the north transept as I expressed your hope of being able to accomplish. Since then I have had an examination made of the condition of the roofs of the choir and its aisles, and beg to put before you the result of that examination."

Although some of the timbers of the choir roof appear to be in fairly good condition, others have defected, and the ends of many of the rafters appear to be decayed. The whole construction, from want of a longitudinal tie, has inclined to the east, exerting a thrust against the east gable. It is probable that when the roof is stripped, some of those timbers which, from the underside, appear to be sound, will prove to be more or less decayed, as leakage in the lead covering must have been going on for very many years. The tie-beams are nearly all defective, and need to be renewed.

The boarding on which the lead is laid is in great part decayed and broken. The lead covering is very faulty, there being holes in many places. Some sheets have slipped down to such an extent that they no longer lap, and the whole surface has been patched and repaired with solder, which has since cracked. The rain admitted by this defective covering is not only causing decay in the roof itself, but is doing mischief to the oak groined ceiling below.

It is most important that the choir roof should be made watertight before any improvements are made to the floors and fittings below. To effect this the whole roof must be stripped, repaired, and re-covered, the present lead being re-cast and re-mast.

The roofs of the aisles and choir are in much the same condition, though here the construction needs strengthening by the insertion of additional timbers, besides the repair of the defective rafters and plates.

The whole of the external masonry, including that of the transept, needs pointing, and in some places the renewal of carvings. Fragments of the tracery and carving frequently fall, doing injury to the roofs, from want of this attention."

The Vicar, the Rev. A. G. Tweedie, is endeavouring to interest the public in this, which may be called a national work, the resources of Selby itself being limited. The Vicar, we understand, takes an entirely conservative view of the matter, and is desirous mainly to preserve the church and put it in proper repair, not to enter upon "restoration" in the sense in which the word is too often understood. It is partly with the desire to aid in this work by calling attention to the grand style of this ancient building that we have made it a prominent feature in the illustrations to this number.

The view, showing the exterior of the choir from the south-east, was drawn expressly for this occasion by Mr. Arnold B. Mitchell, from studies and sketches made on the spot.

We add also a view of a portion of the nave, drawn from a photograph.

"THE PALACE."

ALTHOUGH we know pretty well what a Mediaeval cathedral was like in the days of its splendour, and we can realise the dignity of an abbey and the sombre and solid sternness of an ancient castle, yet we are rather puzzled and confused in our notions of an old Gothic palace. Undoubtedly this arises from the fact that the examples of Mediaeval palaces in an unaltered condition are so extremely rare,—in fact, it may be said, without exaggeration, that we do not possess,—in Northern Europe, at any

rate—a single specimen of a Mediaeval Gothic palace of the first-rate magnitude. We can, of course, find amongst the great palaces of our own country, of France, Germany, and the Netherlands, portions of buildings, and features left from the Middle Ages, but these are surrounded by works of a later time, so that the harmony of the old design is lost. This is exactly the case with the great palaces of Prague, Salzburg, &c. When seen from a distance, with the towers and pinnacles of the Cathedral and Benedictine Church, both of which are enclosed within its walls, rising over it, the palace of the Hradscchin at Prague does indeed give us some notion of the splendours of a Mediaeval Royal palace; but, unfortunately, upon close inspection it will be found to be nothing but a huge architectural patchwork, the greater portion of which is made up of seventeenth and eighteenth century Renaissance erections. The great Hall of Ladislaus, with its vast vaulted roof, and the tower of Daliborka, seem alone to have escaped the botching and plastering-over of the late Renaissance men.

In our article upon Mediaeval Paris, in January last, we showed how the ancient palaces of that city had almost entirely disappeared, and we have also accounted for the disappearance of the palaces of our own Kings in London and Westminster. Of the courts and suburban residences some remains are still to be seen. The hall at Eltham is, indeed, a noble relic, and the old gateway at Richmond not uninteresting. Hampton Court, at least as far as its ancient portion is concerned, can scarcely be looked upon as a "Royal Palace" architecturally considered, for it was constructed to be the dwelling of a churchman, and possesses, in a marked degree, an ecclesiastical character. Much has been said of Wolsey's magnificence and love of ostentation, but it must be acknowledged that they do not display themselves at Hampton Court, which is a singularly sober and quiet example of Tudor architecture, the only very elaborate portion being the Dining Hall, which is known to have been erected after Wolsey's disgrace, and does certainly give us some idea of palatial architecture. Of the old places of Deptford and Kennington we know nothing, Placentia, at Greenwich, and "Nonsuch," in the parish of Cheam, are represented in old drawings, and would appear to have been elaborate buildings. No remains, however, of them at present exist. In the dearth of examples of old Royal palaces, one is thrown back upon descriptions of them, and here none is certainly more interesting than that given by Chaucer in a poem called "The House of Fame," from which we take the following extracts:—

"When I was from the Egle gone
I gan behold upon this place
And certayne or I further passe,
I wold you all the shape devise,
Of house and citee, and all the wise,
How I gan to this place approche,
That stood upon so hie a roche . . .

"The gan I on this hill to gone,
And found on the coppe a wone,
That all the men that been on live,
Ne haue the coning to descrive
The beaute of that like place,
No coud caste no compase,
Such another for to make,
That might of beaute be his make (or "mate")
Ne so wonderly wrought,
That it astoneth yet my thought,
And maketh all my wite to swinke
On this castell for to thinke,
So that the great hoantie,
The caste, craftes, and curiosite,
Ne can I not to you devise,
My wite ys maye me not suffice . . .

All was of stone of Berle,
Both the castell and the toure,
And eke the hall, and every boure,
Without peeces or joyntings,
But many subtell compassings,
As habouries and pinnacles,
Inuageries and tabernacles,
I saw, and full eke of windowes,
As flakes fallen in great snowes,
And eke in each of the pinnacles
Weren sundry habitacles
In which stodeen all withouten,
Full the castle all abouten."

Here follows a description of the statues occupying the various niches, which were so numerous that he says that if he were to describe those

"Of all the people that I sey,
I could not toll till Domesday."

A fine description is given of the palace gate:—

"I gan forth romen till I fonde
The castel gate on my right honde,
Which so well carven was,
That never such another n'as,
And yet it was by aventure
Ywrought by great and subtil our;e
It needeth not you more to tellen,
To make you too long dwellen,
Of these gates florishinges,
Ne of compases, ne of karvings,
Ne how the hoking in masonrys,
As carbettes, and imageries."

This long quotation, which is taken from Chaucer's "House of Fame," gives one some idea of a Mediaeval palace of very extraordinary splendour, and the question arises to one's mind, is the palace here described purely imaginary, or does it, to a certain extent, describe some building which was in existence in Chaucer's time, making allowances for poetical colouring and fancy, such, for instance, as the building constructed of "Beryl stone" without jointings, and its standing upon a rock composed of ice? Of course, it must be remembered that Chaucer had a considerable practical experience of palaces, for in July, 1385, he was appointed "clerk of the works" to the palaces of Westminster, and that within the Tower of London, and of certain works being carried out in the Royal manors of Kennington, Eltham, Clarendon, Cheam, Byfleet, Feckenham, and Windsor. It is true that he filled this office for only two years, according to Sir Harris Nicholas, yet that period, though it might not have given him the experience necessary as a practical builder, or a superintendent of works, would account for his knowledge of architecture, and would suggest the idea that his description of a palace might be founded upon ideas derived from existing edifices. Chaucer, moreover, was a good deal on the Continent. In early life, he got into trouble by joining the Wickliffites, and had to leave the country. He was also sent upon diplomatic missions to Lombardy and to France, and at various times he had visited Hainault, Zealand, and other parts of the Low Countries. We are not aware whether he was ever in Bohemia, though it is not improbable that he knew Prague, at any rate by description, as he was a protégé of Anne of Bohemia, Queen of Richard II., and his wife was a foreign lady attached to her household.

In the drawing we publish we have attempted to portray the sort of building which might have suggested to Chaucer the architectural description which he gives of "The House of Fame." With regard to the dome in the centre of the building it is certainly an unusual feature in Gothic architecture, but domes of this description, though uncommon, were certainly occasionally erected in the Middle Ages. That which crowns the tower of the Cathedral at Frankfort, and the one over the crossing of the minster church at Roëmond, are cases in point.

H. W. B.

MONTROSE MEMORIAL, ST. GILES'S, EDINBURGH.

WE gave some description of this monument at the time of its erection (*Builder*, October 13, 1888, page 264). The engraving here given, made by Mr. J. D. Cooper from a photograph, shows the figure and some of the architectural detail contiguous to it; a sketch of the whole monument is added also.

The architectural portion was designed by Dr. Rowand Anderson, and the figure is the work of Messrs. J. & W. B. Rhind; so we are informed, though we do not well understand how two sculptors can be joint artists of one figure. However it was produced, the figure is fine and impressive in its attitude of armed repose; the architectural portion of the monument is effectively designed, and the whole is not unworthy of the remarkable man to whom, so long after his death, it has been erected.

A SCHEME FOR DINING ROOM DECORATION.

THIS is reproduced from a highly-finished water-colour drawing by Mr. Thomas W. Hay, which was exhibited in the Architectural Room of the last Royal Academy, when we commented on it in mentioning the architectural drawings. The design is mainly Greek, though there is a Pompeian flavour about the frieze

THE MONTROSE MONUMENT, ST. GILES'S CATHEDRAL, EDINBURGH.

(See engraving for figure and architectural detail.)

decorations. The coffers of the ceiling are decorated in gilding on a blue ground.
The drawing was one of the most effective of its class in the Academy Exhibition.

DETAILS, ST. MARK'S, VENICE.

The drawing of the capital, by Mr. Gerald Horsley, was exhibited in the Royal Academy Architectural Room, the year before last. The cap crowns a marble column in the north transept in St. Mark's; the carving is gilt; the ornament of the abacus is inlaid; and the soffit of the arch which it carries is decorated in mosaic. The other drawing, also by Mr. Horsley, represents a niche and emblematic sculpture in the north front of St. Mark's.

CHANCEL, HOLY TRINITY CHURCH, CHELSEA.

The drawing gives a sketch of the chancel of this church as it is intended to be finished, with the chancel screen and gates. The front screen is to be of marble, with wrought-iron gates and copper enrichments. The architect is Mr. J. D. Sedding.

UPPINGHAM SCHOOL, RUTLAND.

The new buildings for Uppingham School now in progress, from Mr. T. G. Jackson's design, consist of a school-house for the head-master, with accommodation for thirty-five boarders, and six class-rooms for the use of the school. They are so arranged as to form a quadrangle in conjunction with the hall and chapel, built by Mr. Street about twenty-five years ago.

The present head-master's house is a picturesque building, but inconvenient for its present purpose; it was originally the hospital for hedgesmen, which formed part of the foundation of Archdeacon Johnson in 1584. This ancient building will, of course, be preserved, though converted to other uses.

The general contractors for the new work are Messrs. Parnell & Son, of Rugby; and the heating and ventilation will be carried out by Messrs. Haden & Son. Mr. Evans is the clerk of works.

FONT AND CANOPY: ST. PETER MANCROFT, NORWICH.

The restoration of this well-known font-canopy was undertaken at the expense of a Norwich gentleman (who, unfortunately, did not live to see the completion of the work), as a memorial of her Majesty's Jubilee. The lower part of the structure, consisting of the octagonal platform, as well as its cresting and the four posts and four corresponding pendants, are original. Before the restoration they were thickly covered with black paint, and the

figures in the niches had been hacked out. A slight structure of no interest, which had once taken the place of the original font-cover, had long been out of use, and was roughly propped upon the platform, over the octagon opening through which the original cover must have slid up and down. Although a careful search was made, no drawing or description of the original upper part of the canopy could be found, and the restoration of the upper part and of the font-cover, which can be slid up into it when the font is in use, is purely conjectural, although founded upon the canopy at Trunch Church in the same county, which is believed to be the only similar structure in the country. The material is oak, and when the black paint was cleaned off it was found that the wood had been at one time coloured, though apparently very roughly, in red, green, and white, with gilt crockets, finials, &c., as is usual in late Medieval woodwork. The old font had lost, evidently by violence, every trace of ornament or moulding, and was replaced by a new one. Mr. J. E. Knox, of Kennington, executed the work with exceptional care and skill. The architect was Mr. Frank T. Baggallay.

ST. PAUL'S CATHEDRAL.

STR.—Hearing that Mr. Watts' design for another of the spandrels in St. Paul's had been executed in glass mosaic, I went round to see it on Saturday, but the day was so dark that the gas had to be lit. The composition seems to me to be very fine, the long sweep of the angels' scroll binding the whole composition together.

I was happy to learn that the remaining five were to be finished in mosaic as rapidly as possible; three more from the designs of the late A. Stevens, and the two others of St. Mark and St. Luke from those of Mr. W. Britten. Some years ago two beautiful dancing figures of his were engraved in the *Art Journal*, and so much did they please that they were at once annexed by an enterprising manufacturer, and we have seen in the last few years figure friezes of his in the exhibitions, so that we may confidently hope that his compositions will not be unworthy of their companions. It is a great deal to say, as the rest are the compositions of two of the great masters of their craft.

It is to be hoped that the rest of the decoration will be now taken in hand. A drawing, or, better still, a painted model, should be prepared, so that the whole tone of colour may be made, not only harmonious, but dignified,—no easy task, when the whole of the architecture is of a very light warm grey. If the composition of the parts were entrusted to able men, and the designs, when done, were submitted to the Royal Academy for criticism and

approval, we should be sure to have something worthy of the metropolis.

Jan. 1, 1890.

G. AITCHISON.

LIMITING THE HEIGHTS OF BUILDINGS

STR.—Mr. Somers Clarke (p. 463 in last week's *Builder*) writes in some dismay at the prospect of 70 ft. being fixed as the limit of the height of front walls in London, thinking that it would be better to arrange for gables and give-and-take adjustments in clause 70 of the new Bill. The clause must be regarded as the first step, and only the first step, in a new direction. The heights of new buildings in new streets of less width than 50 ft. are already determined by sec. 85 of the Act of 1862. Their height cannot exceed 49 ft. 11 in. in a street of that width if the front wall is brought out to the footpath. If it is set back, then the width of the forecourt may be added to the width of the street, in order to give the height of the parapet, or eaves, of any building, "except a church or chapel."

The principle of Mr. Whitmore's Bill once adopted, and the regulation of the heights of buildings in old streets and streets over 50 ft. in width once sanctioned by Parliament, many details will no doubt be dealt with logically as time goes on. We shall, however, all agree that the first step may as well be taken in exactly the right direction.

It will probably be considered undesirable to stop at the mere regulation of the height of front walls, for then ingenious persons will have no hesitation in arranging for roofs out of all proportion. If there are no limits to the heights of roofs, 70 ft. of front wall may occasionally be surmounted by 40 ft. (or more) of curb roof, sloping at the rate of 1 in. to the foot,—3 ft. 4 in. out of the vertical in four stories. This would be looked upon with nearly as much dislike as 110 ft. of vertical wall by the passer-by, and with much disfavour by many others.

Public opinion seems ready for the limitation of the number of dwelling-rooms in roofs,—although, perhaps, not ready for the prohibition of them, as in Vienna. Fearful events, due to large combustible roofs, may startle the world some day, and then, in place of placid acceptance of new legislation, there will be frenzied shrieks for it. Cannot something be done at once in Parliament, without the assistance of the shrieks?

A suggestion has been made that the limit of height should be the top of the topmost story (habitable), and that only two stories in roofs should be allowed. The practical working of this would be that, although the front walls might take any form which the building-owner desired, they would not be carried far above the top ceiling, except by people anxious to contribute to the adornment of our streets. Eccentricity of some sorts is a great trial, but might be tolerated for the sake of the better sort. Additional variety would also result from the London County Council allowing, under special circumstances and proper conditions, habitable rooms to be put at greater heights above the street (but only two stories of them in the roof in any case).

If the height to the ceiling of the topmost story was made the limit, an addition to 70 ft. might be argued for,—70 ft. is, however, no trifling height. It means, at least, six stories above the street level in a good dwelling-house, and reasonable people do not ask for more in any numbers. Rights of light, opposite and around, have to be controlled, and will probably always control, aspirations in many situations; but where there have been no fetters there has rarely been shown a desire for the fatigue of too much freedom. Public buildings must always be regarded as exceptional; and flats, probably,—though their future is as yet very uncertain. The whole subject of the general policy and details should receive careful attention from the profession, and all who are interested in the welfare of cities.

While recognising the comfort and efficiency of a consolidated Act, let me venture to suggest that the supplementing of existing Acts may prove, for the present, a prudent course for the Council. Each amendment is an experiment, and it may be well to obtain authority for novelties, and see the result; and a body new to the work may be pardoned for making haste slowly with heavy tasks. The pruning off of obsolete, and the introduction of new, provisions, the making of one Act, thrown into a

logical form, out of several Acts, is, however, to be hoped for.

It may be desirable in the future to have a new Act at periods of about fifteen years. If the Bill of 1870 could have been altered and passed in 1871 (sixteen years after 1855, when the Act was passed), we should have been entitled, at that rate of change, in 1885 to another consolidated and amended Act. In these quickly-moving days Building Acts should not be kept going after many defects have been discovered. A DISTRICT SURVEYOR.

10, BOW-CHURCHYARD.

Sir,—I observe in your last week's issue a "Note" on No. 10, Bow-churchyard. I described this house in the *Antiquary* for May, 1889, under the sign of the Maidenhead. I am aware that Messrs. Sutton & Co. used to print on their billheads the Royal arms and a bear's head, which they affirm to have been the sign of the house before the present system of numbering came into vogue, but I am inclined to think they are mistaken, as it seems unlikely that the title of a well-known and successful place of business would have been changed without apparent cause. At any rate I await further proof. I have examined the sign very carefully, and it bears no resemblance to a bear's head. One may be tolerably sure that the date is 1669. We know that this part of the city was consumed in the Great Fire, and the date on the eastern is corroborative evidence.

Here is another advertisement inserted from this house; it is inserted in the *London Journal* of 1724:—

"To all Shopkeepers.—At Cher's Printing Office, at the Maidenhead, in Bow Churchyard, shopkeepers' bills and bills of parcels are carefully engraved on copper plates. . . . Titles for Hungary water, directions for Duffey's elixir and the spirits of scurvy grass, funeral tickets in curious borders engraved on copper-plates, may be had the ready printed.

Also receipts for the King's taxes are printed and sold there, wholesale or retail."

I should like the question of the sign to be solved, and I believe the early deeds are non-existent. P. N.

CHURCH BUILDING NEWS.

Bournemouth.—New carved oak choir-stalls and reading-desks are shortly to be placed in St. Michael's Church, Bournemouth, from designs by Mr. Eginald Pinder, F.R.I.B.A. A contract has been entered into with Mr. Holmyard, carver, of Bournemouth, for the first part of the work.

Jesmond (Northumberland).—The chancel of St. George's Church, Jesmond, has now been elaborately decorated. According to the *Newcastle Chronicle*, the entire available wall space has been covered with mosaic, somewhat after the manner of the famous fifth and sixth century mosaics in the churches of Ravenna. On the north and south walls are ranged the twelve Apostles, on a line as to height with the three mosaic figures of Our Lord and the Archangels Michael and Gabriel, which form part of the original decoration of the east wall. At the south side, at the east end, the first figure is that of St. Peter with the keys; next comes St. Andrew with a cross; then St. James the Major, with a staff; next St. John, holding a chalice with a serpent issuing from it, alluding to the legend of his driving the devil in that form from a cup of poison; then St. Philip with a staff and cross; and last St. Bartholomew with a laying-knife, with which he is supposed to have been killed. Following on the north side first comes St. Jude with a halberd; next St. Simon, with a saw, with which he is supposed to have been cut in two; then St. Thomas, with a builder's rule; next St. James the Minor, with a club, with which he is supposed to have been killed; then St. Matthew, with a purse; and lastly, St. Paul (instead of Judas), holding a sword, thus completing the twelve. The background to these figures and to all the forms of ornament embraced in the scheme is of a deep blue, slightly varied in tone over the surface, giving a quality to the colour not possible when such tessera is of a precisely similar tint. The blue ground is carried above the figures for a distance of 2 ft., isolating the figures to some extent from the elaborate composition applied to the higher part of walls, and thus giving form and distinctness to the human element of the scheme. Above the plain surface of background comes a deep band of enriched conventional foliage, disposed in almost imperceptible gradations of colour, so that no part is aggressive, yet the flowing forms of ornament retain their value, and complete the decorative intention up to the wall string, level with the sills of the

clearstory windows. From this point to the roof cornice the space is covered with conventional ornament. On the east wall the same motive underlies the design. The spandrels over the arches to the organ chamber and the morning chapel are filled with figures of angels, having in each one wing outstretched to fill the triangular space of spandrel. The first angel bears the sword and crown symbolical of martyrdom and its crown; the second bears an orb and cross, symbols of Christianity dominating the world; the third and fourth angels represent acts of praise. The massively-pannelled wooden ceiling of the chancel is richly painted in a scheme of blue, ivory, and gold, each panel containing a separate design embracing the legends of the Pelican, the cross of Constantine, and the ingenious arrangements of freely-treated Medieval foliage, &c. The deeply-moulded ribs are overlaid with gold, the combinations giving a most sumptuous decorative result. The entire scheme of decoration is the work of Mr. T. R. Spence, the architect for the church, with the exception of the Apostles, the designs for which were prepared by Mr. C. W. Mitchell. The mosaics have been executed by Messrs. Rust & Co. of London, and the painted ceiling by Mr. C. S. Wardropper, of Gosforth. The whole cost has been defrayed by Mr. Mitchell, of Jesmond Towers, the munificent founder of the church. The cost of the church up to the present has been at least 20,000*l.*

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—I.

INTRODUCTION.

THE following articles are written for those who are already acquainted with such elementary facts and phenomena of electrical science as are fully explained in the many excellent little text-books now published on the subject, but who are desirous of acquiring, in an elementary form, some further knowledge of those branches of the science which are more intimately connected with "Electricity Supply" on a large scale.

Perhaps the simplest method of electrifying bodies, or charging them with electricity, is friction. If two dissimilar bodies are rubbed together, under proper conditions, they become electrified and will attract each other, but if a third body is electrified by contact with either of the rubbed bodies, it will then be repelled from the body with which it has been in contact.

Theories of Electricity.—To account for these facts Symmer suggested the theory that all bodies contain an imponderable fluid, which is a combination of two kinds of electricity—positive (+), and negative (—).

When these two kinds of electrical fluids are present in precisely equal quantities they exactly neutralise each other's effects; but, when a body becomes electrified, it possesses an excess of one or the other of these fluids, and is said to be positively or negatively electrified according as there is present an excess of positive or negative electricity.

This is known as the *two-fluid theory*. Between two bodies similarly electrified there is repulsion, but between a positively and a negatively charged body there is attraction.

It was observed, however, that positive electricity could not be produced without the production of an equal quantity of negative electricity. This fact led Franklin to propose the *one-fluid theory*, and to regard the process of electrification as the transference of electricity from one body to another. A neutral or unelectrified body must, by this theory, be regarded as possessing a certain normal amount of electricity (generally assumed positive), and when a body becomes electrified it is by a second body transferring electric fluid to or taking some from it, hence the expressions positive or negative, implying excess or defect.

Fauly as both these theories may be, they have at all events provided terminology for speaking of and describing certain electrical effects, while avoiding the necessity of any very precise explanation of what electrification really is. But the insufficiency of the old fluid theories is immediately felt the moment the effects, external to charged bodies or to bodies in which electricity is in motion, are considered.

If two bodies, A and B, are placed under the

exhausted receiver of an air-pump and charged, say positively, they repel each other, although there is no material connexion between them. The idea that A can act on B across absolutely empty space, in other words, "action at a distance," becomes the more inconceivable the more it is thought about; to a metaphysician the conception may be possible, but to a thinking physicist such a conviction becomes less and less possible. The real means of communication between A and B may as yet be undiscovered, but that a connexion does exist is felt to be a certainty by at all events the vast majority of those who have given careful thought to the question.

Modern theories of electricity are unhappily far from complete, nor can any attempt be made in a short elementary paper to discuss them; but the following theory is at least nearer the truth than the older ones, and will prove useful by affording some explanation of the electrical phenomena to be hereinafter described.

Electricity may be regarded as an incompressible continuous fluid, which permeates not only all matter,—solid, liquid, or gaseous,—but which fills all space. As matter is built up of material molecules and atoms, so may this fluid be conceived as consisting of electrical molecules and atoms; but though these molecules are absolutely incompressible, they are capable of distortion, and when distorted tend to recover their normal condition. Thus, while a given quantity of electricity cannot change its volume, it is capable of *strain*, and possesses *elasticity*.

In space these molecules of electricity are entangled with one another, or are connected like the surfaces in friction gearing, so that free translation, or the slipping of one molecule past another, is impossible; one molecule cannot even rotate without rotating those next it, but this entanglement or friction is modified by the immediate presence of matter; hence the set of electrical phenomena that can be produced by the aid of suitable arrangements of material, such as, for instance, different kinds of metal in an acid solution, effects that cannot be produced in a vacuum or air alone.

How this continuous incompressible fluid can permeate all matter, and above all how matter can freely move through it, it is difficult to see. These difficulties, however, must not condemn such a theory, for we believe in the truth of many things that are just as difficult to understand. Light comes to us from the sun by means of vibrations in the ether, and recent experiments seem to prove conclusively that all electrical effects are due to this same ether,—briefly, that electricity is ether.

That we can see the sun through a solid piece of glass or feel the heat from a fire through a solid piece of crystal are strange facts, but we nevertheless have no hesitation about believing them. In the same way, then, must be accepted the facts that ether or electricity can go through solids and that solids can go through ether or electricity.

The general and apparently contradictory properties of ether have been well-known and accepted for many years, but the connexion between electrification and ether is a comparatively recently-developed theory.

Returning to the three cases of attraction and repulsion by which alone electricity at rest makes itself manifest. In case (a) (fig. 1,

Fig. 1.

suppose A to be a body, say an insulated pith ball, charged positively; that is, the pressure of the electricity within it has been increased above its normal value, so that the pressure on the entangled electricity in the space around it is increased on all sides, though equally; it does not, therefore, tend to move in one direction more than another. The pressure, or "potential" as it is usually called, in the surrounding medium falls to its normal amount as we recede from A, and does so at an equal rate in all directions.

If a second positively charged body, B, is placed near A, the pressure in the space between A and B does not fall as it does in going in any other direction from A. In other words, the electricity in the space between A and B is more squeezed up than in any other direction, and, being in an entangled state, it is not free to re-establish uniformity of pressure; the result is that A is pressed outwards from B, and, since

matter can pass freely through electricity, A moves away from B unless prevented mechanically from doing so. In case (B) B is charged negatively—that is, the pressure of electricity in B has been lowered, and the electricity between A and B is squeezed together less than in any other direction, and A is pushed more from the side farthest from B than on the side nearest to B: hence if A is positively and B negatively electrified A is attracted to B. Finally, in case (γ), since excess of pressure in A causes it to be urged towards B, defect of pressure or negative electrification will cause it to be repelled from B.

It may be here stated, once and for all, that what might be called the full working details of electricity are not yet understood, and any one who is for the first time regarding electrical phenomena as due to the action of the ether must not feel discouraged if he cannot exactly picture to himself how the ether produces the effects that, with little doubt, it does produce. When two bodies or parts of a system act on one another any theory which supplies a connecting medium must be easier to understand than "action at a distance," which is un-understandable, and it will be seen that this idea of an all-permeating incompressible fluid affords very beautiful explanations of the magnetic and electro-magnetic effects with which these papers will chiefly deal.

Books.

Encyclopédie de l'Architecture et de la Construction. Directeur, P. PLANAT. Vol. iii., premier fascicule. Paris: Dujardin et Cie.

THE first portion of the third volume of M. Planat's dictionary takes us to "châteaux" (monuments), including the important subjects "château" and "chapiteau"; the former written by MM. A. de Rochas and G. Espitalier, the latter by M. Adrien Joly. As in the case of other historical articles to which we have referred, the article "château" is treated from a purely French point of view. In regard to the earlier development of the château into a mansion there is no doubt some excuse for this, as the peculiar type of the Francis I. château, a mansion retaining some castellated characteristics, was in the first instance a French development imitated in other countries. But as the article comes down to later periods the reader is still to be left under the impression that there are no buildings of this class worth taking account of out of France. In the later developments of the word "château" signifies the same class of building which in English is designated as "mansion," but not a single English or German mansion is alluded to or illustrated in any way; such monuments as Heidelberg and Kenilworth have no existence apparently for the French editor, and the Villa Caprarola is the only Italian one that is named. Under "château militaire" it is just the same, only a few French examples are given, and even a building so historically important as the Tower of London is not alluded to. On the other hand, "Chantilly" has fourteen pages to itself as a separate subject, the article being written and the illustrations furnished by M. Horace Daumet, the restoring architect.

The article "Chapiteau" is very well treated in regard to the Classic or antique portion of the subject; that is a class of subject which a French architect always goes into *avec amour*. But the Medieval capital is much less fully treated, and here again every example is from French Gothic, and the student will never learn from this book that English Gothic had a very distinct character of its own in the treatment of capital foliage in Transitional and Early Gothic periods; and the characteristic types of Norman and Early English moulded capital are entirely left out of sight and no hint or illustration of them given. In short, M. Planat had much better frankly alter the title of his publication before going further, and call it "Encyclopédie de l'Architecture Française." As such it will be, we have no doubt, a most full and admirable work of its class; but it is rather a misnomer to give the title of "Encyclopédie" to a work which, except in regard to Classic antiquity, recognises no architectural style and no architectural monuments except those of the Editor's own country.

The Science of Building. By E. WYNDHAM TARN, M.A. Third edition, 1890. Crosby Lockwood & Son.

THIS book contains many useful suggestions

practically expressed, and is one of the best elementary hooks upon construction suitable for the requirements of architectural students. The second edition underwent a thorough revision, and to the present edition tables of the strength of timber, steel, and stone are added. Rules for finding the strength of iron struts and struts of the most usual form of section are given. The friction of water in pipes and principles of ventilation are also alluded to. The work supplies instruction in general mechanical principles; construction of retaining walls, arches, cupolas, and spires; classification, composition and strength of building stones, timber, iron and steel; in short, it may be said that while the book is not exhaustive, it contains in an intelligible manner a very fair epitome of information which could otherwise only be obtained by a perusal of various large and expensive works. Wherever possible, an example of the practical application of a theorem is introduced.

The author's investigations of the thrust of Gothic arches, he reminds us, were first published in the *Builder* for March 31, 1866, and his geometrical process for approximately obtaining the thrust of an arch and the requisite thickness of a pier, was published in our pages, dated December 28, 1867.

The author deserves credit for quoting his authorities, and a copious index concludes the volume.

A Primer of Sculpture. By E. ROSCOE MULLINS. With illustrations. Cassell & Co.; London, Paris, New York, and Melbourne; 1889.

THERE is a great inclination among many people at present, young people especially, to dip amateur hands in the mysteries of sculpture; and we presume it is for the benefit of these aspirants that a *Primer of Sculpture* is called for. Considering that there is perhaps no form of art in which mediocrity is so entirely intolerable as sculpture, and few which make such demands on those who would gain any real excellence in it, we feel some doubt as to the wisdom of offering this kind of encouragement to amateurs to fancy themselves sculptors. The book may, however, serve well as a first instructor for a beginner who wishes to test, or whose friends wish to test, his possession of any such natural powers as would justify him in devoting his life to sculpture.

General principles of working are very clearly and simply set down, and clear directions are given as to the practical requirements in working in clay, building up a life-size model on a proper foundation, plaster casting, &c.,—all this is useful to a beginner who is going to try his hand without a teacher, if there are any so bold. How completely "primary" is the little treatise may be judged by the fact, that the subject of "anatomy" is disposed of in a page and a half, with references to one or two books by the help of which it may be studied.

Taking it for what it is, however, it is well done, and probably the talented sculptor who is the author of it knows as well as any one else that no one will become a sculptor by this means, as indeed he implies in his opening sentence. Perhaps the best recommendation of the book really is, that it gives in a clear manner some general information concerning the process of an art about which many people, even without aspiring to practise it, feel an interest and a desire for knowledge, which Mr. Mullins has imparted in a very agreeable and readable form.

Blackie's Modern Cyclopædia of Universal Information. With numerous pictorial illustrations, and a series of maps. Edited by CHARLES ANNANDALE, M.A., LL.D. Vols. iii. and iv. Blackie & Son, London, Glasgow, Edinburgh, and Dublin; 1889.

THE fourth volume of this Cyclopædia, the earlier volumes of which we have previously noticed, takes the reader well on into the letter I, and from the prompt way in which the successive volumes are appearing we may expect that this Cyclopædia, issued in successive instalments, will really be finished, and within a reasonable period, in which point at least it will have the advantage over some more ambitious works of the same class. The work seems to be quite keeping up to the standard of the first two volumes. The articles on various subjects connected with architecture, though necessarily brief, are well and correctly done as far as they go. Under "Gothic Architecture" a little too much stress is perhaps laid on

the window design of the various English styles, correct illustrations of which are given as identifying the separate styles, which is however perhaps the readiest kind of landmark for the general reader in a dictionary where space cannot be afforded for more varied illustration. It is not quite correct to say that William of Sens introduced the Pointed style into England; it was introducing itself in the transitional abbey arcades before that. Under the head of Greece there is a very fair sketch given in a short space of the characteristics of Greek architecture, and the subject of the correction of optical effects by curvature of the architectural lines is mentioned; a kind of detail not generally found in a popular cyclopædia. The short definitions of "Doric" and other architectural terms are also sufficiently attended to. For its size and scale, the Cyclopædia will be a very useful work.

Mensuration Made Easy; or, the Decimal System for the Million. With its application to the daily employments of the artisan and mechanic. By CHARLES HOABE, Nineteenth Edition. London: Effingham Wilson & Co. 1889.

THE author of this work advocates the use of the decimal system, and has endeavoured, as he states in his preface, "to divest the subject of every difficulty," so as to render it available to the most humble aspirant, and especially to adapt it to the daily employments of the artisan class. Tables of a copious nature are appended at the end of the book, with an explanation of the terms employed,—"terms" being defined by the author as the "Alphabet of Science." We think that, as the author has taken the pains to show on page 83 the method adopted for finding the geometrical mean between any two numbers, and has exhibited the application of such a calculation on page 49, that he would not have exceeded the scope of his object by adding to the Table of Square Roots and Cube Roots the methods by which these results are arrived at. The author expresses the belief that decimal coinage must eventually come into operation in this country.

VARIORUM.

"THE Insurance Year-Book, 1890" (London: Simpkin, Marshall, & Co.) is the fifth annual issue of a very useful work of reference. The present edition more than maintains the excellence of its forerunners, of which we have had occasion to speak in terms of commendation. With regard to the cheap edition, its usefulness would be somewhat increased by printing its title on its back.—"The Gas Engineer's Pocket Almanack and Lighting Table for the Year 1890," issued by Messrs. William Sugg & Co., Limited, London, is a very useful production, and notwithstanding the fact that it is largely occupied with descriptions and illustrations of Messrs. Sugg's many meritorious appliances, it also contains a great variety of information which should certainly be known to all gas-engineers, if not to all gas-fitters and gas-users. We hardly know, though, whether we are right in using the phrase "gas-fitter" now, for just as the plumbers have dubbed themselves "sanitary engineers," the gas-fitters are beginning to call themselves "gas-engineers."—"Sprague's Pocket-book and Diary for Architects and Surveyors" for 1890 (London: Sprague & Co., Martin's-lane, Cannon-street) appears this year in a slightly different cover, but its very useful contents are similar to those of previous issues.—From Mr. Robert Dunthorne, of Vigo-street, we have received a tiny "Calendar for 1890," for carrying in the purse or waistcoat-pocket. Small as it is, it is an admirable specimen of "art-printing" in colours. Opposite to the calendar for each month is a well-executed wood-cut with the appropriate zodiacal sign, treated heraldically. This miniature production is described in the "imprint" as "Made by W. H. Hooper for Robert Dunthorne. Printed by R. & B. Clark, Edinburgh."—The *Field Club* is the name of a new threepenny monthly magazine, edited by the Rev. Theodore Wood, and published by Mr. Elliot Stock, 62, Paternoster-row. Its sub-title is "A Magazine of General Natural History for Scientific and Unscientific Readers." No. 1, for January, contains some interesting articles, and it is nicely printed on good paper. It deserves to succeed.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

106, Chimneys, Chimney-top, &c. E. Hutchins.

According to this invention, a cowl which revolves is so fixed that it, or part of it, may be raised or lowered by a chain which is designed to act as a cleaning chain and to remove soot or obstructive deposit which would otherwise prevent the perfect action of the apparatus.

1,268, Saws. W. Lorenz.

The body of the saw, which is the subject of this patent, only acts as a holder or carrier for changeable cutting edges, which are fixed in grooves or upon heads on the saws or cutters by sliding upon cylindrical-formed ribs or seats on the saw. No springs, screws, pins, or other fastening is employed, and the teeth are preferably made to hump in their rear ends against the next tooth-holder, the front end being left free and formed at an angle suitable for the particular cutting operation.

1,732, Drying or Seasoning Timber. J. W. Scott.

This invention consists in the employment of novel devices whereby a current or currents of air of any desired temperature is, or are, compelled to circulate in such a manner that the air is forced into contact with all the outer surfaces of the pieces of timber or other substances placed in position to be operated upon, and that without depending upon the natural laws governing heated air. Suitable air chambers, with perforated covers, are placed in a building, and air forced over the substances by means of fans. In the case of substances of irregular contour, sheets of fabric are used which deflect the current over every part.

1,863, Sliding Flush Bolt. C. F. Hall.

The bolt which is the subject of this patent is provided with a device by which the rod of the bolt can be raised or lowered without injury to the fingers, and can also be made self-locking, so that it cannot be pushed back from the outside. The automatic fastening is effected by a counterpoise, and the opening is effected by moving a finger-bolt, which turns freely, and is in itself part of the fastening.

16,941, Block Paving. H. D. Blake.

In this system of paving a kind of groove or slot is formed laterally around the blocks, which, when the blocks are laid in place upon the roads or ground, enables them to be keyed together in one piece by the introduction into the joints of a suitable cement or mortar. The blocks are portable, and can be quickly and easily laid by inexperienced workmen without the use of special tools or machinery.

17,067, Wood Screws. C. D. Rogers.

The point portion of the screw combines a plain or unthreaded centreing part which first enters the wood or material into which it may be inserted, and a screw thread, which commences at the base of the plain part of the point, and extends backwards in a gradual increasing curve, till it reaches the base of the point where it unites with, and forms part of, the full thread formed on the cylindrical or body portion of the screw. By means of a point thus formed, the screw may be first entered true and centrally into the wood by a slight blow, the resistance offered being very small, after which it is driven home by a screw-driver in the ordinary way.

NEW APPLICATIONS FOR PATENTS.

Dec. 16.—20,175, B. Pyhus, Door-spring.—20,207, R. Painter, Raising and Lowering Windows.

Dec. 17.—20,240, A. Linford and others, Sash-fasteners.—20,254, S. Eaton and others, Chandeliers.—20,279, A. Chorley Butt, Hinge.—20,294, O. Imray, Metallic Fireproof Structures.—20,303, C. Smith, Artificial Asphalt.—20,307, J. Lorrain, Ventilation, &c.

Dec. 18.—20,341, H. Latham, Fireproof Fire-escape.—20,342, F. Wright and T. Gillott, Flooring for Bridges, &c.—20,344, G. Byrdill, Chisels.

Dec. 19.—20,410, W. Cowlin, Opening or Closing a pair of Double Doors simultaneously.—20,452, G. Hayes, Metallic Lathing.—20,454, D. Hunter, Fences and Gates.—20,497, W. Tattersall, Ventilating, &c.—20,470, J. Campbell, Drying Kilns.—20,510, R. Shapland, Drying, Heating, Ventilating, Timber Drying, &c.—20,518, W. Eckersley, Water-waste Prevention Cisterns.

Dec. 21.—20,528, E. Young, Preventing the rattling or shaking of Window-sashes.

PROVISIONAL SPECIFICATIONS ACCEPTED.

4,730, W. Townsend, Chimney-pots.—7,840, B. Boshier, Carpenter's Compasses.—16,715, J. Keighley, Ventilators for Chimneys.—17,243, E. Hollanders, Door Locks.—17,357, D. Bryce, Wall-braces.—18,622, M. Davidson, Floor and Pavement Lights.—18,765, G. Hall, Brick-making Machinery.—18,862, H. Sutcliffe, Water-closets.—18,866, M. Goodwin and W. Doorwood, Flooring.—19,091, F. Rondell, Attaching Sash-cords to Windows.—19,113, F. Lawrence, Connecting Taps with Pipes.—19,468, S. Bott, Sash-fasteners.—19,481, M. Moore, Chimney Dowsels.—19,500, J. Hamblin, Fences and Gates.—19,527, J. and M. Mann, Kitchen Ranges.—19,783, H. Cowan, Window-

fastener.—19,872, J. Bredeland H. Zulau, Closing Doors.—19,885, J. Miller, Door-locks or Latches.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months.

234, A. Hidge, Opening and Closing Fanlights, &c.—615, A. Day and F. Green, Window-sash Fasteners.—2,692, W. Poole and A. McDonald, Testing Joints and Drainage Pipes, &c.—2,817, W. Laycock, Opening, Closing, and Securing Windows, &c.—2,889, W. Davis and J. Donnell, Grinding and Polishing Marble, &c.—2,946, H. Lake, Brick-making Machines, &c.—2,993, J. W. and R. Mathieson and A. Turnhill, Stoves and Cooking-ranges.—3,190, G. Dickison and W. Brodie, Water-closets and Traps.—4,087, F. Lane, Horizontal Saw-frames.—7,109, A. Rammage, Fireproof Partition for Building Construction.—17,199, D. Mersing, Veneer Saws.

RECENT SALES OF PROPERTY:

ESTATE EXCHANGE REPORT.

DEC. 18.—By CHINNOCK, GALSWORDY, & CO. (at Taunton).
Taunton, near—The Norton Manor Estate, containing 948, 397, 1, &c. a.c. £38,000
Dec. 19.—By DYER, SON, & HILLON (at Woolwich).
East Wickham—Four cottages and 4a. 2r. 2ip. l. r. £61, 16s. 745
By WISEFOLD & HAYWARD (at Dover).
Dover—49, Military-hill, l. r. £15, 15s. 259
2, Bowling Green-hill, l. r. £15, 15s. 175
14, Down-st., rt. 81 yrs., &c. £2,000 270
Buckland, Oswald-pl.—Three plots of land 140

[Contractions used in this list.—E.g.r. for freehold ground-rent; l.g.r. for leasehold ground-rent; l.g.r. for improved ground-rent; g.r. for ground-rent; r. for rent; f. for freehold; c. for copyhold; l. for leasehold; e.r. for estimated rental; u.t. for unexpired term; p.a. for per annum; yrs. for years; st. for street; rd. for road; sq. for square; pl. for place; ter. for terrace; yd. for yard, &c.]

MEETINGS.

SATURDAY, JANUARY 4.

Association of Public Sanitary Inspectors.—The Rev. Arthur Roberts, M.A., on "Human Homes for the Poor, the Question of the Hour" (Carpenters' Hall, London Wall). 6 p.m.

Royal Institution.—Professor A. W. Ricker, M.A., F.R.S., on "Electricity" (adapted to a juvenile audience). 11. 3 p.m.

MONDAY, JANUARY 6.

Surveyors' Institution.—8 p.m.
Clerks of Works' Association (Carpenters' Hall).—Mr. W. Brown on "The Construction of Treaties." 8 p.m.

Liverpool Architectural Association.—Mr. J. L. Thorncroft on "Monumental Brasses, with special reference to the towns of Lancashire and Cheshire." 7 p.m.

TUESDAY, JANUARY 7.

Royal Institution.—Professor A. W. Ricker, M.A., F.R.S., on "Electricity." 8 p.m.
Glasgow Architectural Association.—Mr. F. M. Miller on "Domestic Furniture."

WEDNESDAY, JANUARY 8.

Civil and Mechanical Engineers' Society.—(1) Annual General Meeting for Presentation of Accounts. (2) Mr. H. H. Parkinson on "Prices for Labour and Material in India." 7 p.m.

THURSDAY, JANUARY 9.

Royal Institution.—Professor A. W. Ricker, M.A., F.R.S., on "Electricity." 8 p.m.
Edinburgh Architectural Association.—Mr. J. Balfour Paul on "Some Early Scottish Architects." 8 p.m.

FRIDAY, JANUARY 10.

Institution of Civil Engineers (Students' Meeting).—Mr. A. Chatterton on "The Irrigation Works on the Canavery Delta." 7.30 p.m.

Miscellaneous.

Competition: Free Library, Notting-hill, W.—In a recent limited competition for the proposed new Free Library at Ladbroke-grove, Notting-hill, W., plans were invited from eight architects nominated by the Commissioners. At the final meeting held to consider the plans, the design bearing motto "Tree of Knowledge" was selected, the authors of which were found to be Mr. T. Phillips Figgis, A.R.I.B.A., and Mr. H. Wilson.

Clock, East Garston, Berks.—A large clock has just been erected in East Garston Church Tower,—the anonymous gift of a parishioner. It chimes the quarters on four bells, strikes on the largest bell, and has a bold face fixed on the south side of the tower. The bells have also been re-hung; Mr. White, Appleton, was the bell-hanger, and Messrs. J. Smith & Sons, of Derby, made the clock.

Proposed New Board Schools for Acton.—Mr. Edward Monson, jun., A.R.I.B.A., has been instructed by the Acton School Board to prepare drawings for the erection of the proposed Beaumont Park Schools, Acton-green, which are intended to provide accommodation for 300 boys, 300 girls, and 400 infants.

The Bristol Building Trade in 1889.—

A correspondent writes—"Inquiries made to ascertain the state of the Bristol building trade in 1889 show that a decided improvement has taken place, and local builders, in addition to work in the immediate neighbourhood, have found scope for activity in a number of towns in the west, such as Bath, Trowbridge, Cardiff, Crosscombe, and Shepton Mallet. In house building in Bristol there has been a distinct advance, and the stagnation of several years is quickly passing away. One feature of the modern residence building is that on the whole the quality is much improved to what in too many cases it was formerly noticed to be. This improvement has been seen not only in the better-class houses, but in the smaller residences, rented at between 18*l.* and 30*l.* a year, in which materials and convenience are more studied than they used to be. One of the most frequent faults still to be found in such properties is the insufficient space and ventilation between the flooring and the ground, a method of procedure conducive to unhealthiness and dry rot in joists and sleeper walls. In the neighbourhood of Bishopston, a middle-class district just outside the Bristol boundary, house building has gone on most rapidly."

The Sanitary Institute.—At an examination for Inspectors of Nuisances, held at Manchester on December 20 and 21, twenty candidates presented themselves. Questions were set to be answered in writing on the 20th, and the candidates were examined *visà voce* on the 21st. The following candidates were certified to be competent, as regards their sanitary knowledge, to discharge the duties of Inspectors of Nuisances, viz.:—Messrs. Allen Cameron, Newbottle by Fence Houses; James Crossley, Salford; Samuel Sandders Dean, Hugglescot, near Ashby-de-la-Zouch; Thomas Edlestone, Great Harwood, Blackburn; Edwin Gardiner, Liverpool; John Macleannan, Dunfermline; William Milner, Preston; Christopher Osselton, Houghton-le-Spring; John Shirrs Robertson, Aberdeen; Walter Sutherland, Walton, Liverpool; James Whitehead, Parkgate, Rotherham; and Charles Edward Wood, Wakefield.

Examinations for Plumbers.—Under the auspices of the Plumbers' Company, examinations of candidates for registration have lately been held in Dublin. Mr. John Smeaton, master plumber, and Mr. H. J. Lyne, United Operative Plumbers' Association of Great Britain and Ireland, were present to represent the London Board of Examiners. The local examiners were Messrs. W. Baird, H. Kerrill, J. Smith, D. P. Curtis, and T. W. Little, master plumbers; Messrs. H. Murphy and J. Shiels, operative plumbers; Messrs. Spencer Harty, C.E., City Engineer, P. F. Leonard, C.E., and W. Kaye Parry, C.E., architect. The examinations included tests of practical work and sets of questions relating to materials, construction, and sanitary arrangements. Forty per cent. of the candidates succeeded in passing the examinations.

Partnerships.—Mr. James Hill, of 101, Queen Victoria-street, announces that he has, from the 1st of January, 1890, admitted into partnership Mr. E. J. How and Mr. H. King, both of whom, he says, have rendered him long, valuable, and faithful services in the management of his business. The name and style of the firm will remain "James Hill," as hitherto.

The partnership hitherto existing under the style of "William Hudson, Son, & Booth," architects and surveyors, Bennet's Hill, Doctors' Commons, having expired by the effluxion of time, Mr. William Hudson retires, and Mr. Arthur B. Hudson, F.S.I., and Mr. A. C. Bulmer Booth, A.R.I.B.A., will continue to practise at the same address under the style of "Hudson & Booth."

Electric Lighting.—The St. Pancras Vestry held a special meeting on Wednesday last, January 1, to consider the unanimous recommendation of its Lighting, Parliamentary, and General Purposes Committees to carry out an installation of electric lighting, under their Provisional Order obtained in 1883. The Vestry, by a large majority, adopted the recommendation, and instructed their engineer, Professor Henry Robinson, C.E., to prepare the necessary plans and specifications for a first installation of 10,000 private lights and ninety public lights, involving an outlay of about 60,000*l.*

Royal Engineer Establishment.—The first annual dinner of the Civil Royal Engineer Establishment staff took place at the Holborn Restaurant on Monday, the 23rd ult., Mr. J. Lewis Thomas, Chief Surveyor, in the chair.

Scottish Society for the Registration of Plumbers.—A discussion on the question of the materials and construction of soil-pipes took place on Dec. 27, in connexion with the Scottish Society for the Registration of Plumbers, in the Architectural Association Hall, Gorgie-street, Edinburgh. Mr. Robert Cox of Gorgie presided. Mr. Thomas R. Proctor read a paper opening the discussion. Treating first of material, the lead pipe, he said, was a thing of the past. Then we had the zinc pipe; and now we had come to the age of iron, in which some plumbers thought they had got a material competent for its purpose. He discussed the subject of the expansion of iron pipes, and the relation which the diameter of air-shafts should bear to that of the soil-pipes. He expressed the opinion that a system of soil-pipes and air-shafts within the house was better than an outside system. They could not have a proper current of air in an outside shaft; and with an inside system the ventilating-shafts could be carried to the ridge of the roof without any difficulty. A building, he said, could be so constructed as to have the pipes inside, and at the same time have them well isolated. For inside piping he favoured lead as a material. Mr. Walter Brodie expressed the belief that a good cast-iron pipe was the best pipe. Mr. Thomas Hume said he was of opinion that the size of the soil-pipe now used was too large. Friction was needed as well as flushing to keep pipes in order. As to material, he thought the lead soil-pipe was the best that could be got. No joint could be compared with a solder joint. He expressed the opinion that ventilating pipes should be tested every year as well as soil-pipes themselves. Bailie Russell also argued in favour of a smaller size of soil-pipe. In the matter of material, he expressed a liking for iron pipe compared with lead. Other speakers took part in the discussion, and Mr. Proctor replied. The ventilating shaft, he said, should be of the same size as the soil-pipe itself, in order to prevent the risk of siphonage. The Chairman, in proposing a vote of thanks to Mr. Proctor for his paper, remarked that the points in dispute, and which had been brought up in that discussion, were such as could be readily determined by experiment. A vote of thanks to the chairman brought the proceedings to a close. [We quote the foregoing report from the *Scotman*, but we are entirely adverse to the views expressed in favour of smaller soil-pipes, which we think most mischievous.]

Civil and Mechanical Engineers' Society.—An ordinary meeting of this Society was held at the Westminster Palace Hotel on Dec. 18, the President, Mr. Henry Adams, M.Inst.C.E., in the chair. A paper was read on "Percussive Rock-drilling Machinery," by Mr. Reginald Bolton. After some remarks on the ancient methods of rock-boring, the author traced the history of early English invention in this direction and the gradual development of the machine drill. The busiest period of invention would appear to have been about 1865, when English, German, and American engineers were actively employed on the problem. The parent practical machine drill was "The Burleigh," and the author described the well-known "Ingersoll," "Eclipse," "Mayne," "Schram," and other machines. A number of practical details were given of value to the engineer who may have the charge of such machines. The consumption of power was referred to, and a number of records of good work done by various machines followed as an agenda which will be useful to engineers in selecting a machine for work in certain strata. A list of all the practical rock-boring machines was given by the author, together with diagrams of the leading machines and their details. A discussion followed, in which Sir George Barry and other visitors took part, chiefly devoted to elucidating the best proportions for these machines.

Failures in 1889.—According to *Kemp's Mercantile Gazette*, the "gazetted" failures in the building and timber trades last year were 711 as against 785 in 1888, 761 in 1887, 712 in 1886, and 663 in 1885. The *Gazette* remarks, "It seems pretty certain that we are now entering upon a period of prosperity; or, as we may put it, a cycle of good business. It is hard, if not impossible, to account for these changes in the fortunes of trade; for the risings and fallings in the commercial barometer. They are, in the main, quite inexplicable. But we can judge to some extent by statistics when an improvement has set in, and a steady rise all round the circle of trade is imminent and assured."

Mr. George Jennings's Sanitary Appliances and Materials.—The name of "George Jennings" is known all over the world. The founder of the firm did a very great deal, by his inventiveness and ready perception of what was wanted in the early days of sanitary reform, to help to realise the ideas of the then comparatively few architects and engineers who were fully alive to the importance of maintaining the public health. His sons, called upon to direct a very large and successful business built up by his skill and energy, are evidently not unmindful of the importance of maintaining the prestige of the firm, and they have just issued some new catalogues of hydraulic and sanitary appliances and materials of all kinds. In these catalogues there are figured and described so many appliances that it is difficult to single out any for special mention. Many of them have been tried by the test of years of practical use, and have not been found wanting; others are comparatively new esprits for favour. Amongst these we may mention the "London" grate (George Jennings and E. P. Owens, patentees), which is a "terra-cotta warm fresh air ventilating grate" for slow or quick combustion. Judging from the plan and sections, it must be a very efficient grate, producing little smoke, owing to its comparative perfect degree of combustion. Of baths, lavatories, water-closets, urinals, slop and wash-up sinks, plumbers' brass-work, traps, electric bells, speaking-tubes, stoneware goods, and what not, there is hardly any end, and as, with scarcely an exception, everything is of the best type, the careful perusal of these catalogues will be found very useful by architects, builders, and householders. Supplementary catalogues are devoted to public urinals, and to the architectural and other terra-cotta work manufactured by Mr. Jennings at the South-Western Pottery, Parkstone, Poole. This terra-cotta is a very effective material, capable of producing very good work,—in saying which, however, we must not be supposed to express approval of all the designs figured in the catalogue.

Tramway Extension.—The requisite notices have been given of the proposal to extend the Lea Bridge, Leyton, and Walthamstow Tramways over Lea Bridge westward to the point where the road narrows as it approaches the Clapton-road. There can be no question that this would be an improvement that would be much appreciated by the public, for, in spite of the inconvenience which the necessity of walking to the eastern side of Lea Bridge entails, the tramway is used by many thousands daily in the pleasure season, and in an obvious assistance to the many whose business takes them in that direction at all seasons of the year. We are sorry, therefore, to find that the Hackney Board of Works has taken an objection to the proposal now made, and cannot but think that the position the Board has taken up is the result of misunderstanding. It is true that in the previous Act to regulate the tramway there was a condition involving the widening of the west end of Lea Bridge-road, but it was in consequence of this and similar onerous conditions, we presume, that the tramway was not worked successfully. It has lately been taken in hand by a new company, under a new Act, and we hope the Hackney Board will take this into account, and withdraw their opposition to the new scheme of extension. To insist that the new company should carry out all that the old company proposed, would possibly result in disaster, and the public might be deprived of a means of communication which, from the figures placed before us, is evidently widely appreciated. At all events, Hackney folks should bestir themselves, and exercise the influence they possess to avert action which may have the effect of arresting the extension of a most useful line of communication with the country and Epping Forest.—*East London Observer.*

Very Wide Tendering in South Africa.—The *Johannesburg Star* of Nov. 27 contained the following paragraph:—

"A Barberton paper states that a firm in that town recently had occasion to call for tenders for certain work for which proper plans and specifications were issued. The accepted tender amounted to something under 100l., while one enterprising man's estimate totalled up to over 5,000l. The ambition of some is to make a 'pile' in one grand coup."

We have seen not a few specimens of "wide" tendering in this country, but we certainly never saw a list of tenders in which the highest was fifty times as much as the lowest. Let us hope that the Barberton man whose tender was accepted at less than 100l. will not lose a "pile."

Architects as Scientists.—The second meeting of the winter session of the Northern Architectural Association was held on Monday evening last in the Old Castle, Newcastle, Mr. Joseph Oswald presiding. Mr. J. H. Morton, F.R.I.B.A., read a paper bearing on a paper of Mr. W. H. Dunn, read at the previous meeting, on "Architects as Scientists." In the course of his paper, Mr. Morton said (according to the report in the *Newcastle Chronicle*) he had jotted down some ideas which suggested themselves on reading Mr. Dunn's paper. In Mr. Dunn's paper the merits of engineering had been contrasted with the skill of architecture, to the disparagement of the latter. He (Mr. Morton) thought, with Professor Kerr, that the time had gone by for them as architects to pretend to know all things. Architects had to try to know too much as it was. He might, therefore, endorse Professor Kerr's idea that when any man had work to do to design of any real importance, which was out of the ordinary run of his practice, he need not be ashamed to say that he had called in the assistance of an engineer. On the other hand, why should the engineering constructor not occasionally call in the aid of the architectural designer? Why should all our building operations of the so-called engineering order,—viaducts, bridges, great roofs of railway stations, &c.—be left barren and unfruitful of grace, because the designers of them, professing nothing of the artistic spirit themselves, assumed that it had no connexion with their work?

Memorial of the Royal Stewarts at Paisley Abbey.—The other day Sir Michael Shaw-Stewart, Bart., Lord-Lieutenant of Renfrewshire, unveiled, in the old Abbey grounds, at Paisley, a memorial to the Royal Stewarts buried there. The memorial, which has been erected by the order of her Majesty, the Queen, has been executed by Mr. John Hintonson, R.S.A., sculptor, Edinburgh, and is in the form of a recumbent sculptured cross, similar in style to those which may be seen at Iona and the Western Isles. The base, which measures 8 ft. by 4 ft., is of polished Peterhead granite; on the top of this rests a block of Sicilian marble with bevelled face, upon which is sculptured a Gothic cross of the period of the erection of the Abbey. On the right side is carved an ancient sword with belt entwined,—the symbol of kingly investiture; and on the left side is the Scottish shield with lion rampant, surmounted by a crown, and bearing on a scroll underneath the motto, "Nemo me impune lacessit." The members of the House of Stewart to whom the monument is raised are—Marjory Bruce, the two Queens of Robert I., and Robert III. The monument has been placed on what is supposed to be the grave of King Robert III., which is situated in front of the high altar, at the east end of the ruined choir, behind the present church.

Threatened Water Famine in Bombay.—A special and urgent meeting of the Municipal Corporation was called for on Nov. 25 to discuss the scheme of Mr. Tomlinson, engineer-in-charge of the local waterworks, to provide against a threatened water famine in Bombay. Mr. G. Geary, the President, occupied the chair, and there was a large attendance of members. Major Selby proposed the following resolution:—"That subject to the sanction of the Government of India to the raising of a loan of Rs. 4,55,000, and in view of providing against an almost certain deficiency during the hot weather of 1892, and a possible deficiency during the hot weather of 1891, sanction be given, as recommended by the Standing Committee, to Mr. Tomlinson's scheme for bunding a water supply from Pawa', in the valley below the Vehar dams, and of pumping the impounded water into the Vehar storage reservoir and the mains leading therefrom at a cost of Rs. 4,55,000. That this estimate is exclusive of cost of land, that the land to be submerged will be about 500 acres, which will have to be immediately acquired, and that the question of acquiring the gathering ground may be considered later on. That, pending the raising of the said loan, the cost of this work be paid by advances from available balance to be adjusted against the loan. That, pending the like sanction, sanction be given to the acquisition of the land for the impounded area, the cost in the meantime to be met by similar advances."—*Indian Engineer.*

Removal.—Messrs. Croggon & Co. (Limited) have removed their offices and show-rooms from 200 to 16, Upper Thames-street, London, E.C.

Matheson & Grant's Engineering Traders' Report.—Messrs. Matheson & Grant, in their half-yearly report, issued on the 1st inst., say that there has not been, since the year 1875, so much activity in the engineering trades as during the last few months, and the present improvement is more widespread than in the case of any previous revival; for while on previous occasions export to the United States has been the main factor in determining the prices of iron and steel, such a measure of trade no longer applies. The increased demand for the services of British engineers, and for the products of engineering factories, comes now from all parts of the world. Bridges and structural ironwork are in general demand, and except for the delay in obtaining steel and iron from the rolling mills, manufacturers are well satisfied; for although prices have only slightly advanced beyond what is due to higher costs, the greater tonnage allows a better profit. At home the bridges for the Manchester Ship Canal are being made; the superstructure of the Tower Bridge is commenced; numerous bridges are being built in Dublin, Belfast, and elsewhere in Ireland; bridges are in progress for various new railways in England; while the strengthening and widening of existing bridges on the principal main lines add to the general demand. Market buildings, large hotels, station roofs, and buildings for steel works are examples of other structures now in progress. Competitive designs for the projected high tower in London are being prepared, and this project, if carried out, will surpass the Eiffel Tower in Paris, and render necessary about 10,000 tons of steel. Abroad, bridges and structures for India, Japan, Australia, and South America are being made in the English factories, but the present high prices are likely to restrict new orders for the coming year. Portland cement has been in increased demand during the last few months; prices have risen with the cost of fuel, material, and labour, and are likely to advance further from the same cause. The too frequent reliance of engineers on high tensile tests, rather than on care in the mixing and application of the concrete, has led to some failures in foundations built under such conditions. The specifying of unduly high tests which involve certain risks in quality are being less frequently imposed than formerly, as it is found that cement of the best-known English brands will give, in accustomed hands, the very best results. Attempts to rival such cement in countries where chalk as a material is wanting are made from time to time with unfavourable results.

The City Engineership, Liverpool.—According to the *Liverpool Daily Post*, a special meeting of the Health Committee of the Liverpool Town Council was held on Saturday, to consider the question of selecting a City Engineer in succession to Mr. Clement Dunscombe, who has been appointed Chief Engineer to the London County Council. There were forty-two applications for the position, and after a long sitting the Committee reduced them to seven, as follows:—Percy Boulnois, Borough Engineer of Portsmouth; John Price, Surveyor to the Toxteth Local Board; J. W. Brown, Borough Surveyor, West Hartlepool; A. E. White, Borough Surveyor of Hull; J. B. McCallum, Borough Surveyor of Blackburn; George Broom, Borough Surveyor, St. Helens; and R. E. W. Berrington, Borough Surveyor, Wolverhampton. The salary offered commences at £501 a year. Since this was in type we learn that at a special meeting of the committee on Wednesday the names of Mr. Boulnois, Portsmouth, Mr. McCallum, Blackburn, and Mr. A. E. White, Hull, were selected for further consideration.

Death of Mr. Thomae Oldham Barlow, E.A.—We regret to announce the death of Mr. T. O. Barlow, R.A., which took place at his house in Kensington on Christmas Eve, after an illness of two months. Since the death of Samuel Cousins, Mr. Barlow has been (says the *Times*) regarded as the *doyen* of English mezzotint and "stipple" engravers, and though he was twenty years younger than Cousins, he probably, at his best, came nearest to that eminent engraver in the opinion of his colleagues and the public. Born in 1824, at Oldham, young Barlow very early showed a taste for art; and though he had no artistic friends or interest, his father did not discourage him. At fifteen he was apprenticed to Messrs. Stephenson & Royston engravers of Manchester, and he worked in the then newly-established School of Design in that city.

"INK PHOTO, SPRAGUE & CO., 22 MARTIN LANE, LONDON, E.C."

A SCHEME FOR DINING ROOM

The Phototype Co., 893, Strand, London.

flesh, are equally remarkable, though the work is rather a grand sketch than a finished picture. The face seen in the mirror, by the way, is not of the type or make which the back of the head of the figure suggests, and seems to have been put in hastily without any attempt at realism, which of course was not Velasquez' aim or profession in art. The portrait of "Mariana of Austria" (132), a seated figure in preposterous costume, with a hooped skirt like a round table, and a head-dress standing out in a great bag on each side of her head, is remarkable for the expression of insolent hauteur in the features. What Velasquez really thought of the society of Sultans and Sultanas that he painted it would be interesting to know; but the portrayal of that expression of pride and disdain of the whole world which, as we know from historical and literary evidence, represented the natural mental attitude of the Spanish grandees of the period, was at all events a task singularly congenial to the genius of Velasquez. Vandeyck did something of the same kind in his portraits, but not with the power and thoroughness of Velasquez. There is one Vandeyck in the exhibition, however, the armoured portrait of Count Nassau Dillenbourg (153), which goes near to rival Velasquez in force of expression and character, though not in power of execution. Near this is a remarkable Rembrandt, "Portrait of a Man" (151), a formidable man, whose physiognomy expresses a rock-like stubbornness, possibly in brought to it; for Rembrandt seems often to have made a portrait a groundwork for the expression of his own power. It is interesting to contrast this, in which the head is everything, with the portraits of Velasquez in which, with an equally powerful treatment of the head, costume is also so highly elaborated. Velasquez' treatment suited the stamp of persons whom he had to paint, with whom costume was so very important and elaborate an accessory that it would almost have seemed sometimes that the costume was accessory. In the portrait of "Admiral Pareja" (133) the head itself is of sufficient picturesque power to hold its own against the costume. These three, Pareja by Velasquez, Count Dillenbourg by Vandeyck, are three very remarkable examples of the ideal force of artistic expression which a great painter can infuse into the simple portrait of a man; it is rarely that three such examples by three different painters are to be found in the same room together. In female portraits, except Velasquez already mentioned (Mariana of Austria) the exhibition is not strong this year; the most pleasing are Romney's "Mrs. Stalles and two of her daughters" (154), in which the child in her mother's arms is lovely; and Reynolds's "Viscountess St. Asaph and child" (158), a very charming Reynolds a good deal faded and discoloured; there is a lovely semi-Oriental type and *tournaire* about the head and bust of the countess; the head of the infant on her knees is also beautifully painted and full of life. Romney's portraits of "The Hon. Henry Chaplin, M.P." and "Mrs. Chaplin" (41 and 45) are very good specimens of simple portraiture, the latter is also artistically interesting inasmuch as, in composition and in the treatment of the foliage background, it is an obvious and intentional imitation of the manner of Gainborough. Another portrait in the first room is interesting from the name little more) of "Robert Williams" (24), Captain of the Cumberland Fleet, a Yacht Club of which the Duke of Cumberland was president, and which was the precursor of the present Royal Thames Yacht Club; a portrait of a bluff figure in a nautical costume with a telescope under his arm, by "J. M. W. Turner, R.A." whose name suggests, though the hand of Turner is traceable in the treatment of the sky and background.

Generally speaking, the English pictures of the year are not very much. There are two

Callcotts about which much has been said: "The Shrimper" (44), and "Hamstead Heath" (161). The latter is a really grand thing, so powerful and so like Crome in manner that doubts have been suggested as to whether it is not truly a Crome; we never saw a Callcott at all like it before. "The Shrimper," however, shows the same kind of power in sky and composition, but it has been much over-rated; the breaking sea in the foreground is very bad, and is one of the many examples of the extraordinary blindness to the real forms and movement of sea among painters until a very recent period. A wave is not seen flopping on the beach as it were all one piece of stuff, like the edge of a shaken blanket; Callcott never saw that, nor did Creswick ever see waves as he has represented them in a seapiece opposite (14), with all the waves along the shore of the same section, with a sharp edge at the top and the same concave and convex lines before and behind. Among the old painters Backhuysen is as bad or worse; in his large painting in the second room (102) the square-rigged men-of-war sail about in fine style, no doubt, but the stuff they are sailing on is no more like sea than the movable seas of grey paper inflated by bellows that are sometimes seen in models. In the present day we have several sea painters who really look at the sea and paint it as they see it, though each has, no doubt, his favourite aspect of it: but this is quite a modern accomplishment in art. Even Turner's seas are often quite impossible both as regards colour and movement.

The pictures to look at in Gallery I, which may be called the English room, are, besides those already incidentally mentioned, Landseer's capital painting of a white terrier, "Jocko" (15); Webster's picture, well known from engraving, "The Slide" (23) a good example of a kind of humour in *genre* painting that is somewhat out of date now; James Ward's "Cows" and "Horses" (29, 31); Leslie's "Mother and Child" (381), fine both in drawing and expression; and Reynolds's "Miss Penny Kemble" (49), terribly dilapidated but the remains of a most expressive portrait. Danby's once-admired stage effects, "The Ship on Fire" (36) &c., are melancholy examples of work that has had its day and is of no more value to any one; his smaller painting, "The Grave of the Excommunicated" (40), has a certain poetry and truth of effect.

The pictures of the Dutch realists in the second room have been said in the newspapers to be as remarkable as in any former year, which is certainly an exaggeration; they include some very bad pictures that were never worth exhibiting at all; they also include a minority of works that are first-rate of their kind. Among them are Lord Ashburton's Jan Steen "The Carouse" (93), an interior with many figures, less vulgar and repulsive in physiognomy than is often the case with this painter, and full of life and reality. The same owner's two small works by Maes, "An Interior" and "A Woman Sewing" (100, 104) are beautiful examples of works in which the interest consists in a single figure placed under effective conditions of light and painted with unaffected simplicity. In the first-named work, however, we cannot help thinking some change has taken place in the pigments; the flesh is worked up in the warmer portions with small touches of red which, as now seen, appear far too strong and spotty in effect. The Queen's Teniers, "Woman Peeling Turnips" (103), is essentially a study of still life in foreground objects, first rate of its kind; a more interesting Teniers perhaps is the "Village Dance" (84). Van de Velde's rather large cattle picture (107) should be looked at; but a superior work is the small painting of "The Haymakers" (115), a perfect little work both in regard to the figures and the landscape in which they are placed.

Gallery IV, which marks the limit of the exhibition, is filled with a series of portraits in decorative borders, by Daniel Mytens and unknown painters of the Dutch school, from be collections of the Marquis of Townshend

and the Earl of Sussex. They illustrate a special type of portrait-painting, and have a striking decorative effect in combination, but their artistic interest as pictures is not very high.

SUPERINTENDENCE.—II.

IN the previous article* we took it for granted that the architect writes his own specifications, and does not depute the work to a quantity-surveyor or any other person. In fact, we look upon the specification as an explanation and amplification of the drawings, and consider that the production of the two ought to be as nearly simultaneous as possible. It is certainly difficult to see the wisdom of employing another person to explain and amplify one's own drawings. Opinions, however, differ on this point, but there can be little doubt that an architect will be more likely to make alterations in a specification written by another man, who could not be cognisant of all his ideas, than in one written by himself with the full knowledge of the necessities of the work gained by interviews with his client, by inspection of the site, and by the preparation of the drawings; and it is this deviation from the specification against which the architect must be chiefly on his guard.

Many clients are "kittle cattle" to deal with. There is a story,—true enough, we believe,—told of a certain duke, how, on returning home after a short absence, he saw almost completed an entrance-lodge with an arched gate-way, which doubtless the architect thought very fine; but so the duke. Calling the architect to him, he asked, "Why the — have you built such an ugly thing as that? Pull it down!"—the next day the place was dismantled. There are not many architects who enjoy the patronage and humour the whims of dukes, but many have to bear the vexatious intermeddling of clients, who, unlike the afore-mentioned nobleman, object to pay for the alterations which, as the work proceeds, they demand. The best preventive of so many variations from the contract is for the architect to explain the drawings thoroughly to his client before tenders are obtained, and to state the different kinds of material proposed to be used. In many cases it is wise to take a client, if possible, to rooms of the sizes shown on the drawings, as figured measurements give to most people only a vague idea of the real dimensions. In brief, study the client's requirements carefully, and do not be satisfied until he understands with some degree of minuteness what kind of building is proposed to be erected for him. For all variations from the contract are vexatious, sometimes to the contractor, sometimes to the proprietor, almost invariably to the architect.

The architect must be above all suspicion of unfairness or partiality. He must treat an honest contractor with the same consideration he shows to a good client, and must endeavour to repress the unwarranted grumbling of a crotchety client just as he turns a deaf ear to the specious tales of a smooth-tongued builder.

It is frequently somewhat distasteful to the architect to meet committees or bodies of men for whom work is being carried out, as there are sure to be two or three members of such a body, who,—perhaps because they desired the appointment of another practitioner, perhaps because they are born fault-finders, and find it a necessity to exercise the privilege of grumbling,—at any rate, for one reason or another, seek every occasion of throwing stones at their architect. These malcontents must be boldly faced; to their malice the architect must oppose the most transparent honesty and sincerity. He must seek interviews, rather than decline them, must go before such a body of men unbidden, rather than fail to meet them, for his absence will in the eyes of enemies be an acknowledgment of shortcomings, and behind his

* See page 2 ante.

back more bitter things will he said than before his face, and untrue statements may pass uncontradicted. We could point to so many instances of discredit attaching to architects, simply because of their neglect to appear before clients of this kind, that we consider this note of warning by no means unnecessary. Again, it must be remembered that newspapers report the proceedings of many public bodies, and aspersions on a man's character, which pass uncontradicted at the time of utterance, may stare in print before the public, and will then surely prove detrimental to the architect; there are always wiseacres, "Sir Oracles," who say, "where there is smoke, there must be fire," and so a man's reputation may be endangered. To work harmoniously with a committee is a notoriously difficult matter, and needs all the architect's tact, courage, and truth.

There is one other matter (pertaining chiefly to the proprietor) which we wish to mention, and then we will pass on to the most difficult part of our subject,—the architect's dealings with contractors. There are men, all the world over, who wish to get more than their money's worth. The architect will frequently meet with examples of this class, who, after receiving tenders in open competition, manifest a preference for a builder whose tender is not the lowest, but whom they can trust to do good work; instead, however, of offering him the contract at his own price, they wish him to lower his tender to, or, at any rate, towards, the lowest tender received, and beg their architect to see him with this object. It is dirty work; let the architect wash his hands of it, and attempt to dissuade his employer from such a course, for it will surely be prolific of trouble. But if the proprietor himself arrange with the builder such a reduction, the architect has no option but to accept the arrangement. It is almost certain that the builder will feel justified in attempting to "take out" of the work in quality or finish the value of the reduction, and the architect will, therefore, do well, before permitting him to sign the contract, to give him clearly to understand that, as the original drawings and specifications have not been altered, it is only right that they be strictly adhered to; this is justice, but in such a case we should have little hesitation in tempering justice with mercy.

"Mr. Rickman considered that the first qualification of an architect was to possess patience, and, after that, the most essential quality was decision, and in the latter quality he (Mr. Cates) feared architects were often wanting, especially in insisting that the work should be executed as specified." In the previous article we inveighed against all unnecessary deviations from the specification, and the young architect will do well at the very commencement of practice to set his face dead against all variations from contract which the builder without proper instructions makes in carrying out the work. To pass one thing which is not according to the specification paves the way for passing another; the architect's measure is soon taken by the contractor, and the latter, if dishonest, learns to consider a specification as a document very good, perhaps, in its way, but not by any means intended to be enforced. In estimating for future work he acts on this assumption, and tenders at a price for which the work could not possibly be carried out if the specification were to be strictly interpreted. By "cutting low," as he terms it, he takes work out of the hands of more honest contractors, whose consciences are less accommodating, and whose tenders are consequently higher. The evil done by these cheap (and nasty) builders falls to some extent upon the client, for he gets inferior work, but—he gets it at less cost; it falls more, however, upon all other builders, who, through greater honesty, have submitted higher tenders. This, let us say, is no fancy picture. We are acquainted with one respectable builder, who always, on delivering a tender to a certain architect, accompanied it with such remarks as, "I've quoted for 'thirds' deal; you specify 'best'; but the others will reckon for 'fourths' and 'fifths.'"

His remarks were true enough; and it was a bitter thing for him to see work taken out of his hands by dishonest contractors. He himself would not quote for an inferior quality without acquainting the architect with the fact, but his conscientiousness militated in a great many cases against the acceptance of his tenders. For an architect to pass inferior work is setting a premium on dishonesty, and making the battle of life harder for good men. Young architects must beware, for on the conduct of their first commission will depend, to a great extent, the whole course of their future practice.

In spite, however, of architect's care and contractor's honesty, mistakes will occur and accidents happen to render some portion of the work less perfect than it ought to be. Rain may bow a wall, frost may crumble its mortar, inferior material may be used by a workman if it be nearest at hand, the tramping bricklayer may neglect proper bond or omit the pargetting of flues, the rough-and-ready labourer may put mud or clay into the mortar-mill instead of sand, and so on; for all these the contractor is really responsible, but it would be unwisely harsh of the architect to demand in every case the entire undoing and reconstruction of such work. It would often be more satisfactory, under these circumstances, to make a proportionate deduction rather than shake the building and perhaps cause considerable delay by cutting out the bad and inserting new. In such cases the architect will do well, however, to acquaint his client with the inferiority and proposed deduction, for the latter will be disposed to doubt the architect's vigilance if the information be conveyed to him by any other channel, or if he find it out himself. For a client to find fault justly with work or material does to some extent lessen his confidence in his architect. The client may, however, refuse to be guided by the architect's advice to let such work remain and to accept a certain deduction as compensation, and may peremptorily demand the work to be as specified; in that case it is the architect's duty—a hard one, we know—to require its alteration. The contractor must suffer for his own negligence and that of his men.

Where, however, the architect is convinced that the contractor has of malice aforethought substituted worse material, or scamped the work, his duty is plainer. The work must, if possible, be re-executed. A deaf ear must be turned to the thousand-and-one plausible excuses which the wily contractor will offer for his conduct. An architect writes:—"I remember an instance of a small plumber inserting pieces of 4 lbs. lead in flashings for which 5 lbs. lead was specified. At once I wrote to him demanding the removal of all such lead from the building; the next day he came to the office, threw upon the floor about a dozen pieces of 4 lbs. lead, and in a torrent of words told me 'I'd got 'em all,' wanted to know if I thought him a rogue, and declared that he had used all his 5 lbs. lead on the building, and, rather than delay the work, had made out with just so many pieces of lighter weight. For a moment, I really felt that I must have done the man some wrong—he seemed to think himself not sinning but sinned against. However, I merely told him that it would have looked better if he had mentioned the circumstance to me *before* using the inferior material instead of *after*. I had gained my point, and he has since been more careful." But instances might be multiplied indefinitely; they are plentiful as blackberries. It may be wise and will certainly be courteous of the architect to listen to what a contractor has to say *before* executing work as specified, and to consider any suggestions he may make (remembering always, however, that an architect should be predisposed to adhere to his specification rather than deviate from it); but it is almost invariably foolish, a sign of weakness, to take notice of excuses made by a builder after his dishonesty has been discovered. The best advice we can give to architects on this point is—cultivate decision, and having stated your honest opinion that the workmanship is deliberately slovenly, that the

material is of set purpose worse than that specified, maintain your opinion, and, where possible, demand the re-execution of the work. Let your fiat be unalterable as the laws of the Medes and Persians. Do not be wheedled out of it; if you are a young man, do not be bullied out of it; do not, in any case, be bribed out of it. If you once yield, you have established a precedent, to which the contractor will for ever appeal. If, on the contrary, you compel a builder to undo bad work, to remove inferior material, it is a lesson to him and to all others, and will prevent much trouble in the future; it is a precedent to which you yourself can always appeal with satisfaction, knowing that you have acted justly and have not neglected your client's interests.

As already observed, however, it is not always advisable to have inferior work re-executed, on account of the delay and other damages which such renewal might entail. In this case, a deduction must be made from the amount of the contract, but the question arises, how much must be deducted, merely the difference in value between the work as specified and as executed, or more? At first glance, one might say, the mere difference certainly. Is this really fair, however, to the proprietor? This gentleman has, by his architect, asked for a certain excellent material,—say a building stone sound, hard, and of good weathering qualities,—but in place of this he has been supplied with stone very similar in appearance at first, but soon crumbling. The deception is not discovered until the work is so far advanced that a demand for removal of the inferior stuff might practically be a demand for the demolition of the building and the erection of a new one. The sternest architect and the most irate client would probably stop short of that, but to deduct the mere difference in cost between the two stones would assuredly not be just to the proprietor. Some things are dear at a gift, and an ill-weathering building-stone is one of those things, for it soon makes a building appear scarred, as if afflicted with a skin disease, and necessitates continual expense in repairs. But there is still another point to be considered; the great danger of making a proportionate deduction for the bad work which a contractor has deliberately executed, is this—he is not punished for his dishonesty; he loses nothing by the transaction, and is encouraged, if he be so minded, to continue his malpractices, for, even if he be found out, he is not a loser, and if he be not discovered, he gains considerably. For these two reasons, therefore, it is best to deduct for such inferiority more than the mere difference in value between the work as specified and as executed. If the contractor demur, give him his choice—deduction or re-execution. Only, do not leave the settlement of the amount to be deducted until the completion of the contract; it is best to state, in writing, the demand for re-execution or a certain deduction, at the time of complaint respecting inferiority of the work. This course will save much bitter wrangling afterwards.

It may happen that the builder will refuse to proceed with the work rather than replace the inferior material or submit to the architect's proposed deduction. In ninety-nine cases out of a hundred the client will sustain his architect's position in such a case, and will have no hesitation in dismissing the builder according to the terms of his contract, and in placing the work in other hands.

There are architects, however, who worry contractors unnecessarily by their ill-advised clinging to minor details of construction. It may be that in the detailed drawings of a piece of joinery a certain method of framing and jointing has been shown, but the builder, desirous of saving labour and material, attains the same result in a different manner. By all means, let the builder enjoy the benefit of his superior practical knowledge; he has taught the architect a lesson which it will be unwise of him to despise. It bespeaks a little mind if an architect be ashamed to alter a specification even though he learn, before the

work is done, that a better method of procedure can be adopted without increase of cost.

The general conditions of a specification frequently contain a clause to the effect that "no deviations from the drawings and specifications shall be made without the written authority of the architect," but we wonder how often an architect takes the trouble to carry out his own rule of writing his instructions. Better far to omit the clause altogether than to stultify oneself by not adhering to it, for how can an architect expect a contractor to be bound by a specification part of which he himself sets at nought? But, best of all, to insert the clause and act up to it. It is really not a difficult matter, and its advantages are obvious. We are acquainted with an architect who for this purpose carries what is known as a "Commercial Travellers Order-book," in which, by means of a black sheet and an agate style, two copies are obtained at one impression. One of these copies is given to the contractor, the other remains in the book. For convenience of reference every note is classified under one of four heads,—"extras," "deductions," "alterations" (which are partly extras and partly deductions, one or the other preponderating), and "instructions" (the last comprising all orders for re-execution of bad work, removal of inferior material, deviations from contract involving no variation of cost, and so forth). This system keeps the architect in mind of deductions which he might otherwise forget, and shows the contractor for what extras he can justly claim, and thus vastly facilitates the preparation of the builder's account at the completion of the work.

It may be urged that the architect who spends so much time in the superintendence of work will have no time left for preparing designs or for office-work generally. (There might be no great harm done, if the architect did stick to his drawing-board rather too little, and to his buildings rather too much.) In reply to this, we would say that an architect may, and ought to, employ his pupils partly in this work of superintendence, take them to the building, point out those things to which particular attention must be paid, and let them inspect the works two or three times between his own visits. The pupils would thus obtain much valuable practical knowledge, and would be some check,—however slight,—upon the actions of a dishonest builder. There are many youths at the end of their pupillage, and many assistants of several years' standing, who seem never to have seen work in progress; we cannot think that the architects, who received premiums from such, did their duty in return.

The architect's path is narrow and difficult,—a little slip and he may be ruined. An error in calculation, a manufacturer's mistake, a contractor's carelessness may lead to the collapse of a building, and to a consequent loss of practice. But there is another thing which tells even more severely against a man, and that is the acceptance of illicit commissions, or what in plain English should be called "bribes." Modern trade is honeycombed with this system of dishonesty, and builders' merchants have learnt the trick. The young architect is very likely to be tempted by a dishonest contractor; reject the bribe at once,—the larger the bribe the greater the loathing,—and avoid that builder in future, for he has forfeited his birthright of being considered an honest man. This journal has so frequently inveighed against all illicit commissions that it seems a wearisome reiteration to say anything further on the subject, but as the temptation is usually offered to the architect during the erection of a building, we venture to consider it as one of the dangers of superintendence. The architect must absolutely refuse to accept all secret commissions from firms whose goods he has specified or ordered. The commission really comes out of the client's pocket without his knowledge,—is, in fact, filched from him, and the architect has no more right to it than he has to the goods themselves. It would be a good thing if architects, to whom bribes have

been offered by manufacturers or merchants, would absolutely refuse to have any further dealings with such firms,—boycott them until they saw the folly as well as the dishonesty of the system. Let each individual architect, as he values his own good name, and as he loves his work and has the honour of his profession at heart, do his utmost to put a stop to this corruption.

In conclusion: the architect will do well in trying to put work into the hands of contractors of proved honesty, so that in their case the truth may be shown of that trite proverb,—"Honesty is the best policy."

NOTES.

It is with great regret that we hear from Milan of the untimely death of Signor Brentano, the young architect who gained such a brilliant success almost at the outset of his career in winning the competition for the Milan façade; and who, as was remarked in an article in our columns, had begun his professional career where many would have been only too happy to leave off. He died at Brussels a few days since at the age of twenty-seven. A more melancholy instance of the cutting short of a career of brilliant promise has seldom occurred.

At Florence repairs are being executed with great activity, by order of the Government, in the celebrated Church of Santa Trinità, built by Nicolo Pisano in 1250, and famous in the history of art for its frescoes, painted by Ghirlandajo, Andrea del Castagno, Albertinelli, &c. Unfortunately the rage for modernising everything destroyed a great part of its artistic value when Buontalenti repaired the church and reduced it to about its present state. The works which have already been completed are the following: 1. Two marble altars have been placed in the Spini and Ardinghelli chapels. 2. The architectural and pictorial ornaments of the Strozzi chapel have been repaired. 3. A new decoration in the style of the fourteenth century has been painted in the Spini chapel. 4. Decorative paintings have been restored in the transept of the lateral nave to the right. Excavations have been made in the central nave, and the crypt, built in the twelfth century, has been discovered. The discovery took place while the pavement of the church, which was in a very bad state, was being repaired and brought down to the level of the ancient church, such as it was in the thirteenth century. The crypt is built of *pietra forte*, and has three semicircular apses. When discovered, it was found to have undergone considerable damage, especially when the church was rebuilt in the sixteenth century, as we have already said, and when graves were dug in it in a less remote period. The pavement of this crypt or tribune has also been partially discovered; it is composed of a reddish cement, and before the altar of the chapel was a portion of mosaic of small pieces of white marble, evidently the work of the ninth or tenth century. Round the mosaic is an ornament of white foliage on a black ground. Within the border which this ornament forms, are two symbolical figures of dragons looking towards each other. The discovery is particularly interesting, as no other specimens of mosaic had as yet been found in Florence. These fragments, as well as some remains of a very ancient construction in *pietra forte*, belonged, undoubtedly, to the church which, according to the historian Villani, stood in this spot under the name of Santa Trinità since the year A.D. 801. The excavations were continued, and resulted in the discovery of the crypt, of the ancient doorway and of the staircase leading to it; of this, four steps are still to be seen. Between the ancient pavement and the modern one, which has been removed, a large marble slab has been found, on which a recumbent figure, much worn out, is sculptured; we learn by an inscription that

this was the tomb of Roggero Buondelmonti, General, of the Order of Vallambrosa, who died in 1319. Other researches led to the discovery of some remains of the original fresco ornaments on the wall of the nave, covered with a thick layer of modern plaster. The beautiful marble door belonging to the Chapel of B. Bernardo degli Uberti has likewise been found, and behind the modern façade of Buontalenti, the ancient one in Gothic style, of Nicola Pisano, has been discovered; it has alternate stripes of white and *verde di Prato* marble, in the same manner as in many churches of Pisa, Pistoia, and other towns of Upper Tuscany.

The Imperial German Archeological Institute has just issued its second "Ergänzungsheft." It is entirely devoted to the discussion of the recent excavations at Æge, the interest of which has proved to be mainly architectural, and to be of special importance as throwing light on the more prolific "finds" at the analogous hill city of Pergamos. The contents of this volume are so strictly technical that they can only be profitably discussed in connection with the very abundant illustrations. The ground-plan given shows that Æge,—the modern Nemrud-Kalesi—has yielded up three temples, a theatre, a stadium, various extensive porticoes, a market-hall of which there are substantial remains above ground, and city walls in an unusually good state of preservation. All these are discussed in minute detail by Dr. Richard Bohn, and there are supplementary chapters of the history of the city and the evidence of the inscriptions found by Dr. Shuchardt. We may comment in passing on the wisdom shown by the Institute in allowing these supplementary volumes to be bought separately. Subscribers to the other organs of the Institute need not take them, and the general public can. They relieve the text of the "Jahrbuch," and are each of them addressed to a separate section of archeological specialists. We are promised shortly an "Ergänzungsheft" that will be most eagerly looked for,—a treatise by Dr. Dörpfeld and Dr. Emil Reisch on early Greek theatres recently excavated, and the light they throw on the disposition of the Greek stage.

The last number of the "Jahrbuch" (1889, III.) presents a new feature, which will be gladly welcomed by all archeologists. It has always been the custom to publish in this journal a list of the "recent acquisitions" of the Berlin and British Museums. The directors have wisely decided to publish henceforth a similar list for all the smaller museums. Such a publication is, if possible, almost more necessary for small than large museums, because such are more likely to be overlooked. The present number begins with Dresden, and here, as in some other cases, it has been decided to let the summary extend back over several years. The "Jahrbuch" has also ever since its reorganisation led the way in the matter of giving immediate woodcuts of important acquisitions. This plan can scarcely be too highly commended. It now supersedes the detailed and adequate ultimate publication, but its effect is to put that publication into right hands, and in reality to hasten it. Often an important monument remains unpublished because the local director,—who alone knows of it,—does not happen to be a specialist in the particular line it illustrates, and does not feel equal to expounding it. Now, the right man is sure to know of each newly-acquired monument, and equally sure to ask and obtain permission to publish and elucidate it.

In the January number of *Murray's Magazine* is an exceedingly temperate letter from Sir Arthur Blomfield—wonderfully temperate considering the provocation he has had—in reference to the preposterous article by Lord Grimthorpe to which the editorial wisdom of that magazine recently gave currency. His best sentence is his definition of Lord Grimthorpe's "principles of restoration" as

amounting to this—"Whatever I think right is right, and the opinions of all who do not agree with me are not worth consideration." As Sir Arthur observes, "principles such as these possess the undoubted merit of extreme simplicity and of easy application to every possible subject under all possible circumstances, but they have the serious defect of making discussion impossible." We doubt however the advisability of answering Lord Grimthorpe, whose lucubrations are better regarded as those of a person not perfectly sane. If any one could take away the faculty with which he was foolishly entrusted by an ignorant Chancellor, well and good; but that is the only thing it would be any use doing. Nor is it by any means wise to stick to the theory that the old nave roof and flat ceiling might have been preserved. It might possibly have been done with a great deal of piecing and patching, but neither roof timbers nor ceiling were in a condition to make it worth while; we speak from detailed inspection at the time. The ceiling, besides, though it looked well enough from below, had no artistic value; it only required a pair of compasses to design it. Architects weaken their own position by adhering to an untenable position of this kind. The injuries Lord Grimthorpe has done to St. Albans do not consist nearly so much in what he has taken away as in what he has put in its place.

WHERE seems to be a happy inclination at present among very wealthy people to give large sums for works of public beneficence or utility; and the *Pall Mall Gazette* the other day published a list of suggested good works that might be accomplished, in case any more millionaires are thinking of becoming public benefactors. We will suggest one more for London, a benefit perhaps more for the rich than the poor, but one which commercial enterprise has not been equal to. There was a scheme on foot some years ago, of which we heard indirectly, for the construction of a great sea-water swimming-bath for London, of far larger size than any of the existing swimming-baths (300 ft. by 100 ft. was spoken of); the water to be pumped through a main laid to the nearest point on the coast whence pure and uncontaminated sea-water could be drawn. The scheme had been so far seriously considered that an architect had been consulted as to the site and plans; but capital could not be found for it, apparently, as a commercial speculation. Now if any very rich Londoner is inclined to immortalise himself by a great public benefit at his own cost, here is an opportunity for a work which would be an immense boon to many Londoners. The existing comparatively small (?) water swimming-baths in London are, in the summer, inconveniently crowded at the only time when most people can use them, viz., in the morning before the work of the day begins; and at the best these tepid fresh-water baths, in which so many persons plunge during the day, never have the healthy and bracing effect which could be obtained from a sea-water bath of ten times the area, with sufficiently continuous supply to keep it fresh. We make the suggestion in the hope that it will be considered by some modern Croesus who can afford either to give or to risk the money. It might, in the latter case, bring an adequate return. The waste water might be utilised for street watering; an important saving in the ordinary water supply.

IT is edifying to read the opinions of recent correspondents of the *Times* on the subject of London street paving. One wiseacre actually writes to recommend that we should return to granite cubes (unquestionably an admirable form of pavement for endurance and for draught), forgetting that the very essence of the whole difficulty about London pavement lies in the provision of a pavement which shall be at once durable and noiseless, and that wood and asphalt were tried because

the noise of the constantly-increasing London traffic on stone paving, and even on macadam, was becoming an irritation and a nuisance that could be endured no longer. There are streets of dwelling-houses in London, for some years laid with wood or asphalt, which would be emptied of their tenants in six months if, with the present traffic, granite paving were replaced: people's nerves could never stand it. One man writes to say that asphalt is the most injurious pavement for horses that ever was; another that his carriage horses fell over on it and were not hurt, and therefore he thinks asphalt is "not a bad pavement for horses to fall on." We opine that, to a horse falling, asphalt is not quite so hard and cruel a surface as it looks, and that there is a certain amount of give in it; but we have no doubt whatever that more horses fall on asphalt than on any other form of pavement, and that it is the worst of pavements for a horse to get up from, owing to the want of foot-hold. But we are entirely against the recommendation of Sir Robert Rawlinson in Thursday's *Times*, to adopt wood pavement. We quite concur in his remark that much wood pavement has been unsatisfactorily bedded, and that hollows and sinkings in wood pavement are really the result of bad foundations, not of the defect of wood as a paving material. But this does not affect the fact that for a city like London wood pavement is essentially insanitary, and neither Sir R. Rawlinson nor any lesser letter-writers will persuade us to the contrary. It is desirable to avoid as much as possible the use in London of porous materials which hold dirt and "germs," and no one can possibly doubt that wood is one of these. The general acceptance of wood for street pavements would mean that London would be less clean and less healthy than with most other pavements. The suggestion of "J. P." in the *Times*, that asphalt might be covered with a thin sprinkling of dry sand, is practical as far as the result to be obtained is concerned, but the process of keeping up the sand coating over an area of many miles of streets would be a more serious matter than he has realised. Possibly the solution of the difficulty might be found in a new method of permanently finishing the surface of the asphalt so as to leave a sufficiently roughened surface for better foothold.

THE six candidates for the second competition for the Sheffield Municipal Buildings have been selected, but it is not intended that the names should be officially published. From a Sheffield paper we learn that a well-known Sheffield firm are the authors of one of the selected designs; a communication made to the press, we presume, by the architects themselves. As the Borough Surveyor of Sheffield informs us, in a courteous note, that it is preferred that the names should not be published, we have no wish to encourage competitors to traverse the wishes of the Sheffield authorities, who have shown that they understand their business very well and are carrying on the matter with every wish to act fairly towards all concerned. We are informed that there is an intention to exhibit the non-successful sketch designs, provided a majority of their authors give consent. One of the competing architects writes to us to suggest that this is not the right time to do this; that it should not be done till the final selection is made, when the unsuccessful sketches should be exhibited along with the successful ones, for better purposes of public criticism and comparison. He adds that this would in another sense be more fair to the unsuccessful men, as in spite of their non-success many of their plans may contain valuable suggestions which would be thus thrown open to be studied and possibly assimilated by "the six," or some one of them. There is something in both these arguments, in which we are inclined to concur. We may add that there is much more interest in such an exhibition when the successful designs are included. We remember the exhibition of the

unsuccessful sketch-designs for the Manchester Town Hall, when there was the same feeling expressed by many—that there was very little point in it when it was impossible to compare them with the selected designs.

THE promoters of a small competition for local public offices at South Stockton, not to cost more than 2,500*l.*, have been comparatively liberal in premiums, offering three of 50*l.*, 25*l.*, and 15*l.*; but what they give with one hand they seem to wish to take away with the other: they provide that "the three sets of selected plans, specifications, working drawings, and schedules of quantities, to become the property of the Board, who may employ their own Surveyor or any other person to superintend the erection either with or without any alteration therein. The Board, however, desire to know from competing Architects what remuneration they will require if employed to carry out their own plans and give all needful general superintendence, and a letter giving such information should be sent with the plans." This latter clause, which amounts to a proposition to give the commission, if at all, to the man who will do it cheapest, is a most improper one to offer to the members of a liberal profession, and no architect of good position would have any anything to say to it. The demand for specifications and working drawings with a set of competition drawings is so absurd that it may be charitably supposed it is dictated by ignorance.

AN article on "Hoorn and Enkhuizen," written and illustrated by Mr. Reginald T. Blomfield, appears in the January number of the *English Illustrated Magazine*. Coming as it does so soon after Mr. Blomfield's utterance before the Architectural Association the paper is especially interesting; it shows how well he can practise what he preaches. His drawings, eight in number, are indeed quite different from the "wiry, mechanical pieces of work," which he says are conjured up in a painter's mind by the words "an architect's drawing"; but we cannot think that the effective sketch of "The Harbour Gate, Hoorn," is improved by the scrolls which do duty for a sky. The "Water Gate, Enkhuizen," is a pretty piece of work, and the detail of the doorway to the Burghers' Orphanage at the same place is crisply shown. The article is picturesquely written, but will, we think, be of more interest to architects than to that almost, but not quite, omnivorous creature, the general reader. Two short passages are worth quoting for the sake of showing how carefully Mr. Blomfield has studied the buildings of which he writes—"The two lower niches have cannon-mouths carved in stone and painted black, which the guide-books describe as real guns," and again, "In the top stage of the gable are carved two figures of armed men, supporting the English arms. M. Havad gives a tradition that this shield was captured from an English ship in the days of the redoubtable Van Troup, and set up as a trophy. He describes it as the original shield supported by the effigies of the negroes who took it. One would more easily credit this tradition if it were less circumstantial, for the shield is not of wood but of stone, and the figures that support it are not negroes at all."

THE January number of *The Portfolio* is prefaced by a short sketch of the history of the periodical by the editor, whose writing, whether on himself or on other subjects, is always interesting. The first of a series of articles on "The British Seas," with illustrations of sea and shipping, promises well, and the name of Mr. Clark Russell to the literary portion of it is a guarantee that the subject will be treated with knowledge. An article on Mr. Walter Crane and his works is illustrated by a reproduction of his energetic design of the "Chariots of the Hours."

AN appeal is made for contributions to a fund wherewith to meet the cost of repairing and enlarging the parish church,

St. Mary Magdalen, Woolwich. The church was rebuilt in 1728-33; it has a plain exterior, whilst the interior is after the Classic style then prevalent. It is proposed to add a larger chancel, together with side chapel and organ chamber; to construct a more commodious vestry; to replace the windows; and to restore the stone coping, which is pronounced to be in a damaged state; and to fence in and level the churchyard. The western tower, outer walls, and roof were repaired a few years since, and are in good condition.

THE large pasteboard almanac for this year issued by the Stationers' Company bears a picture of the Tower of London, as seen from the Thames, looking towards the north-east, and embracing the river frontage from the Middle to the Develin (Gallichmae or Iron Gate) Towers. This drawing, made and engraved by Mr. Louis Godfrey, delineates the Tower as it appears after the demolition and more or less superstitious restoration which has been effected, within the past four or five years, by the Office of Works. The cupolas on the four angle-turrets of the White Tower are drawn to a rather too lofty and pointed form. The outline of what we take for the Byward Tower—and it can hardly be any else—is indistinct; whilst the Garden (or Bloody) Tower shows battlements, which that tower has not. The large block, containing the guard-room, with the soldiers' school and reading-rooms, seems to be somewhat out of position. This ugly building has replaced the gabled "Seven Houses of Office," of *temp.* Henry VIII., that stood between the Garden Tower and the Coldharbour, and may be seen in the model of the fortress (1841), which is now preserved in the Armoury as recently rearranged within the central keep.

SOME correspondence has been printed in the *Times* *a propos* of modern and ancient mummies, and the supposed head of the Duke of Suffolk, father of Lady Jane Grey, preserved in Holy Trinity Church, Minorities. Mr. Seymour Haden sees a likeness in the features of that relic to two portraits of the Duke in the Tudor Exhibition, and Mr. J. Standish Haly is satisfied that the more popular belief as to the head being the Duke's is authentic. Some say it is that of the Duke of Monmouth. In our columns of Jan. 9, 1886, we referred to a highly-probable theory of its being the head of Edmund de la Pole, Earl of Suffolk, executed in 1513. Mr. Standish Haly insists upon the circumstance that the Duke of Suffolk, executed in 1554, "resided at the Minorities, that establishment having been granted to him on its suppression as a religious house." But the Minorities did not belong to him up to the period of his death. He lived there in part of Edward VI.'s reign; but made it over in 1552 to his two brothers, Lords John and Thomas, with one Medley, and went to Sheen, where he was living at the time of his share in Wyatt's uprising. On the other hand, Edmund de la Pole, whose family had once owned the manor of the Rose, St. Laurence Poultry, was buried in the Minorities, whilst it was still a convent, as were also his daughter, a nun there, and his wife. Curiously enough, the Rose manor was given, after the Earl's attainder in 1513, by Henry VIII. to his brother-in-law, Charles Brandon, Duke of Suffolk, as Shakespeare reminds us:—

"Not long before your highness sped to France,
The Duke being at the Rose, within the parish
Saint Lawrence Poultry."

—"King Henry VIII." i. 2.

IN his little hook upon the Barbers' Hall*, and that Company's treasures, Mr. Shoppee, F.R.S.B.A., gave an interesting account of the large picture by Holbein, which may now be seen in the Tudor Exhibition.

* Description of "The Pictures and other Objects of Interest in the Hall and Court Room of the Worshipful Company of Barbers," by Charles John Shoppee, some time the Company's architect and surveyor. . . . 1883.]

The painting executed reputedly upon canvas, but really on oaken panel, shows Henry VIII., seated in state, delivering to Thomas Vicary, Master and "King's Surgeon," a new charter (1541) to the then freshly-united companies of Barbers and Chirurgeons. The figures comprise Sir John Ayliffe, Master in 1539; Nicholas Symson and Edward Harman, "King's Barbers;" the celebrated Dr. William Butts, and Dr. John Chamber, Warden of Merton College, Oxford, and Dean of the College of the Virgin and St. Stephen, in Westminster. To the extreme right stands J. Alsop, physician to the King. This picture was lent to James I. and his successor, in order that likenesses of Henry VIII. might be copied therefrom. We may add that the Company's records demonstrate that instead of having suffered damage in the Great Fire, as is asserted by Pepys, who was minded to offer 200*l.* for it (see his diary, 28 August, 1668) the painting had been carefully removed into a house in Moorfields, and so was saved. The day before his visit with Pierce (a surgeon) to the Barbers', Pepys had passed from Whitehall to the Matted Gallery, then under repair, and writes—"And pity to see Holben's work in the ceiling blotted on, and only whited over!" Walpole avers that the picture had been retouched, but its owners say it has undergone no other change than by a careful cleansing in 1719, and again, in 1878, by Mr. George Redford who, *teste* Mr. Shoppee, discovered it was painted upon a gilt ground.

THE *Antiquary* commences a "new series" with the present year. Among the articles is one on a supposed Saxon altar-slab at St. Benet's, Cambridge, by the Rev. G. F. Browne, who has made ancient altar-slabs and tomb-slabs a special study. Among other points the author makes the suggestion whether the ancient practice of cutting five crosses on altar-slabs was done as symbolical of the five wounds of Christ. We should think this extremely probable. "The Church Plate of the County of Dorset," by Mr. F. E. Nightingale, is the subject of an article signed C. R. Manning, including some well-executed illustrations, one of which shows a curious and very unusual cup from Wraxall.

PROFESSOR MIDDLETON proposes during next Easter vacation, from about March 22nd to April 22nd, to give a course of lectures in Athens and the neighbourhood with a joint class of students from Oxford and Cambridge, on the buildings and topography. He will be glad to admit also to these lectures any architectural students from the Royal Academy, the Institute of Architects, or the Architectural Association. Professor Middleton's hook on Rome has proved that he has a quite exceptional faculty of reading and expounding the data of ancient buildings, and those students who are able to avail themselves of this opportunity will find it well worth their while to do so.

Lectures on Architecture and Sculpture at the Royal Academy.—Professor Aitchison, A.R.A., is announced to give the following lectures to the Academy students:—Monday, Jan. 27: "Roman Architecture,"—Preliminary." Thursday, Jan. 30: "The Laurentine Villa of Pliny the Younger. Monday, Feb. 3, Thursday, Feb. 6, Monday, Feb. 10, and Thursday, Feb. 13: four lectures on "The Private Houses and Palaces of the Romans." The lectures on Sculpture will be as follows:—By Mr. A. S. Murray, Keeper of the Greek and Roman Antiquities in the British Museum: three lectures (Monday, Feb. 17, Thursday, Feb. 20, Monday, Feb. 24) on "Sculpture in Greek Temples." By Professor J. H. Middleton: three lectures (Friday, Feb. 28, Monday, Mar. 3, Friday, Mar. 7) on "Florentine Sculpture in the Fourteenth and Fifteenth Centuries."

The North-Sea-Baltic Canal.—It has now been decided that there are to be two gates only on the North Sea-Baltic Canal, viz., at each end. This will enable vessels to pass through the canal at any tide in eight hours.

SPIRES, TOWERS, AND DOMES.*

The title of this paper, "Spires, Towers, and Domes," is a comprehensive one, conjuring up to the imaginative mind a boundless vista of graceful towering monuments of architectural art. Who has not felt the powerful appeal made to the senses as the view of a great city unfolds itself for the first time to the gaze of the traveller, with its well-proportioned monuments reaching into the heavens, viewed on a brilliant morning, or, may be, standing out against the rich red hues of an evening sky, domes, towers, and spires one and all testifying to the artistic feelings and restless industry of mankind in all ages?

It is, and responsible part than the one architects of past ages have taken in the building up of the magnificence of many European cities. On their thought, on their work, without doubt the picturesque, the popularity, the importance, and even the prosperity of many a European capital has rested, and in no more prominent direction has architectural skill contributed to such success than in the design and disposition of the graceful Gothic spire, of the stately campanile, and of the voluptuous symmetry of the classic dome.

Every one here has surely felt the awe-inspiring effects of a grand interior, and yet a flow of sentiment is easily checked, the fire of enthusiasm easily quenched, by a commonplace thought, by a mundane fact. Nothing destroys the poetry of an impression so completely as the consciousness of a material defect associated with the object of our admiration. It is in this regard that we can realise the difficulties that had to be overcome by, and the onerous responsibilities that rested on, the designers of past ages. Their works not only have had to meet the requirements of the ages in which they were built, but they are now subjected to the artistic criticism and the scientific investigation of nineteenth-century enlightenment.

It, then, must ever be the greatest care of designers that there shall be in the creations of their craft nothing that shall suggest instability, nothing to indicate decrepitude, nothing that shall point to a finite existence. If this has been achieved then there will be no danger of the first heat of enthusiastic admiration being chilled by a closer knowledge of the constructive anatomy of our architectural idol, whether it be spire, tower, or dome.

Spires, towers, and domes comprise an important section of an architect's work, and form a subject not limited by the dogmas of a style nor bound by the chronological limits of a period. Its vastness presents a difficulty as to its most profitable treatment in a short paper. The historical, the æsthetic, the constructional and scientific divisions of the subject could each in themselves furnish ample material for separate discourses. This paper, however, will be found to embody a large proportion of the constructional and scientific, clothed with a slight historical and æsthetic mantle.

From the earliest recorded times the greatness of man's mind in the material world has sought expression in lofty erections. In the futile endeavours of the descendants of Noah, 2247 B.C., to ontwit the anticipated wrath of an awful Deity by the erection of Babel's tower, and in the more successful efforts of mankind in other lands and in later centuries, we are conscious of the existence of a sentiment that finds expression in the erection of buildings that point upwards and away from this worldly world. China, India, Asia Minor, Northern Egypt, the Moorish lands, Italy, France, Spain, Germany, our own country, have reared many and glorious examples of spire and tower design, but, strange as it may seem, we turn in vain to Greece, the fountain-head of architectural refinement, for an example, and we find it not. The Grecians, a race gifted beyond measure, intellectual to a degree, ultra-refined, almost divine in their artistic feelings, failed to rise above the worldly horizontality of architrave and cornice.

We have seen the campanile development of Italy, with all its wealth of detail. We are familiar with the solid, sturdy growth of Gothic tower architecture in Northern Europe. We are conscious of the beauties and delicacy of the French treatment. But, with all this knowledge, where can we find towers and spires to

* A paper by Mr. S. B. Beale, read at the meeting of the Architectural Association on the 3rd inst., as elsewhere mentioned.

equal in boldness of conception, grace of outline, and beauty of detail, the Gothic,—aye, and even many of the Classic towers and spires of this or our own country? The sequential development of English architecture as exemplified in the ancient ecclesiastical buildings of the Gothic style is exceptionally marked by the development of spire and tower design.

In reviewing the history of spires, our attention, for strong reasons, must be confined to English forms and English construction.

The simplest form of spire conceivable is the four-sided pyramid rising from the square tower, with its sides parallel to those of the tower, and overhanging, thus forming slightly projecting eaves upon a corbel table. Southwell Tower is an example. In the Romanesque period the spire has its first true conception. Thon Church, Normandy, with a masonry pyramidal termination in height about 1½ diameters, and a steeper one at Valladolid, with a height of 2½ diameters, undoubtedly embody the spire principle.

In the Early Gothic of this country spires obtained a firm hold on English church builders, beginning with the octagonal pyramid and its attendant broaches of masonry springing from the angles of the usually square tower, and butting against the splayed sides of the octagon.

From the simple broached spire we turn to an important change. Instead of the spire projecting slightly beyond the faces of its tower base, it sprang from a base area entirely within the edges of the tower. This modification opened up a wide field for elaboration, which was taken full advantage of during the Decorated period. Beginning with the parapet simply, followed by a combination of parapet and broaches; parapet and pinnacles; parapet, broach, and pinnacles; parapets and angle turrets; elaborated again by double pinnacles, and, finally, by the introduction of miniature flying buttresses springing from the pinnacles or turrets, and abutting against the splayed sides of the spire. The Medieval builders in this period produced spires of complicated design and elaborate detail, contrasting with the effective simplicity of the early broached spire in a very marked manner.

In the early part of the Perpendicular period, the spire had reached its highest state of development and elaboration. Spires were constructed from a vertical polygonal drum standing upon a rectangular tower; the surface of the spire was in some instances enriched with cusped panelling. Crockets had free play on the minor turrets and pinnacles at the spire base, and up the ribs of the spires themselves. Ornaments and features were crowded on until the zenith of spire design was reached. Then the reaction came, and square towers were once again generally erected without the superincumbent spire. The decline did not occur, however, until some very beautiful examples of each of the different kinds here scheduled were left to tell their tale.

There are some unique combinations of spire and tower in the minor English Medieval parish churches, among which may be mentioned an octagonal spire springing from a tower of octagonal plan from base to summit; the same, accompanied with angle turrets springing directly from the ground, of which there are examples at Stanwick, Northamptonshire, and at Wickham Market, Suffolk.

It would be difficult indeed to specify the date of the erection of the earliest tower in Great Britain, and what were the exact reasons that prompted its erection. Reasoning upon probabilities, we may arrive at a tolerably reliable conclusion in the latter case.

The tower, rising as it does above the general height of the buildings reserved for the common use of mankind, possesses physical pre-eminence which naturally suggests its erection in those positions and amongst those buildings which require accentuation either to indicate their positions from afar, or to testify to their public or private importance.

The tower of Medieval times in secular buildings served for a look-out, as a refuge, and as a place of vantage in troublous times. There are a few ecclesiastical towers having some quaint legends and curious histories associated with them. Of these the tower of Boston Church, Lincolnshire (in itself a magnificent example) has been immortalised by the writings of Jean Ingelow. In romantic verse the poetess has told of the pealing forth of the bells in the church tower at a time of particular danger from floods. Many human beings were drowned who were not able to take advantage of the

periodical warning rung out from the bells of Boston tower.

There are numberless reasons given for the erection of towers in connexion with ecclesiastical edifices. Archaeologists assure us that the chief ground for erecting the tower was to procure a position for the hanging and ringing of bells. Now, it is asserted that bells of large size were not cast until a date long after large, massive, and high towers had been in existence. This fact rather destroys the idea of bell-raising being the prime cause for ecclesiastical tower building. Certain it is there were many causes working together to justify the erection of towers for one or other of the purposes enumerated. Towers may form a valuable artistic addition to a fabric, and some may serve a purely utilitarian function. There is a further class, the claim of which to existence it is difficult to define.

As a nation's architecture is mostly measured by the standard of its ecclesiastical work, so must we turn for the best examples of tower design to English and foreign ministers, priories, and cathedrals. At the outset it will be well to notice the positions of the tower in regard to the body of a cathedral or minor edifice consecrated to Divine worship.

In the southern countries of Europe the tower was frequently detached entirely from the main building,—a notable instance being Pisa. It has been suggested that the fear of the vibration set up by bell-ringing in the tower prompted the arrangement. It is to a more powerful reason, however, that we must look as the cause of so marked a feature in church planning. The builders of Italy, for instance, in erecting a tower, never appear to have been satisfied unless they produced walls 10 ft. thick and upwards. The excessive weight of such construction brought abnormal loads upon the foundations, producing subsidence, and it is to this fact (not fully appreciated then, nor has it been properly understood since) that we must look as the reason for the isolation of the tower. A settlement (no uncommon thing) due to the great weight of the tower would have entailed disaster and ruin on the cathedral if the tower had conjoined with the general structure. A diagram on the walls, with a little subsequent explanation, will bear out this view.

The position over the crossing of a church as the site of the tower can scarcely be improved upon, combining, as it does, the essential advantages of a centralised position, all the component portions of the church leading the eye of the observer up to it when seen externally. In view of the modern tendency in church-planning to reserve a large congregational area about the preacher, this central tower affords every facility for the effective lighting of a portion of the church usually in the dark. Of the important English examples of this kind that occur to the mind are the cathedrals of Salisbury, Winchester, Norwich, Worcester, Gloucester, and the Abbey of St. Albans.

Although the central position for the tower possesses many advantages over any other, to the unstable manner in which central towers have been constructed has been ascribed their location at the west end of the nave in more modern instances.

We are reassured by the architectural historians that the great inconvenience to worshippers entailed by the frequent works of reparation to the central tower brought about its removal to a position less contiguous to the area reserved for service. This fact may or may not explain the adoption of the western site as a very suitable one for a single tower; the principal point in which this paper is concerned is, that the ancient builders to whom, in other directions, we owe so much, did not erect their central towers with a sufficient regard to economy of material.

The western site, on the extremity of the longitudinal central line of the nave, is a very general position for the towers of the parish churches of England. The extremities of the aisles sometimes came right up to the front or west wall of the tower, thus flanking it on both sides one story high, and in other cases the tower stands clear of the main edifice, only joined thereto on the east side. It has been advanced that this latter is the proper arrangement for a single west tower, if it is to receive its full significance and importance.

There are other less-favoured positions for the tower of an ecclesiastical building that may be noted. Of these, the least objectionable one is the transept site, north or south. Of the others,

the position for a single tower to be most avoided is that to the north or south of the west front.

The otherwise fine tower of St. Mary Redcliff, Bristol, is to one side of the west front.

In England's cathedral towers are exhibited the respective values of each position. Chichester, with its central and detached tower; Ely, with its central and west tower; the two transept towers of Exeter; the three or more towers of Lincoln, Durham, Wells, York, Canterbury, Peterborough, and Lichfield refer to the mind as showing combinations of towers that are peculiarly successful in their architectural grandeur.

The detailed consideration of tower design in plan, in arrangement, in roofing, and in its strict architectural treatment, cannot be done justice to on this occasion, and is, therefore, not attempted.

Each country has some peculiarity of arrangement. Italy has its circular and polygonal plans. Germany has the characteristic ohlong plan; the towers, usually extending over the whole west-end of the church, have been very aptly termed narthex towers. While of English towers the great majority are square, or very nearly so, in plan.

It is not perhaps just to bring the towers of various countries into review order for critical comparison, when it is remembered upon what widely-differing agents their designers have relied to produce the architectural effect of the whole.

A tower that relies for effect upon the beauty and variety of the coloured marbles used in its erection and embellishment cannot be criticised from exactly the same standpoint as the tower that relies upon its fenestration for its effect, or with the tower that appeals to the eye by reason of its exceeding beauty of outline. The one, when viewed as a distant object in the landscape, may well suggest the pumping-tower of a waterworks, and its beauty will not be appreciated without the aid of a telescope. This tower must be viewed from the area immediately around its base, while the beauty of the other towers may be seen miles away.

We may each have our own sympathies directed towards the tower design of a particular age, style, or country. But there are good grounds, patriotism aside, for maintaining that of the towers and spires remaining from the Medieval ages, in which may be seen grand conception with artistic detail, the erections of North-west Europe, and particularly of our own country, must stand in the first rank.

Unfortunately, many a beautiful spire has been lost to us for ever, its ruin and fall arising out of ignorant construction and misuse of material,—an evil extending into later and even current times.

The Norman period of English architecture is in this country looked upon with peculiar reverence; due, perhaps, more to its romantic associations than to its incipient beauty. Now, whatever æsthetic value there may be wrapped up in the massive grouping and rude ornamentation of Norman work, certain it is that there was in this period, and later, an extraordinary prevalence of bad construction, to which is traceable the ruin of many a fine abbey. The evil effect of it is even felt in this century, and arises in some such manner as the following:—

Contemporary church architecture is not much valued in these days unless a precedent can be stated for each arrangement and each detail of it. It is rank heresy to some minds if the forma and modes of construction now adopted cannot be traced to bygone times. But the designer who draws upon Medieval ages for the basis of his nineteenth-century churches must be capable of windowing the busks from the golden grain.

Although no constructor would in these days build up the shafted pier of a church or cathedral with a thin casing of stone, of a thickness only sufficient to work its mouldings on, and then shoot in a loose rubble core, resting content with the idea that a pier had been obtained capable of sustaining the heavy superstructure of a central tower, with the thrusts from the contiguous nave arching, still there are many peculiarities of Norman construction and constructive principles of later styles which are even now religiously followed, and which must subsequently be attended with no less disastrous results than those chronicled on the exhibited diagram.*

The evil, prevalent in the building of many of England's fairest abbeys, cathedrals, parish and

* The diagram here referred to was a list of cathedral towers which have fallen since Norman times.

other churches, ministers and priories, has been the dangerous overloading of foundations and subsoil bottoms.

This is true of the general body of the cathedrals the author has investigated, the weight brought by nave walls on to the foundations approaching very nearly the supporting power of the soil as far as such strength can be accurately estimated. The evil of overweighted foundations is particularly marked in the locality of the towers, and most notably when the tower is over the crossing. Such an instance was the tower of St. David's, South Wales. This tower, 40 ft. square, and weighing over 4,000 tons, first failed by the bodily sinkage of its western side, crushing down portions of the nave, and generally upsetting the perpendicularity of its piers. The expenditure of 11,000*l.* remedied the want of constructive knowledge on the part of the original builders of this tower.

Failure not infrequently occurred at the west tower foundations, and it will be useful to inquire what are the agents generally at work endangering the stability of great towers. Such causes as badly-selected materials (as in the case of St. Michael's, Coventry) are not now dealt with. First and foremost, the most destructive agent is the great weight of masonry in the tower itself cumbering the ground unduly; this overweight being sometimes further aggravated by a tall spire of heavy construction.

The presence of timber in the foundations, occurring as piles, serving no useful purpose whatever, but subsequently decaying and endangering the superstructure, is another cause of failure. The tower of Ely Cathedral sank 6 in. from some such cause, occasioning, as can well be imagined, great ruin to the adjoining wings of the western transept, one of which was taken down and the other repaired. Although no actual mishap has occurred at York, a writer in 1846, remarking on the Minster of that city, chronicled the fact that the tower stood upon very rotten foundations; they crumbled away at the touch, and could be easily probed with a crowbar. The consequence was that cracks appeared in the great tower.

To explain the constructive failure of so many of our fine cathedral towers, it has been said that the Normans erected their work upon the had foundations of the pre-existing ecclesiastical buildings. This explanation shifts the blame from the Norman builders to their predecessors in these lands; whereas, investigation of the construction, and detailed calculations, show that enormous weights were piled upon a small area of foundation by the Norman builders, a conclusion which rather puts the boot upon the other leg.

It is, of course, possible to build very massive masonry to a great height on ordinary soil if the weight of such construction is evenly and sufficiently distributed over the soil. But what has been the method by which the great weight of many towers has been brought on to their foundations? It has been the almost universal rule to carry central towers upon isolated piers, these piers transmitting the many thousand tons pressure upon usually four points of small area on the cathedral site, showing, in some places, a weight of five tons on the square foot, and in others twenty tons. The very nature of a central tower makes it necessary to carry the upper portion upon piers; but when this is done, the piers should be joined again into a continuous construction under the ground-level by the building of inverted arches of the same width as the upper tower walls, and further, they should be bedded in a wider base of concrete to sufficiently distribute the enormous pressure from the piers of a lantern tower. Some constructors go so far as to say that wherever an arch occurs in masonry or other work which tends to throw unequal weights upon foundations, an inverted arch should be built under the ground-line for each one in the wall above. In church work this system of inverted arches should be built between all the pier bases of the nave arcading, under the chancel arch, and in any other position in which a concentration of pressure is anticipated.

It has been remarked that failure not infrequently occurred at the west tower foundations. In this position, where one would think there was no reason preventing the carrying down of the walls continuously on to the foundation, the walls, in many cases, are arched over, and carried upon four piers at the angles of the tower, presumably with the idea

of economising the material that has been so lavishly bestowed up above, but with the sure result of precipitating the destruction of the fabric.

Bells have always been active agents in tower destruction, both from their weight and vibration. A rule has been published with reference to the necessary thickness of tower walls intended to support bells, and it runs: The mean internal area of a tower should be one half the external area, and then, if well built and of good materials, the tower will safely bear as many bells as can be hung on one level. A calculation based upon this rule for a tower say of 40 ft. side produces walls 6 ft. thick, assuming its height at three or four diameters high, this, with the weight of as many bells as can be hung on one level, will show a pressure of five tons on the square foot of soil. Add to this the possible weight of a spire, and such a pressure is put upon the foundation that it is little wonder failure ensues.

This particular rule takes no account whatever of the height to which the tower may be built.

Such rules commend themselves to the unwary by their simplicity, and yet the two or three minutes spent in a calculation of such a nature has brought about a world of anxiety, years of regret, and, perhaps, professional ruin.

These errors of misjudged construction are not overrated in this paper. Examples known to the whole world testify to the truth, for instance, the dome of St. Peter's, and the various modifications during erection that had to be made before a lantern was built to that edifice that could be relied upon not to bring the dome down with a run; the unfortunate cases of our own cathedrals; or the many French and German collapses. They all point to the conclusion that the knowledge and capabilities with the peculiarities, strength, and capabilities of different materials in all the varying phases of construction, is not on a par with the undoubted standard that has been attained in artistic architecture. The science of architectural construction is as far behind our excellence in aesthetic design as the medical knowledge is behind the surgical attainments of another profession.

The disparity arises in but one way. The student of architecture, either from want of guidance or from misdirection in his earliest years, attempts to produce drawings more or less artistic; he is tempted early to study the aesthetics of architecture, the study becomes engaging, even fascinating, until the whole soul is imbued with romantic tradition and architectural lore. It is easily understood how unromantic, even nauseous, the study of the science of construction, and the strengths of materials with their attendant calculations, must have become. A book of formulae and figures is put aside with impatience, perhaps with disgust. The nourishment of practical knowledge is dropped for the narcotic of archaeology.

The principles which are shown by modern science to underlie architectural construction, are in themselves few and simple, and at the same time reliable. A firm grasp of them may be obtained in the first year or so of study. The mathematical knowledge wrapped up in them is not extensive, and should flow without effort from the mind fresh from college or school. Such knowledge once allowed to rust never regains its old vigour. The mathematical and scientific attainments obtained in college life must be carefully nurtured and trained, or they will wither and die under the fierce glow of aestheticism, a sentiment early permeating the whole being of the earnest student.

The few principles which govern tower building may be enumerated very shortly. After having settled the general plan, outside dimensions, and approximate height, the thickness of walls should be tentatively settled, being dependent upon subsequent calculations. Such preliminary judgment should be based upon the least thickness of masonry that is requisite for keeping out weather, consistent with forming a secure and complete bond in the material, and other practical considerations, as window treatment, provision of sufficient abutment for vault springings and corbelling. The approximate weight of the structure may then be calculated, and attention is then paid to the influences which are likely to endanger the stability of the tower when properly constructed.

Towers and spires, above all other buildings, are exposed to the full fury of gales. The force of wind obviously varies directly as the rate at which it is going along, and is given by the following simple formula: $P = 100V^2$ where

P is the pressure upon the square foot in lbs., and V the velocity in miles of the wind in one hour. The full wind pressure that has been experienced must be allowed for as tending to produce overturning effect. A careful estimate of what the maximum force of the wind is likely to be in the particular situation must be made. This calculation should never be omitted when designing a spire, for the reason that there is no more powerful agent of tower destruction than that which produces the rocking action of an apernucumbent steeple.

The effect of wind pressure upon a tapering Gothic spire is considerably modified by the plan, elevation, and mode of construction of the spire. The inclination of the sides of Gothic spires, varying as it does from about one in five to one in ten, reduces the estimated horizontal wind pressure by 2 lb. and a 3 lb. respectively on the square foot. This is so small an amount as to be negligible. For an architect's purpose it is unnecessary to find what the reduction is for the vertical slope of a particular spire, as the error is on the side of safety. The plan, if polygonal, necessarily reduces the maximum wind pressure from what it would be if acting upon a rectangular-planned spire—a reduction ranging usually from one-third to one-half for plainly-constructed spires.

Further, if the spire is built with rounded or other rolls projecting up the ribs at the line of intersection of the planes of the spire, not only is there more surface exposed to the wind, but the edges of discharge for the wind are cut off, and its impactive force aggravated. From experiments of wind pressure on cellular surfaces composed of test plates with only one, instead of the usual four edges of discharge, the practice is based of adding one-fourth of the registered pressure on the square foot for each of the lines of discharge cut off. This operation has been regarded in the calculations of the tower Pisa on the large diagram.

The vertical faces of lucarnes, or other features, would slightly modify the effective wind pressure upon a spire, and they must be regarded or neglected according to the degree of nicety aimed at.

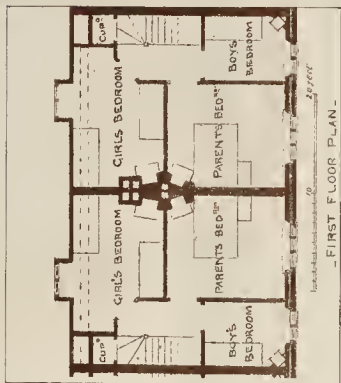

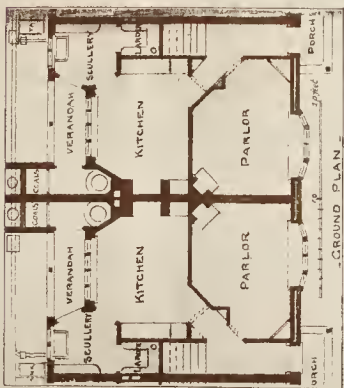

Having at last obtained a careful estimate of wind effect, the approximate weight of the spire with a tentative thickness of material is then estimated, and the subsequent investigation may be either done by calculation of the moments or by graphic resolution. If the investigation be by taking moments, the point about which the forces are estimated as acting should be one-fourth or one-sixth of the least diameter of the spire from the leeward edge, according to its plan. The calculation by moments is advantageous from its allowing any modification of the weight of the spire that may be necessary to balance the respective moments in foot-tons or foot-pounds of the wind pressure and the spire weight. By this means a reliable spire will be produced, possessing the minimum amount of material required for absolute safety and rigidity. Of all the features of spires that do not contribute to their stability the entasised outline is the most prominent. Its introduction to correct a visual delusion surely subverts the important artistic office of the Gothic spire. Who will say that the spire of St. Vincent's, Caythorpe, or St. Helen's, Broughton, Lincolnshire, and many other highly-entasised spires, are not artistic failures? For stability the entasis thickens the spire out at the wrong place; by its adoption the base is cut off at the very point, where, if anything, it should be widened out.

On the other hand, such features as broaches, pinnacles, miniature buttresses, and turrets, add weight and consequent stability to the spire when clustered around its base. To make the investigation complete, a further point that should be inquired into is the tendency of portions of the spire to slide on the bed-joints. This action cannot possibly occur if the total wind force is less than the normal component of the weight of the spire above any bed-joint, multiplied by the co-efficient of friction of the material used in the construction. Failure by crushing should be looked into; the amount of the pressure on the square foot will, in the majority of spires, be greatest at the base, and will vary in disposition and

THE BUILDER, JANUARY 11, 1890

Link-Holders, Siena.

amount according to the distance of the centre of pressure of all the forces acting in and on the spire from the outside edge of the spire. The amount of this pressure upon a unit of area must, of course, be some fraction of the ultimate crushing strength of the material. If the actual pressure is too near the ultimate strength, the thickness of the material of the spire will be modified.

From constructional failures may generally be learnt useful lessons for future work. The failure of the spire of St. Aldate's, Oxford, is a notable instance. The spire, built of stone, 50 ft. high, stood upon a tower 56 ft. high; the spire had become considerably out of the perpendicular and dangerous; it was taken down to the level of the tower. The cause of failure was attributed to the presence of a 1½ in. iron bar inserted in the first or base-course of the spire. The rusting of the bar had burst the masonry away inside and out, and it is averred that the pinnacles at the angles only saved this spire from actually falling. This is but another instance of misapplied material; the spire was 7 in. thick at the base, while to a depth of 10 ft. down from the top it was of solid stone. If these conditions had been reversed the original spire might now be standing.

This habit of self-extinction has been very eccentric in its operations. It has deprived the art-loving world of many beautiful examples of English and Continental spires.

The calculation for a tower runs upon the same lines as those for the spire, the modifications being due to the different plan and elevational shape, and the consequent modification of wind effect. The tower must answer the

same demands for stability against overturn, safety against sliding on any bed-joint, and possess a factor of safety against crushing; lastly, the total weight brought by the structure upon a unit area of the subsoil should be estimated, and be within the limit of safety. An interesting inquiry into the w-towers construction of Contances appeared in one of the professional journals some while ago. The result arrived at showed an excess of material in those towers to the extent of 1,000 tons beyond the needs of the case.

Upon the screen is exhibited a chronicle of some of the constructional failures in tower and spire designs in the limited area of England alone. France, Germany, Spain, Italy must have an extraordinary record in this same respect. By far the larger section of those towers owe their failure to the causes previously enumerated. Too much importance cannot be attached to the failure of the towers of the ecclesiastical buildings scheduled here. For the reason that the architecture of a country, if it is considered at all, is measured by the standard of its ecclesiastical buildings.

If a factory collapses under the effect of wind pressure, and the lives of an appreciable number of persons come to a painful end, the sad occurrence soon passes out of the minds of all but those most nearly related to the sufferers; but when a cathedral spire or tower passes out of existence the world chronicles the fact for all time.

Who will deny that each and every one of those towers would be now existing as they originally existed if they had been proportioned according to the laws of stability as we know

them? Ely Cathedral, and Winchester, Peterborough, and St. David's, with their massive construction, paid the penalty. It is difficult to understand the reason for such massive design as is found in them. The size of a structure can be emphasised without unduly thickening of walls. If for richness of effect, it is a mistake. The luxury of material in the case of a tower can neither be seen advantageously from within nor beheld from without. A window opening may attempt to show the wealth of masonry, while vainly endeavouring to let the light through it, but that is poor satisfaction. The insertion of masonry in spires or towers of a thickness beyond what is absolutely necessary to meet the conditions previously laid down can only be considered as a useless and dangerous practice.*

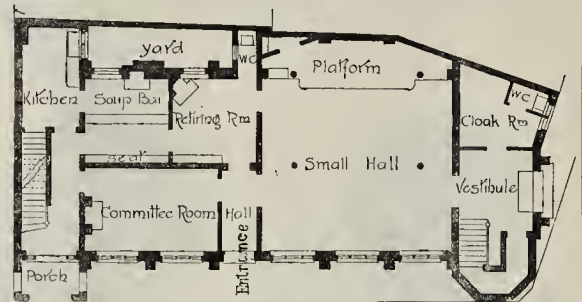

LINK-HOLDERS, SIENA.

THESE metal rings are currently said to have been intended for temporarily placing torches or what in England were called "links" in when not in use; the supposition being that the stem of the torch was run through the ring. Loose rings do not seem the best adapted for that purpose, nor does the decorative scroll above seem very convenient or suitable in such a situation. Their real interest, however, is mainly as bold and fine bits of Renaissance ironwork of a class of which there are examples in Siena that are well known to the curious sketcher.

* The remainder of the paper, with a report of the discussion which followed, in our next.

Illustrations.

SCULPTURE OVER PORTAL, ST. PIERRE, MOISSAC.

THE doorway over which is found this remarkable piece of Early Medieval sculpture is a portion of the remnant left of the eleventh-century church at Moissac, the remainder of the church having been rebuilt in the late Gothic period. The portion itself was originally in all probability an addition to a still earlier church, of the eighth or latter end of the seventh century.

This sculpture, with the portal under it, is the subject of one of the fine series of architectural reproductions in the Trocadero Gallery at Paris, and we referred to it especially in the course of some remarks on the contents of that Gallery in an article published a few months since. Whoever was the unknown sculptor, he was an artist of real genius, in spite of the grotesque of his unlearned modelling. The manner in which the emblems of the four Evangelists are gronped so as to encircle the principal figure is a finestroke of composition, as well as the ardour with which they and the seated figure beneath all turn their faces towards the divine figure. The row of circular carved paterae beneath has a fine decorative effect. The centre pier under the lintel (not seen in the illustration) is formed in the most extraordinary manner, of figures of lions spirally intertwined.

The illustration is reproduced from a photograph.

PRIORY MANSIONS, KILBURN.

THESE mansions have lately been erected in Priory-park-road, Kilburn. Each block contains eight suites, with their front doors opening from general landings and with spacious private halls. Each suite is quite complete in itself, having all accommodation and offices usually provided in well-appointed private residences, including tradesmen's entrances at the back, approached by stone steps on landings on wrought-iron supports. All the floors are so pugged that no noise can pass from one suite to another; even the noise of nailing down a carpet would not be distinguishable in the suite below. The building has been carried out by Mr. George Neal, of Paddington, from the designs of Mr. Richard D. Hansom, architect. A plan of one floor is appended. Bath rooms and w.c.'s are arranged on an entresol floor.

COTTAGE BLOCK AT BISHOPSTOKE, FOR THE SOUTH WESTERN RAILWAY COMPANY.

THESE cottages have been designed for the South-Western Railway Company to accommodate the workmen engaged in the carriage factory, which the company are about to move from Nine Elms.

There are 100 cottages in all, which are arranged in one irregular and one complete quadrangle enclosing village-greens.

Each cottage has a garden of $\frac{1}{4}$ rood, and arrangements are made to supplement this by as much allotment as the men like to take up.

The material is to be red brick in Selenitic mortar, with tiles for the roofs, and the windows are to be of Imperial stone, all wood and paint being thus avoided.

The ground floors are to be bedded on 6 in. of Selenitic concrete laid to leave a clear 1 ft. air space underneath above the ground level. The cost is calculated, on estimates of work already executed, not to exceed an average of 200l. per cottage, exclusive of the value of gravel for concrete, which will be dug on the spot.

The architect is Mr. Ralph Nevill, F.S.A., and the original drawing was exhibited in the Royal Academy last year.

GATE LODGE, TUNBRIDGE WELLS.

THIS building contains four rooms, besides scullery and offices. Externally the ground floor, staircase, tower, and chimneys are of red bricks, the upper portion being, in front, half timbered with shingle-faced panels, and at the rear hung with red tiles. The roof is covered with brown tiles, the tower with lead.

The contractor was Mr. A. A. Gale, of Woking, and the architect Mr. Edwin T. Hall, of London.

ST. MATTHEW'S HALL, BRIXTON.

THIS building is a Mission Hall attached to St. Matthew's Parish Church. It is at the corner of Talma and Probert roads, between Brixton and Herne Hill stations.

It contains on the ground floor a small hall for lectures, work parties, night schools, &c., a retiring room attached; a committee room, a soap bar and kitchen, and a cloak room. The first floor consists of a large hall capable of holding about 300 people, with a retiring-room attached, and a cloak room. There are accesses to this hall from both roads.

The large hall has an open timber roof, the boarding left white, the rafters, &c., stained walnut and varnished; it also has a dado of brown glazed tiles; the walls will be of brown buff, and the other woodwork is sage green. The glazing above the transoms is in lead lights of pale cathedral glass with ruby horders.

The public rooms and vestibules are heated by hot-water pipes.

Externally the building is of stock bricks, relieved in parts with red brick; the strings, cornices and other drawings are of hox ground stone. The roofs are of green slates.

The cost of the building has been about 2,200l. The contractors were Messrs. Foster & Dicksee, of Rugby and London. The architect was Mr. Edwin T. Hall.

Kitwell's Park, Herts.—Extensive alterations have just been completed at Kitwells Park, Shenley, Herts. The hall has been altered and rearranged in Jacobean style, with new staircase, columns, dado, chimney-piece, and ceiling beams, all in oak, from designs by Mr. Reginald Pinder, F.R.I.B.A. New parquet floors have been laid down by Arrowsmith in the reception-rooms and hall, and the old fire-pieces fitted with Pidgeon Teale, and Nautilus grates, and oak Jacobean mantels. All sanitary fittings and baths of the most modern kinds have been put in, and the drains re-arranged on the disconnected and separately-ventilated system. Doulton's patent jointed pipes being used. The stables and model farm (including cow-houses, pig-styes, and poultry-pens) have also been fitted with the best modern appliances. Messrs. Boff Brothers, of St. Albans, has the contract for the work at the house, and Mr. Carter, of Shenley, that for the farm and stables.

CAMPANILE AT VARESE.

THIS is a sketch of the campanile which

Campanile, Varese.

dominates all other buildings in the old silk manufacturing town of Varese, a few miles from Lake Como. T. E. KNIGHTLEY.

THE BRITISH SCHOOL AT ATHENS.

THE first open meeting of the session was held in the library of the School on the afternoon of Jan. 1. The Director, Mr. Ernest Gardner, made a few preliminary remarks on the prospects of the School for the ensuing season. He said that the Committee had offered an exhibition of 50l. at each of the two Universities for the purpose of sending out students to work in Athens for a period of not less than three months; that a scholarship had been established in connexion with the School by

ST. MATTHEW'S PAROCHIAL HALL, BRIXTON, S.W.—MR. EDWIN T. HALL, F.R.I.B.A., ARCHITECT.

Magdalen College, Oxford; and that a special fund was being got together for the purpose of making a complete collection of drawings and studies of the remains of Byzantine architecture in Greece proper. He also mentioned that the surplus of the Newton Testimonial had been handed over to the School as a reserve fund, and that out of this considerable additions were being made to the collection of books in the library. Three students were already in residence, and four others were expected very shortly. In addition to these, two more were on their way to Cyprus to commence excavations on the important site of Salamis, on that island. Excavations would also be conducted this session by the School on Greek soil for the first time. The exact site had not been definitely fixed on, but negotiations were in progress.

Mr. Gardner then read a short paper on a fragment of a sepulchral stele in the museum at Argos, representing the head of a boy smiling, the date of which is fixed by the character of the inscription as fourth century B.C. He compared this head with that of a somewhat older boy found at Papho, in Cyprus, during the excavations carried on there the season before last under his superintendence, and he argued from the striking resemblance between the two heads, that the Papho one belonged also to the fourth century B.C., and not, as some archaeologists asserted, to the Hellenistic age.

Mr. H. A. Tubbs afterwards gave an interesting account of the excavations undertaken last spring at Poli, in Cyprus, by members of the School, under the auspices of the Cyprus Exploration Fund. These excavations were principally confined to tombs, and Mr. Tubbs described in detail the different varieties of the tombs opened, and their various characteristics. He mentioned that this site had previously been worked on to some extent by a private syndicate, and that Dr. Herrmann, of Berlin, had written a brochure on the subject. He criticised Dr. Herrmann's classification of these tombs according to the various forms of the *τρομος*, or approach, regarding these as no certain indication of date. He also pointed out the difficulty of classifying according to the articles found, and showed that the same tombs had been used and re-used at different periods.

Mr. Tubbs then proceeded to describe the pottery found in the excavations, the most distinctive form of which was the black ware, with raised ornamentation. As to the pottery generally, he showed the persistency of types, and the consequent difficulty of dating particular specimens. A detailed report of these excavations will shortly appear in the *Journal of Hellenic Studies*.

These meetings of the School will be held at intervals during the session, and, in addition, the Director proposes lecturing to the students in the museums and elsewhere.

THE ROYAL ACADEMY:

ADMISSIONS TO THE ARCHITECTURAL SCHOOL.
MR. R. PHÉNÉ SPIERS, F.R.I.B.A., the Master of the Architectural School of the Royal Academy, sends us the following list of students admitted this month, viz.:-

Upper School.

- A. E. Bartlett.
- C. H. Norton.
- B. F. Fletcher.

Lower School.

- C. W. Baker.
- R. A. Reid.
- C. Bywater.
- P. D. Smith.
- A. J. Edwards.
- J. S. Stewart.
- E. Gibson.
- G. Streetfield.
- S. M. Herbert.
- H. Tooley.
- H. L. Paterson.
- A. B. Yeates.

Probationers.

- H. P. Adams.
- C. Evans.
- W. E. Barry.
- F. Fellows.
- John Cogg.
- D. B. Niven.
- D. Blow.
- F. Rhoades.
- J. Borrowman.
- A. Dunhar Smith.
- A. W. Cleaver.
- D. C. Veasey.
- J. B. Ellison.
- H. H. Wigglesworth.

The Institution of Civil Engineers-- A new edition of the list of members of the Institution of Civil Engineers, corrected to the 2nd inst., being the seventy-second anniversary of its establishment, has just been prepared, from which it appears that the aggregate number of members of all classes is 5,804.

Some Old Wrought-iron Scraps.

SOME OLD WROUGHT-IRON SCRAPS.

OF the accompanying blocks, A is one of the very few remaining hour-glass holders. It is preserved in Wisley Church, Surrey. Its form should make it applicable to many purposes.

B is a bracket, of the same period, from Effingham Church, Surrey, and C is a hat-rail from the old church at Esher.

ELECTRIC WELDING.

THE electric welding of metals is a very perfect and reliable process. It can be now seen in operation at the small show works of the Electric Welding Syndicate at Hoxton. A display of the process as an experimental illustration was made at Professor Ayrton's lecture at Bath, on the occasion of the British Association meeting about eighteen months ago in that ancient city. The process was also investigated at the Paris Exhibition, and has been a subject of discussion at the Iron and Steel Institute. Prominence was first given to it by Professor Elihu Thomson, at New York, in 1887. The correlation of the physical forces--so concisely and ably elucidated many years ago by Sir William Grove, and which remains one of the brightest accomplishments of that eminent scientist's numerous labours--receives in electric welding one of its most recent and practical illustrations. In the factory at Hoxton, the visitor will see before him the furnace, the boiler, the steam-engine, the dynamo, the copper conductor, the "converter" and the massive copper clamps for holding the bars, pipes, or wires to be welded. Combustion or chemical change in the fuel produces heat; the heat is converted by the steam-engine into motion, the belt conveys this motion to the dynamo, and the revolution of the armature within its magnets converts that motion into electricity, and the current flows along the conductor until it meets with resistance at the intervals where the pieces of metal are placed for welding, and there the electricity is changed into heat. Thus, before our eyes we have the fifty horse-power of the engine converted into most intense local heat and fusing the contiguous surfaces of the two pieces of metal to be welded, so that by mechanically pressing them together they firmly adhere, and a weld surpassing anything the best smith could accomplish is performed in the interval of a few seconds of time.

How this wonderful transformation? To employ a vast current at a very low tension direct would be unprofitable, because the current could not easily be carried to any sufficient distance for handy application with large and costly conductors. To generate at the dynamo machine a current of high tension easily transmissible by a small conductor to long distances, and to convert that tension into quantity when it has arrived at its destination by a "converter," is the plan of the method. Everybody knows the Ruhmkoff coil

by the little toy instruments so very common. The "induction coil," as it is more generally known, has an iron core with a coil of covered copper wire round it. A small primary current of electricity at low tension magnetises the iron core, causing the emission in long sparks of a secondary current induced through the copper coil. If the construction of this induction coil were inverted, the high tension current received by such an instrument would be transformed into a quantity current at very low tension.

In the Hoxton works the electrical current leaves the dynamo at a maximum potential of 300 volts. But when the current reaches the "converter" it is transformed into a quantity current of perhaps some 4,000 amperes, at a potential of only 3 or 4 volts. The interruption of such a current produces enormous heat over a small locality where it is wanted for the work to be done, leaving the current in its changed condition harmless to life, although the electrical energy will probably be at the place of welding nothing under a total of 40,000 watts. By unseen correlations of physical forces, the whole work of that steam-engine is brought to bear upon the weld required to be made in a bar of steel 1 in. in diameter, an iron pipe 3 in. across, or a bar of platinum $\frac{1}{2}$ square inch in section.

By the introduction of a resistance grating the induced current can be modified in power to any extent, so that a metal which melts at 160 deg. of temperature can be as properly brought to its fusion-point, or welding-heat, as another metal requiring 3,000 or more degrees of heat for effecting the like purposes.

In this way the welding of many metals hitherto deemed intractable has been effected, or has become possible. Not only can wrought iron, hard steel, brass, lead, tin, platinum, gold, and cast-iron be welded, but different metals may be actually joined together.

Taking a practical view of electric welding, we have these important advantages:--The welding operation can be seen, and the weld is perfectly clean. The metal is not, as in ordinary smith's work, covered up by coal, with all the attendant risks of cinders getting into the weld; there is an absolute control over the heat as well as over the operation; the homogeneity of the metal, alike in the weld and in the mass of the article, is the same; and, finally, the rapidity and accuracy of execution.

Out of the numerous experiments we have witnessed, two were singularly noticeable,--the welding of a colliery steel-wire rope, and an excellent example of plate rivetting. In the former case, each of the two ends of the wire-rope were hound on an iron ferrule, and then the ends of the rope were filed quite smooth. They were then secured in position by the copper clamps and the current turned on. A perfect weld was speedily effected and the iron ferrules were knocked away.

In the rivetting quarter two inch-plates were placed properly together, and a cold rivet-blank put through the two contiguous holes. The

current was turned on, and in a few seconds the rivet-blank was glowing with white heat. The head-moulds were then pushed forward and the rivet-heads pressed up on both ends with the most perfect results. Afterwards, when it was attempted to cut the rivet-head away, it was found that the chisel could not be got underneath the head, the under-surface of the head being welded down upon the fiat of the plate, and consequently only a clean cut of the head right through could get it away.

At the present time we cannot speak with any accuracy as to the commercial cost of the process, but, without doubt, its value will be such for a great number of purposes that the advantages of its use will outweigh any questions of additional cost,—and those will probably not be such as really would stand in the way of its adoption.

THE HOUSING OF THE WORKING

CLASSES:

ASSOCIATION OF PUBLIC SANITARY INSPECTORS.

THE housing of the working classes was the subject of a paper entitled "Human Homes for the Poor," read at the monthly meeting of this Association, held on Saturday, the 4th inst. at Carpenters' Hall, London-wall, by the Rev. A. Robins, rector of Holy Trinity, Windsor, who has suffered a little martyrdom in consequence of his denunciation of certain Windsor tenements which are unfit for human habitation. The Chairman of the Council, Mr. Hugh Alexander, presided, and there was a large attendance, and in reply to invitations sent to the President of the Local Government Board, Lord Cross, the Earl of Aberdeen, and other prominent sanitarians, letters of regret were received. Mr. Ritchie wrote expressing pleasure that the question of better provision for the housing of the working classes was to be considered, because it was desirable that strong and sound public opinion should be formed in order that full effect might be given to the representations made in his recent circular to local authorities.

In spite of Royal Commissions, as the paper pointed out, and the appeals of philanthropists, the teachings of sanitary reformers, and the public indignation roused from time to time by such revelations as those of "The Bitter Cry,"* the horrible moral cesspools in which scores of thousands of human beings lived in London and various great towns, no corresponding action had been taken by the governing authorities to remedy the evil. The time had come when the nation must be told,—the State and the Church, too, must be told,—that to continue to neglect the question was to be guilty of "criminal indifference." If it was right to confiscate meat offered in the market when it was found unfit for human food, it ought to be considered justifiable to confiscate houses when they were found unfit for human habitation, and as the word "confiscation" might be Statesmen of all shades of politics had followed the sanitary reformers and the philanthropists in their denunciations. It was evident that horses, dogs, and cattle were better housed than their human attendants, that moral advancement was impossible, and that even the physical and mental stamina of the nation were endangered by the existing condition of things, and yet even the boldest seemed to touch the question with timidity. Why? A parson who ventured to cry out louder than his fellows got burned in effigy, and most men who came face to face with the evil became demoralised, paralysed, and dazed, on beholding its magnitude, and on becoming conscious of the fact that so many men, already rich and powerful, made profit and here out of the very horrors of the situation.

In dealing with the gigantic evils of the slums, powers not merely permissive but compulsory must be put into the hands of the proper officials, and the hands of these authorities must be fortified and strengthened. Too many vestrymen and municipal councillors were interested in the continuance of the evil for this power of initiating reforms to be longer left in the hands of such bodies. Before all else, the State must review, revise, and consolidate all Acts dealing with the Public Health, creating the sanitary inspectors officers of the State, and delegating to such officers,

not discretionary powers, subject to the pleasure and approval of local Sanitary Authorities, or Vestries, but compulsory, peremptory authority to deal with insanitary areas. A consolidated and amended Act must declare and define what constituted a house, and what a "human home" must be, what it should comprise, and what it should not comprehend. They would then have Imperial instructions, and such compulsory powers conferred as would enable them to carry them out with effect and authority. Facts with regard to the condition of insanitary houses at Windsor, vouched for by the reports of Dr. Airy and Dr. Taylor, and at Durham by Drs. Vance and Jephson, were adduced to show that while Mr. Ritchie said all the mischief resulted from the halting, hesitating, and unsatisfactory administration of local authorities, the latter retorted that they had no power to do what had been recommended by the Imperial authorities. Such a conflict of authorities must be rendered impossible. They must insist upon the substitution of the compulsory for the permissive principle, and the consolidation of all the Public Health Acts. All Medical Officers of Health must be Her Majesty's Medical Officers of Health, appointed to, and set over a city, or a town, or a district, and that they might be thoroughly disinterested, impartial, and independent, they should be disqualified from taking any private practice.

Such benefactions as that of Sir E. Guinness, noble and munificent as they were, would prove but a drop in the ocean. A question of such infinite magnitude as "the housing of the poor" could only be effectively dealt with by the State. The ways and means, through advances and loans at low interest, could be provided by the State without difficulty, and only the State could solve the difficulty.

In concluding his paper, the Rev. Mr. Robins said:—"A vast proportion of the dwellings of the poor are morally, socially, and physically slaughter-houses. What are they but shambles, for does not depravity destroy our poor within them hourly, and slay them day by day? A distinguished member of Parliament, who has himself a Bill before the House of Commons, wrote to me on Dec. 10 as follows:—"The present state of things is deplorable, and I must say I am not in any way satisfied with Mr. Ritchie's last circular. The real question remains: What is to be done with a Local Authority that will not perform its legitimate duties?" The only possible answer to that question is,—and I desire to set it before you with all the emphasis at my command,—all Medical Officers of Health and Sanitary Inspectors must be responsible only to the Local Government Board, and free of the control of municipalities and vestries, and the powers with which you are invested must be compulsory powers."

As an appendix to the paper, plans were attached of workmen's dwellings designed by Messrs. Knill Freeman & Robins, Newcastle-on-Tyne, with estimates for houses which would be in all respects "human homes," and another appendix contained suggestions by Mr. Stephen Wyborn, architect and surveyor, Windsor, with regard to the necessary improvements in that town. The proposed "homes" are of three types, costing respectively 220*l.*, 200*l.*, 150*l.*, and 135*l.*, according to the estimates of a local builder.

A discussion followed the reading of the paper, in which the Chairman, Mr. Sheffield (Poplar Board of Works), Mr. Mellonds (Windsor), Mr. E. C. Robins, F.R.I.B.A., and other gentlemen, took part. Mr. Mellonds said it was not quite correct to assert that nothing had been done at South-place, Windsor, to remedy the defects complained of. Besides much repairing and cleaning, ventilators had been inserted in the back walls of the rooms, and the tenants had shown their appreciation of this improvement by stopping them up. In summing up the discussion, Mr. Alexander, the Chairman, said a radical cure for the evils pointed out in the paper could only be obtained by an alteration of the Land Laws, by abolishing leaseholds, prohibiting the erection of dwellings with less than 20 ft. frontages, and prescribing that, where there were two rooms in depth, they should measure, from front to back, at least as much as from side to side. Every home, too, should have an open yard with an area at least equal to half that on which the house was built. The proceedings concluded by according to the reverend lecturer a vote of thanks.

THE REGISTRATION OF PLUMBERS.

The Registration Committee of the Worshipful Company of Plumbers, on the invitation of the Court, dined together at Cannon-street Hotel on the 2nd inst. The Master of the Company (Mr. W. H. Bishop), Mr. Philip Wilkins (Renter Warden), Mr. F. Machin, Mr. Alderman and Sheriff Stuart Knill (Past Masters), Mr. John Smeaton (Assistant), represented the Court.

The Master, in the course of his speech welcoming the Committee and reviewing the work of the past year, stated that the work of the examiners was heavier in 1889 than in a previous year by two-thirds. He referred to the necessity for specifying plumbers' work separately in building contracts, and making plumbers responsible for the sanitary efficiency of the whole of their work, from the roof to the main sewer.

Mr. C. Clegg, master plumber, in responding to the toast of "The Registration Committee," referred to the influence of the registration movement on the technical education of plumbers as "the grandest feature of the movement." He suggested that periodical exhibitions of work executed by apprentice plumbers and others should be held under the auspices of the Plumbers' Company.

Mr. L. F. Gilbert, operative plumber, expressed the growing confidence of himself as his fellow-workmen in the advantages which must accrue to the trade from the registration movement, and suggested that a special committee should be appointed to extend the working of the system in Western London.

Mr. Machin, Past Master, in proposing a toast of "The Examiners," referred to the responsible character of the work of the provincial as well as the metropolitan Boards of Examiners and its interest for the inhabitants of the whole kingdom.

Mr. John Smeaton, master plumber, in replying, referred to the recent examinations he had attended at Dublin and Liverpool, remarking that he considered the work of the candidates was fully equal to the average in London, and that some of the specimens of modern plumbing work he had seen in Dublin were of a most superior character. He approved the suggestion of holding periodical exhibitions of plumber work as tending to create healthy emulation among the members of the craft, and he referred to the considerable cost which this and the further development of the Company's educational system would necessarily involve.

Mr. W. H. Webb, master plumber, said that older men in the trade were encouraging the younger men to present themselves for the Company's Examinations.

Mr. R. J. Lyne, operative plumber, said that Dublin members of the United Operative Plumbers' Association were heartily in accord with the examination system, and that they considered it was the only means of protecting the public against "botchers."

Mr. Wilkins, Renter Warden, in proposing the toast, "The Teachers of Technical and Scientific Plumbing," referred to the report made by Mr. Lyne on the exhibits of plumber work in the Paris Exhibition, and the extension of technical education among French plumbers.

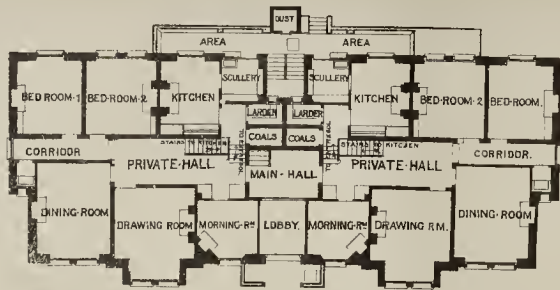

Mr. J. W. Clarke, foreman plumber, said that Plumbing Classes at the Polytechnic were making steady progress, and he found that prizes offered by the Plumbers' Company acted as a considerable incentive to the students. He announced that additional money prizes had been offered by Mr. Titmas, Mr. Clegg, Mr. Hume, Mr. John Smeaton, and Mr. Bostel. He laid much stress on the importance of free-hand and mechanical drawing being taught in Plumbers' Classes.

Mr. Mills, Superintendent of the Trade Classes at the Finsbury and Westminster Institutes, said they found a great impetus had been given to the whole of the trade classes at the Institutions by the action of the Plumbers' Company in promoting classes for plumbers. He pointed out that it was necessary to have separate classes for adult plumbers, mentioning that a class of the kind was held at Westminster. He referred to the course of lectures on Technical Education, specially suited to plumbers, delivered in Dublin, and recommended similar lectures being delivered in other parts of the Kingdom.

Mr. Browning, Teacher of Plumbing Classes at Chelsea, Lambeth, and Clapham, said that practical work of the students was better in the

* Long antecedent to which, however, were the revelations made in the *Builder*, by the late Mr. George Gowlin.—Ed.

PHOTO LITHO SPRINGS 21 & 22 MARSHES LANE CAMDEN ST LONDON 1

Last session than in any previous one. He recommended mutual improvement classes for adult plumbers, who would be both interested and benefited by practical discussions on the details of their trade.

A letter was read from Mr. Emptage, master plumber, of Margate, regretting that he was prevented by illness from being present, and congratulating the Plumbers' Company and the Registration Committee on the growing interest of the public in sanitary matters, and the hearty support which is being accorded to the registration movement by the trade and the public in all parts of the kingdom.

ARCHITECTURAL SOCIETIES.

The Royal Institute of British Architects.—A special general meeting of this Institute (for members only) will be held on Monday next, Jan. 13, to consider a recommendation of the Council, that the form and alternative form of Articles of Pupilage, submitted to the annual general meeting held on May 6, 1889, be printed and published as an Institute Paper, with this modification—that in place of the word "Architect," as descriptive of the "Principal," a blank be left which may be filled in with the words "Architect" or "Architect and Surveyor," as the party or parties may please; and that a note to this effect be printed in the margin against each of the three places in which the word "Architect" appears in each form. On the same evening, at the close of the meeting above-mentioned, a business general meeting (for members only) will be held for the following purposes:—To read the minutes of the ordinary general meeting held on Dec. 16, 1889; to announce donations of books, &c.; to formally admit members attending for the first time since their election; to ballot for candidates who desire to be admitted as Fellows; to elect, under the terms of by-law 9 (b) candidates who desire to be admitted as Associates; to receive the announcement of the award of the studentships and prizes for 1889-90, made by the Council (in accordance with the terms of By-law 66) in writing under the common seal; and, on the motion of Mr. Wm. Woodward, Associate, to consider the "Sundry Powers and Provisions" portion of the London Council (General Powers) Bill. A public exhibition of all the designs, drawings, sketches, &c., submitted for the studentships, medals, and other prizes, 1889-90, will be held in the larger Conduit-street Gallery daily, until Monday, the 20th inst., at 10 p.m.—the Exhibition meanwhile opening at 10 a.m. and closing at 9 p.m. every day. The drawings and sketches made by the Soane Medallist 1888, the Owen-Jones Travelling Student, 1889, and the Pugin Travelling Student, 1889, will also be on view during the same period.

The Architectural Association.—The sixth meeting of this Association for the present session was held on Friday, the 3rd inst., in the meeting-room of the Royal Institute of British Architects, Conduit-street, Mr. T. E. Pryce (Vice-President) in the chair. The following gentlemen were elected members, viz.:—Messrs. G. Stephenson, J. H. Mann, P. Field, P. F. C. Smith, A. E. Seaman, T. Parker, and W. Stewart. Mr. Sydney B. Beale then read a paper on "Spires, Towers, and Domes," the first part on which we print on another page.

Birmingham Architectural Association.—At a meeting of this Association, held on Tuesday evening last, Jan. 7, Mr. W. H. Lloyd, Vice-President, being in the chair, a paper was read by Mr. F. B. Andrews, A.R.I.B.A., on Pershore Abbey. The paper was based on special interest by the very full manner in which it was illustrated by drawings and photos. Of the history of the Abbey, Mr. Andrews said that much was veiled in obscurity, owing greatly to the fact that fires had been of frequent occurrence in the Abbey, destroying, with much else of value, the record of its early years. Various authorities fixed the date of its foundation in 604, 681, 689 A.D., and other dates in the seventh century, of which 618 seemed that most probably correct. It was at first dedicated to SS. Mary, Peter, and Paul, and given to the secular canons, but finally became the Benedictine Abbey of SS. Mary and Edburga. Records are found of its restorations after fires in the years 1020, 1056, 1102, 1223, 1288, the fire in the last-named year reducing nearly the whole abbey to ashes, together with the town of which it was the central building. The remains at present

existing are the choir, choir aisles, south transept and transept tower, and two small chapels north and south of the choir, and sufficient remains of the foundations have been traced to define the form of the Lady Chapel, nave, north transept, cloisters, Abbot's lodge, fratry, common room, and chapter-house. The south transept, built a few years before the Conquest, is the earliest part of the remains, and the nave and lower part of the tower are of the eleventh century, the Lady Chapel of the thirteenth century, and the lantern and belfry stages of the tower of the fourteenth century. The south transept has a small vault of fourteenth century work, hearing amongst others the arms and rebuts of Abbot Newton, 1413-1456. The choir has a semi-hexagonal plan at the east end, though the surrounding ambulatory and the Lady Chapel appear to have been square on plan. The tower is of special interest, from the very marked resemblance, pointed out by the late Sir Gilbert Scott, which it bears to the tower of Salisbury Cathedral, for though comparatively simple in its detail, the belfry stage is throughout a plainer version of the first stage of the fourteenth-century work in the Salisbury tower, and the lantern is an absolute translation into the later work of the thirteenth-century lantern at Salisbury. "The details," says Sir G. Scott, "bear considerable resemblance, the distribution of windows, blanks, and piers is absolutely identical, and so also are the very remarkable bands, quatrefoils, &c. While speaking, however, of the details as being simplified from those at Salisbury, I must except the internal features of the lantern. . . they are far richer and more beautiful; indeed, I scarcely know of a lantern story so beautiful, and it stands, as far as I know, quite alone in its design." In conclusion, Mr. Andrews mentioned the many interesting buildings which surround Pershore, and which, with the Abbey, make the neighbourhood of singular interest to the architect. A hearty vote of thanks was accorded to Mr. Andrews, on the motion of the Chairman, supported by Messrs. Cotton, Doubleday, Bidlake, and H. R. Lloyd.

Liverpool Architectural Society.—The fourth ordinary meeting of the Liverpool Architectural Society was held on Monday evening last, January 6th, the President (Mr. T. Mellard Reade) in the chair. A paper was read by Mr. James L. Thornely entitled "Monumental brasses" with special reference to those of Lancashire and Cheshire. The lecturer, who exhibited a fine collection of rubbings, began his paper by defining a monumental brass, so far as dealt with on this occasion, as a figure or effigy engraved on a brass plate with or without accompanying canopies, inscriptions, or other ornaments, and proceeded to class the examples roughly under five periods, and dealt briefly with the leading characteristics of each, illustrating his remarks by numerous beehall rubbings, which comprised a fairly representative collection of brasses of ecclesiastics, knights, ladies, and civilians. He also pointed out that the early brasses (many of them of Flemish manufacture) were much larger and more bold and free in design than the later, and mentioned that after the introduction of shading by means of cross lines, the vigour and worth of the brasses gradually declined. He further alluded to the former practice of enamelling the brasses, to represent the colouring of heraldic bearings, &c, thereby greatly enhancing them in richness of effect; also to the handsome canopies to be met with in many examples; he pointed out that the various Norman Gothic styles and their transitions can clearly be traced in these portions of the brasses. Mr. Thornely further referred to the curious but discreditable practice of making palimpsest brasses, i.e., reversing an old brass and utilising it to commemorate a subsequent deceased person. He further referred to the devices or marks to be met with upon some brasses indicating the private or company trade-mark of the engraver, and pointed out that companies or fellowships of brass-workers used to exist. In conclusion, after calling attention to the scarcity of brasses in Lancashire and Cheshire, compared with the southern and eastern parts of England, the lecturer referred to rubbings of the following local brasses:—In Cheshire: Sir Rogers del Bothe and Lady Duke, his wife, at Wilmslow; Roger Legh and children, Macclesfield; and a civilian from St. Peter's Church, Chester. In Lancashire: Piers Gerard, and Sir Peter Leger and his lady, at Winwick, near Warrington; a

knight of the Scarisbrick family, Ormskirk; Ralph Catteral, wife and children, from Whalley; Henry Norris, and Clemence his wife, from Childwall, near Liverpool; and Thomas Beri, from Walton-on-the-Hill.

"A QUESTION OF DISTRICT SURVEYOR'S FEES."

HAYWARD v. SANDON BROTHERS.

It will be remembered that in this case Mr. C. F. Hayward, District Surveyor of St. George's and St. Giles's Bloomsbury, sued Messrs. Sandon Bros. to recover an amount of £56. 5s. as fees due to him as District Surveyor upon the erection of the above premises, which consist of four shops and two sets of chambers on the ground-floor, one set of chambers and box-rooms on the basement-floor, and eight sets of chambers on the upper floors, all the latter approached through an entrance, and having one staircase, and being let as separate tenements.

When the matter was brought before Mr. Bridge at Bow-street, on October 4, 1889, he decided in favour of the District Surveyor, upon which Mr. Edward Morten, counsel for the defendants, gave notice of appeal, as his contention and that of Mr. W. Sockham Witherington, defendant's architect, was that sec. 27, rules 1, 2, and 3, applied only as to the "separation of buildings and the limitation of their areas," and not to fees which are settled under sec. 49, schedule 2, part 1, as not to exceed £10. Leave to appeal was given, and Mr. Bridge suggested that Mr. Morten should draw the case, and that it should be approved by Mr. Hayward it should be submitted to him for signature.

When, however, the parties appeared before Mr. Bridge, Mr. Hayward claimed his fees under sec. 27, rule 2; but his solicitor, in approving the case, inserted also rules 1 and 3. Mr. Bridge objected to rules 1 and 3 being mentioned, unless facts could be shown showing what sum Mr. Hayward would be entitled to if rule 3 applied to the question of fees. These could not be arranged, and Mr. Morten pressed the magistrate to state the case under rule 2.

Eventually the magistrate declined to state any case, and the summons was dismissed, Mr. Hayward's solicitor advising him not to take one under rule 2.

No order as to costs was made.—Communicated.

THE ASSOCIATION OF PUBLIC SANITARY INSPECTORS OF GREAT BRITAIN.

SIR,—At the adjourned meeting held on December 21, 1889, the following resolution was passed, and afterwards referred to the Council for consideration:—"That the Council of the Royal Institute of British Architects be asked to define the present status of the Sanitary Inspector; and, having regard to the obvious intentions of the Sanitary Acts of Parliament, the experience of their working since acquired, and the duties actually devolving upon such officers, to further define what ought to be the qualifications of candidates for the said office." The Council are of opinion that the step proposed to be taken by that resolution is an important one, and that such a course should only be taken if approved of by a majority of the members of the Association and its branches, and, therefore, measures are being taken to obtain that opinion. The Council also will be pleased to receive observations thereon from any Sanitary Inspector, though he may not be in membership, as it is upon a matter which equally concerns all Sanitary Inspectors.

SAMUEL C. LEGG, Hon. Sec.

January 8, 1890.

THE MONTROSE MONUMENT.

SIR,—In the notice of the Montrose Memorial, illustrated in your issue of the 4th inst., after stating that Messrs. J. and W. B. Rhind are the sculptors of the monument, you make what seems to me a most unnecessary remark, viz., "so we are informed, though we do not well understand how two sculptors can be joint artists of one figure." My son, W. Birnie Rhind, I have trained as a sculptor, and for the last ten years he has been associated with me in many of my principal works, in addition to what he has been commissioned to execute in his own name. If it is possible for two architects jointly to design a work of art in the shape of a public building, why may not two sculptors combine their efforts in executing a public monument?

JOHN RHIND.

* Partnership in architectural work is not by any means a parallel case. As far as pure design in architecture is concerned, we should say the same as of sculpture—it must be the work of one mind; but the carrying out of a building includes a great many other things—arrangement of plan, details of construction, warming and ventilation, which one

partner may elaborate separately. A partnership association in such a thing as a work of sculpture would appear to many, as it does to us, to savour more of art-manufacture than of art.—Ed.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—II.

MAGNETS.

MAGNET possesses two characteristic properties: (1) if suspended at the earth's surface, so as to turn freely about a vertical axis, it will in general tend to set itself in a certain azimuth, and if disturbed from this position will oscillate about it; (2) it will attract certain substances: iron, steel, lodestone, and nickel among others.

Any substance capable of being attracted by a magnet is called a magnetic substance. All magnets are made of magnetic substances, but all magnetic substances are not capable of becoming permanent magnets; if they are, some, at least, form exceedingly feeble ones. Although magnets may be made of any shape and of a variety of substances, in practice they are made from rods of hardened steel in the form of a bar or bent into the shape of a horseshoe.

The force of attraction of a magnet varies greatly at different points of its surface. It is greatest near the ends, and sinks to zero at the centre of a uniformly-magnetised rod. The points on a magnet where the attractive power ceases are called its neutral points. Near the ends of a magnet where the attraction is greatest, the force seems to spring from two points, called the poles of the magnet.

When dealing with problems concerned with gravitation,—that is, the attraction of one piece of matter for another,—it is frequently useful to conceive the whole of the matter in a body concentrated at one single point. A sphere, for instance, attracts bodies placed outside it precisely as though the whole of its mass had been concentrated at its centre. This point is simply a centre of forces, and, as such, is of enormous importance mathematically, but physically the centre point of the sphere differs in no way from any other point in it.

The poles of a magnet are nothing more than centres of magnetic force, and differ physically in no way from other points in the steel throughout the mass of the magnet. At the same time it is frequently useful to speak as though all the magnetism of magnets, whatever magnetism may be, were concentrated at these two points, and the steel rod merely served as a metal framework holding these two points of magnetism.

It is of importance to call attention to this at the outset, as the poles are so often referred to that students are apt to get in the habit of thinking that the constitution of a magnet at its poles differs from its constitution at any other point.

It is a line joining the poles of a magnet, called the axis, which points magnetic north and south, a direction which is in London some 15 deg. west of true north, called the declination of the compass-needle. The end of the magnet which points to the earth's north pole will be called the north end, and the end which points to the earth's south pole, the south end, the poles of the magnet being respectively called north and south. The facts that the two poles of a magnet are equal in strength and that like poles repel each other while unlike poles attract, besides many other points of similarity between magnetic and electrical effects, led early investigators to suggest fluid theories of magnetism similar to the old fluid theories of electricity. The probable nature of magnetism will be explained in a future article, for the present it is enough to state that there are no sufficient grounds for believing in the existence of magnetic fluids. On the contrary, there is every reason to believe that such fluids do not exist.

If a magnet is broken into any number of pieces, or even ground to powder, each little fragment is a complete magnet with two equal poles, and possesses all the properties of larger magnets. This has led to the belief that each molecule of the substance of which a magnet is composed is a complete little magnet, and that the various effects produced by a magnet, as a whole, are due to arrangement of these molecular magnets.

The experiments of Professor Hughes, published in 1888, have done much to confirm this belief, and to show the various arrangements the molecules of a magnetic substance can be made to assume under suitable treatment. When a piece of iron or steel is in an unmagnetised state, the molecules are, nevertheless, magnetised, and arrange themselves in closed polygons (fig. 2), the north pole of one molecule

Fig. 2.

sticking to the south pole of the next, and thus neutralising each other's external effects.

Fig. 3.

When the metal is magnetised, a certain number of the closed polygons, fig. 2, split up, and the molecules place themselves end to end, fig. 3, the north poles all facing one way, the south poles in the other direction. Fig. 3 shows also how the unneutralised north poles of the molecular magnets form the N pole of the magnet as a whole, and make it appear that magnetism is concentrated at the pole of the magnet, the same, of course, applying to the S pole. Coercive force, the power which enables a magnetic substance to become a permanent magnet, depends upon the degree of freedom with which its molecules can turn. A magnetic substance under external magnetic influences may have a certain proportion of its molecules arranged as in fig. 3, when the external influence is withdrawn, they will tend to re-arrange themselves as in fig. 2, and whether they will do so or not,—that is to say, whether the substance will cease to be magnetised or not,—depends upon the ease or difficulty with which the molecules can turn. In soft iron the coercive force is excessively small; it can therefore be magnetised very easily, but cannot unaided remain a magnet. In steel, on the other hand, coercive force is great; it is harder to magnetise, but, when once magnetised, the molecules retain their positions, and a permanent magnet is the result.

The quantity of a thing can always be measured by measuring the quantity of some effect it produces, without necessarily knowing the precise nature of the thing measured.

If the poles of two magnets are presented to each other there is attraction or repulsion, and this effect is made use of for defining what is meant by a "pole of unit strength," or "a unit pole." Unit magnetic pole is that pole which, placed at a distance of one centimeter from a similar and equal pole, repels it with a force of one dyne.* Coulomb showed that the force between two magnetic poles varies directly as the product of their strengths and inversely as the square of the distance between them. Hence, by the above definition, if m_1, m_2 are the strengths of two poles, d the distance between them in centimeters, and F the force acting in dynes:—

$$F = \frac{m_1 m_2}{d^2}$$

Although it is impossible to get, say, a north pole without a south pole, the south pole may be moved off to as great a distance as we please by making the magnet long enough. We shall frequently, therefore, speak of a north pole as though it could have a separate existence.

If a movable pole is put anywhere in the region round a magnet, it experiences a force urging it in some direction. Each of the poles of the magnet acts on the movable pole with a certain force, and the direction of the resultant of these two forces is the direction in which the pole is urged.

If the pole is allowed to move, it will trace out a "line of force." A line of force is, therefore, a line such that its direction at any point is the direction of the resultant force at that point. In the present case, magnetic lines of force are meant, dealing with the force produced on a magnetic pole as such; but the definition

* If a force of one dyne acts in the same direction on a mass of one gramme for one second, it produces in it a velocity of one centimeter per second.

will, of course, apply to force, no matter how produced, nor on what it acts. Now since the movable pole, unless screened in some way from the action of the magnet, experiences force wherever it is put in the region round it, this space must be filled with "lines of force"; such a region is called a "field of force." A field of force consists of an infinite number of lines of force. The positive direction, or simply direction, of a line of force is the direction along it in which a north pole would move.

If the direction of a line of force at any one point is required, it can be found by freely suspending a little magnetic needle at that point, when it will lie along the line of force passing through it.

Lines of force can almost be said to be made visible by means of iron filings. If a card be placed over a magnet, or in any field of force, and filings shaken from a muslin-bag on to it, the filings become magnetised in the directions of lines of force, and stick together end to end so as to trace out the contour of the field. A few of the beautiful figures so easily obtained in this way will give students an idea of the distribution of lines of force around magnets and systems of magnets that no mere explanations can ever convey.

Books.

A History of Warwickshire. By SAM. TIMMINS, F.S.A. Elliot Stock.

MR WILLIAM DUGDALE'S history of

"That shire, which we the heart of England well may call," is not to be found on many bookshelves, and even when found will not supply all that the modern reader requires. To begin with, it is nearly two-and-a-half centuries old; and, though the edition published by Dr. Thomas in 1730 contains some additions and corrections, we shall look in vain therein for anything but ancient history. The development of Birmingham belongs chiefly to the latter half of the last century, and to the period following the incorporation Charter of 1836; while Leamington, now an important town, owes much of its prosperity to Dr. Jephson, albeit Mr Timmins passes him over unnoticed. Strangely enough, the town of Rugby meets with the same neglect at his hands. Except as the birthplace of Matthew Hobbes, the historian of English Gothic architecture, and as the scene of Dr. Arnold's labours, the place is scarcely mentioned, though its growth has been remarkable. Perhaps an excuse may be suggested by the fact that Mr. Timmins is an antiquary, and that his interest lies chiefly in the past. To him—as in some degree to others also—Stratford-on-Avon is the principal town in Warwickshire, and all that relates to Shakespeare of paramount importance. But Mr. Timmins' sins of omission are not confined to the above examples. In any list of the "Worthies of Warwickshire" we should expect to find the names of the late Mr. Evelyn Shirley and Mr. Chandos Wren Hoskyns. The former,—a genealogist of the first rank (the original of Mr. Ardenne in "Lothair")—was a Warwickshire man to the backbone, and the latter made the county his home after his marriage with the ultimate heiress of Sir Christopher Wren, and wrote at Wroxall Abbey his fascinating "Chronicles of a Clay Farm." We have looked in vain for some other well-known names, but are bound to add that, nevertheless, small as the county is, its list of eminent natives or residents is unusually long. Drayton certainly, and perhaps Will Somerville, may claim a place in the class which Shakespeare heads, and among authors whose fame is neither local nor fugitive we may surely place Addison, Landor, Arnold, and "George Elliot," besides the never-to-be-forgotten Durdale.

If we turn from persons to places, Warwickshire can boast of a goodly number of historic sites and spots of interest. First there is Stratford (whose memories attract more pilgrims than Becket's shrine ever drew). Then Warwick Castle, mainly rebuilt in the 14th century, is full of interesting relics. "The entrance gate," says Mr. Timmins, "only a few years ago, had some of the hooks from which wool-sacks were said to have been suspended to protect the wall from attacks during the great Civil War. The great inner gateway, with its double portcullis and machicolated tower, is an excellent object-lesson of the art of war four centuries ago." But even Warwick, in spite of the grandeur

which has survived the vicissitudes of fortunes, must yield in interest to the ruins of Kenilworth, and to those especially whose knowledge of English history is derived from the Waverley Novels, its picturesque remains will recall many a romantic scene. It does not come within our province to discuss the story of Amy Robsart, if Kenilworth was not her prison, it was certainly that of Edward II. centuries before, and within its walls Leicester's grand tournament in 1268, and Queen Elizabeth's magnificent reception in 1562, were held. Martock Castle lies outside the tourists' beat. It is an excellent specimen of an Edwardian fortress, and has undergone comparatively trifling changes in its external appearance. It lies low, and is surrounded by a moat, across which access to the great court is gained through a gateway, between two lofty hexagonal towers. Tamworth is less pleasing, and, in fact, is little more than a solid square block of masonry, but its very simplicity proclaims its high antiquity. Astley Castle, built of red and grey sandstone, belongs to a much later period, and, though castellated in appearance, is in other respects an Elizabethan dwelling-house. Of far higher interest is Compton Wynayates, built in the early part of the sixteenth century, and in its main features, still unaltered. Mr. Timmins does it only justice in describing it as "a marvellous and artistic combination of stone, wood, and brick." The chimneys alone are a study, and the carved oak work in the rooms and galleries is wonderfully well preserved. No doubt Compton Wynayates owes its preservation to its secluded position, and we can see in its immunity from destruction the reason which impelled builders in olden times, when castles ceased to be erected, to select unobtrusive sites. Equally well preserved, but of smaller size, is Badesley Clinton, a moated manor-house of the latter part of the fifteenth century, which still remains in the same family,—the Ferrers family,—to which it owed its erection. Upon what principle Mr. Timmins has excluded from his book all notice of Aston Hall we are unable to say. It is true that the house and its surrounding park have been purchased by the Corporation of Birmingham, and most of the latter has been built over, but the mansion still stands, and has not wholly ceased to deserve Digdale's encomium: "A noble fabric, which for beauty and state much exceedeth any in these parts." Those who desire to study its features, and compare its plan with that of Compton Wynayates, should consult an excellent work, entitled "Illustrations of old Warwickshire Houses," published some ten years ago by Mr. Niven. We have left ourselves too little space to speak of the churches of the county. Coventry,—that city which is perhaps more full of old buildings than any other in England,—still boasts its "three spires" (though one of them has been perilously near destruction), and we are glad to hear that the "restoration" (we dread the word) of St. Michael's Church has been carried out "with excellent judgment and good taste." We are not great admirers of this great church, with its enormous windows and unsymmetrical form, but the group of buildings of which it is the most prominent member is almost unsurpassed. St. Mary's, Warwick (with the Beauchamp Chapel), the Parish Church of Stratford, Temple Balsall and Colehill churches are well worth notice, but the Midland Counties cannot in this respect vie with the Eastern.

We have not hesitated to point out the defects which we have noticed in Mr. Timmins' volume, but gladly add that both it and the series to which it belongs are of genuine value, and will, we believe, help largely to remove that ignorance of their own land which is a reproach to many of our countrymen.

The Thirlmere Water Scheme.—It is understood that the contract for the work to be done at the foot of Thirlmere Lake in building the dams and diverting roads, &c., in connexion with the Manchester Waterworks has been let to Messrs. Griesenthwaite, Penrith, and Beatty Brothers, Carlisle. The contract is about 120,000*l.*, and in a few weeks it is expected that over 1,000 men will be employed.—*Manchester Courier.*

Results of Auction Sales in 1889.—From extracts from Estate Exchange Registers we learn that the amount of auction sales of property reported to the 31st ult. was 4,218,274*l.*, or, with private contract sales, 4,304,954*l.*, as against 4,417,840*l.* in 1888, 3,989,099*l.* in 1887, and 4,120,044*l.* in 1886.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

12. Instantaneous Grip Vices. J. Singleton.

According to this invention, on the spindle of cabinet-makers' or joiners' vices a collar to join up to the neck of the loose jaw, such collar being for the purpose of drawing out the loose jaw of the vice. A fixed collar is placed upon the spindle to secure one end of the spring placed upon the shafts. The shaft is threaded or screwed so as to fit the hex nut, and by this and other mechanical details the articles are firmly secured in the jaws of the vice. Or instead of the cam being threaded the nut is made in the form of a boss with a solid collar so as to fix on a loose cam, secured by a loose collar, so that the cam can be worked without interfering with the screw part.

15. Lock Knobs. W. H. Bird.

By this invention a metal nut with an internal screw thread moves upon a suitably threaded square lock spindle. This nut has formed upon its circumference a groove into which a dot or a notch attached to the neck of knob closes when in position.

26. Ships' Berths. E. Lawson.

This invention consists in a modification of the ball-bearing used in fitting ships' berths, and is so made turning on bosses or joints, that the rail may be turned up out of the way when not in use, and can be readily removed from the berth when necessary, or can be applied to either end of the berth, if wished.

35. Ornamental Glass Tablets, &c. G. Fyfe.

According to this invention, the surface of the glass is coated with a preparation of isinglass and gold applied. A transfer is then taken from a litho stone, and put on the work before the medium dries. The hack of the transfer is then washed away, leaving the design upon the glass.

107. Wheelbarrow Bodies. J. W. Sankey.

The bodies of the harrows are, according to this invention, stamped in one piece out of a flat plate, the corners being gathered or puckered so as to give the necessary slope or taper to the body, and the surplus metal at the corners is taken up and utilised.

123. Keys or Wedges for Railway Chairs, &c. S. Danrchesky.

This invention relates to wooden keys, which, having some advantages to balance the disadvantages they possess in shrinking and becoming loose in dry weather, are extensively used in railway work. They are simple and readily procurable, holding the rail both laterally and vertically in the chair; they are also elastic and reserve their original dimensions after having been subjected to a heavy compressed force. The key, which is the subject of this patent, is of wood and metal,—a joint key,—and is provided also with a suitable appliance for preventing it dropping out of the chair owing to vibration or shrinkage.

147. Locks. W. Kneen.

The levers of locks are actuated by weights or gravitation instead of springs. The levers or tumblers are made with a weighted end, and the bolt also slides upon an incline, and by its own weight falls into a position for latching or locking the door.

198. Hydraulic Lifts or Hoists. A. A. Vulgrier.

Lifts are generally arranged to rise in a vertical direction. The common centre of gravity of the platform and the load never coincides exactly with the axis of the hydraulic cylinder or with the resultant of the hydraulic pressure if there are several cylinders. The platform is, therefore, subjected to a strain, the moment of which cannot be balanced except by horizontal reactions which, according to the nature of the construction, are either entirely derived from the guides along which the platform rises and falls, or partly from the guides and partly from the packing of the hydraulic cylinder. These reactions produce friction and jamming in certain cases, sufficient to entirely stop the motion of the lift. Instead, therefore, of the axis of the hydraulic cylinder being arranged vertically, it is inclined at a considerable angle, while the platform remains horizontal, suitable guides and wheels being fitted to assist the easy movement.

213. Portable and Collapsible Reading-desk. E. Pillow.

The board of this reading-desk is hinged and folded, and, when open, is inclined. It is provided with spring-clips for holding the book in position; provision is also made for keeping pens and pencils, and a small lantern may be fixed when the desk is used by a lecturer who desires to signal instructions to an assistant or operator.

282. Conduits for Electric-Mains. F. Coates.

By this invention it is proposed to lay conduits in such a manner as to avoid to a great extent the breaking or opening-up of the pavement or roadway when the mains are once laid, and thereby to avoid interfering with the traffic and to facilitate the repairs to mains by constructing the conduits in such a way that they may be easily opened and closed, at the same time providing the conduits

with suitable locks or fastenings to prevent their being tampered with. They are made in stone, earthenware, or cement, and placed at the side of the kerb or roadway.

* * In consequence of the Patent Office authorities not having issued the "Official Journal of Patents," we are compelled to hold over the "New Applications, &c.," till next week.

MEETINGS.

MONDAY, JANUARY 13.

Royal Institute of British Architects.—Special general meeting of members only, to consider the question of "Articles of Pupillage," followed by a business general meeting (for members only) to ballot for new members, to receive the announcement of the awards of studentships and prizes, and to consider the "Sundry Powers and Provisions" portion of the London County Council (General Powers) Bill. 8 p.m.

Royal Academy of Arts.—Prof. J. E. Hodgson, R.A., on "The Old Masters' Exhibition of 1890." III. 8 p.m.

TUESDAY, JANUARY 14.

Institution of Civil Engineers.—Mr. G. F. Lyster on "Recent Dock Extensions at Liverpool." 8 p.m.

Society of Biblical Archaeology.—Anniversary meeting. 8 p.m.

WEDNESDAY, JANUARY 15.

Society of Arts.—Adjourned discussion on Sir Robert Rawlinson's paper on "London Sewerage and Sewage." 8 p.m.

British Archaeological Association.—Mr. A. S. Canham on "The History of Crowland: its Charters and Ancient Crosses." 8 p.m.

Institution of Civil Engineers.—Students' Visit to the Sewage Works at Crossness. (Train to Abbey Wood leaves Charing-cross at 12.20 p.m.)

Architects' Foremen and Clerks of Works Institution.—Annual Meeting. 8.30 p.m.

Inventors' Institute.—(1) Mr. S. J. Mackie on "Lessons Deducible from Recent Fires." (2) Several short descriptive papers will be read on "Inventions for Minimising the Dangers of Fires, and Saving Human Life." 8 p.m.

THURSDAY, JANUARY 16.

Royal Academy of Arts.—Prof. J. E. Hodgson, R.A., on "The Old Masters' Exhibition of 1890." IV. 8 p.m.

FRIDAY, JANUARY 17.

Architectural Association.—Discussion on the Progressive Examinations of the R.I.B.A., to be opened by Mr. Arthur Cates. 7.30 p.m.

Bradford Historical and Antiquarian Society.—Mr. W. Scruton on "Some Fragments of Bradford History." 8 p.m.

Miscellaneous.

Messrs. C. Leary & Co's Annual Circular on Hard Woods states that the hard wood trade of London has had a full share in the general improvement of business which has characterised the year 1889. Apart from a period of stagnation during the dock strike, the record is distinctly satisfactory, a large volume of trade having been combined with a generally good, though not unduly inflated standard of values. At the same time, it is undoubtedly a fact that the business passing through London would be considerably greater if the facilities for handling goods were equal to those afforded by other ports. As to East India teak, the stock of timber and plank is 60 per cent. larger than at the close of 1888, and there are besides 3,750 loads, recently arrived, yet to be taken into account. The tonnage afloat and under charter to load is 32,678 and 24,119 respectively, against 19,468 tons afloat and 25,360 tons to load at the beginning of 1889, but a large number of cargoes are already sold. The year just closed has been remarkable for the imports into Europe having been the largest on record, and for the great activity in the ship-building and rolling-stock industries, which, moreover, promises to continue for some time to come. The market has been in a good position during the greater part of the year, importers not having been under necessity to force sales, and the business in floating cargoes has been very large, and at good prices. Heavy arrivals during the last three months have somewhat unsettled the market, and the tone is less satisfactory. Cargo quotations are 12*l.* to 13*l.* per load.

Resident Engineer for the Bible Works.—The *Manchester Courier* reports that on Monday a meeting of the Bible Committee was held at the Town Hall, Preston, for the purpose of interviewing the six selected candidates who had applied for the position of Resident Engineer to the Bible works. The applicants were reduced to three—Mr. A. F. Fowler, Navigation Engineer to the York Corporation; Mr. Archibald Hamilton, Resident Engineer to the new works on the Clyde Navigation Trust; and Mr. John Stirral, chief assistant to Messrs. D. & T. Stevenson, engineers, Edinburgh.

Messrs. Foy, Murgan, & Co.'s Annual Wood Report, 1889.—Messrs. Foy, Murgan, & Co., in their annual report, say:—"The past year, while not leaving importers as good a result as the one before it, has still been marked by a certain firmness in prices, and although the highest f.o.b. figures of the opening months were not quite maintained, the abatement was neither general nor serious, although at the same time sufficient to enable shippers to realise their stocks. The margin between spot prices and f.o.b. cost has been exceedingly meagre, and while many cargoes have left nothing beyond bare import cost, some have even been distinctly sold at a loss. These drawbacks have to a great extent been discounted by a wonderful absence of bad debts, and by the sound, though quiet state of the building trade, enabling importers to sell retail to consumers at remunerative figures. The hoped-for improvement in the building trade did not manifest itself during the year, but there are signs that its coming may be expected in the near future, owing to the general revival of trade all over the country, and to the general commercial prosperity that has now set in throughout the Kingdom. Upon this will probably depend the stability of the market for the year. The figures of the dock stocks are very similar to those of 1888, the only distinct decrease being in Baltic deals. The effect of the strike was not only felt in the curtailment of the deliveries, but the loss sustained by depreciation, owing to exposure to the weather, of many fine cargoes of deals and battens, was enormous, and has not even yet been fully brought home to bidders. Auctions have not been heavy, and this shows that demand has been continuous, and has at no time required the drastic remedy of forced sales to stimulate consumption. Deliveries from the docks have been good, and had it not been for the unfortunate strike they would have been considerably larger, thus giving an index to the steady demand which has ruled, and which during the autumn has been far better than for a considerable period."

The English Iron Trade.—The English iron trade opens the year with the market in an active and buoyant condition, improvements in prices being reported from all directions and for every description of the crude and finished article. Notwithstanding advanced and advancing rates, business in pig-iron is comparatively brisk. The Glasgow warrant market has been strong, and a large amount of buying has been going on. In several districts makers have practically withdrawn quotations, and they are generally unwilling to commit themselves forward. Where, however, actual business is done, this is effected at higher rates, Scotch makers quote this week from 61. to 1s. 6d. bigger per ton. Cleveland iron has been put up 2s. 6d. a ton, and Bessemer 3s. 6d. in the North-West, where, also, Spiegleisen has advanced to the phenomenal figure of 130s. a ton, being an increase of 32s. 6d., or over 30 per cent. in a week. Finished iron is also much stronger, and both marked and common bars have been raised 10s. per ton, while black sheets and Welsh bars have improved 15s. A similar tendency is displayed by steel. Rails and blooms are 8s. a ton dearer, and billets and slabs, 12s. 6d. Shipbuilders are beginning to book fresh orders with the New Year, notwithstanding the increasing cost of tonnage. Engineers have their hands very full of orders, and plenty of new business is coming forward.—*Iron.*

Yorkshire College Engineering Society.—At the meeting of this society on Monday evening, the President (Professor Arch. Barr, B.Sc.) delivered his annual address. As Professor Barr is leaving Leeds to fill the Chair of Engineering at the University of Glasgow, the opportunity was taken to present him with a testimonial from the members expressive of their appreciation of his services to the society. In the absence through illness of Mr. Josb. Buckton, chairman of the Engineering Committee of the College, Mr. Wicksteed occupied the chair. Professor Barr spoke for an hour on the lessons to be derived from the life of James Watt, the founder of the profession of engineering. Mr. Goodman, the new Professor of Engineering at the College, also spoke.

Birkbeck Institution.—The Monday evening lectures in "Quantity Surveying" are from 6.30 to 7.30, and not from 6 to 7, as advertised in our last issue.

Aberdeen Trade in 1889.—During the past year the various industries followed in Aberdeen have, with one or two minor exceptions, been prosperous, and in some cases workers have shared in the improvement. In the granite trade a large amount of business has been done, although the merchants complain that, owing to over-competition, profits have been forced down to a very low point. In the polished monumental and ornamental granite departments there has been a satisfactory activity and a large export of finished articles to the Colonies and abroad, not to speak of the trade in the home country; and the granite merchants have plenty of orders in hand for the current year. There has been no change in wages. It may be mentioned that, besides the "native" or Aberdeenshire granites, granite of various colours from Sweden and other "foreign" granites are now, to some extent, employed in the trade, and that a commencement has been made in a new branch of industry, in the export to America of stones dressed and ready to be used in building. The "boom" in house-building in Aberdeen is now over, as is evidenced by the fact that the valuation roll shows that there are in the town 1,241 vacant houses and 322 vacant shops, of a united valued annual rental of 16,994l., and by the further fact that the number of plans of buildings lodged with the authorities for sanction has now reached what may be called a normal figure. During the year the Town Council have approved, as regards lines, levels, &c., plans which may be classified as follows:—Dwelling-houses, 116; cottages, 17; alterations and additions, 74; balls, 2; church, 1; miscellaneous (including warehouses, workshops, stables, &c.), 42. In many cases the premises described as "dwelling-houses" are within the bounds of the city proper, and there has also been a considerable amount of building in the suburban districts adjoining. A commencement has been made with the new prison on the south side of the Dee, and work is well advanced at the new Infirmary buildings in Spa-street. There are no other buildings of any special magnitude in prospect. The Town Council have taken the preliminary steps for the formation, under the improvements scheme, of a new street in the east-end running from Castle-street in the direction of the Links.—

Engineering Works on the Danube.—The Hungarian Government are inviting tenders for the engineering works which are to be carried out at Orsova, on the Danube, at the so-called Iron Gate. The work is divided into three sections, viz.—1. The blasting of a channel in the river-bed to a depth of 2 metres below mean level of water, and having a width of 60 metres. The quantity of rock to be removed is about 160,000 cubic metres. 2. The construction of two so-called "Stau" dams, requiring 620,000 cubic metres of rock *débris*, and 100,000 cubic metres of facing stone. 3. Blasting of a channel in order to avoid the worst rapid, requiring the removal of 240,000 metres of rock, and 95,000 cubic metres of facing stone. The most difficult part of the work will consist in the submarine blasting, as the current runs at the rate of 4 metres per second. The Government have already attempted this work by Lieut.-Col. Laner's method, consisting in dropping dynamite cartridges, attached to a fuse, to the bottom, but without success. Tenders are, therefore, now invited, which must be sent in to the Hungarian Minister of Communications at Buda-Pesth, before January 31 next, and who will furnish, for a sum of 20 florins, all drawings, plans, specifications, &c., the amount of caution money to be deposited by the successful tender, the deposits of the unsuccessful ones being, of course, returned.

Obituary.—We regret to bear that Mr. Edward Ellis died at his residence, Bruce Grove, Tottenham, on the 8th inst., after a long and painful illness, in his 73rd year. He had practised as an architect in Fenchurch-street, London, for nearly forty-five years,—during the last ten years in partnership with his son, Mr. Edward Brookes Ellis, A.R.I.B.A., and retired about three years ago in consequence of failing health. He had carried out many large buildings in London, chiefly offices and warehouses; churches at Peterborough and Edmonton; the Corn Exchange at Bury St. Edmunds; vicarages at Oakham, Higham, Edmonton, and Peterborough; schools for the Tottenham School Board; and many private houses in the neighbourhood of London.

Proposed Railway Survey of the Khyber. In connexion with the proposed railway survey of the Khyber, it may be noted that there are at least two feasible routes through the hills to the west of Peshawar,—from Jamrud by the Khyber direct, or by incline along the Kabul River to Dakka. The latter is the one which is to be surveyed at once, or so soon as the needful tribal arrangements are satisfactorily made. By the former route, to Jellalabad, and for some distance beyond, the only really difficult lengths would be from Ali Masjid across the Kotal to Landi Khana, and possibly a short length at Chorgali between comes when a railway has to be made to Kabul itself, there will be no difficulty in carrying the line on from Jellalabad. By the Dorunta Gorge, Kats-i-Ashu, up to the Adrak-Badrak Kotal, not very far from Jagdalak, or to within about fifty miles of Kabul, there would be a certain amount of rock-cutting, though nothing insurmountable. But it would be a question if from Jellalabad a better alignment would not be by the Lugman Valley and the Kabul River. There is every reason to believe that a perfectly practicable route could be obtained in this direction, which in former times was used for the movement of formidable armies, and is only now avoided by kafilas on account of the want of proper escort.—*Indian Engineer.*

Sewer Ventilation into House Chimneys!—Mr. W. Santo Crimp, the Engineer to the Wimbledon Local Board, writes to the *Western Morning News* (Plymouth) as follows:—"I have recently had occasion to examine the literature relating to sewer ventilation, and in the first volume of the Proceedings of the Association of Municipal and Sanitary Engineers I found this paragraph:—

"Plymouth.—The sewers are ventilated by chimneys or shafts into house chimneys. Very few persons know where they are, to prevent prejudice, and the imagination that they are injurious to the residential property. This means, in the cases of those houses where chimneys have been utilised as sewer ventilators, that when down draughts occur the sewer gas is carried into the living-rooms. May not this explain the prevalence of scarlet fever in Plymouth?" Upon which the Editor of the journal in question remarks: "Such a statement, in such a form, ought to be at once replied to. But we should be surprised to find it to be a fact that sewer ventilation is attempted in Plymouth by means of any chimneys of dwelling-houses."

Sir A. B. Walker.—At a special meeting of the Liverpool City Council on Wednesday, the honorary freedom of the City was presented to Sir A. B. Walker, Bart., in recognition of his munificent gifts of an art gallery and of the engineering laboratories in connexion with the University College. The document was enclosed in a casket, and was presented by the Mayor, Mr. Thomas Hughes, on behalf of the inhabitants of the city. Sir Andrew, in acknowledging the gift, expressed his great appreciation of the honour, and said that, with regard to the two institutions he had established, the best thanks he could receive was the consciousness that they were doing a great and important work in the community.

New Swedish Society of Builders.—A new society of builders has been formed in Stockholm, which at its first meeting enrolled over fifty master builders and architects as members. One of the main objects of the association is to improve the relations between employer and workman in the building trades, and to resist strikes. On the latter point the society has been so far successful as to put an end to the recent masons' strike in Stockholm.

The Chief Engineer-Elect of the London County Council.—The *Liverpool Post* states that Mr. Clement Dunscombe, the late Engineer to the Liverpool Corporation (recently appointed Engineer to the London County Council), left Liverpool on Saturday, in Messrs. Elder, Dempster & Co.'s steamer *Calabar*. Mr. Dunscombe is going to Grand Canary for the benefit of the sea trip, and the beautiful climate of the Canaries.

The Proposed Underground Railway in Edinburgh continues to excite much interest in the city. The opposition to it is strong, and, if the scheme is persisted in, steps are to be taken to prevent its fulfilment. Various alternative schemes have been proposed, some of which, it is alleged, would, if carried out, be a greater boon to the public than the Princess-street scheme.

The Proposed Strand Improvements.

The report of the Parliamentary Committee of the Strand Board of Works upon the London Street (Strand Improvement) Bill of the London County Council was adopted at the meeting of the Board on Wednesday. The Board's chief objections to the Bill are according to the Standard in reference to the "betterment clauses," which provide for a rent-charge upon property within a given area. The report protests against the arbitrary way in which the area supposed to be specially benefited by the improvement is defined. It seems to the Committee peculiarly unreasonable to exclude Somerset House, Lancaster-place, the west side of Wellington-street, Wellington-street North, Covent-garden Market, the Law Courts, Lincoln's Inn, the Temple, and Incorporated Law Society from the area supposed to be specially benefited. If there is one thing more than another which has rendered the improvement urgently necessary in the public interest, it is the fact that the Law Courts have been erected in the immediate neighbourhood of the proposed improvement." The Daily Telegraph quotes the following paragraph from the report:—"Our committee desire to call special attention to the fact that it is impossible in the case of this scheme that any new and valuable frontage can be obtained to the widened street by adjoining landowners, as in the case of the Shaftesbury-avenue improvement, inasmuch as the London County Council must purchase both sides of Holywell-street to effect the improvement, and in no case will it be possible for any owner to obtain a frontage to the Strand which he does not now possess. In consequence of the improvement, the London County Council become the sole owners of the new frontages on the north side, while the south side of the Strand will, for business purposes, be deteriorated in value. Our committee are of opinion that an improvement in this locality has been long called for in the interests of the metropolis as a public improvement." The Board resolved to oppose the Bill in Parliament, and to ask Mr. W. H. Smith to receive a deputation on the subject.

Humours of an American Sanitary Journal.

The Sanitary News, of Chicago, in its issue for Dec. 21 last, has been pleased to appropriate from our issue of Nov. 30 not only the report of Mr. Henry Law's paper "On a Method of Regulating the Maximum Discharge of Sewers," but the block (which the Editor, or a clever printer, calls a "Diagram") illustrating the same. If our American contemporary had quoted the source whence he derived his matter, the value would certainly not have been less. However, we will spare a more excellent way, and give all the credit that is due to the Editor of the Journal for the following extract, which is not altogether inapplicable to London just yet, we fear, in spite of the movement for the registration of plumbers:—"Plumber (just commencing business for himself, to his bookkeeper): What is the meaning of sanitary? Bookkeeper (always ready for the occasion): Well, sanitary is one of those words that has a Latin root which enters into the composition of many English words, such as sanguine, sanguinary, sang froid, &c., and means no cure, no pay. Plumber: Say, painter, leave off the sanitary, and make it just plain plumber. Next morning low over the door hung the following sign:—

HENRY H. SMITH
JUST
PLAIN PLUMBER.

PRICES CURRENT OF MATERIALS.

Table listing prices for timber and other materials. Columns include item name, quantity, and price per unit.

Table with columns for 'TIMBER (continued)', 'METALS', and 'OILS'. Lists various materials and their prices.

COMPETITIONS, CONTRACTS, & PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

COMPETITIONS.

Table for competitions with columns: Nature of Work, By whom Required, Premium, Designs to be delivered, Page.

CONTRACTS.

Table for contracts with columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page.

PUBLIC APPOINTMENTS.

Table for public appointments with columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page.

TENDERS.

Multiple sections of tenders for construction projects in various locations including Ashburton, Derby, Gosport, London, and Westminister. Each section lists project details and contractor information.

LONDON.—For erecting factory, Paradise-street, Fishary, for Mr. H. Lebus. Mr. H. Woodzell, architect:—
 J. Anley £4,800 0 0
 Holloway 4,779 0 0
 Lascelles 4,632 0 0
 Grover 4,589 0 0
 Laurence 4,555 0 0
 W. Shurmer 4,572 0 0
 W. Scrivener 4,421 0 0

LONDON.—For alterations, &c. to premises in Commercial-road, E. Mr. H. H. Collins, architect:—
 Kilby & Gayford £1,800 0 0
 Ashby & Horner 1,855 0 0
 W. Shurmer 1,845 0 0
 Hearle & Son 1,753 0 0
 Sabej 1,668 0 0
 Thompson 1,629 0 0
 Culnan 1,545 0 0

LONDON.—For alterations and additions to 25, Sussex-square, for Mr. S. J. Parker, under the superintendence of Messrs. Godwin, Basley, & Co., 23, Cadogan-place, S.W.:—
 Wilkinson & Son £1,416 8 3 1/2
 Bush & Co. 1,415 0 0
 Greatorex & Co. 709 0 1/2

LONDON.—For putweller's work to the "Audley Hotel," Audley-street, for Mr. R. H. Barnes. Mr. H. I. Newton, architect, 49, Victoria-street, Westminster, S.W.:—
 Saunders & Sons, High Holborn* £145 10 0

LOWESTOFT.—For new road, sewer, &c., for the British Land Company, limited, on their Crown Meadows Estate. Mr. Henry B. Michell, surveyor:—
 Bennett, Ipswich £635 0 0
 Gibson, Ipswich 624 0 0
 Pizzey, Hornsey 624 0 0
 Wilson, Walthamstow (accepted) 615 0 0

NOTTINGHAM.—For the restoration of old buildings at the Castle, and conversion of same into an Industrial Art Gallery, for the Corporation of Nottingham. Mr. Herbert Walker, F.R.I.B.A., architect:—
 J. F. Price £3,850 0 0
 E. Hind 3,707 0 0
 Fish & Son 3,700 0 0
 Woodland 3,650 0 0
 H. Vickers 3,637 0 0
 Bell & Son 3,600 0 0
 Wheatley & Maule 3,600 0 0
 Hudson & Son 3,500 0 0
 J. Thomas (accepted) 3,453 0 0

PORTSMOUTH.—For the rebuilding of the "Ship Antelope" beerhouse, for Messrs. Simonds & Co., Winchester. Mr. W. Yeardy, architect, 30, High-street, Gosport:—
 J. Croad, Portsea £724 0 0
 C. H. Roberts, Southsea 670 0 0
 H. Clark & Sons, Landport 633 0 0
 J. Crockerell, Landport 629 0 0
 T. P. Hall, Southsea (accepted) 584 0 0

READING.—For new granary, for Messrs. H. & G. Simonds, the Brewery, Reading:—
 Strong Bros. £1,173 0 0
 Higga & Sons 997 0 0
 Ruffel Bros. 945 0 0
 Bottrell & Son, Reading (accepted) 945 0 0

SWANWICK.—For the erection of "Railway Hotel," stables, coach-house, &c., for Messrs. S. & T. N. Blake & Co., Mr. W. Yeardy, architect, 30, High-street, Gosport. Quantities supplied:—
 C. Roberts, Portsmouth £1,511 0 0
 J. Croad, jun., Gosport 1,505 4 0
 W. Rapley, Gosport 1,382 0 0
 W. Franklin, Southampton 1,364 0 0
 J. Luke & Son, Gosport 1,250 0 0
 Morgan, Islel, & Morgan, Southampton 1,244 0 0
 J. Plummer, Fareham 1,230 0 0
 T. P. Hall, Portsmouth 1,220 0 0
 H. Jones, Portsmouth 1,210 0 0
 C. Wareham, Stubbington 1,170 0 0
 J. Crockerell, Portsmouth* 1,150 0 0

UTTOXETER.—For a 100-quarter malthouse, with cellars, bridge, sub-way, &c., for the Uttoxeter Brewery Company. Mr. R. Hardy, architect, 3, Thurland-street, Nottingham:—
 Baines, Newark £5,525 0 0
 Dennett & Ingle, Nottingham 5,349 0 0
 Bisset, Sheffield 5,285 0 0
 Sicker, Derby 5,056 0 0
 Wood, Derby 4,900 0 0
 Lowe & Son, Burton (accepted) 4,800 0 0

WEST WICKHAM (Kent).—For the erection of a residence, for Mrs. Thomasset. Mr. Alex. R. Fleming, architect, 121, Cannon-street, E.C. Quantities by Messrs. Mew & Overden, 121, Cannon-street, E.C.:—
 T. Crossley, Bromley £4,000 0 0
 Ashby & Horner, Alabate 3,990 0 0
 Mid-Kent Building Works, Beckenham 3,909 0 0
 F. Cooper, Beckenham 3,780 0 0
 S. Sabej & Son, Islington 3,707 0 0
 Syme & Duncan, Beckenham 3,640 0 0
 E. R. Palmer, Beckenham (accepted) 3,585 0 0

SUBSCRIBERS IN LONDON AND THE SUBURBS, by printing at the Publishing Office, 19a, per annum (or 4s. 8d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

TERMS OF SUBSCRIPTION.
 "THE BUILDER" is supplied gratis from the Office to residents in any part of the United Kingdom at the rate of 19s. per annum in advance. To all parts of Europe, America, Australia, and New Zealand, 25s. per annum. To India, China, Ceylon, &c. 30s. per annum. Remittances payable to THOMAS FORBESBURNER, Publisher, No. 45, Catherine-street, W.C.

TO CORRESPONDENTS.
 B. D.—One who objected to compete [we have entire confidence in the bona fides of the promoters in this case]—H. R. C. W.—It is hardly a matter for public discussion to what point one of the County Council are in no way bound to follow the precedent of the Board of Works. E. E.—"A Constant Reader" [we presume you are one of the "practical men" referred to. We presume entirely to the opinion already expressed.—J. Y. should read carefully.—E. B. E. do not insert such announcements unless directly requested by the principal.—H. W. J. H. (no space)—J. C. Bolton (we do not receive reports of such kind).
 All statements of facts, lists of tenders, &c. must be accompanied by the names and addresses of the sender, not necessarily for publication. We are compelled to decline posting out books and giving addresses. Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.
 We cannot undertake to return rejected communications.
 Letters or communications (beyond mere news-items) which have been duplicated for other journals, are NOT DESIRED.
 All communications regarding library and artistic matters should be addressed to THE EDITOR: all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

Scottish Art and Architecture.

THE interesting volume which has been brought out by Mr. Brydall* is in some of its chapters rather a history of Scottish artists than of art in Scotland; at all events such names

as those of Robert Adam and Wilkie certainly belong more to the history of English than of Scottish art. A history of artists who are Scottish in nationality would, when brought down to the present day, include some of the best known names among the members of the Royal Academy of England at this moment, the extent of the Scottish element in which is almost proverbial, inasmuch that it has been insinuated that one of the best qualifications for an artist seeking election as an Associate is to be a Scotchman. But the volume contains a great deal of information in regard to the meagre remains of early Scottish art, the formation and history of the Scottish Academy, and the works and career of many artists of talent whose names are nevertheless little known south of the Tweed.

In the opening chapter on the sculptured stones belonging to the ancient period, the author refers to Mr. Billings's remark that among the Iona stones, along with sculptured forms believed to be very ancient when found on stones in other parts of the country, are found undoubted marks of much later origin, and that some which show characteristics of great age are inscribed with a date in the seventeenth century. This is accounted for by an ambition among some of the Highland chiefs "to appear in the character of Norman knights" (rather a curious way of putting it), and it is added that a document written between 1577 and 1595 mentions, in regard to the hurrying-place at Iona, "in this are all the gentlemen of the Isles buryit as yet." This accounts for these dates in a probable manner; but it would not explain the curious incident which we mentioned in connexion with the historic exhibition in the model of the Bishop's castle at the late Glasgow Exhibition, of the hag-pipe with a Celtic style of ornament and a

date 1500 inscribed upon it: an incident which perhaps suggests that there was even at that time such a thing as a taste for the archaeological reproduction of the decoration of an older period.

We have no doubt Mr. Brydall is right in his estimation of the important amount of artistic work once existing in the architecture and furniture and decoration of Scottish Abbeys and other ecclesiastical buildings; nothing probably like what once existed in England, but still far more than might be hastily estimated from the extent of the remains and records of such work now to be found. It may be assumed that there was a greater extent of destruction of such work in Scotland than even in England, owing to the peculiarly strong anti-papistical feeling of the Scottish reformers; that this feeling was pre-eminently strong and stubborn in Scotland history leaves little doubt; yet it is curious, in respect to this, to read of the caution appended to a letter of instructions given in 1560 for the removal of all altars and "monuments of idolatry" from the churches. This document, signed by "Mr. Argyle, James Stewart, and Ruthven," is a circular of directions of this iconoclastic kind, of general application and with a blank left for the name of the particular church to be operated upon—"Traist friends, after maist hearty commendacioun, we pray you fall not to pass incontinent to the kirk of —, and take down the hail images thereof, and bring down to the kirk-zayrd, and burn thymoppinly." Yet to this heartily-expressed commission is added the postscript "tak guid heid that neither the dasks, windocks, nor darris be ony ways hurt or broken, either glass wark or iron wark." When we compare this with the well known and dramatic account of the Cromwellite emissary in England breaking the stained windows of Canterbury Cathedral with a pole—"rattling down proud Beckett's bones," one cannot but wonder at the apparently greater tenderness towards the windows in Scotland. It is probable however that this is in reality a piece of the "canny" instinct of the north country, which would not readily destroy anything that was necessary to keep the church habitable for service, and which it would be an expense to replace. Perhaps we may also read it as an indication that there was not much stained glass work in the Scottish churches. The author indeed mentions that almost the only fragments of ancient stained glass left in Scotland are those pertaining to the old Maison Dieu

in Edinburgh, "containing the Scottish arms and those of the Queen Regent, Mary of Guise, encircled respectively by a crown of thistles and laurel, with other armorial bearings, and the figure of St. Bartholomew, who has strangely escaped from the destruction of his brother Apostles there in 1559. In these fragments, while the figure is inferior to the other parts, the deep ruby and bright yellow on the Royal Arms exhibit traces of a bold broad manipulation and richness of colour, shewing a good appreciation of the glass-stainer's work." Possibly the importance and prominence of the armorial bearings acted as a protection to the figure of the saint. But if there had been anything like the amount of medieval stained glass in Scotland that there was in England, it seems likely that by similar chances some other relics of it would have escaped to tell the tale; and we imagine that the direction to spare the church glass points in the same direction, and that it was mostly plain glazing not obnoxious to the Reformers.

The author indicates the early seventeenth century as the period when the modern form of architecture began to be developed in Scotland; later than in England, as England was later than the Continent, the spirit of the Renaissance travelling slowly northward towards the outer zone of civilisation. Among the first names of the period when architects began to be known by name is mentioned that of William Schaw, "Master of the King's Works" to James VI., who died early in the seventeenth century, and restored in 1594 the Abbey of Dunfermline. A part of the translation of the Latin inscription on his tomb shows that he was held in high honour, and spent no little pains in the studies whereby he rose to eminence: "he had travelled in France and many other kingdoms for the improvement of his mind; he wanted no liberal training; was most skilful in architecture; was early recommended to great persons for the singular gifts of his mind; and was not only unwearied and indefatigable in labours and business, but constantly active and most vigorous, and was most dear to every good man who knew him: an architect's epitaph that should not be forgotten. The family of the Mylnes succeeded to eminence in architecture; beginning with John Mylne, several of whose predecessors had however also held the office of Master-mason to the King; there is also mention of Alexander Mylne a sculpt-

* Art in Scotland; its Origin and Progress. By Robert Brydall, Master of the St. George's Art School at Glasgow. Edinburgh and London: Blackwood & Sons, 1889.

tor (probably, the author says, the brother of John) who died in 1643, and on whose tomb in the cemetery by Holyrood it is recorded that

"What Myron or Apelles could have done
In brass or patriy, he could that in stone."

Another Mylne was concerned in the building of Holyrood Palace; and a later member of the same family was the Robert Mylne born at Edinburgh in 1734, whose name is well known as the architect of old Blackfriars bridge, and who was afterwards surveyor to the fabric of St. Paul's.

It is only after the lapse of a good many chapters in the book that we return to the subject of Scottish architects in the eighteenth century, about the middle of which century died William Adam, the father of his son, and James Gibbs of Aberdeen. William Adam made an essentially Scottish reputation, but Gibbs was certainly to all intents and purposes an English architect; the only building in Scotland with which his name is said to be probably associated is the church of St. Nicholas in his native city, which the author describes as "professing to be Classic, but of no particular style." He was one of the first noteworthy examples, perhaps, of the many eminent artists who, born in Scotland, have made all their reputation in England, and to whose names a history of Scottish art can hardly make any claim. To the ability of the still more eminent, or at all events more successful English architect of the period who was born in Scotland, Robert Adam (the son, as above indicated, of a true Scottish architect), the author hardly does full justice; perhaps in part owing to Adam's questionable taste in deserting his own country. Now, Robert Adam (for it seems to have been he who was the prevailing genius of the family) accomplished what few single architects in the world's history have accomplished; he made a recognisable style; not a very powerful one certainly, and not perhaps original in any separate detail; but with that harmony and completeness in itself which more than any other quality constitutes style. To say that its characteristics were "the introduction of large windows, often rather half-looking for want of dressing, grouped three or more together, by a great glazed arch" can hardly be called a fair description; it is the selection of a detail which, after all, we have not noticed as especially prominent in his works; but the essence of his style does not consist in this or that separate detail, but in the harmony and completeness of the whole. The author gives a sketch of the curious history of the Adelphi scheme, and its financial failure. In speaking of Adam's early studies, we observe that he retains the spelling "Spalatro," which may be considered as abandoned now for the more correct "Spalato," doubtless an Italian corruption of *palatium*.

Among the artists to whom considerable space is given are William Dyce and Sir Francis Grant, concerning both of whom we confess it was news to us that they were both Scotchmen; their career and fame was entirely English; so was that of David Roberts. Indeed it seems to us, looking over the list of artists' names, that Raeburn was the only one of the highest rank who remained *de facto* a Scotch artist, and made his fame in his own country. Thomson of Duddingston had a reputation beyond the border, but his landscapes, though evincing genius, can hardly be said to keep their place. David Scott, a man of undoubted genius, remained a Scotch artist; the author observes that he has been called "the Scottish Michael-angelo," a comparison rather beyond the mark; his genius had some affinity with that of Blake, though he no doubt drew better than Blake and was (if one may be permitted to say so) more sane in his temperament. Several works of his are mentioned which are unknown, we imagine, to most English readers; among others a reference is made to his remarkable illustrations to the "Pilgrim's Progress." A copy of this work we came upon not long since in a seaside lodging in a little fishing village; a goodly thick quarto ensconced among the family Bibles. Many of

the designs are very powerful, especially that of Christian entering the Valley of the Shadow of Death, where a deep shadow is thrown from a dimly-seen gigantic figure bending forward so that the top of the crowned head is seen; this design is quite in the spirit of Blake. Some very interesting details are given of Raeburn's manner of working, from which we learn that in painting a portrait he never made any preliminary outline of the head or figure, but drew it in at once with the brush. Among the sketches of deceased Scottish artists of recent days we notice that one of the most distinctly Scottish in reputation, Sam Bough, was by birth an Englishman. The short biography of him is very interesting, for the personality of the man was as powerful and original as that of his paintings.

Mr. Brydall has produced a very interesting hook which will fill a gap in libraries of works devoted to art. While on the subject of art in Scotland it will not be out of place to mention another book dedicated to our special branch of art as illustrated in Scotland, namely, the third volume, and a volume of goodly bulk and thickness, of Messrs. MacGibbon and Ross's "Castellated and Domestic Architecture of Scotland."* The authors are now endeavouring to carry out the scheme which they announced, and for which they asked assistance and information at the close of their second volume, of extending the scope of the work so as to include an account and illustrations of every old castle in Scotland; a fourth volume is to follow, and it is intended that there should be a complete record of this class of buildings. This is a very spirited effort, and deserves all recognition. We devoted considerable space to the first two volumes, and it is perhaps only necessary to say here that the third volume is carried out with the same completeness and the same large proportion of plans, sections, and sketches, as the former ones. The plans alone form a most valuable and interesting collection. We have never been able quite to like the style in which the views are drawn; it is rather mechanical and too much overdone with shading lines; but it fulfils all the practical purposes of illustration. Naturally the examples are not of quite the same interest as in the first two volumes, since in those the scheme of complete illustration had not been entered upon, and the most remarkable examples were of course selected; but everyone interested in the subject will be glad to see it thus continued. Among the more picturesque and characteristic examples in the third volume are Meggerie Castle, with its modest dormers ensconced between the square corbelled-out towers at the angles, and Sorn Castle, shown in two small elevations, a solid block of masonry with a great machicolated cornice and angle-turrets, and the windows set out in a very picturesque manner; the well, or rather well-cover, from the Mansion-house at Greenock, with its pyramid of masonry carried on thick cylindrical columns at the angles, is a curious and unusual bit of work, dated 1629. We hope to be able to congratulate the authors soon on the appearance of the fourth and concluding volume of their interesting and valuable book.

Canal Work in Russia.—It seems probable that the Russian Government will shortly begin the construction of the great canal between the Onega Lake and the White Sea, connecting that sea with the Baltic, plans for which have been for some time under consideration. It is estimated that the length will be 235 kilometres, of which 133 kilometres are natural canal, whilst the depth is to be three metres. The cost of the canal alone is estimated at seven and a half million roubles; but with a harbour constructed at Wyg, on the White Sea, and dredging of the river Svir, the cost will be ten million roubles.

* The Castellated and Domestic Architecture of Scotland from the Twelfth to the Eighteenth Century; by David MacGibbon and Thomas Ross, Architects. Volume III. Edinburgh; David Douglas; 1888.

THE LATE SIGNOR BRENTANO.

BY PROFESSOR MELANI, OF MILAN.

HE have referred already to the lamented and untimely death of Giuseppe Brentano, the young Milanese architect, who was victorious in the celebrated competition for the facade of the Duomo at Milan. He closed his career as an artist with an enormous success, which gave him a position such as many would have been well content to earn at the end of a long and laborious life; and has passed away without even seeing the commencement of that work to which he devoted his ceaseless attention, in order that he might make it more worthy of the monument it was to complete.

Giuseppe Brentano was born in 1862. From his early youth he cherished the idea of becoming an engineer, and had attended the technical classes at the Polytechnic, in which he became a pupil, and left these in 1885. When a student at the Polytechnic, Brentano obtained his great triumph, not by the display of his qualities as an engineer, but rather as an architect; a fact which is the more worthy of remark, as the Polytechnic school in question does not offer any special facility or inducement towards the study of architecture. Not that architecture is not studied in the Italian polytechnics, but the study of art does not form any organic element in these institutions, because in them those who belong to the architectural and engineering sections have to frequent for a short time some schools of the Institute of Fine Arts, together with the pupils who have devoted themselves to art, and not to science. The students in these polytechnics benefit very slightly from the artistic instruction in the fine art schools, and are all wrapped up in their studies in the science of construction. In practice they are excellent engineers, whereas as architects they do not go beyond mediocrity, even if they reach that stage, owing to the insufficiency of their artistic training.

However, Brentano was evidently born an architect rather than a scientist, and he left the Polytechnic of Milan with a disposition more susceptible to the attractions of art than to those of science.

In fact, while still at the Polytechnic, a competition was opened at Siena, among the architectural students, for a scholarship, and young Brentano was among the competitors. The subject was a plan for a building for a given purpose, and a study on the history of art. Brentano was successful in this competition, and it was on this occasion that I came to know him personally. Knowing that I had successfully competed in a similar affair in Tuscany, Brentano called on me, and sought from me some information on this matter. I gave it to him very willingly, and encouraged him, after having seen some of his works which he brought for my inspection, and (as he added with extreme courtesy) for my opinion. Brentano wrote me several long letters from Siena, and when he returned to Milan again called on me with his work executed there. I conceived a very favourable opinion of it; but at that time I was much better pleased with a series of water-colour drawings, evincing a bold picturesque spirit,—drawings taken from remains at Florence and at Siena. These were, for the most part, fragments of Mediæval architectural works, to which, Brentano remarked, he felt himself drawn more than to any other style of architecture. The year after this first success, Giuseppe Brentano was made a qualified architectural engineer, and at the annual exhibition of the Institute of Fine Arts he exhibited a design in the Tuscan Mediæval style, which was, if I remember rightly, a very faithful reproduction of the celebrated

* The Italian fine art institutions have an architectural course, in which, together with architectural composition, ancient and modern architectural styles are also taught. The youths who attend these courses are not trained in construction, and hence they cannot exercise the art practically as architects, although even they may come out triumphant in the competitions for large public buildings.

Tabernacle of Orcagna in Or San Michele at Florence: he also exhibited a series of crayon sketches, of extreme delicacy, characterised by exquisite taste. Thenceforth, he was a recognised artist. Then came the International competition for the façade of the Duomo at Milan, and he was immediately urged to compete by his friends. At first the subject of the competition appeared to Brentano beyond his powers and studies (this the writer heard from his own lips), but subsequently he entered on the task, and exhibited two schemes at the preliminary competition; one of these was flanked by two towers, and one was without towers. In these designs there was, to say the truth, a good deal of uncertainty as to the system of treatment to be adopted; but passing over this fault in the two studies by the young Brentano, it was undeniable that in them he proved himself to possess greater strength than he had credit for; in fact, such was the power he evinced, that he was justly selected to be one of the fifteen competitors in the second competition. I can remember the great interest which the two schemes submitted by Brentano awakened in the public mind, because they were submitted in their original form, in the shape of rough sketches and as unelaborated designs, and the interest was so great that very high hopes were at once entertained of him. They showed, in fact, that the author had yet much more to say after these,—his first two efforts,—and the result proved it.

Selected as one of the competitors in the second competition, and before setting to work, Brentano paid a lengthy visit to Germany and Austria, and having secluded himself at Vienna, he devoted several months to work under Hasenauer, the celebrated architect of the Burg Theatre and of the Museum of Fine Arts and Natural Sciences at Vienna; he did this for the purpose of becoming more skilled in that Gothic style which had now become his ruling thought.

Brentano laboured, not only in the studio, but outside it, and wherever he went he carried away with him numerous studies and sketches. After this ample and opportune preparation, he set himself to work, and as soon as his plans were submitted many who saw them foretold the result. When the Exhibition was opened, Brentano at once gained admirers, and as a rule those who had not the courage to support his schemes were, at any rate, of opinion that none of the other competitors (Ciaghin, of St. Petersburg, had died after the preliminary competition) had produced a work which was worthy of being executed. The truth is that Brentano had three other strong competitors, or rather two others, who, supporting his ideas of dispensing with the towers of the façade for the Milan Cathedral, had each of them submitted important designs.

However, Brentano came out of the competition victorious, and his victory was a substantial one, almost without opposition, for he received twelve out of fourteen votes.

Thus it was that the architect Brentano awakened for several years universal interest, and all wondered that such a young artist should have achieved a triumph in such a way, and in an international competition wherein many illustrious men had laboured, and the press published biographies of him, spoke of his works, and praised his talent.

I cannot say how much such a conspicuous success may have affected Brentano, but I can affirm that he made no boast of it whatever; so true is this, that when one of the leading Italian publishers asked him to publish the façade he had designed, he refused the invitation, and preferred postponing it until after the sketch had been executed as a model, for which purpose he required the assistance of several of his colleagues. But, alas! poor Brentano never even had this satisfaction, and when he had barely commenced to execute his model in wood, according to the conditions of the programme, he was attacked by typhoid fever, and died in Milan on the morning of Dec. 31, 1889.

The jury who had declared the scheme of

the young Milanese architect to be not only the best, but also one worthy of being executed, had also evinced the desire to see the crowning of the centre compartment somewhat raised,* in order that the centre feature might be more elaborated than the one shown in the plan. And it appears that Brentano himself was convinced as to this requirement, as also were many at Berlin and elsewhere. Consequently, Brentano had recently devoted himself to working out a different solution of this problem, which, indeed, was far from being a simple one. The fact is, so far as is known, and judging by the recent declarations made by Brentano, that he had not definitely accomplished anything in this direction which would serve as a guide to the modeller Brambilla.

As to the model, it was executed on a scale of 1-20, or, rather, of 1-21; that is, the full size of Brentano's original design. And as it was begun it will now be completed, on the very clear lines traced out by the young architect. Fortunately, the Cathedral authorities agreed on the necessity of having a simple model executed in wood, and this sample, consisting of one portion of a pier, will afford the modeller greater security in the interpretation of Brentano's conception, because it is executed under his own direction and with his approval.† There is only one thing that will leave anything to be desired in the wood model, namely, the proposed variations in the central portion, a matter which it will be exceedingly difficult to proceed with under the present circumstances.

The reader may naturally ask a question on this point, Will Brentano's plan be carried out, or what are the probabilities as to its execution? The reply to this question is by no means easy. I must limit myself to conveying the opinions most in vogue, and the facts which are best known on this subject.

Your readers will remember what gave rise to the present international competition. It was the fact that a bequest was made by a Milanese citizen, Aristide de Togni, in 1884, amounting to 830,000 lire, for the façade in question. This bequest, although very large in itself, was a modest one when compared with the total sum required for a worthy façade to our cathedral; and it was left subject to a condition that, if within twenty years the sum, or a part of it, were not expended on the façade, it would go to the benefit of the city hospitals. Hence the necessity of opening the competition at once, and of stimulating it.

It is certain that there are a great many who even now do not believe that the façade of the Duomo at Milan will be carried out, and there are also many who think that, in spite of De Togni's bequest, the competition which recently took place was merely an academical one,—albeit, one which has left an important page in the annals of the cathedral. The great difficulty which appears at present obvious to every one, arises from the fact that our cathedral is not bereft of a façade; and that, consequently (say some critics), it would be useless piece of extravagance to spend an immense sum in providing it with a new one from the mere desire of improving the style of the monument. The façade of the Milan Duomo, as it stands to-day, is far from being unworthy in the eyes of those who accept with serene impartiality any artistic manifestation which efficiently represents any period in national history, and you will easily understand that if the monuments of Italy were to be improved in style, even limiting ourselves to the most noticeable ones, an end would never come to a work inspired by the very partial judgment of epochs and circumstances. It may be replied that these ideas are not the ideas of our time, and that before opening an international competition with the solemnity which characterised the one for the façade of

* See the official report of the jury, p. 4.

† According to the programme of the competition, Brentano was to superintend the execution of this model in wood, after which he would have received the second half of the prize of 40,000 lire assigned to him (see the Programme of the competition, article 10). The continuation of the model is now being executed under the superintendence of the cathedral authorities.

the Duomo at Milan, consideration ought to have been given to the responsibility assumed; but the fact remains that both in Italy and beyond its shores the idea of improving the style of the façade of our cathedral has opponents; but those who favoured it, having the majority on their side, succeeded, at all events, in bringing about the competition.

Some other difficulties in the way of the execution of Brentano's scheme also arise from the fact that, by its execution, the ensemble of the present façade would not be substantially altered. I should explain that at Milan there existed, and still exists, the false impression that the renovation of the façade should be executed not so much to improve the style of this portion of the monument as to give greater scale to the building. It is a fact that, as compared with the palaces designed by Mengoni and the great arch of the Galleria Vittorio Emanuele, the Duomo of Milan, looked at from the Piazza, presents rather a modest figure. Now, those who think thus, believed (and still believe) and hoped that the new façade would have corrected this obvious disproportion to the prejudice of the Duomo; yet seeing that after all the project to be executed would, from this point of view, leave things pretty much as they are, they do not appear to be over-pleased with it; so that if they do not raise difficulties, they at any rate stand apart with a rather suspicious indifference.

There is also the question of funds, but this, in my opinion, is not so serious as might be believed. In works of this kind Milan would, doubtless, get the support of the Government, and probably the support of Italians generally, although, perhaps, not to a very large extent; yet Milan is the most industrial and the richest city of Italy, and could rely a great deal on her own resources. Her capitalists are not scarce, and their affection to the Cathedral which lends individuality to the city assumes a Chauvinistic character which in England would perhaps hardly be credited. Again, the construction of the façade to the Duomo does not merely mean its commencement and completion in a short space of time. It is probable that the cost would not be far short of ten million lire, according to an approximate estimate; but ten million lire should not be sufficient to alarm us when, as in the present case, the payment is distributed over a number of years. In this amount would not be included the campanile, which would not only be necessary, but indispensable to the Duomo, particularly after the façade was renewed.* But Brentano's scheme is being prepared to stand fire, for further criticism, in the shape of a model. A drawing is one thing and a relief-model is another; and there are people in Milan who are rather doubtful as to the result of this final proof of Brentano's scheme. I, who am a faithful chronicler of what passes before my eyes,—if an opinion were allowed me,—would say that if the relief-model does not succeed in awakening a very lively interest on the part of the public, then adieu to the façade. It would then, I believe, be buried among many other projects of the present and previous, and even earlier centuries.

But even after this proof, admitting that it does awaken the enthusiasm I have referred to, it does not follow that the work will be immediately commenced. The judgment of the international jury requires the sanction, first, of the Preservation of Buildings Committee of the Province of Milan, and secondly, of the Superior Board of Fine Arts, and when so many persons have a right to intervene and express their opinions, especially in questions of works that every one has an ambition to carry out, obstacles easily arise. But there is in favour of Brentano's project and of its execution this

* When Napoleon, King of Italy, in June, 1805 ordered the façade of the Milan Duomo to be completed, the façade at that time had its doors and pilasters decorated up to the first Baldacchini, and as the work was completed with some carelessness, the expense amounted to about four million lire, comparing the money of that time with its present value. (See the Concorso Monumentale per la Nuova facciata del Duomo di Milano." A. Guidini, La facciata del duomo di Milano attraverso i secoli, p. 197.)

fact, that on account of the lamented death of the architect, the scheme may gradually assume, I might also say, an impersonal character, and in this way it would have more than ever an absolute possibility of being carried out (since a committee might be entrusted with it, consisting of this one or that one who on their own merits might aspire to the honours which fell to the lot of poor Brentano).

At the present state of the work, then, there are those who have the fondest faith in seeing Brentano's façade commenced, and there are also those who have no such belief. For my own part, I withhold any decision until I see whether it "stands fire" as a model. And if this test is favourable, as I hope it may be, then no serious difficulties are likely to impede the commencement and the final completion of the work (except, of course, any national calamity); and then, indeed, Giuseppe Brentano will have a lasting and magnificent monument.

To add a few personal details as to the late architect: Brentano was gentle in manner, tall, thin, and pale in appearance, and particularly of late gave rise to many fears among his friends as to his health. He was accustomed to a life almost of luxury, and was in this way quite the opposite to the "Bohemian" artist, a fact worth noting in a city like Milan, where artists are, perhaps, more Bohemian than in any other artistic Italian centre. Brentano used to dress not only with faultless elegance, but even with extravagance. Being a very young man, and new to the life, he had not many acquaintances among artists, but he had many among the upper classes of residents, to which class he himself belonged. Thoroughly devoted to study, Brentano shunned every opportunity of publicity, and when recently at the re-election of the Communal Council he was asked to become a candidate for the Council, he returned thanks and refused; nor, indeed, would he have accepted any office which might have distracted him from his studies or occupied his time. I can also say in his honour that after his triumph he fled from the turmoil of the city as though to fly from the sound of the praises and the gaze of the curious, both of which disturbed him, and he also avoided even that notoriety which was almost inseparable from the nature of his studies, and the responsibility which his triumph had thrown on him. Nor do I exaggerate owing to the affection I bore to my young colleague, nor is it because I think it a duty only to allude to the good works of those who have gone before us, that in writing of Brentano I allude to his blameless life, and I would even have spared myself alluding to it were it not that it contributed to render the young Italian artist more dear to all who knew him.

Before concluding, I should say that the international competition for the façade of the Duomo appears to have been fatal to several of our young colleagues who took part in it. Brentano is the fourth architect among the competitors under thirty years of age who has died. The first was Teodoro Ciaghi, who is one of the fifteen who was to have presented himself in the second competition, and he died before being able to begin the studies requisite. Luigi Tabac, a young artist of Venice, who died at Trieste, was also a very formidable competitor; and Raffaele Cattaneo, an architect and a writer, whose name was connected with the splendid publication issued by the "Organia de la Basilica de S. Marco," at Venice.

ALFREDO MELANI.

Sheffield Municipal Buildings Competition.—In reference to our remark that a well-known Sheffield firm of architects was mentioned in the local papers as among the six selected competitors, the architects in question wish us to state that they did not, as we assumed, make this communication to the local press. The fact that it is known in that case, seems to show how impossible it is to keep these matters secret, in spite of all the efforts made by the authorities.

NOTES.

THE re-opening of the Railway Rates Enquiry last week found the opposing parties no nearer agreement, though Sir Henry James was prepared with a proposal which may simplify matters somewhat. It is suggested that the objections not yet disposed of should be tabulated, and the reasons for making them shortly and concisely stated. The railway companies will then state the grounds on which they decline to comply with the demands made, and the Court would thus be in possession of a revised statement of the points still in dispute. Mr. Balfour Browne took an opportunity of stating that the attitude of the traders represented by him towards terminals was still one of refusal to recognise the right of the companies to make any charge for them at all. Certainly, as matters now stand, in the event of the terminals claimed being disallowed, the railway companies would claim a right to re-cast the whole of the schedules, so as to provide for them in some other way. The form in which they were directed to bring in their proposals gave them a fair ground for assuming that such charges would be dealt with on their merits; and they have adduced a considerable amount of evidence in support of the reasonableness of the sums claimed. The traders will doubtless have to address themselves to the task of rebutting this evidence, as far as they may find themselves able to controvert it, the Board of Trade being hardly the tribunal to decide upon the legal arguments connected with this matter. Much less time was occupied in the examination of witnesses last week than in the case of the representatives of the London and North-Western and Great Western companies, owing to the latter having exhausted so much of the general case for the railways, that there are only certain matters relating to their own particular systems for the other managers to deal with. In defending the proposed classification, Mr. Scotter, of the London and South-Western Railway, maintained that no classification which brought the whole trade of the country into eight classes could hope to be either theoretically or logically perfect. We might add that the modifications already effected as the result of this inquiry afford proof that a full discussion of it by all parties interested will go a good way towards rendering it practically perfect. Mr. Oakley, of the Great Northern Railway, has given his evidence, but the Midland Manager (Mr. Noble) is ill, and unable to attend. The solicitor to the latter Company, Mr. Beale, who attended several of the conferences which preceded this inquiry, appeared on their behalf. Unfortunately, Mr. Courtenay Boyle has since fallen ill, too, and this will necessitate the postponement of the inquiry for a time.

THE discussion on the County Council's proposed amendments of the Metropolitan Building Acts, at the members' meeting of the Institute of Architects on Monday, did not end in anything, the meeting wisely adopting the suggestion of one member that it would be very premature to commit themselves to any decisive expression of opinion, on short notice, on such a matter. On the proposals of the County Council we have already commented at considerable length. Some of the criticisms made on them by Mr. Woodward in a short paper were to the point and of value; some were superfluous or frivolous, and one can hardly say that a critic who finds such difficulty in understanding the wording of an enactment is in the best position to clear the minds of others about it. Mr. Woodward seemed to find the wording of the clause which the Institute print as No. 70, but which we received and printed, more fully, as No. 68 (see *Builder*, December 14, 1889, p. 22), quite unintelligible. The meaning of the words is about as plain as any legal phraseology could be; whether the powers to be taken under the clause are such as it is desirable that the County Council should exercise is a query we have already suggested.

AS in the case of the Royal Academy Gold Medal competition for Architecture, so in that of the Soane Medallion competition at the Institute (the subject being a school), no award has been made this year, except medals of merit to three competitors, Mr. E. W. Gimson, Mr. C. S. Spooner, and Mr. F. W. Bedford. This reservation of the Gold Medal and studentship is probably due principally to the unsatisfactory nature of the plans, though not much can be said for the designs in comparison with some that have been submitted in previous years. Among those selected for mention, the plans of "Nineteenth Century" and "Cedric" are totally devoid of system or of any perception of the actual working of the plan; that of "Georgian" (Mr. F. W. Bedford) is a better plan, but the eccentric colouring and drawing of the perspective view have probably contributed to put the author out of court. The detail elevation, however, shows talent and some originality. Of the Title Prize designs, that to which the prize has been awarded (a stone screen to the entrance of a mansion) "Privacy," by Mr. J. C. Watt, is one of the best designs that has been made for this prize of late years, and is the only one that is in the running at all; the other three are very poor. The perspective is a delicately-executed pencil drawing showing a rusticated and panelled stone screen, with a high block containing a circular archway and gates, rising above the screen-line near each end; these gate-blocks rise somewhat high in proportion to the screen, and rather require connecting with the line of the screen so as to break the abrupt right-angle formed at the junction. This is however a refined piece of work and highly creditable to its author. The prize design for the Grissell Gold Medal (subject, a timber spire) by Mr. Walter Percival, is also an admirable set of drawings made out with great care, and showing no little originality of design; it is a kind of translation of a pinnacle and flying buttress spire into an essentially wooden form of design, which is very cleverly carried out. As a matter of construction, however, we should prefer to see a central vertical tie from the upper portion of the spire rather than depending only on bracing. The collection of drawings for this medal (eight in number) is generally good, which is gratifying, as this exceedingly useful and valuable prize has on some previous occasions not attracted anything like an adequate competition. Mr. Begg's drawings which have gained the Pugin travelling studentship fully justify the award; they are mostly pencil drawings, not highly finished, but drawn in exceedingly good style; a view of Lincoln Cathedral and another of Lincoln Chapter House are especially good. Mr. Macintosh's set of measured drawings of Pluscardyn Abbey, Elginshire, which have gained the Institute Silver Medal for this class of work, are evidently carefully done; they are not so attractive in appearance as the successful drawings for this prize have sometimes been, partly perhaps that the subject does not admit of it. Mr. T. E. Mowlem gains a medal of merit for measured drawings of Cranbourne Manor House for the same prize. The drawings done on tour by the Pugin Student of 1889 (Mr. C. E. Mallows), the Soane Medallist of 1888 (Mr. A. N. Prentice), and the Owen Jones Student of 1889 (Mr. H. V. Lancaster), are exhibited, and form three most interesting and excellent collections of sketches, especially the last-named set; they all thoroughly justify the awards made to their respective authors.

THE new headquarters of the Berlin police are now completed, and the various departments (both civil, political, and criminal) are now moving into their new home. The site on which the building has been erected has a superficial area of nearly 170,000 square feet, 114,000 of which have been actually built upon; so that this new Prussian "Scotland-yard" is the third largest building in Berlin (coming in size directly after the old palace and the new House of Parliament, which latter will not, however, be finished before 1894). The building con-

tains not only the head offices and the whole of the administrative department of the police, the official residences of its chiefs, and quarters for the "A" division of constables and detectives, but also detention cells (and all pertaining thereto—i.e., baths, washhouses, kitchens, &c.) for 328 male and ninety-four female prisoners, stabling (with smithy, &c.) for sixty horses of the mounted police, and thirty horses for the transport vans, and a riding-school (110 ft. by 55 ft.). The planning is considered to be exceedingly practical; an interesting feature is the placing of the horses on two floors connected by a ramp with an incline up and down which the constables can with ease ride their horses. The elevations of the building are in red brick with facings of stone, and, although kept as plain as possible, certainly make a very favourable impression. The courtyards, the central one of which is covered, have their elevations in yellow brick with terra-cotta facings, and show some interesting detail. The building, which has been erected in less than four years, at a cost of 255,000*l.*, has been designed by and carried out under the superintendence of the city architect, "Stadtbaurath" H. Blankenstein.

WE understand that the Glasgow Harbour Tunnel is to be commenced at once in the hands of Messrs. Hugh Kennedy & Sons, Glasgow, whose offer has been accepted by the promoters. The tunnelling works, which will consist of three separate bores of 16 ft. diameter each, one for pedestrians and two for cattle and wheeled traffic, are to be reached on either bank by a perpendicular shaft 80 ft. in diameter, set well back, so as not to interfere with the quays of the harbour, and worked on the hydraulic lift principle. Finnieston Quay, rather over half a mile below Glasgow Bridge, is the chosen place of crossing,—a point about in the centre of the busiest part of the harbour. The new ferry-boat of the Clyde Trust, designed to meet the same want, will ply not many yards away, and the two systems will be in rivalry, at least for a time.

FROM a report, in the *Australian Builders' and Contractors' News* of November 30, of a meeting of the Royal Victorian Institute of Architects, it seems that there is at Victoria a kind of taking-up of Ruskin afresh by architects, just at the time that in England people are beginning to discover the essential futility and weakness of much of his eloquently worded criticism. Mr. H. D. Annear on the occasion referred to read a paper on "John Ruskin and Architecture," and a discussion followed in the course of which one of the speakers said that "though some of them might think Ruskin was too much up in the clouds yet instead of finding fault with him they should toil, patiently and painfully if necessary, after him." If the Victorian architects expect to get any real information on architecture from the study of Ruskin, we fear they will have to toil very painfully and patiently indeed, to accept fancies for facts, and to swallow a great many statements which are pure romance, and romance of a somewhat childish order. It seems rather a pity that this kind of thing should be beginning over again, somewhat after date, at the other side of the globe.

THE first experiences in navigation of the new Loch Lomond tourist steamer have been very trying, and are quite unique in character so far as British waters are concerned. She was lately launched from a Clyde yard, and a few days ago began the ascent of the River Leven, connecting the loch with the Clyde, over a short course of four miles. The Leven falls 20 ft. between its source in the loch and its mouth in tidal waters, but the fall is distributed pretty evenly over the whole distance, there being no lock or any other artificial work, and the result is a winding "rapid" of very considerable force, especially after rains, when the loch is parting with its surplus freely. The

Leven is not navigable in any practicable sense, but it can be traversed by craft of very light draught when in flood, pretty much after the manner of the Canadian *voyageurs*. The old Loch Lomond steamers have not only been all of them built on the Clyde, and in this way tracked up the rushing Leven to the station assigned to them, but they have been brought down periodically for repairs, and in the same way returned. These movements were possible only after the craft had been stripped of all the weight-making portions of their fittings, short of engines and boilers, and including funnels and paddle-box rails, to admit of passage underneath the three or four rigid bridges which span the stream. The new saloon steamer built for the purpose is the largest that has ever attempted this short strip of peculiar navigation, and her experience has shown that the limit of burden is very narrow, and has now been all but overstepped. Abundant haulage power was available, consisting of several hundreds of men on either bank, and some scores of horses, but the stoppages were frequent, owing to grounding, and some of them lasted many hours, so that this short but trying passage of barely four miles ran into days. The current of the Leven is very capricious, swelling rapidly after rains within the great area of the loch watershed, and subsiding as rapidly in obedience to change in the opposite direction. In the case of sustained rainfall the passage is, of course, performed with more certainty, but there is always the risk of delay, even extending to weeks.

WE have received a circular describing what appears a useful and convenient appliance, patented by Mr. Irwin C. Wallas, sanitary engineer, of Kilburn, for testing the gradients of drains as each pipe is laid. This consists of a set of small hard wood blocks, accurately cut to various gradients, so that

on the application of the under-side of the block to a pipe to be laid at the specified gradient, the pipe can be adjusted, as shown by the cut, to the precise gradient required by the application of the spirit-level on the upper surface of the block: when that is proved level the pipe is at the gradient intended.

WE have received some examples of "S. Barter's Manual Training Diagrams" which consist of large coloured diagrams on glazed paper, or details of carpenters and joiners' work, various forms of joints, tenons, &c. They will prove useful in technical schools and Polytechnic institutions.

AT the Burlington Fine Arts Club are collected a number of drawings by the late Mr. Spencer Vincent, who enjoyed the distinction of being eminent both as an amateur athlete and an amateur artist. The drawings exhibited are few of them much finished, but there is plenty of good work in them, and many of them exhibit real genius in regard to the perception and rendering of colour-effect in nature. An interesting portion of the exhibition is a collection of sepia sketches made at the meetings of a sketching-club called "The Os Society," on subjects given for the evening, and we presume treated by each member according to his own fancy. Among these "A well-known spot" (150), "Danger" (152), "A Storm" (154), and "Cloudland" (163) are especially good.

THE Victoria Gallery in Regent-street, where the "Humorous and Grotesque Exhibition" has been for two or three weeks open, is a prettily-arranged gallery for exhibitions, but unfortunately rather deficient in light on the ground-floor: the upper galleries are well lighted. The exhibition contains much that is of interest, though (in spite of its name) it strikes one as a rather melancholy display, in regard to the older works, of spite and ill-nature combined with vulgar and repulsive exaggeration. Rowlandson and Gillray were no doubt terrible caricaturists in regard to their power of giving pain, but they achieved this end by means which would happily be impossible to any caricaturist in the present day, both on the score of decorum and of artistic feeling; they were rather brutal than satirical in the true sense of the word. To art they made no pretence; and as to genuine humour and satire, Mr. Tenniel, Mr. Keene, and Mr. Sambourne are intellectually far beyond any satirical artists of the last century. Cruikshank too appears here as what he was, an artist immensely overrated even as a caricaturist. Hogarth, from whose works a fine set of engravings are here collected, is not to be ranked as a caricaturist, though he chose to be so occasionally; and it is absurd to exhibit his "Marriage à la Mode" and "Rake's Progress" in a "grotesque and humorous" exhibition; pictures more thoroughly serious and tragical were never painted. In general, in the contrast between old and modern humorous drawings, the exhibition may be said to recall the old Latin grammar quotation that Colonel Newcome was so fond of: "Ingenus didicisse fideliter artes emollit mores"; and it is gratifying to think that modern culture and modern manners would no longer tolerate either such drawing or such brutality as was indulged in by Rowlandson, Gillray, and their weaker follower Cruikshank.

AMONG the correspondence on various subjects that usually assists to "pad" the *Times* when Parliament is not sitting have been two or three letters, as often occurs, on the subject of "street music," as it is facetiously called, meaning the instruments of torture called street organs and pianos. As usual, these inflictions and the vagabonds who turn the handle find their defender, this time in a wisecracker who signs himself "Blondel." We owe "Blondel" however one hint which may be turned to good account. He is obliging enough to suggest satirically that the words "nervous invalid" should be written on the houses of those who dislike street organs, and that the operator should be compelled by law to keep at a distance of fifty yards from such houses. It would no doubt be news to scribblers of the stamp of "Blondel" that there are thousands of persons neither nervous nor invalids, but possessed of sane minds in sane bodies, who regard the prevalence of the swarms of barrel organs that are allowed to infest the streets as one of the greatest curses of life in London, and a disgrace to its municipal government. But "Blondel's" suggestion may be turned to a better account than he thinks of. Let a bye-law be passed that all persons who object to these street pests may put up a small notice-board on their houses,—"No organs allowed," and that on the affixing of such notice the organ-grinder should be bound to remain at fifty yards distance from the house without the tenant thereof having to invoke the intervention of the police; on the contrary, let the organ-grinder be liable to be taken in charge by the police on the mere fact of his being found transgressing within fifty yards of a placarded house. This simple arrangement would probably eliminate the organ-grinder. It would go hard if we could not find, in every respectable street, a series of persons separated by a distance of less than 100 yards from each other, who would be only too thankful to adopt this simple means of exterminating a nuisance which is yearly becoming more intolerable.

SPIRES, TOWERS, AND DOMES.*

A VERY forcible example of an ill-conceived tower is the leaning one of Pisa. The diagram on the opposite page is reduced from a measured drawing which was to a scale of 4 25 ft. to the inch.

The tower, circular upon plan, is nearly 178 ft. high, with an out-to-out base diameter of 50 ft., the height bearing a ratio to diameter of 3 1/2 to 1. The wall of the lower story is 13 1/2 ft. thick, and of the upper stories 9 ft. The tower is entirely of marble. The calculations explain themselves. The first item is the superficial area of the foundations. Then comes the cubic contents of the portion of the tower resisting overturn of the wind,—that is, of the exposed part from top to ground line. The weight of the marble is assumed at 170 lb. the cubic foot, and is expressed in decimals of a ton. The total weight of the portion resisting the overturn moment of wind is 15,325 tons (see diagram), and its moment about point A is 91,950 foot-tons.

Point A is $\frac{D}{4}$ from the leeward edge of the tower.

The peculiar case of this tower exhibits graphically the application of the previous remarks of the effect of wind upon cellular surfaces.

The reduction of the wind effect registered upon a flat surface, due to the circular plan of this tower, is annihilated by the galleries, in consequence of their forming cells for the reception of the full force of the wind; in consideration of which a 60 lb. pressure has been calculated. The moment of this force about the point A is ridiculously below the strength of the tower, the ratio being as 1 is to 5 1/2.

The graphic resolution coincides—the distance of the centre line of the three lines marked on the diagram "lines of resolution,"—resultant from the centre of gravity,—only deviates two-elevenths of the distance between the centre of gravity and the point it would be absolutely safe at, showing that notwithstanding the severe inclination there is still a very large margin of safety against the overturning effect of wind.

Next as to the total weight of the tower upon the earth foundation. The soils in the neighbourhood of this tower are not noted for their weight-carrying powers.

The tower brings a pressure of 7 1/2 tons on the square foot, and at a fair computation, the soil, sandy one, is only capable of sustaining 4 1/2 tons. This fact obviates the need of any further inquiry into the causes of the subsidence. The tower is thrown from 12 1/2 ft. to 15 ft. out of the perpendicular, has sunk bodily down some feet into the earth, which has since been excavated away from its plinth.

This tower is a unique example of useless masonry overloading its foundations, still standing, as it does, to tell the tale.

It would be safe to say, from the figures that are before us, that many thousand tons of masonry are in the structure which have no business to be there. It can easily be imagined what the fate of the cathedral would have been with the tower of Pisa joined to it.

The investigations of Canon Moseley, Rankine, and other noted American, French, and German scientists, have now taken a firm hold upon the constructive professions, and these researches are destined to have a far more weighty influence upon architectural construction than has hitherto been the case, tending to produce in our buildings the fullest economy of material consistent with practical needs and lasting stability.

Domes.

Of the numerous domes that have found existence in the last few centuries, how many can be said to be monuments of architectural and constructive skill? The last century has seen great strides made in many branches of science, and yet in the erection of domes, a field in which scientific knowledge could have such full scope, construction is drifting in a backward, rather than in a forward direction. The most recent dome (that for the tomb of the late Emperor of Germany) decides that the *dual* construction still holds the field, so that since the days of Wren there has been seen no legitimate advance in the matter of dome-raising, and it is the opinion of some

that his step was to one side of the obstacle rather than over it.

The cathedral cupola of London was the first of a new race, and in its essential principles one which has been followed by each successive dome constructed of similar materials.

There is no need to recapitulate here the time-honoured theory of the construction upon which have been based the erections of recent centuries. High architectural authorities have satisfied themselves upon the point, and the casual student rests content. It must, however, be felt that the lighting difficulty has not received the attention it deserves as being really the pith of the whole problem. Suppose that the convex surface of the spherical dome, as seen from the exterior, is endowed with the importance and dignity that is consistent with the magnitude of the structure of which it forms part. Then, by nineteenth-century reasoning, the inside surface of this identical shell is unsatisfactory by reason of the unpleasant visual exertion required to grasp its contour,—a disadvantage due to the great distance from the dome to the level of the inside pavement. How can it be otherwise, when the dome shell, even on the St. Paul's plan, is in semi, if not complete, darkness?—a defect undoubtedly due to the system of admitting the light at the wrong place. There is a great deal to support this view.

In the opinion of many, there is no dome interior that satisfies the canons of artistic taste so completely as that of the Pantheon at Rome, an interior lighted directly from the sky.

Again, by universal consent, there is not a more inartistic and depressing dome exterior than that of the same Pantheon at Rome. The evil effect of the flattened appearance of the exterior and its piled-up abutments has been a more powerful factor in modern dome construction than has the principle, almost divine in its simplicity, of admitting the light direct from the heavens. The former has generated the dual and triple constructions of St. Peter's and St. Paul's, and most subsequent domes, while the principle of lighting from the eye of the dome has not been perpetuated with success.

It is not suggested that the great value of top-lighting for the dome has not been fully realised, but rather that its non-adoption has been due to the concomitant difficulties having proved too much of an obstacle to its realisation. What are these difficulties?

In the first place, artistic and even religious sentiment demands that the apex at the crown of the dome shall be surmounted by a lantern erection so as to annihilate the Mahomedan associations attaching to a bald domical sphere. But this very lantern as now built obstructs, rather than lets in the light.

With the example of St. Peter's before him, no dome constructor has again ventured to support a lantern erection upon a single spherical masonry or brickwork-offered dome.

And however we may marvel at the unique construction of the great Sir Christopher, no architect of the present or coming centuries will venture to make such a large draft upon labour and material as was made in the construction of the three roofs to cover the one floor area of St. Paul's.

Granted that for architectural reasons the lantern is essential, then such lantern must be of such a design and of such a size that it conveys a bright strong light from the heavens to the dome interior. If this can be done the need for the dual system ceases to exist. Now the difficulty of carrying a heavy load in the shape of a large lantern at the apex of a spherical dome has hitherto proved insuperable. It will remain so while stone or brick is relied upon as the sole medium of construction.

The materials hitherto composing domical construction, though possessing a full complement of compressive strength, have not possessed that cohesive strength and tensile resistance in sufficient abundance to resist the aggravating bending moments set up by a load at the apex of the dome.

It will here be a fitting opportunity to review the mathematical theories involved in dome construction. So few investigators have brought their work to a practical conclusion, and fewer still have arrived at conclusions that are of the slightest value to the practising architect, that a *review* is not a formidable task. Upon the writings of Bomelet and Venturoli are based the calculations to be found in Gwilt. Mr. Merrifield read a paper many years ago before the Royal Institute of British Architects upon

the dome of *uniform* stress, which showed the shape to be a parabolic cone—a conclusion already arrived at by Wren in designing St. Paul's. Lastly, Mr. Wyndham Tarn has put on record his views. His results, if anything, are more useful than those of the former writers, although he goes about his calculations in a similar manner to the method of Venturoli. His opening steps are common knowledge, and may be followed by any student. By the simple laws of mechanics it is shown that there are two forces generating moments about every point in the arch ring of the dome resting upon an abutment. These forces are the thrust at the crown acting with a leverage about each point in the arch ring, the amount of the leverage varying as the point under consideration alters its position, and the weight of the half-arch acting also with varying leverages about different points.

It must be patent to an observer that there is some point in the dome where the effect of the thrust is greatest,—in other words, where the dome is weakest.

The question arises, where is this point? Mr. Tarn, in a purely mathematical enunciation and proof, in which trigonometry, the calculus, and the higher algebra, involving cubical equations are introduced, demonstrates unquestionably from pure mathematics that the thrust is a maximum at a point 20 deg. from the springing and 70 deg. from the crown. This may be accepted as reliable, inasmuch that on reference to some experiments made by a Mr. Hland on arches composed of wood voussoirs, after careful observation, it was seen that the result first to give way under the thrust was at a point corresponding with Mr. Tarn's mathematic conclusion. At this point, of course, in a masonry dome, the chain would be placed, as has been pointed out.

Given the respective radii of the interior and exterior of a dome-shell, together with the weight of the masonry per cubic foot, the height of the pier, and, lastly, the amount of the thrust at the crown, then, from Mr. Tarn's data it is easy to calculate the amount of thrust passing from the dome to abutment, and the thickness necessary at the abutment to obtain equilibrium and also stability.

A remarkable case is that over Sultan Mohammed's tomb at Gol Gumbaz, at Bejapore. As far as our knowledge of it is correct, its construction is opposed to all modern ideas of good design, the thickness of the shell at the crown being no less than 18 ft., diminishing at various stages to 9 ft. 6 in. at the abutment. Whether it is solid at the thickest part is not known to the author; anyhow, it is the soundest dome existing without extraneous aids at the present time.

The days of masonry and brick domes existing solely as such are numbered, if not even now at an end. And if a dome, such as has been indicated here, can be constructed (and there is no reason why it should not be) satisfactorily from an architectural point of view, when viewed both internally and externally supporting a suitable and effective lantern erection, then the dual construction which has been the great bar to domical roofing development will be superseded, and an architectural sham be abolished for ever.

The question naturally arises, how can this be effected? The following suggestions have been roughly sketched out:—

The introduction of metal into masonry dome construction has had a precedent for a century past in the presence of the iron chain. But suppose the chains are entirely done away with, and a series of iron ribs are fixed radiating from the eye of the dome, formed by a circular metal curb, and abutting upon a similar curb at the base, the whole cross-braced and tied, and fixed upon expansion rollers. By such an erection a framework would be obtained, which could be calculated to resist any bending moment that might be brought upon it by a superimposed lantern, and no thrusts would be transmitted to the drum or abutments. The scheme for covering the metal framework is not a new one, inasmuch that it was suggested some years back to construct a dome entirely of terra-cotta. The idea of the author is that terra-cotta would form a very suitable material for casing the whole of the metal framework, internally and externally alike, by blocks interlocking, and treated architecturally inside, with over-lapping joints externally.

Such a construction would produce a dome which, if suitably treated internally, would be satisfactory artistically, and constructively ex-

Weight of portion of tower resisting overturn			15325	tons
Moment of weight about point A in Diagram	15325 × 6	=	91,950	foot tons
Moment of wind pressure about point A	42.25 × 177 × .0267 × 85.5	=	17,700	"
Pressure of tower on the square foot of foundation	{ (201636 + 80660) × .076 }	÷	2985	= 7½ tons
Safe pressure on the sq. ft. of damp sandy soil, at a depth of 22 ft. from surface - θ = 30° = Ang. of Rep.	$\frac{1 + \sin \theta}{1 - \sin \theta} \times 22 \times .0424$	=	4½	tons

splendid collection of photographs which was exhibited on the screens. He had to confess that he was a little staggered at the vastness of Mr. Beale's subject,—"Domes, Towers, and Spires,"—when he saw it in the syllabus. Obviously, a great deal might be said and written under such a title, but Mr. Beale had wisely confined himself to one side of his subject, and his paper might be described as a plea for the scientific construction of towers, spires, and domes, and not only of towers, spires, and domes, but of all buildings. He did not think that any one would attempt to argue against that for a moment, for it would be absurd, with all the scientific knowledge of the present day, to blindly follow old methods of construction, where they were known to be faulty. They might all learn valuable lessons from the failure of Medieval towers, but he thought they must not go too far in the direction of the advocacy of scientific construction at the expense of the æsthetic side of their studies. Mr. Beale had rather spoken as though the two sides of an architect's education were in antagonism, for he had much glorified the scientific side and thrown cold water on the æsthetic side (Mr. Beale: "No, no!"). He, Mr. Cresswell might have misunderstood him, but he thought it was necessary that they should learn to design before they attempted to construct. Of course, it was impossible to design a building without a knowledge of construction, but he thought that to teach a student how to calculate stresses and strains, before he had learnt anything of the artistic side of his profession, was putting the cart before the horse. He had been very much interested in Mr. Beale's application of scientific principles to the case of the leaning tower of Pisa, to show that it was unstable. His calculation as to the cause of the subsidence of the tower seemed to depend upon a factor which he understood was Rankine's factor of earth-pressures. But he wished to know whether that factor took into account the variety of strata of the earth, and whether it would assist a man who had to deal with earth beneath which there was a running sand or spring the existence of which was unknown to him? For it seemed to him that, under such circumstances, the tower of Pisa might have been constructed with a perfect knowledge of all Mr. Beale's calculations and yet might have failed. Mr. Beale, in speaking of the origin of towers and spires, and more particularly of spires, described the English examples as being very beautiful. Of course, they all admired them very much, but he thought that they must acknowledge that it was to Normandy that they owed the origin of the spire. Mr. Beale had mentioned one example in Normandy, which was the tower of the church of Thaon, a very early church, with a low pyramidal roof of stone to the tower, which was no doubt the first sprout, as it were, from which the later spires were developed. On the subject of detached towers, Mr. Beale had attributed the placing of bell towers in a detached position to the fact that they

ceeding economical, compared in the light of the present accepted modes of dome construction—proof alike against fire, frost, and the dreaded hand of time.*

A few domes are illustrated upon the screens. That of Sta. Maria della Salute, Venice, of which there is a near view and a general one, exhibits an arrangement and general design that is peculiarly graceful externally.

The remarkable central protuberance on the dome over the Pisa Baptistery is a feature more unique than elegant. To it may be traced, perhaps, the bulbous roof terminations on some Belgian and North German Cathedrals.

In drawing attention to the collection of photographs in this hall to-night, comprising as they do examples of many of the principal phases of tower, spire, and dome design, I would venture to say that they are a unique set. They form part of a fine collection gathered together in the course of some forty or more

years. This portion numbers some 240 views. I feel the whole meeting is indebted to the gentleman who has placed these views at our disposal, Mr. James Onbitt, in whose service it has been my privilege to spend some little time; he published seven years ago some notes upon tower design, in which were classified towers of the Romanesque and Gothic styles under two great heads—towers with super-towers and towers without super-towers. Under these two divisions come some hundreds of types classed according to their plan, their roofing, their buttressing, etc. On the tabulated diagrams are scheduled the places where examples of the several types are to be found. The arrangement will repay careful study, and in thus directing attention to these views my paper concludes.

Mr. H. O. Cresswell, in proposing a vote of thanks to Mr. Beale, said he did not think there could be a doubt, as Mr. Beale had said, that they were very much indebted to the gentleman who had so kindly lent them the

* This appears more than doubtful. Had the Pantheon been so constructed, it would not now be standing.—Ed.

would be likely to cause subsidences if they were joined on to the main building. He (Mr. Cresswell) did not think that was entirely the reason. He might be wrong; but in this country, he believed, one reason why towers were detached from the main building was that in early times they were used to a great extent as the strong places in the villages or towns in which they were erected. Many towers, particularly in the West of England, he had always understood, were detached, so that when the people suffered from raids across the marches by the wild men of Wales, they fled to their towers as the strong places of defence. Mr. Cresswell next referred to a list of fallen towers, which were nearly all central towers, and said that Mr. Beale had undoubtedly hit upon the weak point of such towers,—their being carried on four comparatively frail piers, resting on isolated points without any connexion with each other. But for the abutment afforded by contiguous walls, none of the old towers would have stood to the present day. Salisbury Cathedral was one of the most deeply interesting examples, for there they could see the various additions which had been made from time to time to prevent the failure of that spire; if those works had not been done the spire would have collapsed. That spire was said to be in a dangerous state within a short time of its erection, and was several times strengthened to preserve it, and the last restoration on a large scale was carried out by Sir Christopher Wren late in the seventeenth century. With reference to the aesthetic position of towers, he apprehended that with cathedrals in England, it was generally intended that they should have both a central tower and two western towers, and, if they would observe, they would see that that arrangement was suited more particularly to English cathedrals. In England their cathedrals were very long and low, and, consequently, a central tower became an essential and beautiful feature. In France, on the other hand, he thought that the reason of placing the towers and spires at the west end only was that their naves were so very lofty that if a tower had been put upon the crossing it would have had to have been a gigantic affair to tell above the roof. He thought that the French were thus compelled to build their towers at the west end on account of the height of their naves, and to be content with a small niche over the crossing.

Mr. Arnold Mitchell, in seconding the vote of thanks to Mr. Beale, said that differences of taste and education lead them to form varied estimates of the different styles of art, but the most devoted follower of Classical antiquity could scarcely fail to appreciate the intrinsic beauty of the Gothic style. He was very pleased to have heard Mr. Beale emphasize that point in the opening remarks of his paper, although he might have emphasised somewhat more strongly the two distinct varieties of English towers and spires,—viz., the central and the western. Mr. Beale had not, to his mind, laid enough stress upon the fact that the central lantern tower was the legitimate descendant of the Byzantine dome, and that the western tower was the legitimate descendant of the Italian campanile. The little tower of the Church of St. Surplice, on the Lake of Geneva, showed in the most striking way the development which had taken place from the dome to the lantern-tower. At the crossing of the transepts, viewed from the interior, there was a perfect dome. Externally, however, it was a lantern tower. He thought that if they bore this fact in mind when viewing some of our English churches, they would find that some such development had taken place here. The Italian campanile was expressly intended for the hanging of bells, and, although Mr. Beale dissented from that view, it seemed to him (Mr. Mitchell) that he had not made out his case. Mr. Beale had stated that the thickness of the walls of the bell-towers constructed in accordance with the rule quoted by him was out of all proportion to the necessities of the case. Perhaps that was so, but Mr. Beale had gone a step further, and seemed to find fault with the Norman builders for making the walls so much thicker than they need have been. But it should be remembered that the Norman builders were feeling their way; they were building experimentally, so to speak, and did not at first fully understand what they could do with their material. How different was a Norman work, such as the tower of St. Alban's, as compared with an erection of the fifteenth century,—say such an example as that at King's College

Chapel, Cambridge, in which the builders seemed to have pared down every stone to the smallest limits consistent with the work it would have to do. Mr. Beale had stated that he did not know what example to name as the earliest spire in England, but he (Mr. Mitchell) thought there could be little doubt that it was that of Sompoting, in Sussex. That was a Saxon example, prior to the Norman ones by seventy or eighty years. Mr. Beale had mentioned the spire of Thaon, in Normandy, which was, perhaps, the earliest example of a Gothic spire. But he should like to add a curious piece of information to what had already been said, viz., that the interior of that spire was tied with wooden beams. He must dissent from the view which Mr. Beale had taken with reference to the entasis of spires. Mr. Beale had somewhat unfairly quoted Gaythorpe, where entasis had been carried to such an extent that the effect was almost hideous. An entasis of about 3 in. in 180 ft. of height was very small, and did not affect the stability of the structure. He should like to ask Mr. Beale one question, viz., How were the Medieval spires constructed,—with the led-joints horizontal or at right angles to the face? Mr. Beale had spoken of the peculiar formation at the top of the dome of the baptistery at Pisa, as suggesting a lantern; but he had not added that the excessiveness in question was really the top of a large cone, which was carried up from the bottom of the large external dome. The case of the failure of the tower of Pisa could not be attributed to the wind pressure, for we knew that the builders, while building the tower, found that it was rapidly becoming out of the perpendicular, and it was curious to notice how, when they had realised the fact that the tower was leaning, they had tried, by varying the thickness of the masonry and by making the colonnades on one side higher than on the other, to get it into the perpendicular again.

Mr. C. H. Brodie supported the vote of thanks to Mr. Beale, and said he thought their special thanks were due to him and to Mr. James Cubitt for the collection of photographs.

The Chairman (Mr. T. E. Pryce, Vice-President), in putting the motion, said that with regard to the position of towers, he thought that that was a matter of taste. He was more particularly speaking about the small parish churches scattered all over the land; but with great cathedrals it seemed best to place the tower at the crossing. Another thing that struck him as being a matter of taste was the building of detached spires in this country. They were common enough in some parts of England, notably so in Herefordshire. He was not disposed to think that the isolated position of the tower was always due to defensive considerations. He then on an extremely interesting one and the discussion especially so.

The vote of thanks was then put and carried by acclamation.

Mr. Beale, in reply, said he had very few points to reply upon. He had previously had experience of a scientific discussion at that Association, and he thought that it testified very strongly to his view that they did not pay sufficient attention to scientific matters. He had, perhaps, not made himself sufficiently clear to some gentlemen in what he had attempted to say about the diagram of the Pisa tower. What he said was that he thought the tower was perfectly safe against being overturned by the ordinary effects of wind. As regarded the settlement of the tower showing the sinking of the soil, his calculations showed why it sunk, because there was $7\frac{1}{2}$ tons on the foot on ground which was only capable of carrying $4\frac{1}{2}$ tons to the foot. Reference had been made to the fact that the tower had sunk before it was completed, but his figures would show that it would sink before it was half its height. The upper story, which was added much subsequently to the general erection, was made with a thickness which varied, so that the light section was on the lower side of the tower and the heavier masonry was on the upper side. There was an enormous excess weight of marble masonry used, or the tower would not have failed. He had been asked how his calculations would be of service in such an emergency as the unknown percolation of water beneath the structure; but, of course, all calculations of that kind must be taken in a practical spirit, as applying to known facts. His idea was to arrive at a mere estimate by which they might

compute the bearing power of soil, and beyond that he did not go. When engineers and scientists were called in to advise upon any scientific construction, they had to bring common sense to bear, and architects should do the same. A question had been asked as to what knowledge he had of the inclination or otherwise of the heads of the joints of the masonry of ancient spires. His observation was that in Medieval spires the joints were at right-angles to the face, and not horizontal.

Mr. Cresswell here mentioned that the subject had been discussed very fully in a series of letters in the *Builder* some years ago.

Mr. Beale, continuing, said he did not think that discussion came to anything more than what he had mentioned. With regard to the restoration of the tower of St. Michael's, Coventry, he thought that the thickness of the walls was excessive.

The meeting then terminated.

Illustrations.

SKETCHES FROM THE TUDOR EXHIBITION.

 We give this week a number of drawings of various bits of decorative work from objects in the Tudor Exhibition, most of which were alluded to in our note on the Exhibition a week or two back. They are selected of course, for their artistic and not for their popular interest, though the remarkable cup originally given by Queen Elizabeth to Drake includes both kinds of interest. The sword hilts, a few out of a considerable number in the Exhibition, are worth note for their effective treatment.

THE WEIGH-HOUSE CHAPEL.

The Congregational Chapel, School, Institute, and Minister's House, having frontages in Duke-street, Robert-street, and Thomas-street, Grosvenor-square, W., of which we give an illustration, are now in course of erection for the Trustees of the Old King's Weigh-house Chapel, which formerly stood upon the site of the Monument Station, Fish-street-hill, E.C. Mr. A. Waterhouse, R.A., is the architect. The materials are red brick and terra-cotta, the latter manufactured at the Burmantofts Works of the Leeds Fire-clay Company. The general contractors are Messrs. J. Shillifoe & Son, Bury St. Edmunds.

DESIGN FOR PROPOSED HOSPITAL, WEST HAM, ESSEX.

The design, illustrated by perspective view and key-plan, was submitted in an open competition by Messrs. Arthur Crow, A.R.I.B.A., and Philip Henry Tree, A.R.I.B.A. Accommodation was required for twenty-four beds, with provision for extending the building at some future time. These requirements were met by the adoption of two circular ward blocks, on the system advocated by Professor Marshall, each of two floors branching off right and left from a central administrative block. In order to secure, as far as possible, the thorough isolation of the wards, the corridors connecting the same with the administrative block are reduced in height to 7 ft. 6 in., and a space is thus provided for the passage of air above and below same. The small blocks containing the bathroom, w.c., laundry, &c., having been similarly isolated from the wards, an uninterrupted circulation of air is obtained on all sides.

The administrative block contains, on the ground-floor, a casualty-room and matron's sitting-room, with access from central octagonal hall, and opposite the entrance a broad corridor leads to the operating-room at the rear of the building, which is provided with lantern and north lights. Attached to the operating-room is a small consultation-room for surgeons, with w.c., lavatory, &c., in conjunction therewith. A board-room is also provided on this floor. An open well-staircase, planned to receive a patient's lift, leads to the first-floor, on which are placed a small suite of rooms for the resident surgeon, comprising sitting and bed rooms, bathroom, lavatory, and w.c. A convalescents' ward is provided in front of the building, with access to a balcony over entrance. A bedroom for the matron and a single ward are also provided on this floor. On the second-floor are placed the kitchen, offices, and bedrooms for nurses and servants.

As the very restricted nature of the site

Chamber Plan

THE LONDON COUNTY COUNCIL.

THE London County Council held its first meeting since the Christmas recess on Tuesday afternoon last, in the Council Chamber, Guildhall, Lord Rosebery in the chair.

The Proposed Fountain at Piccadilly Circus.

—The Improvements Committee presented a report, in which they said:—"We have proceeded upon the references of the Council relative to appropriating the vacant space at Piccadilly-circus, and we have considered various suggestions. The site in question is of triangular form, containing about 1,620 superficial feet, is a conspicuous and important one, and is therefore specially adapted for some ornamental object, although the surrounding buildings offer little or no architectural attraction. After mature consideration, we formed an opinion that an ornamental fountain, so constructed as to avoid splashing and the carrying of spray by the wind, would be the most appropriate method of utilising the site, and we gave instructions for designs to be prepared accordingly; but just at this juncture we received a communication from the Duke of Westminster, as Chairman of the Shaftesbury Memorial Committee, suggesting that the site might be appropriated to the fountain which the Memorial Committee had ordered to be constructed. We are unanimously of opinion that the spot in question, which is at the termination of Shaftesbury-avenue, is peculiarly suitable for a memorial to this distinguished philanthropist. We have seen the model at the studio of Mr. Alfred Gilbert, the sculptor, and we are assured that it will fulfil the conditions as to spray and splashing. The dimensions are apparently well designed, being as follows:—Height of fountain from base to summit, 30 ft.; height of platform, 2 ft. 6 in. The base of the fountain is octagonal, measuring 10 ft. 8 in. from face to face, surrounded by a platform 2 ft. 6 in. wide, and approached by six steps, the whole occupying an octagonal space of 23 ft. from face to face, and covering a total superficial area of about 450 ft. A margin of pavement would be left of 6 ft. in the narrowest and 2 ft. in the widest part of the present triangular plot. The model is not finished, and the artist hesitates to complete it until the site shall have been decided upon, because certain details will be designed to harmonise with the surroundings. It is, therefore, difficult for us to arrive at a definite decision as to its artistic suitability. We suggested to the Shaftesbury Memorial Committee that a model should be placed on the spot to afford an opportunity of judging of its merits, but again occurred the difficulty of its incompleteness. Neither are we in a position to provide a sketch for the inspection of the Council. Under these circumstances we recommend—

"That a communication be sent to the Duke of Westminster, Chairman of the Shaftesbury Memorial Committee, suggesting to the erection of the fountain at Piccadilly-circus, but with the understanding that in the event of its not proving to be adapted for the site, or not receiving the approval of H. M. Commissioners of Woods, &c., as required by the Metropolitan Improvements Act, 1889, it shall be removed to some other spot, for which facilities will be given by the Council."

This was agreed to without discussion.

The Bethnal-green "Poor's Land."—The Parks and Open Spaces Committee submitted the following report:—"We have again had our attention called to the question of the waste land in the parish of Bethnal-green, known as the 'Bethnal-green Poor's Land,' adjacent to the Bethnal-green Museum Garden, which latter is already under the control of the Council. The Poor's Land is 6½ acres in extent, and is subject to a trust, the provisions of which, since we last reported on the subject, viz. on April 9, 1889, have been dealt with in a draft scheme by the Charity Commissioners. The Commissioners propose that of the 6½ acres, about one acre and a quarter shall be devoted as a site for a public library and town hall (the ground surrounding which to be open to the public), and that a further area of 2½ acres shall be given up for a site for a parish infirmary, leaving 2½ acres to be laid out and maintained as a public recreation ground. Having carefully considered this scheme, we do not consider that it should be adopted in its entirety, as too great a portion of what is now an open space would be devoted to building purposes. The Council, on April 9, 1889, passed the following resolution:—

"That the Council do communicate with the Charity Commissioners, and ascertain if they are prepared to agree to a scheme, to be proposed by the Council, for laying out and maintaining the Bethnal-green Poor's Land as an open space; that the Commissioners be re-

quested not to agree to any scheme for building on the said land; and that the Parliamentary Committee be instructed to watch and report on any Bill promoted with respect to the same."

At that time, neither we nor the Council were in possession of the details of the scheme of the Charity Commissioners. Now, however, that we have had an opportunity of considering the scheme, we have arrived at a conclusion which we think would effect a fair compromise between the various parties interested. We recommend—

"That the resolution of the Council of the 9th of April, 1889, relating to the Bethnal-green Poor's Land, be modified, and that the Charity Commissioners be informed that, in the opinion of the Council, such land (with the exception of a part not exceeding two acres, which may be required for the erection of a parish infirmary) should be handed over to the Council free of cost, to be maintained in perpetuity as an open space."

This recommendation met with strong opposition, and was declared to be due to a "snatch vote" obtained in a thinly-attended Committee meeting called during the recess, both the chairman and vice-chairman of the Committee being opposed to the recommendation. Ultimately, the report was referred back to the Committee for further consideration.

Dealing with Surplus Lands.—On the subject of the mode of dealing with the Council's Surplus Lands, the Corporate Property Committee presented the following important report, the adoption of which was moved by Lord Hobhouse, the Chairman of the Committee:—

"We have to report on the following reference, made to us by the Council on April 11, 1889:—

"That the question of the manner of dealing with land which comes into the possession of the London County Council be referred to the Corporate Property Committee for consideration and report."

1. Land comes into possession of the Council by several different channels and under several kinds of obligations, and in all of these classes except one the powers of the Council to deal with the land are prescribed by law within very narrow limits of discretion.

2. The above reference was made by the Council upon an amendment to a motion made by Mr. W. Saunders in the following terms:—

"That land which shall come into the possession of the London County Council shall not be sold or let on fixed leases, but it may be let on perpetual leases, at rents subject to periodical valuation."

3. We conceive that both motion and amendment referred only to that land which the Council has to dispose of for the purpose of profit, and so as to recoup as far as may be the expense of its acquisition. In this report therefore we note the fact, but without entering into further details, that the following classes of land come into the possession of the Council with narrowly circumscribed powers of management and disposition:—

I. Land devoted to open spaces.
II. Land acquired under the Artisans' Dwellings Acts, and devoted to the provision of dwellings.

III. Those portions of land acquired under Improvement Acts, which are devoted by the same Acts to the restoration of habitations for the artisan classes displaced by the improvements.

4. The class of land to which we address this report is:—

IV. Land which is acquired under Improvement Acts, and which, not being wanted for the intended improvements or devoted by statute to artisans' dwellings, falls into the category of 'superfluous land.'

5. The quantity of superfluous land acquired under Improvement Acts, and now owned by the Council, is about 45 acres, of which about 35 acres are let on leases, at rentals amounting to about 94,000*l.*

6. The obligation imposed by the Lands Clauses Act, 1845, to sell superfluous land within a short time, has been relaxed in the case of the County Council. The periods for which land may be retained unsold are:—

(a) As to land acquired under Improvement Acts passed prior to 1881, the year 1921.

(b) As to land acquired under the Acts of 1885 and 1886, such period as the Council shall think fit.

(c) As to land acquired under the Acts of other years, the year 1941.

7. The modes of dealing with superfluous land allowed by Improvement Acts may be exemplified from the Act of 1888. That Act

would not permit of any ground being set apart as a garden for convalescents, provision was made for an airing-flat, with glazed shelter over each ward block, with access thereto by separate staircases from first-floor.

A small block, consisting of two wards and scullery, with w.c.s and lavatories, was arranged so as to be entirely disconnected from all other buildings with a view to the immediate isolation of any infectious cases which might break out after admission to the hospital.

A mortuary, post-mortem-room, and disinfecting-chamber constitute a separate block, with access from sloping way forming approach for ambulances. In view of the many recent disasters in public buildings through fire, provision was made in this design for easy egress from each ward by means of an escape staircase leading from the bathroom lobby to the ground level.

The size of the ward was calculated on the basis of 100 superficial feet of floor space per patient, and arrangements for ventilation were made by the provision of fresh-air inlets under the head of each bed, in conjunction with the hot-water radiators, so that an ample supply of pure air of enigne temperature could be secured for each patient, special fines of glazed stoneware pipe for the extraction of foul air being carried up in the central stack of fines. In addition to the hot-water radiators three open fire-places are shown in each ward. The internal finishings were intended to be of simple form, with a view to economy, as well as to facilitate the cleansing thereof, and to eliminate as far as possible all projections for the lodgment of dust, &c. The exterior of the building was also designed with due regard to economy, but at the same time a certain amount of character was aimed at to satisfy its demands as a public institution. With this end in view the walls were intended to be faced with red bricks in two tints, the strings, cornices and other features of the design being in terracotta.

THE OLD FOUNTAIN, MARKET-PLACE, MAINZ.

The old Renaissance fountain in the Market-place at Mainz is a characteristic example of a certain school of Renaissance work. The fantastic agglomeration of corrupt ornament which forms the terminal of the triangular erection over the fountain is certainly in very coarse taste, yet there is a kind of power about its exuberance which to some extent atones for the bad character of the detail.

VILLA NEAR STRASBURG.

THIS house, called "Strassburg le Cottage," we give as a typical example of contemporary German taste in domestic architecture. Without expressing admiration for the style of architecture it represents, we believe all who are acquainted with the tendencies of German "picturesque" house architecture will concur with us in thinking that this is a favourable example rather than otherwise of the style of domestic architecture of modern Germany.

MEDALISTS AND PRIZEMEN AT THE INSTITUTE.

At the business general meeting of the Royal Institute of British Architects on Monday evening last, the following awards were made, viz. :—

*Institute Silver Medal (and 10*l.* 10*s.*)*.—To Mr. Alex. Mackintosh. In the same competition, a Medal of Merit was awarded to Mr. J. E. Mowlem (Swanage).

Soane Medallion.—The Soane Medallion was not awarded this year, as elsewhere noticed. But in the same competition Medals of Merit were awarded to Messrs. F. W. Bedford, C. F. Spooner, and E. W. Gimson (Leicester).

Watt's Medal (and a certificate).—Awarded to Mr. James C. Watt, of Aberdeen.

*Grissell Gold Medal (and 10*l.* 10*s.*)*.—Awarded to Mr. W. Percival, of Longton (Staffs). Medals of Merit awarded in the same competition to Messrs. J. A. Pywell and F. F. Pennington.

Pugin Studentship.—Awarded to Mr. John Begg. Medal of Merit to Mr. D. J. Blow.

Godwin Bursary.—Awarded to Mr. A. C. Cox.

Ashpitel Prize.—Awarded to Mr. Herbert Baker.

Scientific Masonry Prizes.—10*l.* 10*s.* to Mr. H. A. Woodington; 5*l.* 5*s.* to Mr. A. W. Anderson.

gives to the Board of Works discretion to let on building leases not exceeding 99 years, with or without option to the lessees to purchase the fee-simple; in sell the reversions on such leases for reasonable prices; to sell at once for reasonable prices; and to let at rack-rent; but all subject to the obligation to get rid of the whole by February, 1941.

8. The legal modes, then, in which the Council may deal with its superfluous land may be thus enumerated:—

(c) By ordinary letting from year to year, or for short terms, at rack-rents. It is obvious that this mode is not applicable to any considerable amount of land, because nearly all that comes to the Council is cleared, and requires building on it in order to be profitable.

(y) By the building lease commonly used in London. The usual term granted by the Board of Works has been eighty years.

(x) By ordinary sale for a gross sum.

(w) By lease with premium. This is obviously not adapted for building land.

9. Another mode would be:—

(v) To sell the fee-simple on a fixed perpetual rent, or to grant a term of years tantamount to it (say 1,000 years) also upon a fixed rent.

The latter form of this mode, which is in law a lease, does not fall within the terms of our leasing powers, and it may be doubted whether the first-mentioned form is authorised by our selling powers.

This mode is not used in London. But it is the favourite method of dealing with building land in Manchester and many other large towns in England, and is also in general use in Scotland. Its advantages to the grantee of the land are easy to see; and those who are in favour of enfranchising leaseholds will probably think that it is more for the public advantage than the London system. Whether it is of equal advantage to the grantor is another question; probably it does not yield so much money to him, but it is difficult to tell without seeing the two systems at work side by side in the same locality.

10. We mention last:—

(z) The plan propounded by Mr. Saunders. The main principle of this plan is to keep the interests in and the profits of the soil quite distinct from the interests in and the profits of the buildings placed upon it. The landowner is to grant the perpetual use of his land, and to receive at once as much rent as the land without buildings will fetch in the market. The grantee is to build upon the land, but the land is never to become the property of the grantee, nor the buildings the property of the landowner. At frequent periods of time (say every five years) the land is to be revalued, not as it stands with buildings upon it, but as it would be without any buildings, and the rent is to rise or fall with the value of the land estimated on that hypothesis.

We are disposed to think, with Mr. Saunders, that such a plan would reduce the temptation which now exists to put up flimsy buildings, and would put an end to the hardships which are now felt by an occupying lessee, and to the contentions between him and the reversioner which at present are incident to the expiry of a long lease. But it is doubtful whether equal contentions between grantor and grantee may not arise from frequent readjustments of rent by valuation; and it is impossible to forecast the other consequences of the principle, as yet wholly untried, of effecting a separation in interest and in ownership between land and the buildings on it, instead of treating them as one entire thing in interest and ownership, which they must necessarily be in use and enjoyment.

Mr. Saunders also claims for his plan that it will diminish the risks of the builder, and so render the trade of building more healthy, and at the same time that it will be more profitable to the landowner. These are conclusions to which we cannot at present see our way.

It is clear that Mr. Saunders' plan is not within our existing powers.

11. It will be observed that there is no legal power for the Council to devote their superfluous land to the purpose of open spaces. It seems reasonable that a body immediately con-

cerned in the maintenance of open spaces should be able to devote to that purpose land which is in its hands, though acquired for another purpose. The power would hardly be needed except for small plots of ground. But we conceive that the Council would do well to ask for it on some fitting occasion.

11A. It appears also to be the case that superfluous land acquired under Improvement Acts cannot be applied in artisans' dwellings in the same manner as if it were acquired under the Artisans' Dwellings Act. Again, it seems reasonable that a body charged with the duty of erecting artisans' dwellings should have the power of using for that purpose land which it is under obligation to let or sell, but which it finds to be a proper site for dwellings.

12. With respect to the above modes (y) and (z) by which the great bulk of property has been dealt with, we have inquired what principle guided the Board in selecting between the two. We are informed that the Board preferred, as a rule, to let on lease, as being the most profitable course; and that they only resorted to sale in cases where they could not effect leases, or where it was inconvenient to hold plots of isolated land, or for some other exceptional reason.

13. We have next considered whether there is any reason for altering the course taken by the Board. If there is, it must rest on one of two grounds: either that more profit can be obtained by some other course, or that it will conduce generally to the advantage of Londoners.

14. As regards the economical ground, the Council are aware that both rent in case of a lease and purchase-money in case of a sale are carried to the Consolidated Loans Fund to meet the debt. But up to the present time new improvements and new loans have demanded much more money than has been either brought in by sales of land, or represented by the acquisition of land. The Comptroller has supplied us with figures which show that during the last ten years the amount of money received from sales, added to the value of the land acquired and retained as the property of the Council, does not exceed one-third of the capital amount expended on improvements. And there are constant demands on us for loans to other Municipal bodies in London.

15. If the question lay between the two alternatives of purchasing our stock at the market price on the one hand, and retaining land to produce rent on the other, it seems clear that the rents would exceed the interest of the stock purchased by selling them, and, though it must always be remembered that the possession of house-property involves charges and liabilities which must be set against the rent, it may be taken that the latter of the two suggested alternatives would be the more lucrative.

16. But so long as we want more money for capital expenditure and loans than can possibly come in by sale of land, there is a third alternative, viz., to sell our land, and to spend the price in the new improvements that are wanted. To work out the probable financial results of such a policy is a matter rather for the Finance Committee than for ourselves; and we have not attempted to solve that problem.

17. Passing from the economical question to that of more general policy, it appears to us that there are two reasons why we should not retain land. One has been already referred to in connexion with the enfranchisement of leaseholds. The property of the Council is, indeed, a very small matter in the mass of London, not equal to one of the larger private estates. Nevertheless, every building-lease that it grants goes to swell the number of leasehold properties, and to diminish the freeholds.

18. The other reason is that, in our judgment, it is not desirable that a Municipal Corporation should, in addition to its other duties and responsibilities, assume the position of an ordinary landowner. It is his interest to deal with his land in the way most profitable to himself, and he has no public or definite duty to the contrary. The Council owe a duty to the ratepayers to make their land profitable, and also have higher duties of control and supervision to perform. It is impossible to suppose that these two sets of duties will not occasionally come into conflict, or that the judgment will not be embarrassed or warped when such a conflict occurs. Moreover, the management of house property, even when let on building lease, requires a considerable amount of detailed supervision which the Council cannot exercise,

nor can its individual members. All must be done by paid agency. At every meeting of this Committee, we have before us numerous questions of detail regarding construction, appearance, insurance, lighting, servitudes, and other matters connected with the properties we let on building lease. In such matters, with trifling exceptions, we are dependent on the report of the Architect. It is impossible for us to act with the promptitude or the freedom of an individual owner, and almost impossible to act with as accurate a judgment. At best a certain amount, and not a very small amount, of energy, which had far better be given to public business, is absorbed into dealings with small details of private property. To a certain extent these mischiefs are unavoidable because we must buy and sell. But they are much enhanced by our letting on lease.

19. For the above reasons we are disposed to think that it is desirable for the Council, and therefore for London, that we should exercise powers of leasing more sparingly, and powers of selling more largely; and especially with regard to property acquired in future, or not yet dealt with.

20. It remains to add something with respect to the modes of dealing which we have classed under heads (r) and (v). We have above intimated that they are beyond our legal powers, but probably the requisite powers could be obtained if the operations were thought desirable. But mode (r) is not used in London, and it is not an easy matter to set afloat new modes of dealing with property among people long accustomed to their own modes. Such experiments are sure to be made, at least in the beginning, at the cost of those who try them. The Council is the owner, not of a large or compact tract of land, but of small plots scattered about London. It is not in a position to exert any great influence on the dealings in the London market. It is not so free to try hazardous experiments with the property of the ratepayers as a private owner is with his own property. And, as practical men, we cannot advise that any systematic attempt should be made to deal with the land of the Council according to this mode. At the same time we have been informed that there are practical men who think it likely that London land may be dealt with under head (v) advantageously both to grantor and grantee. Our own Architect is disposed to think so. And it may be well to have such a mode open to us, in case favourable offers should be made.

21. As to head (z), we have no such evidence. That mode of dealing with land is not only not used in London, but is unknown in England. The obstacles to introducing mode (z) apply with increased force to mode (v). We think it would be premature to make any move in that direction. But if this plan is really sound and practical, the present discussion will probably make it better known, and bring forward further opinion in its favour.

22. We have thought it our duty to answer the reference fully by exhibiting to the Council all such aspects of the question as have occurred to us. But such recommendations as we have to make lie within a very narrow compass. It does not appear to us desirable that the Council should lay down any rigid rule with respect to leasing or selling. The discretion of the Committee, which means the discretion of the Council itself, should, as we think, be left open in each case. But if the Council approves this report without correction, the result will be that, in the future, more sales will take place in proportion to leases, and the tendency of land in the ownership of the Council to increase will be to some extent checked.

23. The distinct recommendations we make are:—

I. That the Council should instruct the Committee to sell the land of the Council in preference to leasing it for 99 years, in cases where there does not exist any special reason for leasing it.

II. That the Council should acquire power to keep superfluous land as open space whenever expedient.

III. That the Council should acquire power to apply to the purposes of artisans' dwellings land acquired under improvement Acts.

IV. That the Council should acquire power to sell land, or demise it for any term of years for a fixed rent. No one of these objects can be called urgent. With respect to the application of purchase-money to new improvements, we are not certain whether any fresh legal facilities are required, but if any are, they will be best indicated by the Finance Committee.

Lord Hobhouse having spoken at some length on the general scope of the report, Lord Lingen referred to the general financial bearings of its

proposals, and moved that the report be referred to the Finance Committee for consideration. This was seconded by Sir John Lubbock, and agreed to *nem. con.*

Proposed Labour Bureau.—Mr. Thornton moved:—"That, recognising the need of a central establishment where masters and men may register their requirements, this Council would be willing, if desired by representative bodies of artisans and labourers, to assist in the establishment of a Labour Bureau." This gave rise to some discussion, and it was ultimately referred to the Contracts Committee to report whether it was possible and desirable to establish such a bureau.

After transacting other business, the Council adjourned.

ARCHITECTURAL SOCIETIES.

Edinburgh Architectural Association.—A lecture on "Some Early Scottish Architects" was given on the 9th inst., by Mr. J. Balfour Paul, advocate, to the members of the Edinburgh Architectural Association, in the hall, 42, George-street. Mr. H. J. Blanc occupied the chair. Having pointed out that few records as to the designers of our cathedrals and castles were available, the lecturer proceeded to mention some of the more prominent of Scottish architects of early times. He said (according to the *Scottishman*) that Gilbert of Moray, Bishop of Caithness, in the first part of the thirteenth century had the credit of designing and building at his own charges the church of Durnoch, the remains of which were still in existence, incorporated with the present parish church. The Castle of Kildrummie, in Aberdeenshire, was also probably erected by him. In the fifteenth century a family of the name of Merlyoun was largely employed by the king in executing work at Stirling Castle, Dunbar, and other Royal fortresses. Thomas Cochrane, the favourite of James III., who fell a victim to the vengeance of Angus and other nobles, was stated to have been an architect, though his exact position in the King's household had always been doubtful. Another architect of that century, Sir James Hamilton of Fyvie, it, about a violent end, being executed on a charge of inventing an infernal machine by which the king was to be shot from the tower of Linlithgow. A distinguished man, William Schaw, held the post of king's architect to James VI., and he restored Dumfermline Abbey, and was hurried there. After alluding to some of the nobles who were instrumental in erecting the leading mansions and castles of Scotland, the lecturer gave an account of the family of the Mylnes. Belonging to Aberdeen, they gradually came south, and in the seventeenth century John Mylne was located in Edinburgh, and was Member of Parliament for the city. He was buried in Greyfriars' Churchyard. His nephew Robert was the builder of Mylne's Court, and several other premises in Edinburgh. A descendant of his built the North Bridge, and another attained eminence in his profession in London. The lecturer subsequently made reference to the claims put forward for Inigo Jones, Wallace, Aytoun, and Balcanquhall as the designers of Heriot's Hospital. He also spoke of Sir William Bruce, of Kinross, who restored Holyrood in 1671. In conclusion, he gave sketches of James Gibbs, Colin Campbell, and the elder Adam. A vote of thanks was passed to Mr. Paul for his lecture.

Glasgow Architectural Association.—The usual monthly meeting was held on the 7th inst., when a paper on "Furniture" was read by Mr. Fred. M. Miller. The chair was occupied by Mr. Wm. James Anderson, vice-president. The paper was well illustrated by examples of old carved cabinet doors and some of Morris's work. A discussion was opened by Mr. Andrew Black, and taken part in by several other members, and at the close a hearty vote of thanks was awarded Mr. Miller.

Manchester Architectural Association.—The members of this Association met on Tuesday evening last at the Diocesan Chambers, when Mr. Lawrence Booth, F.R.I.B.A., a past President of the Association, read a paper on "Commission." The President, Mr. J. H. Woodhouse, was in the chair, and there was a large attendance. The paper dealt with the subject of "Commission" as understood and practised upon in business life, treating it in its several degrees of legitimate, through the questionable, to that of absolute dishonesty; and indicated that many industries were groaning under the

effects of the latter, as an incensus preventing their progress and prosperity. In its application to architectural practice the paper deprecated all secret commissions, and advocated complete candour on the part of the architect towards his client, as "suspicion always dogged the steps of secrecy." The author protested against a very general imputation that architects, being paid by commission, brought about extra expenditure in order to increase the amount of their own charges, and asked men of the world to consider for a moment whether any architect, so depraved as to be willing to squander his client's money in order that a shilling in every pound might find its way into his own pocket, would not be likely to devise some more simple and less palpable method of robbing his employer? Extras of a preventible character did make their appearance, and were frequently the result of the desire of architects, especially new beginners, to put in "all they knew in the way of decorative features and good architectural effect," in the hope of enhancing their own professional reputation. Such efforts had frequently the opposite result, and ought to be avoided, but fell very far short of deserving the condemnation bestowed on gross and corrupt motives. The main argument of the paper was directed against the remuneration of architects being regulated by the amount of money spent, or, in other words, against the principle of payment by commission, and in favour of payment by results, the writer saying:—"It is indeed doubtful whether the community would not long since have compelled us to adopt a more rational method in the assessment of our services if they had been less familiar with payment by commission in their other transactions." A cordial vote of thanks to Mr. Booth was proposed by Mr. A. H. Davies-Colley, seconded by Mr. F. W. Mee, and supported by Messrs. Hodgson, Smith, Mould, Chadwick, and the President. This was carried unanimously.

Royal Institute of the Architects of Ireland.—His Excellency the Lord Lientenant, in replying affirmatively to an address presented to him a few days ago, asking him to become a vice-patron of the Royal Institute of the Architects of Ireland, said—

"I am very glad to learn from your address that you have such good grounds for being satisfied with the results that have been achieved by your Institute during the last half century, and I sincerely hope that a similar success may attend your efforts for the further development of your most ancient and important art. But a few days ago it was my privilege to inspect the noble pile of buildings that have recently been erected for the Science and Art Department, and just what excellent work Irish architects of the present day can produce. I was specially struck by the beauty of the Irish marble that decorates its walls, for I own I had no idea that this country could produce so various and splendid specimens, which compare most favourably with Italy's celebrated marbles. I do not doubt that if their excellence were more widely known an important industry might soon be developed, for the public will not fail to show their practical appreciation once they realise the merits of this native product."

Sheffield Society of Architects and Surveyors.—The usual monthly meeting of this Society was held at the School of Art on Tuesday evening last. Mr. F. Fowler, the President, occupied the chair, and there was a fair attendance of members. Mr. J. B. Simpson was elected an Associate of the Society. Mr. J. B. Mitchell-Withers read an interesting paper entitled "Elementary Notes on the Mouldings of Medieval English Architecture." He quoted the late Mr. Edmund Sharpe's authority for the statement that "English architectural history was written as much in the mouldings as in the general outlines and masses of its old buildings." It was an easy matter for the architect who had diligently drawn and measured old work to understand and trace out its development from early to late forms. The nave of Westminster Abbey was a notable instance of the use in one general grand design of the various styles of mouldings from the thirteenth to the sixteenth century. No architect who had not an intimate knowledge of the subject ought to meddle with any old building, the humblest of which was generally a good school to study in, and young architects should diligently study and draw the buildings of their district. The late Sir Gilbert Scott had laid down that measured and full-sized drawings were far more useful to the architect than photographs, &c. The lecturer gave illustrations on the blackboard of the principles of grouping and designing mouldings of the different periods, and alluded to the best means of drawing them from actual work. He also noticed the nomenclature of Medieval mouldings, quoting from

William Worcester, who wrote at Bristol in the fifteenth century, and the late Mr. E. J. Willson's notes in Pugin's "Specimens." The illustrious French architect, the late M. Viollet-le-Duc, had said that "to the practical architect a knowledge of mouldings was of the first importance," and that the mouldings of the Greeks and thirteenth-century architects "satisfy alike taste and reason." In conclusion, he quoted Professor Ruskin, who, in counselling loving care and reverence in the repairing of ancient buildings, had very beautifully written "that the glory of a building is not in its stones or in its gold. It is in the golden stain of time that we are to look for the real light, colour, and preciousness of its architecture." The lecture was well illustrated by numerous diagrams and measured drawings of the author's, and full-size drawings of the stone details of the south transept of York Minster, lent by Mr. C. Hadfield. On the motion of Mr. E. M. Gibbs, seconded by Mr. C. Hadfield, a hearty vote of thanks was awarded the lecturer.

THE BARBER-SURGEONS' HOLBEIN.

Str.—In your notice (January 11, p. 24) of the large Holbein picture of King Henry VIII. granting the Charter to the Barber-Surgeons' Company, you remark, "Walpole avers that the picture had been retouched, but its owners say it has undergone no other change than by a careful cleansing in 1719, and again in 1878, by Mr. George Bedford."

I think it underwent some change for the better just a quarter of a century ago, when, with the other pictures of the Company, it was entrusted to the care of McLauchlan & Son, then carrying on business at 55, Berners-street.

That it had suffered damage at some period is evident from remaining (chiefly, I think, on the face and hands of the King) in a coarser mode than the rest of the picture. Those who knew the picture before 1855 will remember a very ugly seam from top to bottom, a crack nearly $\frac{1}{2}$ in. wide, which had been filled with putty and coloured in the roughest way to accommodate somehow the two sides of the gap which should have joined. The oak panel is a remarkable piece of work. It is made of two leaves doweled together, and the whole front surface has, apparently, been finished with the greatest care, but the back reveals that it is made of hewn boards, the joints (verticals) are very good, but the surface is as irregular as is possible to imagine, the substance varying from about $\frac{1}{2}$ in. to 1 in. thick. Some slight horizontal battens but at one time been fixed at the back, with the intention, no doubt, of adding strength, but with the effect of resisting shrinkage, and so causing several cracks to appear, and chiefly the opening of the doweled joint in the middle. It was not easy to deal with so large a panel (10 ft. 4 in. by 6 ft. 2 in.), which is very heavy, and I considered it undesirable to lay it flat, for the battens should give and other cracks be formed in the surface, so it was kept upright during the treatment it received from me. Stronger battens with bevelled edges were added between the old ones, but not fastened to the panel. Small blocks (nearly 100) having a corresponding bevel were attached to the irregular surface of the panel, securing it to the battens but allowing them to slide horizontally. As the old offending battens were tightly fixed and could not be removed without considerable risk of damage, small pieces were cut out of the middle of each of them. The two leaves were then pushed further apart, the old putty removed, and the joint made true. Through other blocks fixed near the joint coach screws were used to screw the leaves tightly together.

The surface of the picture was revived, but no attempt was made to remove the thick coatings of old varnish.

The long Latin inscription was in parts illegible, and I received instruction to rewrite it, and did so as nearly as possible over the old letters, leaving untouched the initials, which are finished with as much care as in an old manuscript. A gold ground, no doubt, exists to a considerable extent, and from its peculiar treatment must have been very effective in the early aspect of the painting. Besides the inscription, the only colour then used was a little oil-colour rubbed with the finger on the edges of the doweled joint. F. H. McLAUCHLAN.

Competition: Schools in the Isle of Man.—At the last meeting of the Braddan School Board, designs submitted in open competition by Mr. Thomas W. Cuhnon, architect, Birkenhead, were unanimously adopted for new school buildings about to be erected at Kewlaigue.

Sculpture in Relation to the Age.—This is the title of a course of three lectures to be delivered by Mr. Edwin Roscoe Mullins at the Royal Institution, Albemarle-street, on the following Thursdays, viz., Jan. 23, Jan. 30, and Feb. 6, at 3 p.m. each day.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—III.
MAGNETIC FIELD.

NOT only are lines of force of use in mapping out the contour of fields of force, but they afford graphical methods for solving problems in magnetism that would otherwise present considerable difficulties. The conventions adopted with respect to them, though in some respects similar, differ from those used in ordinary mechanics.

Fig 4.

Suppose M, fig. 4, to be a body near the surface of the earth. Every particle of it is pulled downwards with a certain force, and the lines of force, making up the gravitation field of force in which it is placed, pass vertically through every point in the body to the earth's centre. The effect of the attraction of the earth on such a body is the same as if the whole matter contained by the body were concentrated at a point G, called its centre of gravity. Imagine this done, then, one single line of force, A B, will indicate that part of the gravitation field of force which acts on the matter concentrated at G. The line A B shows no more than the direction in which the body tends to move; it does not in any way indicate the magnitude of the force acting at G. If this force is f number of dynes, imagine a portion G C of the line A C, such that G C is f centimetres long, to become visible; then G C denotes not only the line along which the force acts, but also its magnitude. Put an arrow-head at C, and G C will represent completely, in magnitude and direction, the total force due to gravity acting on M,—that is, its "weight."

It should be remembered that the weight of a body varies slightly with its position at the earth's surface, and also with its height above the sea level; but for the limited space through which any body is likely to be moved, G C may be considered constant.

If all magnetic fields, like the earth's gravitation field, consisted of parallel lines of force, the same means could be adopted for the purpose of completely showing the forces acting on any magnet or system of magnets; it happens, however, that magnetic fields are frequently very curiously shaped, and not only so, but the actual force acting on a pole of any given strength may vary enormously though it change its position very slightly. The force which acts on a pole depends upon the "strength of the field" at that point; the strength of a magnetic field at any point is measured by the force which unit magnetic pole would experience if placed at that point. The strength of a field at any point being F , a pole of strength m placed there will be acted on by a force of $m F$ dynes.

A graphical method, which will not only show the contour of a field but also its strength at any point, will enable us to tell both the magnitude and direction of the force acting on a pole, of known strength, placed anywhere in the field.

Take a simple case where the opposite poles of two magnets face each other, as in fig. 5; in the arrangement under consideration, let it be desired to represent graphically the shape and

strength or intensity of the portion of the whole field included within the dotted circle A B C.

Fig 5.

A magnetic pole will experience some force if placed anywhere within A B C, no matter how weak or strong the poles N and S may be, hence the area selected must be full of lines of force. But by supposing only a certain number of lines to become visible, the number being made greater the stronger the field, such a picture will also indicate the strength of the field. This is done by drawing so many of the lines that if at any point in the field, where the strength is F , a little surface of area a square centimetres is put at right-angles to the lines of force, then n the number of visible lines of force passing through it shall be $a F$, so that since $n = a F$, $F = \frac{n}{a}$ in words—the number of [visible] lines of force per square centimetre of the surface is equal to the strength of the field at that point.

When lines of force are referred to, the word "visible" will be understood, but that the lines of force meant are not all the lines of force must not be forgotten, otherwise a magnetic pole could be placed between the lines of force in the figure where it would not be acted on by any force. This we know to be contrary to fact.

To those unaccustomed to graphical methods, this way of representing a magnetic field may seem artificial and unnecessarily complicated; but a few experiments, made by shaking iron filings from a muslin bag on to a card placed over a single magnet or any arrangement of magnets, and then tapping it slightly, so as to enable the filings more readily to take up their preferred positions, will soon make lines of force seem a reality to the student, and enable him to easily picture to himself the directions of the force, actually producing the effects of magnetism in the medium around a magnet.

Drawing only a certain number of the lines of force is indeed artificial, but it renders easy the solution of many problems that would otherwise require analytical treatment.

CURRENT.

The properties of electricity are so modified by the presence of matter that the older theories only recognised its existence in or upon matter.

Certain substances, pre-eminently the metals, appear to act like lubricants of electricity; the friction, or whatever it may be, which gears the particles of electricity together in space, being so reduced as to allow the free movement of the electricity, contained by these so-called conductors of electricity, within them. A perfect conductor, if such a thing could exist, would be a body which reduced this friction to zero; a perfect non-conductor, insulator, or dielectric is a body in which this electrical friction is infinitely great. Paradoxical as it may seem, pure electricity appears to be a perfect insulator, as space shows no evidence of possessing any conducting power at all. Conductor and insulator, as commonly used, are merely relative terms; it is a matter of opinion when a substance is so bad a conductor as to be called a bad insulator, or vice versa.

Electricity travelling through a conductor is called an electric current.

In all conductors an electric current experiences a force obstructing its flow; this obstructing force is not a constant one, but varies directly with the current, or the quantity of electricity passing any section of the wire or other conductor per second. Now, since there is every reason for believing that electricity is incompressible, if the current is doubled the speed with which the electricity flows past any point must be doubled, and it is found experimentally that double the driving force is required to meet the increased obstruction. This opposing force, then, in the conductor acts like the friction which opposes the flow of liquids. The obstruction which is offered

by a conductor to the flow of electricity is called its "electrical resistance"; and electrical resistance and liquid friction produce analogous effects. When anything is moved against the force of friction, which must necessarily be a force opposing the movement, heat is produced; here again the analogy holds, for an electric current generates heat and raises the temperature of any conductor through which it flows.

As electricity can move in a conductor, if the pressures or potentials at two points are different, a flow takes place until equality of potential throughout the mass is established. Any piece of apparatus, such as a voltaic cell, which is capable of maintaining a current, does so by pumping electricity into a conductor at one end, and pumping it out at the other before equality of potential can be established. Difference of pressure, or whatever causes electricity to flow along a conductor, or try to flow along an insulator, is called *electro-motive force*, frequently written E.M.F.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

18,144, Draining Land. J. H. Rimell and T. Clements.

According to this invention, a plough or tool with cutters is made for use by horse or steam power. In the channel cut by the first of the cutters, a second tool which makes an enlargement of the channel, and a third, smoothing, finishing, or sliding tool, are caused to make a smooth plain channel for drainage.

355, Machinery for Working Stone. F. Trier. By this inventor, many mechanical details are introduced to the ordinary make of machines and tool-holders. The axis of the cutter-spindle is set at an angle to that of the cutter-bush, so that by turning the latter in the socket it produces an effect called step-cutting. Internal and external angles may be cut with the one cutter, the trunion being so mounted as to allow the cutter to act in two angles alternately. Arising cutters and grindstone dressers are also provided by suitable mechanical devices, and connexion of the several parts of the machines.

2,539, Ventilating Apparatus. D. Pennefather.

According to this invention, air is drawn in by leading the pipes in which it is to be conveyed, sometimes by means of the jets employed to light the room; the products of combustion are led away outside the room, or space in which the flame is burning, by a pipe arranged so that it is heated by the gas or the products of the combustion from the gas used in lighting. In lamps of the regenerative type, suitable pipes are fitted from them to effect the thorough ventilation of the apartment.

3,041, Chimney-tops. J. Armitage.

With a view to prevent down-draught, in the periphery of the chimney-top are formed four vertical openings arranged opposite to each other. Each opening, or aperture is covered by a suitable door, which is hinged or pivoted to the framing or casing of the chimney-top, so as to open outwards, and close inwards, each in pairs by a chain to a suitable bar, so that when one door is closed by the air currents the opposite one will be opened for the exit of smoke or other gases. But should the air-current change or veer to the opposite side of the chimney-top, the door on that side will, by the pressure of the current, be instantly closed, also automatically opening the opposite one.

4,220, Sewer and House-drain Traps. W. Smith.

According to this invention, a jet of water is directed by a pipe from an overhead cistern to the bottom of a trap for the purpose of cleansing out any sediment or dirty water.

17,848, Folding Ventilators. F. H. Wilks.

This appliance is principally designed for ships, to conduct fresh air through the air ports. The top part of the ventilator is made of bent pieces of spring steel or sheet metal. They fold down, lapping one over the other; but when in use they are raised by means of a chain to a hood, from which the air is conducted by pipes to cabins or berths. The invention is also applicable to all classes of hooded ventilating cowls.

New Public Building at Eton.

The Daily Telegraph informs its readers that "a handsomely designed building, in the Tudor style of architecture," is being erected by the Bridge Trust at Eton. The edifice, which is of red brick and Bath stone, occupies a prominent site in the High-street on the south-west side of Barnes Pool, and will contain offices for the Trust and the Local Board of Health. The architect is Mr. Robert Aborn, of Eton, and Messrs. Goddard are the builders. The Bridge Trust, from whose funds the cost of the building will be defrayed, originated in the time of Edward I., when a local benefactor left a quantity of land for the construction and maintenance of a bridge connecting the college and town at Barnes Pnol. From a few pounds yearly the annual income derivable from the testator's property has increased to about 350l., and has enabled the Trust, with some extraneous aid, to expend 3,000l. on the erection of the present fine girder bridge between Eton and the school, and the new offices in the High-street.

Engineering Works on the Elbe.

The City of Hamburg is on the point of laying out a sum of 150,000l. in widening, deepening, and otherwise regulating the course of the river Elbe below that city, a plan long contemplated. The Prussian State will also contribute a similar sum upon the work. A plan is also under consideration for the carrying out of similar works on the Upper Elbe, between Magdeburg and Hamburg, which would be of great importance to central Germany.

Museum of Art at Bergen.

A museum of art and industry,—the first of its kind,—has just been opened at Bergen in Norway.

MEETINGS.

MONDAY, JANUARY 20.

Royal Institute of British Architects.—The President (Mr. Alfred Waterhouse, R.A.) will deliver an Address to Students, and will present the several Studentships, Medals, and other Prizes for the year 1889-90. 8 p.m.

Society of Arts (Former Lectures).—Mr. Silvanus P. Thompson, D.Sc., on "The Electromagnet." 1. 8 p.m. Leads and Lectures on "Public Libraries."—Mr. E. W. Mountford on "Public Libraries." 7.30 p.m.

TUESDAY, JANUARY 21.

Institution of Civil Engineers.—Further discussion on Mr. G. F. Lyster's paper on "Recent Dock Extensions at Liverpool." 8 p.m.

Glasgow Architectural Association.—Mr. A. Roche on "Decoration." 8 p.m.

WEDNESDAY, JANUARY 22.

Society of Arts.—Mr. R. B. Carter on "Vision-Testing for Practical Purposes." 8 p.m.

THURSDAY, JANUARY 23.

Royal Institution.—Mr. E. Roscoe Mullins on "Sculpture in Relation to the Age." 1. 3 p.m.

Institution of Electrical Engineers.—Adjourned discussion on the President's address on "Magnetism." 8 p.m.

Edinburgh Architectural Association.—Rev. Edward Sugden on "Synthesis." 8 p.m.

FRIDAY, JANUARY 24.

Royal Institution.—Professor Dewar, M.A., F.R.S., on "The Scientific Work of Joule." 9 p.m.

Institution of Civil Engineers (Students' Meeting).—Mr. T. H. Chapman on "The Up-Keep of Metalled Roads in Ceylon." 7.30 p.m.

SATURDAY, JANUARY 25.

Glasgow Architectural Association.—Visit to the Prudential Insurance Company's new office, Renfield-street.

Miscellaneous.

Registration of Plumbers.—The Mayor of Hull, Dr. Sherburn, presided a few days since at a public meeting held in the Town-hall, Hull, for the distribution of Certificates of Registration granted by the Plumbers' Company, London, to plumbers in the Hull district. There was a large attendance of members of the plumbing trade.—The Mayor, in opening the proceedings, said the work which the Plumbers' Company was carrying on deserved the very highest praise from every citizen, not only in Hull, but throughout the entire country.—Alderman Fraser said the Corporation Sanitary Committee, of which he had the honour to be the chairman, was anxiously desirous of working hand in hand with the plumbers in their efforts to raise the educational status and increase the efficiency of their craft, in the common interest of its members and the public.—Mr. Ferguson, A.R.I.B.A., said he made it a practice to separate the plumbers' work from all other work in his building contracts, and he strongly recommended architects in general to do likewise.—Mr. Councillor Cohen remarked that he believed the effect of the registration system would be to give the public confidence in plumbers, as a body of tradesmen competent in sanitary matters.—Dr. Mason, Medical Officer, supported the remarks of Mr. Councillor Cohen, adding an expression of his opinion that the registration system would be the means of gradually weeding out the incompetent workmen, and thereby, in a great measure, insuring the public against the evil effects of defective plumbers' work.—Several other speakers having addressed the meeting, Certificates of Registration were distributed to a number of master and operative plumbers, and the proceedings terminated with a vote of thanks to the Mayor.—A requisition, signed by the Mayor of Plymouth and a number of representatives of the plumbing trade and the public, has just been received by the Plumbers' Company, desiring that a centre should be formed at Plymouth for carrying out, in South Devon, the Company's national system for the technical education and registration of qualified plumbers.

Death of Mr. Daniel Adamson, C.E.—We regret to see the announcement of the death of Mr. Daniel Adamson, who was the leading promoter of the Manchester Ship Canal scheme during its Parliamentary struggles in the years 1883-85. As chief of the firm of Messrs. D. Adamson & Co., Hyde- junction, he was largely concerned in the introduction of Bessemer steel. He was President of the Iron and Steel Institute in 1887, and was a distinguished member of other mechanical and scientific associations. Born at Shildon, in the county of Durham, in 1818, he was 71 years of age at his decease, which took place at Didsbury on Monday last, after about a year's illness. His early engineering experience was gained in superintendence of the works of the Stockton and Darlington Railway. He was afterward's manager of the Shildon Engine Works.

Royal Meteorological Society.

The annual meeting of this society was held on Wednesday evening last, at the Institution of Civil Engineers, Dr. W. Marcet, F.R.S., President, in the chair. The Council, in their report, congratulated the Fellows on the generally prosperous state of the Society; the past year's work, though not in any respect exceptional, having been thoroughly successful. The total number of Fellows is 650, being an increase of twenty-five on the previous year; the finances are improving, and the Library is overflowing. Mr. Baldwin Latham, M. Inst. C.E., was elected President for the ensuing year. The retiring President, Dr. Marcet, then delivered an address on "Atmospheric Dust," which he divided into organic or combustible, and mineral or incombustible. The dust scattered everywhere in the atmosphere, and which is lighted up in a sunbeam or a ray from an electric-lamp, is of an organic nature. It is seen to consist of countless motes,—rising, falling, or gyrating, although it is impossible to follow any of them with the eye for longer than a fraction of a second. It is difficult to say how much of the dust present in the air may become a source of disease, and how much is innocuous. Many of the motes belong to the class of micro-organisms which are frequently the means of spreading infectious diseases. Many trades, owing to their dusty nature, are very unwholesome. Dust, when mixed with air, is inflammable, and liable to explode. After giving several instances of explosions due to fine dust in flour mills and coal mines, Dr. Marcet referred to inorganic or mineral dust, and gave an account of dust-storms and dust-pillars in India. He then proceeded to describe volcanic dust, which consists mainly of powdered vitrified substances, produced by the action of intense heat. The so-called ashes or scoria shot out in a volcanic eruption are mostly powdered pumice, but they also originate from stones and fragments of rocks, which, striking against each other, are reduced into powder or dust. Volcanic dust has a whitish grey colour, and is sometimes nearly quite white. Dr. Marcet concluded with an account of the great eruption of Krakatoa, in August, 1883. The address was illustrated by a number of lantern slides.

Electinn of City Engineer of Liverpool.

The Liverpool Post announces that a special meeting of the Liverpool City Council was held on Wednesday at the Town-hall, the Mayor presiding, for the purpose of considering the recommendation of the Health Committee that Mr. Henry Percy Boulnois, Borough Engineer of Portsmouth, be appointed City Engineer, in the room of Mr. Clement Dunscombe, at a salary of 850l., with an annual increase of 50l. till it reached 1,000l. Mr. E. H. Cookson, in moving the adoption of the Health Committee's recommendation, read a letter from Sir Frederick Bramwell, in which he said that having had frequent opportunities of observing the mode in which Mr. Boulnois had carried on his work at Portsmouth, he had much pleasure in recommending him to the Corporation of Liverpool. Mr. Cookson said Mr. Boulnois had had an extensive experience. The Health Committee had selected him out of forty-two candidates, and had eventually been unanimous in recommending him. Mr. John Houlding seconded the motion, which was passed without a dissentient. The Corporation of Liverpool are to be congratulated, we think, on what strikes us as a very good appointment.

The English Iron Trade.

Mainly owing to gambling in Scotch warrants, the regular course of business in the iron trade was somewhat interfered with last week, but the market once more emerges from the ordeal in a steady condition, a sign that trade generally is still in as healthy a state as it entered the new year in. Pig-iron has been depressed by the operations in Scotch warrants; but although the latter have experienced a considerable drop, prices of Scotch makers' iron, for which there is a fair demand, have remained steady. Midlands brought pig has lost 3s. 6d. a ton since last week, but hematites in the north-west remain unchanged with makers, and in other districts the value of pig-iron is fairly well maintained. In finished iron business is pretty active, and rates are steady, the result of the quarterly meetings being to confirm the stability of prices. Steel is slightly quieter, but there is no going back from recent advances. Shipbuilders are busy, but no fresh orders are reported this week. Engineers are briskly engaged, with plenty of fresh work offering.—Iron.

The Proposed Fine-Art Galleries and Museum for Glasgow.—Some time since we referred to a report prepared by Mr. Carrick, Master of Works for the restoration of the West-End Park after the removal of the Exhibition buildings, and providing also a site for the proposed Fine-Art Galleries and Museum. In this report Mr. Carrick suggested that the area of the park to the east of Radnor-street should be appropriated for the site in question, and that the portions fronting Sandyford-street and the Park should be set apart for dwelling-houses. This scheme, it was calculated, would have resulted in the realisation of fully 24,000*l.* from the feuing ground, exclusive of the value of the area reserved for the museum and art galleries. About three months ago this report was delineated upon by the committee entrusted with the matter, and various suggestions were made which the Master of Works was asked to consider and to embody in an amended report. This has now been prepared, and we believe that it differs materially from the former one. The feuing proposal has been entirely given up, while the site of the proposed Art Galleries and Museum has been carried westward, as we are informed, to the ground occupied by the machinery section of the late Exhibition. The site extends to 10,000 square yards, carrying a structure 450 ft. in length by 200 ft. in width. Although different in form from that of the earlier plan, the space for the various art departments is virtually unchanged. The proposal is to have a grand central hall, surrounded by corridors, and entered from Sandyford-street and the Park. On the western side will be placed a museum of science and art, with public galleries for housing the collection under the management of the Corporation. Then follow a suite of salons adapted for the exhibition of pictures and sculpture, and an institution of fine art, including the School of Design and Haldane's Academy. The whole accommodation may be placed *en suite* when required, and the scheme of the plan admits of the structure forming the central part of any group of Exhibition buildings that may be projected in the future.—*Glasgow Herald.*

Society of Biblical Archaeology.—The Report of the Secretary (Mr. W. Henry Rylands) for the year 1889 contains the following passages:—"During the past year the Society has suffered severe loss by the death of some of its members, and it is with no ordinary pain that I have to record the names of the Right Rev. J. B. Lightfoot, D.D., &c., Bishop of Durham, Vice-President, and Professor William Wright, D.C.L., LL.D., &c., both of whom from its commencement took the warmest interest in the Society. To Professor Wright we have been often indebted for valuable papers and notes. In vol. ix. of the Proceedings, he commenced a description of the Kufic grave-stones in the British Museum, and he is asked, with his usual kindness, willingly undertook to place the members in possession of descriptions and translations of these ancient and curious memorials of those who lived and died 800 to 1,000 years or more ago. Commenced in June, 1887, a melancholy interest is attached to his second and last communication, which appeared in our Proceedings of June, 1888. Another distinguished member has passed from us, Philip Henry Gosse, F.R.S., well known from his many valuable works on natural history. Although his favourite line of study was foreign to the objects of the Society, his interest in our subjects was very great, and as one of our earliest members, he ever gave the assistance and support in his power, which was continued to the last. It is true our loss has been great, but I am pleased to be able to state that the number on the roll of members, although the increase is not so extensive as might be wished for the welfare of the Society and advantage of present and future members alike, is fairly maintained."

The London Sewage Question.—The adjourned discussion upon Sir Robert Rawlinson's paper on this subject (see last volume of the *Builder*, pp. 444, 457) was continued and concluded at the meeting of the Society of Arts on Wednesday evening last. We hold over our report until next week.

Royal Institution.—The evening meetings will begin on Friday, January 24, at nine o'clock, when Professor Dewar, F.R.S., will give a discourse on the Scientific Work of Joule.

The Clerks of Works Association.—We hear that the annual dinner of this Association takes place on Feb. 10. Mr. J. Macvicar Anderson, V.P.R.I.B.A., is in the chair.

Newspaper Offices, Sydney, N.S.W.—New offices have lately been completed for the Sydney *Daily Telegraph*. They have been erected by Messrs. Harrison & Sons, from designs by Messrs. Mansfield Brothers, to the order of *The Daily Telegraph* Company. The block consists of four floors and a basement let into the solid rock which forms the foundation, and from the footpath to the top central figure of the parapet the height is 71 ft. Our Sydney contemporary thus describes the architectural character of its new building:—"Commencing at the ground-floor, two substantial Doric columns are observed, with rusticated piers on either side to correspond. Two doors give access to the building,—the one on the left leading direct to the stairs communicating with the Henry department, and the one on the right admitting to the commercial section of the establishment, where advertisements are received and all the financial business of the company is transacted. Over the doors are moulded archivolts with carved keystones in high relief, and the window is treated in the same way. Above the columns of the ground-floor come the moulded cornice, frieze and architrave, all agreeing harmoniously with the Doric columns and piers, and the enrichments generally. Here, in raised gun-metal, appear the words '*The Daily Telegraph*.' From the first-floor to the third the front is embellished with fluted columns and pilasters of the Corinthian order. These columns and pilasters are monoliths, and such very fine stones were not easily obtainable. The windows in between are treated with moulded and carved caps and moulded impost, keystones and archivolts, the windows of the first and second floors being divided by moulded hands with Grecian key enrichments. The handsome pilasters and columns are surmounted by Corinthian entablature, with cornice embellished by carved modillions, dentils, and carved panels *en suite*. Then next in order are the frieze and moulded architraves, in strict keeping with the surroundings. The central portion of the cornice is emphasised by a pediment, with similar ornamentation to that of the cornice, and finished off with carved terminals. On the fourth and last story the pilasters of the Doric order supersede the Corinthian, which enrich the central portion of the front. These Doric pilasters have fluted shafts and moulded caps and bases, surmounted by a moulded cornice with segmental pediment, harmonising with the decorative porticos below. The windows are treated with moulded caps and bases, but the central one is varied. This window is brought into prominence by a carved panel in spandrel, moulded architrave, and moulded keystone. Over the top story is a balustrade with moulded base and capping, and with piers and terminals on either side. The central feature of the parapet is raised above the balustrade with moulded cornice, carved terminals and moulded and carved consoles, and thus makes the central portion of the front in keeping with the general treatment of the elevation. The whole of the front is in best quality of rich brown-coloured Pyramont freestone, unrelieved by other stone, and is handsome without being 'loud.'"

A Gift to Leicester by Mr. G. F. Watts, R.A.—In accordance with a promise made some time ago, Mr. G. F. Watts, R.A., has presented to the Leicester Art Gallery his picture, "Orlando pursuing the Fata Morgana," the subject of which is taken from the Italian poet Boggio. The picture has been on view at Birmingham, and is to be sent to Leicester very shortly. In the letter announcing the gift Mr. Watts says:—"My reason for presenting it are desire to help in forming the collection of pictures which I believe the town contemplates making, as I am confident art is a great humanising factor, and I greatly desire to lend what aid I may in aid of general progress. On this occasion I give one of my best pictures in recognition of the services your townsman, Mr. John M. Cook, is rendering, especially in Egypt, to the nation, making its name respected by admirable administration and honourable dealing."

Swedish Glass-painting Industry.—An industry hitherto foreign to Sweden has been that of manufacturing painted glass for architectural decoration, such work having been imported from Germany. Now, however, Herr R. Callander, a well-known Swedish painter, has opened an establishment at Gothenburg for the production of stained glass, which is being well supported by Swedish architects.

New Stock Exchange, Edinburgh.—Hitherto the Edinburgh Stock Exchange has been accommodated in premises held on lease, but a new building for its accommodation has been erected, from designs by Mr. John MacLachlan. The site is at the angle of North St. David-street and Thistle-street, in the immediate vicinity of St. Andrew-square. Mr. MacLachlan has treated the building in a free Classic style. The facade is richly decorated with carving, which has been executed by Mr. John Rhind. Besides the foliated detail, there is a large panel with a figure representative of Commerce, and medallions of female figures emblematical of the four quarters of the globe. The entrance, at the base of an angle tower, opens upon a vestibule giving access to an inner hall, both of which have high dados of Burmantofts faience. The hall in which the business of the Exchange is conducted is a lofty apartment, 46 ft. by 36 ft., lined to the cornice with oak, having large windows filled with tinted opalescent glass and flanked by oak pilasters. The hall is pronounced to be, in every respect, well suited for its purpose. The basement under the hall is occupied as the telegraph department, and in the remainder of the basement are lavatories, heating apparatus, &c. The secretary occupies rooms in an entresol; on the first-floor are the clearing-house and committee-rooms, and on the top flat there is a smoking-room and a care-taker's house. To provide for further extension, should such be required, the adjoining building, to the north, has been designed, and the existing premises are so designed that any addition made to them may add to the general effect. The entire cost of the building, including both sites, is about 25,000*l.*

The Norwegian Stone Industry, 1889.—The Norwegian stone industry last year was not so profitable as in the year before, prices being lower and the demand smaller. This was particularly the case in London, otherwise the best market,—whither less granite was shipped than in 1888. The export amounted to 30,000 tons in 1889, as against 36,000 tons in 1888. However, the demand and prices for paving-stone were good.

The Nicaragua Canal.—Advice from Nicaragua state that the work upon the canal is progressing satisfactorily, and is being carried on with great vigor. The Nicaraguan Government has decided upon forming a large town and constructing a fine harbour at the Atlantic end of the canal, to which end engineers have been dispatched thither. It is to be called "America."

The North-Sea-Baltic Canal.—In order that the work on the North-Sea-Baltic Canal may not be retarded, operations are now being carried on on several sections after dark by the aid of the electric light.

Exhibition of Designs for the Sheffield Municipal Buildings.

ONLY eighty-three, or less than half the number, of the unsuccessful competitors in the preliminary competition for the erection of municipal buildings for Sheffield have thought it worth their

while to allow their designs to be exhibited for the edification, or mystification, of the public of Sheffield, and for the delectation of such of their professional brethren as may take sufficient interest in the matter to go and see them. Of these eighty-three, nine are anonymous. For the absence of the rest the critic, whose business it is to study the eighty-three, must be grateful; but since the six successful designs are also absent, it must be confessed that the exhibition is shorn of an appreciable amount of interest.

It is probable, however, that the designs shown, taken all round and one with another, fairly represent the whole. The particulars placed before competitors so complete and detailed that the general similarity existing among a large number of the designs is no ground for surprise, though in some particulars many of them are practically identical. One may fairly assume that exceptional treatment is not much more frequent among the absent drawings than it is among those that are present, and, though it might be of great interest to competitors to see those few exceptions, yet what is already hung is quite as much as or more than most other people can possibly digest.

To speak first of the points of similarity. Though a few competitors appear to have made the Surrey-street front as important in other respects as that to Pinstone-street, yet not one has ventured to disregard the suggestion that the principal entrance should be in Pinstone-street, and it has been made the central feature of the façade by all but a bare half-dozen. Sixty-three, out of eighty-three, have placed the three reception-rooms *en suite* along the Pinstone-street frontage, and in most of the other cases they come up to one of its corners. Thirty-eight sets of plans are laid out with a continuous internal corridor parallel to all the four sides of the site. No fewer than thirty-seven have placed the

Council-chamber behind the Pinstone-street frontage, facing a court-yard, and separated from the reception-rooms by the grand staircase or by a corridor only. Only one or two have found it possible to do without a mezzanine, or a second lower ground-floor, or a basement the greater part of which is treated as ground-floor. In the great majority of instances the two ground-floors are frankly accepted, and called the upper and the lower. Of the elevations only five could possibly be styled Gothic, and by far the larger number are more or less purely Classic Renaissance designs of one or other period or country. Several gentlemen have borrowed from Messrs. Webb and Bell's Birmingham Assize Courts, others from Mr. Colcutt's Imperial Institute, and one firm have taken Mr. Waterhouse's tower of the National Liberal Club, and stuck it bodily on the corner of their building.

Great difference of opinion seems to have prevailed as to the proper position for the various suites of offices; where a whole department has been relegated to the lower ground-floor, the Health Department has generally been the one chosen, but most competitors have preferred to so treat a few of the less important offices of each suite. The favourite positions for the important Borough Accountant's general office are in the middle of the site beneath the Council-chamber and to the right of the entrance, under the reception-rooms; but it is placed by one architect or another in almost every possible position. The large public lavatories, too, which were required by the conditions, seem to have found no obviously right place, on the whole. The corner of Pinstone and Surrey streets, for men, and the opposite corner, beside the churchyard, for women, of course on the lowest floor,—whether called a ground-floor or a basement,—have been most frequently chosen; the entrances being by staircases either in the areas or within the building, but with external doors to the street. The drawing office of the Water Department, which had to be on the first-floor, seems to have fared badly in many cases, and not infrequently has had to put up with south light.

A large number of competitors have paid no attention to the suggestion that part of the site should be left for future extension, having apparently come to the conclusion that this can hardly be done without spoiling the building now, or spoiling it when complete. Taking into consideration the awkward shape

of the ground, it appears that the accommodation required to be placed on it is as much as it will hold without adding another story to the building. Those who have left part of the site unbuilt upon have done so in one of three ways. Either they have cut their building short, and left a space at the Norfolk-street end; or they have left a corner or section of their building incomplete on the churchyard side; or they have a large internal courtyard, and have suggested the future erection of a connecting corridor and offices across it. In the first two cases the present plans are invariably spoilt, and in the latter the result of carrying out the suggestion would be disastrous to the light and ventilation of the future building.

Taking the designs in the order in which they are hung, the first that calls for mention is No. 12, by Mr. R. A. Briggs. The plan is laid out with a corridor parallel to the four frontages; but a part of the building facing the church is left for completion in the future, so that, for the present, the corridor is not continuous. On the Pinstone-street side it is double, with a grand staircase and two light areas between. The Accountant's general office is opposite a central entrance, and his other rooms to the right; the Water and Surveyor's departments occupying the rest of the ground-floor. The Health Department is on the lower floor, with the public lavatories occupying the two front corners of the building. On the first-floor the reception rooms are on the principal front, while beyond the grand staircase, and equally well served by it, is the Council-chamber, overlooking the courtyard, and approached through the ante-room, which has the cloak-rooms on each side of it. All this part of the arrangement is excellent. The elevation is, perhaps, too tame, but it is appropriate, in good taste, and beautifully drawn.

No. 34, by Mr. W. Henman, of Birmingham, is a plan very similar in general arrangement to the last. A larger part of the building is left to be added, and this part includes half the frontage to Norfolk-street. The Council-chamber is not approached from the principal stairs direct, but is placed further in the rear and reached through its ante-room from the corridor which gives access to the committee-rooms. These committee-rooms are all *en suite* on the churchyard front; which, one may remark, is evidently their right place, for it is sunny and comparatively quiet. It is a happy arrangement which thus connects the Council-chamber with the committee-rooms

directly and somewhat more distantly with the reception-rooms. In this design, as in No. 12, the Surveyor's department occupies, as is right, the most important corner of the ground-floor. The Health Department is to the right of the entrance, the Accountant's offices in the middle, and the Water Department in the rear. The elevation shows an unnecessarily lofty and heavy tower at the principal corner. It owes something to the Birmingham Courts, but is, on the whole, not unpleasing.

An anonymous set of drawings, numbered 48, deserve notice on account of the excellence of the elevation, which, though composed of commonplace elements, is well designed and scholarly; and also for the general convenience of the plan, which is laid out round two corridors parallel to Surrey-street. The Accountant's office is especially well placed, and has two public doors easily accessible from the entrances in Pinstone and Surrey streets respectively.

No. 49, by Messrs. Morris & Hunter, is another good design. As regards the elevation, the extreme severity of its long range of columns and windows may be right or wrong; most people would think it carried too far; but at least the work is that of a man of culture who knows more than most people of the art of architectural design. The plans are spoilt by leaving a ridiculous little corner on two of them for "future extension." The main corridors are chiefly parallel to the frontages, but that on the south side is bent in and joins the front corridor at a right angle, leaving a corner in which the Council-chamber, with the Rates Office beneath it, is placed. This contrivance looks a little awkward in the drawings, but would probably work very well in reality; especially as the Council-chamber is thus made a sort of connecting-link between the reception and committee rooms, and the whole could be made to form, on occasion, a very fine suite indeed.

No. 54, by Mr. R. Stark Wilkinson, bears unmistakable and regrettable marks of hurry. The setting-out of the plan is remarkable; the Surrey-street and Cheney-row frontages have been produced until they met, and the angle has then been bisected by a line which becomes the axis of the building; the general lines of the Pinstone and Norfolk street frontages have been taken at right-angles to it, and thus the general form of the plan has been reduced to a trapezium. It is the only way in which a symmetrical building of the size required could be placed on the site, and it is, architecturally, as satisfactory as it is ingenious. Of course a large corner of ground is thus wasted at the corner of Pinstone-street and Cheney-row, but by rounding the corners of the building, and projecting the middle of it, the waste has been greatly reduced; besides, as Mr. Wilkinson points out, it opens up a view of the old church from the obelisk, which is a matter not to be altogether overlooked. The rounded corners have the further use of hiding the sharpness of the angles. In detail the plans are fairly good, but so nearly like some of those already remarked on that they need not be described in detail. The elevation is well balanced, but too much broken up. Messrs. Farrow & Nisbett, 64, exhibit a prettily-drawn elevation, and a plan in which the reception-rooms are shown side by side instead of end to end, as is done in all other cases.

The clever elevation of No. 73—anonymous—is too good for the plans which accompany it, and which have evidently been spoilt by the supposed necessity for laying out the corridors at right angles, and for leaving a piece of ground at the end for extension. The elevation strikes one as being born before its day, and as belonging rather to the architecture of the future. It would be better still but for the heavy tower over the entrance, which most people would not admire until it became half-ruinous.

No. 83, by Mr. John Johnson, is a plan in which the main corridor runs round the three principal sides of the site only; the reception

rooms are on the main front, and approached by the grand staircase, which, again, gives access to the Council-chamber just behind it, as previously described. This plan is the best of its kind exhibited. Messrs. Boot & Chadwick have adopted the continuous corridor plan, and their elevation is a good study in French Renaissance. Mr. Coates Carter has borrowed from the Birmingham Assize Courts and the Imperial Institute rather too liberally in making his elevation, which, however, does not seem to have suffered thereby. Mr. John Robinson and Mr. Campbell Jones, 96 and 99, have each a creditable design both as regards plan and elevation. The elevation of 96 looks rather too much like a theatre,—that is, like what a theatre ought to be, not like what most of ours are. But the design, as a design, is well grouped, proportioned, and detailed.

No. 123, by Mr. Paul Ogden, is one of the most successful of the designs that have the corridors laid out at right-angles. They are double, and of L shape, parallel to the Pinstone and Surrey street frontages. The whole outline of the building is, too, of the same form, no effort having been made to fill up corners. The reception rooms are in the usual place; the Council-chamber, too, is opposite to them, and reached by a "grand communicating state corridor," which is another name for a space under a great central tower. The Accountant's general office is under the Council-chamber, which, owing to the shape of the plan, faces the churchyard. The whole is symmetrically and well arranged. No. 130, by Mr. W. J. H. Leverton, is another good plan, in which the author has departed from the common arrangement. A courtyard is formed, open on the Surrey-street side. The rooms are placed to right and left of a long central corridor which leads direct from the main entrance to the rear of the site; the scheme works out fairly well except for the circumstance that the corridor would be badly lighted.

Messrs. W. H. Seth-Smith & Fenning, Messrs. Heathcote & Rawl, Messrs. E. H. Selby & H. S. Daniels, and Messrs. Dunn, Hansom, & Dunn, have all good plans of the type so frequently mentioned, and Mr. Alfred J. Pilkington's is also a good one. It is due to these gentlemen to say that the accident of the order of hanging is alone responsible for the fact that other plans have been more fully described. A large number of the schemes are practically identical in their general arrangements; it would be of no public interest to go into the smaller details in which they differ; and it is therefore not desirable to attempt to decide upon the comparative merits of the individual designs.

As regards the plans as a whole, no one appears to have gained very much by departing from the simple and obvious arrangement of the continuous corridor on all four sides, more or less modified to provide for future extension and to bring in the large office required in the Borough Accountant's department on the ground-floor, as well as to provide a quiet situation for the Council-chamber. A large number of designs are of great merit, and would probably work out considerably more than creditably. On the other hand, there is nothing of a very striking character, except, perhaps, Mr. Stark Wilkinson's plan, which, however, is not as good in its details as some of the others, and is wedded to an inferior elevation; it suffers, too, from comparatively careless draughtsmanship. The elevation of No. 73 is the most original, and would be the most successful of those exhibited if it were not out in half by the tower, which is out of scale with the delicate detail of the side portions. Judging by these unsuccessful designs the six selected ones must be very good, and may very probably include two or three that will startle the architectural world when their turn comes to be seen.

The Sheffield public appears to take a considerable interest in the Exhibition; the rooms in the Mappin Art Gallery, where the drawings are hung, attract a comparatively large

number of visitors of all classes, although the building is at some distance from the centre of the town.

PHEIDIAS AND THE PARTHENON.

NOT a little excitement was caused, even beyond the limits of the archeological world, by the report current about a month ago that Dr. Puchstein (Assistant-keeper at the Berlin Museum) had discovered, or believed he had discovered, that the Elgin marbles were "not from the hands of Pheidias himself, but probably from that of Kallimachos, who lived later." The report appeared in the *Standard*, December 16, 1889, from which we quote. Of course, no serious archeologist has for long enough ventured to assert that the decorative sculptures of the Parthenon were literally "from the hands" of the great master. Probably those hands were better employed finishing off the chryselephantine statue of the Parthenon. The point is, were the sculptures of the date of Pheidias and the design by him? Here Dr. Puchstein's investigations promise to be of the deepest interest, and, as this interest is of a special kind to English readers, we translate in full the report of Dr. Puchstein's speech made at the "Winckelmann" anniversary festival at Berlin, and just published (Jan. 18) in the *Berliner Philologische Wochenschrift*. There may be internal reasons of which we know nothing, but in passing we may note that the *Wochenschrift* is almost a proverb of belatedness, and why a speech made December 9, on a subject of the greatest interest, cannot be reported till January 18, remains to the outsider a mystery. "At the end of the meeting Dr. Puchstein made the following remarks on Pheidias:—Of the art of Pheidias, whose works have entirely perished, the student is obliged to frame his conception from a study of the closer copies of the Athene Parthenos, and by the comparison of these with other works of the fifth century B.C. This leads to the conclusion that a peculiar characteristic of the original of the Parthenos was the markedly strong and simple treatment of the drapery, a style not specially adopted by Pheidias in the representation of the goddess out of respect for the Doric architecture of the Parthenon, but simply the natural result of the stage his own development had reached at the time. For the Parthenon, designed before 447 B.C., belongs to the same epoch as, e.g., the Hippodameia of the east pediment, or the Tortonia Hestia. There is, therefore, no justification for the attribution to the original of the Parthenos of the full freedom of style observable in the pediment sculptures or the frieze of the Parthenon. Nor, again, can we justifiably ascribe to Pheidias or his workshop this new, and especially in the treatment of drapery, more highly-developed style. Further, the composition of the pediments and the frieze do not date from Pheidias. For the one composition known to us in detail which is certainly assignable to Pheidias,—the recently-discovered Birth of Pandora, on the Pergamene Parthenon, answers closely in style to the centre group of the Olympian pediment. On the true sculptor of the Parthenon marbles (with the exception of the Metopes) it seems possible, by means of certain technical evidence, to lay a tolerably sure hand. The pediment figures and the frieze are the oldest sculptures in which the so-called *running borer* was employed. They and the reliefs of the Niké balustrade differ from other contemporary and later sculptures precisely by such effects as are producible by this instrument, which effects are absent in these other sculptures,—e.g., Parthenon Metopes, frieze of the Theseion, the greater portion of the frieze of the Niké temple, the Niké of Paionios, which are all executed without the 'running borer.' According to Pausanias, Kallimachos, the inventor of the Corinthian capital, was the first who worked marble with this borer. That this discovery was made just at the time when the Parthenon pediments were set up (434 B.C.) is evident from the fact that

the borer was not employed in the Ionic capital of the Propylæe, which was begun in 437 B.C., but was already manifestly in use in the capital of the Niké temple (B.C. 430 circa). Hence it is not unlikely that the discoverer of this new technique, Kallimachos himself, was the very man who executed the Parthenon pediments, and that in them we may recognise instances of the 'elegantia et subtilitas artis marmorarie' for which he was famous." Evidence of this strictly technical character is, we need scarcely point out, of more value than pages of vague discourse as to style. We wait for the full illustrated demonstration which is looked for from Dr. Puchstein, and meanwhile only note that, so far as we can judge, the theory that the marbles are later than Pheidias seems at once more important and more convincing than their attribution to Kallimachos.

NOTES.

THE proposed plan of the County Council for treating the portion of the Strand adjoining the Church of St. Mary does not promise well for the manner in which this part of their work of improvement is to be dealt with. Instead of attempting to preserve an open space in the line between the churches of St. Mary and St. Clement Danes, so as to get the greatest combined effect from the two buildings, the plan shows a scheme for a block of buildings with an irregular hulging curve of frontage projecting southwards of the present line of Holywell-street, crossing the line connecting the two churches and partially shutting out the one from the other. It has over and over again been urged, in our columns and elsewhere, that advantage should be taken of the opportunity to make a small strip of garden occupying the greater part of the space in the line between the two churches, with the roadway on each side of it; thus introducing a new and agreeable feature in the scene while bringing the two churches together as portions of a great architectural group. If this were well done, it would have a fine effect, and would be one of the best architectural improvements that has ever been made in London, and one that we believe would be fully appreciated. The laying out as proposed in the County Council plan would render any such effect for ever impossible, and entirely muddle and throw away a great opportunity. It is to be hoped this ill-devised scheme will be reconsidered. We have been spoiling all our best chances for London improvements, in an architectural sense, for years past; and it is very disheartening to see the same thing beginning over again under the new governing body.

MR. COURTENAY BOYLE having recovered from his indisposition, the Railway Rates Inquiry was resumed this week, and a large portion of the case for the railway companies disposed of. The representatives of no fewer than seven companies were examined on Monday (including the South-Eastern, the Great Eastern, and the Brighton line), and Sir Henry James stated that the case for the railways would probably be concluded this week. Mr. Stanforth, for the last-named company, made a statement which will surprise many,—including, perhaps, Brighton shareholders themselves. He says that their goods traffic, of itself, is carried at a loss. Earlier in the inquiry it was stated on behalf of another company that a certain description of traffic was carried at a loss on account of the low rates charged, upon which it was promptly pointed out by Mr. Balfour Browne that this state of things proved that an undue preference existed. He contended that in such a case the company must recoup themselves by charging proportionally unfair rates upon other classes of traffic. In the case of merchandise sent by the London and Brighton line, it certainly cannot be urged that the loss is caused through unduly low rates being charged;

nor, on the whole, that exceptionally high passenger fares are charged. "Cheap trippers" are favoured to such an extent that the average passenger fares on this line are not very excessive; and yet, apparently, the whole of the dividend is derived from them, besides a certain sum to make up for the loss on merchandise. Nothing, perhaps, which has previously transpired during the course of this inquiry, has so exemplified the difficulty which the Board of Trade has to overcome in deciding as to the reasonableness of the rates claimed for merchandise; for it illustrates in such a forcible manner the widely-differing circumstances under which the traffic is carried upon different systems. Some are entirely dependent upon their goods traffic; while others, it appears, are not only independent of it, but find it a clog,—even while charging rates which are often loudly complained about. But as it is practically out of the question on most lines to advance passenger fares, the margin for all contingencies must necessarily be provided for in fixing the maximum goods rates.

THE disaster at the Forest Gate schools, by which, early in the morning of New Year's Day, twenty-six poor lads were suffocated by the smoke from a fire,—which broke out, it is now supposed, through the ignition of some soot in a disused fireplace behind a wooden chimney-board,—is fraught with two or three important lessons. We have refrained from commenting upon the case while the inquest has been pending, but now that the jury have given their verdict, which does not impute culpable negligence to any one, we may say that we quite agree with the very obvious recommendation of the jury that where fireplaces have to be blocked up (especially those beneath flues into which iron stove-pipes from detached stoves are led) iron plates should be used instead of wooden screens. We also agree with the jury in thinking that there ought to have been a night watchman, and that there should be a responsible officer in charge of each dormitory every night. Boys ought not to be locked in alone. We cannot but think that in all probability none of these poor boys would have lost their lives had proper precautions been taken. In going over Dr. Barnardo's Home for Boys at Stepney nearly two years ago (see *Builder* for March 17, 1888) we were much impressed by the admirable precautions then taken to prevent catastrophes of this kind. In that institution a watchman (checked by a "Lincoln" tell-tale) visits each dormitory every hour. In a corner of each dormitory is a bed-room (with a window looking into the dormitory) for the officer in charge of that dormitory. In each of these officers' bedrooms is a button, by pressing which any officer on any floor can immediately open the safety-doors of all the dormitories. These safety-doors open on to an external iron staircase, specially provided for use in case of fire. The opening of these doors is effected by electrical apparatus, and the pressing of the button in any of the officers' rooms not only throws open all the fire-escape doors, but sets ringing a powerful alarm-bell in each dormitory. This bell continues to ring until the door is set wide open. The action of these doors is tested daily, and, as a further precaution, each dormitory officer is supplied with a key which may be used to open either of the doors in case of the failure of the electric current. The electric locks, &c., are by Mr. Julius Sax.

IT had been expected that operations would be now commenced on the Argyllshire Railway, a work sanctioned in the Session of 1887, and intended to be carried out at once, but afterwards, for various reasons, delayed from time to time; but further unexpected causes of delay seems to have supervened. This scheme, an account of which was given in the *Builder* of December 31, 1887, is to connect Glasgow and converging lines with Loch Crinan, an inlet of the Atlantic, by way of Helensburgh, Holy

Loch, Loch Fyne, and Glen Air, a distance in all of about forty-six miles, eleven of which are over water. The most interesting feature, perhaps, is the crossing of Loch Fyne, between Newton Bay and Furnace, about fifteen miles from the head of this long arm of the sea, where it is barely one mile in width. Here the trains, passenger trains as well as goods trains, will be ferried over bodily, accompanied in each case by the locomotive, which, by an ingenious adjustment of shore levels, will be enabled to draw its load on board at all times of tide, and in like manner steam on to the land-rails at the other side. It is expected, also, that from each crossing locomotive will be drawn the steam necessary for working the engines of the boat, thereby obviating the need of a separate force of firemen—an important matter where the trains, in winter at least, will amount to no more than two or three daily each way. From Helensburgh, on the Clyde, traffic will be transported by water to Sandbank on the Holy Loch where the new line begins, a distance of about ten miles. This service will be performed by the boats of the present North British Railway Forth Ferry between Granton (Edinburgh) and Burntisland, to be discontinued on the opening of the Forth Bridge now impending; and it is to differ from the mode of the Loch Fyne crossing above described, inasmuch as passengers will embark in the ordinary way, and no locomotives will be carried. For the goods traffic there are special boats with rails, on to which the trucks are lowered by an inclined plane, consisting of a hinged gangway which rises and falls with the tide. The new line crosses from the Holy Loch (an inlet of the Clyde estuary opposite Greenock) to the shores of Loch Fyne by way of Glen Eck, over the moderate summit level of 120 ft. only, and with a gradient which at no point exceeds 1 in 50. From Loch Fyne to the Atlantic seaboard at Crinan there is stiffer work, a summit level of 400 ft. having to be surmounted, but, the line being a single one and designed for light loads only, this will be overcome without difficulty. Within a few miles of its western terminus the new line throws off a short branch to Ardrishaig, on the inner shore of the Cantyre isthmus and an important tourist station, being the eastern termination of the Crinan Canal through which the chief stream of the summer Hebridean traffic is attracted. From the Loch Fyne Ferry there will be a boat connexion with Inverary, which is the capital town of this region, though really of quite small dimensions. The estimated cost of this ingeniously-devised line is 150,000, only, with powers to borrow 60,000, more. It will be in the hands of the North British Railway Company. Last week an inspection of the route was made by a company, consisting of Mr. Aird (of Messrs. Lucas & Aird, contractors), London; Mr. Forman, Glasgow, the engineer of the line; Mr. Walker, the general manager of the North British Railway Co., and some others.

THE failure of the Chelsea Trustee Savings' Bank raises the question whether the time has not arrived for an Act of Parliament to be passed putting an end altogether to this class of savings' bank. Not very long ago the Cardiff bank failed, and now comes the collapse of the Chelsea bank. By the institution of Post Office Savings' Banks, the country has laid it down as a principle that it is the duty of the administration to give facilities for thrift. Now that a national system of savings' banks exists, the necessity for trustee savings' banks has ceased. It would be far better, therefore, if these amateur institutions were taken over by the Government, depositors having their accounts transferred to a Post Office bank, and being allowed on old deposits the same interest as they now receive. It is a distinct blow to habits of thrift when institutions such as the Chelsea Bank collapse; and as this class of bank is gradually dying out, it would be better at once to administer a death-blow to the old system. At the same time, it may

be well to point out that the Post Office fails to bring the national system sufficiently home to the poorer classes. Leaflets pointing out the way in which money can be invested at post-offices should be distributed at all houses once a quarter by the postmen who deliver letters. These would reach thousands; at present men must go to the office for information, which many artisans and labourers will not do.

A CASE is reported in the current number of the Law Reports, which at first sight is likely to puzzle some readers. We refer to the decision "*In re an arbitration between the London, Tilbury, and Southend Railway Company and the Trustees of the Gowver Walk Schools.*" The facts were that the Trustees of the Gowver Schools erected a new building on the site of an old one, the windows of which enjoyed a presumptive right to the light. Some only of the new windows coincided with the old ones, and therefore in the case of an ordinary obstruction no complaint could have been made except in regard to the coinciding windows, as they may be termed. The above Railway Company erected a warehouse on the opposite side of the street to which the schools were, which obstructed the light both to the coinciding and the non-coinciding windows in the new building. The question then arose whether compensation could be claimed in respect of both classes of windows. The Court held that it could be, because under the statute all damages of whatever kind were to be paid by the Company under the Acts of Parliament by which the matter is governed. To say whether the decision be right or wrong would raise a long and complicated argument; it is sufficient now to state the actual result of the decision.

NOT one of the forty-nine designs sent in for the "New Houses of Parliament Competition" for Rome has been considered suitable for the purpose. Five premiums of 5,000 fr. each have, however, been distributed, the winners being the architects Moretti, Broggi & Sommaruga, Quaglia & Benvenuto, Basile, and Ristori.

COLOGNE is to have a memorial statue of the late Emperor William,—the figure on horseback, but whether in connexion with a fountain, as suggested, is as yet uncertain. The cost is not to exceed 15,000*l.*, and the design will be selected in competition amongst German artists only. The names of the jury are published, and consist of five gentlemen, namely, two architects, two sculptors, and one painter. There will be five prizes,—one of 300*l.*, one of 200*l.*, and three of 100*l.*

IT seems that there is a section of traders in the West of Scotland opposed to the formation of the proposed Forth and Clyde Ship Canal. The promoters are doing their utmost to convince their opponents that, instead of being a disadvantage to the Clyde, the canal would still further develop shipping and commerce in Glasgow. It is considered that the North of Ireland would be greatly benefited by the canal, and the scheme has been most favourably entertained in that quarter. Baltic traders are also said to be in favour of the project. Meetings are to be held in Edinburgh and Glasgow for the purpose of discussing the scheme with a view to disarming opposition to an application to Parliament for the necessary powers.

WE have before mentioned that important works are now being executed in Rome for the improvement of the Tiber, but that, unfortunately, these works, which are indispensable for the hygienic condition of the city and for its growth, have considerably damaged some ancient monuments. (See *Builder*, April 6, 1889, "Ancient and New Bridges across the Tiber.") At this moment, the construction of the great drain on the right shore, and of the embankment wall, is said to necessitate the demolition of a great part of the Mediæval fortifications belonging

to the Castle of St. Angelo, especially of those near the river (see plan). It is very difficult

to ascertain the exact date at which the castle was first used as a fortress; some say this happened under Honorius, about A.D. 423; others, on the contrary, are of opinion that Theodoric, King of the Goths, was the first to fortify the Mausoleum of Hadrian. At any rate, it is certain that since the fifth century it has been used as a fortress. In the course of its later history it was temporarily occupied by the adventurer Crescentius Nomentanus, who endeavoured to revive the ancient office of Consul in his own person, and increased the fortifications to defend himself against the Emperor Otto III. From this personage it acquired the name of "Castellum Crescentii." In the eleventh and twelfth centuries it was held by the Orsini. The castle was reduced to its present condition by Alexander VI. in 1499, as we learn by the great inscription which can still be seen on the castle keep. Pope Borgia faced with masonry the central part of Hadrian's edifice, which had become a simple mass of stones after its coating of marble blocks had been removed. He put a finish to the repairs by a row of battlements, which can still be distinguished perfectly well among the subsequent repairs executed on the summit of the castle by order of Paul III. and Clement VIII. Alexander VI. completed also the covered gallery which leads from the castle to the Vatican, begun by John XXIII. on the foundations of the Leonine walls. But the most important parts of the works executed by Pope Borgia are doubtless the fortifications round the Mausoleum, consisting of four strong polygonal bastions, built of masonry, with travertine angles, and a scarp; the whole was surrounded by a moat, very deep and wide, in which the Tiber water flowed. The bastions were united by a very thick stone wall, faced with masonry, and battlemented. The works were confided to Tuscan artists, under the direction of Sangallo, who had already built the forts of Civita Castellana and of Suhiaco, and some towers for the defence of the coast, by order of Pope Borgia. It is the front part of Sangallo's fortifications that the office of "Genio Civile" now proposes to demolish for the improvement of the Tiber, and by this scheme the two foremost bastions, A, B, and a great part of the wall that unites them, would be destroyed. A general cry of indignation has risen against this project, which would injure one of the most characteristic monuments which have come down to us from the Middle Ages. But, fortunately, the last word has not yet been spoken, and it is hoped that good sense will triumph, and that the Office for the Preservation of Ancient Monuments will resolutely oppose the fulfilment of the scheme.

Captain Signor Borgatti will shortly publish an important book, the outcome of patient and diligent researches for some years past, concerning the castle.

THE last number of the *American Journal of Archeology* (vol. v., No. 3) is in the main devoted to a full report of the American excavations at Sikyon, the chief interest of which has certainly centred in the theatre, and especially in the arches by which the *καίον* was entered on either side. A detailed plan is given, and two views,—one of the stage foundations, the other of the seats and conduits surrounding the orchestra. The report is written by Mr. M. L. Earle, a member of the American School, and he also publishes the one statue of any considerable interest found at Sikyon; he devotes to the interpretation of this work an amount of learning and careful ingenuity which we must say seems to us excessive, and finally concludes that we have in it a statue of the youthful Dionysos, of good workmanship, a product of Sikyonian art, and that the work may be assigned to the third century B.C. So far, few will dispute his conclusions, but Mr. Earle goes on to say that presumably it is by one of the more distant followers of Lysippus,—for this not a scrap of positive evidence is advanced; further, we are told that "Thoinias, son of Teiskraes, was active at Sikyon and elsewhere in the Greek world in the middle and latter half of the third century B.C." and lastly, that "we have in our work a certain pan-Hellenic spirit, such as we may apprehend could have been exhibited by Thoinias." The reader is left with a sort of shadowy implication that the statue may, or might, or could have been by Thoinias. The desire to bring literary and monumental evidence into relation is just now engendering a perfect plague of hypothetical attributions, and it is a tendency against which, in the name of English common sense, we feel bound to protest.

IN connexion with the University Extension Society, Miss Harrison intends to give a course of ten lectures on "Athens, its Mythology and Art," on Friday afternoons, at 6.15 p.m., commencing January 24. The first lecture will be given at the Chelsea Town Hall; the remainder of the course at the South Kensington Museum. According to the prospectus issued, the aim of the lectures will be to give a detailed picture of the City of Athens; its rise from the small beginnings of a primeval rock city; its growth and development. The course will embrace not only the famous monuments, already widely familiar, such as the Parthenon and the Dionysiac theatre, but also recent discoveries about the agora of Athens, its great hospital known as the Asklepieion, and the early temple of Athene on the Acropolis lately laid bare, as well as the remarkable series of archaic figures found near the Erechtheion, which have gone far to revolutionise existing theories as to early Greek art.

UNDER the supervision of an officer of the Royal Engineers, workmen are engaged in removing a portion of the Castle Rock of Edinburgh. Such an operation would justly be stigmatised as an act of vandalism were it not a necessity. It appears that certain portions of the rock to the south-east, below the junction of the old hospital and the surgeons' quarters, have become loose, and that there is danger of their falling upon the roadway beneath, with the probable result of damage both to life and property. Besides a quantity of *débris*, there has been removed two masses of rock containing about 30 cubic feet and 50 cubic feet respectively, and of the weight of about 3 and 4½ tons each. There is another huge boulder, estimated to weigh between 50 and 70 tons, which looked at from certain points of view seems to be in a very dangerous position as regards stability, but when looked at from above it seems to be securely placed. The chief risk involved in leaving it where it is arises from the fact that there is a space behind it and the solid rock

where water may lodge, which, if frozen, would by expansion loosen the houlder and cause its dislodgment. Efforts have been made to remove this mass of rock, but, as yet, unsuccessfully. It is stated that from its position it would be very difficult to dispose of it in detail, and to remove it in mass, in regard to which there would be little difficulty, would be most dangerous. The operations are carried on in a very simple manner by means of a rope attached to the bars of a window in the basement of the surgeons' quarters, which reaches to the base of the rock; by this means the workmen, by dint of hard scrambling, attain the point to be operated upon.

IMMEDIATELY to the eastward of the scene of operations above referred to similar work had to be done, several years ago, on the southern bank of the esplanade. This bank exhibits what Sir Roderick Murchison considered one of the most interesting and instructive lessons in geology. The Castle Rock consists of trap rock almost perpendicular on the three sides to the north, west, and south: but there is a gradual slope from the east side forming the esplanade. This slope is formed principally of earth, through which there run layers of sandstone; and it was these layers of sandstone which gave way, where exposed, and had to be operated upon. The theory of Sir Roderick Murchison was that, during the geological period, the rock stood in the midst of a vast stream flowing from west to east, and that the esplanade was formed by the deposits made by that stream.

BY order of the late Miss Edwards's trustees, as appointed by her will, the freehold of Langham House,—No. 11, Portland-place, western side,—will be offered for sale by auction at the Mart on the 17th proximo. This mansion and its opposite neighbour recall, by their names, the original Foley House and the once adjoining residence of Sir James Langham, Bart. Foley House is distinguished by name in R. Wilkinson's Map of London, 1799, and is shown with grounds extending from Mortimer-street to Duchess-street. It is also cited in John Lockie's "Topography of London" (1810), as being on the eastern side of Chandos-street. Here it remained for a few years more; its low elevation and high wall stretching across the southern end of Portland-place, where a few of the garden trees are yet preserved. It is said that Lord Foley, himself not a rich man, gave the means wherewith to live to Lord Mansfield before he had begun to earn much at the Bar, and here, until recently, stood the town mansion of the Lord Chief Justice's successors in the peerage. Southwards lay the former Langham House, of which John Nash was architect—according to a note written by Frederick, father of the late John Gregory, Craze, on one of the two water-colour views thereof in the British Museum. The eastern front had along its entire length an octastyle portico, of the Ionic order. Foley-house was purchased for 70,000*l.* for the laying-out of Regent-street, over the sites in this quarter of the then Ogle and Bolsover-streets. Nearly the whole of the sites of the three houses we mention is occupied by the Langham Hotel, erected about twenty-five years ago, from the designs of Messrs. Giles & Murray, architects.

WE read that the Right Hon. W. H. Smith, M.P., has subscribed 2,500*l.* towards the restoration fund for the two churches of the united living of St. Germoe and St. Breage, near to Helston, in Cornwall. In the churchyard of the former is a supposed burial-vault over which stands a stone seat, carved in stone, popularly known as the throne of King Germocus, or Saint Germoe's chair. It measures about 6ft. by 3ft.; the central division of the triple seat bears the curving of a head with an ancient crown; on the other side are three rounded columns carrying two pointed arches. In St. Breage Church are

monuments of the Godolphin family, including one to the wife of the first Earl (1678) Godolphin, *olim* Godolean, is the name of a hamlet in Breage. William of Worcester mentions "Godollen Castle" in his Itinerary of Cornwall, *temp.* Edward IV.; the "Carne Godolean" is cited by Leland. Sir Francis Godolphin, who rebuilt the castle in Queen Elizabeth's reign, effected productive improvements in the working and smelting of the tin and copper ores of this district. His descendant, Sir Sidney, was elevated Baron Godolphin of Rialton, and advanced Earl Godolphin. He was the celebrated Lord High Treasurer in the reign of Queen Anne. In 1744 these estates passed to the house of Osborne by the marriage of Mary, sole heir of Francis, Lord Godolphin, with Thomas, fourth Duke of Leeds.

MR. BRUDENELL CARTER'S lecture at the Society of Arts on Wednesday, on "Practical Vision-Testing," ought to be of interest to the general public as well as to scientific men. The fact, as stated by Mr. Carter, that a red-blind eye nevertheless sees a red light, not as red but as a fainter light than a white one of equal intensity,—a different light in one sense but not in the intended sense,—shows how unsatisfactory a railway-test must be in which a man is merely asked to say which of three lights is red, green, or white, he knowing beforehand what colours are among the three. As Mr. Carter says, the object of a test should be not merely to show that a man does not make a mistake in one instance, but that he will not make mistakes in a number of instances. Holmgren's test, which Mr. Carter recommends, requires a man to select from a number of variously-coloured skreens all that tally in colour with a given sample, without troubling him with names. This, it is obvious, if properly carried out, must be a severe test of colour-perception; quite different from showing a man two or three coloured lamps to pick out the "stop" signal from. An engine-driver at the meeting, who questioned whether any railway accidents had really been traced to want of perception of colour on the part of the driver, may have been right, as drivers are always taken over the road many times before working it themselves; but the possibility of such an accident ought to be ensured against by a real and not a possibly fallacious test.

AS might be expected, the artistic interest of the exhibition of "Works of Art connected with Sport" at the Grosvenor Gallery is not of the highest. There are some good pictures, and others which are historically interesting; among the latter may be named the two cricket pictures, that by Richard Wilson "Cricket at Hampton Wick" (75), painted for David Garrick, and the well known one by Hayman belonging to the Marylebone Cricket Club, and representing "Cricket in Marylebone Fields" (111). In this are shown the curved hat of the period, and the wicket consisting of two stumps only; and both show the old cricketing costume with the tall hat, to our modern ideas so peculiarly unsuitable to any athletic game. There are naturally a good many Landseers, among the most interesting of which are the well-known large picture of "The Swannery Invaded by Eagles" (68); the small sketches and studies of stags and dogs in the East Gallery; "The Pensioners" (15), a couple of old hunters in a paddock excited at the sight of the hunt; and the life-size picture called "The Chase" (189), a stag pursued by a hound, a picture which was painted, it appears, to serve as a target, but which the owner framed, and Landseer completed the picture by adding the dog and placing his nose so as to cover the mark that had been made as a bull's-eye to show the right spot for hitting a deer. The agonised expression of the hunted animal's eye is painfully true. Landseer's portrait of himself with

* Holmgren's test is fully described, and illustrated by examples, in Mr. Charles Roberts's little work on "The Detection of Colour Blindness and Imperfect Eyesight" (J. & A. Churchill; 1884).

two dogs looking over his shoulder at his drawing, "The Connoisseurs" (115) is a welcome old friend; but the well-known painting of "The Sanctuary" (67) looks sadly hard and commonplace now. Ansdell's "Grouse Driving" (185), painted fifty years ago, though old-fashioned in style, is a real picture, beautifully composed, and far less hard and finer in colour than the works of the artist's later years. One of the finest paintings in the gallery is "The Lost Royal" (172) by Mr. Stuart Wortley, who first made his mark at the Grosvenor Gallery with a sporting subject; this shows a hunted and exhausted stag crouched on a hill overlooking the sea. Randolph Caldecott's "The Last Flight" (178) and Rosa Bonheur's "Otter-hounds" (166) are among the fine paintings in the collection, and Ward's "Cub-hunting" (58), a huntsman taking a leap (very different from the average hunting picture, and reminding one rather of Moriand), and some of Stubbs's horses. Of the arms the only specimens that are of artistic interest are some of the old powder-flasks in the cases in the East Gallery. There are a number of specimens of plate which have been made as turf prizes, of which it may be said that the majority of the modern ones exhibit not the slightest artistic interest or value of any kind, and only serve to illustrate painfully to how low a pitch English taste, invention, and execution have sunk in such matters.

ROYAL INSTITUTE OF BRITISH ARCHITECTS:

THE PRESIDENT'S ADDRESS TO STUDENTS.

THE fifth ordinary general meeting of this Institute for the present session was held on Monday last, Mr. Alfred Waterhouse, R.A. (President), in the chair. The minutes of the recent special and business meetings having been read by Mr. Aston Webb, hon. sec. (in the absence of Mr. William H. White, the Secretary, who was said to be suffering from influenza).

The President said: Before we proceed to business, perhaps you will allow me to express the sorrow I feel as a member of the jury in the competition for the refronting of Milan Cathedral, that an architect of very great promise,—Signor Brentano,—whose design was selected above all others as best fitted for adoption, has died, at the early age of twenty-seven. I believe that little or nothing had been done towards realising his project before his death, and his loss is certainly a very great one, not only to Italy, but I may say to Europe.

The President then delivered the following address to students:—

Gentlemen,—Last year, when I had the honour of addressing you before the annual distribution of prizes, I spoke to you on the subject of competitions, and ventured to give a few hints to those who might be intending to try their fortunes in these contests. Having lately had fresh experience of the vital interest this question must possess to most young architects, I propose this evening again to revert to the subject, with a few remarks on a recent competition.

I should be glad to think the day not far distant when competitors would be rarely, if ever, resorted to, except for works of the greatest national importance. I lament their frequency chiefly because of the enormous amount of unproductive labour they involve, and I confess I do not see at present any tendency towards their diminution. This being so, it seems most important that those who are concerned as assessors in drawing up instructions should see that they are prepared not only to secure the best results from the promoter's point of view, but also to subserve as much as possible the interests of the profession,—first, by saving the architects competing from all unnecessary work; and secondly, by not hampering competitors with vexatious restrictions, thus leaving them free to solve in their own way the problem put before them, without the feeling that if all the accommodation asked for is not exactly of a certain size, and every room of certain dimensions, they will be adjudged out of the competition. I would have every competitor put as nearly as may be in the position of an architect acting for a private client, who, though he may have suggested his requirements, would probably listen to his professional

adviser if he gave good reasons for not literally adhering to them in all cases. I have endeavoured, when acting as assessor, to use my influence to keep the instructions thus elastic; but I have frequently had to regret that they had not been more so, when, after the designs themselves had come under review, some of general excellence had to be set aside for breach of conditions in some point of minor importance, on which the instructions, unfortunately, had been allowed to speak too decidedly.

Having lately, as I have already hinted, been engaged upon such a labour (a very arduous one, owing to the way in which the profession had responded to the invitation) in the first or sketch competition for the Sheffield Municipal Buildings, and being very much interested in the work, and full of the subject, I have thought that I could not do better to-night than bring before you some special facts in connexion with that competition and some special considerations which may prove of use to some of my hearers.

The instructions in this particular case were issued in August last, and invited certain drawings to $\frac{1}{16}$ in. scale, viz., a plan of each floor of the proposed building, two cross-sections, and one elevation. They were all to be on stretchers of the smallest possible size, — 2 ft. by 1 ft. 6 in., — so as to be kept near the eye-line when hung on wall or screen, and easily handled for reference. No mottoes or distinguishing borders or devices were allowed. When a case containing a design was opened, it was numbered by a progressive number, and every drawing and document within the case was marked for identification with the same number. Alternative schemes were ruled out of court altogether; for I believe that, as a rule, those architects whose exuberant imagination would induce them to send in alternative schemes, or to cover their plans with flaps, showing how they could vary their arrangements, lose much by so doing. They may show themselves men of varied resources, but hardly architects convinced of the perfection of the scheme they propose for adoption; and I submit that the time spent in preparing two schemes would be much more profitably spent in perfecting one.

I must, however, ask permission to leave Sheffield for the moment, to tell you of one exception to this rule which I encountered many years ago. It was in a competition for the Bristol Assize Courts. I was asked by the Corporation to assist them in awarding the three prizes they had to dispense for the first, second, and third best designs among those sent in which agreed with their instructions. I had not much difficulty in discovering what, in my opinion, were the best of the series, nor of placing them in their order of merit; but though they were in different types of Gothic, — one round-arched, another thirteenth-century, and the third of a later style, — I confess I was somewhat troubled in dividing, and that for two reasons, that they were all by the same hand. The first it was difficult to be sure about, as the lettering, mounting, and colouring of each set were entirely different, as well as the styles and disposition of plan; but they had all a vigorous character and individuality about them which appeared to flow from one and the same source of inspiration. Secondly, they all showed on their block plan an insignificant feature of an adjacent building, which I had myself observed in visiting the site, but which was not on the lithographed block plan given to each competitor, and which was omitted from all other designs in the room. When meeting the Committee, therefore, for the purpose of making my report, I thought it desirable to inquire whether it would in their opinion be proper to give all three prizes to one competitor, provided the three designs, best, according to the judgment of the assessor, should prove to be by one and the same hand. At first they said "No"; but one of the Committee, who appeared to be conversant with affairs of the turf, remarked that if he entered three horses for a race, and they all three reached the winning-post before the rest of the field, there was no reason against his being accredited with the first three places; and that what was fair with horses was equally fair with architects' designs. This argument settled the point. I gave my award, the seals were broken, and the late gifted E. W. Godwin carried off all three premiums. What Edward Godwin might venture upon with success, it is not given to everybody to imitate with equal success, — and, as it was, this brilliant exploit did not secure him the execution of the work.

Another competition was decided upon, in which, after what I have told you, I declined to act again as assessor.

But to return to Sheffield. The accommodation there required was given in the form of a schedule, in which the sizes of rooms were only suggested sizes. A general compliance with the dimensions contained in this schedule was all that was insisted upon. The total number of superficial feet of suggested accommodation was also given at the end of the schedule, the blank columns of which had to be filled in by each competitor to show at a glance what he was providing in each particular case, and also what was the total aggregate of his accommodation. The schedule so filled up has been of the greatest use in the examination and comparison of the different designs.

As usual, no sooner were competitors fairly at work than numberless letters came from them on the subject of the instructions. They did not like being compelled to limit the amount of their work, and would have preferred sending in more drawings. Partners would have liked each to send in a separate design. Others wanted to make more elevations, and detailed drawings, and perspective views. In fact, it seemed difficult for some of them to see that the rigour of the rule against receiving more than the prescribed drawings was really made in their interest, and not in that of the Corporation of Sheffield.

At length, in the beginning of October, it was thought that the time had come to send answers to all the questions which had up to that time been received. So on the 9th a copy of the printed replies to 121 questions was sent by the Town Clerk to everybody who had obtained instructions; after this we answered no further questions.

Early in December the designs were sent in, — 178 in all. One of the competitors transgressed the instructions by applying a motto to his stretchers. Three or four other designs were sent in so unfinished as to be hardly in a condition to enter the lists; while a few, — but very few, — had not kept to the letter of the instructions in other points. On the whole, however, the competition was to be looked upon as a great success. An unusually large number of good thoughtful designs were submitted, many of them in their elevation showing an excellent originality. Whether the shape of the site, verging towards a triangle, suggested it or not I cannot tell, but a considerable proportion of the plans bore too great a resemblance to a recent building erected for a nearly similar use, the details of which I have reason to be familiar with, and which in some cases has been followed even to its faults. One of the greatest faults in the Manchester Town Hall has always seemed to me the position of its Council Chamber, overlooking as it does Albert-square, a position its architect thought unavoidable owing to the public hall occupying the centre of the site. But in Sheffield no public hall is required, and therefore that position is available for the Council Chamber; as is also the south front, where there is a good light, and no thoroughfare for carriages.

Perhaps owing to competitors not having been allowed to submit an elevation of the south front, which will in reality be very conspicuous even from a distance over the adjoining disused churchyard, many designs have a very jagged outline on plan on this side, something like the west coast of Norway, and which their authors would, I think, find it very difficult to clothe with dignity, or even picturesque-ness, were they asked for its elevation.

The west front, an elevation of which was alone asked for in this competition, is about 200 ft. in length. Across the adjacent street on the north is a new building (the Yorkshire Penny Bank and Albany Hotel) about 56 ft. high, while on the south is the before-mentioned churchyard, with the church in its centre having a tower surmounted by a spire. The height of the adjacent buildings does not appear to have been duly considered by every competitor; perhaps some had not visited the site; and no doubt the instructions suggesting the required accommodation almost exclusively on the ground or first-floor had a good deal to do with the unfortunate fact that this, the principal front of the Municipal Buildings, was sometimes drawn with a parapet not more than 45 ft. from the street level. The want of height in the horizontal features of the front has been, however, generally made up for either by a central tower on a line with the front, or by one set back behind the State apartments,

which apartments naturally, in the greater portion of the designs, occupy this front (in the latter position the effect of such a tower would be in a great measure lost), or by a tower at one or other extremity of the front. In some cases this lateral tower was placed, not on the western front at all, but facing the side street just behind the principal apartments where it would fulfil the useful function of interposing a break between the lofty State rooms and the lower business offices which overlook the side street. These towers, many of them, show great ingenuity in their design. One had its square trunk surrounded by four gables, not subtending the whole width of each side, but long and slender, with a pierced arcade parapet on either side in the style of Bishop Gower of St. David's, through which passed the high-pitched, slated, and hipped roof, filling in the angle spaces between the gables. The whole was surmounted by a well-designed fîche, and formed altogether a very original and elegant campanile. I dwelt on some of these Sheffield towers with tenderness, and when they had to be put aside, with sincere regret. Many of them were of great beauty, and some few were entirely free from all suspicion of ever having served an ecclesiastical turn in another state of existence, — in fact, they seemed quite original. In some few instances a dome took the place of a tower.

When placed behind intervening roofs the dome suffers more than the tower, but in one or two cases the dome was brought to the front of the building. These massive features do not in all cases stand on sufficiently massive supports. Are we most of us occasionally tempted, or forced, to use iron or steel more freely than is desirable in support of walls, but would it not be well to make a rule to dispense with any feature of a non-essential character in a monumental stone building, whenever its introduction demands the use of iron girders and stanchions?

Another frequent feature at Sheffield, — like the tower, entirely optional (neither being mentioned in the instructions), — was the *porte-cochère*. Among the 121 questions was one asking whether such a feature might be thrown out beyond the prescribed limits of the site. Leave to introduce this feature being in this way obtained, by far the greater part of the competitors availed themselves of it, but I cannot say generally to the improvement of their elevations. I would ask you why it is so difficult to make the *porte-cochère* marry with the elevation against which it is placed, — unless, indeed, the same treatment, e.g. arading, is carried through the whole of the ground-floor of the front, and the *porte-cochère* also? I can conceive some unity of effect thus obtainable, even if the arches in the building itself were afterwards partially filled in. I say nothing about the draughtiness of the carriage-porch, and of the gloom it occasions in the interior, if the entrance-hall, unless the latter happens to have windows beyond or above the roof of the feature in question. These disadvantages may be set against the comfort of being set down by one's carriage in the dry. It is its unfortunate effect on the elevation of the building to which I would draw special attention. By the great projection of the *porte-cochère* it hides half the front from view if seen in quick perspective; by its height and projection it seriously dwarfs the elevation; or, if to avoid these disadvantages it is kept very low, it looks very mean. Lastly, its peculiarities of construction involve too often a want of harmony between it and the building it serves. The best treatment I have seen is when the carriage-way goes behind an open arcade which supports an advancing central gable; and where the wings of the façade also advance there is, I think, much to be said for this arrangement. This, however, was not in favour in Sheffield, though in one case the carriage-way was carried within the walls of the building. I noticed, also, in connexion with the main entrance, that it seemed to be in many cases intended to provide a pair of heavy outer doors only, without the usual inner swing-doors, two pairs of which, one within the other, one would suppose necessary to keep out the wind on a western front.

At Sheffield I again observed what is but too general in most competitions, that the anxiety to get all the accommodation of the suggested dimensions into his plan has often prevented the competitor from ascertaining that his rooms have been made of a proportion which would be intolerable if carried out, — e.g., 50 × 30 × 12 ft

high. Also, many plans that looked at first most promising were found to have their walls over voids, the chimney-stacks on the lower story giving no account of themselves on the upper floors, and staircases shown on plan which could never have been constructed.

Then, again, there is the great light question. In the majority of cases the use to which the light from small areas was put was the best possible,—that is, it was used to give side light to corridors, which, as they were seldom more than 7 or 8 ft. wide, could, of course, be lighted across their width much more easily than a room 30 ft. from back to front could be. And yet in other designs there were such rooms only about 12-6 high, and with windows inconveniently low for a room of such a depth,—even if the light came uninterrupted from the horizon,—which windows were expected to give light enough for important office-work in a smoky town, where the holdings opposite were lofty. When such windows look into a deep and narrow area, nothing but disappointment must be the result. I confess that the exceptional favour some competitors expect from the sun fills me with amazement. For the sake of light, air, general cheerfulness, and architectural effect, it is most desirable that internal areas in a building should be as few and as large as possible, instead of many and small. If one large area be adopted instead of many small ones, which has, of course, the advantage of securing a much better architectural effect, it may be difficult to light the corridors only from this source; but if thus deprived of a continuous side light by the interposition of rooms looking into the area the skillful designer will see that they are never dark, especially at their extremities, where they turn, or where there is a change of level,—if, indeed, such be necessary in any case.

With regard to staircases, it ought not to be necessary to say that a principal flight of stairs in such a building could hardly with propriety have steps less than 6 or 8 ft. wide, with treads and risers 12 in. by 6 in., or, better, 12½ in. or 13 in. by 5½ in., and that until you are able to secure so much ease of going and space in a single staircase it would be folly to think of double flights in the same staircase, still less of twin stairs in all respects repeating each other. One dignified stairway, well considered, thoughtfully designed, with something unusual in it, if attainable without sacrifice of convenience in any way, is infinitely to be preferred to a couple of commonplace, steep, and cramped ascents. In one design I observed that additional charm had been secured to such a single principal stairway as I have described for approbation, by allowing a business staircase to be separated from it merely by a stone screen or open arcade, so that one stair could be seen from the other, greatly adding to the effect of both. These business stairs also should be so placed as to be as accessible as possible from the offices in their neighbourhood, thus avoiding all needless traversing of corridors to reach them; and yet none should be inserted not absolutely needed. In no case should a staircase run up in the ordinary width of a corridor, so reducing its width and the view down it, as is common in goals, and there permissible for a strictly utilitarian reason.

In municipal buildings in places where, as in Sheffield, there is no special residence for the chief magistrate, there will almost certainly be a suite of reception rooms. These rooms and the approaches thereto should be so arranged as to be cut off from the business portion of the building when required without in any way interfering with access to the latter; further, such rooms as the Council-Chamber and the Committee-rooms, while having, as is frequently found desirable, approaches from the corridors of the reception suite, should invariably be accessible also from the departmental corridors for ordinary business purposes. The corridors of approach to these reception-rooms should be at no point cramped, especially at the head of the grand staircase, or, on crowded assemblies, an inconvenient block will necessarily ensue.

Sanitary considerations make it imperative that closets should each be lighted with a separate window, and that the ante-room of approach should be lighted and ventilated otherwise than through the closets themselves. This is not always remembered by architects competing, who seem to forget that buildings which met with approbation some years ago may have sanitary arrangements then regarded as satisfactory which may now be condemned.

One well-lighted and well-ventilated closet is worth half-a-dozen of the sort one so frequently sees on competition plans. It is also most desirable that such sanitary appliances should be kept as much as possible together both on plan and vertically.

I have enumerated some of the points I thought most open to criticism in the Sheffield sketches, but there is no doubt that the design of the elevations especially is of a higher average than that which has distinguished some late competitions, as those of you will see who care to visit Sheffield, where all the designs are now, I believe, on exhibition,* except the six selected for the second and final competition, and those whose authors wished to withdraw them before the exhibition. Wherever the authors are so willing, their name is now attached to their designs, and I trust that the publicity thus given to merit may be some compensation for the absence of other remuneration.

In the case of the six, their sketches are to be hung side by side with their elaborated designs when complete; but in accordance with precedent, for which there is something to be said, they are not to be exhibited until the final competition is over.

I believe that in many a competition the expenses to which our profession is put before any contract drawings are prepared for a building thus competed for would, if accurately calculated, be found to amount to many times the total of the successful competitor's commission. So that, except for the educational benefit to be derived from having designed and elaborated the details of some important building, there is to the hody of the candidates very little profit to be gained from a system which most of us deplore, but do not at present see how to supersede.

I must apologise to you if I have occupied your time unworthily or at too great a length on design as applied to competitions. My remarks, I know, have most of them been trite remarks; but I have been addressing students. I must ask those of my hearers who could lecture me on this subject with so much profit to myself to forgive my prolixity, and, as assessors in other competitions, to excuse my having ventured to suggest a way of making them as useful as possible to our profession. I would ask the students also to take my remarks in good part. I hope that what I have said will offend no one, but conduce, in however feeble a way, to the help and encouragement of the earnest student of practical architecture.

Mr. J. Macvicar Anderson: I think, Sir, your address should scarcely be allowed to pass unnoticed. I believe I may venture to say that in some respects we have made progress in the Institute of late years. I do not say made "reforms," because I do not like the word "reform"; but I certainly think we have made improvements, and one of the most conspicuous is in relation to the subject for which we have met together to-night, viz., the students' work and prizes for the year. In place of the designs being submitted in one portion of the year, as formerly, the awards announced in another, and the prizes presented when we had forgotten who the competitors were, as well as their work, we have now so arranged the matter that the whole thing is brought into one focus. We receive the drawings; they are immediately hung; the awards are affixed; and no time is lost in presenting them. A further improvement, I think, has been the institution of the custom of offering a few words of encouragement and counsel to the students from the President on these occasions. I think that not only the younger members of the profession who are present to-night, but those who have had experience in these matters, may take his words of counsel to heart. They are words which come from a man with probably more experience in these matters than is possessed by any other man in the profession. I hope, therefore, you will allow me to move a very hearty vote of thanks to you, Sir, for the excellent counsel which you have embodied in your address this evening.

Mr. Campbell Douglass (Glasgow): I have much pleasure in seconding the very well-timed remarks of Mr. Anderson. I am sure there are many valuable hints to us all contained in the President's excellent address.

* As will be seen from our article in another column, only about half of the designs that were sent in are actually exhibited.—Ed.

The motion was then put, and carried by acclamation.

The President then presented the prizes to the successful competitors.

The Institute Silver Medal and 10l. 10s. fell to Mr. Alexander Mackintosh; and in the same competition a Medal of Merit was awarded to Mr. J. E. Mowlem, of Swanage.

In the Soane Medallion Competition, three Medals of Merit only were awarded this year, viz., to Messrs. F. W. Beaford, C. F. Spooner, and E. W. Gimson (Leicester).

The Tite Prize of 30l. and a Certificate fell to Mr. James C. Watt, of Aberdeen.

The Grissell Gold Medal and 10l. 10s. were gained by Mr. Walter Percival, of Longton, Staffordshire. Medals of Merit in the same competition were awarded to Messrs. J. A. Pywell and T. F. Pennington (associate).

The Pugin Studentship was awarded to Mr. John Begg, and a Medal of Merit to Mr. D. J. Blow.

The Scientific Masonry Prizes were awarded as follows:—10l. 10s. to Mr. H. A. Woodington, and 5l. 5s. to Mr. A. W. Anderson.

The President, in this connexion, regretted that Mr. Arthur Cates, who was interested as one of the donors of these prizes, was unable to be present. The Class, he might say, had set itself to improving one of his own vaults, and he believed it was the opinion of Mr. Harvey that they had done so very successfully. The Class was one which deserved the most hearty support, because those who took the trouble,—for it involved hard work,—of mastering the problems Mr. Harvey set before them, would be more efficient both as assistants and principals.

Mr. Octavius Hansard considered that a debt of gratitude was due to the three gentlemen who had given the Scientific Masonry Prizes. They could scarcely be expected to do so every year, and if twenty men could be found to give a guinea each for so good a purpose, he would be prepared to head the list.

Mr. Macvicar Anderson said he also would be very happy to subscribe.

The Godwin Bursary for 1890 was gained by Mr. A. A. Cox (associate).

The Asplintel Prize was awarded to Mr. Herbert Baker.

The President, at the close of the presentation, said: I think we must all very much regret that there have been no candidates for the Essay Prize. It is a great pity, and I can only hope that many gentlemen are holding themselves in reserve for another year. I think I ought also to say that Mr. Masey, who has just completed his work in Italy for the Soane Travelling Studentship, had to return home ill before he had quite finished the time he had intended to be there. For the future the Soane Studentship will be held for a shorter length of time than hitherto, which will be of advantage to the students of the future.

The President then intimated that the next meeting would be held on Monday, February 3, when a paper would be read by Mr. J. A. Gotch, on "The Renaissance in Northamptonshire."

EXAMINATION IN ARCHITECTURE: IN THE PAST, THE PRESENT, AND THE FUTURE.

AT the ordinary fortnightly meeting of the Architectural Association, held in the rooms of the Royal Institute of British Architects on Friday, the 17th inst., Mr. Arthur Cates, Vice-President, R.I.B.A., read the following paper on the Architectural Examinations:—

Mr. President and Gentlemen,—In response to the request of your Committee that I should read a short paper to open a discussion on the Progressive Examinations, I propose to place before you a succinct account of the Examination, from the first steps taken towards its establishment, with some observations on the new programme which is coming into force.

The subject of a diploma for architects having been much discussed in France, there appeared in August and November, 1854, and in March, 1855, in the "Encyclopédie d'Architecture" (vol. iv., pp. 113 and 167; vol. v., p. 33), three articles under the title "Du Diplôme d'Architecture." These articles dealt in detail with the education of an architect as it should be, and were brought by me under the notice of members of the Architectural Association, of which I was then secretary.

The propriety of conferring a diploma on architects was the subject of a paper read before

the Association in the summer of 1855 by Mr. J. H. Chamberlain.

In his address, at the opening meeting of the Association for the Session 1855-56, on October 5, 1855, Mr. Alfred Bailey, the President of the year, dealt at considerable length with the intention of the Association to memorialise the Institute on the subject. He urged the necessity for the institution of a public architectural examination, not necessarily compulsory, but

"Let the examination only be a good one and a stiff one, let the 'plunkings' be tolerably numerous, and he was sure that there would be no necessity for a penal law to create candidates."

Mr. William Tite, M.P., who attended as a visitor, spoke at length on the question of scientific education. He considered the great defects were the want of a good, sound, elementary education, and proper examination afterwards by the Institute or some competent body, so as to give the scientific teaching at lectures or in the architect's office a proper direction.

Mr. Tite, further, on November 5, 1855, in his observations at the opening of the Session 1855-56 of the Royal Institute of British Architects, made special reference to Mr. Bailey's Address, and warmly commended the object he had in view, the institution of an examination, and of its necessary result, a diploma.

The three articles above referred to having been reprinted in pamphlet form, a copy was presented by the author, M. Adolphe Lance, through Mr. John W. Papworth, to the Royal Institute of British Architects.

On November 19, 1855, Mr. John W. Papworth read before the Institute a Paper, "An Abridgment of M. Lance's Essay, entitled, 'On a Diploma in Architecture,' with Remarks and Suggestions."

In the meantime, the Association had prepared and transmitted to the Institute the memorial determined on in October, which was read to the meeting on December 3, 1855, as follows:—

"TO THE PRESIDENT AND COUNCIL OF THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The Memorial of the Architectural Association.

MY LORD AND GENTLEMEN,—Your memorialists, representing the younger members of the architectural profession, beg to lay before the Royal Institute of British Architects their desire for the establishment of an examination, which should eventually serve as the basis for the issue of such a diploma as shall certify that the holder thereof is fully qualified to practise as an architect. They have been induced to take this step, from the consideration of the difficulties which, in the present day, beset the early stages of architectural education.

In preparation for entrance upon their articles, in studies during the period of their sojourn in an office, and in the critical interval from the completion of their articles to the moment of commencement of practice, the students of architecture are without sufficient guidance. In no case have they that important and valuable direction given to their several studies which is found to be so successful an inducement to the complete mastery of other professions, and this evil produces its more important effects when students of architecture, having completed their articles, commence practice on their own responsibility.

The want of proper knowledge on the part of the architect, combined as it is with a want of information on the part of the public, leads to many of the anomalies which are now so frequently observed in the practice of the profession, and the presence in its ranks of many who have not the power, and in many cases of those who have not the will, to uphold its credit.

So much attention has been lately turned towards the necessity of testing by examination the competency of all candidates for public employment, that your memorialists are led to submit that the present is a highly opportune period for bringing the subject under your consideration. They feel that they are addressing those who represent the architectural profession, and by whom only an authoritative step towards the establishment of an examination, or the granting of a diploma, could be taken. They are also assured that the senior members of the profession could hardly take the initiative till the necessity for that course had been brought before them by those who have more recently entered the profession.

Your memorialists do not feel themselves called upon to enter into further details, because they are convinced that the members of the Institute must, from their position, be fully cognizant of the evil aspects of the present system; and, therefore, do not doubt that the Council will take an early opportunity of organizing an examination, such as shall be found best calculated to aid and direct the student, and to bring the real qualifications of the architect before the public.

ALFRED BAILEY,
President of the Architectural Association."

It seems to me, Gentlemen, that that Memorial might almost have been sent up by us quite recently. Affairs moved slowly; active opposition, and not less formidable veiled hostility, raised obstacles, not the least of which was the idea that the architect being an artist must, like the poet, be born, and therefore could not be made: such a course of education as was shadowed forth by the Memorial was by many deemed not only unnecessary, but actually un-

desirable; while others thought that the "run of the office" was quite sufficient to provide all the "education" a young architect could require; and it was not until June 25, 1860, that the Institute arrived at the conclusion "that it is desirable to afford an opportunity for a Voluntary Professional examination"; and at a Special General Meeting held on January 14, 1861, it was resolved

"That the Council be instructed to proceed with the preparation of a curriculum and by-laws, and be recommended to appoint a Committee to this end, and to report to a General Meeting."

This resulted in the establishment of the Voluntary Architectural Examination, the Programme of Regulations, and Course of Examination, with list of books recommended to candidates, and a sketch of a form of Examination Paper, being issued in May, 1862.

These documents, elaborated in the most careful manner, were widely comprehensive, and so complete, that they have been used effectively in the arrangements for the Examinations now in force.

Mr. Arthur Ashpitel took the most lively interest in the success of the Voluntary Examination. On November 29, 1862, he attended a meeting of the Association, and in an earnest address advocated its adoption; he also, by bequest of certain shares (since added to by other donations), founded in 1872 the "Ashpitel Prize," now annually awarded to the candidate recommended as having most highly distinguished himself in the Examinations held in the current year.

The first Voluntary Examination (Proficiency) was held in January, 1863, and the last in June, 1881.

Within this period of nineteen years twelve examinations were held, at which forty-seven candidates passed the Preliminary Examination, which lapsed in 1879; thirty-seven passed in the Class of Proficiency, four of whom had passed the Preliminary. While of those who had passed the Proficiency Examination, only three passed the Class of Distinction; these I may mention by name as R. R. Bayne, R. Phené Spiers, T. H. Watson—deserving of all honour.

Notwithstanding the great care taken by the promoters of this Examination in the preparation of the admirable programme, it did not satisfy the requirements of the day, and as it was gradually failing to command any interest in the student class, some effective measure was necessary to meet the needs of the architectural student as expressed in the Memorial of 1855.

This was in some degree attained by a resolution of the Institute passed on March 14, 1877, establishing a new by-law, by which it was provided that

"All gentlemen engaged in the study or practice of civil architecture, before presenting themselves for election as Associates, shall, after May, 1882, be required to pass an examination before their election, according to a standard to be fixed from time to time by the Council."

The regulations and programme governing this qualifying or obligatory Examination were adopted by the Institute on January 3, 1881, and are those now in force for it.

The first of these Qualifying Examinations was held in March, 1882, and since that date fourteen examinations have been held in London, two in Manchester, and one each in Glasgow, Leeds, and Liverpool—nineteen examinations in all. At these examinations, 310 candidates have passed, and twenty-three who have been relegated to their studies are entitled to come up again without further payment.

Thus, in nineteen years (1863-81) the number of candidates passed in the Voluntary Examination Class of Proficiency was only thirty-seven. In eight years (1882-89) the numbers passed in the Obligatory Examination were 310—the candidates who passed in the year 1889 having been seventy-nine, with twenty-three relegated to their studies, to come up at future examinations. The number of candidates who passed in each year is: 1882 twenty-one, 1883 nine, 1884 twenty-one, 1885 seventeen, 1886 thirty-nine, 1887 forty-four, 1888 eighty, 1889 seventy-nine. The steady increase, as the examination has become better known and appreciated, is most satisfactory; and there is good ground for believing that this success will continue.

The system of relegation, by which candidates who, while not failing entirely, have not succeeded in obtaining a sufficient number of marks to pass, are permitted to come up at a future examination, either for the whole, or for that particular section in which they may have

failed to satisfy the examiners, has been most successful, and in a remarkable degree so advantageous to the candidates that it will be continued in the Progressive Examinations now established.

Until the "Final" of the Progressive Examinations comes into force, in not less than three years time, the Qualifying Examination as at present conducted will be continued; it is, therefore, desirable that young men in practice, whether in London or the provinces, who ought to appreciate the great advantages to be derived from the preparation for and passing this examination, should in that interval follow the good example of so many similarly situated, who have passed this test satisfactorily, and greatly to their own benefit; it is for young architects of this class that this examination is particularly adapted. The close relationship now being established between the central body in London and the local societies should materially promote the accession of candidates from the provinces, and it cannot be too distinctly understood that the special circumstances of architects who may have been in practice for a few years, and offer themselves for examination, receive the fullest consideration from the Board of Examiners, and thus all ground for hesitation on their part should be removed.

Satisfactory as has been the working of the Qualifying Examination, and well adapted as it is to meet the requirements of young architects between the ages of 23 and 30, the experience gained in the past eight years, much conference with the younger candidates, and careful study of the answers to the questions set, made it evident that in the interests of the student it would be desirable to establish a more elementary examination, which would secure that they were well grounded in the first principles of the subjects to be dealt with before proceeding to more advanced studies.

The first public step in this direction was taken on May 4, 1887, at a meeting of the General Conference of Architects on "Education," when, after the reading and discussion of various Papers tending more or less directly to this end,* the following resolutions were unanimously adopted:—

1. That it is desirable that the guidance and direction of the education of those entering the architectural profession should be undertaken by the Royal Institute of British Architects.

2. That to realise this end the Royal Institute of British Architects should prepare a scheme of a complete system of examinations.

3. That such system should comprise:—1st, Preliminary, for pupils entering the profession, as a test of general knowledge—those passing this to be "Probationers R.I.B.A.;" 2nd, Intermediate, for pupils in their third year of earlier, for the general principles of Art and Construction—those passing this to be "Students R.I.B.A.;" 3rd, Final, an examination to qualify for A.R.I.B.A., at twenty-three years of age or earlier.

For some unexplained reason the proceedings of recent Conferences have not been reported and issued in the *Transactions* or in the *Journal* of the R.I.B.A.; but this meeting appeared to me to be of so much importance that I reprinted from the *Builder* report the papers read, added an appendix containing full details of the French and American systems of education, issued the whole in pamphlet form, sent a copy by post to every member of the R.I.B.A., and distributed a large number among local societies, and in quarters where the subject was likely to arouse interest.

The three resolutions were formally referred to the Council, with a request to take the necessary steps to carry them out, and ultimately to realise this scheme.

The Institute, acting under the authority of the New Charter and By-laws, by resolutions passed April 8, 1889, established a system of Progressive Examinations:—1. Preliminary; 2. Intermediate; 3. Final or Qualifying.

The Preliminary Examination is to test the general knowledge of aspirants entering, or who have just entered, the profession. The first Preliminary was held in November last, and may be considered to have been satisfactory. An analysis of the result shows that out of 107 candidates who were admitted to the examination, 44 were declared exempt, 43 passed, and 23 were relegated to their studies: so that at this first examination 87 candidates have been entered on the Register of Probationers of the Royal Institute.

* These Papers, by Professor Babcock, Cornell University, U.S.A., Mr. E. C. Robinson, F.R.S., Sir Philip Magnus, Mr. Arthur Hill, B.E. (Cork), Professor Atkinson, A.R.A., Professor E. Roger Smith, Messrs. R. Phené Spiers, F.S.A., Lawrence Booth (Manchester), and J. Alfred Gutch (Kettering), with the discussion thereon, are to be found in the *Builder* of May 7, 1887, and merit careful perusal. A.C.

The programme of subjects included in the examination is very clear; they are all of a simple elementary character, with which any intelligent schoolboy should either be acquainted, or be able with short preparation to make himself acquainted; but some of the candidates appear to have thought it unnecessary to trouble themselves to acquire any accurate knowledge in some of the subjects, and in consequence have been sent back.

Great importance is attached to this preliminary Examination, since when well-established, it will certainly influence the concluding portion of the school education of youths destined to enter the profession, and thus prepare them with a good foundation for their further studies.

The Probationers now registered will in not less than two years,* on submitting satisfactory "Testimonies of Study," as particularised in the programme, be admitted to the Intermediate Examination, the successful passing of which will qualify the student for registration as a Student R.I.B.A.

Not less than two years after having passed the Intermediate, the student—provided that he further "Testimonies of Study" he will be required to produce are satisfactory—he will be admitted to the Final Examination, to qualify or candidature as Associate R.I.B.A. Except as regards the "Testimonies of Study," which are of a more complete character than the "Probationary work" now required, this Final Examination will cover very much the same ground as the present Examination in Architecture; but with the preliminary training necessitated by the Intermediate Examination, it is anticipated that the results, so far as regards the attainments of the candidates, will be even more satisfactory than at present.

As in the present "Examination in Architecture" special provision is made for, and particular consideration given to, the candidature of architects actually in practice, so in like manner when this Examination in some three or four years' time has become merged in the final, some adequate provision will for a few years be made to meet the cases of architects in practice, whom it would not be reasonable to require to pass the two previous examinations, and from whom it would be equally unreasonable to require the full Testimonies of Study which the student candidate would produce in the ordinary course of his preparation.

Although it is to be presumed that every one who takes an interest in the subject is fully acquainted with the details of the Programme of the Progressive Examinations, published at length in the *Kalendar of the R.I.B.A.*, or if not so acquainted, will, by acquiring the *Kalendar*, obtain the necessary information, I will venture to occupy your time, not by a dry recital of particulars there to be ascertained, but with a short comment explanatory of the views with which those details were settled; and, first, I desire to impress on you that these details have been arranged with a desire that the student, in whatever part of the country he may be, should be guided gradually forward in a sound course of study, but should at the same time he left quite free as to the sources from which he may attain the necessary knowledge, and that so far as possible in arranging such a course all unhelpful academic influences might be avoided, and the natural abilities and proclivities of the student allowed free play, consistent with the acquisition of sound elementary knowledge essential to enable him to practise his profession with advantage to his client and credit to himself. The Memorial of 1855 pointed out that students of architecture were without sufficient guidance at three periods of their career before entering into practice,—viz., "in preparation for entrance upon their articles," "during the period of their sojourn in an office," and "in the critical period from the completion of their articles to the moment of commencing practice." The Progressive Examinations meet these periods exactly, and the subjects which must be included in them are defined in the By-laws, which have been approved by the Privy Council, viz.:

By-law 2, Examinations, provides that

"The Examination for candidates for Association shall be written, graphic, and oral, and shall relate to the history of architecture, the characteristics and

* In compliance with representations made by some of the Probationers, the Council have decided that, should not less than six Probationers offer sufficient testimonies of study, and have fully advanced in their studies, they may, by special exception, be admitted to an intermediate Examination, which will then be held for that purpose in November, 1890.

details of architectural styles, the nature or properties, and application of building materials, sanitary science, the principles and practice of construction, the design and arrangement of buildings, professional practice, and such other subjects as the Council may from time to time determine."

The Preliminary Examination exacts knowledge of the elementary branches of an English education, and of one language—French, German, Italian, or Latin. Also the special knowledge of geometrical and freehand drawing, elementary perspective, and of elementary mechanics and physics, which should be readily acquired by a youth of about sixteen.

When this Examination is firmly established the managers of educational establishments will certainly take note of its requirements to secure the necessary qualifications in youths intended for the profession.

An important feature of the scheme for both the "Intermediate" and "Final" Examinations is the "Testimonies of Study," which must be submitted by the candidate and be accepted as satisfactory, as a condition precedent for admission to the Examination.

For the "Intermediate" these "Testimonies" consist of drawings—which in the Art section cover the elementary features of Classic and Medieval architecture, and in the Science section the elements of ordinary construction. These drawings will be used in the oral examination to test the candidate's knowledge of what he has drawn, and thus secure some protection from mere unintelligent, slavish copying.

Concurrently with the production of these "Testimonies," the student will be preparing for the Examination itself by acquiring the necessary knowledge on the subjects set out in the Programme—all of an elementary nature, but essential to be mastered as the sound basis for further study. Among these subjects the application of geometry to actual work, the projection of solids, and development of surfaces, will assume the importance they deserve.

The lines on which this Programme has been founded have been indicated by the deficiencies in elementary knowledge evinced by candidates at the Obligatory Examination. It is, therefore, hoped that students following this course with care will lay a good sound foundation for those more advanced studies required to secure a pass in the Final.

The work thus set out for the aspirant to enable him to pass the Intermediate may appear formidable on paper, but really does not demand any particular exertion from an ordinary student. Continuous and well-directed application by home or class study after office hours will, of course, be essential to attain success; but much of the work, especially the completed "Testimonies" of study and the necessary preliminary work, should be carried out in the office, under the eye and guiding hand of the architect-master who has undertaken to instruct his pupil in the art and mystery of the profession of an architect. Such master will certainly in every case greatly benefit by the improved intelligence of the pupil, and the more advanced knowledge he will bring to hear on the active work of the office, and may, in some instances, be rewarded for the loss of the services of such pupil as an office-help,—spending his days in endless tracing, copying specifications, drawing plans on skins for leases, and the like drudgery, profitable enough to the master, but the merest waste of time for the poor pupil,—by the conviction that he is in some degree fulfilling the obligation he undertook when he accepted the responsibility of taking the future of the pupil into his hands.

The subjects of study exactly follow the lines laid down in the By-law I have quoted, to which, I may say, particular attention was given by the Privy Council, who required the specific subjects to be particularly stated as there set out; but, of course, at this early stage these subjects can only be dealt with in an elementary manner to form the basis of more mature study.

This preparation, the experience gained by passing through this examination, the encouragement and advice the student is certain to receive at the Oral Examination, will induce him to enter on preparation for the Final, not only with a good elementary knowledge, but with an interest in the further prosecution of his studies which will naturally follow the acquisition of such knowledge.

This Final Examination fits in exactly with the third period of the Memorial, since it is neither desired nor expected that a student should offer himself immediately after the

expiration of his articles, for although if a candidate who has just completed twenty-one years of age should offer himself and satisfy the conditions, he could not be rejected, it is not desirable that any one less than twenty-three years of age should come up, and the instances in which one of younger age could pass would be few indeed.

The "Testimonies of Study" required for admission to the Final comprise three most important subjects not included in the examination which this will supersede—viz., drawings from some historical building made from actual measurement, with the joining of the masonry, &c., correctly shown, and the construction—with details of full size—the original sketches measured and plotted on the spot being appended, which will ensure that some attention has been given to the monuments of the past; while the satisfactory evidence of having followed the carrying-out of building works, and notes of the progress and conduct of such works which will be required, will provide for attention being given to the practical work which cannot be omitted.

The two sheets of diagrams of constructive masonry,—arches, vaults, or groined vaults, with the projections of the arch and vault stones,—are intended to promote the study of projection and geometry,—now, alas! almost absolutely neglected by the architect, but, when mastered, of the greatest value to him, and these drawings being obligatory, good results may be expected to follow. I may say, added Mr. Cates, parenthetically, that Mr. Lawrence Harvey, in his classes at the City and Guilds' Institute, had several building artisans, but only one young architect,—a fact which is, I think, hardly creditable to this Association.

The other subjects fixed for the "Testimonies of Study" touch on the principal points with which acquaintance is desirable, but the limits are so wide that the fullest opportunity is afforded to the student for the development and display of his particular ability; while the present Qualifying Examination, modified only to meet the more advanced position of the student, may be considered as fairly representing the written, graphic, and oral portions of the Final.

The interest which has been evinced in the Preliminary Examination by leading men in Dublin, Glasgow, Bristol, Leicester, Liverpool, Manchester, Newcastle, Nottingham, Sheffield, and other places, is of good augury for the future, especially as many of the candidates have been sent up by architects who are not as yet members of the Institute. Thus it may be hoped that by the aid of such centres, which year by year will certainly be extended, the pupil even in remote country places may be reached, and the whole of the rising students throughout the United Kingdom, and, hereafter, also in the Colonies and Dependencies of this Empire, be brought under the influence of these Progressive Examinations.

The first step towards this is that every architect, whether or not a member of the Institute, should appreciate that it is an obligation on him to see that his pupils are duly prepared for and successfully passed through the full course; and should further feel that in failing to do this he fails to fulfil the obligation he undertook when accepting the pupil; for I sincerely trust that such wicked waste of a youth's best years as giving him, in exchange for handsome money consideration, "the run of the office," will soon come to an end.

This Association can greatly help in forwarding the success of the undertaking, not only by its classes,—so advantageous to those to whom by good fortune they are accessible,—but also by the personal influence of individual members, so many of whom have passed one or other of former examinations.

Further, the Architectural Association of London has effected so much good for the young student by its system of classes, that so excellent a model might well be followed by the pupils and clerks engaged in provincial offices, who should, in every town where a sufficient number could be brought together, form an Association on lines similar to this, and, with the programme of the Progressive Examinations before them, work together and mutually assist in acquiring and maturing the necessary knowledge. I cannot but think that this Association might do good service for architectural students in the provinces could the executive take some measure to promote these local Associations—to work in conjunction with it; and this may now be the more readily initiated since in many

important centres there are in alliance with the Institute professional societies under whose guidance such junior Associations might be established, and whose effective assistance might be obtained by the originating idea being duly communicated to them through this Association.

In other towns, where such societies do not as yet exist, the young architects, students, and assistants may with great advantage combine to promote by mutual instruction the study of subjects included in the programme; it should surely need but the first suggestion, and the guidance which the experience of this Association would enable your executive to give, to lead to such associations being formed wherever a dozen, or even fewer, students could be brought together to work in harmony for one common end.

I earnestly commend this to the favourable consideration of your committee, and hope that effective steps will be taken for its realisation, being convinced that it is only by such combination, commencing with the first years of pupillage, and with a clear and definite programme of the *minimum* amount of knowledge which will be required being placed at once before the youthful aspirant, that the future of the profession can be influenced in the manner which we all desire, to the advantage equally of all its members and of the public, its clients.

[The discussion which followed was a very important one, and as it extends to great length, we hold it over until next week, as we desire to give an adequate report of it.]

Church of St. Paul, Grangetown, Cardiff.—Plan.

Illustrations.

LADY CHAPEL, NEW (R.C.) CHURCH, FOLKESTONE.

THIS illustration shows part of the new R.C. church in Guildford-street, Folkestone, as originally designed by Mr. Leonard Stokes. The church, as executed, was illustrated in the *Builder* for June 1, by view and plan. The original drawing was exhibited in the Royal Academy of 1888.

CHURCH OF ST. PAUL, GRANGETOWN, CARDIFF.

THE Church of St. Paul, Grangetown, is being built by Lord Windsor to provide for the wants of a poor and rapidly-growing district of Cardiff. When finished it will accommodate 600 people, and will consist of a nave and aisles, with chancel, side-chapel, and vestries, with organ-loft above the chapel, and a second vestry above that shown on the ground-plan. The materials used are, for the external walling, a local limestone, in courses averaging about 2½ in.; the dressings of the doors and windows are of Penkridge stone; and the quoins and other plainer dressings are of Portland cement concrete cast in moulds. Internally the dressings are of the same materials, and the walls between them are plastered, and will eventually be decorated in colour. The roof is of red deal, and will also be decorated in colour. Externally it is covered with red Broseley tiles. The architects are Messrs. John P. Seddon and J. Coates Carter, of Westminster and Cardiff, and the illustration is from Mr. Carter's drawing.

"SANDGATE," SUSSEX.

THIS house occupies a fine site just within the South Down range, between Pulborough and Steyning. Originally of modest proportions, it was considerably extended some twenty years or so ago, under Mr. Wm. Milford Tenon, architect, when it assumed the form indicated in the small outline, "View previously." The building has now been completed by the present owner, as our illustration shows. A new dining-room and servery have enabled the dinner route to be diverted from crossing the entrance, and at the same time shortened by half; whilst a reconstruction of the entrance itself has afforded means of obtaining a gentlemen's cloak-room in connexion with it and with the billiard-room. Externally, on the south front, the new dining-room wing has been made to balance with the previously-existing drawing-room wing—a new parapet between the two being introduced with the object of hiding the whole façade into one composition.

The conservatory was shifted bodily into its new position without breakage of glass.

The contractors for the work that has been done are Messrs. A. Bush & Sons, and the architect is Mr. Walter Millard. The drawing from which our illustration is reproduced was exhibited last year in the Architectural Room of the Royal Academy.

DESIGN FOR PUBLIC BATHS.

WE publish this design under peculiar circumstances. The author, Mr. Peter Anderson, prepared it in competition for the Royal Academy Gold Medal and Travelling Studentship in Architecture, which our readers may remember, was not awarded on the last occasion at the close of last year, as none of the designs sent in were considered equal to the occasion. Mr. Anderson's design, which is better than any of those that were accepted and exhibited, was ruled out on account of the author having missed, as we understand it, one out of the series of lectures which the students are required to attend in order to qualify for the competitions. Mr. Anderson states that he inquired at the office of the Royal Academy as to whether he had fulfilled all the required routine, and was told that he had; but on sending in his design it was refused on the ground that one lecture attendance was wanting in his list. As it does not appear that there was any desire on the part of the candidate to evade his duties, and that it was a mistake, it appears to us that Mr. Anderson has been hardly used in being denied a competition which he would probably have won on a mere ground of "red tape"; and we are therefore glad to show our sympathy for his disappointment in a practical manner by publishing a design which, as a student's work, is certainly of considerable merit.

The author says:—

"In designing a large building of this description one of the principal objects is to have each portion of it separate, and, as far as practicable, complete in itself, and all parts of easy access from the central hall or vestibule.

The large swimming-bath in centre is entered by a passageway, 10 ft. high, and, besides the dressing-boxes shown, has thirty-two similar boxes or balconies. The bath itself is formed of concrete from 2 ft. to 3 ft. 6 in. thick, faced with tiles, and open all round for the free passage of fresh air. The bath is entirely lit from the roof.

The gymnasium is separated from the swimming bath by a glazed screen, and which would be thrown open during any displays. A gymnasts' room fitted up with clothes-boxes, and having w.c.'s and urinal, is under the tepidarium of Turkish-bath. The instructor's-room is under circular end of laundry. The gymnasium is lit entirely from the roof. The Turkish-bath is on the left of entrance hall, the furnace-room for it being under the two end hot-rooms. A filter for the swimming-baths is placed here. A passage from this room along one of swimming-bath goes to laundry and boiler-house on opposite side.

The laundry is lit principally from the roof. The ladies' private and swimming baths are on the right of entrance hall, and although an exit is shown of this side from gymnasium, if it were not used, this could be kept entirely separate for ladies.

The gentlemen's private baths, 1st class (9), 2nd class (12), 3rd class (24), are on the floor over, extending along the entire side to boiler house.

There is a stair and lift from laundry to the floor. The hot-water cisterns are placed high up in the boiler-house. The central portion of front elevation on first floor contains a lecture-hall (seating 370) with raised side galleries, and under the lavatories, &c., for ladies and gentlemen. There is a lecturer's-room at side. Over the Turkish bath as far as the tepidarium, there is a library and

Old Houses in The Market, Warwick -

reading-room (with separate entrances), with librarian and attendants' rooms. Over the tepidarium are the residences of the caretaker and fireman, these having an entrance from the street. With the exception of these residences the building would be entirely heated by steam."

One remark we may make on the plan, that it is a mistake, in planning public baths, to make the men's and women's entrance from the street by the same door and into the same entrance-hall. It is a mistake that has been made in other plans for baths, executed and unexecuted, that have come before us. The women's entrance should always be a separate one from the street.

OLD HOUSES, WARWICK.

This illustration of a picturesque and rather rich example of ancient English half-timbered houses is reproduced from a sketch by Mr. A. A. Perkins. The contrasting effect of the oblique strutting with the rectangular work, in the second story, is unusual and effective.

RECENT DOCK EXTENSIONS AT LIVERPOOL:

THE INSTITUTION OF CIVIL ENGINEERS.

At the seventh ordinary meeting of the session, held on Tuesday evening, Jan. 14, the President, Sir John Coode, K.C.M.G., being in the chair, the paper read was on "Recent Dock Extensions at Liverpool, with a general description of the Mersey Dock Estate, the Port of Liverpool, and the River Mersey," by Mr. George Fosbery Lyster, M. Inst. C.E.

The description of the dock extensions, which were more particularly the subject of this paper, was prefaced by some general remarks on the physical characteristics of the River Mersey and the trade of the Port of Liverpool. The geographical position of Liverpool, its unrivalled water frontage, and its proximity to the great manufacturing districts and to the coal and mineral fields of the North of England and Wales, could not fail to ensure its becoming a

great port; and the result was seen in its continuous advance from the condition of a fishing village to that of one of the foremost seaports of the world. Its revenue at the beginning of this century, 23,380*l.*, on 450,060 tons, had increased, in 1889, to 990,000*l.*, from dues on 9,292,000 tons. The Mersey estuary was of peculiar form, roughly resembling a bottle, the wide upper estuary from Runcorn to Liverpool forming the body, and the six miles of narrows between Liverpool and Birkenhead the neck. The maintenance of the full capacity of the upper estuary was of vital importance to the port, and in this work the incessant changing of the low-water channel of the upper estuary was one of the prime factors. It was computed that on a spring-tide about 710,000,000 cubic yards, and on a neap-tide about 281,000,000 cubic yards, of water passed in and out at the mouth of the river at New Brighton. The ebb and flow of these vast quantities of water maintained channels through the wide sandbanks of Liverpool Bay. The principal channel was an excellent one as regarded width and direction; and as regarded depth, there was twice every twenty-four hours sufficient for the largest vessels, there being 10 ft. of water on the bar at dead low-water of spring-tides, giving 40 ft. at high-water springs, and 30 ft. at high-water neaps. Time was, however, now a most important element of successful trading, and the tendency was to increase the size of ships, so that a greater depth of water in the approaches to the Mersey was highly desirable in order to avoid delay off the port. The attainment of such an end was, however, surrounded with physical and financial difficulties of no ordinary character; but the question was kept prominently in view, and the Mersey Docks and Harbour Board had recently decided to spend a certain amount of money on an experimental dredging of the bar by sand-pumps. The first Liverpool Dock, the "Old Dock," was constructed under powers obtained in the reign of Queen Anne, in 1708. The site was part of the old pool, a tidal creek on the right bank of the Mersey. This dock was the first wet-dock constructed in England, its area was four acres,

and it had within it, on lowest neap-tides, 10 ft. depth of water. Since the construction of the "Old Dock," others had been built from time to time as trade required, the site chosen for them being the river foreshore in front of the town of Liverpool. In the second quarter of this century especially, many new docks were constructed by Mr. Jesse Hartley, dock engineer, to whose ability and practical knowledge Liverpool undoubtedly owed much of its commercial greatness. From 1845, also, Birkenhead, on the Cheshire or left bank of the Mersey, entered into competition with Liverpool. Docks on a very large scale had been laid out there, and already partly constructed, when, in 1858, the Mersey Docks and Harbour Board was incorporated by Act of Parliament to take over and manage as one concern the whole of the Liverpool and Birkenhead Docks, which, since the date named, had formed one estate. In 1871, although the Birkenhead Dock system had been for some time completed according to the Parliamentary plans, the Dock Board was urged to consider the desirability of commencing, without delay, further dock extensions on the Liverpool side of the river, on such a scale as would meet the pressing wants of trade, and provide for the growing requirements of shipping, which was everywhere advancing in size and tonnage. The result of this pressure was an exhaustive inquiry into the question by a Committee of the Board, with the outcome that the author was directed to consider and report as to the alterations and additions which might be requisite to meet the probable requirements of the great and increasing commerce of the port. Reports and plans were duly submitted by the author, showing schemes of dock extension both at the north and the south ends of the Board's Liverpool estate; and in the Session of 1873 Parliamentary powers were obtained for the construction of new dock works, estimated to cost on the whole 4,100,000*l.* The works referred to were designed to meet the wants of the port for some time in advance from the date of the Act. It was, therefore, provided that the expenditure was not to exceed 500,000*l.* per annum, and, accord-

ingly, the works had been spread over many years. The effect had been that, before any of the several new docks were opened, trade in its natural advance had been ready to fill them. The general design of the New North Docks comprised the enlargement of the Canada Basin, and the improvement of its entrance, so as to make it available for vessels of the largest class, and the construction of the following new docks:—The Langton Dock, of 18 acres, serving as a half-tide dock; the Alexandra Dock and branches, 41 acres; and the Hornby Dock, 17 acres. The Canada Basin and Langton entrances had been designed to give as direct a lead from the river as possible, so that vessels could pass quickly through, allowing of a large number docking on one tide. They had been found to work excellently; large steamers of 34,197 tons aggregate burden had been docked and undocked in one tide of two and one-third hours. A most important point in connexion with the Canada Basin and approaches was that of depth. After careful consideration, it was decided to lay the sills of the entrances at the level of 12 ft. below Old Dock Sill, or 2 ft. below low-water of equinoctial spring-tides, and the floor of the basin and approaches at a level 2 ft. lower. In order to ensure the maintenance of the required depth without dredging, special means had to be adopted to clear away the silt deposited every tide; and to this end sluicing-culverts had been constructed in all the walls of the basin, the flow of water from which cleared silt away for a considerable distance in front of the walls. To effect the removal of silt deposited beyond the range of the wall-slucies, sluice-pipes had also been laid under the floor of the basin; and these were fitted at short intervals with vertical branches having outlets through the floor of the basin. The outlets were closed by framed disks of greenheart, which effected the distribution of the sluicing-water over the area to be cleared. The fairway to the basin was also maintained clear by sluices laid in the foundations of the north and south jetties, which, besides serving for this purpose, limited the area within which deep water had to be maintained, and acted as guides against which vessels entering or leaving the basin might bear. The Langton Dock had an area of 18 acres, and served as a vestibule for shipping, while its north and west quays were provided with sheds suitable for the discharge of vessels of the largest class. The graving-docks, situate on the east side of the Langton Dock, were each 950 ft. in length, but had intermediate gates in the centre, so that the inner chambers could be used as "long-time" while the outer were used as "short-time" docks. The graving-docks were built entirely of concrete. A 30-ton hydraulic crane furnished means of handling screws, rudders, &c., and was so arranged as to be capable of being used at any of the four graving-dock chambers. At the entrance to the graving-docks was an engine-house, which was the centre of power for the district; it contained hydraulic main-engines of 350 h.p., besides powerful engines and pumps for draining the graving-docks of such water as could not be run off with the tide. On the south quay of the Langton Branch Dock was a hydraulic crane of 100 tons power, of a novel character, the lift being made by a direct-acting inverted hydraulic cylinder—a mode of working which permitted of nice adjustment of the loads. The Alexandra Dock, designed to accommodate the largest steamers, had a length of 1,600 ft., and its quays were all provided with substantial sheds, 95 ft. wide in one span. The Hornby Dock was partly used as a timber dock, partly for ordinary trade; for the latter purpose a shed, 125 ft. wide, was now in course of erection on its south quay. The principal points of these northern docks were illuminated at night by electric lights, placed on masts 90 ft. high. The total estimated cost of the whole of the works was 2,727,000*l.*, and, since their completion, they had accommodated sea-going ships of the largest class, with an aggregate of 18,000,000 tons. The New Southern Extension comprised a chain of docks from the Herculaneum, which had been constructed by the author in 1868, to the old Brunswick Dock. These new docks had been named the Harrington, Toxteth, and Union, the latter forming the link between the new system and the old. At the same time the Herculaneum had been greatly enlarged, and on its eastern and southern quays special accommodation for petroleum had been provided by the excavation of casemates in the solid rock. The Harrington

and Toxteth Docks were laid out for general trade, and were provided with first-class sheds, those on the western quays being single-story sheds, 150 ft. wide, whilst on the east side double-storey sheds of novel character had been erected, the width of these sheds being 95 ft. The discharge of goods on to the floors of the latter sheds was effected by a number of hydraulic cranes, mounted on the roof, and capable of dealing with any load up to 30 cwt. Through the Union Dock, vessels which could not on neap-tides, by reason of their deep draught, get into the river over the Pluckington Bank and shallow sills of the older docks, were enabled to dock and undock through the chain of new docks into the river, by the Herculaneum entrances, now deepened to 12 ft. below Old Dock Sill. The level of the water in the older docks referred to would be maintained, when necessary, by impounding and pumping. The bulk of the excavation from these docks was a soft sandstone rock, and, no place of deposit being obtainable, it became necessary to send the rubbish to sea, which was done in steam-hopper barges of 500 tons capacity. The estimated cost of the New South Docks was 1,373,000*l.* By the north and south extensions, forming the subject of the paper, the area of the Liverpool Docks had been increased from 252 acres,—the area at the time of the passing of the Act of 1873,—to 363 acres, the present area, and the quayage from 18 miles to 24 miles.

THE LONDON COUNTY COUNCIL.

The usual weekly meeting of the London County Council was held on Tuesday last at Guildhall, Lord Rosebery in the chair.

Proposed New Council Chamber.—Sir T. H. Farrer moved:—

"That it be an instruction to the Council Chamber and Officers Committee to consider and report as to acquiring a suitable site for a Council Chamber and offices."

In the course of a long speech he advanced the reasons he had for making his motion. Although, he said, the enlarged Council-room at Spring-gardens would, when completed, be large enough for their meetings, the office accommodation there was most inadequate, and was so overcrowded that their work and the health of their clerks were seriously suffering.

Mr. Acworth formally moved the following amendment, which stood in the name of Mr. Rhodes:—

"To omit all words after 'That' in order to insert the words 'having regard to financial and other general considerations, and having regard to the inexpediency of any proceedings in the nature of a possible hindrance to the ultimate fusion of the ancient Municipality of the City of London and the newly-formed Council of the Administrative County of London in one great corporation, it is not desirable at present to press on the seeking for a site for new Council offices.'"

Mr. Acworth said that he agreed with almost every word that Sir Thomas Farrer had said, and there was a good deal in Mr. Rhodes's motion with which he did not agree entirely; but he did not think that the fusion with the City need be seriously considered in reference to this matter. Subsequently Mr. Acworth withdrew this amendment in favour of that which stood in the name of Sir Walter de Souza.

Sir W. De Souza moved:—

"That the Council, whilst recognising that in due course a site will have to be acquired, and municipal buildings erected suitable for all the requirements of the Council, feels that it is not in a position to judge what the future requirements of the Council will be, and for this and other reasons is of opinion that it is at present premature to consider any scheme for the purchase of a site and the erection of municipal buildings."

This amendment was lost, on a division, by fifty votes against thirty-nine votes, and the further discussion of the subject was postponed.

The Architect's Department.—Arising out of some recommendations of the Standing Committee as to the appointment of some temporary draughtsmen and assistants in this department, it was incidentally stated that the Standing Committee would shortly present a report dealing with the whole organisation of the department.

After transacting further business the Council adjourned.

Houses of Parliament, Berlin.—On the 13th inst. the "Controlling Committee" at last (after discussing the subject for nearly two years) sanctioned the erection of a large central cupola, according to the designs of the architect of the building, Herr Wallot.

THE GUINNESS FUND.

SIR,—The princely donation of Sir Edward Guinness being the first step towards the attempt to solve the difficult and embarrassing problem as to the practical way of properly housing the poor will doubtless cause the matter to be taken up in earnest. With this view I venture to repeat a suggestion I made when Mr. George Peabody announced his intention of devoting a large sum of money for a like purpose,—viz., that instead of a body of trustees attempting themselves to erect dwellings, they should offer to lend a considerable portion of the money required at a low rate of interest,—the interest of which and the principal to be repaid in equal quarterly instalments extending over say thirty years or redeemable at pleasure. The advantages would be that the difference between the amount lent and that required would encourage private investment and increase the available fund, which would be further increased by donations, or if necessary by public grants. The low rate of interest would give a margin that would just turn the scale from a loss to a profit. The lenders would have control not only in the planning and construction of the buildings, but also in their ultimate use (at any rate for thirty years), so that their purpose may not be lost. Each year would render the security greater, and by the constant repayment the fund would be practically inexhaustible. If some such plan as this had been adopted by the Peabody trustees I believe the difficult question would by this time have been nearly settled.

J. DOUGLASS MATHEWS.

HAYWARD (DISTRICT SURVEYOR) v. SANDON.

SIR,—In some remarks regarding this matter which you published on the 14th inst., I wish to point out some misleading statements which I beg you to correct.

It is stated that the "summons was dismissed," yet that could scarcely be, as no summons has issued by the one heard on Oct. 4, 1889, when the magistrate decided in favour of the District Surveyor, giving him also costs in the case.

Also it is stated that my "sollicitor" gave me certain advice, which he actually did not give. But why anyone should write to you professing to know and publish what passed between "my solicitor" and myself I am at a loss to conceive, though in justice to Messrs. Sandon's adviser, I should say that I am led to believe this statement did not emanate from him.

What actually happened was this. Messrs. Sandon being dissatisfied with the magistrate's decision, and the order that he made on Oct. 4 that they should pay the District Surveyor the specified fees, endeavoured to get a case stated for the Superior Courts.

Failing to obtain this in their own way, it was discussed in the magistrate's own private room and "dismissed"—if that is the word—and so the matter remained in *status quo*.

As I made no demand for costs, of course, none were given.

Since then the matter has been settled by Messrs. Sandon paying me what I have chosen to accept in satisfaction of my fees. But be it quite understood that the decision of the Bow-street Court confirming that of all other Courts in favour of the District Surveyor's contention is unshaken, and that Clause XXVII. of the Act remains to be read as it always has been, and Messrs. Sandon's contention has only confirmed its meaning to be just what it says in its several rules.

C. F. HAYWARD.

SCHOOL-PLANNING.

SIR,—The writer of the article on p. 4, *ante*, recommends asphalt for school floors. I have, however, frequently heard complaints from men employed in City warehouses of the asphalt floors upon which they have to stand all day; they attribute to its effects the shortening of the lives of their fellow-workmen. Employers who have to stand continually on linoleum or oilcloth also complain that these floor-coverings "draw their feet." It has been suggested that asphalt and these coverings are good conductors of heat, and are the means of a too rapid loss of heat; another notion is that the interposition of these substances causes an interference with the normal electric condition of the body. What are the electrical conductive conditions of these substances I do not know, but it would be useful to your readers if some of your scientific subscribers would kindly give us some information on the matter.

A. H.

DADLINGTON CHURCH, LEICESTERSHIRE.

SIR,—In Vol. I. of the *Builder*, July 8, 1843, there appears an engraving of this old church with its quaint, square wood belfry, covered with oak shingles.

Archeologists, and everyone who takes a delight

THE BUILDER. JANUARY 25, 1890.

GROUND-FLOOR PLAN

FRONT-ELEVATION

By Mr. PETER ANDERSON.

SIDE ELEVATION

PHOTO LITHO BRUNNELL & CO. 25, MARTIN LANE, LONDON, E.C.

and pride in our village churches, will learn with mingled feelings of disgust, shame, and regret that this unique old belfry has disappeared, and in its place a fourth-rate, fancy-tiled, villa-turret type of thing put up. The curious old windows, which did duty for a clearstory, have been ruthlessly brickied-up with red bricks, and other vagaries are contemplated with the old wood porch and its fine old door, "if the funds hold out." Surely, some steps can be taken to stop the destroyer's hand. I understand no architect has been called in, but, from a personal inspection of this old belfry in August last, I do not hesitate to say that, with judicious repair at a comparatively small outlay, it would have done duty for centuries.

The chancel was faithfully repaired and partly re-built two or three years since under Mr. Ewan Christian, the architect to the Ecclesiastical Commissioners. H.

PROVINCIAL NEWS.

Smetwiche.—A number of residences are about being commenced at Smetwiche, Bloxwich (near Walsall), and near Solihull (Birmingham). These houses will be of a size and character adapted to the requirements of clerks and the higher class of skilled artisans. The total cost of erection is estimated at about 23,000*l.* The architect is Mr. John Statham Davis, Birmingham.

Swansea.—The Alexandra-arcade, Swansea, has now been completed. According to the *Western Mail*, the architect is Mr. E. Bath, of Swansea, and the builder Mr. Henry Billings, Swansea. The arcade contains twenty-seven shops, and is furnished throughout with a complete installation of electric light. Its principal novelty, however (amongst South Wales arcades), is the principle which has been adopted of building a second row of shops above the first, and giving access to the upper row by galleries or balconies, which lead all along the building. The public go up flights of massive stone steps at either end, and pass along a fairly broad pavement in front of all the shops. The arcade is traversed by bridges at either end and at the centre, and the public can thus pass freely to all parts. The arcade leads from High-street to Alexandra-road. The latter thoroughfare is at present showing some signs of advancement, and it is hoped that it will in time become as important a thoroughfare as High-street itself.

Walsall.—A new hall for the Walsall Spiritualistic Society is now in course of erection. The hall will consist of basement and three storeys, the top one being devoted to the caretaker's rooms and the basement to the cooking kitchens and other offices. The principal part of the building will be two halls of 36 ft. by 54 ft. each, with ante-rooms and lavatories, the height of the building being 34 ft. to the wall-plate. The building will be almost entirely of brick, with Corinthian columns and elaborate cornices. Mr. W. E. Jackson, Walsall Wood, is the architect, and Mr. R. Evans, Thorpe-road, is the builder. The contract for the building is 1,000*l.*, and the total cost is expected to be about 1,200*l.*

CHURCH BUILDING NEWS.

Alnwick.—An organ-chamber has been added on the north side of the ancient parish church of St. Michael, at Alnwick, opening out of the chancel under a Perpendicular arch made to correspond with the character of the chancel. The ancient window formerly in the wall, at the point now occupied by this arch, was carefully taken down, marked stone by stone, and erected precisely as before in the north wall of the new chamber. Mr. F. R. Wilson is the architect. A new organ, estimated to cost 630*l.*, is to be placed in it when the necessary funds are gathered together. The Duke of Northumberland has generously contributed upwards of three hundred guineas towards the expenses of the improvements. The ancient fabric here and there shows traces of the munificence of the ancient Percies in features bearing their heraldic insignia. It is, perhaps, still better known among antiquarians as possessing one of the rare reacon turrets, from which intelligence was flashed, by means of a beacon flare, to distant parts.

Liskeard.—The parish church of Liskeard has lately been reopened, after the completion of its restoration. According to the *Western Morning News*, the work of restoring the church has been done, during a long series of years, in a somewhat fragmentary manner, but about ten or eleven years ago an important contribution to this work was made, nearly 4,000*l.* being

then spent in the erection of a new roof, the removal of the organ-gallery, the rebuilding of the north-east angle of the north aisle, and the provision of new mullions and tracery heads to some of the windows. The contract was entrusted to Mr. Thomas Lang, and the church was reopened on March 12, 1879. The committee at that time, although desirous of completing the restoration of the chancel, deemed it advisable to postpone further operations. Ten years having elapsed, an effort was made which has resulted in seeing the desired alterations and improvements carried out. The first stage of the work of the present restoration, which has been carried out from designs by, and under the superintendence of, Mr. John Sansom, architect, of Liskeard, was the demolition of the old and dilapidated vestry, and rebuilding on the same site a structure in the fifteenth century style, to harmonise with the church, the windows, doorways, and other dressings being of granite, interior fittings of oak, and tiled floor. This vestry is a memorial to the late Rev. James F. Todd, a former vicar, and carries out the desire entertained for its erection by his successor, the Rev. Flavel Cook. Mr. T. E. Madams, of Liskeard, was the builder. The old chancel, which measures 40 ft. long and 21 ft. 6 in. wide, and has now undergone restoration, was very badly arranged, and there was no apparent distinction between it and the other portion of the church. The view of the east-end was, moreover, obstructed by the position of the pulpit, which stood on the south side of the nave aisle, near the old high pews of the Corporation, whilst on the north side of the nave aisle was a high reading-desk, the clerk's desk, and churchwarden's pew. These constructions have now been removed, and a passage carried across the east end of the nave. The old oak pulpit, which is a fine specimen of carving, and bears date "Anno Domini, 1636," has been refixed on a moulded granite base much lower than it previously stood, and is approached from the chancel by four granite steps corresponding with its base; it is somewhat further south than formerly. The chancel has been entirely rearranged, the floor raised one step above the nave, and the new choir stalls, erected in teak, are of handsome design and elaborately carved, while the poppy heads are worthy of special mention. The two steps leading from the chancel to the sacristan are of polished red Ogwell marble, and supplied by Messrs. Blackler & Son, Torquay. The altar railing, which is of solid brass, polished and furnished, with moulded top rail of oak, was manufactured by Messrs. Hart, Son, Peard, & Co., London. The floors of the entire chancel are paved with rich encaustic Minton tiles of special design. The east wall of the chancel has been taken down and rebuilt, and a new granite five-light window and tracery lights has been filled with stained glass by Messrs. Clayton & Bell, Regent-street, London, illustrative of the Ascension of our Lord. Underneath this window stands the reredos, in Beer stone. It has three main panels divided by pinnacles and buttresses, the centre panel by a crocketed canopy. The two panels on each side of the reredos are similar in character to the centre. The whole is rich in carving and tracery. The Communion and credence tables, which have been made in Jerusalem of oak from Mount Hebron and olive-wood from Gethsemane, were designed by the architect. The table has an elaborate tracery front, and the sedilia is in teak of similar character and design to the choir stalls. The east window of the north chancel aisle has also had a new granite five-light window; this has been filled with stained glass by Messrs. A. Savill & Co., of London, and is erected to the memory of the late Mr. Christopher Childs by his widow and four sons, Mr. Torlase Childs, Dr. Childs, Mr. Walter Childs, and Mr. John F. Childs, and illustrates the text, "Consider the lilies of the field." In the north and south chancel aisles the seats have been rearranged so as to afford passages behind the choir stalls, and the Corporation pews are placed in front of the nave seats, the bench ends being carved with the borough arms, poppy heads, and tracery panels, the seat for the Mayor being placed in the centre of the first pew. The heating apparatus has been rearranged by Messrs. Longthorpe, of Leeds. The wrought-iron reading-desk placed in the nave is the work of Mr. John Davey, of Liskeard. The work generally has been carried out by Mr. Philip Blowey, contractor, of Plymouth, and has been to the satisfaction of the architect

and committee, whilst the carving, both in wood and stone, has been executed by Mr. Harry Hems, of Exeter. The granite work was supplied by Messrs. Nicholls & Son, Liskeard. The amount expended has been about 1,800*l.*

Perth.—It has been decided to restore the ancient kirk of St. John, Perth.

Wimbish (Essex).—We learn from the *Essex County Chronicle* that it is proposed to complete the restoration of this church by "the rebuilding of the tower," and the carrying out of other works, at an estimated cost of 1,300*l.* Mr. Nelson Jones is named as the architect. The ancient tower, it appears, fell down about 130 years ago. The chancel was rebuilt in 1872.

STAINED GLASS.

Cardiff.—A stained-glass window, for St. John's Church, Cardiff, is on view at Messrs. Belham & Co.'s studio in Buckingham Palace-road. It is in three lights, and illustrates the subject of Christ blessing little children, the figure of Christ occupying the centre compartment, with groups on either side compartment composed in relation to the centre one. The design of the figures is good, and Messrs. Belham's peculiar thick rough glass makes the most of the colour effect. The window has been carried out by Messrs. Belham & Co. from a design by Mr. J. P. Seddon.

Charlestown (Cornwall).—According to the *Western Morning News*, a stained-glass window, from the studio of Messrs. Fournace & Watson, has just been placed in St. Paul's Church, Charlestown, in memory of William Vawdrey, the eldest son of the late Dr. Vawdrey, of St. Anstel. The subject is a figure of Solomon, King of Israel, holding a model of the Temple at Jerusalem in his hand. The inscription states that William Vawdrey died at Shanghai in 1883.

Kenilworth.—In the south transept of St. Nicholas Church, Kenilworth, a memorial window has just been placed. The window is of two openings, which are filled with the subject, carried over both lights, of "Our Lord's Charge to St. Peter," with ornamental canopy. Under the window a brass-plate is fixed with inscription. The work has been designed and executed by Messrs. F. Holt & Co., Warwick.

Little Burstead (Essex).—The east window of the parish church of Little Burstead has lately been filled with stained glass, the gift of Mr. John Ismay French. According to the *Essex County Chronicle*, the window is the work of Messrs. Clayton & Bell, and it consists of three lights, containing the following subjects, under canopies:—In the northern light, the Annunciation; in the southern light, the Presentation; and in the central light, the Crucifixion. In the tracery above are angels with inscribed scrolls. The work is treated in the richest manner, and has been carried out strictly in accordance with the characteristics of the fourteenth-century period.

London.—St. Clement's Church, Eastcheap, has lately received an addition to its stained glass, in its east window, from the studio of Mr. Taylor, of Berners-street, the subject being the "Agnus Dei," carried out in Renaissance style under the direction of Mr. Butterfield, the architect, who has just completed the redecoration of the church.

Surveyorship, West Hartlepool.—At the last meeting of the Town Council, the salary of the Borough Engineer, Mr. J. W. Brown, Assoc. M. Inst. C. E., F. G. S., was, by a large majority, increased from 400*l.* to 500*l.* per annum. Mr. Brown was outvoted on the efficient and able way in which his department is conducted, and on the skillful manner in which he had designed and carried out the engineering work of the Corporation. Many extensive schemes are in hand and in contemplation in this rapidly developing port.

Advance in the Price of Bricks.—A well-attended meeting of brickmasters was held at Cannon-street Hotel on the 13th inst., at which the leading manufacturers of the various districts supplying the London market were present. The following resolutions were proposed, seconded, and unanimously passed:—

- (1) "That in the opinion of this meeting of brickmasters supplying the London market, an advance in the selling price of bricks is imperative to meet the increased cost of fuel and materials, and the advance given in the price of labour.
- (2) "That in the opinion of this meeting it would prove of great advantage to the industry, if brickmasters supplying the London district would cooperate in dealing with the various labour questions as they arise."

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—IV.
CURRENT (continued).

IMPORTANT as are the effects produced within a conductor through which an electric current is flowing, still more important are the phenomena occurring in the medium around it. A suspended magnetic needle brought near a wire, carrying an electric current, tends to set itself at right angles to the conductor, showing that a current produces a magnetic field in the surrounding medium, and thus establishing a connection between electricity in motion and magnetism. An investigation of the magnetic field so produced, by means of iron filings and a needle suspended in such a manner that it can point in any direction, shows that a current is surrounded by a series of circular lines of force, whose planes are perpendicular to the current, and whose centres lie in it. A field of this shape is frequently called a "whirl" of force.

Fig. 6.

Fig. 6 shows the relative directions of the current and of the circular lines of force. The diagram should be committed to memory, but the following rule, known as Ampère's, is also useful.—"Imagine yourself swimming in the current, so that it flows from your feet to your head, then if you face the magnetic needle, its north pole will be turned to your left hand."

It is the strength of the magnetic field produced by a current that is used for determining the strength of the current itself.

Fig. 7.

If a current is sent from A to B (Fig. 7) through a solid conductor, and at B split up into three or more parts, so that from B to C a number of currents are flowing, which, added together, equal the current in A B, it will be found, the distances being in both cases the same, that the field produced by the current in A B at an external point is the same as that produced by the currents in B C. Again, if a given current flows along a straight conductor the number of lines of force produced by it will be proportional to its length. We say straight, because a conductor might be increased in length, but the added portion so shaped that the new lines of force neutralised some of the old ones, in which case the total number of lines would be diminished instead of increased. Before the strength of a current can be determined by measuring the field at a point external to it yet one thing must be known, and that is, how the strength of the magnetic field varies as we recede from the conductor. If we attempted to investigate this question by measuring the strength of field at various distances from a straight conductor, mathematical difficulties would arise in examining the results, firstly, from the fact that different portions of the current would be at different distances from the point in the field under consideration; secondly, because as we recede from the conductor in any direction, the distances from different parts of the current do not increase in the same ratio.

These difficulties can be got over by using conductors bent into circles, and noting the fields produced at their centres, from which, of course, every portion of the current is equidistant, taking into account the increased length of conductor when the distance is increased by the use of larger circles. The following very simple demonstration of the law of the inverse square of the distance is due to Professor Silvanus Thompson.

A circular bobbin B, (Fig. 8), of radius r_1 , is wound with n_1 turns of wire, the total length of which is therefore $2 \pi r_1 n_1$; a second smaller bobbin B, of radius r_2 , is wound with n_2 turns of wire, and placed in the plane of the first bobbin, so as to have its centre O in

common with it. A small magnetic needle is pivoted about one of its poles and placed so that when the plane of the coils faces east and west the second pole is at O. The connexions are made as shown in the figure, the connecting

Fig. 8.

wires P and Q, leading the current to and from the terminals T_1 and T_2 and to and from the bobbins, being placed side by side, so that the whirl of force produced by the current in one wire is neutralised by the whirl produced by the same current going in the opposite direction in the other wire. It will be noticed that when a current is sent from T_1 to T_2 , through the apparatus, the fields produced by the bobbins B_1 and B_2 tend to neutralise each other; the turns of wire are so adjusted that no matter how much current is sent through the instrument the needle remains undeflected, that is, the bobbins exactly counteract each other's effects at O. On cutting the turns of wire, it will be found that

$$n_1 : n_2 :: r_1 : r_2 \quad (i)$$

Let $[r]$ be the mathematical expression which gives the variation of strength of field with distance.

Then the strengths of field produced at O by the bobbins, since the same current traverses both, are proportional to $2 \pi r_1 n_1 [r_1]$ and $2 \pi r_2 n_2 [r_2]$, but matters have been so adjusted that these fields are equal, hence

$$2 \pi r_1 n_1 [r_1] = 2 \pi r_2 n_2 [r_2]$$

therefore $\frac{[r_1]}{[r_2]} = \frac{r_2 n_2}{r_1 n_1}$ (ii)

but from (i) $\frac{n_2}{n_1} = \frac{r_1}{r_2}$ substituting this value

$$\text{in (ii)} \quad \frac{[r_1]}{[r_2]} = \frac{r_2^2}{r_1^2} = \frac{1}{\frac{r_1}{r_2}}$$

$$\text{or} \quad [r] \propto \frac{1}{r^2}$$

That is to say, the force varies inversely as the square of the distance. In the figure the radius of the outer bobbin is twice that of the inner one, so that one turn on B_2 balances two turns on B_1 .

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

18,802, Improvements in Water-closets. H. S. Booth.

In order to utilise the inflow of water under pressure to draw or force out the confined air and effluvia, an ejector, with controlling mechanism, is, according to this patentee, fixed so that the operation of flushing the closet automatically purifies the air.

1,578, Paint and Pigments. R. Stone.

The body of the paint which is the subject of this patent is made of China clay, marble, or any earthy substance of a fine, fibrous, silky nature. One or more of these or similar substances are mixed with petroleum oils or spirits, or with nitric or sulphuric acid. The mixture is then burned, which gives it a colour which is permanent and not likely to fade, and the resultant material is also fire and waterproof. Proportions of both pigments and media are varied at will, but the burning of the mass is an essential part of the invention.

2,121, Improved Building Block, Tile, or Slab. G. A. Wright.

According to this invention, a noiseless, non-absorbent tile is made of burnt clay, terra-cotta, concrete, or suitable material, and the face is dipped into india-rubber or such like solution; and while this is liquid, metal, flint, or granite powdered fine is sprinkled on the surface. The blocks are cemented together with bituminous cement.

19,829, Clamp. T. Metham.

The clamp, grip, or vice which is the subject of this patent is particularly adapted for the use of carpenters, joiners, or woodworkers, although it may be also utilised in other trades. It is formed of a combined set of levers or arms, in the shape of a fork or prong, upon the ends of which is fixed the grip or claw for compressing the material. The arms are actuated by means of a screw or screws, so placed that working it to right or left hand will cause the levers to expand or contract as may be required.

14,012, Substitute for Wood. H. B. Bentzen.

According to this invention, material for use in imitating wood-carvings is made by mixing dextrine, glue, and sawdust. For imitation carvings, the mass is mixed with dark sawdust and moulded under pressure, when the ornaments produced are of considerable strength and can be speedily and cheaply produced.

17,032, Portable Scaffold. A. T. Nygren.

This invention, which hails from Sweden, provides a hoist or scaffold which may be substituted for the ordinary stationary scaffold. Elaborate fixing by means of bars, screws, and bolts is provided, and a runner is clamped to the sloping roof and the cornice of the building. From the runner a kind of chair moved by ropes and winches depends, and this may be moved about to any part of the structure. The point of fastening, which looks strangely weak in proportion to the work required of it, is ingenious, but difficult to describe briefly.

NEW APPLICATIONS FOR PATENTS.

- Jan. 6.—205, H. Johnson, Window Fasteners.
- Jan. 7.—256, W. Halladay, Saw Sharpening Machines. 257, L. Halladay, Saw Swages. 258, L. Halladay, Saw Sharpening Machines. 263, J. Soketchazy, Portable Framework for Bridges. 274, A. Waterer, Electric Bells. 276, A. Bout, Sash Balances. 285, W. Kneen, Attaching Door Knobs to Spindles. 301, A. Lewis and J. Donaldson, Door Detainer.
- Jan. 8.—330, J. Dunning and B. Priestley, Sash Fasteners. 353, N. Scott Russell, Combined Door Springs and Checks.
- Jan. 9.—392, R. Brown, Batten Nail. 423, W. Silverlock, Ventilating Sowers, Drains, &c. 428, A. Wright, Weathered Facing Brick.
- Jan. 10.—436, S. Hill and R. Hodges, Door Catches and Door Fasteners. 479, A. Marshall, Sewer Inverts. 481, E. Burtwell, "Rise and Fall" Brackets for Shop Window Fittings. 482, E. Burtwell, Sash Fasteners. 497, J. Gizeux, Closing Doors.
- Jan. 11.—509, W. Reynor, Testing and Flushing House Drains.

PROVISIONAL SPECIFICATIONS ACCEPTED.

- 19,393, W. Davis, Material for covering walls.—19,524, S. Empsall and W. Fish, Syphon Water Flushers for closets.—19,586, C. Smith, Imitation Marble, &c.—19,617, M. Wardie, Self-acting Window Wedge.—20,470, J. Campbell, Drying Machine.—20,591, B. Little, Fresh-air Induction Pipes for Warm Air Buildings, &c.—20,711, S. Danischewsky, Door-fastener.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months.

- 1,952, J. Merryweather, Paving.—2,780 and 22,731, A. Fenton and others, Artificial Stone.—4,005, J. Hall, Norfolk Latches.—4,965, W. Davidson, Fastenings for Rain-water Pipes, &c.—7,020, H. Kimpton, Tip over Flushing Tank.—10,759, E. Massey, Fireplaces.—16,774, H. Maddean, Carpenter's Ploughs and Fillisters.—17,918, P. Knight and G. Hoyes, Door Knobs.—18,076, H. Lake, White Lead.—19,258, W. Wheatley, Roofs.—19,852, F. Prosser and W. Carter, Staining and Mottling Wood.

(Contracts used in these lists.—E.g.r. for freehold ground-rent; l.g.r. for leasehold ground-rent; i.g.r. for improved ground-rent; g.r. for ground-rent; r. for rent; f. for freehold; c. for copyhold; l. for leasehold; e.r. for estimated rental; n.t. for unexpired term; p.a. for per annum; yrs. for years; st. for street; rd. for road; sq. for square; pl. for place; ter. for terrace; yd. for yard, &c.)

MEETINGS.

MONDAY, JANUARY 27.
 Royal Academy.—Professor Aitchison, A.R.A., on "Roman Architecture." Preliminary. 8 p.m.
 Surveyors' Institution.—Mr. H. H. Smith, on "Landed Incomes." 8 p.m.
 Society of Arts (Cantor Lectures).—Mr. Silvanus P. Thompson, D.Sc., on "The Electromagnet." II. 8 p.m.

TUESDAY, JANUARY 28.
 Institution of Civil Engineers.—(1) Further discussion on Mr. G. F. Lyster's paper on "Recent Dock Extensions at Liverpool." (3. Time permitting) Mr. W. H. Wheeler, on "Bars at the Mouths of Tidal Estuaries." 8 p.m.
 Society of Arts (Applied Art Section).—Mr. E. C. Hoehn, F.R.S.A., on "The Relation of the Fine Arts to the Applied Arts." Mr. Walter Crane will preside. 8 p.m.

WEDNESDAY, JANUARY 29.
 Society of Arts.—Mr. Gilbert Redgrave on "The Utilisation of Blast-furnace Slag." Prof. W. C. Roberts-Austen, F.R.S., will preside.

THURSDAY, JANUARY 30.
 Royal Academy.—Professor Aitchison, A.R.A., on "The Laurentine Villa of Pliny the Younger." 8 p.m.
 Royal Institution.—Mr. E. Roscoe Mullins on "Sculpture in Relation to the Age." II. 3 p.m.
 Institution of Civil Engineers.—Students' visits to (1) the Deptford Station of the London Electric Supply Corporation. 11 a.m. (2) The New Chiml-rooms at the Foreign Cattle Market, Deptford. 2 p.m.

FRIDAY, JANUARY 31.
 Architectural Association.—Mr. E. W. Mountford, on "Free Libraries." 7.30 p.m.

SATURDAY, FEBRUARY 1.
 Association of Public Sanitary Inspectors.—Sixth Annual Dinner.

Miscellaneous.

Lectures under the Auspices of the Worshipful Company of Carpenters.—The following course of free lectures on matters connected with building will be delivered at Carpenters' Hall, London Wall, on the Wednesday evenings named, each lecture to commence at 8 o'clock p.m.:—Feb. 5, Mr. Banister Fletcher, on "Architecture in all Ages," illustrated by large drawings, expressly prepared, and photographs; the Rt. Hon. Sir John Lubbock, Bart., in the chair. Feb. 12, Prof. T. Roger Smith, F.R.I.B.A., on "Drawing—Geometrical and Perspective," Sir J. C. Lawrence, Bart., in the chair. Feb. 19, Prof. W. H. Corfield, M.A., M.D., on "Modern Sanitation"; Mr. H. J. Kennard, in the chair. Feb. 26, Professor Armstrong, Ph.D., F.R.S., on "The Domestic Fireplace"; Mr. Charles Barry, F.S.A., F.R.I.B.A., in the chair. March 5, Prof. A. B. W. Kennedy, F.R.S., on "The Forth Bridge"; Mr. Alfred Preston, in the chair. March 12, Prof. Marshall Ward, M.A., on "The Tree, from the Sapling to the Bench"; Mr. Wyatt Papworth, F.R.I.B.A., Master of the Clothworkers' Company, in the chair. March 19, Prof. W. C. Unwin, F.R.S., on "The Construction of Walls"; Mr. Banister Fletcher, J.P., Master of the Carpenters' Company, in the chair.

The New Law Courts, Rome.—The concrete foundation-plate of the New Law Courts has been completed. The layer of *biton* has a thickness varying from 2'00 to 2'80 m., and has been spread over the whole of the building site at a depth of about 7'50 m. below street-level. It took two parties of men, each 700 strong, working day and night, in three shifts of eight hours' duration, to get the work done in thirteen weeks. The 56,000 cb. metres of material used were mixed by hand, the proportion being three parts broken stone to two parts pozzolano and one part lime-paste.

New Imperial Palace at Frankfort.—A new palace is to be built for the Emperor at Frankfort-on-the-Main, at a cost of 100,000*l.* It will, it is said, be one of the finest palaces around that city, although the town is so rich in these from the Hesse, Nassau, and Grand-Ducal Homburg times. There is to be a banqueting hall capable of seating 120, and twenty-eight minor halls and saloons.

The Growth of Hong-Kong.—The *Times* says that at the opening of the session of the Hong-Kong Legislative Council on November 20, Governor Des-Vaux laid on the table a copy of an elaborate dispatch which he had just addressed to Lord Knutsford on the growth and prosperity of the colony. The document refers at length to everything connected with the recent growth of Hong-Kong. A striking evidence of the increase of wealth will be found in the prices of land. Since 1881 the price of marine lots has risen 50 per cent., and of those inland from 10 to 20 per cent. Land in Victoria in the best sites is worth about 180,000*l.* an acre, and lots have exchanged hands at such prices as 70,000*l.*, 95,000*l.*, 90,000*l.* an acre, and so on. In the Chinese business quarters it is not to be obtained at less than 97,000*l.* to 130,000*l.* per acre, while hill lots have increased in even greater proportion. Government lands which could not have been sold at 5 per cent. per square foot within the present decade have lately been sold at public auction for more than ten times that amount. The sums derived from land premiums, or the sums received from leases, are not included in the ordinary revenue, but are kept separate as matter of account, and are applied to defences and other permanent works. Next to the defences works, the greatest public work of recent years is the Tytam reservoir, which confines 350 million gallons of water behind a dam composed of granite and concrete, at a distance of five miles from the city of Victoria, and the conveyance of the supply by means of a tunnel 2,450 yards in length, and a cut granite aqueduct for the remaining distance. In concluding his long and interesting report, Sir William Des-Vaux says:—"There must be some still living who saw the island before the British occupation. If one of them, having been absent during the whole interval, were now to return, even the extremely salient and beautiful features of the natural landscape would scarcely enable him to identify with the Hong-Kong of to-day what he would remember as a bare rock, with a fisherman's hut here and there as the only sign of habitation, and a great sea-basin only very rarely disturbed by a passing keel. For now he would see a city of closely-built houses stretching for some four miles along the island shore, and rising, tier over tier, up the slopes of the mountain,—those on the upper levels interspersed with abundant foliage, while on the opposite peninsula of Kowloon, which was (until very recently) an uninhabited waste of undulating red rock, he would now see,—in the distance prevalent verdure,—in the foreground and along the whole sea-board numerous houses, together with docks, great warehouses, and other evidence of a large and thriving population. . . . "Going ashore our visitor would see long lines of quays and wharves, large warehouses teeming with merchandise, shops stocked with all the luxuries as well as the needs of two civilisations; in the European quarter a fine town-hall, stately banks, and other large buildings of stone; in the Chinese quarters houses, constructed after a pattern peculiar to China, of almost equally solid materials, but packed so closely together, and thronged so densely, as to be in this respect probably without parallel in the world."

The English Iron Trade.—The English iron market is quieter; but, although lower prices have been accepted during the week, it has lost nothing in its steadiness. Pig-iron has been further depressed in price, owing to the decline in warrants. Scotch warrants have been flat, and there has been some excitement in the market. Scotch makers' iron is still pretty strong, however, notwithstanding the adverse influence of warrants upon prices. Cleveland iron is 1s. 6d. per ton lower with makers, while merchants quote 3s. per ton less. There is less firmness in Lancashire and Midland brands generally; but Staffordshire pigs remain stiff. Bessemer iron in the North-west has lost 6d. a ton on the week, with makers firm at their quotations. Old materials are steady at a rise of 10s. per ton. The business doing in finished iron is moderate, and prices are easier in the North of England, but in Lancashire and Staffordshire they are strong, though common crown bars and sheets being 5s. per ton dearer. Steel continues in good demand, and is steady. Although billets and slabs are 2s. 6d. a ton lower in the North-west, blooms have gone up 2s. 6d. Shipbuilders continue busy, but not many new orders are hooked. The condition of the engineering trades remains the same as reported last week.—*Iron.*

Liverpool Engineering Society.—The seventh meeting of the present session was held on Wednesday, the 15th inst., at the Royal Institution, Colquitt-street, Mr. Henry H. West, M.Inst.C.E., President, in the chair. After the usual routine business had been transacted, a paper entitled "Mechanical Refrigeration and the Manufacture of Ice" was read by Mr. M. C. Bannister. Having pointed out that artificially-produced cold had now become an absolute necessity, not only for the maintenance of our food supplies, but also for the economical prosecution of many chemical processes, the author gave a brief summary of the laws regulating the transmission of heat or cold from one medium to another. He then reviewed the various chemical and mechanical methods which have been used for the artificial production of cold, after which he proceeded to treat thermodynamically the various systems of refrigeration now in use, namely, those known as the cold air, sulphuric ether, sulphurous anhydride, carbonic anhydride, ammonia compression, and ammonia absorption. Each of these systems he dealt with separately, resolving all to a common thermal basis, viz., the heat units in one pound of coal consumed to raise steam to be used in a fairly high-class modern steam-engine. The general results obtained were demonstrated by graphic thermal diagrams, showing the various losses and ultimate useful effect of each system, and tables giving the vapour tensions and latent heat units of various temperatures. The author then briefly sketched the mechanical details of ice-manufacture, explaining his own recent improvements for the more economical manufacture of crystal ice in large blocks. The paper, which throughout was of a very interesting and exhaustive character, was concluded by some sketches of the floral crystalline formation of ice. The discussion upon the paper was adjourned until February 12.—The annual dinner of the Society took place on the 17th inst. at the Adelphi Hotel. The chair was taken by the President, Mr. Henry H. West, M.Inst.C.E., and there were about ninety members of the Society and other gentlemen present. The tables having been cleared, and the patriotic toast honoured, the Mayor (Mr. Thos. Hughes) proposed "The Engineering Profession," and referred to the triumphs of English engineering throughout the world, particularly pointing out as instances the Mersey Tunnel, the bridge across the Dee, and the docks at Liverpool, in regard to which no one could recognise more than he did the science that had been developed in this direction by his friend Mr. George Fosbery Lyster. None could doubt but that it was owing to the skill, perseverance, and energy of English engineers that this country had practically become the carrying power of the world. Sir John Coode, M.I.C.E., K.C.M.G., responded. The President then referred to the humble beginnings of their Society, and stated that some fifteen years ago it was held alternately in the homes of the members, but in course of time it had grown to be one of the most important auxiliaries of the parent Society. A move, he might mention, was being made to bring the whole into one common fold. He thought this was a step in the right direction. While not destroying the individuality of each Society, they would, by coming into communication with each other, tend to promote a higher standard of skill. Sir Charles Darbishire then proposed the toast of "Kindred Societies." Mr. T. Mellard Reade, F.G.S., responded, and expressed the opinion, as regards the two professions, that whilst emulation might be encouraged, there was no fear of competition.

The Corinth Canal.—The work on the Corinth Canal is again being actively prosecuted. Of the 12,000,000 cubic metres of earth to be removed, two-thirds have already been excavated. It may be remembered that the Canal Company was in financial difficulties a little while ago, but these are now said to have been overcome. The Governments of Greece, Italy, and Austria having promised an interest guarantee of 10,000,000 francs. It is however expected that the canal cannot be finished in less than three years. It may be mentioned that this undertaking was in reality begun in the reign of Emperor Nero, over 1,700 years ago, but has been abandoned from time to time.

Oundle Sewerage.—Mr. W. H. Radford C.E., Nottingham, has been instructed to prepare plans for intercepting sewers and sewage precipitation-tanks at Oundle.

British Archaeological Association.—At the meeting of this Association on Wednesday, the 15th inst., Mr. C. H. Compton in the chair, a communication was read from the owner of Eggeston Abbey, near Barnard Castle, denying that any of the ancient ruins had been purposely removed. A portion had been blown down, but the remainder would be carefully preserved. Mr. Loftus Brock, F.S.A., exhibited an old German book of sermons printed in 1516,—a fine specimen of monastic binding, in stamped leather, with brass bosses, of contemporary date. Mr. A. G. Langdon exhibited designs of a series of bench-ends which have been destroyed with the church of Levenhock, Cornwall, recently burnt. Mr. Earle Way exhibited a series of examples of fictile ware found on the site of the old Marshalsea prison, Southwark. These remains are of Roman date, one being a curious imitation of a thin Samian ware bowl, in black Upchurch pottery. The chairman announced his recent correspondence with the Historical Manuscripts Commission relative to the records of Creakle Abbey, preserved at Cambridge. A paper was then read by the Rev. Denny Gedge, on the brass of Sir Adam de Clifton, who died 1367, formerly existing in the Church of Methwold. It was sold by the sexton in 1680, to a travelling tinker, who broke it to pieces and melted a portion. The remainder was recovered and preserved in the parish church in a fragmentary condition, but in more recent years they again left the church. The pieces have now been put together and the brass fixed to the wall of the church. The brass is one of very considerable beauty, and the face appears to be a portrait. The second paper was on the Ancient Charters and the Boundaries of Crowland Abbey, by Mr. A. S. Canham. These documents are remarkable for being so full of inaccuracies, and it is well known that doubt has been thrown upon their value. The author contended that these were occasioned by the error of transcription either from memory or from poor copies, after the burning of the originals in Norman times. The matter was correct, although names and dates were often misleading. The boundaries were then discussed and all the names recorded in the old documents identified by the modern designations and the six boundary crosses which still remain. A seventh was ploughed up in 1848.

Installation of Mechanical Engineers.—The annual general meeting of this Institution will be held on Wednesday, Thursday, and Friday, Jan. 29, 30, and 31 respectively, in the hall of the Institution of Civil Engineers, Great George-street, Westminster. The following papers will be read, viz., "On the Compounding of Locomotives burning Petroleum Refuse in Russia," by Mr. Thomas Druhart, Locomotive Superintendent, Graz and Teasritz Railway, South-East Russia; "On the Burning of Colonial Coal in the Locomotives of the Cape Government Railways," by Mr. Michael Stephens, Chief Locomotive Superintendent; "On the Mechanical Appliances employed in the Manufacture and Storage of Oxygen," by Mr. Kenneth S. Murray, of London. Communicated through Mr. Henry Chapman.

The Royal Arcade, Melbourne, Australia.—A short time ago Mr. Howard Spensley invited competitive designs for enlarging the Royal Arcade, Bonrke-street, by adding an annex to run from Elizabeth-street and join the present arcade about the centre. A number of designs were submitted from the Colonies, and also from London, and after careful consideration the choice fell upon the design bearing the motto "Arcadia," which was awarded first premium, and was prepared by Mr. J. W. Lockwood, architect, Melbourne. The second premium fell to the lot of "Orient," Mr. John E. Still, architect, of London. It is intended to proceed with the erection of the building immediately. — *Melbourne Argus*, Dec. 6, 1889.

The New Government Buildings at Christiana.—In consequence of the unsatisfactory nature of the designs sent in for the new Government buildings at Christiana, the committee of adjudicators will, most likely, it is said, invite another competition. The two architects gaining the first and second premiums were Messrs. Lenschow and First, the former's grouping of the details of the facade being commended, whilst the design of the latter is considered suitable for acceptance in the main; but neither of them satisfies the requirements set forth in the programme in its entirety.

Pavements and Horses.—It would be a step in advance if, failing the best of all pavements,—yet to be invented,—London, and for that matter other towns and cities as well, could be paved in some uniform pattern. In that case horse-owners could, at least, try to cope with whatever slipperiness might be inseparable from the use of some particular material, by adopting a modified shoe, or by using some sort of appliance adapted to counteract the tendency to slip. We have no desire, in connexion with this subject, to re-open the horseshoe question. It is sufficient to say that, notwithstanding all arguments and inventions, the great majority of our working horses are shod in the ordinary manner,—a manner which, whatever advantages may be claimed for it, is but ill suited for use upon wood or asphalt. Still, were London to be paved throughout its length and breadth upon some uniform plan, there need be little doubt that some kind of modification of the present style of shoe would be indispensable; but an present it is probably an impossibility to find a system which shall succeed equally well with all horses on all roads. It need to be an old coachman's maxim that accidents usually occurred at starting or pulling up; and the saying holds good now, not only in its original sense, but also in the matter of passing from one kind of pavement to another; for every practical coachman knows that, putting aside gradients, sharp stops, or exceptionally slippery portions of roadway, his horses nearly always either fall, or threaten to do so, when they come suddenly on to one substance after travelling on another. It is, however, worthy of note that some of the teams working in and out of London wear indiarubber pads, and the coachmen, amateur and professional, are unanimous in declaring that they prevent slipping, and enable the horses to travel at the requisite speed without any great amount of inconvenience.—*The Field*.

Plumbing Examinations at Bristol.—An examination of candidates for certificates of registration, under the auspices of the local district council, took place on Saturday last, at the Merchant Venturers' School, Bristol. The Worshipful Company of Plumbers were represented by Mr. W. C. Timms, master plumber, and Mr. L. F. Gilbert, representative of the Operative Plumbers' Society of Great Britain, and the local examiners were Dr. D. S. Davies, Medical Officer of Health; Mr. T. S. Pope, architect; Mr. George Bracher, master plumber; Messrs. W. H. Hobbs and T. J. Edmonds, representing the local operatives' society, and Mr. Walter H. Perry, assistant honorary secretary. Candidates attended from Bristol, Bath, Crewkerne, Gloucester, and other places, and were examined in the theory and practice of plumbing, the theoretical questions being such (according to the *Western Daily Press*) as to test their knowledge of sanitary matters, besides other branches of the craft. The work done in both sections was of such a character that only 20 per cent. passed.

Cologne Cathedral.—The Society of Private Architects has published a circular-letter containing certain proposals for the opening-up of better views of the Cologne Cathedral, especially from the south-west corner. This new scheme has, however, come rather late, as alterations in the neighbourhood of the Dom are at present being carried out in accordance with the plans set up some time ago by Mr. Stnebbens. Both ideas might, however, yet be combined, and a very great improvement he then made, which would, however, require some 20,000, more than has been granted as yet for the project.

The Archer Patent Water-tight Drain-pipe.—We hear that the drains at the Royal Barracks, Windsor, are being taken up and relaid with the Archer patent water-tight pipes, as it was found that many of the ordinary pipes had become broken through settlement of the ground. The Walthamstow Local Board have just adopted the Archer stoneware pipes for a main sewer through the marshy, water-logged ground near the river Lea. The Archer joint has been fully described and illustrated in the *Builder*.

The North Sea-Cattegat Canal.—A Bill empowering the construction of a canal between the North Sea and the Cattegat, *via* the Simfjord, in Jutland,—a scheme to which we referred last year,—has been introduced into the Danish Parliament. The *concessionnaires* demand a State interest guarantee of 3 per cent. for fifteen years, the guarantee to commence a year after the completion of the canal.

Norwegian Wooden Villas.—Apropos of the Norwegian and Swedish wooden villas, of which specimens have been seen at various continental exhibitions in recent years, and which are finding much favour in other countries, a discussion has been started between certain Norwegian architects in their organ, the *Teknisk Ugeblad*, as to the merits of the architectural style adopted in the same. On one side it is argued that the style is not pure Norwegian at all, but a modern concoction, the true Norwegian style being that of the so-called Stabur, the peculiar style of architecture seen in some very old churches, and the building termed Staburs on old farms. It reminds one somewhat of the Chinese pagoda. On the other side it is argued that the "villa" style is preferred to the Stabur style abroad. The two styles might have been contrasted at the last Paris Exhibition, where the villa (now standing at the foot of the Eiffel Tower) obtained two gold medals, but it should be pointed out that the Stabur was unfortunately not raised till after the jury's award. The latter is now shown in the Museum Van Kunstinvertreed at Harlem. This style has been adopted, with certain necessary modifications, for nearly all rural railway stations in Norway. Finally, Herr Karl Norma, a well-known architect, whose speciality in the Stabur or Old Norse style of architecture, maintains that this style cannot be called Norse at all, but is a conglomeration of Roman, Gothic, and Renaissance, the treatment of which generally indicates a primitive and low intellectual standpoint of the builder. He considers, however, that the style is highly suitable as groundwork for picturesque villas.

COMPETITION, CONTRACTS, & PUBLIC APPOINTMENTS. Epitome of Advertisements in this Number.

COMPETITION.

Table with 5 columns: Nature of Work, By whom Required, Premium, Designs to be delivered, Page. Includes Market House and Public Offices.

CONTRACTS.

Table with 5 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page. Includes alterations, etc., to Offices, Board Room, etc.

PUBLIC APPOINTMENTS.

Table with 5 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page. Includes Surveyor, Road Surveyors, etc.

TENDERS.

[Communications for insertion under this heading must reach us not later than 12 noon on Thursdays.]

Table of tenders for BRISTOL, including Eastbrook & Sons, Church, Wm., Bathery, E. T., etc.

Table of tenders for BRISTOL, including Stephens & Bastow, Eastbrook & Sons, W. Church, etc.

Table of tenders for BRISTOL, including William Lindsay & Co., Westminister (accepted).

Table of tenders for BROMLEY (Kent), including Vaughan & Brown, Warner & Sons, etc.

Table of tenders for CANTERBURY, including low-pressure system the Sidney Cooper School of Art Gallery, etc.

Table of tenders for CHESTER, including alterations and additions to premises at the corner of Foregate-street and Soller-street, etc.

Table of tenders for CHISWICK, including for making up roads, etc., at Chiswick for the Chiswick Local Board.

Table of tenders for BARROWGATE-ROAD, including Scrif, Hoole, & Co., Adams, etc.

COLCHESTER.—For the erection of stables, and alterations, at William's Walk, for Mr. G. W. Mallinson. Mr. J. W. Starr, architect, Gups Chambers, Colchester:—

Table of tenders for COLCHESTER, including T. J. Ward, A. Doss, F. Dupont, etc.

HOLMWOOD (Surrey).—For repairs to 'Redland's Bank,' Holmwood, for Mrs. Ann Gammon. Messrs. H. M. & W. Grellier, architects:—

Table of tenders for HOLMWOOD, including Colls & Sons, W. J. Chivington, William Edger, etc.

ILLOGAN (Cornwall).—For the erection and completion of new school buildings at Illogan, near Redruth, together with enclosures, and providing for complete water supply. Mr. Sampson Hill, Redruth, architect:—

Table of tenders for ILLOGAN, including J. Odgers, Redruth, J. Julian, Truro, etc.

LONDON.—For rebuilding the Divisional Police-station, Leman-street, Whitechapel, for the Receiver for the Metropolitan Police District. Mr. John Butler, F.R.I.B.A., architect. Quantities by Mr. W. H. Thurgood:—

Table of tenders for LONDON, including W. Scrivener & Co., Kirk & Randall, Birge & Hill, etc.

LONDON.—For alterations and additions to the 'Duke of York,' Victoria-street, Westminster, for Mr. S. Stopp. Messrs. Saville & Martin, architects, 36 and 37, Strand, W.C.:—

Table of tenders for LONDON, including Putnam & Fotheringham, Ward & Lambie, Ansell, etc.

LONDON.—For the erection of three shops and dwelling-houses, Roslyn-hill, Hampstead, for Mr. James Grimbridge. Mr. Albert E. Fridmore, architect, 2, Broad Street-buildings, E.C. Quantities by Mr. Alfred Griggs:—

Table of tenders for LONDON, including G. Lyford, Poley & Son, Garnar, A. & W., Taylor & Son, etc.

LONDON.—For alterations at 5, Carter-lane, E.C., for Miss Heald. Messrs. Hudson and Booth, architects:—

Table of tenders for LONDON, including Hall, Biddall, & Co., Spencer & Co., J. Greenwood.

LONDON.—For paving, kerbing, &c., for the Camberwell Vestry. Mr. J. C. Reynolds, Surveyor:—

Table of tenders for LONDON, including Mrs. Gatty, Camberwell, Jas. Stowell, Camberwell, etc.

LONDON.—For alterations and sundry works to premises, Heath-street, Hampstead, for Mr. I. T. Richardson. Mr. Albert E. Fridmore, architect, 2, Broad-street-buildings, E.C.:—

Table of tenders for LONDON, including H. & W. Grey, Taylor & Son, W. Birch, E. E. Annan.

LONDON.—For the erection of a shop and dwelling house, Rosslyn-hill, Hampstead, for Miss Emma Day, Mr. Albert E. Pridmore, architect, 3, Broad-street Buildings, E.C. Quantities by Mr. Alfred Griggs:—
 Lyford, G. £2,142 0 0
 Taylor & Son 1,377 0 0
 Gurnar, A. & W. 1,309 0 0
 Tombs, E. 1,339 0 0
 McCormick & Sons 1,293 0 0
 Grover & Son 1,261 0 0
 Kilby & Gayford 1,234 0 0
 *H. King & Co., Hampstead. 1,146 0 0
 Potter & Son 1,140 0 0
 *Accepted. (No shop-front in this contract.)

LONDON.—For alterations at No. 2, Little Howland-street, W., for the West-end Glass and China Burning Company. Mr. John James Downes, architect, 11, The Parade, Lewisham High-road, S.E.:—
 Catechpo £204 0 0
 John Grover & Son 174 10 0
 Sydney Best (accepted) 163 0 0

LONDON.—For alterations and additions to the "King's Arms" Tavern, Fulham-road, for Mr. W. Hancock, Mr. H. J. Newton, architect, No. 5, St. Margaret's Chambers, 49, Victoria-street, Westminster.
 Kellaway £2,440 0 0
 Lambie 2,240 0 0
 Godden 2,273 0 0
 Burman 2,230 0 0
 J. Beale 2,030 0 0

LONDON.—For alterations and additions to the Morning Advertiser office, 127, Fleet-street, for the Incorporated Society of Licensed Victuallers, Messrs. Treacher & Fisher, architects, 30, Coleman-street, E.C.:—
 Walker £212 0 0
 Burman 439 0 0
 Few 440 0 0
 Spencer & Co. 440 0 0
 J. Beale 391 0 0

LONDON.—For alterations and general repairs to the "Malmore Arms," Peckham Park-road, for Mr. P. O'Callaghan.
 J. Beale £293 0 0
 [No competition.]

SCAWBY (Lincolnshire).—For building mansion, Seaby Grove (exclusive of stabling and lodge), for Mr. Joseph Cliff, J.P. Mr. E. W. Farebrother, architect, Grimsby:—
 Holmes & Co., Wainfleet £3,275 0 0
 Enoch Hind, Nottingham 8,247 0 0
 C. Baines, Newark 8,100 0 0
 H. S. and W. Close, Lincoln 7,783 0 0
 J. Guy & Co., Grimsby (accepted). 7,690 0 0

WOOLWICH.—For alterations and additions to the "King's Arms," Woolwich Common, for Mr. T. W. Earle. Mr. R. A. Lewcock, architect, 83, Bishopsgate Within:—
 Todd £1,034 0 0
 Allen & Son 986 0 0
 Spencer & Co. 990 0 0
 J. Beale 845 0 0

SUBSCRIBERS IN LONDON and the SUBURBS, by prepaying at the Publishing Office, 12s. per annum (or 4s. 9d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

TO CORRESPONDENTS.

(we do not charge for the insertion of tenders, but they must comply with our conditions, one of which is that the amount should be stated). We cannot insert tenders for small lots below 10s. in amount).—J. D. (we do not insert such items at all unless they are of general interest).—Met. & Sons (should have sent account).—W. (too late).—W. A. L. (sent too late for any comment).—W. & F. C. (too late).—W. A. B. (too late). All statements of fact (like notices, &c.) must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline pointing out books and giving addresses. Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications. Letters or communications (beyond mere news-items) which have been applied for other journals, are NOT DESIRED. All communications respecting literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

TERMS OF SUBSCRIPTION.
 "THE BUILDER" is supplied twice from the Office to residents in every part of the United Kingdom at the rate of 12s. per annum (Postage to all parts of Europe, America, Australia, and New Zealand, 3s. per annum. To India, China, Ceylon, &c. 5s. per annum. Remittances payable to DOUGLAS FOUBRENIER, Publisher, 54, Catherine-street, W.O.

PUBLISHER'S NOTICES.

Registered Telegraphic Address, "THE BUILDER, LONDON."
 THE INDEX and TITLE-PAGE for Volume LVII, (July to Dec. 1889) were given as a Supplement with the Personal application at the Office.
 A COLOURED TITLE-PAGE may be had, gratis, on personal application at the Office.
 CLOTH CASES for Binding the Numbers are now ready, price 2s. 6d. each; also
 READING CASES (Gilt), with Straps, price 9d. each.
 THE FIFTY-SEVENTH VOLUME of "The Builder" (bound), price 7s. 6d. (about fifty words) or under. 4s. 6d.
 Each additional line (about ten words) 0s. 6d.
 Terms for Series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction &c. may be obtained on application to the Publisher.
 SUBSCRIBERS' VOLUMES, on being sent to the Office, will be bound at a cost of 3s. 6d. each.

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APPLICANTS, TRADE, AND GENERAL ADVERTISEMENTS.
 Six lines (about fifty words) or under. 4s. 6d.
 Each additional line (about ten words) 0s. 6d.
 Terms for Series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction &c. may be obtained on application to the Publisher.

SITUATIONS WANTED.

FOUR Lines (about thirty words) or under. 2s. 6d.
 Each additional line (about ten words) 0s. 6d.
 PREPAYMENT IS ABSOLUTELY NECESSARY.

* * * * * Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.O. to DOUGLAS FOUBRENIER, Publisher.
 Addressed to No. 46, Catherine-street, W.O.

Advertisements for the current week's issue must reach the Office before FIVE O'CLOCK P.M. on WEDNESDAY, but those intended for the front page should be in by the same hour on WEDNESDAY.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS.

NOTICES or ORDERS TO DISCONTINUE same must reach the Office before TEN O'CLOCK on WEDNESDAY morning.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to advertisements, and strongly recommends that of the latter COPIES ON "IT" should be sent.

PERSONS advertising in "The Builder" may have Copies addressed to the Office, 54, Catherine-street, Covent-garden, W.O. free of charge. Letters will be forwarded if addressed in envelopes are sent, together with sufficient stamps to cover the postage.

AN EDITION PRINTED ON THIN PAPER, for FOREIGN and COLONIAL CIRCULATION, is issued every week.

Now ready, **READINO CASES,** (By post carefully packed), 1s.

Aid-Book to Engineering Enterprise.

THE comprehensive work published under this title* forms a modern encyclopedia of civil engineering, judging from the wide range of subjects enumerated in the table of contents.

In the chapters which follow, the author gives great prominence to the financial aspect of engineering. The book is remarkable for the practical hints it contains, while avoiding all mathematical investigation of the dimensions and strengths of structures,—a striking contrast to most other aid books, which usually supply various rules, tables, &c. The present volume is divided into two parts, which, with forty-four pages of a copious index, arranged in double columns, forms a book of 865 pages. These parts, prior to revision, were sold in separate volumes. Upon the publication of the first edition of Part I, we said that "its study might save much time and much money," and when the first edition of Part II appeared, we characterised it "as common sense made available to the enquirer in a systematic form." We also prophesied in our notice of the first edition that a new edition could only be a question of time, and so it has proved.

The first part is intended to serve as a guide to projectors of engineering undertakings in our colonies and abroad, the experience gained in this country being stated as an aid to colonial and foreign practice. The amount of capital expended upon railways already equals, or exceeds, that invested in all other modern works of construction put together; yet, even in this country, many loop and junction lines are continually being projected. The construction of telegraphs is also dealt with, for which the author truly states it is always economy to employ the best materials for any except temporary lines. Referring to submarine work, the first submerged cable in salt water was successfully laid from Dover to Calais in 1851. The line between Spezzia and Corsica, laid in 1854, was found in 1876 to be in good working order, thus proving that a cable, properly made and laid, has a life long enough to amply

repay prime cost. Other chapters in this useful book describe the formation of harbours, the building of breakwaters, piers, and jetties as subsidiary to the greater work of harbours; the design, exigencies of site, erection and classification of various iron bridges, a subject upon which the author is fully qualified to advise. He particularly emphasizes the importance of securing complete information as to foundations and conditions of site when a bridge is ordered to be designed and constructed for export. "Ten pounds (he remarks) have, perhaps, been saved by omitting to examine the river-bed, and five hundred pounds wasted in unnecessary screw piles." The comparison he furnishes of eighteen examples of bridges, of similar span, but each fulfilling very different requirements, is very valuable, and he includes an allusion to the ingenious design he proposed for a bridge over the River Thames at the Tower, consisting of a single span, in which the upper member formed a continuous arch, and the lower member supporting the platform could be divided in the centre for the convenience of ships passing up and down the river. Irrigation schemes and reclamations of land are justly classed by the author as among the most important of public works; while the supply of water stands first among municipal works. He ably deals with various systems and sources of water supply, and argues that the increase in the number of waterworks passing into the control of municipal hands is advantageous, as a stoppage in the supply of water to a district would be disastrous; but he does not recommend the management of manufacturing enterprises by public bodies. In treating of town drainage, he asserts "it is the misuse of the water systems which alone renders them open to condemnation." Sewage irrigation, as well as its treatment with chemicals, are alluded to, but no mention is made of the International Water and Sewage Purification system, which first met with favour at Acton. Gas and electric lighting are contrasted, both as regards cost and results attained. In large cities illuminating gas can be sold, with profit, at prices much below what is possible in small towns. The cost of the gas itself, the author states, depends principally upon the cost of the fuel and the sale of by-products; but "as the cheapest kind of gas for use as fuel in steel-making and other metallurgical operations is made by private persons at as low as from 1d. to 4d. per 1,000 feet, though such gas is cheap because a high degree of purity and illuminating power is not required, the

experience so gained (in the author's opinion) points the way to further economy in gas for lighting." With regard to the adoption of electrical energy, upon "the extent and kind of lighting and the distances apart will depend whether the whole will be best served from one central station or whether the area should be divided into several circuits or districts."

To Part I, a chapter on mining enterprise in coal, copper, gold, iron, lead, silver, and tin, has been added to the second edition. The chapter, also, which compares English and foreign legislation gives valuable hints upon guarantees for foreign concessions. The facilities for acquiring land for the site of engineering projects in foreign countries have greatly encouraged English enterprise abroad. It is shown that the gauge of a new railway, whether for light or heavy traffic, should from the commencement accord with that of the neighbouring railway, as the new rolling-stock may have to travel over the old lines, and the saving in land by the use of narrow gauges is inconsiderable. In American cities where the streets are generally badly paved, and unfenced railroads cross public streets, iron tramways were adopted at an earlier date than elsewhere. The working of horse and steam-tramways in town and country is fully described in this book.

The volume also contains chapters upon the important subjects of contract and purchase in the engineering trades; the establishment of factories; the purchase of steam, portable, and gas engines; air, water, oil, and electric motors; railway equipment; locomotives; rolling stock; pumping and fire engines; tanks; pipes; tubes; machine tools; smithy tools and steam hammers; derrick, jib, and travelling cranes; steam cranes; excavating machines; boring tools; rock-drills; dredgers; pile-drivers; diving apparatus; Portland cement: its manufacture, uses, and advantages. Among market buildings, the author includes the covered market building at Carlisle, opened so recently as October, 1889, and expresses the opinion that, "as fit projects for official management, markets should take precedence of such undertakings as water or gas supply, which may with more propriety be left to private enterprise." He deals in a masterly manner with the subject of iron buildings, roofs, and lighthouses. The notes upon the manufacture and modern uses of steel for ships, girders, stanchions, and boilers have been re-written and extended in the second edition. In his remarks upon iron and steel manufacture, Farnley and Lowmoor iron are mentioned four times in the volume

* Aid Book to Engineering Enterprise, by Ewing Matheson, M. Inst. C. E. Second edition. London: E. & F. N. Spon, 1889.

† See *The Builder*, April 27, 1878.

‡ See *The Builder*, July 2, 1881.

as the highest quality of malleable iron. The author's present intimate acquaintance with the Farnley Iron Works entitles us to draw attention to this recommendation. Indeed, throughout the book, those paragraphs which relate to iron and steel deserve the highest encomiums and the gratitude of the profession. He explains the Bessemer, the basic, and other processes of steel manufacture, but does not recommend the use of a complete steel roof as economical for spans of less than 100 feet. The author remarks that special tools and processes in manufacture are continually being introduced; but that almost invariably the manufacturer, who by these means does his work best, also executes it at the cheapest rate. The apparatus for electric welding is likely to take the place of the ordinary process, where the pieces are of moderate size, and where the repetition is sufficient to repay the cost of special plant. The accessories consist of an electric "transformer," worked by a steam engine or other motor, for producing by induction a current of the necessary strength to heat the iron or steel. The heating is rapid and clean, and the parts to be welded are pressed together when white hot. Its application to the welding of dissimilar metals is remarkable. Reference is also made to other modern applications of electricity. The transmission of power has not, the author states, received so much attention as the application of power. Steam, it is asserted, can, under special conditions, be conducted 2,000 ft. with a loss of only 5 lb. pressure. If the power required, as in a crane or hoist, is for direct action, then hydraulic transmission is probably the best. There is practically no limit to the distance through which power can be transmitted by water, but for rotary motion the author recommends compressed-air or wire rope when electricity cannot be applied. The latter he considers the best alternative for any system. Transmission of gross power by belts he states to be more general in America than in this country, where toothed wheels are usually employed as gear. Even for such a purpose as imparting motion to har-iron rolling mills, belting has, he informs us, been applied with success.

The headings in the margin to each page assist in rendering the remarkable compilation of facts contained in this volume easy to be referred to; and at the end of each of the thirty chapters the reader is referred to other chapters in the book which bear upon the subject of an individual chapter. This method is excellent, because it aids in rendering each special chapter complete, without repeating matter in the volume.

THE MAINTENANCE OF COUNTY ROADS.

BY MAJOR-GENERAL LUARD, R.E.

THE condition of the roads in the counties surrounding the Metropolis is a matter of no small moment to the inhabitants of the great City. Though they have nothing to do with paying for them, their furniture-movers, travellers, tourists, cyclists, and many others make free use of them, and criticise them freely too, in case they are not satisfied. This criticism is not without its beneficial effect, and certainly does no harm, even if it produces pain in the minds of Highway Authorities.

After a deliberation of a year, and sending the County Surveyor on a tour of personal investigation, the Committee for Roads and Bridges in Kent laid before the Council of that county, at the quarterly meeting at Maidstone on the 15th ult., the scheme which they had evolved for the future management of the main roads of the county. As this scheme differs very much (so far as I am aware) from that which has been recommended for any other county in England, and as it has been adopted by the Council, it is a matter of general interest to examine it a

little, weigh its merits, and attempt to forecast its probable success or failure.

Kent is to be tried for a year in two ways: one, which practically embraces the geographical district of East Kent, is that of contract with Highway Authorities, and the other, for the remainder of Kent, is that of contract with private firms. The first is one with which we are all familiar, having been suggested in clause 11 (4) of the Local Government Act of 1888, and very generally acted on throughout the country as a trial scheme for the first year of the existence of County Councils. How it has worked no one quite knows yet, but no sign of improvement in the main roads of Kent is yet visible. However, the Kent Roads and Bridges Committee say that they intend in future to tie down the Highway Boards of East Kent with specifications, schedules of quantities of materials, and the superintendence of assistants to the County Surveyor, and we may presume, therefore, that the local Highway Surveyors will still be in charge of the execution of the work for their respective Boards, but under constant supervision by the County Surveyors, two assistants having been allotted to East Kent for about 250 miles of main road, with a proposed salary of £300 each (including all expenses). Now as regards such contracts, there is, in the first place, no competition, and the Highway Boards are not at all likely to accept contracts which are not quite certain to leave a satisfactory margin for themselves, and a consequent loss to the other party to the contract,—the county. In the second place, if the terms offered are not financially agreeable to the Highway Boards, no alternative scheme has been approved by the Council for carrying out the work. The County Surveyor of Kent had with much pains drawn up a scheme, which was practically and admittedly in accordance with the suggestions of Mr. Codrington of the Local Government Board, in the pamphlet he has recently issued, placing the whole of the execution of, and payment for, the work on main roads in the hands of the County Surveyors; and, although there are some manifest objections to such a scheme, there is much to be said in favour of it. But the Kent Roads Committee have, anyhow, seen fit, and perhaps wisely, to reject the adoption of their Surveyor's proposals, and have preferred to try contracts. But when the contractors have been made with the Highway Boards, they will naturally save as much as they can on those contracts for the benefit of the remainder of the roads in their districts and for the pockets of their ratepayers. How will this benefit the condition of the main roads?

But we are told this is to be tried for one year only. Turning now to the other part of the scheme, it appears that the main roads of West Kent are to be let by tender to private firms,—let by dribblets of a few miles here and a few miles there, with again the specifications and schedules of quantities of materials, and superintendence of Assistant County Surveyors. In this case the Highway Surveyors of the Boards will be snuffed out *in toto*, for the contractors will, of course, decline to submit to be supervised by two sets of Surveyors, whose ideas of road management might not correspond.

Will the condition of the main roads be thus benefited? The contractors must make their profit, specifications and so on notwithstanding; and they can have no security, however well they may perform their contracts, that the system will be continued. There can be no guarantee, however small a profit they may content themselves with, that they will be able to obtain further contracts. The system, if continued, must be one embracing a large area, and not confined, after the lapse of a year, to those portions in which the contracts have been well done, reverting to a different system for those portions of main road which have been unsatisfactorily maintained. Will not the contractors generally observe the adage that the "one bird in the hand is worth two in the bush"? And what about the local Highway Surveyors? It

has been somewhat the fashion to abuse this class, overlooking the very difficult position in which they have been placed; and now, without the chance of their assenting or dissenting, a very important share of the work of the Highway Boards in West Kent is to be wrested from them, whether their Surveyors have proved themselves intelligent or the reverse.

Whoever may have been the authors of these remarkable proposals, we cannot look forward with any confidence either to one part or the other of this contract system holding out a promise of any measure of success. It smacks of the cry of "save, save, save!" so often sounded at meetings of certain local bodies, whether the "save" is a real economy or not; and we might reasonably have expected a somewhat broader and more comprehensive scheme to have emanated from the collective wisdom of the Roads Committee of so large and important a county as Kent. The present writer did make a distinct protest at the recent County Council meeting at Maidstone against these proposals in the form of the following resolution:—

"That the Highway Boards of Kent be invited to form a Roads Union under the auspices of the County Council."

That the principles on which such Union be founded be as follows:—

- Finance to be under the chief control of the County Council, assisted by the Highway Boards.
- Work to be under a professional staff, entitled the "Kent Roads Staff," consisting of road-gangers, highway surveyors, inspectors, and chief inspector, under the Roads Committee.
- Waywardens to assist in local supervision.
- The whole to work together for mutual assistance and the public benefit."

I prefaced these motions with a further one, to the effect that the report of the Roads Committee be not adopted; but as the agenda of business to be despatched was a very long one, and as these propositions were brought forward at the last moment without its having been practicable to discuss them previously with others, they were (I think very naturally) discarded in favour of the plans recommended by the Roads and Bridges Committee. But I brought forward these motions with the conviction that the suggestions of the Roads Committee were not good ones, and also that it was not fitting to find fault with other people's plans unless you can suggest something better. Prevention is also better than cure, and it is better to try and upset bad plans before they are acted on than to have to substitute better ones subsequently. This want of prevision is the cause of endless trouble and a great waste of money.

If we come to look thoroughly into the subject of what are called main roads, we shall see that their position relatively to that of the other roads in a county has been very much changed. The State does not endow the main roads with portions of the State revenues for similar reasons to those which obtain on the Continent, viz., military transport, but to relieve local rural taxation. If this has been the case ever since the system has been in force of contributing to the maintenance of main roads, it has been still further accentuated by the Local Government Act of 1888, the principle being that the towns should help the country in this large item of expense. But the time must arrive when it can be shown that justice has been done, that the contributions from town and country respectively towards the whole cost of maintenance of all the roads in the county has been equitably adjusted, and it is evident that when that time arrives and that agreement has been arrived at, the necessity for the legislative distinction between main roads and ordinary roads will no longer exist,—a distinction which gives rise to much friction between the county and the local authorities, and is a distinction which no one has yet been able to distinctly define.

It would be a decided convenience to every one if this legislative distinction could be abolished, leaving it to the counties to ex-

pend appropriate sums on their roads in accordance with their relative use. This was pointedly recognised by the Committee of the House of Lords on the working of the Highway Acts in 1881, who, in their report, see page xxi., considered that this distinction might be abolished if the proceeds of some local tax could be contributed by the county in aid of highway rates.

It is quite possible that with a slight addition to the taxes allotted for local purposes, it would be found that this is now the case; but it is a matter of calculation, and it is only by treating it generally,—i.e., by taking the whole area of the rural portions of the county, and not its districts separately,—that we can arrive at any conclusion on the point of equitability. If in each district we had a similar proportional mileage of main road, it might be taken on such a basis; but that is not the case. The proportion of mileage varies very much; and even if it did not, the cost per mile must necessarily vary very much from a great variety of causes,—soil, skill, railways, harbours, &c., &c. If it can be arrived at, and I think it can, it would seem best from every point of view that the amount of the rate in the £ paid by every person in the rural districts of the counties for the maintenance of the roads in their respective counties should be equalised. This is perfectly practicable if a general confidence can be established, that the same beneficial and really economical principles of road management shall be extended throughout the length and breadth of each county, and that the question of whether the roads are kept in proper or improper order shall no longer be entirely dependent on the accidental circumstance of one road-surveyor being more capable or honest than another, or one set of highway guardians being more capable of taking broader views than other sets. The economical maintenance of the ordinary roads is just as important a matter relatively as the economical management of the main roads, and now that the latter are to be entirely paid, of still greater local importance. The principles of management which apply in one case apply equally in the other; but, according to the plans of the Roads Committee for Kent, the ordinary roads of West Kent are to be left to the management of the discarded highway surveyors and the perforated Highway Boards.

In Kent we have been fortunate enough, or sufficiently clear-sighted, to have (with a few trifling exceptions) adopted the plan throughout the county of grouping the parishes into districts for highway purposes under the Act of 1862. The advantage of having done so is very generally admitted; and it seems probable that the time has now arrived for an extension of the system of grouping,—viz., by uniting the highway districts, even as the parishes have been united. If so, it is manifest that each Board should be directly represented on the County Roads Committee, or Board, which, in such a case, would be composed partly of County Councillors and partly of *ex-officio* delegates, in some cases the chosen representative of the Board being the Councillor for the district. All Councillors should also be *ex-officio* members of the Highway Boards in their respective districts. By this means the interest would be generalised, and as a rate, though a smaller rate than that now usually levied, would still have to be charged, the Boards would still have a direct interest in keeping a good watch over all their roads, but not merely in the future for their own immediate good, but for the benefit of the county at large, a lesson in unselfishness and mutual regard which would bear good fruit throughout the county. A further safeguard and increased local interest would be obtained by polishing up the office of Waywarden, an office the duties of which have, perhaps, scarcely been attended to with as much zeal or intelligence as could be desired, but which might be made far more useful if the waywardens were better instructed in the true principles of road management, and received copies of the various returns and reports relating

to the roads of their respective parishes, districts, and the county. If this union of Highway Districts were effected, the working staff of professional men should be a county body, and not a number of disjointed sets of men without connexion or organization of any kind. Starting from the road-ganger, in many cases of an improved description possibly, he should have the chance of obtaining promotion when vacancies occur amongst highway surveyors; the highway surveyor should have a chance of becoming an inspector, and an inspector a chance of becoming chief inspector. In Essex they have appointed an Inspector of Roads and Bridges independent of the County Surveyor, who has plenty of work on his hands without having the roads as well. In Kent the same argument holds good, and probably in all large counties, and possibly in most small counties also, more especially if all the roads were under the Roads Committee of the Council.

The Inspectors should be the best men obtainable,—men who would sooner put their hands in the fire than soil them by receiving commissions or indirect remunerations extra to their salaries,—and their salaries should be clear of all necessary expenses, or large enough to enable them to travel freely and constantly through their districts. In Kent there should be five Inspectors in charge of the highway districts, in North, East, South, West, and Mid Kent respectively, and supervisors of the main road contracts with boroughs and urban districts. Over four thousand miles would be divided between them, the cost of which would be about 130,000*l.* per annum. The Chief Inspector would have his office in the county town, and be the chief professional adviser on all highway matters to the County Council.

In Kent the salaries of such Inspectors should not be less than 300*l.*, and of the Chief Inspector 500*l.*, in each case free of all expenses, and if the ratepayers are considered in the light of shareholders in this business, and the Roads Committee the Directors, such salaries cannot be looked on as extravagant for a general manager and his assistants. The Highway Surveyors' salaries should also, in many cases, be raised as soon as their merit had been recognised, so as to place them more above temptation, and vacancies should be filled by public advertisement. It is ill muzzling the ox that treads out the corn. The road-gangers should be paid a fixed weekly wage whatever the weather, and raised or lowered according to their merit and zeal, and (as previously stated) have some prospect of advancement open to those who show themselves worthy of it. Local clerks and treasurers should also be included.

In Kent, and in many other counties also, one of the most pressing necessities in the way of economising road maintenance is the subsoil drainage of our roads; but it would be almost impracticable to undertake this satisfactorily under the present disjointed system. Many of the roads lie below the level of the fields and woods through which they run, and in stiff soils may be said never to have a dry subsoil. This makes muddy roads, muddy roads cost much in scraping, besides being a nuisance, the limestone (Kentish Rag), which is so plentifully used in Kent, becomes disintegrated far more quickly, and has to be renewed far more frequently than is necessary, and general waste of money is going on everywhere. But the cost of drainage should be spread over a considerable number of years, and the appropriate method and extent of drainage requires to be most carefully gone into in every single instance where it is required; that which is right for one description of soil or gradient or width of road being wrong for another. If not so dealt with, much waste of money would ensue.

It is very much open to question whether the large sums which the Councils are obliged by the Act of 1888 to pay to the Unions for the salaries of Poor Law Officers would not be better appropriated towards meeting the cost of the roads. We do not want to en-

courage unnecessary expense in connexion with the paupers, for whom the cost of establishment seems to be something very remarkable, but we do want to save the payment of rates for a distinct branch of county work which is of increasing benefit to the rateable value of the county. The Council has no authority over the Unions, nor a voice in the salaries of the officials, and yet has to pay those salaries, whatever they may be. In Kent this amounts to 42,000*l.*, which, if allotted to the roads, would reduce the rates by 2*½*d. in the pound, after transferring to Urban Authorities their appropriate share, and leaving the poor rate no higher than before. This would be a point very easily recognised by every ratepayer.

From returns which have been most kindly prepared and forwarded to me from the majority of the Highway Boards and Town Councils in Kent on a form supplied by me, I have been able to obtain very important statistical data relating to the highways of all kinds. I will not enter on them now further than to remark that in the towns and urban districts the rateable value increases 2*½* per cent. per annum, and that in the country districts it decreases 1*½* per cent. per annum, or a total difference between them of 4 per cent. The mileage or amount of main road that should be maintained by the county should, therefore, in fairness have been increased at a similar rate, viz., 4 per cent. per annum, whilst it has hardly been increased at all. But if all the roads were in the hands of the County Council (through the Roads Committee) the increasing value of the towns would bring corresponding increases in the licence and probate dues (and van and wheel tax), and the finances would be self-adjusting.

The position of the Local Government Board would be precisely the same as at present, except that it would receive its returns of local road expenditure through the county, in place of directly from the Highway Boards. If it so desired, it could have periodical inspections made of main roads to see that they were properly kept up, and the expense of such inspections, if any, might be paid out of county funds.

Very little legislation would be necessary beyond the arrangements necessary for the appointment of the various classes of the paid staff, and omission of clauses in Highway Acts relating to main roads.

I have now pointed out most of the reforms which appear to be necessary, and which will have to be effected before we can be satisfied that this matter is being properly treated. Success in any business depends on a combination of three things,—knowledge, skill, and means,—and road business is no exception to this rule. The Scotch have had no difficulty in satisfying themselves for many years past that it is better to manage all their roads by large areas in place of dividing the maintenance of one set from the maintenance of the other, and there is no superhuman difficulty about adopting a similar sensible plan in England, which involves everything which is best. Knowing that roads cannot be economically maintained unless they are scientifically managed, I urge that more science should be brought to bear on this very important item of local expense, and I am not disposed to be deterred from publishing my views because they are not yet, using a very hackneyed expression, "within the present range of practical politics"; but the sooner they are so, the better will it be for every one.

C. E. LUARD.

The Wimbledon Common Estate of the National Rifle Association.—It was generally understood last summer that the meeting then held by this Association was the last that would take place at Wimbledon. This is confirmed by a notification in our advertising columns. The Association is about to remove its depot to Bisley, in connexion with the rifle butts which are now being formed there, and the freehold site of the depot, abutting upon Wimbledon Common, is to be sold by Messrs. Debenham, Tewson, Farmer, & Bridgewater.

NOTES.

THE "Lion of Tegea" has been known to and frequently described by archaeologists, ever since Ross visited Tegea in 1834, but somehow,—it is hard to say why,—it has always, up to the present time, escaped publication. Possibly its interest has been thrown into the shade by the Tegean pediment sculptures, which have the double claim of their certain link with Scopas and their mythological interest. We are glad that M. Gustave Fougères has at last given to the public a reproduction of a photograph taken by him in the local museum of Piali, where the lion bas-relief still lies,—unless, indeed, it has, as is quite possible, been transplanted with the other Tegean sculptures to the Central Museum at Athens,—a point on which we are uncertain. From the crouching pose of the lion, M. Fougères (*Bulletin de Correspondance Hellénique*, pl. vi., p. 477) concludes that another slab existed on which the opponent of the lion was sculptured. He also makes the interesting conjecture that the slabs may have formed part of a frieze decorating the cella wall of the Great Temple of Athene Alea, to which the pedimental sculptures by Scopas are known to have belonged. The bas-relief lion is, indeed, a piece of work not unworthy to decorate such a temple. That a frieze of animals alone was not considered inappropriate is sufficiently shown by the archaic frieze from Assos, now in the Louvre. In the same number of the *Bulletin* are also published some interesting archaic statuettes found at Cyme. They represent Cybele seated in a small shrine (*naiskos*). Their great importance consists in the fact that they are early instances of a type popular in Athens in the fifth century, and that hence they form a link connecting the well-known Oriental Cybele, of Babylon (*Diod. Sic.*, ii., 9-5), with the statue of Cybele, by Pheidias, in the Metron at Athens. The famous rock Niobe of Sipylus is—it is now universally recognised—a Thrygian example of this type.

RAILWAY chairmen are, not unnaturally, somewhat elated at the improved position in which they find themselves this year, and the ubiquitous Sir Edward Watkin,—who is presiding over meetings in various parts of the country in quick succession,—is certainly no exception. Indeed, at the South-Eastern meeting, the loquacious baronet fairly surpassed himself, indulging in a string of superlatives irresistibly suggestive of "The Greatest Show on Earth." After commenting upon the really remarkable fact that not a single passenger has been killed on the South-Eastern during the last twenty-five years, and explaining that unpunctuality is often caused by excessive desire for safety, he said that there was not a better staff than theirs in the world, that their line was the safest in existence, and that there was no property anywhere in which a trustee might invest his money with greater safety and profit! Is this "after" Barnum?

IN the course of his speech delivered on November 16 last at Cavendish College, Cambridge, Lord Hartington referred to the just aspirations of those who hope to see our Universities exert a powerful and beneficent influence upon the national life of England. Our own generation has seen those great centres of intellectual life awaken to the fact that the country at large is entitled to share in the heritage and increment of their learning. Side by side with the University Extension movement, there is "ample room and verge enough" for a kindred advance in connexion with our national collections. Mr. Louis Fagan, of the British Museum, may legitimately claim precedence as the pioneer in this direction. Stimulated by the success that attended his delivery last year of a course of lectures in some of our principal seats of commercial industry, he has undertaken to give a further course in London, on the

evenings of the 13th, 20th, and 25th inst., at the Steinway Hall. Mr. Fagan's lectures will deal with certain of the more interesting and most valuable objects preserved in the British Museum, whose history, and existence even, are less commonly known than they should be. His subject-matter will be illustrated with a large number of photographic reproductions, prepared under his own care, and illuminated by oxy-hydrogen light. The concluding lecture is to be mainly devoted to the MSS. and Prints, of which latter Mr. Fagan's official position, combined with his well-known attainments, renders him a trustworthy and skilled expositor.

AT SALZBURG, in consideration of the enormous success of the Bayreuth plays, and the genuine interest which the model representation of Mozart's "Don Juan" at Salzburg excited some two years ago, steps have been taken to ensure the erection of a "Mozart Festspielhaus" in the town. This enterprise, which is to be carried out on the same lines as Wagner's at Bayreuth, will require 400,000fl. for the building, and the sum of 150,000fl. annually for a series of twenty representations to be given in the summer. This amount will be raised by a committee, at the head of which is the architect, Karl Domel, and the profits which are expected will fall to the benefit of the music school of the "Mozarteum." The building, which is to be erected on the beautifully-situated "Mönchsberg," will hold an audience of from 1,500 to 1,800 persons, and its stage will have the most modern technical and scenic apparatus. The first performance in the new house is expected to be held in 1891, and, considering that the town has a yearly average of visitors numbering 60,000, besides being within easy reach from Reichenhall, Gastein, Ischl, Gmünd, &c., there need be no fear of seeing empty benches.

AT the general meeting of the shareholders of the Zürich "Theater-Aktiengesellschaft," it has been decided to rebuild the old theatre burnt down last New Year's night. A different site is to be chosen for the new house, in which performances are proposed to be given during the winter season 1891-92, and which will hold an audience numbering at least 1,200 persons. The building will not be characterised either by over-decoration of the façades nor by any special glitter in its interior; but the shareholders wish the theatre to be a model one in regard to safety, practicability, and acoustic properties, and no expense will be spared to obtain these qualities.

THERE is a movement on foot to have the Abbey Church of Haddington restored, and a report has been made by Messrs. Hay & Henderson, of Edinburgh, who were the architects employed in the restoration of St. Giles' Cathedral there. In 1811, the nave, which was in use as the parish church, was fitted up under the supervision of Mr. Elliot, of Edinburgh, who designed St. Paul's Church, York-place, and other public buildings in the city, at a cost of 6,000l. The nave consists of five bays, and, according to the taste of the period, galleries were placed in the aisles as well as across the west and east ends, the central bay of the south aisle being left free for the pulpit. Accommodation was provided for a congregation of 1,230 persons. Messrs. Hay & Henderson report that the church is not now in a fitting state for public worship. In restoring the nave, it was suggested that the galleries should be dispensed with, and the cost of restoration was estimated at 4,450l. The choir and transepts are in a ruinous condition, and should the galleries in the nave be dispensed with, it was proposed by the architects to restore the transepts, and thus provide the requisite number of sittings. This would cost an additional sum of 6,500l. Should it be resolved to restore the chancel also, this could be done at a cost of 12,000l. The total cost of restoration would thus be 22,950l. An account of the history of the church and site,

with some sketches, was published in the *Builder* for June 15, 1889.

IN a paragraph directing attention to the present condition of Hogarth's house at Chiswick, the *Athenæum* says that it "is in a sad state of dilapidation, showing, among other injuries, a hole in the roof, and many more signs of ruinous neglect." The house abuts against the left-hand side of Hogarth-lane, leading from the main street to the Duke of Devonshire's villa, Chiswick House. Hogarth bought it shortly after his unlucky visit to Calais; he occupied it as a summer residence until his death, on Oct. 26, 1764, in Leicester-fields. In this same house died, in 1844, Cary, the translator of Dante; who, as also Hogarth and his wife, was buried in Chiswick churchyard. The Hogarth tomb, bearing Garrick's epitaph as amended by Dr. Johnson, was restored *à curis* a Scotsman, namesake of him—"whose pictured morals charm the mind," in 1850. Tom Taylor, writing thirty years ago, mentions the mulberry-tree as still standing in the front garden, but he found that the three mural tablets on which Hogarth commemorated his pet animals had disappeared, and his painting-room had been dismantled. At Chiswick Hogarth passed the last few months of his life, in directing the touching up of some of his plates. Nichols, in his "Biographical Anecdotes" (1782), tells us that upon the day preceding that of his death, the day he returned to town, Hogarth worked upon the second state of "The Bench,"—a view, with portraits of the four judges, of the Court of Common Pleas. The plates of Hell Gate, Satan, Sin, and Death, originally painted, but not completed on the canvas, for Garrick; and of Finis, or the Bathos, are also ascribed to the year 1764, and are said to have been engraved in this house. A view of it, with the workshop, will be found in Faulkner's "Brentford, Ealing, and Chiswick" (1845). The parish church has lately been almost entirely rebuilt, after the Early English style, by Mr. J. L. Pearson, R.A.

SOME extensive alterations are about to be made, says the *City Press*, at Grocers' Hall, Prince's-street, in the shape of new reception rooms over the adjoining square, together with other apartments on the garden plot. The present hall, being virtually the third to occupy this site, was built in 1798-1802, after the designs of Thomas Leverton, architect. It was thoroughly repaired twenty-five years later. The first hall was erected (1428) in Coneyshop, or Coneyhope, lane—since Grocers' Hall-lane—the old name being derived from a sign of three rabbits over a poultry-stall therein. The ground, included within Chepe Ward and lying near to the Wall brook, had been occupied by the Lord Fitzwalter's town mansion or inn, whose tower was incorporated in the new building. Thither, in 1641, the Grand Committee of Safety removed their sittings from Guildhall. Its walls survived the Great Fire. In 1668-9 Sir John Cutler rebuilt the parlour and dinner-room. During the interval, 1681-1735, Grocers' Hall served as the Lord Mayor's official residence; from 1694 to 1735 it was used for business purposes by the Bank of England directors. The company of Peppercorers and Spicers, for awhile united with the Apothecaries, and whose coat-of-arms bears a charge of nine cloves, and carries for crest a loaded camel, originated in a club of spice-sellers that used to meet in Soper-lane, Queen-street, Cheap-side. On June 12, 1345, this fraternity formed themselves into a trading company by style of the Grocers, and received a charter of incorporation that same year. They first met together in the inn of the Abbots of Bury (Hevis Marks), and, subsequently, after many migrations meanwhile—to Garlickhythe; to Cornettes Tower, Bucklersbury, King Edward III.'s Exchequer and Exchange, &c.; bought Lord Fitz-Walters' Chapel of the Fratres du Sac, Old Jewry, whence they removed to his house hard by. The Weigh House Chapel,—the new buildings for which we illustrated in our columns

on January 18,—derives its name from the King's beam, at the Woolwharf, near to East Chepe, which had formerly been placed in the Grocers' custody. For the making of Princes-street the Company had to surrender a portion of their garden, but they sold the land at a prodigious profit, receiving more than 20,000*l.* for what, in 1433, cost them but 3*l.* 16*s.* 8*d.*

FROM the report in the local prints of a prosecution at the Watford police-court in respect of a nuisance at Rickmansworth, it would appear that the sanitary state of that town is by no means satisfactory. "Wherever it was possible," the prosecuting solicitor informed the bench, "dry earth-closets had been established." In the present case, however, the house was drained into a cesspool which overflowed into the road. Of course the bench made an order to abate the nuisance, directing that small catch-pits should be constructed from which the sewage could be emptied at frequent intervals; but it is perfectly clear from this report that the sanitary system of Rickmansworth is of a very happy-go-lucky kind. Some houses have earth-closets and some cesspools. But it is equally certain that no town, even a small one, can be in a thoroughly healthy condition where the cess-pool system exists, more especially in a low-lying spot in the valley of the Colne, where the soil is gravel and much permeated by spring water. This matter is of some importance, because, owing to the extension of the Metropolitan Railway, land is being laid out for building, and Rickmansworth itself has now become a practicable residence for workers in the Metropolis. It is well also to bear in mind that during the present winter, Uxbridge, also in the valley of the Colne, has been troubled by an outbreak of diphtheria. It is therefore high time that the people of Rickmansworth set to work to establish an efficient sanitary system before any considerable number of new houses are built.

IN reference to a small instrument for testing the gradients of pipes which we noticed and illustrated, page 41 *ante*, Mr. J. Leslie Anderson, of Newcastle-on-Tyne, sends us a sketch of a simple instrument which he has used for the same purpose, of which an illustration is subjoined. Mr. Anderson says: "By

simply laying it on its side over a detail of the required gradient the instrument can be at once adjusted, there being no need to mark a scale of gradients on the slide, although that could be done if desired."

SIR EDWARD WATKIN'S speech at the recent half-yearly meeting of the Metropolitan Railway has at length clearly disclosed his policy in regard to the Northern extensions. The Manchester and Sheffield and the South-Eastern are to become the partners of the Metropolitan in a new trunk line. It is clear from this that the original Metropoli-

tan Railway will be swamped in a much larger undertaking, and it is probable that sooner or later the present ordinary shareholders of the Metropolitan Railway will obtain some kind of preferential dividend, low in amount, but also a fixed charge; for it is perfectly evident that a large amount of capital will have to be created before the London end of the northern extensions will be fit for through and long-distance traffic. The development of Sir Edward Watkin's policy will be watched with interest by the public at large,—by the shareholders of the Metropolitan, probably, with some perturbation.

THE collection of water-colour drawings of Cambridge, by Mr. Fulleylove, now on view at the Fine Art Society's Gallery in New Bond-street, may almost be said to be a collection of gems, both as regards subject and execution. No artist has more precisely the gift for treating subjects consisting of old Renaissance architecture combined with lawns, gardens, and foliage, than Mr. Fulleylove; and nowhere could he find subjects more suited to his pencil than at Cambridge. The series seems to us to be artistically superior to that from Oxford which was formerly exhibited in the same galleries: the drawings are more delicate and refined in execution and in their effects of light and colour, and more equable in style. Among those which are especially successful are "Trinity Avenue" (8); a very small, clear, and sparkling view of the "Great Court of Trinity" (5); "Fountain Court, King's" (15); "Clare from King's Bridge" (24) "Wren's Bridge, John's" (25); "King's Parade" (34), a very small drawing with the houses along the street beautifully touched, and not less so the figures crossing the lawn in the foreground; "Cloister-court, Queen's" (55), with its quaint tumble-down canted bay window; we could have wished to see a little more of the characteristic brick cloister arcade of Queen's. All who know and are interested in Cambridge should see this collection; and those who are unacquainted with Cambridge will gain from these drawings a new idea of the beautiful combinations of stately architecture with lawns and trees, which characterise the scenery of the University town.

Plumbers in the Manchester District.—A large public meeting was held in the Manchester Town Hall on the evening of the 22*nd* ult., under the presidency of the Mayor (Mr. Alderman Mark), for the distribution of certificates granted by the Plumbers' Company to plumbers in the Manchester district. The Mayor said that no body of workmen engaged in the construction of dwelling-houses could, through ignorance or carelessness, inflict so much danger on the public health, or cause so much inconvenience to one's family or pocket, as the plumbers. The length of time a man had been in the trade was no guarantee of his efficiency, and a careful technical examination was the only test which would satisfy the requirements of public comfort, and avert the existing dangers to the public health. He urged that even those plumbers of many years' experience in the trade should avail themselves of the facilities provided at the technical school to learn something of the modern science connected with the plumber's art. Mr. John Holden, Chairman of the Manchester Council, moved that,—

"The Registration System, properly carried out, will afford great protection to the public against the effects of defective plumbing, particularly in respect of sanitary arrangements; and, inasmuch as the system must tend to raise the status of the plumbers' craft, it deserves the support of the trade."

Mr. Councillor Corbett (Salford) supported the motion, which was unanimously carried.

The Institute of Builders.—At a meeting of this Institute to be held on Thursday, February 13, a paper will be read by Mr. Thomas M. Rickman, F.S.A., entitled "An Edinburgh Contract."

Letter from Paris.—Owing to the space occupied by the Royal Academy lecture and the discussion on Architectural Examinations, we are compelled to hold over our usual monthly Paris letter till next week.

ROMAN ARCHITECTURE.*

BY PROFESSOR AITCHISON, A.R.A.

THE magnificent public buildings of Ancient Rome attracted the attention and excited the admiration of mankind from the time of their erection, and nearly all the Roman writers have mentioned them with affection or pride, from Plautus (254 to 184 B.C.) to Ammianus Marcellinus (370 to 390 A.D.), who was the last of the Roman writers, and he tells us of the admiration excited in Constantine the Great by the sight of the following buildings in Rome:—The Temple of the Tarpeian Jove, the Baths as high as provinces, the mass of the Colosseum, the shape and doming of the Pantheon, the Temple of the City, the Forum of Peace, the Theatre of Pompey, the Odeum, and the Stadium, and the astonishment he showed at the sight of Trajan's Forum.

On the irruption of the Barbarians, most, if not all, of the public buildings were plundered and partly destroyed. The Popes were, however, enabled to save some by consecrating them as churches, for the Barbarians seemed to have had some respect for places of worship in use, though the Scythians burnt the Temple of Diana at Ephesus in the third century (A.D. 260).

The Pantheon was dedicated to the Virgin and Martyrs in the early part of the seventh century by Boniface IV. (608-615), and it has thus been preserved to the present day.

The Gothic King, Theodoric, as early as the fifth century (455-526), repaired some of the buildings that had fallen into decay, notably the Baths. But the successive irruptions of hordes of savages, whose only delight was slaughter and destruction, converted whole tracts of the Roman territory into wildernesses, thus almost annihilating industry and commerce, and so cutting off the resources from which the public buildings were supported and repaired. The change, too, of faith, of circumstances, of habits, and modes of thought, caused the abandonment of many of them, and those so abandoned were used as quarries; the burnt bricks, and the stonework, the columns, and the costly marbles were used in the construction or in the adornment of new buildings; the absence of commerce made the very iron cramps so valuable that it was found worth while to cut through solid stonework to obtain them; but what was even more destructive was the conversion of the stone and marble into lime, which is generally wanted where human life exists. We know that the mausoleum was made into lime by the Knights of Rhodes, even so late as the fifteenth century.

Roman architecture has claims upon our attention, not only for its intrinsic merits, but as a continuation of Greek architecture, though with the addition of the arch, the vault, and the dome, and was, in fact, mainly designed by Greek architects who were slaves or freedmen; but it has an even greater interest as being the mother of the Byzantine, the Romanesque, the Saracenic, and we may almost say of the Gothic.

The grand ruins themselves attracted attention as soon as the Barbarians had settled down to peaceful avocations. Scholars, too, sought to identify the ruins of the ancient buildings with those described by the Latin authors. Taste and patriotism both combined to make men antiquarians; they grieved over the daily destruction of beautiful things, and they saw that each beautiful thing destroyed, each column burnt into lime, each building ruined for its brick facing, was lessening the evidence of Rome's former greatness.

Cola di Rienzi, the tribune of the people (1313-1354), was one of the most prominent of the early antiquaries. As soon as new buildings of grandeur and importance were required amongst the settled towns of Italy, architects were attracted to the Roman ruins, and endeavoured to extort from them their secrets. All architects have read in Vasari of the time spent by Brunelleschi in measuring and studying the Roman ruins, when he was solving the problem of how to dome the Cathedral of

* Being the first Royal Academy lecture on Architecture this season. Delivered on Monday evening last, Jan. 27.

† Piro Ligorio says that even large marble cornices and an infinite number of statues found in the Temple of Mars were broken up and burnt into lime. Prof. Middleton, "MSS. notes by Piro Ligorio," Society of Antiquaries, 1830. Pope Pius II. (Eneas Sylvius Piccolomini), 1458-1464 A.D., also wrote the following lines on the subject:—

"sed tuus hic populus muris defossa vetustis
caedis in obsequium marmoris dura coquit."

Florence, and Donato was his companion in

Brunelleschi was born in 1377, and died in 1441. In 1453 Constantinople fell, and a fresh impetus was given to the Renaissance by the influx of books, MSS., and works of art, as well as by the scholars, artists, and skilled workmen who had escaped from it.

In the high tide of the Renaissance, architects flocked to Rome from every part of the Christian world to measure and study the remains of Roman architecture, while a new light was thrown on the remains by the treatise of Vitruvius, as new lights were thrown on Vitruvius by their study.

Vitruvius's book probably held its place as the teacher of architecture throughout the Middle Ages. Gallani, in the preface to his Vitruvius of 1758, tells us from Panormita, that Alfonso the Magnanimous, King of Arragon, wishing to restore the new Castle of Naples, had no recourse to others, but to Vitruvius; and because Panormita gave him his Vitruvius, which was without ornament or boards, the King reprehended him, saying that so important a book did not deserve to remain uncovered, from which we learn so well how to cover ourselves,* and at once ordered him to have it nicely bound.

Professor Cockerell, in his pamphlet "On the Architectural Works of William of Wykeham" (Svo. London, 1846. Note, page 33), erroneously supposes that this was Alfonso III. (whom he calls the philosopher, who lived about 1281. It was Alfonso V., who reigned from 1416 to 1458, and whose sayings Beccadelli (called Paormita, from his being born at Palermo) recorded, and which were published in 1485. In this same note, Professor Cockerell says—"The evidence of the estimation in which Vitruvius was held in the Middle Ages abound. The citation of his name in the earliest and most authentic documents of the Freemasons is seldom wanting. The church in the Castle of Nuremberg, built by Barbarossa, in 1158, and the Frauenkirk, in the centre of that great city, probably of later date, are exact illustrations of the 'Temple in Antis' of Vitruvius, as given by Cosarino (Lib. III., fol. 52) . . . In fact, it appears that in the Middle Ages, scarcely less than now, it was the intention and aim of the architects, on all occasions, to establish their rules upon Vitruvian authority; and the illustrations given in the plates of Caesarians may be adduced as sufficient evidences of this traditional respect for the father of architectural legislation."

Vitruvius's book was first printed in Rome in 1486, edited by Sulpicius, and was re-edited and illustrated with woodcuts by Fra Giocondo in 1511, who tells us in one of his books that he shed tears over the destruction of the buildings and works of ancient art that took place in his day.

Amongst the Italian architects we have a succession of those who published drawings of some of the ruins of Roman buildings: L. B. Alberti, Sebastian Serlio, who is supposed to have published in his book the drawings of Baldassare Peruzzi, Palladio, Antonio Labacco, Vignola, V. Scamozzi, and others, up to the present century, in which Contini published his "Edifices of Ancient Rome," in six volumes (1848-56), and doubtless there is a great mass of unpublished drawings. Thirty folio volumes of Piero Ligorio's "L'Antichità di Roma," are amongst the Royal Archives at Turin. In the 17th century, France took up the task, and we have the edifices of ancient Rome by A. Desgodetz (1682).

England at last followed, and Taylor and Cressy's book on the architectural antiquities of Rome was published in 1821-22. I have not mentioned the monographs on Roman buildings, which are numberless.

We all know that every book on architecture, and most of those on any of the building trades up to the middle of the last century, had illustrations of the Roman orders, and had illustrations of them by the eminent Italian architects; and many books on architecture even to this day contain them.

Looking at the effluence of information we

* Cum inchoata illam arceem Neapolitanam instaurare institisset, Vitruvii librum qui de Architectura in scribitur, afferri ad se iussit. Altem est, quando quidem in promptu erat Vitruvius necesse fuit, quidem sine ornatu alio, sine asseribus: quem rex simul atque in promptu, non decere hunc potissimum librum uti nos quoniamdo condecorare, tam belle doceret, detectum incedere, eumque inibi perquam polite ac subito cooperiri mandavit. Lib. I., Par. 44, Antoull Panormite, dictis et factis Alphonsi regis Arragonum.

possess on the architecture of the public buildings of Rome, it seemed to me to be more useful to speak of the private houses. Under the head of private houses I include those in town and country, as well as those in the capital. I shall try and touch on some of the palaces, as they are but glorified houses.

Roughly speaking, the Roman house must necessarily have been the model from which most of the houses of the Western world have been derived, not to speak of the cloisters of cathedrals and abbey churches, which, with their gardens, are supposed to have been copied from the atrium of the Roman house. In England the Roman villa was different to that in Italy,—the atrium became the forecourt, the rooms at the end and part of the two sides sometimes having a verandah next the court; the open space was the compluvium, or impluvium, on an extended scale: but in Spain the general arrangement of the Roman house is still adhered to.

It is interesting to know something of the type from which most subsequent civilised house-building took its rise, more especially when that wonderful people, the Roman had, within a short time after its death-struggle with Carthage, virtually conquered the whole of those countries which surround the Mediterranean, and had thus become acquainted with the houses and palaces of Greece, Illyria, Epirus, Macedonia, Thrace, Asia Minor, Syria, Palestine, Egypt, and Numidia.

The Romans were, of all people, the readiest to adopt all they considered excellent, and we cannot suppose that they did not seize on each particular form or arrangement that recommended itself to them in the houses and palaces of those countries. We know from Plutarch that Pompey copied his theatre from the one at Mitylene, in the island of Lesbos.

In reading the descriptions of the villas of Cicero, of Trimalchio, and of Pliny the Younger, we see the care that was taken to secure proper aspects and delightful views, silence in bedrooms, quietness and pleasant prospects in studies, and to provide libraries, picture-galleries, baths, and tennis courts; we learn, too, how the houses were kept warm; if we were without any express statements of their being warmed, we could see the provisions for warming them in the ruins of the Roman villas in our own country.

We have, again, the precise instructions of Vitruvius for proportioning the separate parts of houses. This subject is greatly neglected in the present day, although it is vitally important if we wish to make our rooms captivating to the eye. I recollect hearing Professor Cockerell praise the Library of University College, London, which Professor Donaldson had just built, and say it was elegantly proportioned, and showed the ripe study that had been bestowed on it. He added that young men were often excellent in ornament but rarely attained excellence in proportion, as they had not as yet been duly impressed by its importance.

We in England too greatly neglect that training which is got by the restoration on paper of ancient buildings.

Although the Younger Pliny's descriptions of his villas are said to be the most favourite exercises for architects I only recollect a single published restoration by an Englishman, that of R. Castell in his "Villas of the Ancients." For though the Roman house in the learned Newton's Vitruvius has evidently been inspired by Pliny's Laurentine villa, it is not a restoration of it. The restoration of one or both of these villas has exercised the ingenuity and displayed the knowledge of Italians and Frenchmen. Why were the Italians of the Renaissance the best architects, and why are the French now? Mainly because the former were, and the latter are, better trained than the architects of the rest of the Christian world. Let us take an analogous case, the invincibility of the Roman legions. We are apt to take for granted that the Roman legions were invincible because the Romans were a fighting, determined, and well-disciplined people; but Polybius, who was a Greek, and a hostage, and had, therefore, no particular reason to love the Romans, explains to us that the Roman legions were largely composed of other nationalities, and that their invincibility arose from the discipline, and not from the men; and that great master of the art of war, Marshal Saxe, makes a similar remark about the men of his day. We are too apt to omit the complete training obtained by the restoration of ancient buildings, until the problems of actual practice come before us, so

that we only get, perfectly trained after being engaged in a large practice, whereas we ought to come to our first building in a well-trained state.

We saw in the Paris Exhibition of last year a series of magnificent restorations of Greek and Roman buildings: the Acropolis of Athens, the Parthenon, the Theseum, the Temple of Demeter at Eleusis, the Temple at Olympia, the Palace of the Cæsars at Rome, Diocletian's Baths, a portion of Hadrian's Villa at Tivoli, the Pantheon, the Temple of Concord, and the Arch of Titus. Many of the sets comprise the plans and elevations of the ruins as they now exist, as well as the restorations, and some of the drawings must be at least 15 ft. long, with every detail of the construction drawn and the colour decorations restored, and this not by very young students, but by men who would here be in practice.

M. Paulin's restoration of Diocletian's Baths was admirable, and has an artistic grace that was probably wanting in the original, while some of the mosaic has that dignity of colour that befits a grand public building. This is especially notable in that with the white ground.

This practice of restoration has often been as much objected to by the French public as it has been neglected here. But what does M. Chas. Garnier reply to the objectors who say,—"What is the use of it?" "Why, unjust and childish souls, it is useful for the history and palpitating life of the arts, it serves to compare the past with the present, and it serves, above all (for that is its end), the artist who has worked! Do you think the time he has passed in measuring those fragments, in interrogating those ruins, in assigning them their place, and in their employment, do you believe that this time has been lost to the artist? He has familiarised himself with the first notions of art and construction; he has lived the life of other times; he has brought together the history of men and of stones; he has learned to study, to compare, to reason, which he must do later when he builds for you; he has, in short, the alphabet of architecture. Whatever may be his ideas in the future, he will know how to express them. If his colleagues have already done similar work, is that a reason why he should not do them? If my neighbour at college has translated Virgil or Cicero, is that a reason why I should not in my turn? Does the education of one man give education to another? Do not laugh at these ignorant attacks; it is noble self-denial to study one's art in youth, in the hope of becoming later a master in one's turn."

To plan well is an important part of the architect's duties, though not the most important, and it means grouping rooms of the requisite size and shape in a convenient manner, and with the least loss of space.

The Roman architects were excellent planners, and we learn something of this by restoration; besides, the exercise of adapting plans to other requirements than those of the present day gives additional breadth to the architect's mind; and we have, too, in some Roman buildings, vast rooms that are unusual in England.

Hitherto I have been speaking about fulfilling the programme in planning, but there is another object we have to attain in important buildings; for want of a better word I may call it noble planning, when the rooms have to be elegantly or majestically proportioned, to be diversified in shape and size, and so contrasted as to set one another off to the best advantage; this sort of planning is mostly required in buildings of state, where beauty, dignity, and magnificence are chiefly aimed at; and what applies to planning is equally true of other parts of the tremendous and complex profession that we follow.

We must have deeply studied noble planning as well as that which is merely suitable, if we are to be successful in making noble plans; so must we study dignified proportion, and exercise ourselves in producing it on paper, if we want our buildings or our rooms to be dignified.

No one was a more diligent student of the antique, nor restored more ancient buildings than Palladio, and he was one of the few who succeeded in attaining the dignity and fine proportions of Roman architecture.

To compose well pre-supposes a study of the art of composition, practice in that art, as well as natural genius; and the same study, and the same genius are required for all the different æsthetic branches of our art. Nothing can be a better study for grace and refinement than

* M. C. Garnier, "A Travers les Arts." Svo. Paris, 1869.

Greek mouldings, only they are not suited to our climate. We, in England, therefore, also want to study Gothic mouldings for their effects of light and shade, so that our mouldings may have the grace and refinement of the former, and the effects of light and shade that are obtained by the latter.

I have always been struck in London by the variety and originality of the buildings, but in too many instances the architecture lacks knowledge, taste, and care.

In the introductory lecture of a course, some digression may, I think, be allowed; as it has to point out the general objects we should all have in view, and how some of these may be obtained by the studies recommended, while the subsequent lectures keep more closely to the subject of those studies.

M. César Daly published a pamphlet on "High Studies in Architecture," which has been largely circulated among architects. He accuses all the various French schools of not devoting any serious attention to this subject. As the French schools are very like our own, I may give his enumeration of them. The Paris School of Fine Arts, the Architectural Schools of Paris and the Provinces, the School of Rome and of the diplomaed, the Diocesan, *i.e.*, Gothic, which he says, knows most about the history of the styles that it cries up, the Independents and the "Don't care a— school." I do not think this is the time to discuss all his propositions, but there are two or three which will, I think, be both interesting and instructive, namely, the programmes for the Bordin and Duc prizes. That for the first is—

"To seek if there be a common æsthetic law, applicable to the monuments of the great epochs of art, and from this point of view to study the monuments of the Egyptians, Greeks, Romans, and those of the Middle Ages, of the Renaissance, and of modern times, to the end of the eighteenth century."

This study is not without its use. A clever and indefatigable student might possibly discover laws that have hitherto been overlooked, but one can scarcely hope that one law can be discovered that would ensure success in every building, no matter what was its style. We should then have discovered the philosopher's stone of architecture. M. C. Daly says:—"Englishmen are practical." So I think without going so far afield. Those who aim high may be recommended to take the best of each of the different sorts of buildings in the style which each one affects, obtain their size, and then carefully calculate the general proportions for the general effect and the particular proportions for the particular parts.

I have mentioned here before that Sir C. Barry's Reform Club was designed,—as far as general proportions go,—on an average of those found in the principal Italian palaces, and it is certainly one of the finest proportioned buildings in England, if not in Europe. There can, I think, be little doubt that the Greeks, Romans, Byzantines, Saracens, and Mediaevals had some rules for the due proportioning of their buildings.

M. César Daly ventures to say that "architecture is a social expression." I say "ventures," because, as far as we can see, different nations at different epochs had but one chance,—*i.e.*, the style in vogue. Though there must have been some passion in each nation, or in the architects as a body, to produce those modifications whose ultimate development we call styles, and those peculiarities we call schools, at each epoch there must have been a taste for some particular characteristic, *i.e.*, for massiveness, exquisiteness, or magnificence, for height, or for width, for complexity, or for simplicity, as well as a marked liking for particular features, such as the pediment or gable, the arch, the vault, the dome, or the tower; though the arch was an economic invention, and the vault was a preservative from fire. Cicero thought there must be pediments in Elysium. Procopius is never weary of praising the dome of Sta. Sophia, "pendent by subtle magic." But who can say now that there is a predominant admiration for any particular form of architecture?

The programme of Joseph Louis Duc's prize is as follows:—"To determine by special studies the style of modern architecture."

In the ordinary sense, one would say that it is every style and no style, but there can be no doubt that every modern building which is not a copy, and few are copies, has a nineteenth-century air about it. We cannot imagine Ictinus or Mnesicles saying of one of our Grecian buildings, "this is Greek." Cossutius or Vitruvius

would not say of our Roman buildings, "these are Roman"; nor would Villard de Honnecourt, or William of Wykeham, say of our modern churches or cathedrals, "these are Gothic"; they would all probably say, "these are not in our style"; but I cannot admit that this flavour amounts to a style, it is only fish, flesh, and fowl, with nineteenth-century sauce. For the architecture of to-day to claim the designation of a new style, it must have adopted new forms by reason of new wants or new materials, or it must have embodied in its buildings the aspiration of the people, so that each building is so presented by it as to give them all a family likeness, but alas! the people have no aspiration to embody. Eclecticism itself would constitute a new style, if all pillaged the same things, and arranged them more or less in the same manner.

I gather from M. César Daly that Duc expected that the competitors should attempt to show the new style in their designs. No man can create a new style, though if he be a great genius with a strong personality, he may considerably modify the existing ones.

As far as we can now see, styles gradually grew up, certain things or certain new forms were wanted, and in striving to get these, some part had to be modified. We see in the Roman baths how the entablatures were cut through by the large arches, and were thus obliged to be mitred round each column, the long entablature perished and with it the prevalence of horizontal lines connecting the columns, and in its place are isolated columns with a scrap of entablature over each, so that the prevailing principle was vertically.

In Diocletian's Palace (probably built about A.D. 305) we see that the architects had got tired of sham imitations, and where they could, used round arches in their place. The architects found, too, that mitred entablatures on isolated columns were in the way where arching was used; so, when it could be managed, the arches were made to spring either directly from the caps of the columns, or from blocks on them. Small colonnades or arcades, when used as decoration only, were carried on corbels, while the traditional ornament was still carried out to the best of their ability.

In 532 A.D., some 200 years later, Justinian had Sta. Sophia built; then all traces of entablature over the columns had gone, and it had taken its place over the arcades; the capitals take a new form and are enriched with a new scheme of ornament; and the dome rests on pendentives. Anthemius of Tralles, who built Sta. Sophia, was doubtless the great architect of his day, and the possessor of the traditions and practices of his day, and had doubtless used pendentives before on a small scale.

The Koptic architect who built the brick mosque for Touloun in the ninth century (876 A.D.) at Cairo, was merely possessed of the Byzantine traditions as carried on in Egypt, and possibly was the introducer of the small arches that take the place of pendentives in the dome. His successors gradually worked out those arches into the form of stalactites that were so much affected by the Arabs and Moors, until at last we get the Alhambra and the Alcazar, which scarcely bear any resemblance to Byzantine work.

The Romanesque architects, who eventually developed Gothic, went to the Crusades, saw the principal buildings in Rome, Constantinople, Asia Minor, Syria, and Palestine, and either from being prisoners themselves or from intercourse with Saracen architects who had been taken prisoners, became possessed of the geometry so much cultivated by the Saracens, and also adopted their methods of design, particularly in producing effect by the constant repetition of parts. So I think we may say that new styles are developed in the course of ages, from the introduction of new methods of construction, new ideals, and to some extent through the love of new forms of ornament.

In the present day, iron, in the form of cast-iron, wrought-iron, and steel, is insensibly affecting architecture,—I mean stone and brick architecture, for scarcely any large building solves all its problems without the use of iron. As far as buildings of cast-iron go, there have been no great achievements yet within the pale of architecture, and as far as wrought-iron and steel go, none. I do not say that nothing has been attempted, but no success has as yet been achieved, and for these reasons, that it has hitherto been too costly to mould wrought iron and steel, and buildings have not been big

enough to use the ready-made forms as units of enrichment, nor have artistic gifts been vouchsafed to the engineers; when good effects have been attained, they have been attained by chance. I do not complain of this, because in most engineering structures the main difficulty has been to do them at all.

I think we cannot help noticing that there has been an effort at the Paris Exhibition to try what can be done with these materials, so as to bring them within the pale of architecture. A witty English architect described the Eiffel Tower as "a factory chimney in lace," but this is an engineering work, its claim to our admiration is rather founded on the solution of a problem in construction that was looked on as insoluble, than as the solution of one in beauty; this was, at most, considered to be of slight importance.

The treatment of cast-iron at the Exhibition buildings at Paris in the shape of columns has been so successfully achieved as to make the columns perfectly harmonise with the decorated wall they carry; for we have now become so well acquainted with the strength of cast-iron as to tolerate its bulk being small in proportion to the weight it has to carry, and in this case the contrast is agreeable.

I cannot too much praise those flanks of the Exhibition buildings, where cast-iron has been used for supports in association with mouldings, sculpture, mosaic, and colour; but when it was wanted to bring wrought-iron within the pale, it defied solution. All honour to the attempt. The wrought-iron stanchions filled with terracotta only suggest that the terra-cotta has been thus packed in iron crates for travelling by rail. In the domes the ribs are unobjectionable by reason of their slowness: they are mere cobwebs.

M. Dienlafay's spoils of Darius's Palace have taken root and blossomed, for the external domes of the Exhibition in coloured and enamelled bricks are a lovely invention—I think it may be called an invention in spite of its traditional use in Persia. The adoption of coloured and enamelled bricks for the roofs of vaulted and domed structures, possibly even of ordinary-pitched roofs, would add much to the beauty of modern cities.

I think I am not singular in looking on the Royal Academy as being desirous of encouraging the higher studies.

It does not so much profess to teach that alone by which the student may get an honourable living, as to try to fit him for the highest employment—*i.e.*, the designing of grand public and private monuments,—monuments that by their durability and beauty may give a notion of the magnificence and taste of this day to succeeding generations,—may, whose very ruins may speak of the greatness of our time, and give lessons in taste, planning, and construction to future architects, when even our language has become the province of a few scholars.

No architect should forget that some ruins still excite our admiration, though the written language of their builders is incomprehensible. I may instance the Pelagiac and the Etruscan.

I think I may here interpolate a maxim,—Never allow your indignation or despondency to prevent you from still doing your best when you have been thwarted in your favourite schemes. Always think of Wren. Your indignation and despair will end with your life, even if they last so long, while your building may last for centuries. Let not the future cultivated student of your building say, the architect of this was not steadfast to the end.

I will now give you a slight sketch of what we know about the Roman houses and palaces, and of what we may gain by the study of them. Most of the private houses of the Romans have been utterly destroyed, except those in Herculaneum and Pompeii, and we may at present exclude the former from our consideration, as so few have been excavated.

It was only after the publication of Sir W. Gell's "Pompeiana," at the end of the first quarter of the present century, that much was known about the houses of the Romans, except to those had seen the excavations. Since his day many splendid monographs have appeared on the subject; the works of Zahn, Müller, Mann, and Niccolini, have become text-books. The plan of Hadrian's Villa, near Tivoli, taken by Pirro Ligorio, was published in 1751, by Contini, and Contini himself published another in 1768.

Robert Adam, in 1764, published his restoration of the Emperor Diocletian's Palace at

Illustrations.

THE BRONZE DOORS FOR COLOGNE CATHEDRAL.

THE illustration shows the first of the modern bronze doors which are to be added to Cologne Cathedral; this door having been very recently fixed. There are to be not less than twelve of these doors to the several entrances of the cathedral, the general design and certain ornaments and enriched mouldings being in all cases the same, but the subjects in the panels varying in each door. The designs were prepared by the Gothic architect, Herr Schneider, of Cassel, under the general superintendence of the architect to the Chapter, Baurath Voigtel, and the execution was intrusted to the sculptor Mengesche, a native of Aachen. The bronze plates are five-sixteenths of an inch thick, exclusive of the raised portions, and are screwed to massive and strongly-braced oak skeleton frames, each door being 11 ft. 5½ in. high by 7 ft. 2½ in. wide. The repetitions are in cast bronze, and have come out so sharp that they could be left without further work upon them, a circumstance which materially affected the price, which is 750*l.* for each door, or 9,000*l.* for the twelve. At present only one of them is hung (in one of the openings in the west front), and it is this first sample which we publish to-day from a photograph sent to us by the Court Photographer, Mr. Anselm Schmitz, of Cologne. The three crowns, of course, allude to the three Magi, whose bones are supposed to rest in the Cathedral.

HOUSE, EDGE HILL-ROAD, EALING.

THIS house has been built from the designs of Mr. L. A. Shuffrey, for his own occupation, on Castlebar Hill, Ealing.

The walls are of Acton red bricks, with Box-ground Bath stone dressings, the window-cills and thin copings being of Portland stone. For the roofs Reading tiles are used, with sanded face. The dormer window shown in the sketch lights a sitting-room, and commands an extensive view over Harrow and neighbourhood. The left hand of the two gables contains the main staircase, which is continued up to the top floor.

The building contractor was Mr. Jas. Chapman, of Hackney, and the plumbing work was executed by Mr. John Smeaton, of London.

DRAWING OF SOUTH AISLE, GADDESBY, LEICESTERSHIRE.

THE Church of St. Luke, Gaddesby, is situated about six miles from Melton Mowbray, and is of the Early English period. The south aisle, the subject of the sketch, was added in the fourteenth century.

The oak benches, in their original position, may be seen in the nave, and a portion of mural decoration on the chancel wall.

The church is unrestored.

ARTHUR H. HIND.

PARISH ROOMS, ST. GILES'S, NORTHAMPTON.

THIS building is situated in a leading thoroughfare of the town. The hall, or parish-room, occupies the whole of the first floor. On the ground floor are four good rooms for various church purposes. In the basement are lavatories, cloak-room, kitchen, storeroom, and two other rooms. A lift for use at tea-meetings runs from the kitchen to the upper rooms.

The architect is Mr. Samuel J. Newman, of Northampton, whose design was selected in a limited competition on the recommendation of Prof. Roger Smith, who was called in by the committee to adjudicate.

In execution, the exterior especially has been somewhat reduced in cost. This illustration is the original design. The builder is Mr. J. Buswell Clarke, of Northampton, the contract being 1,888*l.*; but more than 100*l.* additional has been spent in obtaining a good foundation, it being found that the site was an old stone-pit excavated to very irregular depths, varying from 25 ft. to 8 ft. below the basement, and at some time since filled with loose material. This necessitated great care with the foundations. The system of concrete piers adopted has, however, successfully met the difficulty, no settlement whatever having occurred.

The building is heated throughout by hot water, executed by Mr. W. Stainton, of London, at a cost of 103*l.* 10*s.*

TWO SEMI-DETACHED HOUSES, KNIGHTON, NEAR LEICESTER.

THESE houses have been built from designs by Mr. Isaac Barradale, of Leicester, the contractor being Mr. Peter Lowery. Besides the accommodation shown on the ground floor plan, the upper floor contains large drawing-room, five bedrooms, dressing-room, linen store, bath-room, w.c., &c.

Local red bricks have been used for the exterior, red Broseley tiles for the roof, and the timber work has been coated with Stockholm tar.

THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

NEW "JUBILEE" WING.

THE arrangements of the plans for the new Jubilee Wing of this hospital have been founded on instructions to the architect by the Committee, the result of anxious and detailed consideration of the various suggestions and advice tendered to them by the medical staff and the nursing staff of the hospital, and derived from their long experience.

The basement floor, which is on the same level as that of the present building, will contain an additional large out-patients' receiving room, approached from Powis-place, with a room attached for such slight surgical operations as can be effected at once; a special waiting-room for whooping-cough cases, and another for infectious cases, each carefully separated from the above large room; while to each of these three receiving rooms separate lavatories and closets are attached.

On this floor is a large Housekeeper's Room, sewing and mending room, a receiving-room for linen, and also linen stores. There is also a room denominated the Samaritan Room. A passage from the present kitchen (which is to be enlarged), kept separate from all the above, leads to a lobby, whence lifts for food, and also for coals, rise to the upper floors of the new wing.

The ground-floor contains an in-patients' receiving-room (the want of which has been seriously felt in the present building), fitted with bath-rooms, available for immediate use at any time. A small accident-room is also provided for urgent cases. On one side of the hall of entrance from Great Ormond-street there is a suitable committee-room, with Secretary's room and clerks' office adjacent; and on the other side of the entrance-hall is a waiting-room, the lady superintendent's room, medical officers' room, a common-room for the nursing sisters, and another for the use of lady pupils. The centre of the wing is occupied by the principal staircase, which is carried the whole height of the building, and lighted both laterally and from above.

The mezzanine floor contains a large dining-room for the nurses, with service-room attached fitted with lifts from the kitchen; also a common-room for the use of the nurses; bed-rooms for the lady superintendent, the lady pupils, and the sisters, bath-room, and other necessities.

The first and second floors are similarly planned, and contain two new wards on each floor, rather more lofty than the present ones, with a room for the sister in charge. On each floor is a ward-kitchen fitted with lift from the kitchen in basement; a vestuary, bath-room, and other necessities. These wards contain sixty-two beds, each bed having allowed to it 1,000 cubic feet of air in the ward. The new wards are so planned as to be lighted on each side, thus ensuring cheerful appearance and thorough natural ventilation.

The third floor contains accommodation for which the medical staff have long been anxious, viz., a large separate ward, containing thirteen beds, and specially devoted to whooping-cough. A small separate ward, containing three beds, is adjacent, intended for very special cases. As with the wards below, a sister's room, as well as a ward kitchen, vestuary, bath-room, &c., is provided.

In all, there will be an addition to the accommodation, including the rearrangement of the north end of the second floor of the present hospital, of eighty-nine beds, including those in small special wards, making a total of 214 beds.

The attic floor contains the sleeping accommodation for the nurses and the female servants of the Hospital. These have, of course, separate approach, and in each case good-sized and well-lighted cubicles are arranged for one occu-

pant each. On this floor is also the housekeeper's bedroom. Bathrooms, &c., are also provided.

It should be mentioned that all floors, staircases, and passages are constructed of fireproof material; that the walls of the several wards will be faced internally with glazed bricks of suitable colour; and that the warming will be by open-fire Galton stoves, so arranged and fitted as to assist largely in the ventilation of the wards.

Several improvements in the present building are also provided, including the enlargement of the Diphtheria ward on the second floor, enlargement of the kitchen and heating apparatus room, providing three additional bedrooms for the use of the porters, and also a second consulting-room attached to each of the present patients' waiting-halls, which last have been found greatly needed from the large attendance of out-patients, and to avoid unnecessary delay in attending to them by the attendance daily of two medical men instead of one as at present.

The design externally has necessarily been varied from that of the present building, as the levels of all floors, except the basement, are different. The wards are more lofty, and the windows are larger.

Tenders for the erection of the carcass of the building have been received, and that by Mr. W. T. Mitchell, of Dulwich, has been accepted at 14,493*l.* It is intended to commence the work forthwith, but until further money can be raised the completion of the building, with all internal finishings, estimated at about 6,000*l.*, must necessarily be deferred. It is, however, hoped that before the completion of the work now to be undertaken the necessary funds for the completion will be forthcoming.

EXAMINATION IN ARCHITECTURE:

THE ARCHITECTURAL ASSOCIATION.

THE seventh meeting of this Association for the present session was held on Friday, the 17th ult., in the meeting-room of the Royal Institute of British Architects, Conduit-street, Mr. Leonard Stokes (President) in the chair.

Messrs. F. W. Cowley and S. Dawe were elected members.

Mr. Farrow, hon. secretary, called attention to the Painter-Stainers' Company's Travelling Studentship, for which the Association had the privilege of nominating two competitors.

Mr. E. S. Gale, hon. sec., announced that arrangements had been made for the first seasonal visit, which would be to Mr. D'Oyly Carte's new theatre in Shaftesbury-avenue, on Saturday afternoon, February 8.

The Chairman then called upon Mr. Arthur Cates to open a discussion on the Progressive Examinations of the Royal Institute of British Architects, and in doing so said that he thought he ought to mention that Mr. Cates had come down to them that evening in defiance of his doctors. It was extremely kind of him to do so, and he (the Chairman) hoped that Mr. Cates would not be any the worse for having come out. As most of them knew, Mr. Cates had not been at all well lately, and his presence under the circumstances showed what great interest he took in them and in the cause of the Examinations.

Mr. Arthur Cates then read his paper, which was entitled "Examination in Architecture: In the Past, the Present, and the Future." We printed it *in extenso* last week. In the discussion which followed,—

Mr. J. A. Gotch said he had great pleasure in proposing a vote of thanks to Mr. Cates for attending and giving them his paper, which he thought was a very valuable one, for two reasons. In the first place, it was an historical account of the Examinations, and therefore of much interest; and in the second place it would be a guide and a great help to those who had pupils, as well as to the pupils themselves and the younger members of the profession. He thought that no better service could be rendered to a young man beginning his architectural training than to put into his hands a copy of Mr. Cates's paper. As Mr. Cates was reading the memorial which was prepared by the Architectural Association for presentation to the Institute in 1855, it struck him that, as Mr. Cates had said, the terms of it applied very much to the present day, for, even now, "the students of Architecture are without sufficient guidance." The examinations which had been instituted by the Institute were a very good sign-post, but they wanted

From a Photograph by Anselm Schmitz, Cologne.

something more than that; they wanted not only to have the task set them, but some better means of enabling them to grapple with that task, and he trusted that before long they would evolve, not only a better system of architectural examination, but a better system for enabling them to acquire the necessary knowledge to pass the examinations. He thoroughly and heartily endorsed what Mr. Cates had said about principals insisting upon their pupils preparing for and passing these examinations. In the office in which he was a partner, when a pupil was articled to them they made it a stipulation that he should go in for these examinations, and they also made it a part of the articles that they should offer him facilities for acquiring suitable knowledge apart from what might be going on in the office. That seemed to him to be the most essential, and if all architects would take a similar course, and if they could induce their assistants to pass the Examinations as well, it would be for the benefit of the profession. As regarded architects' assistants, he found that they were generally very willing to go in for the examinations; men who did not come in touch with the Association, or with London at all, except through what they saw in the papers, welcomed these examinations; and he thought it would take very little trouble, and very little persuasion on the part of the principals, to get their assistants to enter for them. One advantage that the progressive system had was that from the very outset of his career a young architect was more or less in touch with the Institute. The very fact of their becoming probationers was a help to them, as well as a help to the Institute; he was thoroughly satisfied that it was to the Institute that they must look for maintaining the prestige of the profession, and the more they could get the young men to be in touch with the Institute, the better it would be for the profession. It must be remembered that those who passed the preliminary examination became probationers of the Institute, and thus obtained a certain standing in the profession which they would not otherwise have.

Mr. H. D. Appleton, in seconding the vote of thanks to Mr. Cates, referred to the action of the Association with regard to the affiliation of local societies, which Mr. Cates had alluded to. He (Mr. Appleton) had taken some little interest in that matter, and wished to make one or two remarks on the subject. In endeavouring to promote the formation of local associations in country towns, the first difficulty which they were always met with was the fact that architects engaged in practice in those towns were extremely jealous of their pupils and assistants coming together; and he was afraid that that was the great difficulty with which they would have to contend. Provincial architects seemed to think that if the assistants were to meet together in classes in that way, they would get talking about office-work in general, and thus rival practitioners would learn what business was going on in each others' offices. He had always endeavoured to point out that no harm of that kind had ever occurred in connexion with the Architectural Association; and that, moreover, architects' pupils and assistants were possessed of sufficient *esprit de corps* to render it well-nigh impossible that they should talk about office secrets. Another difficulty which they had experienced was the fact that the Institute having a federation scheme on hand, the student societies which they had approached had in one or two instances said that they would prefer to become connected with the Institute instead of with the Association; but he thought it was not the intention of the Institute to federate with the student societies. The question of the way in which isolated students in the country could derive benefit from the work of the Architectural Association had long been one of great difficulty; but they last year instituted the first of what they had hoped would be a series of correspondence classes for those students, but they only had twelve members, he thought, in the class which was started, and it was not kept up with very much vigour. But he sincerely trusted that the Association would still endeavour to assist those students who unfortunately were not living in places where they could derive benefit from attending classes. It seemed to him that there was wanted some sort of organised system to take the country students' work and to bring it before the classes in London, for they did not seem to derive sufficient benefit from the present system. Of course, the members of the affiliated societies had the benefit of seeing the work submitted

in the London classes, which was sent down to them; but it would not be possible for it to be sent round for isolated students to see, for it would be worn out before it got back. There was one point in the preliminary examination scheme about which there was some difficulty; for the list of drawings set out in the Institute "Kalendar" mentioned that "two sheets of the Orders of Architecture" were required for that examination. Did that mean that the whole of the five orders were to be put upon the two sheets?

Mr. Cates said that the requirement in question related to the Intermediate Examination, and having read the paragraph referred to from p. 153 of the Institute "Kalendar," he said that the whole five orders were not wanted: the candidate could select any two, putting one order on one sheet and one on the other.

Mr. John Slater said he felt himself in some difficulty in speaking that night, because there was very little more to say upon the Examination part of the question than had been said by Mr. Cates. But there was a great deal more to be said on the educational aspect of the question, and with regard to that his tongue was to a certain extent tied, because, as perhaps they knew, he was one of the members of the Educational Committee now sitting, which was not yet quite in a position to report; and he could not very well divulge the secrets of that committee, nor could he mention there the conclusions towards which he thought they were drifting. But with regard to the Examinations themselves, he wished to say one or two words. The Preliminary Examination which had been instituted had been alluded to by Mr. Cates, who had mentioned the fact that although the programme of that examination was very precise in its terms, a number of candidates who came up for the Examination seemed to ignore altogether the fact that they would be examined in the subjects in which they had been told they were to be examined. It was no good for the Institute to carefully prepare a programme if it were to be ignored. He did not suppose that he was speaking to any candidates who had been up for examination and had failed, but he hoped he was speaking to many who would be going up for the Intermediate Examination, and he wished to impress upon them that if there were subjects set down in the programme of that Examination it would not do for them to think that if they ignored these subjects, and did well in others, that they would pass. To use a Shakespearian quotation, he "could a tale unfold" as to the Preliminary Examination which would move them to laughter. Answers were given on some subjects which showed that some of the candidates had not the very remotest ghost of a shadow of a knowledge of the subjects in which they were examined. He could not help thinking that whatever system of education, or whatever system of guidance, they might have in the way of classes, a very great deal depended, as Mr. Gotch had said, upon the personal influence of the master under whom the pupil was placed; and he (Mr. Slater) thoroughly agreed with Mr. Gotch as to its being absolutely incumbent upon a master to give his pupils time to prepare for these examinations, not only out of office-hours, but in office-hours. But they must bear in mind also that whatever amount of guidance they could get in the office, whatever amount of help they might get from classes and lectures, without their own individual effort all would be of no avail. They could not expect to become architects, or even to take a medium position in the architectural world, without hard work; and without hard work they had better give up architecture altogether. He was very sorry to hear what Mr. Appleton had said about the difficulties in the way of students and assistants associating with one another in the country, for he was quite sure that a great deal of good was to be gained by assistants and pupils meeting for mutual discussion; and he could not help thinking that it was a shortsighted policy on the part of the masters in provincial towns to prevent their students from doing that. Much, even in the masters' interests, was to be gained from such mutual discussion; for although one pupil or assistant might be very well up in some subjects, he might be deficient in others, and would be glad of such information as he might be able to get from his own fellow students and assistants. He would also urge upon the architect students to avoid all *mauvaise*

honte or shyness. They were not to be ashamed of showing their drawings freely to their fellows; for it was only by having the bad points criticised that they would learn the good. As he had said before, he could not now enter upon the question of the educational aspect of the question, but he thought it would be a very great help to the Educational Committee now sitting if they had the views of the younger members of the Association, for they would be able to say what they wanted. He had great pleasure in supporting the vote of thanks to Mr. Cates, and he was quite sure that if they knew what an effort it had been for Mr. Cates to be there that evening, they would hardly know how to adequately express their thanks.

Mr. H. O. Cresswell said there were some few points, he thought, in Mr. Cates's paper which ought to be a source of great satisfaction to them. They would see from the Memorial of 1855 that it was really the Architectural Association which first prominently drew the attention of the Institute to the fact that it was necessary for the Institute to found an examination at all; and, as Mr. Cates had said, that memorial might almost have been formulated within the last few years. It was almost marvellous to younger members like himself to find that, although the Architectural Association sent in its Memorial in 1855, it was only in 1889 that they had had anything like a realization of it. They did, indeed, travel slowly in the architectural profession. He thought that the description which Mr. Cates had given of the published returns of the increasing number of candidates for the Examination was eminently satisfactory, and that they might feel that the Examination could now take care of itself under the guidance of the Institute; at all events, he thought that the Association might very well leave it to the care of the Institute. But they had another question for them,—a very much more important one,—and that was education. He was not trammelled as Mr. Slater was, for he did not happen to sit on the Educational Committee to which reference had been made; he would therefore take the opportunity of expressing his opinions, and as they had Mr. Cates and other members of the Institute there that evening, he thought it would be much better to express their feelings freely and openly than to send official letters which only elicited very polite official replies. They were now all in a state of turmoil in that Association on the subject of education. They began their session by a very suggestive and interesting address from their President, which, however, hinted doubts as to whether they were on the right track at all, and whether they ought not to reconsider the whole of their system of education from beginning to end,—one of the principal reasons being that an organisation which worked very well with a small number of members, such as the Association possessed years ago, was not adequate now, considering their largely increased numbers. In addition to that, the requirements and needs of the scientific education of the present day were very much wider and larger; and they had also before them the Institute Examination, which said that if they wished to become members of the Institute they must qualify for that Examination. Was the Association able to give its members the necessary instruction to fit them for that examination? Were they able to do that in the same way that they had been doing hitherto? Those were questions which the Educational Committee had been appointed to consider, and he trusted that they would give them some practical advice on the subject; for he was perfectly sure that if any good was to come out of their Educational Committee, and if the instruction now gratuitously and voluntarily given was to be continued, they must be backed up by the Institute to a certain extent. For instance, supposing that their Education Committee and the general body were to suggest the institution of afternoon classes, would the Institute give them the benefit of its authority over its own members so far as to make the institution of afternoon classes a success? If the members of the Institute would not combine to promise that all their pupils should be free to attend such afternoon classes, the institution of such classes would be quite useless. He had much pleasure in supporting the vote of thanks to Mr. Cates, who was always very willing to help them with all the weight of his experience and authority.

Mr. A. Beresford Pite said he could not help feeling that their gratitude to Mr. Cates would hardly be met by a vote of thanks, for

he had descended from the lofty throne of the Chairman of the Board of Examiners for the discussion. The most practical way in which they could show their appreciation of his kindness would be to continue the discussion freely and frankly. Many of them had been seriously concerned for some months past to hear of the indisposition of Mr. Cates, and they would all congratulate him upon his restoration to health. Those of them who had been through the terrors of the Examination all felt under a great obligation to the Chairman of the Board of Examiners. A distinguished member of the Association said to him,—he was sure Mr. Cates would pardon him for mentioning it,—that, descending to the obnoxious Examination room, shaking with terror, it was like passing into the presence of the sun in mid-winter to meet the Chairman of the Board of Examiners. They had very cordially to thank him for all that he (Mr. Cates) was, and all that he had done for the trembling aspen-leaves of students who had fluttered down those stairs. With regard to the present discussion, it seemed to him that the underlying question,—the underlying principle,—of architectural education was—What was to be the object of that education? When he was asked, in the dim and distant past, the object which he set before himself was to learn to build a thoroughly successful building. Institute Examinations were not heard of then, and he was sure that he would have been considerably flattered if he had had to go up and be examined as to the contents of architectural dictionaries and encyclopedias. If the Institute Examination programme had been put into his hands, and he had been asked to sketch and give a description of a "squint," he was afraid that the "squint" he should have illustrated would not have been a hioscope. If asked to illustrate what was meant by a "respond," he was afraid he should have felt himself equally at a loss. It seemed to him that the programme of the Examination was not calculated to kindle enthusiasm in the breast of a young man who had a love for art. If the Institute would endeavour to develop in the student that artistic instinct which produced enthusiasm, they would find that education need not require forcing upon students: the divine afflatus would extend rapidly if it were delicately fanned by those who understood the fine qualities and the magnificent enthusiasm which the greatest architects had experienced. Enthusiasm was a quality which ought to be encouraged in the architectural student. A very distinguished student, who obtained the Association Travelling Studentship and the Bagin Travelling Studentship, and passed from one of the leading architects' offices in London to the University of Cambridge and took his M.A. degree, said that he was articled for five years to an architect in Manchester, and during that time he never thought that there was anything in architecture. It was not until he came to London that he had excited in him anything like enthusiasm; it was only when he came into contact with artistic souls that he found that there was something in it. Now, he (Mr. Pite) regretted to say that he could find very few traces of enthusiasm in the Institute Examination programme. The candidate was virtually asked to fill up the gaps in a dictionary which began with A and ended with S. He could not help thinking that there was something lacking on the part of the Examination,—something was missing in the way of encouragement to students who were enthusiastic. He found that the most successful architectural students had not of necessity had the greatest educational advantages; in fact, on the contrary, they found that some of the most distinguished architects had been country pupils and assistants, who had come up and put London students to shame by doing work which had set a seal of genius to their claim to be considered architects. Such men had in them qualities, of course, which they could not expect to find ready-made in the ordinary architectural pupil. Such a man naturally had an eye for proportion; he naturally understood what was beautiful in a building; he was able to tell them in a very decided manner, and with very good reason, as a rule, why he liked this and did not like that; why that building pleasantly affected his artistic sense, and why another building offended it. He firmly believed that it was possible to cultivate this artistic sense of architectural beauty even in those in whom it did not appear to exist at all; he thought it was possible to open men's eyes to architec-

tural qualities by architectural rather than what he must call for the moment educational means. It was not impossible to develop the critical faculties of the student. It was possible to obtain from the student an analysis of the impression produced on his mind by an important building. But he would like to know what sort of an answer was expected to question 5 in the programme,— "Describe fully the Parthenon," &c. The answer which would satisfy the Examiners would no doubt be a statement of the number of columns, their height, the number of steps, and so on, instead of a genuinely architectural description. With regard to detail, why not expect from the student, in his description of the Ionic volute, an answer which should illustrate his artistic perception of the reason why the curvilinear form of the volute was introduced in conjunction with the straight lines of trabeate construction? He not only ventured to suggest those points, but he thought that the Board of Examiners of the Institute should defer more fully to the suggestions of Professor Aitchison on such matters. It was with some amount of regret that he noticed that the recommendations of Professor Aitchison had not been followed. The architectural student should also be early set to fully measure buildings; such work should not be left until just before the Final Examination. Personally, he should always feel grateful to his father for paying 10s. to an old sexton in return for the use of ladders and other facilities in enabling him (the speaker) to draw and measure-up a church during the first year of his articled. Moreover, the cultivation of the power of detail drawing was most essential to an architectural student. The study of architectural detail was of great use, and he should be very early put to the measuring-up of detail, for the beauty of buildings must with largely depend upon detail. And he could not help commenting, with tears in his soul, upon the fact that students in the final examination were obliged to bring up drawings of mouldings a *quarter-fall size*. Why, that was disastrous, as mouldings could only be studied real size! He did hope that there was nothing more than a slip on the part of the Examiners; if not, it showed that they were not accustomed to measure-up old mouldings themselves. He thought that if they could draw out the experience of others in that room, the discussion might really be brought to a very profitable issue. He would add an expression of his sense of the extreme kindness of Mr. Cates in being there that evening.

Mr. Walter Millard said that while the Association had to thank Mr. Cates for attending that meeting, the whole profession had to thank him for the way in which he, during the last few years, had conducted affairs, sitting as Chairman of the Board of Examiners, and bringing to a head a scheme which he had aimed at for many years, and which might never have come to a head then but for his labours. Mr. Cates's work in that direction was not thoroughly appreciated yet, but it would be some day. The Association's memorial presented in 1855 was only fulfilled last year. It might even be sent up to the Institute now with one change made in it; for the word "examination" substitute the word "education," and they might send it up to-day. And why should it not be sent? It appeared to him that if they had done that at first, and had asked for education in 1855, it would have been a better way of going about the attainment of their object. He did not want to pick holes in what had been done, for they were only too thankful for it, but why should they not have asked for education first? The Association came into existence for that purpose; it came into existence by force of necessity; and what were they discussing now? How they might best promote architectural education. It seemed evident enough to him that every profession as a body had to see after the education of its members; but here they had had the Institute in existence for more than fifty years, and it had only succeeded in establishing an examination! Men were still asking to be prepared for that examination. How was such preparation to be accomplished? Time might have been saved in the past, and time might yet be saved, by fixing attention upon that one point more closely, instead of bothering about the details of examination. Better and more systematic means of instruction were required. Give these things, and the Examination became a secondary matter. The Association had struggled on all these years]

it grew out of sheer necessity, and at the time of its establishment afforded the only available means for mutual help. But, after all, it was an amateur effort, so to speak. Had they asked in 1855 for the establishment of a thorough scheme of education under a body which represented and was responsible to the whole profession, they would not find themselves in their present backward state. But instead of that the Institute had shirked its responsibility of educating its students, a duty which it owed to the whole profession,* while the Association had gone on playing at independence. He could not help thinking that there was room for change in these respects, and the sooner it came the better. Then, as to the Examination, he had to confess to a sneaking partiality to what Mr. Cates would call, he supposed, Professor Aitchison's "heresy," viz., that there were certain things which were essential to an architect, and there were things which were not absolutely essential. He meant, when he said an architect, an architectural practitioner of to-day. It was possible to distinguish between things which an architect could not ignore,—things in which he must be competent,—and things which might be termed accomplishments. He did not say he would give the title of architect to a man who did not know anything of architectural history or about the detail of past styles; but assuredly there was a difference in degree between that kind of knowledge and what might be described as the knowledge of "bricks and mortar,"—knowledge that the architect must have when he entered upon the practical work of building. Could not those two classes of subjects be dealt with in such a way that the former might be taken as optional subjects, allowing men to go in for honours for subjects beyond those which were compulsory? There was something in Professor Aitchison's contention that, in order to be able to make good bread, it was not necessary to know the name of Pharaoh's chief baker. There was undoubtedly a great difference between the various candidates who presented themselves, but under the present system they were all rolled out like one another. Could not the Examiners indicate to some degree the relative ability of the candidates who passed? Would not the adoption of such a course be an encouragement to candidates themselves? He had in his mind a notion of what he thought would be an ideal Examining Board, consisting of, say, one-third architects, one-third builders' foremen, and the remaining third of master builders, with, perhaps, a sprinkling of clients of both sexes.

Mr. Wilson said that he cordially agreed with the remarks which had fallen from Mr. Pite's lips. He had served his articled in Manchester, and he learned enough, no doubt, to enable him to pass the Examination; but he felt that if he had not come up to London, although he might have become a tolerably good clerk of works as the result of the Examination, he would never have had a chance of becoming an architect. He certainly learned more the first year in London than he had in the previous five years of his life. The Progressive Examinations, Preliminary, Intermediate, and Final, were more calculated to ensure qualified clerks of works than architects. There was one matter to which he would like to draw attention, and that was the present method of classifying the successful candidates, who, he believed, were put in alphabetical order. It seemed to him that course was somewhat conducive to cramming, for so long as a candidate just scrambled through by getting the requisite number of marks he stood as well on the list as much better men. There was no inducement offered by this arrangement to attempt to take high honours, and he would venture to invite Mr. Cates's attention to that subject.

Mr. Cole A. Adams said that if it were only for the purpose of superfluous the vote of thanks to Mr. Cates, he must rise to express, in the very strongest terms, their indebtedness to that gentleman. Every speaker who had risen had testified to the great advantages which Mr. Cates had been the means of giving to the students of the architectural profession, and, from a long acquaintance with his work, he

* We have before pointed out that this idea, which is taken hold of by some of the younger members of the profession, is completely illusory. The Institute of Architects was not founded with any idea of provision for its being an educating body (except in an indirect manner), and more than that the Institution of Civil Engineers; and it is perfectly absurd to expect that it could be so. An examining body it may be, and has in fact become, with very good results.—Ed.

could unhesitatingly say that there was no man who had done more to promote the study of architecture in this country. As years went on they would look upon him as the great founder of a system of architectural education in this country. Their thanks were more especially due to him, after recovering from a severe illness, for coming out that night and reading the paper which had given rise to so much discussion. One of the things which struck him was that now that the Examination was fairly launched, it of course brought with it the question of the education of the student preparing for it. He was not one of those who were disposed to look back with vain regrets at the disadvantages which pupils had had in the past, nor could he hold up his hands with horror at their disadvantages in the present day. Why, the advantages of the student of architecture in the present day were enormous, as compared with the advantages of the students of years gone by. The fact was that it rested with the student to get over what difficulties there might be in his way. If there were no difficulties to be surmounted, what was the use of the Examination? He hoped that things had not come to such a pass that the students of to-day expected everything to be cut and dried for them. That was decidedly a wrong view to take. Nevertheless, he thought that the conditions of the Examination might be improved, and he would be very glad to know whether in the future it would be possible to bring the question of the education of pupils more directly before the principals themselves. He was afraid there would be some difficulty. Mr. Cates and other speakers had laid stress upon the fact that principals would take premiums from their pupils, and the only *quid pro quo* was that the pupils might have "the run of the office." That was a very wrong state of things indeed, and he hoped that the Institute would be able to bring its members to see that they ought to afford facilities for their pupils' attendance at afternoon classes. Pressure must be brought to bear upon the masters to that end. They (the principals) would be gainers by afternoon classes, as well as their pupils. There were many pupils who were not able to attend classes in London during the evening. Mr. Pite had referred to the value of enthusiasm, and there was not one of them who did not recognise that enthusiasm was a quality eminently necessary to those who sought the highest success in their art. They must have enthusiasm, but he really did not know how they were to establish an examination in enthusiasm. That was a quality which must be cultivated in the "Common Room" of the Association, in the classes, in the Royal Academy schools, and wherever students congregated; but it would be a difficult thing to bring it into an examination. An examination, look at it as they would, was necessarily somewhat high and dry. As to the question of how the present advantages of professional education were to be brought home more closely to the men in the country, Mr. Appleton, who had had large experience in such matters, had told them of the objections which the country architects had to their assistants meeting together. Let them see if they could not take a hint from another profession. Solicitors in the country had their agents in London, and he believed it was the practice that every country practitioner taking a pupil sent him up to his agent in London for at least one year of his time; and while in London he had the advantage of studying and presenting himself for his examination. The application of any such a scheme to the needs of the architectural profession just yet was perhaps Utopian; but if in the future some scheme could be devised by which the country student might spend some of his time with a London architect, or if they might look forward to the establishment, not only of a few afternoon classes, but of a building where facilities would be given for further professional instruction, then, he thought, it might be possible for country students to come up to London and enjoy those privileges which were enjoyed by London students, and might have their enthusiasm stirred, and all the best qualities of the mind promoted, not by examination merely, but by contact with others and the contemplation of good work.

Mr. T. M. Rickman said he should be very sorry to go away from that meeting without giving expression to one or two things. One was to thank Mr. Cates, who had done so much for that Association. So long ago as 1855 Mr. Cates was working for them, and was head and

front in the preparation of the Memorial which he had read. He must congratulate the Association upon having at last obtained a paper from Mr. Cates, for he (Mr. Rickman) believed that during the last thirty or forty years they had never had a paper from Mr. Cates, although they had long tried to get one on pendentives, which they hoped to get even now, for that had been a special study with him. As one of those who had assisted in drawing up the Memorial of 1856 he (Mr. Rickman) would like to point out that most of those who formed the membership of the Architectural Association from the year 1852 to 1855, were men who were partly in practice for themselves, but who were partly architects' clerks. They were hardly of the student or pupil class; they were men who were seeking to practise for themselves, but who felt that they had very little chance of doing so without further professional education. They thought the one thing necessary for them was some guiding-post—something to point out what they should learn. At the present time they had plenty of books, small and large, which were most serviceable to them if they wanted to read up any question. They could go to the Institute Library and find not only ancient folios, but modern small hand-books, which put into their hands in a small compass and readily digested the information which they wanted, but which in the old days they did not know how to get. He was perfectly satisfied that, if he had been able to get those books when he was in his articles, he would have been saved a great deal of time which he could have devoted to practice or other subjects. He still leaned to the opinion that they had not been wrong in getting the Examination first, and now that they had it they must not seek to make it too easy. What they needed now, it struck him, was the cultivation of the habit of synthesis, or putting things together. In the early days of the Association they were obliged to proceed slowly and laboriously by analysis. The advantages were all in favour of the present generation of students making themselves masters of their subjects.

Mr. A. W. Earle said that, as other speakers had already stated, it was mainly due to Mr. Cates that they had examinations, and particularly progressive examinations. He had listened to Mr. Cates's address that evening, and had also read through his remarks at the Conference of Architects in 1887, but he was unable to find whether Mr. Cates in any way proposed any process or supplement to the present system of architectural pupillage, so as to enable students to pass the examinations promoted by the Institute. He would suggest that in addition to the establishment of the afternoon classes, which had been spoken of by several members that evening, what they really wanted was a proper system of, say, two years of architectural training, preparatory to, or in some cases succeeding, the serving of a pupillage. He thought that the Association might develop itself into the central architectural school, and that it should provide a course of study of from one to two years.

Mr. F. T. W. Goldsmith said that Mr. Cates must have been pleased with the discussion which his paper had called forth. Mr. Cole Adams and Mr. Pite had struck the keynote of the whole matter in what they said about enthusiasm. He thought that every student, whether young or old, whether just beginning practice, or an old master, must be perfectly aware of the lack of enthusiasm in the present day. He was not a very old student, but he fancied that in the days of his pupillage, when pupils were beset with more difficulties than they met with in the present day, there existed much more enthusiasm. If they were enthusiasts on the lines indicated by Mr. Pite, they would be thorough in their work, but it was just that kind of enthusiasm which the Institute Examinations did not encourage. Those Examinations put a premium on mediocrity, and that was the bane of the whole system. As one speaker had already pointed out, the plan of putting the names of the candidates in alphabetical order was not encouraging. What they wanted was a list of passed candidates published in the order of the number of marks that they received. Then they wanted that old spirit of real love for architecture, not love for mere bricks and mortar, to be recognised. It was only by being brought into contact with great masters of their art, by having opportunities of seeing the masterpieces of their art, and by having opportunities of measuring and studying those works, that enthusiasm

could be aroused. That kind of enthusiasm among the candidates for examination might have been greatly fostered by the Institute, but the Examination which it had imposed upon them was not calculated to encourage that feeling, but rather to put a sort of premium on mediocrity. On the other hand, the Institute had not provided them with any educational means whatever. The medical profession, the legal profession, and other professions had all their systems of teaching; they had their staffs of professors; they had their accepted courses of training and their universities. Only as a result of the *esprit de corps* which resulted from such organisation could they get enthusiasm. The great defects appeared to him to be the absence of early training and the absence of means of finished training in London for country pupils. The practice of country solicitors sending their articled pupils up to London for study had been referred to, and it was, perhaps, owing to that system that he had such a number of thoroughly qualified solicitors. The proposed afternoon classes appeared to him to be most essential, and he was quite sure that Mr. Cates, with other members of the Institute of Architects, would bring their moral force to bear upon their fellow-members to induce them to allow their pupils to absent themselves for the purpose of attending such classes, with the view of presenting themselves ultimately for examination.

Mr. F. R. Farrow said that a suggestion had been made in the course of the discussion for the classification of candidates who had passed the Institute Examination. At one time, when he knew less about the Examinations than he now did, he was strongly in favour of the proposal which had been made, as at the time that he was a candidate he felt, as others felt, that there was no incentive for any one, unless he was going in for the Asphit prize, to work for more than a mere pass. From that point of view it would no doubt be an advantage if the list of passed candidates was published with the names in their order of merit; but at present, at any rate, there was one very serious objection to that proposal, namely, that there were now entering and passing the Examination men in various positions in the profession; there were those who had been many years in practice, and there were at the same time men who were their assistants. He had known principals and assistants who had gone in for the Examination at the same time, and hence he thought it was better that the candidates who passed should be classified together. A classification in order of merit might possibly have the result that the principal might come out of the Examination below his assistant, not necessarily because he did not possess a similar amount of knowledge, but because, having the cares of practice, he had a great deal more to think about than his assistant, and a great many more claims upon his time and attention, so that he would not be able to give the same amount of time and thought to his work as a man who was an assistant. That, then, was the objection which he saw to the adoption of a list of passed candidates classified according to merit. On every other ground he was strongly of opinion that the adoption of a list of names according to merit would be advisable, and he had no doubt that it would be possible in the future, when all the men in practice had passed the Examination, and when those going up were simply students entering for the three progressive Examinations. He would next like to touch upon some points raised by Mr. Pite in his criticisms of the Examinations. He cordially agreed with Mr. Pite in the adverse criticisms which he had been bold enough to utter against the Examination questions as they were now set. It was perfectly heartrending to look through the Examination questions as they were set for candidates, and to have to advise men to get up subjects which were simply "cram," and which were not likely to be of any earthly use to them the day after the Examination,—matters which, as they were only to be retained for the Examination by a sheer effort of memory, were consequently only got up for the Examination, and were forgotten soon after. Mr. Pite, like many others, was very much irritated by the sort of questions that were put. Candidates were asked the names of architects of celebrated buildings, and the dates of their erection; but very often there was no question asked about the artistic design of those buildings. For example, there were no questions about the design of the Parthenon, and he had never seen a question set in the Institute Examination

papers asking candidates to say why the Parthenon was a Doric building, and why the Erechtheion was an Ionic building. These were questions of a great deal more importance than mere strings of questions as to dates and names. The establishment of afternoon lectures, which had been shadowed forth by many speakers, would undoubtedly meet with the approval of the majority of the members of the Association; and if the principals were not amenable to the moral force which it had been suggested the Institute might exercise, he thought the Association was strong enough, with its thousand members, to force the question upon the attention of the principals. But he did not think that force would be necessary; he thought the masters would be only too pleased to allow their pupils to attend classes during office hours. With regard to the difficulties of which Mr. Appleton had spoken in connexion with the affiliated societies, although the Committee had had the matter in hand some time, they had, unfortunately, only two affiliated societies, one of which was the Birmingham Association, and the other was the Glasgow Association, and the affiliation of the latter was nothing more than nominal. It was a difficult matter to deal with. They had been able to get a few young men to meet together in provincial towns, but he was afraid that, with the country students at large, the only means of education that they could offer them,—except where they were sufficiently large and numerous to form associations of their own,—was that of instruction by correspondence. But he had carefully studied that subject, and well knew that such a method of instruction was attended by enormous difficulties, for each man had to be taught individually. They could not form "classes" of corresponding pupils—that was perfectly impossible; and, as Mr. Appleton had said, they could not send the work of the London classes down to them in the country. The country students would have to send their work up to the classes in London, where it would be criticised and then sent back. Under certain circumstances education in London had advantages over country education; there were, on the other hand, many advantages which the country student possessed which they did not have in London. If they were to improve their educational system in the Association they must have money to do it with, and that was the way in which the Institute could help them, not perhaps directly from their own funds,—for their balance-sheet was sometimes not very much better than that of the Association, bearing in mind the relative incomes of the two societies. With the support of the Institute and the provincial societies they of the Association would be able to get funds which would enable them to start a good system of education.

The President, in putting the vote of thanks, said that he had made several notes upon points as to which he should have liked to say something, but as the hour was late and Mr. Cates would have to reply, he would abstain from making those remarks that he otherwise should have done.

The vote of thanks was then put and carried unanimously.

Mr. Cates, in replying on the discussion, said he had to thank them for the manner in which they had received his contribution on that important question. He had listened to the discussion with very great interest, notwithstanding that there had been some severe criticisms of the details of the Examination programme; he must say, however, that he concurred generally with the observations that had been made, although some of them might appear adverse to the work which he had done, which work could only succeed by being possible and meeting all requirements. Enthusiasm such as was manifested by Mr. Pite and Mr. Goldsmith was to be admired, commended, and encouraged in every student; but he did not see how they were to examine students in "enthusiasm." Possibly, as the Examiners became more experienced in the character of the candidates, and in the manner in which they were prepared to meet the questions put to them, some of the views which had been so ably put forth in the discussion would find acceptance, and no doubt questions which would satisfy all possible yearnings after enthusiasm and critical inquiry into what they used to consider the principles of beauty in art,—questions he would

say they used to discuss in the Association many years ago, with an enthusiasm not less than that of Messrs. Pite and Goldsmith. When that advance had been made the student would be able to satisfy his yearnings in those important matters, which the Examination in its present form, perhaps, did not encourage, but which, he hoped, it did not discourage. The programme as it stood, however, in his opinion gave sufficient scope and freedom for the development of that enthusiasm which seemed to be so much desiderated. He was sorry to have heard the observations of Mr. Appleton as to the difficulties which had arisen with regard to the combination of country students for purposes of mutual instruction. He feared that something of that kind would be said, but he thought the difficulty was one which could be overcome as soon as young country pupils and assistants found that they would derive advantages by combination. Young London architects availed themselves of combination in the early days of the Association, when the most active members of that Association were engaged in rival offices,—offices which were as antagonistic as any offices in the country could be; but he was not aware that any harm to their principals ever came of their meeting together. The advantages that followed from associations such as that were many, and the greater the number of such associations the more would old prejudices be broken down and harmony promoted between all classes of the profession. As regarded isolated students, great care had been taken in the Examination programme to give them such indications as to their course of study that, if they had a fair amount of that enthusiasm which was rightly said to be so necessary, they would be enabled to follow out their studies to great advantage, although somewhat independently. There were few towns where a student had not some opportunities for studying, although he might be isolated; there were public libraries and other institutions, of which the student should take advantage, and he was convinced, from the experience which he had of students who had come up from country towns,—from towns which were themselves almost as isolated as the students who resided there,—that there was no difficulty which could not be overcome in acquiring an amount of knowledge sufficient to pass the Examination. Of course, it required energy and perseverance. He could mention several instances in which gentlemen who had been living in country towns had prepared themselves by their own individual efforts, and, without the help of any college or special system of instruction, had passed the Examination in a most creditable manner. It was a most unfortunate thing to hold out to the student the idea that he must rest upon a college or courses of lectures for everything, and that he must have everything set out ready for him. He ought to try and shape his own path, to develop his own individuality,—an effort in which the Examination programme was, he (Mr. Cates) thought, well calculated to help him. He really could not conceive that any knowledge which might be acquired in order to pass the Institute Examination would be of no use to him next day, or that any one could be so foolish as to cast it aside directly, as Mr. Farrow had said. He thought Mr. Farrow had made a great mistake in his remarks about "cram," which every effort was made to discourage. Mr. Farrow himself had done a great deal of good service, if not as a "crammer" at any rate as a "coach" to candidates for the Examination. His system had certainly been most advantageous to many candidates, not by way of "cram," but by consolidating what they had learnt, and showing them how and where to acquire further knowledge intelligently and independently. Notwithstanding what Professor Aitchison had said on the occasion referred to in the discussion, he (Mr. Cates) contended that there was not a single thing in the programme of the Institute Examination that any one who professed to be an architect and a gentleman ought not to acquire; and he hoped that the day would come when that fact would be appreciated by all interested in the success of the Examination. An architect in these days had to come in contact with his clients, and if he was to take his proper position he surely ought to know at least as much of the history of architecture as his client was likely to know; unless the architect had that knowledge, he took an inferior position to his client. Those who criticised

the Examination programme so freely should recollect that that programme was really at present only tentative; the Board of Examiners were, as it were, only feeling their way at present; it was somewhat unreasonable to expect an elaborate programme of that kind to be perfect immediately; it was brought out; they had done their best to make it suitable to the requirements of the general body of students, and if it were found necessary from time to time to make alterations in it, as no doubt it would be found necessary, such alterations and modifications would be made, and the criticisms that had been made that evening would certainly be duly considered. Some remarks had been made about the pass-list, but he thought there was no need to touch upon that beyond saying that he agreed with Mr. Farrow's remarks in reply to those made by Mr. Millard on that point. He thought it was no doubt true that the publication of a class list with the names given in order of merit would do something towards raising the enthusiasm of the candidates; but at the present time the difficulties and objections appeared to be insuperable. At some future period, when no such difficulty as had been pointed out could happen, it would no doubt be a question worthy of consideration whether such a class list as had been asked for should be provided; or, better still, an honours list, after special examination for honours, which would signify distinction in scientific and artistic knowledge. He did not think that at so late an hour he need say much more, for he found that the observations of several of the speakers had been met by those who followed them in the discussion. He would only say, in conclusion, that in drawing up the Examination programme, the endeavour had been made to set forth only those things which were essential to an architect in these days,—no more and no less. He thanked the members for the attention which they had given to the subject, and for the great kindness with which they had received him.

The meeting then terminated.

CONCRETE FLOORS.

SIR,—In your article on "Concrete Floors," in the *Builder* of October 26, 1889, you remark that you know of no experiments on concrete beams. A few such experiments were made by Mr. C. Colson, M.L.C.E., in 1887, and were printed in the *Proceedings Inst. C.E.*, vol. 54.

The proportions of the concrete used were 6 screened, rounded, and smooth harbour shingle, 3 sand, and 1 Portland cement.

In these experiments a beam 1 ft. 9 in. by 9 in. deep, 8 ft. 3 in. span, tested at twenty-eight days, broke under 5 cwt. centre load, when simply laid on supports, but another of these same dimensions and proportions, but securely bracked at the ends, and tested at thirty days, cracked on the underside under a centre load of 5 cwt., but only ultimately failed by complete disintegration of the materials under a centre load of 1-292 tons, thereby showing that a great increase of strength was caused by blocking the ends so as to entirely prevent longitudinal movement, and, in fact, making the beam serve as a flat arch.

Does not this seem to show that Mr. Caws's floors are standing as domes and not as simple supported slabs?

C. H. COLSON.

H. M. Dockyard, Malta, Jan 21.

"POPE'S CHIMNEY VALVES."

SIR,—Can you or any of your correspondents, tell me where to obtain "Pope's chimney valves"? These valves were a patent of Messrs. Pope, Iron-mongers of the Edgware-road, but they have now retired from business, and I cannot learn to what firm the patent has been transferred. These valves were made to fit in the place of the ordinary registers of a grate, and, having two ground surfaces, they wore, when closed, air and smoke-tight, and prevented the nuisance of down-draught where two fire-places happened to be in rooms communicating.

W. H. C.

TAR PAVING.

SIR,—I shall be much obliged if some correspondent will inform me of a good plan, not too expensive, for making tar foot-paving for a provincial town; or refer me to the *Builder* within the last ten years.

A. NOVICK.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—V.

PRACTICAL UNITS.

EARLY all the quantities with which physical science deals can be measured in units derived from the three fundamental units of Length, Mass, and Time. The fundamental units which have been chosen are the centimetre, the gramme, the second. Any system of units based on these three standards is said to belong to the centimetre-gramme-second system, or, briefly, to the C. G. S. system.

For the purposes of electrical measurements two C. G. S. systems are used,—the electrostatic and the electro-magnetic. The former is based upon the force of attraction or repulsion which two electrically-charged bodies exert on each other; the latter upon the force which an electric current exerts on a magnetic pole. The electrostatic units are of great use in dealing with problems concerning electricity at rest. The electro-magnetic units are employed for measuring the effects of electricity in motion; and, as these papers are concerned almost entirely with electric currents and magnetism, we shall confine our attention to the electro-magnetic system.

Unfortunately, the C. G. S., also called the "absolute" electro-magnetic units, cannot be conveniently used in practice; indeed, they have never been named. Some are many millions of times too small; others as many times too great.

The practical units, which are suitable for telegraphic or electric lighting purposes, are multiples or fractions of the absolute units, and they are defined so that the same relationship holds between them as between the absolute ones. As the practical electrical units alone have received definite names, the fact of naming a unit will at once distinguish it from the corresponding absolute unit.

It has been shown, fig. 6, p. 66, how a conductor carrying a current is surrounded by a magnetic field. If such a conductor is bent into a circle, a certain field is produced at the centre, and it is the strength of this field that is used for defining "unit current" flowing in the ring.

"Absolute unit of current flowing in an arc 1 centimetre long, and of 1 centimetre radius, produces unit magnetic field at the centre of the arc."

The Ampere is one-tenth the value of the absolute unit of current.

As it is impossible to get a field from an isolated arc of current, a complete circle has to be used in practice, the length of its circumference being 2π centimetres; hence, the absolute unit of current flowing in a circle of one centimetre radius produces a field of strength 2π at the centre, and the Ampere produces a field of strength $\frac{2}{5}\pi$.

The Coulomb is the quantity of electricity conveyed past any section of a conductor by one Ampere in one second.

It may be advisable at this point to make a slight digression, so as to make more clear the nature of the quantity measured. Let Fig. 9

Fig. 9.

represent a portion of a conductor through which an electric current is flowing from A to B. We have assumed electricity to be an incompressible fluid, so that a flow of electricity in the conductor A B is analogous in many respects to a flow of water in a cast-iron pipe A B. In the case of water, if we know the area of the section of the pipe, S, and also the number of grammes that flow across S per second, it would be easy to calculate the average speed with which the particles of water travel at S. We can do this, because at any temperature we know the volume of a gramme of water. With electricity it is different. By measuring the current in Amperes, we know at once the number of Coulombs that pass through S, a section of the conductor; but not knowing the volume of a Coulomb, we cannot calculate the velocity proper of the electricity as it passes S. On this point confusion sometimes arises as to the nature of the electric current, because it is known that if an electrical disturbance takes place at A, its effect may be transmitted to B at a velocity of about 185,000 miles per second; but this proves nothing concerning the speed of electricity in a current.

If A B is a pipe full of water, and more water is forced in at A, water begins to flow out at B at virtually the same instant. This does not prove that water is flowing from A to B with practically infinite velocity; on the contrary, the highest speed at which any portion of the water is flowing may be but one centimetre per hour or less.

Certain so-called measurements of the speed at which a current flows, and deductions therefrom, have been made from time to time. It is therefore of as much importance, when dealing with the question of measurement, that a student should know what he cannot measure, as well as what he can and does.

Returning to fig. 9, if A B is an electrical conductor, and electricity is being driven from A to B, a certain electro-motive force is necessary, and in forcing the current against the resistance or other obstruction, a certain amount of work is done, the effects of which reappear as heat, chemical decomposition, or some other form of energy.

When the quantity of work done in A B is 10^7 ergs* for every coulomb which passes S, the electro-motive force, or difference of potential, between A and B is a Volt.

The word resistance as applied to electrical phenomena has a somewhat restricted sense. It is used to denote the obstruction that a current experiences when it flows through a conductor, which has been called friction; and the sole effect produced when "resistance" in its restricted sense, is the only obstruction encountered, is the production of heat. The unit of resistance is the Ohm. A conductor of 1 Ohm resistance allows a current of 1 ampere to flow through it when a difference of potential of 1 volt is maintained between its ends.

The relationship between the ampere, volt, and ohm may be roughly expressed by saying that "1 volt drives 1 ampere through 1 ohm."

When an insulated conductor is given a charge of electricity its potential rises, and the amount by which a given charge will raise the potential depends upon the conductor's size, shape, and position with respect to other conductors; or, what is called its "capacity for electricity." When a charge of one coulomb raises the potential of a conductor by one volt its capacity is one Farad.

The Coulomb, Ampere, Volt, Ohm, and Farad are all the electrical units with which we have to deal at present.

Occasionally when measuring very large or very small quantities, the prefixes meg(a) and micr(o), respectively multiplying and dividing the units before which they are placed by a million, are used. Thus the farad is inconveniently large, so that capacities are generally measured in micro-farads; while again, when enormously high resistances have to be measured, they are expressed in megohms.

The nature of the "resistance" which an ordinary conductor offers to the flow of electricity within it has already been explained in a previous article; knowing, in addition, the relations of the ampere, volt, and ohm, to one another, it is now possible to write down the equation expressing "Ohm's Law,"—

$$C = \frac{E}{R}$$

Showing the current C, which the electro-motive force E will send through a conductor of resistance R. Ohm's law is best regarded as the mathematical definition of what is meant by the resistance of a conductor. The above equation should then be written in the form:—

$$R = \frac{E}{C}$$

The daily use of the practical units has led electrical engineers to adopt two new mechanical units, the Joule and the Watt. The Joule is a unit of work or energy equal to 10^7 ergs, and before being called the Joule was called the volt-coulomb. The reason will be seen on referring to the definition, previously given, of the volt. The Watt was called the volt-ampere. It is therefore a measure of power, and is the rate at which work is done when a volt is producing a current of one ampere.

Let $E = c.m.f.$, producing a current in a circuit, $C = \text{current}$, $R = \text{resistance}$, $t = \text{the time the current has been flowing}$, then $Q = Ct$

* When the point of application of a force of 1 dyne moves through a distance of 1 centimetre in the direction of the force, the quantity of work done is 1 erg.

is the quantity of electricity that has been transferred past any point.

The total amount of work done is:—

$$J = EQ$$

The rate at which this work has been done is:—

$$W = \frac{EQ}{t} = EC$$

from Ohm's law, the number of watts, which is the quantity generally required, may be equally well calculated from any of the following expressions:— EC , C^2R , $\frac{E^2}{R}$, $\frac{J}{t}$, according to the details of the circuit given. The time, t , must always be measured in seconds.

The following quotation from Clerk Maxwell should be thoroughly appreciated by all those who are engaged in making scientific measurements of any description:—"Every expression of a Quantity consists of two factors or components. One of these is the name of a certain known quantity of the same kind as the quantity to be expressed, which is taken as a standard of reference. The other component is the number of times the standard is to be taken in order to make up the required quantity. The standard quantity is technically called the Unit, and the number is called the Numerical Value of the quantity." Attention must be specially directed to the words: ". . . the name of a certain known quantity of the same kind as the quantity to be expressed. . . ."

The veriest beginner does not need to be told that to refer to "3 watts" as "3 wats" would be wrong, there is never any difficulty with the "numerical value." Yet it is but too common to hear of "the work of so many watts" or "a power of so many joules," although the same people would never be guilty of saying "the weight of eight seconds" or "length of three pounds." It may be well to collect together the various units referred to and to state distinctly of what kind of quantity they are the standards.

Electrical Units.

THE AMPERE is the unit of CURRENT.

" COULOMB " " QUANTITY.

" VOLT " " E. M. F.

" OHM " " RESISTANCE.

" FARAD " " CAPACITY.

Mechanical Units.

THE JOULE is the unit of WORK and ENERGY.

" WATT " " POWER.

There is nothing absolutely wrong in speaking of a current of six amperes as a current of six coulombs per second, a power of eight watts as a power of eight joules per second or four hundred and eighty joules per minute; it is simply inconvenient and as unnecessary as to refer to a mass of "one gramme" as "the mass of a cubic centimetre of water at its maximum density"; it is foolish to use eight words where one will do, though not positively wrong.

The most important step made in any science is when experimental results which have previously been qualitative are made quantitative. Beginners cannot do better therefore than duly consider in every case what "kind of quantity" is referred to, and by the aid of what single unit it can be measured.

Berlin Technical College.—The official *Centralblatt der Bauverwaltung* publishes a notice showing that 1,043 matriculated, and 414 non-matriculated students are this winter attending the lectures, classes, and practical courses of the Royal Technical College at Berlin. Of the 1,043 matriculated students, 176 are non-German; of which number 58 fall to Russia, 31 to Norway, 17 to Austria, and 10 to England. North America and Luxemburg each have 8, Holland 7, Roumania 6, Sweden and Switzerland each 5, Greece 4, the Brazilian Republic and Japan each 3, Italy, Chili, and Servia each 2, whilst Spain, Turkey, the Argentine Republic, Mexico and Siam each have one representative. Of the ten Englishmen, two are studying architecture, two are attending the chemistry courses, and the remaining six are working with the engineers. The educational staff of the college consists of 63 professors in ordinary, 29 visitors, and 96 assistants. Professor Jacobsthal, of the Architectural Division, holds the title of "Rector" for the year 1889-90, and Professor Schlichting, of the Civil Engineering Division, who held the title for the year 1888-89, being "Pro-rector." The very popular Professor Ende, Hon. Corresponding Member of the R.I.B.A., has not been able to read this session on account of ill-health.

RECENT SALES OF PROPERTY:

MEETINGS.

- SATURDAY, FEBRUARY 1.
St. Paul's Ecclesiological Society.—Annual Meeting. 2.30 p.m.
Association of Public Sanitary Inspectors.—Sixth Annual Dinner. 6 p.m.
- MONDAY, FEBRUARY 3.
Royal Institute of British Architects.—(1) Announcement of the name of the person the Council propose to submit to Her Majesty the Queen as the recipient of the Royal Gold Medal, 1890. (2) Mr. J. Alfred Gatch on "The Renaissance in Northamptonshire." 8 p.m.
Royal Academy.—Professor Aitchison, A.R.A., on "The Private Houses and Palaces of the Romans." 8 p.m.
Royal Institution.—General Meeting. 8 p.m.
Society of Engineers.—Presentation of Premiums awarded for papers read during the past year. (2) The President, Mr. Henry Adams, will deliver his Inaugural Address. 7.30 p.m.
Society of Arts (Centur Lectures).—Mr. Silvanus P. Thompson, D.Sc., on "The Electro-magnet." III. 8 p.m.
Victoria Institute.—8 p.m.
Cloths of Works Association (Carpenters' Hall).—Monthly Meeting. 8 p.m.
Leeds and Yorkshire Architectural Society.—Mr. E. Sulistars on "Mural Painting." 7.30 p.m.
Liverpool Architectural Society.—Mr. T. Haigh on "Mouldings." 7 p.m.
- TUESDAY, FEBRUARY 4.
Institution of Civil Engineers.—Mr. W. H. Wheeler, on "Bars at the Mouths of Tidal Estuaries." 8 p.m.
Society of Biblical Archaeology.—8 p.m.
Glasgow Architectural Association.—Mr. H. D. Walton on "The Influence of French Renaissance on Modern Architecture." 8 p.m.
- WEDNESDAY, FEBRUARY 5.
Free Lectures to Artisans and others on Matters Connected with Building.—Mr. Banister Fletcher on "Architecture in all Ages," Carpenters' Hall, London-wall. 8 p.m.
Civil and Mechanical Engineers' Society.—Mr. C. H. Cooper on "Recent Progress in Sewage Treatment." 7 p.m.
British Archaeological Association.—Mr. Michael Drury on "A causeway, supposed to be Roman, at Lincoln." 8 p.m.
Builders' Workmen and Clerks of Works Institution.—Ordinary meeting. 8.30 p.m.
- THURSDAY, FEBRUARY 6.
Royal Academy.—Professor Aitchison, A.R.A., on "The Private Houses and Palaces of the Romans." II. 8 p.m.
Royal Institution.—Mr. E. Roscoe Mullins on "Sculpture in Relation to the Age." III. 8 p.m.
Edinburgh Architectural Association.—Mr. J. Kinnear will read a paper. 8 p.m.
- FRIDAY, FEBRUARY 7.
Institution of Civil Engineers (Students' Meeting).—Mr. C. F. Fowler on "Reclamation of Land on the River Tees." 7.30 p.m.
Society of Arts (Indian Section).—Dr. Schlich on "The Utility of Forests and the Study of Forestry." 5 p.m.
- SATURDAY, FEBRUARY 8.
Architectural Association.—Visit to Mr. Doyle Cart's theatre, Shaftesbury-avenue.

Miscellaneous.

The Sanitary Institute.—A course of thirteen lectures for sanitary officers, specially adapted for candidates preparing for the Institute's examination for inspectors of nuisances, has been arranged for. These lectures are a continuation of the courses previously held by the Parkes Museum, and it is proposed to repeat the course twice each year, to suit the requirements of persons preparing for the examinations of the Institute. The lectures will comprise the subjects scheduled for those examinations. The course will have a further use in supplying the wants of acting inspectors and of other persons desirous of obtaining a practical knowledge of sanitary requirements and regulations. At the close of each lecture, students will be allowed to ask questions upon the subjects treated of. The lectures will be given on Tuesdays and Fridays, at 8 p.m., in the Parkes Museum, 71A, Margaret-street, W., and students attending the course will be granted free admission to the Museum and Library during February and March.

The Berlin Building Trade.—The building trade in Berlin last year was very brisk, the population of the German capital increasing through immigration so rapidly that the demand for dwellings nearly exceeds the supply. This is particularly the case with small houses, the rents of which have in consequence risen greatly; but this was not the case with more expensive dwellings. There was a great deal of speculation in house property in Berlin last year, and as it was often recklessly indulged, a building crisis like that prevailing in certain Italian towns was feared, but it was averted. Several new house-building companies were floated last year, and certain desirable house properties changed hands three to four times at advancing prices.

St. Giles's, Cripplegate.—In continuation of last year's restoration of this church, when Messrs. Jones & Willis made and fixed the wrought-iron screen and the oak and ebony altar-table, they have now completed the new system of lighting. The whole of the old fittings, pipes, &c., have been removed. The new system embraces the lighting of the nave and chancel by drops from the centre of each arch; the coronæ are each of eight lights, and are of hammered leaf-work to match the screen. The whole work has been carried out from the designs and under the superintendence of Mr. F. Hammond, architect.

Wood-paving in Berlin and Paris.—A German contemporary draws attention to the small progress made in wood-paving in Berlin compared with other European capitals; for instance, Paris and London. It is further pointed out that, whilst the wood-paved roads in the two latter towns are comparatively smooth and even, they are in Berlin rough and cut-up, owing, it is said, to the different modes of shoeing horses in use; but more probably to a defective system of laying.

The New Swedish Houses of Parliament.—The designs sent in for the new Houses of Parliament to be erected in Stockholm are now being exhibited. The deciding jury has, in addition to the prizes awarded, and to which we recently referred, decided upon purchasing two more designs, by Herr E. Strömkir and Herr G. Krüger for 1,000 kronor each, in order that they may be used in parts for the final design.

Royal Victoria Hall (the People's Palace for South London), Waterloo-road.—The following science lectures will be given during February at the above Hall:—Feb. 4, "Algeria and Morocco," by Mr. Henry Backburn; Feb. 11, "Arsenic," by Mr. Ward Goldridge; Feb. 18, "Eyesight and some of its Defects," by Dr. Collins; Feb. 25, "Sinal and Pale-tine," by Sir Charles Wilson.

New Married Quarters, Royal Marines, Chatham.—The tender Messrs. J. G. Naylar & Son, of Rochester, has been accepted by the Lords of the Admiralty for the erection of these buildings. The cost of the work will be between 5,000*l.* and 6,000*l.*

Election of a Royal Academician.—At a general assembly of the members of the Royal Academy last week, Mr. Ernest Albert Waterlay, painter, was elected an Associate.

Mr. F. W. Maxwell, of Manchester, having successfully passed the requisite examination, has been admitted as a Fellow of the Surveyors' Institution.

Electric Lighting at the British Museum.—On Tuesday evening there was a "private view" of the installation of electric lighting just carried out at the British Museum. On November 17, 1888, when the Museum Estimates were discussed in the House of Commons, the Government were pressed from both sides of the House to open the British Museum in the evening. The First Lord of the Treasury undertook to communicate with the Trustees with that view. Provision was made in the Museum Estimates for 1889-90 for installation of the electric light in the public galleries, in addition to the then existing limited installation which served the Reading Room, entrance-hall, &c. This latter partial installation has now been incorporated into the new system. The public galleries on the ground-floor are lighted by arc lamps, sixty-nine in number, of various powers. Those on the upper floor are lighted partly by arc lamps, partly by glow lamps. The arc lamps are fifty-seven in number; the glow lamps, which are used in the long suite of vase and bronze rooms on the west, and in the ethnographical gallery on the east, where the exhibits are seen to better advantage under this kind of light, are 627 in number. In addition, there are five large arc lamps in the Reading Room, and six in the courtyard, and upwards of 200 glow lamps in offices and passages. The total current required to work the whole of the lamps is nearly 1,200 amperes, with an E.M.F. of 115 volts at the lamp terminals; and this output is produced by the expenditure of nearly 200 horse-horse power. The current is generated by four Siemens dynamo machines, each capable of giving an output of 450 amperes and 130 volts, which are connected to a general switch-board in the engine-room by means of which they can be put to work in parallel to any or all of the circuits. The switchboard is fitted with instruments indicating the current given off by each dynamo, and four circuits are led from it round the Museum, two for the upper and two for the lower floor. The main wires are laid outside the building. In order to insure safety, and to guard, as far as possible, against failure of light, the motive-power is in duplicate. The four dynamos are driven in pairs, each pair by a separate engine with a separate countershaft. Each engine has a separate steam-pipe, in direct communication with the boilers, and there is an ample reserve of boiler power. The power of the engines and dynamos is so adjusted that each of the two sets is capable of working the whole of the lamps in those galleries proposed to be lighted in any one evening, the other set standing by ready to work. The eastern and western wings of the Museum will be opened on alternate week-day evenings. Further, in order to work, if required, at half-power, or in order to provide half-light for the whole of the galleries, which light should suffice for an emergency such as a sudden fog or accident, the lamps are connected in pairs alternately, so that, half of the number being cut off, the light of the other half still remains evenly distributed. The steam-engines have been supplied and erected by Messrs. Marshall, Sons, & Co., Limited, of Gainsborough, and the electrical work has been executed by Messrs. Siemens Brothers, & Co., Limited. The installation has been carried out under the supervision of Mr. W. H. Prece, a F.R.S. Electrician to the General Post-office, who acts as Consulting Engineer to the Trustees of the British Museum.

The Association of Manchester Students of the Institution of Civil Engineers held their annual dinner on Wednesday evening, Jan. 22, at the Victoria Hall, Manchester, the President, Mr. F. Crook, M.Inst.C.E., in the chair, supported by Mr. J. Alderman W. H. Bailey, J.P., Mr. J. D. Moulden, sec. of the Manchester Architectural Association, Mr. J. H. Lynde, and many other gentlemen.

Main Drainage and Sewerage Works, West Ham.—The Local Government Board have recently held two inquiries at West Ham upon the application of the Corporation for permission to carry out a large extension of the main drainage system, pumping, and outfall works adjoining the metropolitan boundary, designed by the Borough Engineer, Mr. Lewis Angell; and on the 23rd ult. sanction was given for a total expenditure of 98,620*l.*

The New City Engineer of Liverpool.—The *Liverpool Daily Post* says that Mr. H. Percy Bonhous, the new City Engineer, will commence his duties on the 8th inst.

LONDON.—For the erection of a school to provide accommodation for 708 children on the site in Cubitt Town, for the School Board for London. Mr. T. J. Bailey, architect.

Table listing contractors and amounts for the school project in Cubitt Town, including Kilby & Gayford, W. Cubitt & Co., D. Charlton, etc.

LONDON.—For new bank premises, No. 275, Brixton-road, S.W. for the North Brixton Branch of the London and South-Western Bank, Limited.

Table listing contractors and amounts for the bank premises at No. 275, Brixton-road, including Co-operative Builders Society, Nightingale, etc.

LONDON.—For the erection of a school-keeper's house and a cookery centre on the Baltic-street site, for the School Board for London.

Table listing contractors and amounts for the school-keeper's house and cookery centre, including Kilby & Gayford, W. Cubitt & Co., etc.

LONDON.—For alterations and additions to the Alexandra Club, 12 Grosvenor-street, London, W.

Table listing contractors and amounts for the Alexandra Club alterations, including Aldin Bros. & Davies.

LONDON.—For alterations and additions to the "Ford Burrell" Tavern, Vauxhall Bridge-road.

Table listing contractors and amounts for the Ford Burrell Tavern alterations, including Mollett, Head, etc.

YARMOUTH.—For concrete paving, for the Corporation of Great Yarmouth.

Table listing contractors and amounts for the concrete paving in Yarmouth, including J. Lawrence, W. B. Wilkinson, etc.

REDHILL (Surrey).—For the erection of a new printing warehouse, and additions to existing printing works, for The Homard Publishing Union (Limited).

Table listing contractors and amounts for the printing warehouse in Redhill, including Gills & Sons, Gould & Brand, etc.

STRATFORD.—For certain alterations and additions to No. 32, Broadway, Stratford, E.

Table listing contractors and amounts for alterations at No. 32, Broadway, including B. E. Nightingale, J. S. S. Williams & Son, etc.

SUBSCRIBERS in LONDON and the SUBURBS, by prepaying at the Publishing Office, 19s. per annum.

TO CORRESPONDENTS. If then your notices of architectural sites must be very limited.

Terms of Subscription. THE BUILDER is supplied twice from the Office to residents in any part of the United Kingdom at the rate of 19s. per annum.

W.H. Lascelles & Co. 121, BUNHILL ROW, LONDON, E.C. Telephone No. 270.

HIGH-CLASS JOINERY. LASCELLES' CONCRETE. ARCHITECTS' Designs are carried out with the greatest care.

BEST BATH STONE. CORSHAM DOWN. FARLEIGH DOWN. WESTWOOD GROUND. STOKES GROUND.

THE CHELYNCH STONE. THE BRAMBLEDITCH STONE. Prices, and every information given, on application to CHARLES TRASK & SONS.

HAM HILL STONE. The attention of Architects is especially invited to the durability and beautiful colour of this material.

Asphalte.—The Seyssel and Metallo Lava Asphalt Company (Mr. H. Glenn), Office, 42, Poultry, E.C.

SPRAGUE & CO'S INK-PHOTO PROCESS, 22, Martin's-lane, Cannon-street, E.C.

DRY MAHOGANY, WAINSCOT, WALNUT, TEAK, &c. EXTENSIVE AND VARIED STOCK.

WILLIAM BLOORE, 80 to 90, BOND STREET, VAUXHALL, and 57 to 67, SOUTH LAMBETH ROAD, S.W.

MICHELMORE & REAP, Manufacturers of CHARLES COLLINGES' PATENT COLLINGES' PATENT HINGES.

TWELVE GOLD AND SILVER MEDALS AWARDED. IRON CISTERNS F BRABY & CO. VERY PROMPT SUPPLY. LARGE STOCK READY. CYLINDERS FOR HOT-WATER CIRCULATION.

The Builder.

On the Weathering of Oolite Building Stones.

For the greater number of the freestones used in building in the South and East of England are geologically known as oolites. Portland, Bath, Douling, Chilmark, Minchiampton, Ancaster, and Weldon, are amongst the principal stones included under this term. Everyone knows that the value of these materials in regard to their weather-resisting properties is not the same: that they are widely divergent in this respect. Some of the stones are softer than others, their grain and lie are different, and what may be suitable for some purposes may not be recommended for others,—they have specific uses. It is remarkable that so little attention has hitherto been paid by scientists to the causes of this variation in weathering, and it is yet more surprising that educated people who deal with this class of freestone every day of their lives in their business avocations should understand so little concerning the properties of the material. They know by repute that one stone is better than another, though they would in many cases not be able to make the differentiation were the blocks of each kind placed before them for selection. A certain stone may be specified for a building, but many amongst us could not say, definitely, from an inspection of the stone itself brought on to the work, whether this was what was ordered or not. From our faith in those who have executed the order for us we have often every reason to believe that the material supplied is that which was specified, but it is not advisable to be more independent in the matter? It is not a difficult thing to learn the peculiarities of, say, a dozen of the leading oolites in the market, but they must be carefully and minutely studied in the first instance.

An oolite is a limestone differing from all other calcareous building-stones in that it is largely made up (sometimes entirely) of small shot-like granules, often bound together with a cementing material. This congregation of granules imparts to the stone the appearance of the roe of a fish, hence the name oolite (Gr. *oou*, egg; *lithos*, stone). Oolites differ

from each other in the size and abundance of the granules, the nature of the cementing material, and the presence of more or less foreign matter, such as shells, grains of sand, &c., intercalated amongst and bound together with the granules. They may also be distinguished, in some cases with comparative ease, by difference in tint, though when spread over a wide geographical area this character is of no importance. It should be distinctly remembered that these peculiarities are not necessarily confined to any one district, or even to one quarry. That is to say, we do not find that a peculiar class of structure is indigenous to a definite area, but, on the contrary, we may, and do, get four or five entirely distinct kinds of structure in the oolite from one quarry. But in the vast majority of instances these different appearances occur along separate horizons,—each horizon presents some readily distinguishable feature, known perfectly well to the quarrymen. Where all the kinds of stone from a quarry are, to the superficial eye, of distinct tint or grain, the outsider has no difficulty in seeing that the stone specified is that actually sent on the building; but where (as is often the case) the quarry presents two stones having a general resemblance to each other, they may not be distinguishable except to the trained eye, and the difficulty of seeing that the specification has been adhered to proportionately increases. Outward appearances of stone are very deceptive. A stone derives a certain amount of local repute from its having weathered well in old buildings, and rightly so; but it by no means follows that because a somewhat similar material is found in the vicinity that it will weather as well, though this is the kind of conviction that is largely traded upon. Two oolites having the same general appearance may weather very differently from each other, one being good stone and the other bad, the cause of which will presently be explained.

If we take any horizon in a quarry, as defined by jointing, and examine the stone at intervals along the bed, we shall find that, except in a few notorious instances, it very seldom varies in structure or quality for short distances; but, when that same horizon is traced into another quarry a few hundred yards off, or even in the same quarry where the workings run underground for long distances, the character of the stone often varies, it may be slightly, yet quite enough to alter a good horizon into a bad one. Conversely, a horizon that may give a had stone

in one quarry may improve in quality as it is traced a short distance away into another. We mention these facts to show how fallacious it often is to specify a stone bearing a good name, and found along a definite horizon, unless the quarry from which it is to come is also mentioned; and, likewise, how absurd it is to depreciate the value of the material solely because stone of the same name has proved to weather indifferently. The bad stone may have come from a point three miles off from where the stone bearing the same name is of excellent quality. The circumstance is not always appreciated, and it serves to explain many apparent anomalies in regard to the weathering of oolites.

Let us now examine the mode of weathering more minutely. In all works treating of the disintegration of stone, we find that great stress is laid on chemical composition; it is a fundamental axiom that stones largely made up of certain mineral matter of known chemical composition are proportionately attacked by atmospheric agencies. If the chemical composition in the aggregate is such that, theoretically, it is capable of being readily disintegrated, the stone is judged from that standpoint. This is why we find, in the elaborate treatises referred to, that attention is first paid to chemical analysis of the material. Stone merchants and quarry-owners are usually careful to circulate the results of a chemical examination of their stone, and we have often wondered whether they know what it really means, and whether the recipients of the circulars are any the wiser after reading them. Once we put the question to a well-known quarry-owner as to why he had had his material chemically analysed, and his reply was that "It was the proper thing to do." Another answered that, "By means of the chemical analysis we are enabled to tell how the stone will resist the action of the weather." Pressed as to how he would, within reason, judge of the analysis in this respect, he said that "He himself did not sufficiently understand the subject"; and this we find is the refuge behind which most people take their stand. The fact is that the value of chemical analyses in regard to estimating the weathering qualities of stones, and particularly oolites, has been very much overrated. We do not deny that in a general sense this analysis is good; it might be useful, for instance, in assisting us to distinguish a limestone from a magnesian limestone, or from a close-grained sandstone. In other words, it is useful in differentiating

rocks of extreme character. But when we come to consider any particular section of building-stones, such as the oolite freestones now under discussion, the value of a chemical analysis is reduced to a minimum. Oolite after oolite may be subjected to the chemist, and, within very circumscribed limits, the result in each case is about the same; we get a large proportion of carbonate of lime, a little carbonate of magnesia, iron, alumina, silica, &c. Two stones may show an almost identical chemical composition, and yet one is known by experience to weather well and the other badly. Where, then, does the use of the chemical analysis come in? Clearly in a case like this it is of no practical value whatever. But this is not all. We should not mind so much if the results of the chemical analysis were only negative in character; when, however, we come to learn that in certain cases they are so very misleading as to result in an altogether incorrect idea of the value of the materials to which they refer, and especially when we know that the erroneous impressions are being traded upon, we can hardly refrain from inquiring further into the matter.

We give a few published analyses of well-known oolite building-stones by way of illustration:—

Chemical Analyses of Oolites.

	Bath Box.	Portland.	Chilmark.	Doubling.	Amcastar.	Barnack Mill.	Ketton.
Carbonate of lime	94.52	95.16	76.0	95.89	93.59	93.4	92.17
Carbonate of magnesia	2.50	1.20	3.7	0.11
Silica	1.24	10.4	2.44	2.90	3.8	4.10
Iron	1.29	0.50	2.0	0.83	0.80	1.3	0.99
Alumina	0.79
Water	1.73	1.94	4.2	0.28	..	2.71	1.5
Loss	2.33
Bitumen	trace	trace	trace	trace

We will now endeavour to trace the connection between denuding agents and the weathering of oolites from a chemical point of view. It will be noticed in the above table that carbonate of lime is the main constituent of each rock mentioned, and there can be no doubt that this is the mineral chiefly attacked in the process of disintegration, and the great chemical disintegrator is rain. Carbonate of lime is insoluble in water, but as rain contains a certain proportion of carbonic acid, the carbonate of lime is reduced by this acid to a bicarbonate, which is soluble, and in the end the surface of the stone is dissolved; and washed away, and each successive surface is treated in a similar manner. *Ceteris paribus*, it would appear that the stone containing the highest percentage of carbonate of lime is the worst in quality; yet this is not necessarily so,—it is not even the rule. Anyone who understands the relative qualities of the stones mentioned in the table, will see what we mean. The chemical analysis of chalk is practically identical with that of pure statuary marble, both being wholly composed of carbonate of lime, but everybody would admit the absurdity of suggesting that the former substance is as durable as the latter. Why not, if the percentage of carbonate of lime present has anything to do with it?

The same remarks apply to the carbonate of magnesia. Again, we hear on all sides that it is desirable for an oolite to possess a great proportion of silica, on the ground that silica is to all intents and purposes an insoluble mineral. But we submit that a chemical analysis is wholly incapable of determining the question as to whether an oolite more durable or not. Suppose (as we know is frequently the case) the silica is present only in the form of grains of sand interspersed amongst the oolite granules, in what way can its presence render the stone more durable as a whole? On the stone being attacked by carbonic, hydrochloric, sulphuric, or other acid in the atmosphere, the grain of sand would simply be weathered out

and fall away,—it would lend no support to the material. Then, again, the presence of iron might be thought to be deleterious to preservation, and so it is in anything like large quantities; but its presence in oolite building stone is manifested by the colour of the rock, for the cream and blue tints are mainly due to iron; so that the presence of the mineral can be foretold merely by an appeal to common knowledge, and without an analysis. Iron does not enter so materially into the composition of the stones under consideration as to affect their weathering properties to an appreciable extent, though in certain oolites not used as building stones that mineral is sufficiently abundant to afford an excellent iron ore. In certain stones iron occurs as pyrites.

Alumina is clayey matter found but sparsely in good oolites, and does not affect our chief arguments.

Seeing, then, that an ordinary chemical analysis is of so little use in enabling us to determine the durability of oolite, we may inquire whether any other and better method is known. Considerable light may be thrown on the subject by studying the origin and structure of the stone. It has hitherto been customary for so-called "practical" people to altogether ignore the origin of different kinds of building stone, on the ground that it has no direct bearing on the practical side of the question, it being merely of philosophical interest. But this is not so. We do not for a moment contend that it is necessary for practical purposes to enter into the intricacies of the divers hypotheses concerning the origin of all known kinds of stone,—that would be absurd. What we do say is that by gaining some idea of the main facts concerning "origin," the *raison d'être* of the all-important factor in building-stone selection,—structure,—is intuitively learnt also. To no class of stone does this more closely apply than to that now under review. Before explaining what is known concerning the origin of oolite, however, we must know something of its structure. This is best studied by examining very thin, transparent sections of the stone under the microscope. We shall then see (in a typical representative of the group) that the small granules alluded to in the earlier part of this article usually exhibit the following structure:—In the centre of the majority of the granules we observe a minute grain of sand, shell, or other fragment which serves as a nucleus around which successive layers of carbonate of lime occur, not unlike the coatings of an onion. Occasionally the centre is a hollow cavity, produced, probably, by the dissolution of what was once there. From the centre to the circumference, exceedingly minute lines or cracks radiate. The stone is made up of myriads of these granules, which sometimes adhere to each other without having much cementing material between, but more often are joined together by a considerable amount of mineral matter. In some of the Lincolnshire oolites, the granules are relatively far apart, and do not form more than half the bulk of the stone, the spaces between being filled in with natural cement, of which more anon. Except in rare instances, however, we shall observe that large shells and other fossils are present, imbedded in the cementing material between the grains, and it may be that the granules are cemented closely to the shells.

Fossil shells enter largely into the composition of Portland, Bath, and nearly all the best-known oolites. The shells are of marine origin; and it is quite clear, therefore, that the stone itself was originally formed in the sea. It has been shown that, at the present day, granules of similar structure to those of oolite are forming near the coral reefs of the Bahamas, and off the coast of Jamaica; and it would appear that the granules are made by particles of sand, or other objects, being kept in motion in water highly charged with carbonate of lime, which latter is deposited and encrusts the particles, so that they eventually become enveloped by successive coats of the mineral. Oolitic grains of this character are also being formed in the

springs of Carlshad (Sprudelstein). At the same time, whilst it may be admitted that oolitic structure in general has been produced in this manner, we have unequivocal proof that it has also occasionally been formed in the stone subsequent to its deposition. Quite recently, again, it has been shown that in certain oolitic stones of very coarse grain (pisolites) the spherules are of entirely different origin. Mr. E. Wethered, F.G.S., has discovered* that in these cases the nuclei are enveloped by minute tubes of peculiar organisms; and two months since he further described them before a meeting of the Geological Society. On that occasion, also, Professor Judd, F.R.S., stated† that he had examined some recently-formed oolitic grains, and that the structure of some of them was very similar to the tubifolium pisolite referred to. So much for the origin of the granules.

We now approach the most important part of the structure of oolite,—the nature of the mineral matter which cements the granules and shells together. It will be obvious that the rate of weathering of the stone is almost entirely dependent on the character of this cement, for assuming it did not exist, we should merely have a deposit of loose material like sand, instead of a stone. There is every gradation of compactness, from an incipient substance in which the grains are only just held together, up to a rock so hard and close as to be difficult to tool. As we have before stated, the chemical composition of these two kinds of oolite,—the soft and the hard,—is often identical. What greater proof is needed of the futility of an aggregate chemical analysis in showing the weathering properties of the stone? Further, suppose every space between the granules has been filled up with what we know to be carbonate of lime, *per se* this is no guarantee that the stone will weather any the better for it. When carbonate of lime is amorphous (having no crystalline form) it is readily washed out of the stone by the action of rain, and so the fabric decays; but when the lime is crystalline, leaving taken on the form of calcite, it resists the weather for a very much longer period, and the oolite is better in quality. It depends whether the cement is crystalline or not.

Now we have to consider the structure of the shelly matter found in the stone. In the first place it is necessary to explain that, generally, the original shells have disappeared long ago. They have been dissolved out of the rock by the action of percolating water containing acid, and the cavities thus formed have been refilled by other mineral matter,—mostly carbonate of lime,—deposited from solution, and this secondary mineral has nearly always taken on a crystalline form. But here, again, we have to pause in considering that carbonate of lime crystallises in two different ways, producing two distinct minerals, calcite and aragonite, the former being much more durable than the latter. From the fact that aragonite is harder and heavier than calcite, it might be supposed that the reverse would be the case. It is another proof that the hardest minerals are not always the most durable. In examining stone in buildings erected only a few years since, we often find the surface pitted with holes and cavities, &c., which are mainly the result of the weathering out of aragonite shells. Where the oolite is largely made of such shells, it becomes a serious matter, for the whole substance gradually wastes away.

It may be asked, seeing that calcite and aragonite are of identical composition, how can they be differentiated? This is done by the aid of the microscope and polariscope, the optical characters of the two minerals being very distinctive. There can be no question that a microscopic examination is the best available method of determining the relative durability of oolites. By it we can arrive at the whole structure of the stone, the state of crystallisation of the component minerals, and the nature and disposition of the foreign frag-

* "Geological Magazine," N.S., Dec. 3, vol. vi. (1889) p. 190.
 † "Abstracts Proc. Geol. Soc.," Dec. 18, 1889, p. 25.

ments which so frequently prejudice the chemical analytical method. If the material contains an abnormal quantity of silica it is only by an appeal to the microscope that we can say whether that durable mineral, in a particular case, adds to the strength of the stone by entering into its constructive framework, or is merely present as the nuclei of granules. Microscopic analysis must, therefore, become the method of the future.

So far, we have only discussed the weathering of oolites from chemical and mineralogical points of view. Like other stones, they are disintegrated to a certain extent by the action of frost and wind; and in this connexion it is important to know how much water they absorb. The position in which they are built with reference to the rainfall of the district is also an important factor. But these things are now tolerably well known,—and they refer to all kinds of stone alike,—and their consideration does not fall within the province of the present article.

We may take this opportunity, however, of correcting a rather popular error in regard to the method of placing laminated stones in buildings in course of erection. It is everywhere understood that it is the correct thing to lay the stones so that the bedding is horizontal, and specifications frequently insist on this point. This is because of the well-known fact that laminated stone built exteriorly, with the bedding planes parallel to the face of the building, weather by flaking off, coat after coat being removed, whereas when the bedding planes are horizontal, the stone cannot flake in this manner. This is quite right, but laminated stones could also be safely built with the bedding-planes vertically disposed "end on," and suffer none the more for it, providing they are not placed at corners. Such, in fact, should be the proper positions of the key-stones of arches subjected to great stress.

The vexed question as to when it is advisable to clean down freestone buildings is more intimately connected with oolite than with any other class of stone. It is known that Bath and other similar limestone chemically forms a hard crust on exposure to the atmosphere for lengthened periods, and that this crust acts as a protection to the rest of the material. It is equally clear that if this hardened surface is cleaned off that it does not re-form so perfectly as before, and that the stone, consequently, is more easily weathered. This being so, the question arises whether it is advisable to clean down a building during process of erection, or subsequently; or whether the stone to be used should be seasoned or otherwise. We think that this depends very largely on the length of time to which the actual face finally to be left has been exposed to the atmosphere since it was quarried. The protective crust is derived from a slight decomposition or alteration taking place uniformly within about the depth of an inch or so of the exposed part of the stone. If the material is first seasoned at the quarry, and the seasoned surface is subsequently left in the building in an exposed position, any attempt at cleaning down will assist the disintegration of the stone; but if the latter is seasoned at the quarry, and the outside inch or two is tooled off on its being built up, the stone may be cleaned down during erection, as another hard surface will form, though, as far as our observations go, it is not quite as perfect as it might be. Under other conditions it is often advisable to use unseasoned stone after the moisture has fairly dried out. It is certainly not desirable to scrape down old buildings of oolite, as the weathering of the stone is much facilitated thereby.

London Geological Field Class.—A course of four lectures will be delivered by Prof. H. G. Seeley, F.R.S., on February 15 and the three following Saturday afternoons, at four o'clock, by the kind permission of the Gresham Committee, at the Gresham College, Basinghall-street. Subject: "The Tertiary rocks on which London stands."

NOTES.

THE Railway Rates Inquiry has now entered upon its second phase, Mr. Balfour Browne having opened the case for the traders in a speech of four days' duration. The efforts of the learned counsel were mainly directed to demolishing the statements and figures put in by the railway companies,—indeed, he asked the Court to disregard the whole of them as absolutely worthless. Seeing that the London and North-Western Company alone have spent 10,000*l.* in the preparation of these figures, this seems rather too much to ask; in fact, Mr. Balfour Browne proceeded to deal with them for what he considered them to be worth, being quite disposed, apparently, to adopt certain of them which bore out his own views. He maintains that Parliament never said that the traders were to be constructive in the making of schedules and classifications, but that the constructive work was to be done by the Board of Trade if they could not agree with the proposals of the railway companies. His principal objection to the proposed maximum rates is that they are based upon existing powers, instead of actual rates; and the evidence of his witnesses will probably be directed to this latter point, as the railway companies have avoided it. By the by, it is proposed to call no fewer than 136 witnesses on behalf of the Mansion House Committee alone, but endeavours will doubtless be made to dispense with some of the number. As to classification, Mr. Balfour Browne acknowledges that if that compiled by the Railway Clearing House were honestly made the basis of the new one, the traders would have no great cause to complain. The recent conference have resulted in the departures from this classification being so reduced in number that we think this condition may be looked upon as complied with,—the remaining points of difference being still left open to discussion. Having regard to the inevitable authorisation of "terminals" in some shape or another, Mr. Balfour Browne makes a very practical suggestion. He said that the evidence showed that even in the case of an important firm like Huntley & Palmer, although they have their own siding and do their own work, the rates charged to them are precisely the same as those charged to other traders at Reading. He asks the Court to fix maximum charges for every terminal service, separately, and to give the trader a rebate where the services are not performed. Of course there are difficulties in the way, as the Court is dependent upon the railway companies for evidence as to the cost of all these various services; and seeing that there are a host of objections raised against such figures of this nature as have already been submitted, it would no doubt be very difficult to arrive at a satisfactory understanding as to the reasonableness of the amounts for which they would ask Parliamentary sanction.

IN regard to the possible new offices for the London County Council, a correspondent (a London architect) writes:—"It is no secret that the City authorities are most anxious to thrust on the Council a piece of land facing the Embankment, near Blackfriars. I would beg of you to consider the advisability of suggesting,—amongst other sites that I daresay will occur to you,—the identical site of Whitehall Palace, where proposed to be placed by Inigo Jones. One advantage, possibly, would be that this site is already covered with one building which might be suitable,—viz., a Banqueting Hall. Besides this building the site is occupied with the statue of James II., the office of the Board of Trade (which wants re-building), and about a dozen private houses. I believe all the land is Crown property, so that compensation for disturbances could not be serious, and there would be no hurry to pull down the existing buildings. It is possible the site is not well known to many among your readers; I would explain, therefore, that I mean that if the road at present leading from

the east side of Whitehall to Whitehall-gardens, along the north side of the Duke of Buccleuch, were continued right through to the Embankment, and if the road, or rather the "Slough of Despond," at the north side of the Banqueting House, were also continued right through to the Embankment, a grand rectangular site would be obtained, with a long frontage to new streets on the north and south, a long frontage to the widest part of Whitehall on the west, and the same length of frontage to the Embankment on the east. I need hardly point out what a grand addition to the Embankment such offices might be, or how centrally situated amongst Parliamentary, Police, and Home Offices is such a site."

THE death of Dr. Salvati is announced, at the age of seventy-four. His name has been to a great extent identified in Venice and in England with the revival of the art of mosaic and of the Venetian artistic glass industry. He was not himself an artist or designer, and his efforts in setting up again these two artistic crafts on their old ground seem to have been prompted a good deal by patriotic feeling, coupled with that kind of insight which enables the possessor of it to foresee a probable demand and provide for it. In as far as the Murano glass manufacture was concerned, it was carried on in too archæological a spirit, even to the conscious production of irregularities and crookednesses of make; a kind of thing which took the public when it was novel, but which the best artists saw through and on occasion denounced. In regard to this kind of effort the Murano glass work has had its day of fashion, and capricious modern taste is getting tired of it, as is pretty sure to be the case with all art work which is a revival of old fashions for the sake of revival; but there is no doubt that incidentally it gave an impulse to the long-forgotten idea that table glass was a thing capable of beautiful artistic design and expression, and not merely a utilitarian class of goods for practical use; and most of the other efforts at giving artistic form and spirit to glass utensils have been at all events stimulated by the example of Salvati's enterprise or the desire to rival it. In regard to mosaic, the position taken by Salvati and his coadjutors is more stable. They provided for the manufacture of the material and the proper carrying out of the process of fixing; and though a good deal of too archæic work was done by them for church architects in the high tide of the Gothic movement, the more rational artistic use of the material by designers has now brought mosaic decoration into higher repute, and the gratitude of the artistic world is equally due to the man who recalled and revived the use of such a splendid medium for architectural decoration.

MR. ROBINS'S paper on "The Relation of the Fine Arts to the Applied Arts," recently read at the Society of Arts, and published in the last issue of the Society's *Journal*, had for its main object the suggestion that technical schools should include art-teaching in their curriculum, instead of leaving those who receive instruction in technical processes of manufacture to learn elsewhere how to apply design in these processes, or to leave that little matter altogether unlearned. Mr. Robins said:—

"At the Central Institution no such art teaching has been commenced, although that was the first intention, and a portion of the building was set apart for the fine arts, which has since been devoted to science-teaching purposes, and no professors of the fine arts have as yet been appointed."

This branch, however, is never found wanting in foreign polytechnics, which are not considered complete without their art side,—with its staff of professors of architecture and construction and painting and sculpture. The Professor of Architecture at Carlsruhe was the architect of the new Strasburg University, which has cost half a million of money. In this particular, therefore, the Central Institution in its present development cannot compare with foreign polytechnica, being almost exclusively devoted to the applied sciences; and my regret that this should be the case has had its influence in determining the subject of this paper. During the delivery of Mr. Alan Cole's in-

interesting paper on Irish Lace Industries last Session, a striking example was given of the importance of maintaining a close alliance between the fine arts and the applied arts. The paper was illustrated by enlarged photographs of original laces, contrasting designs made before and after art lessons had been introduced into that country, and showing the waste of energy which had long been expended in bad designs, wherein the workmanship was beautiful, but the value was deteriorated by reason of the lack of taste in the design, and the absence of fine art culture observable in its general arrangement and ornamental detail."

In the course of his paper Mr. Robins frequently quoted from the volume of papers read at the Liverpool Art Congress, which, as he truly said, formed too valuable a *resumé* of opinions and suggestions upon art to be left buried in the recesses of libraries.

THE London County Council, at their meeting on Tuesday last, as reported in another column, received with much surprise, and many expressions of regret, the intimation from Sir John Lubbock, the Vice-Chairman, that Mr. Clement Duncombe, late of Liverpool, who was elected to the post of Chief Engineer of the Council so recently as December 3 last, in succession to the late Mr. Gordon, had written tendering his resignation, on the ground of ill-health. We are very sorry indeed to hear of this. As was recently mentioned in our column, Mr. Duncombe, on leaving his duties as City Engineer of Liverpool, went for a sea voyage as far as the Canary Islands, preparatory to entering upon his duties in London. The London County Council and the inhabitants of London are to be consoled with on the loss, within so very short a period, of the services of two gentlemen who stood in the very front rank of municipal engineers. Mr. Gordon's very sudden death on November 9 last, after only about two months' tenure of office, will be fresh in the recollection of our readers; and now his successor, Mr. Duncombe, has felt compelled to tender his resignation owing to ill-health, just as he was about to enter upon the important duties of the office to which he had been elected. We had hoped much for Londoners from the professional ability first of Mr. Gordon and then of Mr. Duncombe. The London County Council have decided to fill up the vacancy as soon as possible. We trust that they will secure a capable man, and one whose tenure of the post of Chief Engineer will be very much longer than that of his predecessors. In the meantime, the Council appear to us to have made a very good appointment in electing Mr. W. Santo Crisp (Engineer to the Wimbledon Local Board) as Assistant-Engineer, in the room of Mr. Thomas Lovick, who is about to retire after a long period of service under Sir Joseph Bazalgette.

DR. CHARLES WALDSTEIN, the Director of the American School of Classical Studies at Athens, gave his inaugural address for the present session in the School Library, on Monday, January 27. Dr. Waldstein, who holds the appointment of Reader in Classical Archaeology at Cambridge, has recently resigned the Curatorship of the Fitzwilliam Museum there, in order to devote more time to the furtherance of the objects of the American School. He will reside in Greece each session from Christmas till Easter, and during this time, in addition to directing the general work of the School and any excavations that it may have in progress, he will give a series of lectures to students, both in the School and at the museums, on various archaeological subjects. This year he is devoting his attention to sculpture, while Mr. Gardner, the Director of our British School, has taken up vases and topography, the two Directors being particularly anxious that the English-speaking schools should combine and work together as much as possible in this way. In addition to their permanent Director, the Committee of Management in America, which is composed of representatives from the principal American colleges, appoint annually a second director, generally one of their professors of

Greek, who more particularly undertakes the superintendence of the students' work in the classical languages and literature, the American school differing from ours in being a school of classical studies as well as of archaeology. Dr. Waldstein began his address by speaking of the increased facilities now offered to students in the museums of Athens, and in Greece generally, owing to the enlightened zeal and energy of the General Ephor of antiquities, Dr. Kabbadias, who is busily arranging the vast quantities of materials of all kinds, the products of the various diggings which are constantly being carried on by the Government, the Greek Archeological Society, and the various foreign schools. He insisted on the necessity for the formation in Athens of a vast museum of casts embracing the whole range of Greek sculpture, and he appealed to the patriotism of the wealthier Greeks, who have already done so much for the Athens of to-day, to make this want a reality.

REFERRING to the water-supply of St. Petersburg, a correspondent states that it is still very defective. The water is obtained from the Neva, and last autumn, for the first time, a certain system of filtration was introduced, but has failed to improve the condition of the water, as it is rendered impure in filthy cisterns on the roofs of the houses, into which dangerous rubbish is often thrown. In consequence, the hygienic state of the Russian capital is very bad; and in December last, the rate of mortality rose to double that of London. Proposals, however, have been made to the City authorities for erecting modern water-works, the proposal being to obtain the water from a couple of lakes some distance from St. Petersburg.

A GENOA journal draws attention to the increasing erection of timber dwellings in Northern Italy since the earthquakes in 1887. As is well known, the latter are far safer than stone houses in this respect. However, the opinion is expressed that along the Riviera these houses cannot pay, on account of the great expenses attending the excavation of the rocky ground. For instance, in Genoa, houses have to be run up eight or ten stories, in order to yield a return upon the capital invested. It is also doubted whether timber will be able to withstand the great summer heat prevailing in the Mediterranean and keep free from rot. As to the reputed greater coolness in summer of wooden houses, the journal in question points out that no houses can be cooler than the thick-walled stone buildings of Italy, Spain, &c.

A REPORT by Dr. Parsons to the Local Government Board (dated December 21, 1889) on certain outbreaks of diphtheria in the Leek Rural Sanitary District, Staffordshire, gives, among others, the following particulars as to the sanitary state of some of the houses in which the disease appeared. In one case,—

"The sanitary state of the house is very imperfect. The whole family sleep in a single bedroom of about 950 cubic feet capacity. There is another small bedroom, but it is not used, as it is dark and unventilated, having only a single small window which will not open. The privy is close to the pantry-window, and the smell from it is complained of. Drainage is into a cesspool; the drain has an untrapped inlet out of doors, but close to the house. (Both the untrapped inlet and the fixed window, it is right to say, were put in by the tenant himself, who is a mason by trade.)"

Of another case we read:—

"The house, like most of the cottages in the district, has windows in the front only, and the window of the downstairs room does not open. There are two bedrooms. The back wall is partly below the level of the ground. There is no drain, slops being thrown over a low wall on the farther side of the footpath in front of the house. For the four houses there are two privies, which are at the upper end of the row; they are low and dilapidated, with wet cess-pits, of which the contents ooze out on the surface of the ground."

Another infected house is described as follows:—

"The house stands by itself among fields; the surroundings are uncleanly. The drain is a rough

stone sough, the flat bottom of which is covered 3 in. deep with black stinking sediment. It is in direct untrapped communication with the interior of the house, and ends in a field, with an open mouth, so that when the wind is in that direction all the foul air generated in the drain must be blown up into the house. The privy, with a wet, open pit, is built against the end of the house; the wall of the living room at that point is saturated with damp, and a bad smell is complained of as being perceived in the house. Fowls are kept in a dirt-stato in a shed abutting against the back of the house, and water from an old land drain, which is blocked sometimes, wells up into the pantry."

In regard to general considerations as to the sanitary state of the district, Dr. Parsons says:—

"A primary duty of a sanitary authority, which requires more attention than it receives in this district, is the remedying of unwholesome conditions of houses and their surroundings. It will be seen from the foregoing pages that at all the houses where diphtheria had occurred gross and dangerous nuisances were to be met with, such as a damp, dilapidated, and ill-ventilated condition of the house; defective drains, some in direct connexion with the interior of the house; faulty-placed privies; and water supplies exposed to contamination; and though there is no sufficient ground for ascribing the origin of the diphtheria solely to such defects, it is likely enough that they assisted its spread and aggravated its severity. Yet (with the single exception of Horton Vicarage, where efficient works had been spontaneously carried out by the vicar) I found that these conditions had remained entirely unremedied or without any effectual remedy up to the time of my visit. In some cases they had occurred since others had been removed and been served, but not complied with; and in other cases trivial works had been done, which were insufficient for their purpose. In the latter cases, the failure to secure the effectual carrying out of the required works appeared to be the result of the view locally taken of the legal powers of the Authority—namely, that the Act in question has been superseded by recent legal decisions—viz. that the authority have only power to order the abatement of a nuisance, and must not specify in their notice the particular works required to be executed for the purpose. However this may be, having regard to the prevalent want of sanitary knowledge, the difficulty of getting country workmen to carry out works in any way but that to which they have been accustomed, and the hardships felt by owners when works which they have had carried out to the best of their knowledge and ability are not found satisfactory, it seems desirable, in the interests of owners themselves as well as of the public health, that when they are called upon to execute structural works for the abatement of nuisances, they should be told what the required works are, and the best way (which is by no means necessarily the most expensive one) of carrying them out."

BY direction under the will of the late Lord Falmouth, who died on Nov. 6 last, his town house, in St. James's-square, together with his property at Newmarket, is to be sold. The house, No. 2, on the eastern side, has long been distinguished by a row of posts, which are ship's cannon. These were put by Admiral Edward Boscawen, son of Hugh, first Viscount Falmouth, and ancestor of the first and second Earls of that title, at the capture of the French fleet by Anson, off Cape Finisterre, on May 3, 1747. It was about this time that Savage and Dr. Johnson, having no resting-place, spent a summer's night in walking round the square, resolute "to stand by their country." A print of 1773 shows the rows of ordinary posts around the pavement, the octagonal enclosure having obelisks and lamps at its angles, and the central oval-shaped pond, with a fountain, where Bacon's statue of William III. was afterwards set up. In the Parish Clerks' "New Remarks of London," 1732, it is stated that the pedestal for the statue was already there, and that the enclosure "was done at the Expence of the Nobility and Gentry inhabiting the East, West, and North sides of the square, who obtained an Act of Parliament for the performance thereof." This was the pond into which the "No Popery" rioters threw the keys of Newgate Gaol in 1780; and there they were found many years later.

BY the incorporation of Paul's Chain and Godliman-street with the existing thoroughfare of Bennet's-hill, two old landmarks will disappear from the maps of London. A court in Godliman-street still commemorates the name and situation of the

baking-house for the supply of bread to the Church of St. Paul, latterly the Admiralty Registry. By Paul's Chain—the "south chain of Paul's," mentioned by Stow—we are reminded of the old practice of stopping traffic around this side of the Cathedral during the hours of service therein. The whole of its eastern side is now in course of demolition. Godliman-street also lay within St. Gregory's parish. The derivation of its name appears to be uncertainly known. Some regard it as a corruption of Godalming, or Godalmin, street: early in the last century it was styled Godly-man-street. No less an authority than Edward Cocker once lived on the southern side of the church, over against Paul's Chain, and there in 1660 he wrote his masterpiece of calligraphy, "The Pen's Transcendancy." He was buried in the former church of St. George the Martyr, Southwark, *teste* Hatton, who was so told by the sexton.

IN the very interesting "Early Diary of Fanny Burney," just published, is a reference to Robert Adam, the eminent architect, which places him in a very agreeable light in his social character. Miss Burney, then seventeen, first recalls meeting Robert and James Adam at a dance at her friend Mrs. Debieg's; like many writers of the present day, even professed writers on architecture, she makes the mistake of writing the surname "Adams" instead of Adam (though this is corrected in a subsequent chapter of the diary). "Mr. Adams, very sensible, very polite, very agreeable,—the most so, Mr. Debieg excepted, of the whole party, Mr. — Adams, his younger brother, a well-behaved good sort of young man." Another passage later on shows that Robert and James were the two special brothers present on this occasion; and this rather melancholy praise of James, the younger, as "a good sort of young man," confirms the opinion we recently expressed, in reviewing Mr. Brydall's book on Art in Scotland, that Robert was in every way the master personality in the family. But as Fanny's reminiscences of the evening proceed, her recollections of Robert Adam grow still more pleasing; in the quotation we give Adam his proper surname, which Miss Burney did not get right till a year or two later in her diary, though her reference there leaves no doubt of the identity of the man:

"We then left off for supper. During the time of rest, I was happier than in dancing, for I was more pleased with the conversations I then had with Mr. Dundas, Mr. Adam, and others, than with my partners, and they all in turn came to chat with me, with as much good humour as if I had been as good a talker as I am a listener. Mr. Dundas the elder and Mr. Adam are quite high conversers. I was never more pleased. . . ."

"When supper was over, all who had voices worth hearing were made to sing,—none whose more than Mr. Adam; though in truth he had little or no voice . . . yet he sang with so much taste and feeling, that few very fine voices could give equal pleasure: I cannot but much regret the probability there is of my never seeing him again. I may see many fools ere I see such a sensible man again."

On the matter of Mr. Adam's taste in singing the opinion of Dr. Burney's daughter, who lived in the midst of music and musicians, was of course a sound one; and no one who reads her diary will doubt that she was an equally good judge of personal charm of manner and conversation. It might have pleased Robert Adam as much as his architectural success, to have known that a century later his name would be found recorded, in the diary of one of the most lively and attractive young girls of her day, as the most pleasant and accomplished man she had met in society.

Bridge Across the Bosphorus.—The Constantinople journal *Habibak* states that a syndicate of French capitalists has obtained a concession for the construction of a bridge across the Bosphorus in the narrowest part, between Rumeli and Anadol-Hissar. It is to have a length of 800 metres, with a height above the water level of 80 metres.

* The break here is in the Diary.

LETTER FROM PARIS.*

THE conflict which has arisen in the ranks of the Société des Artistes Français, referred to in our last,† far from having subsided, has assumed such proportions that the rupture between the two parties in that body is now complete, and this year we shall have, along with the old Salon exhibition of the Palais d'Industrie, a rival exhibition organised under the auspices of the new association, which will bear the title of "Société Nationale des Beaux-Arts."

Laudable efforts were no doubt made to prevent this ill-adviced schism. On the part of the old Société, MM. Guillaume, Bonnat, and Chas. Garnier have vainly attempted an overture of conciliation, which was refused categorically by M. Meissonier, who is supported in his position by numerous adherents. A committee, including MM. Puvis de Chavannes, Carolus Duran, Roll, Gervex, Galland, Cazin, and Bracquemond, has drawn up the statutes of the new society, which will be composed of "Membres Fondateurs," "Membres Sociétaires," and "Membres Associés." The "Sociétaires" will be artists, either French or foreign, who shall give their adherence to the statutes of the Society on the invitation of the Membres Fondateurs. The Associés will be artists whose works have been admitted into the exhibitions of the Society, and who will have been adjudged worthy of the title at a general assembly of the Sociétaires. Associés can become Sociétaires by the vote of the general assembly. The number of Sociétaires and Associés is not limited.

The title of "Membre d'Honneur" or "Membre Adhérent" can be conferred by the Sociétaires on persons who have rendered services to art or to the Society, but these titles will not confer any right to take part in the deliberations of the Society.

The funds of the Society will be devoted to the establishment of annual exhibitions, and to the expenditure arising therefrom. The surplus revenue will be devoted to the purchase of works of art, which may be offered to the State museums, to the formation of a reserve fund, &c.

The administration of the new Society will be confided to a delegated Council of Membres Fondateurs, Sociétaires, or Associés. Such are the general terms of the constitution of the new Société Nationale, which will distribute no medals or rewards. Members will not be limited as to the number of works they may exhibit, but they will, on the other hand, be formally interdicted from exhibiting at the old Salon. The "Salon Nationale" will open every year on the 15th of May, fifteen days after the other Salon, an arrangement which will at all events render matters easier for the art-critics. It will last a month, and will be held, pretty certainly, in the Palais des Beaux-Arts at the Champ-de-Mars; the building has not been either offered or asked for as yet, but there is no doubt the Government will give the use of it when asked.

What will be the future effect of this movement it is difficult to predict. On the one hand we have a Society of long standing and prestige, numbering many eminent men in its ranks, and presided over by the venerable M. Bally, who is beloved by everyone and has devoted himself heart and soul to the cause. The old Society has been for a long time the battle-field in which all the young artists have first taken up arms, and it has enjoyed long successes and honours. On the other hand, the new Society, with a title which is somewhat pretentious and in bad taste, since it does not, in fact, represent the national art any more than the other body, has obtained the adhesion of nearly all the representatives of the younger school, and its ranks are augmenting every day. Among the new recruits are already to be counted Ribot, Stevens, Lhermitte, Rixens, Sargent, Boldini, Boivin, Dinet, Maurice Courant, &c. There is therefore a great deal of curiosity and interest about it on the part of the public; and as, in reality, it is a movement of decentralisation in artistic matters, we have no objection to make to this dualism, provided that the State, which is always indulging the hope of resuming its original authority over the artists, does not profit by these divisions to assert an official right to interfere in questions which ought to be decided wholly by artists, instead of confining itself to the wholesome office of encouraging art by purchasing such works as seem worthy of acquisition for State collections.

Among other artists who have joined the new

* Unavoidably held over from last week, as we then stated.

† See p. 7, ante.

Salon, besides those already mentioned, are MM. Lambert, Edelfelt, Mesdag, Mathey, Toulmonche, John Lewis Brown, Dubufe, Mdma. Madeleine Lemaire, &c. The new Salon exhibitions will be open not only to all French but to all foreign artists, whose works must be sent in from the 1st to the 8th of March. The Sociétaires will have to the 26th April to complete and send in their works for exhibition.

From among the list of Sociétaires twenty names will be selected by lot to form a jury of examination of works sent in; but these names will not be published until the jury have completed their task.

It is hardly necessary to add that this event has given special importance to the annual election of officers of the Société des Artistes Français, which has just taken place. The election left no doubt, however, of the determination of the Société to affirm its position: M. Billy was re-elected President by 60 votes out of 64; the two vice-Presidents, MM. Guillaume and Bouguereau, also obtained a large majority, and the secretaries, M. Chas. Garnier among them, were re-elected by acclamation.

The season of "expositions particulières" in Paris has commenced. At the Galerie Georges Petit is to be seen that of the works of M. Leopold Berstamm, sculptor, who has made a speciality of the exotic types of the Universal Exhibition (Indians, Javanese, Soudanese, &c.) an exhibition indicating at all events great ability and cleverness of execution. After this will follow the annual exhibition of the club of the Rue Volney, that of the water-colours of Madame Madeleine Lemaire at Gonpils, that of the "Peintres-Graveurs" at Durand-Ruel's; and, in a few weeks, the exhibition of the "Union Artistique" and that of the Water-Colour Society.

At its last sitting, the Municipal Council approved of the permanent retention not only of the Palaces of M. Formigé and the Galerie des Machines, but of the 30-mètre gallery and the Bouvard dome.* The Council has now to decide the treatment of the large space of ground between this latter building and the Seine. The scheme for this has actually been submitted to Parliament, which will pronounce upon it shortly. In the meantime the work of demolition goes on, and on the Esplanade des Invalides the Palais des Colonies, the Pagoda, and two or three foreign pavilions alone remain: even the elaborate and solid-looking palace of the Ministry of War has entirely disappeared. On the Champ-de-Mars the principal foreign pavilions are still in position; but the "Histoire de l'habitation" has disappeared.

While removing the remains of the Exhibition, the Government is at the same time occupied in dealing with those of the Cour des Comptes, which have for twenty years been an eyesore on the Quai d'Orsay. A special committee deputed by the Ministry of Instruction to report on the matter has sent in its report, which unfortunately points to a necessarily great expenditure: seven million francs for reconstruction if the two principal façades are utilised; ten millions if they are razed and rebuilt. The original foundations can in any case be utilised. It remains to be settled what, after all, will be built or rebuilt on the site. Will it be the ancient Cour des Comptes, or the new Musée des Arts Décoratifs asked for by M. Antonin Prost? The Committee has suggested nothing, and the Government authorities are perplexed. *Adiuvato sub iudice lis est*: and it is to be feared that in this doubtful case things will still be let alone, though it is really almost a public duty to remove this painful reminder of our civil discords; not to speak of other public interests that might be affected. There is a kind of demand for public work to put new life into the building trade of Paris—not that there is any lack of possible projects waiting for execution; besides the proposed new water supply from the sources of the Avey and the Vigne, there is the removal of the Gare des Sceaux, the new line from the Invalides to Moulins, and the metropolitan railway scheme. With this latter scheme are connected also important street improvements. Then there are the haulage railways for Belleville and Montmartre, and the "chemin-de-fer glissant," which it is proposed to establish on the old exterior boulevards,

* This unexpected decision we think a serious mistake. M. Bouvard's dome and facade might pass muster as a temporary exhibition design, but regarded as a permanent building it is little better than architectural gingerbread.—Ed.

from the Place Clichy to La Villette. There is, moreover, the long-desired completion of the Boulevard Haussmann; and here at least, considering the recent state of things, there ought to be decisive action. In view of the crowded state of the Boulevards Montmartre and des Italiens, and the narrowness of the adjacent streets, people are asking emphatically why the completion of this work has been so long delayed.

The École de Droit is soon to be enlarged, M. Lheureux being the architect entrusted with the work. The establishment as enlarged will occupy all the space between the Place du Panthéon and the Rues Cojart, Jacques, and Soufflot. The new buildings, which will cost about 250,000 francs, are to be carried out partly at the expense of the Government. They are to include an entrance-court from the Rue St. Jacques, with a vestibule and corridor connecting the new building with the old, a large theatre, lecture rooms on different floors, a hall for the distribution of prizes, and the enlargement of the library.

Another intended construction is an iron bridge at Conflans, between Charenton and Ivry, at a cost of about 850,000 francs.

The two national museums are to undergo some important alterations. At the Luxembourg, where the objects lent for the Centennial Exhibition have been reinstated, several new works are to be hung, among them the "Femibre Maria Lamécie" of M. Roll and the "Rêve" of M. Détaillé. The Museum at present contains 430 works, of which 300 are pictures. At the Louvre, the galleries on the first floor devoted to ceramics are to be considerably rearranged. In the Pastels room an allegorical ceiling by M. Hector Leroux has been fixed, divided into three compartments. The most important composition represents the triumph of Venus, another represents "Junon au bain," and the third the union of Greek and Latin poetry. In the Louvre there are also to be placed the "Sacre" of David, the fine portrait of General Fournier Sarlovèze by Gros, and the "18 Brumaire" of Bonchot. It has been said also that the Louvre is to have Manet's "Olympia," but this seems to be a mistake; a group of artists and amateurs combined to purchase this work of the impressionist master, but the Louvre is not concerned in the purchase.

At the École des Beaux-Arts the eighty-seven competitive designs in the second class, for a Maritime Sanatorium or hospital for children, have been before a jury presided over by M. Ginain; but only "mentions" have been awarded, "premiers" to MM. Fiault, Petin, Armbruster, and Bretagne, and thirty-four "secondes mentions" to other competitors. In the competition in "éléments analytiques," subject a funeral chapel, fifty-one "mentions" have been given among sixty-one competitors; and in the sketch competition for a Prefecture of Police, "mentions" have been awarded to ten out of 132 competitors.

The competition in decorative composition for students in the three classes, the subject for which was a "cadran solaire,"* has been a rather remarkable one, and after having voted a "première médaille" to M. Armbruster and second medals to M. Desgardin and M. Berger, the jury have added an expression of general satisfaction at the very high style of work exhibited.

For subjects modelled after casts, by architects, M. Baot has obtained a medal, and for figures drawn after nature and after the antique thirteen "mentions" have been awarded. The level of architectural students' work this year, therefore, seems to be very good.

The month of January has brought a long obituary list, in part caused by the influenza epidemic, directly or indirectly. Among the deceased is an eminent member of the Académie des Beaux-Arts, Arthur Stanislaus Diet, a former pupil of Duban and Bloet, who has died at the age of sixty-three. He was Honorary Inspector-General of "Batiments Civils et Palais Nationaux," and Honorary Architect-in-Chief to the City of Paris. He obtained the Prix de Rome in 1853, the Cross of the Legion of Honour in 1867, and a medal of the first class in the Exhibition of 1878. In 1884 he was created Officer of the Legion of Honour and Member of the Institut. Diet was the architect of numerous important works; among which may be specially mentioned the completion of the Museum at Amiens, the new Prefecture of

Police at Paris, the new Hôtel Dieu, the completion of the hospice of Charanton, and the architectural treatment of the new reservoirs of Montmartre. He was a fine artist and a man of benevolent character, and is universally regretted.

Another architect, Demangeat, has died in his 71st year: he took part in the construction of the quartier de l'Europe and of the old Gare St. Lazare.

Among engravers we have to record the death of Etienne Guillaumot, the illustrator of M. Alphonse's "Promenades de Paris;" and that of Joseph Lefman, whose name is connected with the discovery of zingography, and who did a great deal generally to promote the art of facsimile reproduction.

Among painters who have died during the month are Bouquet, Sauzier, Mayeur, and Protais. Michel Bouquet, who received a medal as long ago as 1835, and was 82 at the time of his death, excelled as a painter of faience "sur cra," and all the ceramic museums possess examples of landscapes and seascapes painted on faience by him. Noël Sauzier, the landscape painter, who has died at the early age of 42, was a pupil of Pils, a modest and hard-working artist, whose exhibits at the annual Salons were much esteemed. Max Mayeur, also a landscape painter, has exhibited every year for twenty years past works of excellent character and truthfulness.

Alexandre Protais had made for himself a special name and fame in military subjects, in which he may be said to have been the precursor of Détaillé and De Nerville. He has died of heart disease at the age of sixty-four. From 1853 to 1855 he painted various classes of subjects, but on the commencement of the Crimean War he followed the whole campaign, studying closely the military life which he so ably reproduced in his paintings. In 1857 he exhibited "The Battle of Inkerman," "The Taking of a Battery on the Mamelon," "The Death of Colonel Brancion," and the "Devoir." The success which these works had plainly pointed out his future path. In 1859 he followed the campaign in Italy, and returned with numerous studies. In 1861 he exhibited the "Deux Blessés" and "Une Sentinelle," the picture which drew from Thophile Gautier the remark that "M. Protais a trouvé la Poésie du Soldat." The "Matin avant l'Attaque" and the "Soir après le Combat," exhibited in 1863, brought his reputation to its height. During the last war he served in the army under General Ladmirault.

Protais had received medals in 1863, 1864, and 1865; he became officer of the Legion of Honour in 1877, and obtained a medal at the 1878 Exhibition. By his artistic truthfulness, his perfect courtesy, and the great "distinction" of manner which characterised his personal bearing, he had gained the regard and esteem of artists of all schools, and in his later years was appointed on the jury regularly at each annual exhibition. He was not only an excellent painter, but a thoroughly good man.

We hear at the last moment of the death of M. Jules André, architect and member of the Académie des Beaux-Arts. André was born in Paris in 1819, and studied at the École des Beaux-Arts; he obtained the second prize in architecture in 1842, and the Prix de Rome in 1847, in a competition of which the subject was "Une Chambre des Députés." He went to Rome, and thence to Greece, where he executed a fine restoration of the Temple of Theseus. On his return to Paris in 1852, he was appointed "Inspecteur des Travaux" at the Natural History Museum, and "Sous-inspecteur" at the National Library, and subsequently diocesan architect for Corsica. In 1867 he was appointed chief architect to the Museum, and built the gallery with the monumental façade which terminates the main avenue of the Jardin des Plantes.

André was an officer of the Legion of Honour, and a distinguished professor at the École des Beaux-Arts; and in 1834 he succeeded to the place formerly filled by Lesueur in the Institut.

The New Harbour at Copenhagen.—The Danish Government has presented a bill to the Parliament for the immediate construction of a new harbour at Copenhagen, a scheme under contemplation for some time. It will be situated on the so-called "Castle Point," and divided into two parts, covering a total of about four million cubic feet.

ROMAN ARCHITECTURE.*

BY PROFESSOR AITCHISON, A.R.A.

PLINY THE YOUNGER'S LAURENTINE AND TUSCAN VILLAS.

THERE are but few sources from which we can get a distinct idea of the arrangement of a Roman house. These sources are the remains at Herculaneum and Pompeii (although Pompeii was probably a sort of Roman Margate or Broadstairs), the descriptions of houses and villas in the Roman writers, and the description of some of the parts of a house in the treatise of Vitruvius.

We must bear in mind that Vitruvius's treatise was published with illustrations, though they have unfortunately perished, and that he never describes anything that was well-known to his contemporaries; so we are unable to construct a house from his description. He seems to have published his treatise just as the great improvements in Rome were begun by Augustus, when the Roman peace allowed wealth to accumulate, and architecture and building to develop throughout the civilised world. We cannot, therefore, be sure that great variations in the arrangement of houses did not take place after the publication of Vitruvius's treatise.

The parts of a house Vitruvius mentions are these:—The Vestibulum, or vestibule, where the toga was put on before going out; the Cavadium, or atrium, the first main hall, though Pliny calls this the Atrium only, and the second, or innermost one, the Cavadium,—the middle one he merely calls a portico; the Alae, or wings; the Tablinum, or meeting-room, which was used as a hall of audience; the Fanees, passages that ran on each side of the Vestibulum to the back or private part of the house; Cubicula, living-rooms, but where one might take a midday nap; Peristylum, the peristyle round the garden at the back of the Tablinum; Triclinium, the dining or banquetting-room; Exedrae, rooms for conversation; Cœci, halls, often used for banquets, called tetrastyle, Corinthian, Egyptian, and Cyclicæ; Pinacotheca, the picture-gallery; Bibliotheca, the library; Balneum, the bath; Calia, the kitchen; Cœnaculum, originally a supper-room above the ground-floor, but eventually used to describe the garret or cock-loft; and, in noblemen's houses, the Basilica, originally a hall for trying cases referred to them, or for meetings on party questions, and subsequently for recitations.

After hearing the names of the rooms that are given by Vitruvius, we shall best see their arrangement in the description of his villas by Caius Plinius Cæcilius Secundus, commonly called the Younger Pliny, or Pliny the Consul, the nephew and adopted son of Pliny the Elder, who wrote the Natural History. It must be borne in mind that his Laurentine Villa was a suburban retreat, mainly used in the winter (for he tells us that he resided at his Tuscan villa in the summer), and it was mainly used in the afternoon and at night, when his work in Rome was done.

In giving the translation, I have inserted the Latin names of such portions as may be necessary to identify them with those described by Vitruvius, though there are several parts whose names are not found in that author.

Pliny describes his Laurentine Villa in a letter to Gallus (Lib. 2, 17). The translation given is by Melmoth, as emended by the Rev. F. C. T. Bosanquet, but I must warn you that the English words used as translations of the parts of the villa may mislead you, for it is by no means certain that they adequately convey the meaning of the Latin ones; e.g., atrium is translated by "courtyard," while it is still a question as to what it was, and according to Vitruvius it was a covered hall, with or without an opening in the middle. I now give you Pliny's words:—

"My villa is of convenient size, without being expensive to keep up. The courtyard (atrium) in front is plain, but not mean, through which you enter the porticoes, shaped into the form of the letter D," (but Mr. Bosanquet is of opinion that there were two D-shaped porticoes, and that the space between them was the area. In some editions the letter is "O," and a circular or oval portico was shown by the elder restorers) "enclosing a small but cheerful area between. These make a capital retreat for had weather, not only as

* It would seem from this that the attention which has been given to the subject of sundials the last year or so is not peculiar to England.—Ed.

* Being the second Royal Academy Lecture on Architecture this season. Delivered on Thursday evening, January 30.

they are shut in with windows (specularibus), but particularly as they are sheltered by a projection of the roof." (I believe he means by "imminentibus tectis" covered by a lean-to roof, otherwise the passage is nonsense, if the windows were wholly glazed.) "From the middle of these porticoes you pass into a bright pleasant inner court (Cavædium), and out of that into a handsome hall (Triclinium—a dining or banqueting room) running out towards the sea shore, so that when there is a S.W. breeze, it is gently washed with the waves, which spend themselves at its base. On every side of this hall (the dining-room) there are either folding doors, or windows equally large, by which means you have a view, from the front and two sides, of three different seas, as it were—from the back you see the middle court, the portico, and the area; and from another point (about which there is nothing in the original) you look through the portico into the courtyard (Atrium), and out upon the woods and distant mountains beyond.

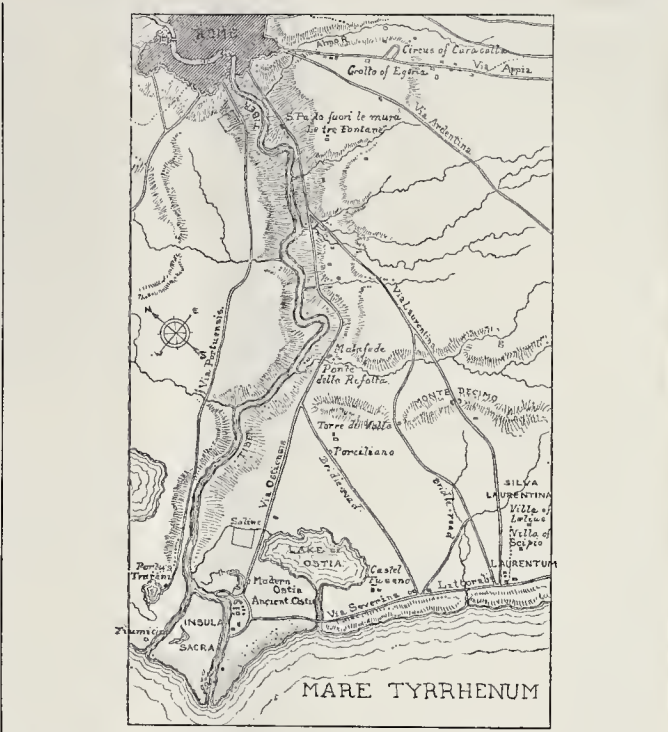

On the left hand of this hall (the dining-room) a little farther from the sea lies a large drawing-room (cubiculum, a sitting-room, or a room in which you might sleep, but not a night bedroom), and beyond that a second of smaller size, which has one window to the rising, and another to the setting sun; this as well has a view of the sea, but more distant and agreeable. The angle formed by the projection of the dining-room with this drawing-room retains and intensifies the warmth of the sun, and this forms our winter quarters, and family gymnasium" (family, here applies to his slaves and freedmen), "which is sheltered from all the winds, except those which bring on clouds, but the clear sky comes out again before the warmth has gone out of the place. Adjoining this angle is a room forming the segment of a circle (inapsida curvatum), the windows of which are so arranged as to get the sun all through the day. In the walls are contrived sorts of cases, containing a collection of authors who can never be read too often. Next to this is a bedroom" ("membrum dormitorium": I incline to the opinion that this is a wing of bedrooms) "connected with it by a raised passage furnished with flue-pipes (this should be a hanging passage, "suspensns et tabulatus"), which supply at a wholesome temperature, and distribute to all parts of this room the heat they receive.

The rest of this side of the house is appropriated to the use of my slaves and freedmen; but most of the rooms are respectable enough to put my guests into.

In the opposite wing is a most elegant, tastefully fitted-up bedroom, next to which lies another, which you may call a large bedroom, or modified dining-room" (I believe he means a moderate-sized eating-room). "It is very warm and light, not only from the direct rays of the sun, but by their reflection from the sea. Beyond this is a bedroom, with an ante-room (procceton), the height of which renders it cool in summer, its thick walls warm in winter, for it is sheltered every way from the wind. To this apartment another ante-room (procceton) is joined by one common wall.

Thence you enter into the wide and spacious cooling-room (cella frigidaria) belonging to the bath (balneum), from the opposite walls of which two curved basins (baptisteria) are thrown out, so to speak; which are more than large enough, if you consider that the sea is close at hand." (This seems rather far-fetched, and I believe he means, if you like to swim in what is close at hand.) "Adjacent to this is the anointing-room (unctarium), the sweating-room (hypocauston), and beyond that the bath heating-room (propriogion). Adjoining are two other little bath-rooms, elegantly, rather than sumptuously, fitted up. Annexed to them is a warm bath (calida piscina) of wonderful construction, in which one can swim, and take a view of the sea at the same time. Not far from this stands the tennis-court (spheristerium), which lies open to the warmth of the afternoon sun.

Thence you go up a sort of turret, which has two rooms (diæta) below with the same number above, besides a dining-room (œcunatio), commanding a very extensive look-out on to the sea, the coast, and the beautiful villas scattered along the shore-line." (It seems to me that what Pliny says is that on this a tower or belvedere is built, for the space contains two rooms and a dining-room, so you could scarcely call it a turret.) "At the other end is a second turret, containing a room (cubiculum) that gets the rising and setting sun. Behind this is a large

Map of the Country between Rome and Laurentum, showing the Site of Pliny's Laurentine Villa.

store-room and granary" (Apotheca et Horreum; it is supposed that this latter was not a granary, but a room for curiosities). "and, underneath, a spacious dining-room, where only the murmur and break of the sea can be heard even in a storm. It looks out upon the garden, and the gestatio running round the garden. The gestatio is bordered round with box, and, where that is decayed, with rosemary; for the box, wherever sheltered by the buildings, grows plentifully, but, when it lies open and exposed to the weather and spray from the sea, though at some distance from this latter, it quite withers up. Next the gestatio, and running along inside it, is a shady vine plantation" (I presume what the Italians call a pergola), "the path of which is so soft and easy to the tread that you may walk barefoot upon it. The garden is chiefly planted with fig and mulberry trees, to which the soil is as favourable as it is averse from all others.

Here is a dining-room (œcunatio) which, though it stands away from the sea, enjoys the garden view, which is just as pleasant: two apartments (diæta) run round the back part of it, the windows of which look out upon the entrance of the villa (Vestibulum villæ), and into a fine kitchen-garden. From here extends an enclosed portico (cryptoporticus), which from its great length you might take for a public one. It has a range of windows on either side, but more on the side facing the sea, and fewer on the garden side, and these, single windows and alternate with the opposite rows. In calm, clear weather, these are all thrown open; but if it blows, those on the weather side are closed, whilst those away from the wind can remain open without any inconvenience. Before this enclosed portico lies a terrace (Xystus) fragrant with the scent of violets, and warmed by the reflexion of the sun from the portico, which, while it retains the rays, keeps away the North-East wind; and it is as warm on this side as it is cool on the side opposite; in the same way it is a protection against the wind from the south-west, and thus, in short, by means of its several sides, breaks the force of the winds from whatever quarter they may blow. These are some of its winter advantages. They are still more appreciable in the summer time; for at that season it throws

a shade upon the terrace (Xystus) during the whole of the forenoon, and upon the adjoining portion of the gestatio and garden in the afternoon, casting a greater or less shade on this side, or on that, as the day increases or decreases. But the portico itself is coolest just at the time when the sun is at its hottest, that is, when the rays fall directly upon the roof. Also, by opening the windows, you let in the western breezes in a free current, which prevents the place getting oppressive with the close and stagnant air. At the upper end of the terrace and portico stands a detached garden building, which I call my favourite; my favourite, indeed, as I put it up myself. It contains a very warm winter room (Heliocaminus), one side of which looks down on to the terrace (Xystus), while the other has a view of the sea, and both lie exposed to the sun. The bedroom opens on to the covered portico by means of folding doors, while its window looks out upon the sea." (This last sentence seems to me to be altogether incorrect, though correctly given by Melmoth as follows:—"Through the folding-doors you see the opposite chamber, and from the window is a prospect of the enclosed portico.")

"On that side next the sea, and facing the middle wall, is formed a very elegant little recess, which by means of transparent windows (specularibus) and curtains (Velis) drawn to or aside, can be made part of the adjoining room, or separated from it. It contains a couch and two chairs; as you lie upon this couch, from where your feet are you get a peep of the sea; looking behind you, you see the neighbouring villas, and from the head you may have a view of the woods; these three views may be seen either separately, from so many different windows, or blended together in one.

Adjoining this is a bedroom (Cubiculum noctis et somni) which neither the servants' voices, the murmuring of the sea, the glare of lightning, nor daylight itself can penetrate, unless you open the windows. This profound tranquillity and seclusion are occasioned by a passage (Andiön) separating the wall from that of the garden, and thus, by means of this intervening space, every noise is drowned." (This word "Andiön" was used by the Greek writers for the public dining-rooms for men.

It is mentioned by Vitruvius, lib. 6, cap. 7, p. 5, in his description of Greek buildings:—"But between the two peristyles there are passages, which are called Mesaulæ, because they are placed in the middle between two halls; but our people call them Andions. But this is very remarkable, for it neither suits Greek nor Latin. The Greeks call these halls *Ἀνδριῶνας* where the men's banquets are, because women do not go there." The word is still in use in Italy. Andron is defined as "a covered place, long and narrow, which goes from the street-door to the staircase or to the court in houses which have no Atrium or Vestibule." *Vide* Vocabolario Domestico, by Carona. 1859.

"Annexed to this is a tiny stove-room, which by opening or shutting a little aperture lets out or retains the heat from underneath, according as you require. Beyond this lies a bedroom (Cubiculum), and ante-room (Procoena), which enjoy the sun, though obliquely, indeed, from the time it rises till the afternoon." (I have taken no notice of any part of the translation I did not agree with, except such parts as relate to the buildings.)

Although this letter seems to me to be a very agreeable one, I fear it has appeared rather long to you; but as it is the programme on which V. Scamozzi, J. P. Felibien des Avaux, R. Castell, P. Marquet, Macquet, Haudebourt, and Bouchet have constructed their restorations, I did not see how I could help giving it you.

Pliny describes himself as not rich, but when one considers that he had a town house, this suburban retreat, and his country house at Città de Castello, in Tuscany, and tells us that he had several villas on Lake Larius (the Lake of Como), two of which he liked best, and villas at Frascati, Tivoli, and Paestrina, that he built a temple, endowed a college, presented money to his friends, and bought a small piece of property for 24,000*l.*, we must suppose him to have been comfortably off.

You have probably observed that he does not say a word about those parts of the house that were used by his wife, nor does he give the slightest indication of the outward appearance of his villa, nor deign to mention the architect of this or any other of his villas; and from what he says of the other Fine Arts, we may judge of the still lower estimation in which he held our profession—*e.g.*: "However, as you would direct a painter or sculptor who was representing the figure of your son what parts he should re-touch or express, so I hope you will guide and inform my hand in this more durable, or (as you are pleased to think it) this immortal likeness which I am endeavouring to execute." He thought polite letter-writing was not only the highest art, but so much beyond comparison with all others, that he scarcely deigns to mention the architect. When Pliny was about to rebuild the Temple of Ceres, he wrote the following letter to Mestius, who is supposed to have been an architect, and Haudebourt supposes he was the architect who built the Laurentine Villa:—

"In compliance with the advice of the Atruspices, I intend to enlarge and beautify the Temple of Ceres, which stands upon my estate. It is indeed a very ancient fabric, and though extremely small, yet upon a certain stated anniversary is much frequented. On Sept. 13, great numbers of people from all the country round assemble there, at which time many affairs are transacted, and many vows paid and offered; but there is no shelter at hand for them either from sun or rain. I think, therefore, I shall perform an act both of piety and munificence if, at the same time that I build a beautiful temple, I add to it a spacious portico; the first for the service of the goddess, the other for the use of the people. I beg, therefore, you would purchase for me four marble pillars, of whatever kind you shall think proper; as well as a quantity of marble for laying the floor and encrusting the walls. You must also either buy a statue of the goddess or get one made; for age has maimed, in some parts, the ancient one of wood which stands there at present. With respect to the portico, I do not recollect there being anything you can send me that will be serviceable, unless you will sketch me out a plan suitable to the situation of the place. It is not practicable to build it round the temple, because it is encompassed on one side by the river, whose banks are exceedingly steep, and on the other by the high road. Beyond this road lies a very large meadow, in which the portico may be conveniently enough placed,

* See plans of six of these restorations in this week's *Builder*.—Ed

opposite to the temple; unless you, who know so well how to conquer the inconveniences of nature by art, can hit upon some better plan.—Farewell."—(Pliny's Letters, lib. 9, lit. 39.)

Scamozzi's is, I believe, the first attempt at a restoration. It is published in his book called "An Idea of Universal Architecture," in 1615, and by Felibien, but it is not much more like the villa Pliny describes than Newton's.* In his drawing, the shape of the portico was given as an O, and he makes it circular [see lithograph in this number of *Builder*], and he seems to believe that the Atrium and Cavadium were both open; he puts the Cyziene Hall into the sea, and supposes the second bedroom to the left to be the gymnasium; he puts the two towers over his garden entrances on either side, and the bath-rooms are not distinguished from the other rooms, and his cloisters (Cryptoporticus) he puts on both sides of the Atrium and circular portico, without any regard to Pliny's description of the position of his single cloister, and omits the garden pavilion altogether. Scamozzi's plan is a very fine one, with the internal circular portico, but can hardly be looked on as a serious attempt to reconstruct the villa from Pliny's description.

Jean François Felibien des Avaux, who was secretary to the Academy of Architecture, published his book at Paris in 1699, though the one most commonly known in England was published in London in 1707. He, being an antiquary, has made a much more careful attempt to construct the plan in accordance with Pliny's words than Scamozzi, though the plan is by no means so good, merely looked on as a plan; this, however, was to be expected, for we naturally look for a good plan from an architect of Scamozzi's reputation.

To return to Felibien's plan [see lithograph] his Atrium is a very shallow portico preceding the large circular one, his Cavadium is a large open court, and his Cyziene dining-room keeps quite clear of the sea, and so leaves a terrace for the athletic exercises, but if the sea washed the foot of the dining-room, I fear it would wash the terrace too. In the angle room at the extreme left he altogether ignores the Apse. To the right of the dining-room we get a room, and ante-room, not mentioned in Pliny's description, nor does the Piscina correspond with the description, as it is doubtful if you could get a glimpse of the sea from it while swimming; there is no nectarium, and the tennis-court has only two small windows to the west, the main light being from the north. There are no staircases shown to the two towers, and it is by no means certain that the dining-room, with its two chambers, was detached; instead of two, he makes seven chambers, beside the dining-room. The *Dinctor* is sometimes used like the French word *apartment*, meaning a suite of rooms.

The Garden Pavilion certainly does not answer to the description as regards the dining-room, for the Cryptoporticus could not be seen from its window; The night bedroom opens on to the area of a peristyle which does not seem to answer to the common acceptance of Andron, and the store-room and granary are omitted. It is possible that he supposed these to be over the dining-room as Haudebourt does, but it seems rather a curious position for them, though Pliny himself uses the word horreum for a museum, repository, or lumber-room for curiosities (see letter 13, book 8, Pliny's Epistles).

As Pliny does not give a single dimension (what would we not give for him to have stepped the width and depth of his villa and those of some of the main parts), he does not name the offices nor give the number of his servants' rooms, is vague about the connexion of the various parts of the villa, and does not tell us which way they turn, it is not easy to solve the problem, nor is it wonderful that everyone who has attempted the solution has constructed it differently.

R. Castell, in his book on the villas of the ancients (fol. London, 1728), gives his translation of Pliny's letter to Gallus describing his Laurentine villa, and is quite original in his restoration; though we must not forget that before the excavations at Pompeii, architects knew even less than they do at present about Roman houses. The Atrium is shown as a great

* This learned translator of Vitruvius gives an illustration of the villa pseudo-urbanæ, founded on Pliny's description.

† We do not quite understand this criticism of Professor Aitchison's; as in the translation of Pliny's letter, as given above, it is not said that the windows of this chamber looked upon the Cryptoporticus.—Ed.

open forecourt the whole width of the villa [see lithograph], and about two-thirds of its width in depth.

The portico, in the shape of an O, is a large oval. The Cavadium is also open, with two porticoes projecting into it, on the right and left; the one on the right being the width of the cold room; the Cyziene dining-room has a portico in front that forms a vestibule to it, and the room itself scarcely extends to the edge of the shore. He makes the rooms to the right and left of the dining-room of the same size, and gets a vestibule, the small room, and the library into the left apsidal wing. His supper-room to the right corresponds with the other wing, the end being also apsidal; he then gets the bedroom and ante-room on the left. The cold room of the bath on the right flank is very large, with two semicircular baths, a large anointing-room, and the two bath-rooms; but his hypocaust is the furnace for heating the water, and not the sweating-room. Beyond these, again, is the tennis-court, and attached to the angle of that are enormous dining-rooms. He puts his swimming-bath on the first floor, as well as the two apartments, and the other rooms he puts on the second floor. The covered portico he makes wide enough to require two columns in its width, and consequently to form three aisles; he attaches it to the side of his Atrium, with the garden face to the west; the supper-room and two suites of rooms next the Atrium; and the small garden pavilion at the other end.

The recess in this pavilion that held the couch and two chairs he makes come out of the warm-room, as Haudebourt has done after him. No hypocaust is shown, and the bedroom windows look out on one side into a dark passage (Andron) and on the other into the covered portico.

P. Marquet, who was, I believe, a Mexican priest, published at Rome his restoration in 1796. He shows the villa of much greater pretensions than the description of the owner would lead us to believe, as he shows two open courts [see lithograph], with the surrounding chambers to the right and left of the buildings on either side of the Cavadium, about which there is not a word in Pliny's letter. He gives a vestibule, a small Atrium, and puts his circular portico into the open space which he calls the Cavadium; the Cyziene dining-room is far from the sea; he gives no tennis-court, and supposes they played on the terrace; he shows two towers, with the barn and store-house between them; the Cryptoporticus has a bend in it; his garden pavilion is in pieces, the Heliocaminus being detached.

Haudebourt is the next who has made a restoration; he was a French architect, known throughout Christendom by his work on P. Peruzzi's Palazzo Massimi at Rome, and who had also the advantage of having seen the published drawings of Pompeii, and the ruins themselves; in most respects his restoration agrees best with the description.

He shows a vast portico in front, not mentioned by Pliny [see lithograph]; behind it are the two front cells of the Oestiarium and Atrienis (though he allots both to the Atrienis), with the passage between them, leading into a tetrastyle Atrium with Alm, but no tablinum; the portico is D shaped, and the peristyle of it has square piers; he does not leave the Cavadium as an open space, but surrounds it with porticoes, eight columns lengthwise to each side, and six to the shorter ends. It is hardly likely that an open court should be left as the only means of getting to the banquetting-hall in a villa that was mainly used as a winter residence, as all the other restorers have done; but one of these porticoes, *i.e.*, that on the left, would prevent the setting sun from entering the back window of the smaller room to the left of the main banquetting-hall. The apsidal room is made circular inside, but square outside, with recesses for the book cases. In the bath, the warm swimming-bath (Calida piscina) is very small, and the sweating-room (Hypocaust) circular. The tennis-court (Spheristerium) is open to the north-west; the inclosed portico (Cryptoporticus), after running parallel with the sea, turns towards it at a right angle, and runs nearly to it. At the end is the garden pavilion, projecting a little into the sea, but he makes the Heliocaminus the room with the recess, which does not seem to me to be what Pliny describes.

I cannot pass to the next restorer, Bouchet, without paying an affectionate tribute to the memory of this delightful enthusiast, who trudged

THE BUILDER, FEBRUARY 8, 1890.

Bronze Statue of Victory

1887

DRAWN BY MR. GERALD C. HORSLEY, A.R.I.B.A.

PHOTO LITHO SPRAGUE & CO. 22 MARTIN LANE LONDON E.C.

from Rome to Ostia, along the road Pliny once travelled, slept on rushes in the prison there, and walked over the ruins, then covered with earth and verdure, visited the Holy Island made by the fork of River Tiber, between Ostia and Fimicino, which once contained a Temple of Apollo,—and where games in his honour were celebrated,—and trudged back to Rome, by the Laurentine-road, close to the villas of Scipio and Lælius, and dreamt that he had an introduction to Pliny, who showed him over part of his villa, and then turned him over to his architect, Mustius, to show him the rest. The relish with which he discourses every part of the Roman house and the learning he displays is both delightful and admirable. I found I had been forestalled by him in the scraps of knowledge I fancied I was bringing fresh to the subject from Plautus and Terence (Plant. Mil. Glor. Act 2, S. 3, line 16; and Act 2, S. 2, line 4, Amp. 5, 1, 59, Epid. 2, 2, 43, Terence Eun. 3, 5, 41), for Vitruvius calls the opening in the roof of the Atrium "Compluvium," while Plautus and Terence call it "Impluvium."

Jules Bouchet, a French architect, published his restoration at Paris in 1852, and though he owes much to Haudebourt, he has taken great pains, and shows great ingenuity in trying to make his plan agree with the description.

He puts a decastyle portico in the front [see lithograph], with four columns on each flank, about which Pliny is silent; he has two porters' rooms with the passage between, and a tetrastyle Atrium with Aile; he adds a tablinum, not mentioned by Pliny, with one passage, and rooms on either side the tablinum. His portico takes the D shape of the late editions of Pliny; his Cavadium is a vast open court from which the Cyclic dining-room opens directly.

To get the sea washing its foot he has made it very long, and broken the terrace so that to the left is a wide terrace for the athletic exercises. To the left of the dining-room are the two chambers, and the third one with an apsidal end, and he has shown the space between that and the warmed bedroom, which Pliny describes. To the right are the other two chambers, though Pliny says nothing about the further one being apsidal. He makes an ample ante-room to lead to the Baths, and another large room adjoining it. The cold room has two ample cold baths, but the anointing-room, the sweating-room, and the furnace-room can only be got at from the two chambers. The hall containing the piscina takes the whole depth of the building, with porticoes at each end, and the tennis-court is separated from the baths by a long passage, with stairs to the towers at each end. Under the south tower are the two rooms and the dining-room. By breaking back the coast-line, he gets a view of the sea from the window on the west side of the dining-room, but he leaves out the museum and the store-room, though possibly he makes them on the first floor. He translates the obscure passage about the north tower as having the bedroom above, and the little pavilion fulfils all the requirements, except that the sleeping-room has only one window, and Pliny says "windows." Bouchet gives all the plans but one of the former restorers, as well as one by Macquet not published, but he omits Castell's.

I give you the extracts from Pliny's letter to Domitius Apollinaris (Lih. 5, Let. 6), describing his Tuscan villa, partly because Felibien, Castell, and Marquez have tried to restore it, and partly because you may as well have as much additional light as it can throw on the Laurentine. In this description, however, there is such an absence of method and such vagueness that any attempt to restore it is merely an exercise of the imagination.

[We omit here the letter describing the Tuscan villa of Pliny, as we shall be able to give next week Castell's restoration of it, and the description will be of more interest when taken in connexion with the plan.]

In spite of the charges of luxury and vanity that have been made against Pliny, which perhaps are not altogether without foundation, he seems to have been a courageous and hard-working man, and one determined to do right in spite of consequences, for he was proscribed by Domitian, and only escaped through the tyrant's death. He was certainly a liberal man, with kindly feelings, and humane enough not to have his farm filled by chained slaves; of refined tastes, and enjoying the friendship of all the principal authors of his time.

Pliny is a sufficiently interesting man to

make it perhaps worth one's while to investigate the charges against him. The charge of luxury seems to be founded mainly on the number of his villas. There were eight at least, but most of these were farms from which came the greater part of his income, for he tells us so, and that he only had a portion of his money at usury. No one would now call a man a sycophant if he had forty farms. A town and country house and a suburban villa is not more than many a successful barrister of the present day indulges in. Pliny, unfortunately, does not give us the bill of fare of his banquet, but three snails are all the meat, or, as the Italian would say, fish, he provides for the dinner he has with a friend; he sees the rope-dancing, pantomimes, and the can-can at his neighbour's houses, but does not have them at home. Very few rich men now are Anachorites.

He was evidently a case-winner as a harrister; he was Governor of Bitynia, and a friend of Trajan. Success, high employment, and the friendship of the great do not usually conduce to great modesty, and though vanity lies mainly in the temperament, would not most of us be vain if we spent so much time on our works that we could even hope they might last and be popular for 1800 years? Perhaps we cannot place much reliance on Martial's panegyric, as Pliny paid his travelling expenses to Spain. I now give you his account of how he spent his time in the country—

"You want to know how I portion out my day in my summer villa at Tuscum? I get up just when I please; generally about sunrise, often earlier, but seldom later than this. I keep the shutters closed, as darkness and silence wonderfully promote meditation. Thus free and abstracted from those outward objects which dissipate attention, I am left to my own thoughts; nor suffer my mind to wander with my eyes, but keep my eyes in subjection to my mind, which, when they are not distracted by a multiplicity of external objects, see nothing but what the imagination represents to them. If I have any work in hand, this is the time I choose for thinking it out, word for word, even to the minutest accuracy of expression. In this way I compose more or less, according as the subject is more or less difficult, and I find myself able to retain it. I then call my secretary, and opening the shutters, dictate to him what I have put into shape, after which I dismiss him; then call him in again, and again I do not observe one fixed hour, according to the weather, I either walk upon my terrace, or in the covered portico, and there I continue to meditate or dictate what remains upon the subject in which I am engaged. This completed, I get into my chariot, where I employ myself as before, when I was walking, or in my study; and find this change of scene refreshes, and keeps up my attention. On my return home, I take a little nap, then a walk, and after that, repeat out loud and distinctly some Greek or Latin speech, not so much for the sake of strengthening my voice, as my digestion; though indeed the voice at the same time is strengthened by this practice.

I then take another walk, am anointed, do my exercises, and go into the bath. At supper, if I have only my wife or a few friends with me, some author is read to us; and after supper we are entertained either with music or an interlude. When that is finished I take my walk with my family, amongst whom I am not without some scholars. Thus we pass our evenings in varied conversation; and the day, even when at the longest, steals imperceptibly away. Upon some occasions I change the order in certain of the articles above mentioned. For instance, if I have studied longer, or walked more than usual, after my second sleep, and reading a speech or two aloud, instead of using my chariot, I get on horseback, by which means I ensure as much exercise and lose less time. The visits of my friends from the neighbouring villages claim some part of the day; and sometimes, by an agreeable interruption, they come in very seasonably to relieve me when I am feeling tired. I now and then amuse myself with hunting, but always take my tablets into the field, that if I should meet with no game I may at least bring home something. Part of my time, too (though not so much as they desire), is allotted to my tenants, whose rustic complaints, along with these city occupations, make my literary studies still more delightful to me. Farewell!"

* Book IX. Letter 56. To PUSCUM.

ARCHITECTURAL SOCIETIES.

The Architectural Association.—The ordinary fortnightly meeting of this Association was held on Friday, Jan. 31, the President, Mr. Leonard Stokes, in the chair.—Mr. E. S. Gale, hon. secretary, announced that the first sessional visit would be made this day, Saturday, Feb. 8, to Mr. D'Oyly Carte's new theatre in Cambridge-circus, Shaftesbury-avenue. Arrangements had also been made for the second sessional visit, which would be to the Imperial Institute, South Kensington, on Saturday, the 22nd inst., when Mr. Colcott, the architect of that building, had promised to meet the party.—Mr. F. R. Farrow, senior hon. secretary, announced that the "Common Room" discussion which should have taken place on the 28th ult. had been postponed to Tuesday, Feb. 11, when the subject to be discussed will be "A Revised Scheme of Architectural Training." The discussion will be opened by Mr. A. W. Earle.—Mr. Farrow also read a letter from the Rev. T. H. Le Bouf, rector of Croylaud, appealing for subscriptions for the restoration of Croylaud Abbey. About 3,000*l.* is the sum needed.—The Chairman said he regretted to announce that Mr. Mountford, who was to have read a paper on "Free Libraries," was confined to his bed by an attack of influenza; but he had entrusted his paper to Mr. H. D. Appleton, who then proceeded to read it. We regret, however, that in consequence of the space occupied by Professor Atchison's lecture, we must hold over our detailed report of the meeting and discussion until next week.

Liverpool Architectural Society.—The fifth ordinary meeting of this society was held on Monday evening, in the Royal Institution, Colquhoun-street. Mr. T. Mellard Heade occupied the chair, and there was a pretty numerous attendance. The principal business before the meeting was a paper entitled "Mouldings," read by Mr. T. H. Haigh. The lecturer spoke of mouldings as being of the very first importance in all architectural detail, so much so that unless a student or professor had a sound and thorough knowledge of its alphabet, it was impossible for him to produce any work of any really true or artistic merit. Great ignorance of the subject prevailed among architects of fifty years ago, and though much progress had been made in recent years in this department, the knowledge of modern architects on the subject was not so complete as could be desired, many important buildings being woefully deficient in detail. A knowledge of mouldings was also most essential to the architect in enabling him to determine the dates of old buildings, their mouldings being often the only guide. In main lines and features the ancient builder sometimes copied work of a much earlier period than his own, but their mouldings were almost invariably to be depended upon as those of their own epoch.

Manchester Architectural Association.—At a meeting of this Association, held at the Diocesan Buildings on Tuesday last, Mr. J. H. Woodhouse, President, in the chair, Mr. J. A. Gotch, F.R.I.B.A., of Kettering, read a paper on "The Homes of Queen Elizabeth's Courtiers." After giving a general sketch of the domestic arrangements of the homes of the nobles prior to this period, he pointed out that it was about this epoch that house-planning took a new departure. Whereas formerly safety from invasion was the chief object to be attained, even at the sacrifice of convenience, internal comfort began to be studied. Light was admitted by large window openings in place of narrow slits. In speaking of Hardwick Hall, with its large and numerous windows, Lord Bacon remarked "there was too much light, it was impossible to get out of the sun, always streaming through the windows." The paper was illustrated by views shown by an oxy-hydrogen lantern. A vote of thanks was proposed by Mr. Booth, seconded by Mr. Davies-Colley, and supported by Messrs. Mould, Mee, Hodgson, and Chadwick.

SURVEYORSHIPS.

Aberdare.—Mr. T. Lloyd Edwards has resigned his position as Surveyor to the Aberdare Local Board.

Wimbledon.—Mr. W. Santo Crimp, Engineer and Surveyor to the Wimbledon Local Board, has been elected Assistant Engineer to the London County Council.

Illustrations.

BRONZE STATUE OF VICTORY, ROMAN MUSEUM, BRESCIA.

THE statue is a little over life-size, and a beautiful bronze casting. It has the distinction of being, we believe, the most complete large statue of "Victory" yet found, as only the shield, and the helmet under the foot, are restorations. The drawing was made in pen-and-ink on the spot, and was exhibited at the Royal Academy, 1888.

RESTORED PLANS OF PLINY'S LAURENTINE VILLA.

THREE-FOURTHS of our illustration plates are occupied this week by reproductions of the various plans for the restoration of Pliny's villa collected by Professor Aitchison as illustrations to the second of his present series of Royal Academy lectures. They are referred to and described in the lecture, printed in full in another column.

As embodying the ideas of eminent architects of various periods since the Renaissance in regard to the plan of a typical Roman villa, we hope their juxtaposition in one issue, and its connexion with Professor Aitchison's interesting and learned lectures, may be of permanent value to students of Roman architecture.

We are indebted to Professor Aitchison's courtesy in placing the plans, as prepared by him, at our disposal.

HOGARTH'S HOUSE, CHISWICK.

THIS house, which stands about half-way up Hogarth-lane, on the west side, is a good specimen of the brick house of the eighteenth century. The walls generally are of red stock bricks with rubbed brick dressings. The chief features are a bold wooden bay-window on the north side (which is the principal front) supported not on an iron column, and a moulded wooden eaves course. The gutter has disappeared, and the roof is in a ruinous condition. There are two good gate-posts, but the old gates which were probably here have been replaced by a wooden door.

The entrance-door is just to the right of the bay-window, on the ground floor, and near this is a window retaining some lead glazing. The house stands at a sharp angle with the road, the east wall abutting on it.

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE sixth ordinary meeting of this Institute for the present session took place on Monday evening last, Mr. Arthur Cates, Vice-President, in the chair.

Obituary.

Mr. W. H. White (Secretary) said:—I have to announce with deep regret the decease of Mr. Edward William Stephens, Fellow, of Maidstone, and also of M. Jules Louis André, Hon. Corresponding Member, of Paris. M. André died on January 30, and he was buried to-day. He was a member of the Institute of France in the Section of Architecture of the Academy of Fine Arts, also a member of the Société Centrale, and architect of the Museum of Natural History in Paris, a Professor of the School of Fine Arts, a Commander of the Legion of Honour, and was also perhaps most distinguished as the master of many hundreds of pupils.

The Royal Gold Medal, 1890.

The Secretary having read By-law No. 64, relating to the award of the Royal Gold Medal,

The Chairman said:—I have now to announce that the Council propose to submit to her Majesty the Queen the name of John Gibson, past Vice-President, as the recipient of the Royal Gold Medal for the current year, for his works as an architect.

The Renaissance in Northamptonshire.

Mr. J. Alfred Gotch then read a paper, entitled "The Renaissance in Northamptonshire." The author, in his opening remarks, referred to the influence of Italy in the middle of the sixteenth century on the arts and literature of England, but considered that up to the third quarter of the century the Tudor style of architecture still reigned supreme. About 1550 to 1560 the new forms were universally adopted, and the comparative quietude of the age, and

Hogarth's House, Chiswick.

the great wealth of many ministers and courtiers of Elizabeth, enabled them to build mansions in which to establish themselves and their posterity. Lord Burghley, Sir Christopher Hatton, and Sir Thomas Tresham were the most illustrious builders in Northamptonshire. The capricious way in which the details of the period varied in excellence was most striking. Side by side, so to speak, might be found work the most delicate and refined, and work the most coarse and clumsy; but there was no gradual growth and decadence, no possibility of assigning a date to the work by slight changes in the detail or modification of the mouldings. In Northamptonshire, however, the work was of more even excellence, and, on the whole, of more intrinsic merit, than that of any other district with which the author was acquainted. Although one John Norden, in his "Delineation of Northamptonshire," in 1610, enumerated some fifty seats of noblemen and squires, there now only remained about ten for him to refer to, some having entirely disappeared and others being completely modernised. The first described by Mr. Gotch was Dingley Hall, built about 1558, which still retained some notable specimens of the early Renaissance, the work of Edward Griffin, Attorney-General to Queen Mary, who not only made use of most eccentric mouldings, but adorned his work with highly curious inscriptions, of which examples were quoted. Burghley House was next dealt with, and letters written by workpeople at Burghley to Sir William Cecil in London referred to, which, in common with others relating to Holdenby House, Hatfield House, and Cobham Hall, threw some light on methods of procedure connected with building in that era. The workpeople appeared to have applied direct to the owners for instructions; of the architect, as such, not a word was mentioned. A surveyor was here and there spoken of as going to inspect the works, but he was not always the same man. The owner apparently arranged everything and furnished the drawings, the carrying-out of which was entrusted to a foreman or clerk of works, who hired the workmen on behalf of his master. The details seemed to have been generally left to the fancy of the various artificers, who probably carried out the small scale drawings according to their own lights, though occasionally requests were met with for full details, which in some cases appeared to have been supplied by Thorpe, John Shute, Henryck, and others. Mr. Gotch then gave quotations from letters addressed to Sir William Cecil from the mason, foreman, and others at Burghley, and having alluded to Wothorpe, the Dover House at Burghley, which was built about 1600, proceeded to describe Sir Christopher Hatton's palace at Holdenby, and quoted the commendations of Lord Burghley and Sir Thomas Henshaw upon it. Turning next to Sir Christopher's purchase of Kirby Hall, Mr. Gotch thought there could be no doubt that the whole of the main building was built by the Staffords, and from Thorpe's plan it was known that he laid the first stone in 1570, and the work appeared

to have gone on until 1576, while subsequent to 1580 various extensions took place. Fifty years later, under Inigo Jones, another and the last period of active building set in, and fortunately the judicious care of the present owner was preventing Kirby, as far as possible, from falling into the same state as Holdenby. Reference was then made to John Thorpe's connexion with the building of Kirby Hall, Burghley, and Holdenby, and also to his plans of Lyveden New Building, which was built for Sir Thomas Tresham, who presented to the town of Rothwell a new market-house, which, however, was never finished, and had never had a roof. It was in some respects a typical Elizabethan building, and though its detail was coarse, yet it could not be denied that the whole composition had the merit of vigour and piquancy. Having remarked upon the chequered life of Sir Thomas Tresham, reference was made by the author to the Triangular Lodge, Rushton Hall, and the Lyveden New Building, which were all about the same date, the last two being described in considerable detail. Mr. Gotch considered Tresham's work more severe than that of his successors, the Cokaynes. His gables were straight, theirs were many of them curved, and all his architectural work was simple, elegant, and suggestive. Aphetorpe Hall, one of the most striking specimens of Renaissance in the county, was next described, and its similarity to Rushton pointed out. At Lilford, a few miles from Oundle, was a fine example of the circular bay, but there was something in the stiff arrangement of the windows that told of the tame slavery to which architecture in England was about to succumb. At Drayton House was a veritable storehouse of architecture, from walls and gateways of the Edwards, to pediments and panelling of William III. One wing was dated 1584, and the exterior still proclaimed its date; the principal interest, however, lay in the vaulted cellars, which a close inspection showed to be vaulting of the days of Elizabeth. Buckingham Castle was enlarged in similar manner to Drayton House, and was well worthy of inspection. Turning to the southern part of the county there was not much Renaissance, but Canons Ashby and Castle Ashby could not be omitted. The former was a beautiful old house, presenting work of the end of the fifteenth, the end of the sixteenth, and the beginning of the eighteenth centuries. Castle Ashby was begun about 1583, and the bay windows of that time were easily recognised, while the fine entrance screen was the work of Inigo Jones, dated 1624. The Renaissance impressed itself not only on the great houses; every kind of building was touched, from the palace of Holdenby to the little cottages of Brigstock and Geddington, and the author considered there were few districts in England where more suggestive features could be found for stone treatment. Having alluded to the almshouses at Weekley, Mr. Gotch, in conclusion, said the style was the outcome of a fascinating period. All England was quivering with vitality; when Dingley was built, Spenser was sixty years old; when Thorpe laid the first stone of Kirby, Shakspeare was the same age;

when Lilford was rising above the Nene, Ben Jonson was still alive; while, between the stoppage of Rothwell Market-house and the beginning of the Triangular Lodge, the great Armada was shattered. It was no wonder that the architecture of the time was interesting. Into the stones of their houses the men of Elizabeth's time hewed their greatness and their simplicity. The paper was copiously illustrated by lantern views and plans of the buildings referred to.

Mr. Wyatt Papworth proposed a vote of thanks to Mr. Gotch, who, he said, had certainly given the members great enlightenment on the subject of his paper. They all knew the interest which he (Mr. Papworth) had taken in the subject of the introduction of Renaissance architecture into England. The difficulty had always been to know who were the persons employed. His own impression, from the researches he had made, was that a great deal of the work of those buildings was done by the local masons. The County of Northampton contained a large number of good stone quarries, and the masons who wrought the stone apparently came of families who inherited considerable taste in the use of the material. He had been rather more strongly impressed with that view after reading Professor Willis's and Mr. Clark's History of Cambridge. He found that there was the old family of Grimbold, who did a good deal of the work of the Colleges, who apparently settled at Cambridge and became contracting architects. The buildings shown by Mr. Gotch seemed to convey some traditional work of the Early Tudor period, continued later down even through the transitional period of the introduction of Renaissance architecture. They were still in the dark as to how the Italian work came into England, and Mr. Gotch had scarcely touched upon that matter. It was known that John Shute was sent over by the Duke of Northumberland to Italy to study architecture. Unfortunately, however, he died a year or two after he published his interesting and scarce book; but although his epitaph stated he had erected a number of buildings, we did not know the name of a single one, and that was the misfortune with so many of those architects. It had been for a long time a matter of doubt as to whether such a person as John Thorpe ever really existed. His book in the Soane Museum, from which Mr. Gotch had copied some of the plans that had been shown on the screen, was well known; but whether Thorpe designed or sketched the buildings referred to there was great uncertainty; in fact, there was not a single record connecting his name with these valuable buildings. He (the speaker) had been able to discover a few records connected with Crown Lands, which Mr. Gotch was in possession of. There was one curious point which he had come upon lately, and that was the finding out where John Thorpe had lived, and almost where he died. In looking into an old volume of the *Builder*—one of his fine old bottles of crusted port—he found a reference by Henry Cunningham to a work by Pecham. In hunting that up, he found there was a family of the name of Thorpe who were surveyors, and lived in St. Martin's-in-the-Fields. From the context it was evident there was a father and a son, and if that was the case, it threw them into the difficulty as to which of the two designed the buildings. Having searched the registers of St. Martin's-in-the-Fields from about 1600 to 1624, he found three Thorpes. In 1618,—a rather peculiar date from other circumstances,—the burial of John "Thorpes" was registered, and the question was whether this was their John Thorpe. He also came across a book called "The Northampton and Rutland Wills of 1570 to 1602," and looking through the index that he found the names of various Thorpes; while in 1566 there appeared the name of Ann Thorpe, of Oakham, which would rather confirm the suggestion he had made that "Thorpe" and "Thrope" were the same name. As to the word "trick," which had been mentioned, it was an old expression for a drawing, while the word "plat" was the same as the present word "plan." He thanked Mr. Gotch for the very interesting, elaborate, and entertaining paper he had read, and hoped that some of their friends might take up the other counties, and illustrate them in the same way. If that were done, they might then get a very interesting idea of a most important part of the history of architecture in England.

Mr. Ralph Nevill, F.S.A., seconded the resolution, and referred to the excellent views of the buildings which had been given on the screen. It was evident that the subject was deeply im-

planted in Mr. Gotch's brain, and the only complaint that he had to make was that the lecturer had not described more fully the insides of the buildings, which were, in some respects, more interesting than the exteriors. To many, the woodwork and interior fittings of that period were far more interesting than the exteriors. Few, if any, of the buildings they had seen that evening could really be regarded as very fine specimens of architecture, and that led him to the consideration of the point Mr. Gotch had brought forward, as to how they became designed. The first indication of the style came to England in the time of Henry VIII., who was an extravagant builder of palaces. There were records in the Bodleian Library that in particular the joiners engaged on works in the period under review had mostly Italian and French names, which proved conclusively that they were brought over to this country, and no doubt introduced the new style. The early woodwork and the mantel-pieces in the good houses were obviously the work of cultured and skilled people, and it was only in small things, and at later times, that rude copies were to be found. When those skilled workmen had died out their successors produced rude and rough carving, which was infinitely inferior to the early work. Although some of these looked nice enough, it was due to the colour which age had given them. At Kirby nobody could recommend the use of the plasters, nor other Classic features of the design, although the cornices and details were as exquisite as need be. It was left to the masons to carry out the details to the best of their ability, and these were men who were perfectly able by tradition to carry out the ornament, though they were not able to carry out any grander scheme. He believed that might account in some way for certain failures that were to be seen. Wherever buildings of a humbler aspect were to be found, and where there was a greater mixture of the old style, there would be found greater skill, as at Rushden and other Tudor outside. Mr. Gotch had spoken about the survival of masons, but in stone counties these had lived to an even later date than he had mentioned. He (the speaker) had seen them in Gloucestershire, and he was not sure, as a matter of fact, that they had ever died out, although the fashionable large houses had gone in entirely for sash windows. No doubt the style in Northamptonshire had been introduced by the great courtiers, who become possessors there, and that was the case everywhere. The proprietors throughout England in those days were nearly always non-resident, and where the court influence was not felt the old style lived on very much longer than where they had so thorough a disturbance as took place in the home counties, in which some of the new style of work was produced somewhat in advance of the date Mr. Gotch had given. It seemed to him in all these things that the workman's skill was considerably in advance of the general designer's, until at a later date, when such men as Inigo Jones went to Italy and really studied architecture at first hand. He thought that there were many other parts of England where the larger buildings, though not more important, were in a sense more graceful and correct than some of those that had been shown to them that evening. It was, however, a great boon to them all that such a work as Mr. Gotch had engaged in should be taken up, and the buildings commemorated while there was still time. As they had seen from the photographs, many of the structures were going fast to ruin, and if some of the enthusiastic architects scattered about the country turned their attention to this work they would be able to lay up a treasure which future generations would highly appreciate.

The Chairman suggested that Mr. Nevill himself should take a step in that direction, by preparing an appendix containing extracts from the archives of the Bodleian Library.

Mr. Nevill replied that he had not the time, but perhaps Mr. Brnton, of Oxford, who was present that evening, might be able to undertake the work.

Mr. E. G. Brnton, F.S.A., expressed the pleasure he had felt in listening to Mr. Gotch's lecture and in witnessing the views. He was afraid there was no chance of his being able to carry out what Mr. Nevill had suggested, as the work he had to do rendered it impossible. With regard to the similarity of the Northamptonshire buildings to those in Oxford, he could not find from his knowledge of the Oxford work

that they were familiar to him. There was a very different feeling to be found in the Oxford buildings from what they found in the buildings of Northamptonshire. It would be interesting to compare them, and if they could collect the names of the persons who did the work in those days, it might lead to some interesting discoveries.

Mr. S. Flint Clarkson suggested that the drawings known as "John Thorpe's" had been made by the actual designer of the buildings, as they showed the flues on the upper floors in several cases.

Mr. H. D. Appleton said that it had occurred to him whether the person who ordered the inscription "God save the King, 1560," quoted by Mr. Gotch, was not an old lawyer. Some two or three years ago, when Lord Coleridge took the chair at a King's College annual dinner, he took exception to the toast of "The Church and Queen," saying it should be "The Church and King." The head of the State, Lord Coleridge then maintained, was always a king, even if a woman were sitting on the throne. We always spoke of "the United Kingdom."

Mr. Brydon remarked that much of the work in Northamptonshire which had been referred to was the outcome of the revival of learning which made its way into England, bringing its architecture with it. At the same time, there was a vigor about the whole work, and a distinctive national character, which marked it out as worthy of study. The builders of those days were a most vigorous race, and the result was a strength of detail and character in the work. His only regret was that Mr. Gotch had not taken them inside some of the houses. The plaster-work was very fine all through that period, and there was an exuberance about the detail that was very characteristic. He often wondered why so many of the young men of the present day rushed off to foreign countries when they had at their own doors such excellent English work to study, and which was so full of suggestion to the architect.

Mr. Paul Waterhouse drew attention to the light that was thrown upon the architecture of the period by contemporary painting, and he instanced two pictures in the Tudor Exhibition among several containing architectural back-ground.

The vote of thanks was then put, and very heartily received.

Mr. Gotch, in reply, said that the reason he had not given more views of the insides of the houses was the difficulty of getting good photographs of interiors, and the fact that the houses he had referred to had not much inside them worth being photographed. At the same time, he agreed with the idea that inside the houses architects could get as many suggestions as from the outside. With regard to Oxford, it had been said that the work there was very like the work in Northamptonshire, but it had always struck him that the obliquity which was heaped on the work of the period by the advocates of the Gothic style some thirty years ago, and notably by the late Mr. J. H. Parker, was occasioned by the Renaissance work which that gentleman saw round him in Oxford. It certainly struck him (the speaker) that the Oxford work, on the whole, was not anything like so interesting and suggestive as the work in Northamptonshire, although there was a family likeness. The materials of Lyveden were in great part removed to Oundle. Some of these remained on the ground, and his attention was called to them last year, when, under a heap of nettles, a mass of stones was pointed out. These the agent caused to be turned over, and upon some of them were found details with the trefoil and the Tresham coat of arms, but no date. Mr. Clarkson's suggestion that what were called Thorpe's drawings must have been made by the designer of the buildings, because they showed the course of the flues, was ingenious, and a good deal of weight might be attached to it. One suggestion was that he was simply a surveyor measuring the buildings for the owners, and that might be the case in some respects, but the opinion he had come to from a very careful inspection of the plans was that they might see in it the work of the designer as it came from the mind. It was proposed that Oundle Market House should have a roof put upon it, but that was waiting for want of funds, and any gentleman who felt interested in the subject could not do better than contribute to the building fund. With regard to the Tudor

Exhibition, he thought it was discreditable to the promoters—that there was not a single reference to or illustration of architecture, as an art, to be found in it.

The Chairman intimated that the next meeting would be held on the 17th inst., when a paper will be read by Mr. John Slater on "Building Legislation."

The proceedings then terminated.

THE LONDON COUNTY COUNCIL.

The ordinary weekly meeting of this Council was held on Tuesday afternoon last, in the Council Chamber of the Corporation of London, Guildhall. Sir John Lubbock, Vice-Chairman, occupied the chair in the absence of the Chairman, Lord Rosebery, who was unable to be present.

Resignation of the newly-elected Chief Engineer.—The Chairman said he regretted to have to announce that he had received a letter from Mr. Clement Dunscombe, resigning the office of Chief Engineer, to which he was elected only a short time ago.* In answer to a question from the Chairman, the Chairman said that Mr. Dunscombe's letter could be read, if the Council wished, but the resignation was tendered entirely on the ground of ill-health. After some discussion, it was decided to refer to the Standing Committee, in conjunction with the Chairmen of those Committees which were concerned with engineering work (such as the Main Drainage Committee and the Bridges Committee), the question of selecting a successor. With so many candidates for the office recently before the Council, it was decided not to re-advertise for candidates.

Election of an Assistant Engineer.—The Standing Committee brought up the following report and recommendation:—"We have to report that, in accordance with the directions given by the Council on the 3rd of December, an advertisement was issued inviting applications for the appointment of Assistant Engineer, in the place of Mr. Lovick, at a salary of 600*l.* a year. These applications were referred in the first instance to the Main Drainage Committee, with a request that that Committee would advise us as to the three candidates who might appear to them the most suitable for the post. The total number of applications received was 67, but this number was reduced, by setting aside the applications of candidates who had had no experience in the drainage of towns and in the service of municipal bodies, to 44. Of this latter number, 12 were seen by the Main Drainage Committee, who selected Mr. W. S. Crimp, Mr. H. A. Roebing, and Mr. A. B. Allan, as in their opinion the most suitable. In submitting these candidates to us the Committee stated that they had put the names in the order of what appeared to them the relative suitability of the three candidates for the office. The three gentlemen thus selected have since appeared before us, and we have done our best, by inquiry into their previous experience and the work they have been engaged upon, to form a judgment as to their respective merits. In doing so we have paid great deference to the opinion of the Main Drainage Committee, but we have not found ourselves able to agree altogether with the conclusion arrived at by that Committee. We cannot help feeling that they have very naturally dwelt mainly upon the special requirements of their own department; and we are of opinion that we should most faithfully carry out our opinion in the matter, and best serve the general interests of the Council, by submitting the names of Messrs. Crimp and Allan, without indicating any preference between them. We accordingly recommend—

"That the Council do select either Mr. A. B. Allan or Mr. W. S. Crimp for the vacant office of Assistant Engineer, and that the appointment be made on the conditions set forth in the minutes of the Council of 3rd December, 1889."

This recommendation gave rise to some discussion on the merits of the two candidates named, and on a show of hands being taken the numbers were: For Mr. W. S. Crimp, 44; for Mr. Allan, 39. A division being demanded and taken, there were: For Mr. Crimp, 47; for Mr. Allan, 46. Mr. Crimp was therefore declared elected.

The Main Drainage Question.—The Main Drainage Committee reported as follows:—"In accordance with the resolution of the Council of December 17, 1889,† instructing the

Main Drainage Committee to secure the services of an eminent Civil Engineer to join the Engineer of the Council in a thorough examination of the whole sewage system; and that the Engineers desired to include in their report an approximate estimate of the cost of taking the whole of the sewage to sea, your Committee have obtained from Mr. Benjamin Baker his consent so to act with the Engineer of the Council, his fee to be a retaining-fee of fifty guineas, and fifteen guineas per day occupied, the whole not to exceed 500 guineas. Your Committee recommend that this arrangement be approved."

This was agreed to without discussion.

The Fishers' Wages.—On the recommendation of the same Committee it was agreed—

"That the wages of fishers at Barking be at the rate of 7*d.* an hour, the work to be arranged in shifts of eight hours, in consequence of the work having to be continued throughout the twenty-four hours, with half an hour allowed for refreshment, the men to be booked ready for work at the hour of starting; that the work be carried on, as far as practicable, continuously throughout the week, and that the number of men employed be no more than the number sufficient to deal with the amount of sludge which under existing circumstances can be carried out to sea."

After transacting some further business the Council adjourned, after sitting for more than four hours.

THE INSTITUTE OF BUILDERS.

The sixth annual general meeting of this Institute was held at the offices on the 4th instant, Mr. F. May, J.P., in the chair.

The Secretary, Mr. Richard S. Henshaw, read the following report:—

"1. In presenting their Sixth Annual Report, the Council are pleased to be able to state that there is an increase in the number of members of the Institute, though they regret to have to record the loss by death of Mr. H. C. Lansdown.

"2. Several Bills relating to the Building Trade came under consideration during the Session, and were carefully watched by the Parliamentary Committee, and where considered desirable, necessary action was taken.

"3. It will be remembered that the Council in their last Report had appointed a Committee to confer with the Surveyors' Institution, in consequence of the legal decision in the case of Priestley v. Stone. The Committee, consisting of Messrs. H. T. Ashby, S. G. Bird, and Frank May, after considerable correspondence, succeeded in obtaining an interview with an equal number of gentlemen representing the Surveyors' Institution, and after some discussion it was thought desirable by the representatives of both Societies that the number should be increased to nine on each side. The Representatives then consisted of—

Mr. H. T. Ashby.	Builders.	Mr. F. J. Dove.
" H. H. Bartlett.	"	" A. J. Mansfield.
" S. G. Bird.	"	" Frank May.
" J. T. Chappell.	"	" J. Randall.
" J. H. Colla.	"	

Mr. C. R. Ardling.	Surveyors.	Mr. C. J. Shoppee.
" T. C. Clarke.	"	" H. T. Steward.
" C. J. Mann.	"	" W. H. Strudwick.
" T. M. Rickman.	"	" F. G. Widnell.
" C. F. Selby.	"	

"4. The powers granted to the Committee by the Council of this Institute were:—

"To consider the responsibility of Quantity Surveyors for their quantities and matters incidental to the preparation and compilation of Bills and Quantities and Specifications, or arising thereout, especially as regards provisional amounts and work and the employment of specified firms for goods or work."

"5. The Committee placed their views before the representatives of the Surveyors' Institution, but after considerable discussion the representatives of the Surveyors did not see their way to recommend members of their Institution to accept any legal responsibility for their work, and after further discussion the subject was, on the proposition of the Surveyors, adjourned *sine die*.

"6. In the early part of the year Mr. G. S. Stevens, the Past-President, and Mr. G. Watson, a member of the Directorate of the National Association of Builders of America, visited this country. Several interviews took place between them and several members of this Institute, and it is hoped that the interchange of information and ideas may lead to the mutual benefit of both Societies and to a further extension of courtesies. They were entertained at dinner by some of the London builders.

"7. The Council have made a grant of 25*l.* to the Library Fund from the funds of the Institute, and they also have to express their thanks to the Royal Institute of British Architects and the National Association of Builders of America, and other friends, for the presentation of books, &c.

"8. In addition to the usual grants from the Benevolent Fund to the Builders' Benevolent Institution, the President Institution of Builders' Foremen and Clerks of works, the Council have also had the pleasure of granting some assistance to two private applicants.

"9. The Council have to announce that in future, instead of making an annual grant to the Builders' Benevolent Institution, they have made arrangements for the support of one pensioner to be selected by them from the list of candidates approved by the Builders' Benevolent Institution.

"10. Permission, during the pleasure of the Council, has been granted to the Home Counties Volunteer In-

stitution to use the rooms of this Institute for meetings, when not required for other purposes.

"11. The Council have to tender their thanks to Mr. Joseph Randall for the paper read by him at the Institute, which they considered of great interest and value.

"12. Under the Articles of Association, no provision is made for retaining Past Presidents upon the Council and benefiting by their experience and advice."

"13. Under these circumstances the Council wish the members to consider the desirability of altering the Articles of Association to the extent of making all Past Presidents Honorary Vice-Presidents.

"14. In accordance with the Articles of Association, the President, Mr. Frank May; one of the Vice-Presidents, Mr. R. J. Waller; the Treasurer, Mr. George Flucknott; one of the Auditors, Mr. H. I. Sanders; and four members of the Council, Mr. James Greenwood, Mr. Woodman Hill, Mr. Robert Neill, junr., Mr. J. H. Trollope, retire, but are eligible for re-election."

On the motion of the Chairman, the report was received and adopted, and

Mr. Thomas F. Rider was unanimously elected President for the ensuing year. Mr. R. J. Waller was elected, and Mr. A. J. Mansfield was re-elected Treasurer; Mr. Frank May was elected a Member of the Council, in the place of Mr. A. J. Mansfield; and the following members were elected and re-elected on the Council, viz.:—Mr. John M. Burt, Mr. Woodman Hill, Mr. Robert Neill, junr., and Mr. J. H. Trollope. Mr. H. J. Sanders was re-elected one of the auditors.

A vote of thanks to the Chairman concluded the proceedings.

THE SOCIETY OF ENGINEERS:

THE PRESIDENT'S ADDRESS.

The first ordinary meeting of the Society of Engineers for the present year was held on Monday evening, February 3, at the Town Hall, Westminster. Mr. Jonathan R. Baillie, the President for 1889, first occupied the chair, and presented the premiums of hooks awarded for papers read during his year of office, viz.:—

"The President's Premium to Mr. G. M. Lawford for his paper on "Fireproof Floors." The "Bessemer Premium" to Mr. Samuel Griffin for his paper on "Modern Gas-tight Practice." A "Society's Premium" to Mr. Henry Pajia for his paper on "Forced Filtration of Water through Concrete," and to Mr. George R. Stracian for his paper on "The Construction and Repair of Roads."

Mr. Baillie introduced the President for the present year, Mr. Henry Adams, to the meeting, and retired from the chair, receiving a hearty and unanimous vote of thanks for his services during the past year.

Mr. Adams then took the chair, and proceeded to deliver his inaugural address. He briefly alluded to the satisfactory position of the Society, which now numbers 417 members of all classes, and mentioned the loss by death of Mr. Percy, and the addition of Mr. Earl Granville, Lord Armstrong, Lord Brassey, Sir Wm. Thomson, Mr. Wm. Anderson, and Mr. Benjamin Baker to the roll of honorary members. He commented on the principal points of the papers read during the session, and described the features of interest in the works visited by the members during the vacation, which included the East London Waterworks, the Sewage Outfall Precipitation Works at Crossness, the Central Station of the London Electric Supply Corporation, and the Foreign Cattle Market, Deptford. The President then referred to the progress of technical education, noticing particularly the work of the Science and Art Department and that of the City and Guilds of London Institute, and incidentally gave some particulars of the City of London College, where he has been for twenty-one years the Professor of Engineering.

Remarking that a wider field of enterprise than that contained within the shores of the United Kingdom was necessary for engineers, he gave statistics showing that about 30 per cent. of the English engineers were now practising abroad. The extended use of mild steel and some of its disadvantages were noticed, and the President then passed on to a consideration of our fuel supply. He believed that the days of coal were surely numbered, and that it behoved us to seek other means of generating power, and in the meantime to practise the greatest economy in the use of the mainstay of England's prosperity. Under the head of railways some figures were given showing the vastness of the traffic upon them, and that, notwithstanding the rapidity of transit, according to the last statistics only one passenger was injured in

* Dec. 3 inst. See *Builder* for Dec. 7, p. 494.
† See *Builder*, Dec. 21 inst, p. 446.

13 millions, and not more than one in 80 millions was killed by causes beyond their own control. Several large bridges were described, the Forth Bridge, of course, occupying the place of honour, and references were made to many other engineering works and processes which have occupied public attention. In conclusion, attention was directed to the necessity for specialisation in the studies of engineers, the multifarious sub-divisions rendering it physically impossible for one man to thoroughly master more than one or two branches, and hence the necessity for the existence of such bodies as the Society of Engineers, where experiences could be freely exchanged.

NATIONAL ASSOCIATION OF MASTER BUILDERS OF GREAT BRITAIN.

THE twenty fourth half-yearly meeting of this Association was held on Wednesday, January 29, at the rooms of the Central Association of Master Builders of London, Bedford-street, Strand, London; Mr. J. Howard Colls, President, in the chair; and local Associations were represented by master builders from London, Manchester, Liverpool, Birmingham, Leeds, Hull, Bristol, Southampton, Gosport, and Bolton.

The report and accounts for the past half-year were discussed and adopted. The demands made by the operatives in Birmingham, Blackburn, Bradford, Dundee, Edinburgh and Leith, Glasgow, Hamilton, Leeds, Liverpool, Birkenhead, Norwich, Rochdale, and Southampton, were fully discussed.

From Bristol, the representative reported that the amicable relations there existing are maintained by meetings of the workmen with a committee of the Builders' Association, and that mutual concessions will conduce to the same end.

The question of any alterations in the Employers' Liability Bill was fully discussed, also insuring for any alteration that may be made in the Act. The Steam Engine and Boiler on Land (Person in Charge) Bill was also discussed.

The Council reported that the Association is keeping up correspondence with the National Association of Master Builders of the United States of America, which by a curious coincidence held its meeting on the same day, at St. Paul's, in Minnesota.

It was decided to hold the next meeting in Southampton.

In the evening the members of the Association dined together.

ASSOCIATION OF PUBLIC SANITARY INSPECTORS OF GREAT BRITAIN.

THE seventh annual dinner of this Association was held on Saturday evening last at the First Avenue Hotel, Holborn. Mr. Richardson presided, and among the company present, in all one hundred persons, were Dr. R. Farquharson, M.P., Surgeon-General C. A. Gordon, the Mayor of Leamington, Mr. E. C. Robins, Mr. Banister Fletcher (Master of the Carpenters' Company), Dr. Danford Thomas, Dr. Dudfield, Mr. Hugh Alexander (Chairman of the Council), Mr. Stanton Wm. Preston, Mr. C. W. Raymond, and Mr. S. C. Legg (hon. sec).

In giving the toast of "The Association and its President, Sir Edwin Chadwick," Dr. Richardson gave a sketch of the history of the society. When the Medical Officers of Health were first appointed, it was asked on all sides where the assistants of these medical officers would come from, and when they were found what would they be called. Assistants were found at last, though considerable difficulty was experienced in getting competent men for the work; and the name of sanitary inspectors was fixed upon. Though the first race of inspectors was largely untutored, now that a generation had passed away who had learned their duties and understood the importance of them, they were called. As for the subject of union in strength, the Association was formed in 1883. Its formation he considered to be the triumph of honest work, honourably conceived. The duties of the Association were to teach and protect its members—to teach them how their tasks should be carried out, and to protect them in the exercise of them; and having found by experience throughout the country, said the speaker, ought to belong to it; and he hoped that the apathy at present shown by too many of them would not last any longer. But there was something more to which the Association ought to turn its attention, and that was provision for the future. The British sanitary inspectors were decided to stand on the subject of pensions, and he believed that in a few years' time there would be no such things as pensions for officials holding public offices. The Association should now take upon itself the duties of a pro-

vident society, and insure its members against the evils of an unprovided old age. Referring to Sir Edwin Chadwick, who had been the President of the Association since its formation, Dr. Richardson said that the record of the work he had done was written in the history of the century. Though brought up for the Bar, with great abilities in that direction, he had lent himself to new and simpler work. For a period of over sixty years he had continued to spread sanitary light in England; and had made sanitation what it never could have been if he had not lived to be its guide, philosopher, and friend.

At the conclusion of his speech the chairman presented to Mr. S. C. Legg, the honorary secretary of the Association, an illuminated address and a purse of gold on behalf of the members, and in recognition of his ability and services. Other toasts followed, including that of "The Executive," proposed by Mr. S. F. Murphy, Medical Officer to the London County Council.

ROYAL ACADEMY LECTURES.

SIR,—In my first Royal Academy lecture, published in your issue of the 1st inst., I said, "The Koptic architect who built the brick mosque for Foulon in the ninth century, and possibly was the introducer of the small arches that take the place of pendentives in the dome." My friend, Mr. R. Pbené Spiers, has pointed out that these arches are not coeval with the original mosque.

Mr. Stanley Lane-Poole, in his "Art of the Saracens in Egypt," says of the brick dome, at page 64, "It was built, however, a century later than the mosque itself," and at page 64, "There is such a cupola over the niche in Ibn-Tuln, and though this is probably of the date of the restoration by Lagin in 1296, to judge by the wooden stalactites, which are found in no other part of this mosque." GEORGE AITCHISON. 150, Harley-street, W., Feb. 4, 1890.

THE LONDON SEWAGE QUESTION.

SIR,—In the discussion at the Society of Arts upon Sir Robert Rawlinson's paper, Mr. W. C. Sillar spoke to the effect that if the effluent or water from the A B C process was good enough to go into the Thames above Teddington Lock, it was surely good enough to go into the same river at Barking Creek, or into the Clyde at Glasgow. Now, as I understand Mr. Sillar to state, when here, that the amount of the Kingston-on-Thames sewage effluent in dry weather is only about a million and a quarter of gallons daily, while the flow of the Thames there amounted to about four hundred millions of gallons daily, it follows that the Kingston effluent only amounts to about one part in 325 of the Thames water. Moreover, the flow of the Thames is continually carrying away this effluent. The circumstances here are quite different from those either at London or Glasgow, for in the former the sewage effluent rises up to about one-third of the flow of the Thames, while at Glasgow in dry weather the effluent is equal to about half the amount of the flow of the Clyde. In dry weather, also, there is no sensible flow of the river towards from the harbour as the tide comes up past Glasgow. In these circumstances no proper comparison can be drawn between the effect of the small quantity of sewage effluent at Kingston and the large amount at both London and Glasgow,—in the latter case about 50,000,000 gallons daily, which we have been told would produce 44,000 tons of sludge a year, which sludge is calculated to realize (on paper at least) £22,000 a year, at 10s. a ton. I observe Mr. Clare Sewell Read stating that "the actual sludge, after it was dried, would not answer the purpose of any farmer to carry it four or five miles." The yearly Glasgow sewage revenue (if anything) might, therefore, really be only 22,000 farthings, not pounds sterling.

W. P. BUCHAN.

CARY'S GRAVE.

SIR,—In your interesting note on Hogarth House, Chiswick, occurs the sentence:—"In this same house died, in 1544, Cary, the translator of Dante; who, as also Hogarth and his wife, was buried in Chiswick churchyard." This statement is hardly correct as it stands, from the fact that Cary is not buried in Chiswick churchyard, but in Westminster Abbey.

As your journal is not the first publication wherein I have seen this erroneous assertion respecting Cary's place of sepulture, perhaps I may not be considered out of place if I ask the writer of the paragraph to state his authority in this instance.

The *Advertiser* of August 21, 1844, contained an obituary notice of Cary, from which I quote the following words:—"Mr. Cary well deserved a few lines in Poet's Corner in Westminster Abbey, which on Wednesday last was granted to his remains." His grave is next to that of the poet Campbell, and

from the slab which covers it I have copied the following inscription:—

UNDERNEATH
LIE THE REMAINS OF
HENRY FRANCIS CARY, M.A.
VICAR OF ABBOTS BRONLEY
FORMERLY VICAR OF KINGSBURY WARWICK
TRANSLATOR OF DANTE
BORN DEC. 6 1772
DIED AUG. 14 1814

I am, Sir, yours &c., JOHN T. PAGE.

* * * We are obliged to Mr. Page for preventing the further circulation of a mistake. Our authority was Thornbury & Valford's "Old and New London," vol. vi.—"Cary [*sic*], the translator of Dante, resided at Chiswick, in Hogarth's house, and lies buried in the churchyard, close under the south wall of the chancel. His monument was a few years ago rescued from oblivion, and restored at the expense of the vicar, who carefully enclosed it with iron railings."

THE SHEFFIELD MUNICIPAL BUILDINGS COMPETITION.

SIR,—Kindly correct a mistake which appeared in your issue of the 25th ult. In reviewing the plans exhibited at Sheffield of competitors for the Municipal Buildings you mention one by Messrs. Dunn, Hanson, & Dunn. This, as it stands, is incorrect, as my name should have been added, but through an oversight, probably of the clerk employed to label the designs, it has not appeared. The plans were drawn up by Messrs. Dunn, Hanson, and Dunn in conjunction with myself, and, I may add, were executed entirely in our Bristol office.

I shall be much obliged if you will let this letter appear, in order to remove misconceptions. FREDK. BUGH BOND. Liverpool Chambers, Corn-street, Bristol. February 3, 1890.

CHURCH BUILDING NEWS.

Eastham, Tenbury.—The Church of SS. Peter and Paul at Eastham, Tenbury, Worcestershire, in the diocese of Hereford, was re-opened on Thursday, Jan. 23rd, after undergoing a complete restoration of the nave. The fabric is of Norman work dating from 1080 to 1120, with some insertions in the north and south walls of the fourteenth and fifteenth centuries. The southern doorway, a beautiful specimen of Norman architecture, now opened for re-use, was blocked up in 1831, and the chancel arch, of similar design, was then destroyed, through some mistaken zeal. Above the southern doorway is some well-preserved wall arcading with intersecting arches, a rare example, in that position, of the change of style or period of transition. The restoration has been carried out as a memorial to the late George Browne, M.A., Q.C., formerly Recorder of Ludlow, by his widow, and his brother, the Rev. Henry Browne, rector of Eastham, Nash, in his History of Worcestershire, says:—"From the mention of a Presbyter in the Domesday survey of this Manor here was a church in the Saxon Age." The architect for the restoration was Mr. H. Hardwick Langston, of London; the works have been executed by local tradesmen, Mr. Hill and Mr. Hurds; Mr. John Kaye, of Camberwell, supplied the new stonework.

Fire Drill in Schools.—*Appropos* of the disaster at the Forest Gate Schools, upon which we commented a fortnight ago (see *Builder*, p. 55, *ante*), Messrs. Merryweather & Sons write to say that the Warehousemen and Clerks' Schools, at Russell Hill, Caterham, were two years ago fitted up by them with hydrants and other fire-extinguishing apparatus. With these appliances the boys are periodically drilled. The executive of the schools at Russell Hill were amongst the first to acknowledge the value of fire-drills, which, while assisting in the healthy development of muscle, is likely to be of service to the boys and to the country in after life. Many of these boys will go into city warehouses, and will take with them the knowledge which comparatively few people possess—viz., "how to act in case of fire," should necessity arise, much to the benefit of their employers. The question of fire-drill was mentioned at the inquest which was held on the lamentable disaster at Forest Gate, the jury strongly advising a periodical drill with the fire apparatus; and we trust that this recommendation will not be lost upon those who are interested in the management of our large schools.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—VI.

MAGNETISM.

IF a wire is wound into a spiral or helix, fig. 10, and a current sent through it, a set of lines of force is formed by the combination of the circular lines produced round every point in the wire; these resultant lines run through the helix parallel with its axis and curve back through the air outside. The coil or helix being closely wound with insulated wire, experiments show that the shape of the external field produced by the current is the same as it would be if the space occupied by the helix were filled by a piece of steel uniformly magnetised. A piece of soft iron, so made as to just fit the interior of the coil, inserted into it increases enormously the strength of the field, but does not alter its shape; the external effects are the same as they would be on increasing the strength of the current. It is, of course, impossible to map out the paths of the lines of force within the mass of metal, but there is no reason for supposing the shape of the field they form is essentially different from that traced out in the air within it by the helix alone.

It is a remarkable fact, and one of extreme importance, that if a piece of steel be taken and cut so that its edge follows exactly the curve or curves traced by a wire carrying an electric current, and if, furthermore, it be magnetised so that the direction of magnetisation at every point is the same as that of the line of force produced by the current alone; then the magnet so formed produces a field precisely similar to the one produced by the current; indeed, the magnet may be substituted for the voltaic circuit, and *vice versa*.

This interchangeability of magnet and circuit leads us at once to Ampère's theory of magnetism. In what has been said about magnets no attempt has been made to explain the magnetisation of the ultimate molecule of a piece of iron or steel. Ampère supposed that around every molecule of a magnet there flows an electric current. As a permanent magnet does not get hot nor require a constant supply of energy furnished to it in order that it may maintain its magnetised state, this theory also leads to the assumption that in each molecule there is at least one path that offers no resistance to the flow of electricity.

Fig 10.

Fig 11.

Suppose fig. 11 to represent a slice of steel, one molecule thick, cut from the north end of a steel magnet. The squares are individual molecules with their equal currents flowing round them. It will be seen from the figure that the external effect of each part of the current in an internal molecule must be neutralised by the current flowing in the opposite direction in that part of the neighbour with which it is in contact, although the direction of the current in each individual molecule is the same, *viz.*, opposite to that of the hands of a watch; this process of neutralisation goes on everywhere except at the periphery of the slice, that is at the surface of the magnet where there consequently exist unneutralised portions of molecular currents all flowing in the same direction.

This collection of currents in the surface of a steel magnet is equivalent to a current flowing in a wire similarly shaped, and hence it is that a suitably-shaped and magnetised piece of steel can produce the external effects of a voltaic circuit, or *vice versa*. Together with what has been written under "Magnets," the above completes the theory of magnetism as far as the magnet itself is concerned. Briefly, each molecule of a magnet has an electric current whirling round within it; when the metal composing the magnet is in a neutral or "unmagnetised" state, the axes of these whirls form closed curves within the mass of the metal; when the metal is magnetised, these whirls of current are

arranged so that their axes emerge from the metal into the surrounding medium.

But a magnet is of practical use only by virtue of the field of force in the air or other medium surrounding it, and the nature of the lines of force making up this field must be considered.

Fig. 12.

Fig. 12 has already been used to show the relative directions of an electric current AB, and the circular lines of force enveloping it. The electricity in the conductor can move bodily forward in the direction of the arrow; but the electricity outside is entangled or bound together so that it is incapable of such motion of translation. At the surface of the conductor the particles of electricity in the stream run against those outside, and the lines of force are due to this rubbing.

A rough idea of what is likely to happen may be got by standing on the bank of a river and looking at the water near the edge of the stream; the water is prevented by the friction of the banks from moving forward readily with the main current, and a number of little eddies or whirlpools are formed whose axes of rotation are at right-angles to the direction of flow of the main body of water.

In the case of the electric current, the electricity outside the conductor cannot move for-

Fig 13

ward at all, it can only spin round; hence in fig. 13, if AB is the current, it will set the particles of electricity at its surface spinning round in the direction of the arrow δ , and these will cause the similar rotation of the particles beyond them, the axes of rotation of the particles forming closed rings round the conductor. A line of force, then, is simply an axis around which electricity is rotating. In fig. 13, D is the direction of the current, δ the direction of the line of force, θ the direction of rotation of the electricity surrounding the conductor.

Fig. 12 can, without any alteration, be made to show the relative directions of current and line of force in two distinct cases. (1) If AB is an electric current, then the circles show the shape and direction of lines of force. (2) If the circles represent conductors carrying currents of electricity, then AB shows in shape and direction a line of force passing through them. The diagram in the latter case is of use in connection with electro-magnets. Ampère's rule, already given, may be written so as to include both cases:—

If you stand in a current which goes from your feet to your head and look at a current it is directed towards your left hand."

Laborer and Wagee in China—According to some recent United States Consular reports, in Hong Kong, Chinese workmen get from 12s. 5s. per annum, with board and lodging. Mechanics without board are paid per day:—Blacksmiths, 1s. 8d. to 1s. 2d.; bricklayers, 1s. 3d. to 1s. 8d.; carpenters and joiners, 10d. to 2s. 1d.; masons, 1s. 3d. to 1s. 8d.; labourers, 10d. and upwards. In the district of Ningpo the rates of wages are, for

Blacksmiths	per month	£1 0 10
Bricklayers	per day	0 10
Carpenters	"	0 11
Coppersmiths	"	1 3
Gold and silver workers	"	19j to 1 8
Painters	"	0 10j
Plumbers	"	1 0

Wages have not increased here for years, and strikes never occur. Trouble is rarely experienced, as labourers are confined to the districts in which they are employed. No labourer is allowed to be employed outside of his district; he may by general consent join the labourers of another district—not otherwise.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

2,741, Door Springs and Checks. G. F. Newman.

By the apparatus which is the subject of this patent the door is closed by a pulling action, and the closing apparatus is fixed either on the door frame or on the inside of the door. Within an upright barrel is a volute or band spring, whose inner and outer ends are connected to the inside of the barrel part and to an adjustable plate. The plate, which is rigidly connected to the central axis, lies upon the top face of the lower bracket under the barrel, while the axis, which is threaded through the spring and body part, has its end passing and working through the middle of the brackets. An arm and link aid the movement of the spring by bringing it into direct purchase. The tension of the wound-up spring causes the arm to move back, when the door is liberated, to its usual position with a pulling action to the link, and through the link to the door.

2,817, Window Sash-fasteners. W. S. Laycock.

A rack and pinion is the actuating power of the fastener which is the subject of this patent, and the catch can be operated by throwing the same in or out of gear, which can be done from inside the window, the mechanism being mounted in a suitable framing.

2,946, Brick and Tile Machines. J. Morhard.

This invention relates to machines for cutting and pressing bricks from clay. The material is first subjected to suitable pressure in a two-part separable case and by means of a revolving cutting-tool, which is caused to pass transversely through the pressed mass of material at the line of separation of the form or mould. At the time of such separation, after the pressing operation, a portion of the pressed material of suitable size to form a brick or block is smoothly cut from the end portion of the material. After this cutting operation, an elevating and discharging device receives and raises the cut-off portion clear of the form, and brings it into position to be readily taken out of the machine, and at such time the two-part form is moved in such a manner as to uncover and leave the finished block entirely clear of the form.

16,209, Windows. A. Heinrich.

The unpleasant propensity of window panes subjected to the influence of the various states of the atmosphere to be transformed into a non-transparent sweating or frozen state is, it is claimed, obviated by this invention. Two panes of glass coated with an alkali space between them, and in the frame a channel is made for carrying away moisture.

17,199, Veneer Saws. D. P. A. Messing.

The object of this invention is to enable the veneer-saws to act in both upward and downward directions. For this purpose the teeth are made M shape, and set at different angles, as in most cross-cut or wood saws.

7,109, Fireproof Partitions. A. W. Rammage.

In order to provide a partition which is fireproof and rigid, partitions are, according to this invention, made with iron or steel rods of T, L, or round or square section, and at the point of intersection they are fixed by a rivet, and the interstices are filled in with concrete, &c. Channel iron is used when necessary to aid in a better foundation for the concrete.

1,262, Blocks of Artificial Stone. A. McLean.

The artificial stone which is the subject of this patent is made of granite clippings and Portland cement. These are mixed with water and submitted to very heavy pressure. The effect of the heavy pressure is to produce on the surface a thin skin of fine cement, which is removed by rubbing down, and a very good polish is obtained. Mechanical and hydraulic means of pressure are mentioned in the specification.

3,144, Bricks, Bell & Sons.

The object of this invention is to produce bricks for building so made as to receive plugs, so that when built into a wall, woodwork or other materials may be attached thereto. To this end recesses are formed in the faces of the bricks, which, after baking, may be filled in by wood or other porous substance. The bricks are built into the wall where it is desired to secure woodwork, as, for instance, they may be built into doorways, and the door-frames secured thereto by nails or screws driven into plugs in the bricks. By this invention the fastening is rendered more secure, and the objectionable practice of driving plugs between the mortar-courses is avoided.

3,355, Wall-Tiles and Lining. W. Hubbard and Others.

According to this invention tiles are made thin and of a uniform thickness, most of the nature of artificial stone or siliceous substances. They are made also with rebates, grooves, or recesses, and the joints are covered by bosses, strips, or other

ornamental forms. The leading point is the unshrinkable nature of the material of which the tiles are made.

3,371, Fireplaces. H. M. Ashley.

The jams and lintel of the fireplace are, according to this invention, made of metal, hollow, so that there is a cavity between their fronts and the wall against which they are fixed. A door is also provided, which can, when required, be turned up into a horizontal position, and a gas burner, which is usually accommodated within the chamber, can be turned down to receive over it, and under the turned-up door, a saucepan or other cooking utensil.

3,516, Windows and Window-Fastenings. A. Ferret.

In order to allow of the lower sash being drawn out, the beads are, by this invention, hung on butt hinges, and this, with a fastening by means of a spring bolt secured to the top rail of the lower sash, constitutes the novelty of the invention.

3,563, Improvements in Water-closets. H. Lord.

The improvements which are the subject of this patent consist chiefly in so arranging the cistern sideway in a line with the apparatus, with a passage between the two, that the water in the cistern will flow into the pan to the same level as that in the cistern, an ordinary ball-tap being used to regulate the height or level of water in the cistern. A flap or clack suitably arranged hermetically seals the lower portion of the pan when the closet is not in use, but when the contents of the cistern are desired to be flushed to the sewer, the flap or clack is lowered by pulling a handle.

NEW APPLICATIONS FOR PATENTS.

New Harbours in Germany.—The German Government has decided upon constructing two new harbours in Schleswig-Holstein, viz., at Husum, on the south-west coast of Schleswig, and at Aaröund, in the Little Belt.

MEETINGS.

SATURDAY, FEBRUARY 8. Architectural Association.—Visit to Dr. Pojly Cart's Theatre, Shaftesbury-avenue.

MONDAY, FEBRUARY 10. Royal Academy.—Professor Altchison, A.R.A., on "The Private Houses and Palaces of the Romans." III. 8 p.m.

Surveyors' Institution.—Mr. G. M. Freeman on "Some Suggested Amendments in the Law and Practice of Compensation." 8 p.m. Society of Arts (Cantor Lectures).—Mr. Stivanus P. Thompson, D.Sc., on "The Electro-magnet." IV. 8 p.m. Clerks of Works' Association.—Seventh Annual Dinner, Holborn Restaurant. 6.30 p.m.

TUESDAY, FEBRUARY 11. Institution of Civil Engineers.—Further discussion on Mr. W. H. Wheeler's paper on "Bars at the Mouths of Tidal Estuaries." 8 p.m. Society of Arts (Applied Arts Section).—Mr. W. R. Leithy on "Cast Iron and its Treatment for Artistic Purposes." 8 p.m.

WEDNESDAY, FEBRUARY 12. Sanitary Institute.—Mr. Keith D. Young, F.R.I.B.A., on "Dwellings for the Labouring Classes." 8 p.m. Free Lectures to Artisans and others on Matters Connected with Building.—Professor T. Rogers Smith, on "Drawing: Geometrical and Perspective," Carpenters' Hall, London-wall. 8 p.m. Society of Arts.—Mr. G. Phindley (General Manager of the London and North-Western Railway) on "Modern Improvements in Facilities for Railway Travelling." 8 p.m.

THURSDAY, FEBRUARY 13. Royal Academy.—Professor Altchison, A.R.A., on "The Private Houses and Palaces of the Romans." IV. 8 p.m. Institute of Builders.—Mr. T. M. Rickman, F.S.A., on "An Edinburgh Contract." 8 p.m. Institution of Civil Engineers.—Students' visit to the Telegraph Department, General Post Office, St. Martin's-le-Grand.

Institution of Electrical Engineers.—Mr. J. Swinburne on "The Theory of Armature Reaction in Dynamos and Motors." 8 p.m.

FRIDAY, FEBRUARY 14. Architectural Association.—Mr. R. Elsey Smith on "Some Typical Greek Buildings." 7.30 p.m. Royal Institution.—Professor J. A. Fleming, M.A., D.Sc., on "Problems in the Physics of an Electric Lamp." 9 p.m.

SATURDAY, FEBRUARY 15. Royal Institution.—The Right Hon. Lord Rayleigh, M.A., F.R.S., on "Electricity and Magnetism." I. 8 p.m.

Miscellaneous.

Improvements in Rome.—According to a recent report of the British Consul at Rome, the Municipality of that city has, during the last seven years, undertaken an expenditure upon works of public improvement, governmental and municipal, of 11,000,000*l.*, the larger part, 9,500,000*l.*, being for works of a municipal character, comprising bridges, markets, new quarters, new streets, sewerage, water supply, &c. Of this expenditure 80 per cent. is represented by the indemnities paid for expropriation of houses and land. The demolition of old houses, and other works, have been proceeded with regularly. The works connected with the Tiber embankment proceed steadily, in accordance with the approved plans. The compressed air "caissons" are still made use of in laying down the foundations of the embankment, having proved very successful. The construction of the huge sewers proceeds in the same regular manner as the embankment. The sewers are to branch off in various directions, thus forming a general system of sewerage, placed at a considerable depth under the streets, and flushed by abundant streams of water. The Anglo-Roman Company for the illumination of Rome by gas and other systems, who have also undertaken the supply of electric light, intend utilising the hydraulic power which can be obtained at Tivoli, twenty miles from Rome, and to transmit the electric power thence, so as to illuminate Rome on a much larger scale than at present. The company will set up at Tivoli the necessary apparatus so as to obtain 1,700-horse power (electric). The current will be transmitted by overhead wires to a receiving station at Porta Pia. From there the electric light will be distributed by two systems—an overhead for public, and an underground for private illumination. The copper wires to be used for the overhead system are to be provided by the Società Metallurgica Italiana of Leghorn. The enterprise is to be completed within sixteen months, and is considered the most extensive application of the latest improvement for transmitting electric power to great distances.

Art Exhibition in Stockholm.—An art exhibition is to be opened in Stockholm, in March next, under the auspices of the Swedish Society of Arts.

St. Paul's Ecclesiological Society.—The eleventh annual report of this Society, which was presented to the annual meeting, held on Saturday last, says that the proceedings of the past year have been very satisfactory. The papers read at the evening meetings have been of great interest, and the visits, with one exception, have been very largely attended. During the year ten meetings have been held in the Chapter House, and the following papers have been read:—Two by Mr. A. Oliver, one on "Monumental Brasses and their Details," and one on "Flemish Brasses in England;" by the Rev. Ernest Geldart, on "Transepts;" by the Rev. E. S. Dewick, on "Christian Art on Coins from the time of Constantine the Great;" two, by Mr. G. H. Birch, on "Round Churches;" by the Rev. H. Hamilton Kelly, entitled, "A Study of Precedents for Liturgical Developments;" by Dr. J. Wickham Legg, on "The Divine Service in the Sixteenth Century, illustrated by the Reform of the Breviary of the Humiliati in 1548;" and by Mr. F. Hamilton Jackson, on "Mural Decoration in Churches;" and on one evening members were invited to bring for exhibition, and to describe, objects of ecclesiological interest. This was a new departure, but the result was so successful as to warrant a repetition of the experiment in the future. Afternoon visits were made to the churches of St. Mary Abbots, Kensington; St. Cuthbert Kensington, and Hammersmith; to All Saints, Fulham; to Chiswick Parish Church; to St. Alhans; to Bow and Stepey; to Wennington; and to Aveley. A whole-day visit was made to Norwich, but owing to the distance very few members attended. Part IV. of Volume II. of the "Transactions" has been issued during the year, and the Council venture to say that it is a publication of which the Society may well be proud. Attention is drawn to the fact (as shown in the balance-sheet) that the illustrations have been largely due to special contributions. The thanks of the Society are due to those who have thus contributed, and to the Rev. E. S. Dewick for the excellent service he renders the Society as honorary editor. The balance-sheet, although showing a deficit of about 12%, is regarded as satisfactory, the chief outlay being for the "Transactions," and as these are now published they will probably speedily repay their cost. Twenty-two new members have been elected during the year; the number on the register is now 274.

Liverpool Engineering Society.—The eighth ordinary meeting of the present session of this society was held on January 29 at the Royal Institution, Colquhoun-street, Mr. Henry H. West, M.Inst.C.E., President, in the chair. After the usual business, Mr. Charles H. Yeaman, A.I.C.E., &c., read a paper entitled "Notes on Central Station Electric Lighting." In giving an account of several stations at present supplying current on a commercial basis, he described the West Brompton High Tension, Glasgow High Tension, Hastings, Eastbourne, and Brighton Stations, Crompton's Battery System used at Kensington Court, and King's Subdivided Battery System in use at Chelsea, and illustrated his descriptions by mounted prints and diagrams. The history of the stations was traced, and the changes in the various systems employed noted. The author then compared and discussed the methods adopted to generate, measure, and distribute the electric energy, with regard to their general advantages, and drew conclusions therefrom as to the system of supply which will probably become general. Complete sets of junction and distributing boxes and samples of the mains employed and in use at Liverpool were shown. Samples of Fowler's cables, as used by the Horse-to-House Company in London and at Eastbourne, were also exhibited. In concluding, the author gave a short account of what is required of an Electric Supply Company under law and by the public demand, with special reference to the Board of Trade rules and to the curves of supply obtained from the various stations alluded to. The discussion upon the paper was adjourned till Feb. 26.

Art Applied to Cast-iron.—This will be the subject of a paper to be read on Tuesday evening next, at the Society of Arts, by Mr. W. R. Lethaby. The chair will be taken by Mr. H. H. Statham.

The "Herculea" Street-cleaning Machine.—We witnessed some trials of this machine last Saturday at Westminster, but want of space compels us to hold over what we have to say about it until next week.

New York Cathedral Competition.—When the choice of four plans was made by the Building Committee, of which the Rev. Dr. Morgan Dix is chairman, out of the large number of designs submitted for the proposed Protestant Episcopal Cathedral of St. John the Divine, it was decided to return these to the architects for elaboration and further competition. These plans, from which the final choice of a design was to have been made, were submitted by William A. Potter, Heins & Lafarge, J. Halsey Woods, and George Martin Huss. February 1, 1890, was set as the date of the final competition. No decision is likely, however, to be reached at that time, and from present indications it appears altogether probable that no decided steps will be taken in that direction for a year or two to come. The property upon which it is proposed to erect the cathedral is included in the site selected for the World's Fair, and pending the determination as to whether the exposition is to be held in this city, the Building Committee has decided to defer positive action in respect to plans for the proposed structure. Both Mr. Potter and Mr. Lafarge said that nothing had been done by them in the way of elaborating the plans on the part of the architects, and that the entire matter was *in statu quo*. The Board of Trustees had taken no formal action, but the architects had been unofficially notified that the requirement as to February 1 would be waived. Mr. Lafarge added that the delay was likely to prove of benefit to all parties in interest. The working out of the details of an undertaking of the magnitude of the proposed cathedral required a great deal of care and thought, and the additional time would be appreciated by the architects.—*New York Times.*

The English Iron Trade.—The stability of the English iron market has been disturbed this week by a further fall in warrants, and as a consequence *bonâ fide* business has been greatly hindered, if not entirely checked. Makers of pig-iron are holding still firmly to their quotations, because of the large amount of work they have yet before them; but the decline of warrants has been persistent. The Glasgow warrant market has almost entirely collapsed under the pressure of heavy selling. Scotch makers' prices are in consequence easier, inferior brands having been reduced as much as 5s. and 7s. a ton. There has been some selling by weak holders of Cleveland pig as low as 52s., which is a reduction of 5s. a ton since last week, but makers generally are not being frightened by this sudden drop. As a consequence, very little business is being done in the North of England as well as in Lancashire and Staffordshire, and prices in the Midlands are hardly as strong as they were. Bessemer iron has also felt the pinch, but none of the makers in the North-west have as yet made any alteration in their rates. In sympathy with crude iron, finished iron and steel are easier in tone. As, however, manufacturers of the finished products are placed as favourably with regard to orders as producers of pig-iron, and seeing that high prices of fuel and a high rate of wages will not permit them to give way much, the markets for manufactured iron and steel are pretty stable. The orders at present received for new ships are few in number and of small importance; but both shipbuilders and engineers are still as busy as they can be, and as they will be for some time to come.—*Iron.*

Competition. The Hull Branch of the York Union Bank.—The *Eastern Morning News* says that at a meeting of the directors of the York Union Bank, Limited, held in York, the plans of Messrs. Smith and Brodric, architects, of Hull, were selected from the designs submitted in a limited competition. The building will be stone, and in the Flemish Renaissance style, and will be erected at the corner of Lowgate and Bowalley-lane. The ground floor will be occupied by the banking premises of the York Union Bank, above which will be commodious offices for letting purposes. It is proposed to commence the building forthwith.

Free Lectures at Carpenters' Hall.—The first of a series of free lectures on matters connected with building was delivered in the Carpenters' Hall, London-wall, on Wednesday evening last, by Mr. Banister Fletcher, F.R.I.B.A., Master of the Company, his subject being "Architecture of the World in all Ages," illustrated by large drawings, expressly prepared, and photographs. Sir John Lubbock, Bart., M.P., presided, and there was a large attendance. We hope to be able to give a report next week.

The American Production of Pig-iron.—The output of pig-iron in the United States in 1889, as we learn from the statistics promptly issued by the American Iron and Steel Association, amounted to 7,604,625 tons, against 6,489,738 tons in 1888, which shows an increase for last year of 1,114,787 tons, or over 17 per cent. As the American production of pig-iron in 1888 was the largest, up to that year, in the history of the American iron trade, the increase of over 1,000,000 tons in 1889 is remarkable. The question as to when the United States will surpass Great Britain in the output of crude iron is illustrated by some figures which are given in the returns. In 1882 Great Britain produced 8,586,680 tons, against 4,623,323 tons turned out by the United States. In 1883 the production was 8,529,360 and 4,505,510 tons, respectively; in 1884, 7,811,727 and 4,097,868 tons; in 1885, 7,415,469 and 4,044,626 tons; in 1886, 7,009,751 and 3,683,223 tons; in 1887, 7,555,518 and 6,417,148 tons; in 1888, 7,998,967 tons. For 1889 the production of pig-iron of Great Britain is estimated at 8,300,000 tons, while the output of the United States, of which we have actual figures, reaches 7,604,625 tons, a total slightly higher than the production of Great Britain in 1887.

Application of Photography to Meteorology.—The Council of the Royal Meteorological Society have arranged to hold, at 25, Great George-street, Westminster (by permission of the Council of the Institution of Civil Engineers), on March 18 to 21 next, an exhibition of instruments and photographs illustrating the application of photography to meteorology. The Committee will also be glad to show any new meteorological instruments or apparatus invented, or first constructed, since last March; as well as photographs and drawings possessing meteorological interest.

CONTRACTS & PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

CONTRACTS.

Table with 5 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page. Includes entries for paving-up roads, water and other works, and various construction contracts.

PUBLIC APPOINTMENTS.

Table with 5 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page. Lists appointments for various roles like Foreman, Surveyors, and Inspectors.

TENDERS.

Multiple sections of tender notices for various projects including alterations to schools, bridges, and public buildings in locations like Leytonstone, London, and Bristol.

LONDON.—For the removal of fifth at Barking-outfall works for the London County Council:— C. Abbott & Sons, Hertford road, Kingsland, £820 0 0

LONDON.—For altering, adapting and painting the University Hall, Gordon-square, for the trustees of the late Dr. Daniel Williams. Mr. T. Chatfield Clarke, architect, 25, Bishopsgate-street, E.C. Quantities by Messrs. Leonard & Clarke, 205, Bishopsgate-street, E.C.:

LONDON.—For rebuilding No. 50, Tottenham-court-road, for Mr. Frank Moss. Messrs. Edmeston & Gabriel, architects, 42, Old Broad-street, E.C. Quantities supplied by Mr. G. R. Tasker, 38, John-street, Bedford-row, W.C.:

LONDON.—For alterations to shop front, &c., at No. 85, Brompton-road, S.W. Mr. Morewood, architect. No quantities:—

LONDON.—For alterations at the "Ranelagh Arms," Ranelagh-road, Old Ford, E. Mr. R. A. Lewcock, architect, 88, Bishopsgate-street Within, E.C.:

LONDON.—For alterations, &c., at "The Manor House," Finsbury Park, for Mr. J. Swinayr. Mr. John E. Finley, architect and surveyor, Bridge House, South Tottenham:

LONDON.—For alterations to the "Brewery," Seans-street, Haggerston, for Messrs. Danell & Sons. Messrs. Jamieson, Mr. J. W. Start, surveyor, Cups Chambers, Colchester:

LONDON.—For further additions at 39, Red Cross-street, E.C., for Messrs. Capua & Co. Messrs. Edmeston & Gabriel, architects, 42, Old Broad-street, E.C.:

LONG EATON.—For works for water supply for the Long Eaton Local Board. Mr. Geo. Hodson, M.Inst.C.E., engineer, Loughborough:—

LONDON.—For certain alterations, painting, and decorating, for new dining-room at the "Criterion" Restaurant, Piccadilly, for Messrs. Spiers & Pond & Co. B. E. Nightingale (accepted) £200 0 0

Art and Architecture in Browning's Poetry.

POETRY was defined by a great English critic, Matthew Arnold, as being essentially "a criticism of Life"; a definition which, if not the whole truth, at all events is one which applies with peculiar

fitness to the remarkable poet whose obsequies were celebrated a few weeks since in Westminster Abbey. The extent and variety of knowledge of and interest in all kinds of subjects which permeates Browning's poetry is extraordinary, and can only be fully realised by those who have been careful students of his works. Nothing seems to have escaped him: the most out-of-the-way events in history, the most curious phases of human character, the most minute incidents in nature, are referred to as passing illustrations, or dwelt upon with minute knowledge and insight—and among the subjects he knew best and delighted to discuss most were those connected with art, including music, architecture and painting. In the short poem entitled "How it Strikes a Contemporary," in which he gives a kind of ideal sketch of a poet as he appeared to the people about him, he represents him characteristically as a man who was remarked upon as taking note of everything around him, including the new buildings: the scene is laid in Spain—

"You saw go up and down Valladolid
A man of mark, to know next time you saw."

"You'd come upon his scrutinising hat,
Making a peaked shade blacker than itself
Against the single window spared some house
Intact yet with its mouldered Moorish work—
Or else surprise the ferrule of his stick
Trying the mortar's temper 'tween the chinks
Of some new shop a-building, French and fine."

The artist will not fail to note the truth of observation in the incident of the hat making a shadow "blacker than itself." In music Browning was one of the most acute and thoughtful of critics, with a wide range of knowledge of the art, the scientific basis of which he had systematically studied; and in regard to the history of painting and painters (Italian especially) he possessed such an amount of special knowledge that he would sometimes startle professed artists or art-critics by information in regard to some half-

forgotten painter whose name they hardly knew. In one of his later volumes, "Parleyings with Certain People," out of the seven persons of more or less *passé* reputations who are "parleyed" with, two are painters and one a musician; and of the two painters dealt with it would be interesting to know how many ordinary readers ever heard of "Francis Purini" or "Gerard de Lairese"; though both, as Browning leaves us in no doubt, were important persons in their day and in their artistic ambition.

In the main, however, the references to art in Browning's poems are not so much accessions to our knowledge as vivid side-lights, sometimes of criticism, sometimes of reminiscence and description, generally thrown out in passing, as illustrations of a thought, or as picturesque associations connected with the main subject in hand. There occasionally occurs a poem dedicated primarily to some artistic subject, but these are in the minority. In general, what we get from Browning are passing thoughts on the *raison d'être* of this or that form of art, or vivid touches of description which seem to flash a sudden light on some building or picture, and leave it in the memory with a new meaning for the future.

There are, however, two or three special poems which are definitely, though in a more or less indirect manner, studies in art criticism, or in the philosophy of art. One of the best and most characteristic of these is the semi-prose lyric, "Master Hugues of Saxe-Gotha," which however, being directly and mainly concerned with musical form, is out of our proper function here, though it has at the close a wider application to art generally as well as to the relation between life and nature, the conventional and the real. The two most important of the poems which are concerned with the philosophy of painting are entitled after the names of painters, "Fra Lippo Lippi" and "Andrea del Sarto," put probably not without intention next to each other in the old edition; the one the philosophy of the man who was content with a cheerful realism, the other that of the man who, if he did not truly aspire after idealism, at least regretted that he had not. "Lippo Lippi" contains things that come so appropriately into the modern art philosophy, that it has been quoted by writers and lecturers on art, if not *ad nauseam*, at least to the point of becoming somewhat hackneyed. The poem is, to begin with, a capital sketch of the jovial

but not very reputable painter who, as he complained, had been inducted with monkish vows when he was eight years old and knew no better, and who delivers his disjointed talk, intermixed with snatches of song, to a knot of men who catch him in a summer night in the streets of old Florence over some kind of escapade, and slips away with a "zooks!" as the dawn shows. Lippi was found by the monks, as he grew up, to be a good hand at painting; he was given a piece of cloister wall, and painted all sorts of people who came to the convent, to the delight of the crowd, who found the figures as real as life, but to the scandal of the Prior and the more learned brethren, who found this realism quite from the true mark of painting—

"Your business is not to catch men with show,
With homage to the perishable clay,
But lift them over it, ignore it all,
Make them forget there's such a thing as flesh;
Your business is to paint the souls of men"

Lippo wants to know how he is to do this without painting their bodies as well as possible first—

"Or say there's beauty with no soul at all
(I never saw it—put the case the same—)
If you get simple beauty and naught else,
You get about the best thing God invents:"

a distich not to be lightly forgotten. "Andrea del Sarto," a poem in a far more serious vein, may be taken as putting the other side of the question. Andrea is in the main pleased and satisfied with his reputation as the "perfect painter;" what he paints, as he boasts to his wife, he can do perfectly and with ease.—"No sketches first, no studies, that's long past,"—he can do with ease what many agonise to do and fail. But a revulsion comes over him; does not there perhaps burn a truer light of God in some of these unsuccessful ones, striving after an ideal they could not reach? Andrea is a man of art for Art's sake, as he admirably describes his abstraction in his own aim—

"I, painting from myself and to myself,
Know what I do, am unmoved by men's blame
Or their praise either. Somebody remarks
Morello's outline* there is wrongly traced,
His hue mistaken; what of that? or else,
Rightly traced and well ordered; what of that?
Speak as they please, what does the mountain care?
Ah, but a man's reach should exceed his grasp,
Or what's a heaven for? All is silver grey,
Placid and perfect with my art: the worse!"

* Apparently Morello was a hill visible from the window where the artist and his wife were supposed to be seated.

Truly Raphael was not equal to him as a draughtsman; Agnolo himself had said so; and there was a design of Raphael's on the wall which did not appear in all things correctly foreshortened—

"Indeed the arm is wrong;
I hardly dare . . . Yet, only you to see,
Give the chalk here—quick, thus the line should
go
Ay, but the soul! He's Raphael! rub it out!"

It was not without reason, either, that Browning placed in immediate juxtaposition with these two poems the one entitled "Pictor Ignotus: Florence, 15—": the soliloquy of the monk who felt he might have gained renown too as a painter—

"Nor will I say I have not dreamed (how well!)
Of going—I, in each new picture,—forth,
As, making new hearts beat and bosoms swell,
To Pope or Kaiser, East, West, South, or North,
Bound for the calmly satisfied great state
Or glad aspiring little burgh, it went,
Flowers cast upon the car which bore the freight
Through old streets named arch from the event."

lines which at once recall Sir F. Leighton's early picture of the procession of Cimabue's Madonna, the festival time when picture painting was a great discovery, a new power and glory among men. But alas! our speaker with prophetic eye sees another phase in the future—

"Who summoned those cold faces that hegun
To press on me and judge me? . . ."

These buy and sell our pictures, take and give,
Count them for furniture and household stuff,
And where they live needs must our pictures
live,

And see their faces, listen to their prate,
Partakers of their daily pettiness;
Disursed of—'Tis I love, and this I hate,
This likes me more, and this attracts me least,
Wherefore I choose my portion."

which was, to paint endless cloisters with virgins and saints, holy but monotonous, left to linger and decay there, but at least never to become the sport of the modern picture dealer and collector, to furnish the walls of some railway or commercial magnate, knowing in the market value of pictures, but as incapable of feeling the soul in them as the wall he hangs them on. Certainly it is not superfluous that the poet, the seer, should remind us in this dramatic manner of the gulf that lies between the popular view of painting in the early cinque-cento period and in the present day.

Following upon the three last-mentioned poems comes that remarkable sketch of the æsthetic worship characteristic of the Renaissance period, "The bishop orders his tomb in St. Praxed's Church: Rome, 15—": the Renaissance bishop, whose whole soul, as he felt death approaching was set upon having a truly artistic tomb built of the richest materials, such as would put to shame that of his predecessor—

"Old Gandolf with his paltry onion-stone."

Gandolf had indeed taken the best niche from him:—

"Shrewd was that snatch from out the corner
south

He graced his carrion with, God curse the same!
Yet still my niche is not so cramped but thence
One sees the pulp of 'the epistle-side,
And somewhat of the choir, those silent seats,
And up into the sky dome where live
The angels, and a sunbeam's sure to lurk:
And I shall fill my slab of basalt there,
And 'neath my tabernacle take my rest,
With those nine columns round me, two and two,
The odd one at my feet where Anselm stands:
Peach-blossom marble all, the rare, the ripe,
Like fresh poured red wine of a mighty pulse."

So did the bishop of the Renaissance muse as he lay dying on his bed—

"And let the bedclothes, for a mort-cloth, drop
Into great laps and folds of sculptor's work,"

and suggested to the hystanders the subjects which should compose the frieze, as Pans and nymphs, a tripod, thyrus, a vase or so, and the Saviour at his Sermon on the Mount, with the delightful illogical jumble of Pagan and Christian which seemed nowise incongruous in those days of the religion of art and

letters. This, like other touches here and there in Browning's poems, shows how remarkably he had penetrated and could express the very spirit of the art and the taste and feeling of a past age.

If we turn from sketches of former periods of art to our poet's teaching on art as it is, we shall not find him wanting there either. Lippo Lippi thought simple beauty and nought else about the best of God's inventions; but the poet, speaking his own feeling (as we may certainly conclude), in a passage from the poem entitled "James Lee's Wife," goes further than that and in a nobler strain, in showing the beauty that is to be found by the artist even where it may be missed by the careless observer. Is there nothing, do you say, in an ordinary hand?

"As like as a hand to another Hand?"
Who said that, never took his stand,
Found and followed, like me, an hour,
The beauty in this,—how free, how fine,
To fear, almost, of the limit-line!

'Art is dull and staidy void!
So sayest thou? So said not I,
Who threw the faulty pencil by,
And years instead of hours employed,
Learning the veritable use
Of flesh and bone and nerve beneath
Lines and hue of the outer sheath,
If haply I might reproduce
One motive of the mechanism,
Flesh and blood and nerve that make
The poorest coarsest human hand
An object worthy to be scanned
A whole life long for their sole sake."

Has anything better been said than that burst of enthusiasm over the sacredness, as it may be termed, of the conscientious study of the artist from nature? It is worthy to be copied and hung up, as a poet's sermon on art, in all the art-schools of the kingdom.

We referred above to the "Parleyings with certain people." "Gerard de Lairesse" is apropos of a painter who became blind in his latter days, and solaced himself by a treatise on the art of painting, and more especially of landscape painting and what might be expressed thereby, which gives Browning a cue for a splendid series of sketches of scenery in not too smooth verse; but the poem is rather a study in nature than in art. The one on "Francis Furini" has more special point in regard to art and to some questions of the present day, and might almost seem to have been written, or some parts of it, with sarcastic reference to the correspondence initiated some years ago in the *Times* by a correspondent who made herself unhappily proverbial as the "British Matron." Furini was an artist skilled in nude painting, whose pictures have still, we believe, an artistic value; concerning whom was circulated a tradition that on his death-bed he had begged that his works should be burned; a tradition which the poet in no wise accepts as probable. But it seems, at all events, that Furini was attacked by certain moral critics of his own day concerning his art, more especially as to his sources of study—

"For, whom had he to thank,
This self-appointed Nature-student? Whence
Ficked he up practice? By what evidence
Did he become unhandsonely adept
In simulating bodies? How except
By sight of such?"

"Unhandsonely adept" is good (to borrow Polonius's phrase). To which Furini makes the answer of the artist in all ages:—

"Did you but know, as I,
O scruple-splitting sickly-sensitive
Mild-moral-monger, what the agony
Of Art is ere Art satisfy herself
In imitating Nature!":—

And on the general subject of the mental and moral sense of "the Satyr masked as Matron" the poet has some remarks as strong as they are true, but which unfortunately are not likely to reach those who stand most in need of them.

In regard to architecture Browning is constantly throwing bright though momentary lights on the architecture of the past, often dropped in the most casual way in a sentence referring mainly to something else. He writes as if the old thing, now gone and forgotten,

were before his eyes. In "Sordello," for example, the Pope's Legate approaching Ferrara after the city had been sacked, is described as looking wistfully from outside the city ditch after "the flock of steeples" which were there in Este's time, and with which he used to be so familiar. These were by no means church steeples, but the tall narrow towers which were in the middle ages habitually attached to the houses of the principal families in Italian cities, for defence or as places of retreat in extremity. It may be doubted whether another poet of the day knew that; but Browning writes as if he had the old towns before his very eye. Another picturesque bit of old architecture brought into what is really a beautiful love-lyric, "By the Fireside," is interesting both as a picturesque addition to the scenery of the poem, and as illustrating Browning's loving eye for old bits of art-work wherever met with. The husband and wife are recalling their walk long ago as lovers:—

"And yonder, at foot of the fronting ridge
That takes the turn to a range beyond,
Is the chapel reached by the one-arched bridge
Where the water is stopped in a stagnant pool,
Danced over by the bridge.

The chapel and bridge are of stone alike,
Blackish grey and mostly wet;

It has some protension too, this front,

With its bit of fresco half-moon wise
Set over the porch, Art's early wont:
'Tis John in the Desert, I surmise,
But has borne the weather's brunt.

Not from the fault of the builder, though,
For a pent-house properly projects
Where three carved beams make a certain show,
Dating—good thought of our architect's—
'Fivo, six, nine, he lets you know."

If this means, as we presume, 1569, of course the reference to the fresco as "art's early wont" merely means that it is a survival of an older habitude. And if we turn to the poem called "Christmas Eve" we can see in section X. how Browning dwells with equal sympathy on the great basilica as on the little roadside chapel,—on the front of St. Peter's with its colonnades,—

"With arms wide open to embrace
The entry of the human race."

And Browning had prophecies for the future as well as love for the past of architecture. The main point and climax of his poem called "Old Pictures in Florence" lies in the suggestion of the enthusiasm with which the completion of the Florence campanile would be hailed; Browning being one of the few people who had eyes to see that the campanile is incomplete and requires a spire or lantern, and contemplating the day when the campanile

"Shall soar up in gold full fifty braccio
Completing Florence, as Florence Italy.
Shall I be alive that morning the sea-ford
Is broken away, and the long pent fire
Like the golden hope of the world, unbuffed
Springs from its sleep, and up goes the spire,
While, 'God and the people' plain for its motto,
Thence the new tricolor flaps at the sky?
At least to foresee that glory of Giotto
And Florence together, the first am I!"

Alas! the poet is no longer alive and the campanile not yet completed. The poem was written, as every reader will perceive, many years ago, when the idea was afloat that Florence was to take the lead as the capital of Italy, and when, as aforesaid, it first occurred to Browning, of modern writers, that

"Thy great campanile is still to finish."

The whole poem is full of vivid pictures, commencing with the City of Our Lady of the Flowers herself, as seen glorious in the morning sunlight

"In the valley beneath wher, white and wide,
And washed by the morning water-gold,
Florence lay out on the mountain side.
River and bridge and street and square
Lay mine, as much at my beck and call
Through the live translucent bath of air,
As the sights in a magic crystal ball."

But the fair Florence contains sights to mourn over, too; how the dear old frescoes

drop from the walls, and how the poet laments hopelessly over it, a sad spectator—

"Wherever a fresco peels and drops,
Wherever an outline weakens and wanes
Till the latest life in the painting stops,
Stands One whom each fainter pulse-tick pains;
One, wishful each scrap should clutch the brick,
Each thine not wholly escape the plaster
—A lion who bites of an ass's kick,
The wronged great soul of an ancient master.

Their ghosts still stand, as I said before,
Watching each fresco flaked and rasped,
Blocked up, knocked out, or whitewashed o'er
—No getting again what the Church has grasped.

The works on the wall must take their chance,
Works never conceded to England's thick
air.

(I hope they prefer their inheritance
Of a bucketful of Italian quicklime.)"

In some ways, unhappily, things seem to be almost worse in regard to the decaying remnants of early Italian art now than ever; there is a well-educated minority who regard them with reverence, but the desire to modernise (not altogether an unreasonable one, be it said) seems to be pervading Venice, Rome, and Florence one after another, and things are fading away or being removed which are among the last material links with the souls of wonderful generations of men gone before.

Among the touches of architectural details in landscape is an admirable one in "Pippa Passes," in the passage where Ottima leans out of the window of the villa in the morning—

"Ah! the clear morning! I can see St. Mark's;
That black streak is the belfry. Stop; Vicenza
Should lie . . . there's Padua, plain enough,
that blue!"

a bit of distance in which the "black streak" of the belfry stands out as clear as if we saw it. The fourth scene in "Pippa Passes," in the sculptor's studio, is full of fine suggestions as to style and subject in sculpture; interesting among other things as showing Browning's acute perception of the relation of material to design; when the sculptor's bride looks at the plaster model of one statue he checks her—

"Ah! do not mind that—better that will look
When cast in bronze—an Almain Kaiser, that,
Swart-green and gold, with truncheon based on
hip:"

the very thing to look best "when cast in bronze"; while for marble we have

—"Hippolyta
Naked upon her bright Numidian horse."

There follows a splendid description of a subject for a bas-relief panel—the minstrel singing the praise of Hipparchus, with face upturned and a background of eager listening faces behind him: a passage we really wonder that no sculptor has (as far as we know) thought it worth while to take up and try to realise; there is a splendid subject, as it were, going begging; but our artists (judging from the scraps of quotation we see appended to the titles in Royal Academy catalogues) seem to pay little attention to the suggestions they might find in high-class poetry and literature, and run mostly after literary commonplaces and hackneyed passages that suggest nothing but commonplace ideas. There is a fine passage further on in the same scene, on the same subject of the tools and materials of the sculptor's art—

"But of the stuffs one can be master of,
How I divined their capabilities!
From the soft-rinded smoothing facile chalk
That yields your outline to the air's embrace
Half-softened by a halo's poorly gloom;
Down to the crisp imperious steel, so sure
Do out its one confident thought clean out
Of all the world. But marble!—neath my tools
More pliant than jelly—as it were
Some clear primordially creature dug from depths
In the earth's heart, where itself breeds itself,
And whence all baser substance may be worked;
Refine it off to air, you may,—condense it
Down to the diamond!—is not metal there,
When o'er the sudden smelt my chisel trips?
Not flesh, as flake off flake I scale, approach,
Lay bare those bluish veins of blood asleep!"

Sculptors, at any rate, must admit that they have their poet in Browning.

To return, in conclusion, to architecture, the most remarkable passage certainly on that subject is in "Sordello," that supposed incomprehensible poem of which it has been said that "the foot of every page is marked by the tombstones of those who have perished in the attempt." The poem is not so obscure as is supposed, when the clue to its peculiar style is once obtained: we are not concerned, however, with expounding more than the special passage now referred to, at the commencement of the fifth book. This is really a rapid sketch of the development of architecture, suggested by a passing reference in the poem to the thought that "Rome was not built in a day." It might stand as a kind of brief poetic *résumé* of Viollet-le-Duc's "History of the Habitation"; the idea being that we follow the various aspects of architecture as if we had lived through all the ages, or revisited the world from time to time to see how building was getting on. The remarkable thing in Browning's passage is the amount that he contrives to suggest in a few words. We append one or two explanatory notes for those who find the poet's form of expression somewhat too cursory. We commence with the time when all that is wanted is mere shelter for this or that half-savage human creature:—

"Study mere shelter, now, for him, and him.
Nay, even the worst,—just house them! any cave
Suffices: throw out earth! A loophole! Brave!"
They ask to feel the sun shine, see the grass
Grow, hear the larks sing! Dead art thou, alas,
As I am dead! But here's our son excels
At hurdle-weaving any Scythian, fells
Oak and devises rafters, dreams and shapes
His dream into a doerpest, just escapes
The mystery of hinges. Lie we both
Perilous an' o'er age. The goodly growth
Of brick and stone! Our building-pelt was rough;
But that descendant's garb suits well enough
A portico contriver. Speed the years—
What's time to us? § At last a city rears
Itself! nay, enter—what's the grave to us?
Lo, our forlorn acquaintance carry thus
The head! † Successively sower, forum, cirque—
Last age, an aqueduct was counted work,
But now they are the artificer upon
Blank alabaster, black obsidian
—Careful, Jove's face be duly fulgurant,
And mother Venus' kiss-crested nipples pant
Back into pristine pulpiness, ere fixed
Above the baths."

Admitting the rather obscure wording here and there, it would be difficult to praise too highly the masterly manner in which the main characteristics of various ages of architecture are touched upon, from the time when to primitive man a hinge was a mystery just beyond the mental grasp, dimly foreshadowed perhaps in the still half brute intellect, down to the Roman sculpture decoration in marble and obsidian, the intellectual value of which is so accurately and half-sarcastically hinted at in reference to the care that Jove's face should be "fulgurant enough"; a sufficiently thunder-wielding sort of god the Roman sculptor could make him, but hardly soared beyond this accepted and conventional type, which answered well enough for decorative purposes, and was repeated with little other aim.

We have said and quoted enough, we hope, to suggest to artists and architects that it is worth their while to know their Browning, for congenial intellectual recreation if not for artistic suggestion and inspiration. We will conclude with one other short quotation in prose from the penultimate scene of "Pippa Passes," which has a peculiarly real application at a time when there is so much striving after originality in art, so much complaint that the old ideals are worn out, the old tracks beaten bare: a time too when there is rather a tendency among artists to try their hand at other branches of art than those which they have ostensibly and formally studied. The old church dignitary, referring to a determination of Jules, the sculptor (he of the previously-named

* The first rude idea of the window obtained.
† The cave generations pass away, to be succeeded by the hut-builders.
‡ "Felt," a raw hide; our hut-building men were clad only in a rough hide while at their work; our portico man has developed a civilised drapery.
§ It having been agreed that we are to be supposed to live from age to age to see the spectacle.

studio scene) to forsake sculpture and try to find a new path in painting, observes meditatively, "Foolish Jules! and yet, after all, why foolish? He may,—probably will, fail egregiously; but if there should arise a new painter, will it not be in some such way, by a poet now, or a musician (spirits who have conceived and perfected an ideal through some other channel) transferring it to this, and escaping our conventional roads by pure ignorance of them?"

NOTES.

MEMORIAL signed by a very large number of the leading artists of England, as well as by educated persons interested in art, was forwarded some time since to the Mayor and Corporation of Liverpool from the Committee of the National Art Association, expressing a hope that they would reconsider their decision to discontinue the decoration of St. George's Hall by Mr. Stirling Lee's sculpture panels, two of which are *in situ*, and have been the object of the most stupid and ignorant abuse by people who had too little idealism to understand their meaning. The letter was read at the last meeting of the Liverpool Town Council, and ordered to be referred to the Finance Committee; some opposition to this being withdrawn on the representation that it would be a want of courtesy to the artists of England to refuse to consider it. We are glad to hear that the Liverpool Town Council have got as far as that, at all events. A letter was read from Mr. P. H. Rathbone, offering to bear the sole cost of the execution of the four remaining panels, on condition that the whole should remain for public criticism for five years. This reasonable and liberal proposal was described by Alderman Livingston, who appears to be the leader of the Philistines in the Council, as "amounting to something like arrogance." Mr. Rathbone, in the course of some remarks, quoted a letter from Mr. Gilbert, the sculptor, stating that the panels already executed were the best things of their kind in England: in which we certainly believe he is right. Mr. Rathbone does not always show the wisdom of the serpent in his championship of art, but he understands thoroughly what he is talking about, and his proposition seems a most reasonable as well as liberal one. When the Liverpool public found, as they probably would find, that the completed series was a thing that visitors would come out of their way to see, they would possibly recognise the fact that they had made a serious blunder in their treatment of Mr. Lee and his work. Mr. Rathbone's offer also is at all events to have consideration, and we hope it will be accepted. The town ought to be very grateful to him for it.

THE first witness examined on behalf of the traders who have lodged objections to the proposed railway rates was Mr. Marshall Stevens, who has given much attention to this subject. He considers that the estimated loss to the companies owing to the rise in the price of coal has been exaggerated, seeing that the prices only went up in prosperous times when the railways were doing an increased business. The improving dividends in the face of the recent advances may be looked upon as supporting this contention, but at the same time it must be remembered that the greatest effect of the rise will be felt in the contracts for the current half-year. As a set-off against the array of figures brought forward by the railway companies, an interesting calculation which was given by Mr. Stevens is worthy of notice. Assuming the proportion of capital devoted to goods and mineral traffic to be 265,841,172*s.*, he estimates that an addition of 1*½*d. to the rates would yield one per cent. on the capital. Other calculations which were submitted would have been of more interest had not the correctness of the estimates been open to question, but in cross-examination by

Sir Henry James this part of the evidence was somewhat shaken. Sir H. James also scored a point on Monday with reference to the rates on French railways, which, the witness had asserted, could be "found at a glance." When furnished with a French rate-book, however, although assisted by a French witness, he unfortunately failed to find certain rates on a French line which Sir Henry called for,—the result of this challenge causing some amusement. Mr. Stevens expressed his readiness to prepare a revised classification if the Court would intimate their willingness to accept it,—which, of course, they were unable to do. It would appear that the proposals are based upon the Railway Clearing-house classification, but more classes would be added, and each article classed both at company's and owners' risk, and also in regard to the smallest and the largest quantity usually carried. It was also suggested, with respect to terminals, that the charge for actual services should be based upon the actual cost, with an addition of 10 per cent. as a margin. This is the course pursued by the Mersey Docks and Harbour Board; and, as Mr. Marshall Stevens is an official of the Manchester Ship Canal, we suppose that they will adopt it also.

THE Queen's Speech promises legislation on several matters of interest to the readers of this journal. Bills are to be brought forward for the consolidation and amendment of the laws with respect to public health in the metropolis and to the dwellings of the working-classes. Consolidation will probably be accompanied by some small improvement in the substance of the law. A Bill for the better regulation of savings banks and friendly societies, which is also promised, is much needed, and we hope some member may criticise the administration of the Post Office Savings Banks, which are not as popular as they might be. Having over and over again called attention to the bad state of the barracks all over the United Kingdom, it is satisfactory to find that the attention of Parliament will be directed to the making of better provision for barrack accommodation and the health of the troops. It is only to be regretted that measures with this object were not earlier taken—but at any rate, late is better than never. When these several subjects come in detail before the House of Commons they will, doubtless, be open to abundant criticism.

SO much has been said lately on the thorny question of assessment for "betterment" of private property by the carrying out of public improvements, and so much more is likely to be heard of it in the immediate future in connexion with the "betterment" clauses of the London County Council's Bill to authorise the Strand Improvement, that we quote from a letter in the *Speaker* for February 8 the following passages as to the practice of assessing for "betterment" in the United States. The writer, whose name does not appear, but who is stated to be an American, says:—

"I have asked several lawyers, and they report that they know of no State which does not assess property benefited by improvements. There is the mode in New York State, and, substantially, in Pennsylvania and Eastern States generally:—

1. General Tax, including Police, Lighting, and State Tax.

2. Water Tax.

3. Assessment for Local Improvements. The last is assessed by a Commission of three members appointed by the Supreme Court of the State, 'to appraise damages and assess benefits.' This Commission defines areas affected, to begin with. They can also place part of assessment upon the city as a whole. All their proceedings reported and subject to Supreme Court; but Court approves, except in very rare instances indeed.

Second Branch, Permanent Board of Assessors appointed by City authorities (Councils in some States), controls grading, sewerage, paving, &c., of streets, subject to confirmation of a 'Board of Revision,' composed of City Controller, City Recorder, and Corporation Counsel.

The principle is . . . universally recognised. . . . When States adopt new Constitutions it

may be inserted, and others pass general laws. Nevertheless, all cities practice assessments for benefits and damages for injuries to property affected within a defined area."

This is interesting, as showing that not only "betterment" but "worsement" (to use the barbarous words which figure in the controversy) is provided for. The question hitherto with difficulties. A course of procedure which may have been found to work well in a new country is not easy of application in an old country with old institutions. Nevertheless, it appears to be only just that owners whose property is clearly and permanently increased in value by public improvements should contribute *pro rata* to the cost of such improvements, and that the whole cost should not fall upon the temporary occupiers of the property.*

A HOUSEHOLDER (Mr. George Tonge) writes to the *Times* of Monday a letter with regard to the insanitary state of his house and the results which, if the facts are correctly given, is very significant. Various members of the family were attacked with diphtheria, and the doctor sent a notice to the local sanitary authority (the house was in West Hampstead) expressing an opinion that something must be wrong with the drainage. The house was visited by an Inspector of Nuisances, "who after a few inquiries and a cursory examination pronounced everything right." The tenant appealed twice for further examination and received a written certificate that nothing was wrong with the house. Diphtheria and sore throats continued to develop however. Mr. Tonge says:

"Our doctor gave immediate information to the authorities of the reappearance of the disease, adding, 'second outbreak in six months; something must be wrong.' My wife also wrote a strong letter asking prompt attention. After the lapse of three or four days the inspector came, having made an arrangement with the builder to meet him here. In reply to my wife's statement, he said after so thorough an examination as had been made no further inspection was necessary. He recommended us to change our milkman, and added he supposed we wanted the boards up, and suggested our having an independent surveyor."

The independent surveyor was called in, and on opening of the drains brought to light the fact that "the passage to the main drain was blocked, and the pipes under the house not water-tight, and the sewage had leaked, contaminating the basement." We suspect the statement that "the passage to the main drain was blocked" is an exaggeration, perhaps made under a misapprehension: if that had been the case it would have been impossible for any inspector (or tenant) not to know at once that something serious was wrong. But the defective jointing of drains under a house is common and probable enough, and quite sufficient in itself to account for the illness mentioned, and we should like to know whether the perfunctory pretence at examination which failed to discover this is typical of the manner in which Sanitary Inspectors perform their duties. If so, the sooner there is a reform the better. Defects of this kind cannot be diagnosed by asking questions and looking at the walls and floors of a house. The Inspector could probably have tested the drains even without having "the boards up," and ought to have done so in the first instance.

AGAIN German artists have an opportunity of showing their rival merits in designing a suitable memorial for the late Emperor William. This time it is the province of Westphalia that intends honouring the memory of the deceased monarch, and a site has been chosen on the famous Wittekind's-mount of the Porta Westphalia, near Minden, for a monument of mainly architectural structure. The official conditions tell the would-be competitor that he is required to make his design harmonise with the landscape surrounding it, and that his work

* We have, at the last moment, received a statement of reasons against the "betterment" principle, issued by the Council of the Surveyors' Institution, to which we may call further attention.

should be able to demonstrate to the stranger who views the erection from a distance that it is a memorial to an Emperor that he has in sight. A statue of the deceased has to be brought into the design, and suggestions for relief sculpture are desired. The cost, including sculpture, is not to exceed 30,000*l.*, and specifications have to be handed in to show that the design will not require a higher sum. Four premiums, two of 75*l.* and two of 50*l.*, have been offered, and if it were not for the great honour of coming out first in this patriotic competition, these premiums, so utterly out of proportion* to the amount of work required, would in themselves scarcely entice artists to compete. The names of the nine members of the jury have been published.

THERE seems to be some probability of the architectural profession being represented in the Imperial Reichstag. Among the candidates for the general elections, which take place this month, we find the names of Baurath Wallbrecht, Hanover; Baunsp. Zeidler, Stettin; and Herr Baumeister Anke, Chemnitz. Dr. Römer, who has up till now been the only member in any way associated with architecture, has been obliged to refuse his candidature on account of ill-health.

THE Prince Regent of Bavaria intends giving Munich a personal present, in form of a bridge over the river Isar. This bridge, which will be situated between the Maximilian and Bogenhauser crossings, is to be an iron-arch one, with a span of 46.60 m. The carriage-road will be 9.60 m. broad, and the two footpaths each 2.70 m. "Oberbaurdirektor" von Siebert, who has designed the bridge in conjunction with the Director of the South German Bridge-building Company, Herr Gerber, is to have the superintendence of the work, which is to be commenced as soon as possible. In order to have some decoration on the otherwise very plain elevation, four obelisks and sixteen very handsome candelabra will give the bridge a finish. The Crown Surveyor's estimate shows that the magnificent gift will cost Prince Luipold some 15,000*l.*

ON account of the continual stoppage of railway traffic during the winter months, caused by snow-drifts, the Prussian Government has asked the "Landtag" to grant 35,000*l.* for the purpose of erecting snow-shelters for those cuttings most liable to be blocked, and also for the acquisition of modern snow-ploughs constructed on the American system, which are to be kept in readiness at stations within reach of the aforesaid cuttings.

AT a recent meeting of the American Society of Mechanical Engineers, Prof. H. B. Gale, of St. Louis, presented a paper upon the construction of chimney-shafts, in which he criticises the formula hitherto followed by Pictet, Rankine, Morin, and Weisbach. Prof. Gale advocates a free access of the air to the fire-grate, and that the smoke canals from the boiler to the chimney be as circular as possible, smooth, and without sharp curves. There should also be a regulating valve in the chimney or fireplace, with an automatic regulator. As to the choice of material, Prof. Gale considers that this entirely depends upon the cost, duration, and the architectural appearance. It has no special effect upon the draught whether the shaft be of iron or bricks, inasmuch as the more rapid cooling of the former material is counterbalanced by the greater frictional resistance and lesser density of the latter. As the draught in a circular chimney is only one or two per cent. higher than in a square one of the same diameter, the Professor considers that the latter should be preferred on account of its cheapness. It may also without appreciable detriment be built equally wide at the top and bottom.

* See, for instance, Cologne competition (*Builder*, Jan. 25, 1890): five premiums, total value 600*l.* to a cost of 15,000*l.*

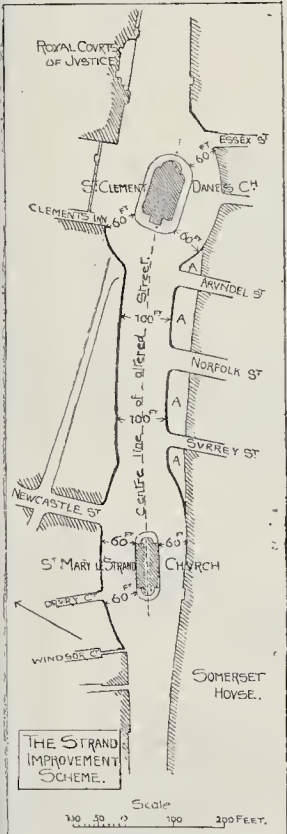

CASTLE OF S. ANGELO
TEMP NICHOLAS V

CASTLE OF S. ANGELO TEMP ALEXANDER VI (from an Ancient Sketch).

THE annexed plan shows a scheme, suggested by Mr. Arthur Cawston, for dealing with the Strand, by altering the line of the south side also, in order to lay out the street in a curve in direct architectural relation to the two churches. Mr. Cawston says:—"The land marked A.A.A.A. is proposed to be 'grabbed' by the County Council. It might be let in plots, at a

THE Academy says that Wadham College, Oxford, has recently acquired, for the chapel there, the old communion table of Ilminster Church. Our contemporary states that this is the table "at which Sir Nicholas and Dorothy Wadham must have been in the habit of communicating. It is of oak, handsomely carved, and undoubtedly good Elizabethan work." Mr. Nicholas Wadham, of Merefield, *obit* 1609, and his widow, Dorothy, were buried beneath an altar tomb, bearing their effigies inlaid in brass, in the north transept of St. Mary's Church, Ilminster. Dorothy carried out her husband's unaccomplished purpose at Oxford, where, on the site of an Augustinian Priory without Smyth-gate, was opened, on 20th April, 1613, a college which, like Clare, Cambridge, is conspicuous for the completeness of its design, and for the, as yet, little changed aspect of its buildings. She had bought the land for 600*l*. Mr. John Fulleylove's water-colour drawing of the Fellows' Garden, as lately exhibited in the gallery of the Fine Art Society, is reproduced in his "Oxford," which we reviewed on January 5th of last year. Other structural features of Wadham are cited in a notice which we printed of the Architectural Association's visit to Oxford in 1886.* Sir Christopher Wren entered Wadham in or about 1647, was there under the learned Dr. John Wilkins, and, receiving the degree of M.A. in 1653, was, four years later, elected Professor of Astronomy at Gresham College. For All Souls, whereof he was elected Fellow on February 5, 1660, he designed a dial which was set up outside the chapel; as we read in Gutch's edition of A. & Wood's work.

THE rooms of the Institute of Painters in Water Colours are occupied just now by one of the oddest-looking collections of work that has ever been seen in galleries usually devoted to picture exhibitions which aim at all events at being high-class artistic work. This is the outcome of the competition organized by Messrs. Raphael Tuck & Sons for prizes for copies made from the studies sold by them for copying in oil and water colours, and open to amateurs only. It seems to be almost entirely a ladies' exhibition, and nearly all the visitors as well as the exhibitors were ladies. Twenty thousand competitors entered their names for this, and many thousands of drawings were sent in, of which nearly 2,500 were accepted and hung. The judges were Sir John Millais, Mr. Marcus Stone, Mr. Boughton, and Mr. S. J. Solomon, who have spoken favourably of the amount of conscientious work done; and, from the standpoint of the exhibition, with reason. Nevertheless, the effect of these walls covered with repetitions, good, bad and indifferent, of various studies, painted in many cases rather too obviously from chromo-lithographs, is bewildering and not altogether cheerful. The most successful drawing we noticed among the prize drawings was not by a lady, being Mr. Alfred Rendell's "Getting under Weigh" (128), which, had it been an original work, would have stood high for its class of subject. In spite, however, of the respect naturally inspired by the names of the judges, we doubt very much whether the enterprise is in any way beneficial to art. When we received some time ago a notice announcing the intentions of the promoters of the exhibition, we formed the impression that they were about to organize an exhibition of amateur talent in original work. That would have been of some interest, and might have drawn the best class of amateur artists, who of course would not be likely to put into a competition in copied drawings.

THE Trustees of the British Institution Fund announce that they are prepared to elect, in July of the present year, five scholars,—two in painting, one in sculpture, one in architecture and one in engineering; the scholarships being of the value of £50 each, and tenable for two years.

THE Carpenters' Company has very commendably added to its other good and useful work in the promotion of technical education by the establishment of "The Carpenters' Company's School of Wood-Carving." The idea of the Company, as expressed in a letter which we have received from the Clerk, Mr. Stanton W. Preston, is that "there is plenty of talent in wood-carving in this country, but that it wants developing; and the Company, in conjunction with the Institute of British Wood-Carvers, which has been in existence some years, hope that it will be a successful movement. It is intended purely for the trade, and we have put the terms low, so that it may well be within the reach of all who would be likely to make use of the instruction to be given. We want to foster real talent, and not merely mechanical carving, and for that reason include Modelling and Drawing." Some further particulars were given in an advertisement which appeared in our last number.

THE CASTLE OF ST. ANGELO, ROME.

AN interesting discovery has been made in the course of recent excavations in Sangallo's bastion, called *di San Giovanni*, at the right of the mausoleum of Hadrian. A cylindrical tower has been found, well preserved, belonging to the fortification constructed between 1447-1455 A.D. under the pontificate of Nicolas V. There are in existence drawings representing the Castle of St. Angelo as it was at the time of Nicolas V. (see cents above), and especially two sketches contained in a volume (in the "Biblioteca Barberini"), in which are numerous drawings and plans of the ancient monuments of Rome by Giuliano da Sangallo (1465). Other representations of the Castle of St. Angelo at the same time are to be found in a sketch by Schedel, and in that of Mantova, and in a medal of Alexander VI. When Antonio da Sangallo, by order of this Pope, repaired and completed the fortification of the Castle, enclosed the cylindrical towers of Nicolas V. in a polygonal sloping bastion, as we have learnt through the recent discovery, the tower was entirely filled up with cannon-balls of Greek marble and granite, undoubtedly made with ancient statues or other ornaments.

L. B.

* See the *Builder*, 28th August, 1886.

moderate ground rent, to the occupiers of each house, to induce them to extend at once, to the new frontage line, all the shops on ground floor only. When it suited the occupiers to rebuild their whole premises, the ground might be sold to them. If the shops only are brought forward, they should possibly be built of uniform height, with parapet and balustrade, as approved." We do not adopt the suggestion, but we think it is worth publication, and the result, as a matter of architectural effect, would certainly be good.

LIMITS TO HEIGHTS OF BUILDINGS.

WITHOUT a table under headings comparison of the regulations in different cities is very difficult. We have, therefore, compiled the table given below as a specimen, and hope to furnish others. We have to thank the gentlemen who have kindly supplied information as to the regulations now actually in force; and shall be glad to have in the same form statements as to other cities. If such a clause as that proposed by the London County Council is made law, it will doubtless serve as a precedent for other parts of the country, so that the matter is one of much interest to all who have to do with buildings:—

	Width of Street.	Height.	Roofs.	Number of Stories.	Remarks.
PARIS. Décret du 23 Juillet, 1884. (The regulations for provincial towns are similar in principle, but varied in detail, to suit local circumstances, climate, &c.)	Ft. in. 25 6 or less,	Ft. in. 39 3	 <p>R = half the legal or actual width between the building frontages; but may not exceed 27 ft. 6 in. As a minimum 16 ft. 4 in. is permitted.</p>	Not more than seven stories above the street level, including mezzanine and attics.	Dormer and other windows may not project beyond the frontage-line, but may extend 1 ft. 7 in. beyond the perimeter of roof, provided their collective width does not exceed two-thirds of the width of the street-front.
	25 6 to 31 10	49 1			
	31 10 to 65 6	58 11			
	65 6 and upwards.	65 6			
	Measured between the authorised lines of building frontage.	Measured from the highest part of the footway along the facade to the top of the front wall.			

Authority:—

Francis Hooper, A.R.I.B.A.,
Holder of the Godwin Bursary,
1888.

These regulations do not apply to public buildings, and may be modified in the case of other buildings on the recommendation of the General Council for Buildings, with the sanction of the Minister of the Interior.

	Old quarters.				
SWEDEN. The building regulations for old towns are framed in accordance with the Royal Ordinance of 1875 by the Municipal Authorities, and necessarily vary much in matters of detail. 	for lines of main traffic	Other enclosing walls, 78 8			
		W = width between front wall of building and boundary of ground plot opposite, or a building line or corrected line set back from it. M = the maximum for any part except architectural projections, projections above roofs, and chimney-shafts.			

Authority:—

Hugh McLachlan, A.R.I.B.A.,
Holder of the Godwin Bursary,
1883.
(Building Police Regulations, 1882.)

These regulations as to height may be modified by the Senate for public buildings, and in other special cases where a greater height is required.

	Old portions.				
BERLIN.	Ft. in. 24 7 to 74 2	<p>Old and new portions.</p> <p>Ft. in. 39 4 to 74 2</p>	<p>When above the height allowed for walls,—roofs not steeper than 45 deg.</p> <p>Special regulations for turrets, dormers, and architectural features.</p>	<p>No dwelling-rooms higher than the fifth story above the footway. Floor of topmost story of dwelling-rooms not more than 57 ft. 4 in. above the footway.</p>	<p>Building may be carried higher if set back; but must be lowered to allow for cornices if projecting more than 1 ft. 7½ in.</p> <p>Regulations for proportioning the height of back buildings according to the width of court-yards to allow sufficiency of light and air.</p>
	74 2 New portions.				
	62 4 (minimum)				
	to				
	93 5				

Authority:—

Hugh McLachlan, A.R.I.B.A.,
(Building Police Regulations, 1887.)

In streets with buildings on one side only the maximum 74 ft. 2 in. is allowed. In other cases height equals width between the street lines. Averages for corner buildings and streets of uneven width. Corrected street lines laid down by authority for new buildings in narrow streets,—streets widened gradually, as in the City of London. Large clearances are also made at times for widening, and new street lines laid down.

ROMAN ARCHITECTURE.*

BY PROFESSOR AITCHISON, A.R.A.

Private Houses.

The first step in the discovery of Pompeii was made in 1748 by a Spanish Colonel of Engineers named Don Rocca Alcubierre, who began his researches in the Street of the Fortuna, a continuation of the Street of the Discoveries was made in 1764, and the account of the discoveries was kept in Spanish until 1764, after which the Italian language was used. The name of Pompeii was first given it at the end of the year 1756, and any doubt of that being the real name of the town was set at rest by the discovery of an inscription near the tomb of Mammia in 1763. In 1817-19 Sir W. Gell and J. P. Gandy, R.A., published their celebrated book on Pompeii, called "Pompeiana," and subsequently a continuation in 1835, giving the excavations since 1819. John Goldie published his hand-coloured specimens of ancient decorations from Pompeii in 1825; and Mr. E. Falkener had two houses excavated at Pompeii, plans and accounts of which are given in his "Museum of Classical Antiquities."

Although a vast extent of Pompeii has been excavated since the year 1826, when Sir W. Gell gave his plan, I do not know that a more characteristic house has been excavated than that of Pansa. [See Lithograph.]

You all probably know that the names of the houses were given them either from the paintings or from the inscriptions found in the houses, or from some striking feature of the house or its adjuncts, and this house is so called from the words "Pansam Ed." being found painted in red near the door.

It seems to have been a common practice to invoke the Ædile by name, in this case to suggest that Pansa should be Ædile. This large house, with its dependent houses and shops, forms an island; i.e., is surrounded by streets. Its front is in the Street of the Baths, its back towards the north is in the little Alley of Mercury, its east flank is bounded by the Lane of the Fuller's Shop, and its west by the Alley of Modestus. The island is about 100 ft. wide by about 300 ft. long, which would be a large plot of ground for a house in London; but its front and flanks are decreased by rows of shops and houses, and these extend on the flanks up to the garden, which is about one-third of the whole depth of the island. The entrance itself is not more than about 10 ft. wide.

There is a shallow vestibule, then a Prothyrum, or entrance lobby, a Tuscan Atrium, Cavadium, or hall, with an Impluvium, or Compluvium, i.e., a space of the hall-floor open to the sky usually containing a rain-water tank; the Atrium has Alle, and whether these be the recesses only at the end of the Atrium, or include the three chambers on each side of the Atrium, we will discuss hereafter. Whether five of these rooms were guests' rooms, servants' rooms, or for other purposes, we do not know. One of these, nearest the entrance, was possibly devoted to the Atrianis, or slave of the hall; we don't know if the janitor, or Ostiarius, slept on the threshold, for he might have used one of the other rooms at the side of the Atrium for sleeping in. At the end of the Atrium is the Tablinum, or muniment-room, used also as the Hall of Audience, where clients were received. To the east of this there is only one of the Fances, or passages, to the private part of the house. To the east of this is a room about 16 ft. by 10 ft., while to the west of the Tablinum is another room about 16 ft. square. The passage leads us into the second hall, or Cavadium, which has a peristyle of sixteen columns, with a large tank in its open area. It is pretty clear, from Pliny's account of his Laurentine villa, that the second hall in his days was called the Cavadium (Pliny, Lib. II., 1st. 17). There are two recesses at the south end of the Cavadium—one on the east, from which a passage goes to the hack door, and in this passage is a staircase, and one on the west side. On the east, towards the north end, is a small room, supposed to be a library, entered from the cloister of the peristyle, and communicating with a big room beyond at the north-east end, supposed to be a Triclinium, or dining-room. At the north end of the Cavadium are two large rooms of different size; the smaller one is supposed to be another Triclinium, and the big one a hall (Œcus), possibly a modified Cyclicone one, and opening at the north end to

the garden cloister. At the side of this last hall is a passage leading to a Cryptoporticus, or cloister, running the whole width of the island, open towards the garden, and this had a story over it. At the back of the Triclinium is a little room, opening and looking into the cloister; beyond the garden-cloister is the garden, with a tank and reservoir in the north-east corner; to the left, or west of the passage from the Cavadium to the garden-cloister, and adjoining the Cavadium, is a kitchen and servants' hall and another room, both the latter opening into the Alley of Modestus. Beyond, to the south, is an open court and staircase; the court lights the north-west room in the Cavadium, and opens into the alley beyond. Stretching southward from the kitchen are four rooms, commonly called bedrooms, though it is believed that bedrooms were mostly above the ground-floor.

In front of the house are three shops on both sides of the entrance, the corner shops being bakers'; next to the west one on the south front is a shop connected with the house of Pansa by a door into the south-west room of the Atrium; in this shop the wine or country products of the owner were probably sold, as wine is still sold in noblemen's houses in Italy.

On the west flank, and forming part of the baker's premises, is a large bakehouse, with mills, a kneading-trough, a table, and an oven; beyond this are two small houses. On the east, next the Lane of the fuller's shop, are the baker's premises of the fuller's shop, at the angle. There is a bakehouse with a large oven beyond the shop, and another room, and then three houses of considerable size, each consisting of several rooms. In the one nearest the gardens of Pansa's house were found the skeletons of four women, whose ear and finger rings had engraved gems in them, showing, at any rate, that the inhabitants were not of the poorest sort.

The painted decorations of this house, which was one of the earliest excavated, have mostly perished.

The house itself, as regards its plan, is a typical one, and has some family resemblance to the house of Germanicus on the Palatine at Rome.

It may be well just to name the parts and rooms, and then to discuss each part. In quoting Vitruvius, I use the Leipzig edition of 1863, which is almost identical with Schneider of 1807:—

Vestibulum—a vestibule.

Prothyrum—an entrance lobby.

Impluvium or Compluvium—the opening in the roof, or the open space on the floor of the hall.

Impluvium—the rain-water tank.

Also—the wings.

Tablinum—the muniment-room.

Cubicula or Cubilia—rooms, sometimes bed-rooms.

Fances—passages.

Peristylum—a colonnaded court.

Bibliotheca—a library.

Pinaotheca—a picture gallery.

Triclinium—a dining-room.

Exhedra—a parlour, or room for conversation.

Œcus—a hall.

Basilica—a long hall, which seems first to have been used for political meetings, and afterwards for recitations.

Textrina plumarium—an embroidering-room.

Officina pictorum—a studio, or painter's shop.

Culina—the kitchen.

Cella Penuria—the pantry or larder, not mentioned by Vitruvius, but found in Suetonius, who tells us Augustus is reputed to have been born in one at Velltre.

Cryptoporticus—a cloister or gallery.

Posticum—the hack door.

Hortus—the garden.

Proceon—an ante-room.

Dieta—a room, sometimes a breakfast-room; or a suite of apartments; sometimes a summer-house.

Dieta hypocausta—a bathhouse.

Cocatio—a supper-room; also

Cocaculum—an upper room to sup in, but used afterwards merely as a garret.

Andron—a passage.

Horreum—a lumber-room or museum, though its original meaning was a barn.

Apotheca—a store-room.

Balneum or Balneum—a bath-room or rooms.

Spharisterium—a tennis-court.

Gymnasium—exercising-rooms, though when not done out of doors the exercises in private houses were mostly carried on in the tennis-court.

Crypta—a vault, sometimes a grotto.

Solaria—balconies, terraces, or flat roofs where the sun can be enjoyed.

The very first part, described by the word "Vestibulum," is still the subject of controversy. That it originally meant the place where the toga was put on is, I believe, acknowledged; but whether it was a bit of open fore-court; or of covered passage, no one knows. Vitruvius uses the word, and says:—"Becomingness, indeed, is thus expressed, according to custom, when in buildings with magnificent interiors the vestibules are made with convenience and elegance" (Vit., Lib. I., cap. 2, par. 6) In the well-known line of Virgil, "Vestibulum ante ipsum primisque in faucibus orci" (Æneid, 6, 273), he seems rather to speak of an avenue or approach, which Dryden translates as "Just in the gate, and in the jaws of hell" (Dryden's "Virgil," Lib. VI., l. 384).

Prothyrum, the entrance lobby, is thus mentioned in Vitruvius in his description of the buildings of the Greeks (VI., 7, 5):—"The vestibules which are before the doors are called prothyra in Greek."

Atrium, or Cavadium, the hall, is understood in different ways, because it did not mean the same thing in a Roman house in every country. In Italy, it was mostly a covered room with a hole in the middle of the roof, as you can see in the Roman house at the Crystal Palace; but sometimes it had no hole, and was called a roofed hall (Atrium Testudinatum), because there were rooms over it, as Vitruvius tells us (VI., 3, 2).

Such a hall, wholly roofed, could only be made when the span was small, and then we wonder how any light was got; but in England, when there was a courtyard with the house round three sides of it, sometimes with verandahs, next the court, the courtyard was possibly called the Atrium.* We know that in France the open square with porticoes round it, in front of a cathedral, was called the Atrium.

Vitruvius names five sorts of cavadia—the Tuscan, Corinthian, tetrastyle, displuviate, and roofed, or tortoise-shaped—and says:—"The Tuscan ones are those in which the girders thrown across the Atrium have trimmings between them, and valleys running from the angles of the wall to the angles of the rafters; likewise with eaves dripping into the middle Compluvium. In the Corinthian, the girders and opening are the same; but the girders receding from the walls are arranged in a circuit round the columns" (by this I understand on the columns). "The Tetrastyles are those which, by columns at the angles being put under the girders, afford firmness, because they are neither obliged to have long spans nor are loaded by the trimmings. But the Displuviate are those in which hips sustaining the trough gutter throw off the drippings. These offer great advantages for winter rooms, because the upright opening does not obstruct the window of the dining-rooms, but these cause great annoyance in the way of repairs; the pipes check the drippings flowing round the walls, which (pipes) do not rapidly receive the water flowing from the gutters; thus the redundant water overflows and rots the inside work and walls in these kinds of buildings. The roofed, or arched, made when the span is not great, and spacious rooms are got by means of joisting" (Lib. VI., 3, 1 and 2).

Some of these passages are supposed to be corrupt, so I am very far from asserting that this is a correct translation, but it is the best I can make of it.

Impluvium, or Compluvium, was used differently for the opening in the roof; but I think Impluvium only is used for the open space on the hall floor (the Patio of a Spanish house), and I think Impluvium is sometimes used for the rain-water tank. Vitruvius (Lib VI., cap. 3, par. 1 and 6) certainly speaks of the Compluvium as the opening in the roof, and this seems to be confirmed by Varro; but in Plautus ("Miles Gloriosus") the opening in the roof was called Impluvium. The Captain's slave looks through this hole when he has been following a strayed monkey of his master's on to the neighbour's roof. Our English translators call it a skylight, and the "Vestes impluviarum" of Plautus are translated "skylight dresses," whether from their shape or colour we do not know. The following passage in the "Epidicus" of Plautus speaks of these "Vestes Impluviarum."

Periphanes says to his slave:—"What was she dressed in? Was it a royal robe, or was it a plain dress?"

* I am indebted to Prof. Middleton for this illustration of the Roman Villa at Spoonley, Gloucestershire.

"Epidicus: A skylight one, according as these women coin names for garments.
"Periphanes: What! Was she dressed in a skylight?"

Terence also speaks of the Impluvium as the opening in the roof (Eun. A. III., s. 5, line 41); but without doubt Compluvium was the proper technical word.

Also, the wings. These are generally supposed to be the two recesses to the right and left of the Atrium, but I presume that they included also the chambers on either side of the Atrium. Vitruvius would hardly have devoted so much space to their proportion in relation to the length of the Atrium if they had been only two recesses, and say nothing about the rooms which are three times as wide. In these two recesses statues seem to have been placed, and I suppose that those were the statues in wax of the owner's ancestors, which were carried in procession at the funerals of the family, about which Polybius has written so enthusiastically.

The Tablinum, sometimes spelled Tabulinum, and supposed to be derived from Tabula, was the muniment-room, where the archives of the family were stored. It appears to have been situated at the end of the Atrium, opposite the front entrance. It was open at both ends, and enclosed with curtains, so far as shutting off light is concerned, for the back is believed to have been shut off by doors in open work of wood or metal, so that when it was not in use, and the curtains were open, there was a view from the entrance-lobby across the Atrium, and through the Tablinum to the Peristyle and garden. Vitruvius gives its width in proportion to the width of the Atrium, and describes it as having a coffered ceiling (Vit., Lib. VI., cap. 3, pp. 5 and 6). Pliny ("Nat. Hist.," 35, 2) says:—"Their muniment-rooms, too, were filled with archives and memoirs, stating what each had done when holding the magistracy."

Cubicula, or more rarely Cubilia (from Cumbo, to lie), means rooms where you could recline, even where they were not absolutely bedrooms. Vitruvius seems to use the word Cubiculum for a bedroom only (Lib. I., cap. 2, p. 7); he speaks of the propriety of making them so. In a warm country, and where candles are dear, people mostly get up at dawn. He says (Lib. VI., cap. 4, p. 1). "Bed-chambers and libraries should be towards the east, for their purposes require the morning light." Cubilia he only uses as the bed of a brick, a stone, or a beam (Vit., Lib. II., cap. 8, p. 1; Lib. IV., c. 2, p. 4). There were Cubicula Diurna and Nocturna, day and night rooms, as well as Estiva and Hiberna, summer and winter ones.

Young Pliny calls his bedroom "Cubiculum Noctis et Somni," the chamber of night and sleep. A hall of audience was sometimes called Cubile Saluatorium.

Fauces mean the passages on either side of the Tablinum to the Peristyle or private part of the house, though at Pompeii there is mostly only one passage on one side of the Tablinum, but the Latin word has no singular.

Peristylum, the Peristyle. Vitruvius in his third chap. of the sixth book, is mostly occupied with the description of the construction and proportion of the parts of a house, and in this case wholly with the proportions, and he says it should be one-third wider than its depth.

In the house of Pansa it is just the reverse, as its width is only three-fifths of its depth; but in many houses the peristyle nearly agrees with Vitruvius's description. In the open area of the peristyle a tank or basin of water was generally constructed. When the area was large a building was sometimes erected in the centre space. In Pliny's letter to Trajan (X. 75) he mentions a temple to Claudius being erected in the peristyle of a house.

Bibliotheca, the library. Probably the number of books was small in most private houses, and, from the fact of their being rolled, they took up but a small space. You recollect the description of Pliny's apsidal bedroom, with bookcases in the wall, in his Laurentine villa. The one found at Herculaneum was very small, not much above 6 or 7 ft. wide, with a bookcase down the centre. I believe books were also bound, as we bind them now, with parchment covers, coloured and ornamented with rosettes.

Triclinium, the dining or banqueting-hall. Vitruvius only mentions the ordinary oblong ones, and says they should be twice as long as they are wide, and their height should be half the sum of their length and breadth.

(Eons, a hall. Of these there were three sorts,—the Corinthian, the Egyptian, and the Cyclicone,—which were also used for banqueting-halls. Vitruvius says the Corinthian balls merely have columns on the ground, or on a Podium; are sometimes tetrastyle, and have an arched ceiling. The Egyptian had two ranges of columns, one over the other. From the entablature of the lower range of columns to the walls, these roofs were raised, and open to the sky, with windows between the upper columns, so that the hall was like a basilica. The Egyptian Hall at the Mansion House was originally said to be built in this fashion, and named accordingly.

The Cyclicone was a Greek fashion; it was placed mostly to the north, projected into the garden, and had sash doors of two leaves, at the end and sides, so that the garden could be seen from the couches, and these Cyclicone halls were big enough to have two dinner tables opposite each other, and space for the actors, musicians, rope-dancers, mountebanks, or buffoons to perform in.

As a rule, there were from three to nine persons at a table. When there were nine persons there were three couches, arranged on three sides of a square, with the table in the middle. When round tables were used, with curved couches, these latter were called Sigmas. How the guests were arranged when they were more numerous, I do not know.

Suetonius (Claud., cap. 32) says Claudius was fond of having large dinner-parties, and sometimes had as many as 600 guests. One would think that these dinners must have been in the open air, under marquees, or possibly in one of the large peristyles of the palace, covered with awnings.

I think the arrangement of the diners at table may be noticed here, for the width of a dining-room depends on the width of the table.

The Triclinium, or dining-room, was so called from having the three couches (Triclinia in it, each called Lectus Tricliniaris. Each couch, at a full dinner-party, held three persons. Looking at the arrangement from the open end, the couches formed three sides of a hollow square, with the table in the middle; the middle couch (Medias) was opposite you; the upper couch (Summus) on the right hand; and the lower one (Imus) on the left. At the top of each couch there was sometimes a railing for the guest next it to rest his left arm on, while the others on the couch used pillows. As each guest reclined on his left arm, the top of the lower couch was opposite the bottom of the upper one. In the upper and lower couches the place of honour was next the railing, but in the middle one it was at the bottom; and the cause of this is supposed to be that the principal guest was generally a consul, a general, or some other man in office, and looked to the vacant angle, so that he could see messengers who came to him, and hand papers to them, without turning his head, and at a pinch might go away without disturbing his fellow-guests.

The host, unless he had resigned his place to some one more fitted to do the honours, or the king of the feast had been chosen by throwing dice, was the first on the lower couch—i.e., nearest to the most honoured guest at the bottom of the middle couch—and, with the exception of the middle couch, the places ranked according to their number, first, second, and third, the first being the most honourable, and the third the least.

The places were named Summus, Medius, and Imus, and as the names of the couches were the same, a verbal description is apt to be puzzling.

Summus in Imo, or No. 1 on the lower couch, is the host's place; Imus in Medio, is the place of the most honoured guest. To take one couch only as an instance, say the upper table Summus, No. 1 was Summus in Summo; No. 2, Medias in Summo; No. 3, Imus in Summo.

There seems to be a divergence of opinion about the relative dignity of the places; for some are of opinion, from passages in the classics, that the second or middle place on each couch was the most honourable; it is possible that there were changes in course of time in the honour of the places.

In Horace's Satire (Lib. II., Sat. 8, line 20) there is the placing of the guests; and there is nothing to show that Mæcenas was not at the bottom of the middle table, Imus in Medio. The host, Nasidienus, had given up his place to Nomentanus to do the honours of the table, and Fundanius is speaking of the arrangement.

In his translation, Sir Theodore Martin makes Mæcenas in the middle; probably this arrangement was required by the exigencies of the verse, but there seems to me nothing in the Latin to show that Mæcenas was in the middle. Horace says, "With Servilius Balatro, Vibidius, whom Mæcenas brought along with him, unbidden guests (Umbras). Sir Theodore Martin gives the passage as follows:—

"I was at top, and next to me,
Viscus Thurinus; Varius, he—
Yes, it was he—came next below;
Then, with Servilius Balatro,
Vibidius—one at either end."
Each came there as Mæcenas' friend;
Next Nomentanus, who was put
At top, our host, and at the foot
Porcina."
Sir T. Martin's "Horace."

When round tables with round seats became fashionable, they usually held six, seven, or eight people, and the seats were called Sigmas or Stibadia (Mart. 14, 87).

The children mostly sat on stools at the bottom of the couches at the ordinary Triclinia. Suetonius says (Aug. 64), speaking of Augustus, that "he never stopped but he had them (his grandsons) sitting at the foot of his couch." A summer Triclinium under a Pergola was found at the house of Sallust, Pompeii. Here the couches appear to have been built, and there are no angles unfilled. The couches there are sloped up to the edge, next to the table, so forming hips at the intersections. I can only imagine that in this case the guests lay on their faces at right angles to the edge of the table. This Triclinium is shown in Mazois (F. Mazois's "Le Palais de Scaurus," 8vo, Paris, 1855).

At Trimalchio's feast, we read of him putting both elbows on the table, and of some of the guests also resting on both elbows.

Mercurialis gives two cuts of the ancient dining: one in which a man and two women are on one couch helping themselves from a round table; and the other in which a party of thirteen are drinking. The skin of wine is in front of the middle couch; seven are sitting on the middle couch, and three are lying on the upper, and three on the lower couch. He says the cut is from the Rhamsianum marble, which has almost perished through time and exposure (H. Mercurialis' "De Arte Gymnastica," 4to, Venice, 1573. Lib. I., cap. 11).

Vitruvius, in his description of the Greek house, speaks of square halls (Eci) (Vit. VI., 7, 3) of such ample size that four Triclinia could be laid and attended to, with plenty of space left for the acting; and we believe that his Greek house was the description of the houses built for those Romans who affected Greek habits. Vitruvius, in his description of the Roman house, also mentions square halls (Vit. VI., 3, 8).

Exhedra, a room for conversation, the original meaning of our word parlour. Vitruvius merely says that some are square, and all should be of ample size.

Pinacotheca, a picture gallery. Vitruvius shows by his silence how little was the weight of the importance of the proper lighting of them; he merely says that they are to be of ample size, and to the north, that the colours may not fade.

Textrina Plumbariorum, the embroidery-room. This is mainly of importance as showing that there might possibly be such a room in a house, and Vitruvius advises it being to the north, on account of the equality of the light.

Officina Pictorum. Whether this was a painter's shop or an artist's studio I do not know; but this also was to be to the north, on account of the light, and as it and the former one are mixed up with the rooms of houses, it may have been used in some houses. Caius Fabius Pictor probably had a studio in his house; possibly there was one in the house of Æmilius Paulus when his sons were studying painting and sculpture; and some of the Roman emperors employed some of their spare time in the practice of these fine arts.

It is of no use to go through a list of names twice over, if one can give no further information, so I shall only mention the following:—

Calina, the kitchen. In the house of Pansa, we find the kitchen is about 15 ft. square, has a row of brick stoves, very like those found in a modern house abroad, with a flat piece in front, on which a knife, a saucenpan-lid, and a pan for frying or poaching four eggs at once were found.

There is said to be an inscription mentioning a kitchen 148 ft. long, and if Claudius had his party of 600 guests fed with dishes cooked in

his own kitchen, it must have been pretty large.

In large houses, where they ground their own corn and made their own bread, there was probably a bakehouse; it is also probable that there were separate kitchens for the large roast and boiled meats. Trimalchio had a sow end calf boiled whole. Kitchens such as Pansa's were mainly for boiled, stewed, and fried meats, in small quantities, unless, indeed, they could roast on spits over several of the stoves at once. There was probably a still-room for the pastry, preserves, and confectionery.

Almost all the other parts of a large house are mentioned in Pliny's villas, and it is natural to suppose that the baths, private gymnasia, and tennis-courts were like the public ones, only on a small scale.

Solaria, balconies, terraces, or flat roofs for taking the sun. These were, when large, ornamented with shrubs and beds of flowers. Sometimes they had fish-ponds in them, and fruit-trees growing on them (Seneca). Claudius was said to have hidden behind the door-curtain of a balcony (Solarium) when he was taken by the guard to be made Emperor (Suet. "Claudius," 10); and Nero had porticoes built in the front of all the houses in Rome, with terraces on them (Solaria) to effect the opportunity of extinguishing fires (Suet. "Nero," 16).

The gardens of Roman houses, even in the capital, were often celebrated, and they naturally formed an important feature in the villas. Most of us have heard of the gardens of Lucullus, Sallust, Seneca, and others (Juv. Sat., 16). Like all aristocratic nations, the possession of land was one of the sources of the importance of the great Roman families, as it is the source of subsistence to all nations, aristocratic, democratic, or otherwise. So long as the right of voting was confined to the native freeholder, so long did the institutions of the city flourish; but so soon as the vote passed into the hands of the landless rabble, largely composed, too, of foreigners from the East as well as from the West, so soon did virtue decay and liberty expire. Up to the middle period of the Empire the old landed proprietors gave some thing of respectability to the government. The Roman landed gentry, like our own, were learned in the raising of stock, and in the means of improving the fertility of their fields, and probably took as much pride in their gardens as we do. The Laureate's description of Sir Walter Vivian would doubtless have applied equally well to many a Roman knight or noble.

"No little hly-handed Baronet he,
A great, broad-shouldered, genial Englishman,
A Lord of fat prize-oxen, and of sheep,
A raiser of huge melons and of pine."

Some of you may probably think, What has gardening to do with architecture? I think Le Nôtre, Sir William Chambers, and "Capability" Brown, were landscape gardeners as well as architects, and it is not uncommon, even in the present day, for the landscape gardener to recommend the architect to build a house that will set off his garden.

I have been led, however, to speak of gardens because they were so intimately connected with the houses and villas, and formed a feature in every house of the least pretension, for the area of the last peristyle was universally laid out as a garden. Greenhouses and hot-houses were common, if not so common as they are now, and window gardening was greatly in fashion.

Martial wishes to be his friend's apple-trees rather than his guest, as they are protected from the cold by glass or talc, while his bedroom window had none (Mart. VIII., 14), and he compares the grapes seen through the hot-house windows during a frost to a lady in gauze (Mart. VIII., 68). He also speaks of conservatories of lilies and roses (Mart. IV., 22), and he jokes a friend who has given him a small garden by saying that he has a bigger one on his window-sill (Mart. XI., 19).

Pliny also speaks of the window gardens of the poor in Rome (Pliny's "Natural History," Lib. XIX., cap. 19).

Although the Roman flowers were small in number as compared with our own, they had roses, violets, and lilies, the asphodel (corrupted by us into daffodil from the Old French *Asphodille* or *affrodille*), the crocus, narcissus, gladioli, the iris, and the hyacinth, the poppy, the amarantus, the anemone, the periwinkle, the convolvulus, the crane's-bill, and probably the chrysanthemum, not to speak of flowering shrubs, as the oleander, the flowering willow, the rhododendron, the mallow, and all the

flowering fruit trees, including the gorgeous pomegranate.

I may here mention a curious derivation of periwinkle I once met with in the hook of some etymologist: he said many flowers were introduced by the monks, and got their name from the church to which the monastery was attached, and so derived periwinkle from St. Peter ad Vincula, corrupted by the French into "Pervenche," whereas the Roman name for it was "Pervinea." If, too, it is remembered that the guests were often crowned with flowers at a dinner party, and always were at a drinking bout, flowers must have been in great request. We read of crowns of hot-house roses being presented to his guests by one of the Caesars in winter time, and they were also imported from Pæstum, and from Egypt, for the same purpose (Mart., Lib. VI., epig. 80).

The gardens were laid out very much as our gardens were in the last century, before Sir W. Chambers introduced the landscape gardening of China; the beds were bordered with clipped box, yew, cypress, and rosemary, and the trees and hedges were clipped into every kind of fanciful shape of animals, ships, obelisks, and letters.

Martial tells the story of a young boy thrusting his hand into the open mouth of a bear, cut in a plane tree, and being bitten by a serpent hidden there (Mart. III., 19).

Some of the beds in the garden seem to have been made cushion-shaped, and covered with acanthus or moss. A wall covered with trellises, over which vines were trained,—the modern Italian Pergola—was much in fashion, and ivy was trained round the trunks of trees, and made to hang from one tree to another.

Pliny, in his description of his Tuscan villa, describes this latter method. He says:—"It is set round with plane trees covered with ivy, so that, while their tops flourish with their own green, towards the roots their verdure is borrowed from the ivy that twines round the trunk and branches, spreads from tree to tree, and connects them together." And afterwards, speaking of the Hippodrome, he says:—"This straight boundary to the Hippodrome alters its shape at the farther end, bending into a semi-circle, which is planted round, snt in with cypresses, and casts a deeper and gloomier shade, while the inner circular walks,—for there are several,—enjoying an open exposure, are filled with plenty of roses, and correct, by a very pleasant contrast, the coolness of the shade with the warmth of the sun. Having passed through these several winding alleys, you enter a straight walk, which breaks out into a variety of others, partitioned off by box-wood hedges. In one place you have a little meadow, in another the box is cut into a thousand different forms, sometimes into letters, expressing the master's name, sometimes the artificer's, whilst here and there rise little obelisks with fruit-trees alternately intermixed" (Lib. V., let. 6).

In his description of his Laurentine villa, though it is mostly confined to the house, we get a glimpse or two of the garden. "The Gestatio is bordered round with box, and, where that is decayed, with rosemary: for the box, wherever sheltered by the buildings grows plentifully, but where it lies open and exposed to the weather and spray from the sea, though at some distance from this latter, it quite withers up. Next the Gestatio, and running along inside it, is a shady vine plantation, the path of which is so soft and easy to the tread that you may walk barefoot upon it."

Speaking of the Cryptoporticus, he says:—"Before this enclosed portico lies a terrace fragrant with the scent of violets."

The Romans were quite as fond of shrubs, flowers, and verdure as we are, and had probably flowers in pots or boxes round the Impluvium of the Atrium, as you see them in the Paros of Spain; and where there was a second area of a Peristyle this was bordered with moss and flowers round the basin, and probably pots of flowers were placed elsewhere, and ivy made to twine round the columns. The area of the D or O shaped portico of the Laurentine villa which Pliny calls gay, was doubtless gay with flowers.

The landscape gardeners, the gardeners, and water engineers were among the superior slaves: the first were called Topiarii, the second Viridarii, and the water engineers Aquarii; they were classed with the architects* (Architecti).

*It appears therefore that Mr. Ayrton's famous classification, "architects and market gardeners," had at all events a kind of precedent in Roman practice.—Ed.

itecti), the builders (Fabri), the ornamental plasterers (Tectores), the staturaries (Steturarii), the painters (Pictores), the inlayers (Cælatores), and the embroiderers (Pumarii).

In what relation this class of slaves stood to those who were grammarians (Grammatici or Literati), exponents of the poets (Lectores), readers (Lectores or Anagostæ), and librarians, including copyists, letter-writers (Librarii), and to those who were physicians (Medici), surgeons (Chirurgi or Vulerarii), and professional mblers (Iatraliptæ), I do not know. In a lower grade were the choristers (Symphoniaci), the pantomime players (Ludiones), the mimics (Mimi), the rope dancers (Funambuli or Schœnobatæ), the tumblers (Petanristæ), the dancers (Saltatores and Saltatrices), and the gladiators (Gladiatores). And still lower were the fools (Mortones), the idiots (Fæta), the dwarfs (Nani), and the pigmies (Pumiliones).

Now I am on the subject of the slaves I may as well finish with the household ones. At the end of the Republic and under the Empire the number kept was enormous, and what is said to be the Indian fashion, of having a servant for each separate duty, was pursued in Rome.

A rich and noble Roman only did these things himself: he thought, spoke, fought, exercised, bathed, and ate and drank—everything else was done by his slaves. Young Pliny mentions C. Cæcilius Claudius Isidorus, who left 4,116 slaves when he died, although he had lost much in the Civil War; and, even making the fullest allowance for husbandmen and herdsmen, we must consider that a large proportion of these were mere household servants.

When the news of what happened in one day on one of his estates is read to Trimalchio, he finds that thirty boys and forty girls were born on his estate at Cumæ, and he says that he does not believe a tenth part knew their master; and, though this book of Petronius is supposed to be a satire in which a little exaggeration may be allowed, we have no reason to suppose it was a mere burlesque.

The whole body of slaves belonging to one owner was called the family (familia), and each slave "Servus"; but they were divided into the bought (empti) and those born in the house (verna). The upper slaves (ordinarii) were allowed to have slaves of their own—vicars or deputies (vicarii), who often did their duties for them.

In the "Ass Dealer" of Plautus (act ii. sc. 4, lines 26 to 28) one of the slaves (Leonia), who personates the steward (Sæura), asks another slave (Lihanus) if he has been paid some money; Libanus says, "It has been paid." Leon: "To whom was it given?" "To Stichus himself, your deputy" (Sticho vicario ipso tuo). The steward was the head of the household, and seems to have been called the Procurator, or Procurator rationis. We must, of course, recollect that there may have been great alterations from the age of the first literature in the days of the Second Punic War (about 200 B.C.) to the sack of Rome by Genseric in 455 A.D.

Dispensator—the treasurer.
Promus, or Condus Promus—the butler.
Atriensis—the overseer of the Atrium; the major domo, and helow the butler.
Trichinarches—the overseer of the slaves of the table.
Archimagirus—the house steward; maître d'hôtel.
Supra Coquus—the head cook or chef.
Coquus and Offarius—the cook.
Focarius—the scullion.
Pistor—the baker.
Dulciarius—the pastry-cook.
Structor—who laid the tables.

The Structor was also called the maître d'hôtel, and designed the shapes of the fancy dishes. At Trimalchio's feast it was the Structor who ornamented the round tray with the gilded top, with the twelve signs of the zodiac, and had the meats proper to each sign placed behind them. I suppose the tray had a sort of projecting zone with twelve small dishes in it.

Scissor—the carver.
Ostiarus or Janitor—the doorkeeper or porter.
Velarius—who opened and drew the curtains to the doors.
Cubicularius—the groom of the bed-chamber.
Notarius—the shorthand writer, secretary.
Servus a manu—secretary.
Lector, or Anagostia—reader.
Nomenclator—the prompter, who told his master the names of the clients who

waited on him at his levee, and his consultants when he went out.
 Lictoratus—the chairman; one of the bearers of the litter.
 Precursor—a runner before the litter.
 Pædagogus—footman who walked behind his master, or the litter.
 Pædagogus—originally an upper slave who took the children to school. After the Empire, a page-boy.
 Nuncius—the errand-boy.
 Tabellarius—the letter-carrier or courier.
 Tonsor—the barber.
 Ciniflo—the hair-carrier.
 Vestiplicus—the clothes-folder and ironer.

One would have to give the names of all the servants in the most punctilious Court of Europe to find a tithe of the names of the legions of slaves employed, and when one had finished the list of slaves attendant on the master of the house, one would have to begin again with the more numerous slaves of the mistress. It is said that from ten to twenty thousand slaves were held by rich men, and after dividing the town from the country slaves, one would have to divide the former into house slaves and personal slaves, and divide these again into their several departments.

I have given you the names and duties of a few of the principal slaves of the household. I have not given more, because I thought it would only be wearisome to give a list of upwards of 300.

I presume that, with the exception of a few of the head slaves, the rest were housed in barracks, in the garrets, and cellars. People who thought it fashionable to have the unfortunate porter chained by the leg to his box, who mostly tilted their land with chain-gangs, and kept a professional torturer for the household, were not likely to have been very particular about the housing of their slaves.

Illustrations.

DESIGN FOR GREEK ROOM.

THOUGH, as Englishmen, we are very proud of the "home comforts" of our living-rooms, we shall find, if we look at the average dwelling-room of the present day, that it is furnished rather as a tent than as part of a residence held on lease for a term of seven, fourteen, or twenty-one years. Everything in it of the nature of furniture or adornment, except the wall-paper, could easily be moved out of it in half an hour. The heavy furniture that stands against the wall is kept an inch or so away from it by the skirting-board, leaving an unswEEPing space for the accumulation of dust and "flue." Dust also finds an asylum on the tops and at the backs of pictures, usually placed in heavy gold frames, and hung with a slight slant forwards.

The room I am about to describe is furnished on a contrary scheme, and is decorated in a free reading of the Greek style. As a collection of Greek pottery is its chief decorative feature, the pattern work has mostly been taken from Greek vases, care being taken to select those that have not been vulgarised by constant and inappropriate copying.

To a height of 6 ft. from the floor the walls are painted of a darkish green, this dado of colour being terminated at the top by a simple wooden moulding. Enclosed in panels, framed with a stencilled ivy-leaf pattern in delicate blue, I painted a series of little pictures, at the height of the spectator's eye. These paintings, which were not completed when the photographs were taken, represent sea nymphs, mermaids, and the like. Above the 6-ft. dado the walls are of a delicate ivory-white, variously decorated by figures of Bacchantes in relief, modelled by me in "gesso" and afterwards coloured, by pictures painted on the wall itself, by inscriptions, and by a tinted plaster frieze of ornament.

In the other plate is shown the overmantel, designed to carry several important pieces of Greek pottery. It is made of wood, decorated with Greek patterns in composition; painted ivory-white, and enriched in places with colour and stencilled ornament. The small recesses at its foot serve to contain flower-pots, so that the columns of the little shrine may be appropriately adorned with living vegetation.

On the opposite wall is a large cupboard carrying three great Greek vases, a collection of antique drinking-cups, &c., and some glass goblets for use. This piece of furniture is fitted

symmetrically and accurately into its place, and fastened firmly to the wall. In consequence of this the Greek pottery, though unprotected by glass, is in perfect security; as no shock can in any degree shake its resting-place. Being fixed to the wall, the depth of this piece of woodwork is not so great as is necessary in sideboards, &c., that support themselves; and, though its cupboards contain ample room for all they are required to hold, it takes up very little space compared with its importance; a distinct advantage in a small room. Furniture designed on this principle, it is needless to say, may be in any other style as well as Greek, which is by no means universally appropriate.

The plaster frieze and rosettes I selected from patterns kept in stock by Messrs. Jackson, of Bathbone-place. The four large drinking-goblets (shown in one of the plates) were made from my design, in crystal and green glass, by Messrs. Powell; and the overmantel and cupboard were executed from my full-sized drawings by Mr. W. Eglestone.

H. ARTHUR KENNEDY.

DESIGN FOR A SCREEN FOR A TOWN MANSION.

This design, by Mr. James C. Watt, is the one which obtained this year the Tite Prize at the Institute of Architects. We made some comment on it at the time the students' drawings were hung, and entirely concur in the award; though, as before observed, we do not think the upper portion of the gates very well joined to the rest of the structure.

The design has the merit of being really in the style which Sir William Tite intended to encourage by his bequest: occasionally designs have been submitted which were not Italian at all in the sense intended by the founder of the prize.

PLAN OF THE HOUSE OF PANSA, POMPEII.

THE restored plan of this well-known Pompeian house is given here as one of the illustrations to Mr. Aitchison's third Royal Academy lecture, which is printed in another column.

ROMAN CAPITALS FROM POMPEII.

THESE are also among the illustrations to Professor Aitchison's third lecture. They are enlarged, he tells us, from a drawing by Niccolini.

We are indebted to Professor Aitchison for this and the Pansa plan.

THE PLANNING OF FREE PUBLIC LIBRARIES:

THE ARCHITECTURAL ASSOCIATION.

AT the meeting of this Association on the 31st ult., the following paper, by Mr. E. W. Mountford, was read, in the absence of its author through illness (as mentioned by us last week, p. 97 *ante*) by Mr. H. D. Appleton. Mr. Appleton, before proceeding to read the paper, said that, owing evidently to some unfortunate misunderstanding, which he regretted very much, Mr. Mountford's drawings in illustration of his paper had not been sent.* Mr. J. M. Brydon had very kindly sent his drawings of the Chelsea Free Public Library, now being erected under his superintendence.† Mr. Appleton then proceeded to read Mr. Mountford's paper, of which the following are the most salient portions:—

Mr. Mountford commenced by saying that he did not think he had anything original or new to say upon the subject, but his hope was that some good might arise from its discussion. It was exceedingly difficult for a young architect who was suddenly called upon to design a free library to obtain any information as to the requirements of such buildings. It was only within the last few years that the movement in their favour had come to the front, and no book had yet been written which was of much use to the architect, except the admirable little work, "Free Public Libraries," by Mr. Thomas Greenwood; and that, indeed, treated but slightly of the architectural question. Mr.

* We supply this omission, as far as possible, by stating that in the *Builder* for Dec. 8, 1888, will be found a view and plans of Mr. Mountford's first preliminary design for the Battersea Public Library, which has been carried out under his supervision. Also in the *Builder* for June 8, 1889, we gave an elevation and plan of the design submitted by Mr. Mountford in the Chelsea Library competition, for which he received the second premium. † Illustrated in the *Builder* for June 8, 1888.

E. C. Robins had made a list of very useful suggestions as to various points to be considered in designing a library. These suggestions were to be found in the "Proceedings" of the Royal Institute of British Architects for May 23, 1889. But the architect had necessarily to turn to the librarians for information, and very ready they were to impart it, although some of them complained that architects too often produced buildings handsome, certainly, but unsuited to their purpose: beautiful to look at, difficult to read in, with scant storage for books, and altogether inconvenient for those who had to work in them. Having briefly discussed the historical aspect of free libraries, in the course of which he quoted from a paper by Mr. John Taylor, Chief Librarian of the Bristol Free Libraries, claiming that Bristol established a free public library in 1613, forty years previous to that of Humphrey Chetham, in Manchester, Mr. Mountford gave a sketch of the present movement in favour of free libraries, which commenced in 1849, when Mr. William Ewart's Bill, empowering British municipalities to erect public libraries, and to levy a local rate for that purpose, was introduced into the House of Commons. The Bill was passed in 1850. Subsequent legislative measures followed, including the Public Libraries Act of 1856, and the amending Acts of 1866 and 1877. Coming to the consideration of the building itself, Mr. Mountford said that, in designing a new building for a public library, the chief points to be aimed at were plenty of storage room for books, sufficient light, room, and comfort for the readers, and facility of superintendence and management. A badly-arranged plan would not only increase the anxiety and labour of the librarian, who was responsible for keeping order in the building, but might necessitate the employment of one or more extra assistants, thus adding to the cost of maintenance. In the smallest library three distinct departments were essential, a reading library, a reference library, and a reading-room. Furthermore, there should be a fair-sized entrance hall, a private room for the librarian, and, where possible, separate reading-rooms for ladies and boys respectively, all rooms being in direct communication with the hall, so that no one of them need be used as a passage to another. The reading-room should be in two parts, divided by a screen: one for newspapers, the other for magazines, reviews, and such-like works; or, better still, there might be two distinct rooms. Store-rooms for books, in connexion with both reference and lending libraries, would probably be required, a work-room for bookbinding and repairing, and a receiving and unpacking room. Generally, a dwelling for the caretaker, consisting of sitting-room, two bedrooms, and a kitchen, would be asked for, and it was an advantage to provide a room for assistant librarians. If a librarian's residence be required it should contain two reception-rooms, kitchen, three or four bedrooms, and a bath-room. The desirability of providing lavatories and other conveniences for the public was questioned by some librarians of experience, who stated that such accommodation was likely to be abused and become a nuisance. It was certain that where provided they had, in some instances, afterwards been closed, but of course they must be provided for the officials. Although in some cases more rooms than were here enumerated might be required, these were sufficient for all ordinary purposes. Considering the various apartments separately, the entrance-hall naturally came first. It should be as roomy as possible. In arranging an economical plan the tendency was to reduce the hall to a minimum; but with people coming and going to and from all the rooms opening out of it, probably often stopping to chat, a small hall must at times become inconveniently crowded. It should have an outer porch, wherein, before the library itself was opened in the morning, copies of the daily papers might be posted for the benefit of men who, being out of employment, wanted to see the advertisements in good time. The lending library must always be on the ground-floor, as near as might be to the principal entrance. Abundance of light was essential; and should top-lighting be out of the question, there must be plenty of windows, with reference to the position of which the book-cases would have to be arranged. The room should not be less than 13 ft. high (Mr. Robins thought not less than 14 ft., and no doubt he was right if the money sufficed), the windows being kept up as high as possible in order to

row light over the tops of the book-cases and permit dwarf book-cases being placed against the wall beneath them. The old-fashioned stem of arranging the books in alcoves, while very pleasant and quite adequate for college and similar libraries, was quite out of the question for free libraries, where every inch of space was wanted for some purpose. The bookcases were before generally arranged, so far as the lending library and storerooms were concerned, in rows across the floor at right-angles to the counter, to save the steps of the assistants, and the principal windows, in order to get the light between the stacks upon the backs of all the books. As much counter-space should be provided as could be, not less than 30 ft. in length, in order to allow sufficient room for the "indicators" and the serving-desks. Two doorways should be provided for the public, as far from each other as space would permit, in order to facilitate the free circulation of borrowers. With one doorway for egress and ingress also, books must be placed on crowded occasions, such as Saturday nights. The doors here, as well as in the reading-rooms generally, must be on swing hinges, with the upper parts glazed. The Reference Library should be placed in the quietest part of the building, away from street noises, and "far from the madding crowd" of newspaper and novel-readers. In this room the readers occupied the whole of the centre; so the books required all the wall-space, thus necessitating top-lighting, which, however, was the best for other reasons. For all these reasons might with advantage be placed on the first floor,—the more so as a comparatively small number of people used it. In order to increase the storage capacity, a gallery might be provided about 10 ft. from the floor, which need not be more than 3 ft. 6 in. wide,—just sufficient for a hook-case against the wall and room to pass in front of it, the book-case it carried being 8 ft. high; that made the minimum height of the plate 18 ft. Round the room in front of the bookcases there would be a rail, and near the door a counter with desk for the assistant librarian. Probably the best way of arranging the tables used by the public was to have seats upon one side only, all the readers facing the counter, partly to check conversation and partly to protect the books, which in this room were often valuable, and liable to mutilation or theft by unscrupulous persons. Under that arrangement the tables need only be 2 ft. wide, but they must be 4 ft. if readers occupied both sides. Two feet in the length of the table should be allowed for each reader. Long tables were the most economical of space, but for other reasons short ones were preferable. With readers upon both sides, 6 ft. should be allowed between the tables; with the single arrangement 5 ft., or a trifle less, would suffice. In the News-room,—where there was another reading-room in the building,—was devoted entirely to newspapers, which were placed upon upright stands, just as in a club. To economise space the stands were made double, to allow of readers upon each side, and they should, of course, be placed at right-angles to the windows. The spacing out of the windows and size of the room should be regulated by the reading-desks. Experience showed that the desks might conveniently be placed about 6 ft. 6 in., or 7 ft. apart from centre to centre, and being a foot wide, that allowed room for two rows of readers, and the necessary passing and repassing between. The windows might be 4 ft., or even more, above the floor, as no benefit was derived from their coming lower, and looking out of them was distinctly to be discouraged. In the Magazine-room, tables would be required, and here readers would be placed upon both sides, but, of course, not at the ends. A width of 3 ft. was enough for these tables, and they should be at least 6 ft. apart. Allowing for everything, 14 square feet is the minimum allowance to be recommended for each reader. The position of the librarian's room needed to be very carefully considered. Without being overlooked himself, he should be able to see all that went on. It should adjoin and communicate with the lending library, and at the same time command the News-room and staircase,—in fact all the building, if possible. By means of speaking-tubes, the librarian should be in communication with his assistants in all the other rooms, without rising from his table. The room might possibly be used for the meetings of the Commissioners, which would, of course, necessitate its being of a good size, there being always nine of those gentlemen. But it was much better

to provide a separate room for them in a quiet part of the building, not too far from the librarian's room, and they liked to have a long table with a separate lock-up drawer for each. A lavatory should be provided for the use of the Commissioners and librarians. Of the Ladies' reading-room and the Boys' reading-room nothing need be said, excepting that the latter must be placed where it was constantly under the eye of some official. If a retiring-room for ladies were provided, it should lead out of their reading-room; but nearly all librarians agreed that such accommodation was better dispensed with. The number and size of book-stores would be regulated by the number of hooks the Commissioners proposed that the library should contain. For the reference library and its stores six volumes might be calculated to the lineal foot of shelving. For the lending library eight volumes to the foot. Mr Robins said nine and ten volumes respectively, but Mr. Mountford thought his own figures were nearer the mark. The height of cases being fixed generally at 8 ft., and containing eight shelves, the requisite length for any given number of hooks might easily be calculated. If the library consisted of two or more stories there must be a lift for hooks communicating with the various rooms, and there should be a private stair for the use of the officials. Nothing spoilt the binding of hooks more than gas; therefore, until the use of the electric light became general, plenty of outlet ventilators should be provided by means of flues formed in the walls or chimney shafts, by openings in the roof, or the use of ventilating lights, and the burners should be kept as far above the level of the books as possible. The heating should be by means of hot water or steam, and coils were to be preferred to rows of pipes. The rooms for librarian and Commissioners should have open fireplaces. That seemed to be all that need be said about the internal arrangements of the building. Of the exterior, everyone would probably have his own idea. The author had hitherto thought that the elevations should be rather of a domestic than of a municipal type, but events had considerably modified his views upon that point. The great thing was to have plenty of windows, kept well up from the floor, and all made to open. The building should be of fire-proof construction if funds would permit, and wood-block flooring was very preferable to any other, because of its noiselessness. Plate glass was desirable for the windows, for the better shutting-out of external sounds. The first and most important of the fittings were the book-cases. As had been said, those in the Reference Library were placed round the walls, being protected from the general public by a rail placed about 3 ft. from them. But in the Lending Library and book stores, where the public had no access to them, the cases were placed in rows across the floor, with narrow aisles between, and were made double,—i.e. with books facing both ways. These double cases were better without a central partition between the books, although sometimes a small fillet was nailed along the centre of the shelves to prevent the books in one row from actually touching those in the other. The omission of the central partition allowed of freer access of air to all the books, did away with any corners for the accumulation of dust, and facilitated the dusting or washing of the shelves. A few general principles should be borne in mind in planning the shelves of a room. First, full capacity required that, up to 7 ft. 8 in. or 8 ft., all wall space and both sides of all aisles be covered with hook backs. Except doors, windows, and the narrow ends of double book-cases, there should be nothing in sight but the backs of hooks and the occasional narrow edges of the uprights. Any scheme falling thus was wasting shelving capacity. Every aisle was equally valuable for reaching hooks on either side; every face of books must have half an aisle vacant in front of it. If a face had a whole aisle, there was obvious waste in planning; 8 in. more space would give an entire extra face of hooks. An individual shelf should not be more than 3 ft. 6 in. long, nor less than 8 in. broad. Wood shelves were almost universally 1 in. thick,—that was to say, 1 in. Long shelves were awkward in use, because they did not afford enough uprights to support the hooks properly, but we were helped to the selection of the golden mean by the experience that shelves over 3 ft. 6 in. long sagged in the centre when full of books. The shorter the shelves the less the danger of warping, and the greater convenience

of the frequent uprights which served as book supports. The only objections were the extra cost of the uprights and the slight space lost. On the whole, 30 in. was about the best length for a shelf. Iron shelves had been used, but wood-shelving was superior to iron, because it was cheaper, admitted of a better finish, looked better, and was less harsh and abrading to the binding of books. When used in the British Museum the iron shelves had to be covered with leather. The reason given for the use of iron shelving was that it was incombustible; but, unless the whole building was absolutely fireproof, it was obvious that iron shelves were useless for this purpose. In America, gaspipe frames for bookshelves were advocated by the superintendent of Buffalo Library, who claimed to secure by their use—first, economy of material and light-

Book-stack for double row of books: all shelves movable.

ness; second, economy of room (the divisions between the sections of shelves being of light sheet-iron, no appreciable space was taken up by anything but the books themselves); third, the least possible obstruction of light; fourth, the freest circulation of air among the books, to the benefit of the bindings; fifth, cleanliness. There are different kinds of indicators in use; the two most commonly used being the "Cotgreave" and the "Elliot." The Cotgreave might be described in general terms as consisting of an iron frame, fitted with as many thousand small zinc shelves as there were books to be recorded; upon each of these shelves was placed a small metallic-cased ledger, numbered alike at both ends, but in different colours,—blue one end, red the other. If the blue end of the little ledger was turned towards the public the volume was available; if the red end, the book was "out." This indicator occupied a space of 4 ft. by 6 ft. for every 5,000 volumes. The Elliot indicator had no little books, the borrowers' ticket being placed in the numbered space when a book was issued. Its size was 3 ft. square for every 1,000 volumes. There were many other systems in use, but generally they took much more counter-space than the Cotgreave. The counters must be 2 ft. wide at least, the inner side being fitted up with shelves and drawers, of which each librarian had his own views. That in the reference library might contain a row of drawers on the outer or public side, to contain the card catalogue, each drawer being 11 or 12 in. wide, some 24 in. long, and 5 in. deep. A thin partition divided the drawer into two compartments longitudinally, and they had double fronts, the outer ones being hinged and locked. In the inner front were two small holes, in which were placed the ends of two brass rods, one to each compartment of drawers, which ran through perforations in the cards contained in the drawers. The outer front being secured, it was impossible to withdraw the rods or remove one of the cards. All counter-tops should be of polished hard wood. In conclusion, Mr. Mountford said his object in writing this paper had been to raise a discussion upon this important subject, which had hitherto received but little attention from architects as a body.

In the discussion which followed, Mr J. M. Brydon said that he had listened with much pleasure to the paper, for he knew that Mr. Mountford had given a great deal of consideration to the subject. Mr. Mountford had very justly summed up the essential points in the planning of a free public library, viz., plenty of space for books, abundance of light, adequate means of ventilation, and ease and economy of supervision. Free libraries, as we now understood them, were almost a new problem in architecture, at any rate so far as the provision of district libraries, such as were now being erected in various parishes in London, was concerned. One point which it was very essential to bear in mind was that these local libraries had to be supervised by very limited staffs. It was, therefore, desirable that in planning these libraries the rooms should be so arranged that the attendants in passing to and fro should be able to see into all the rooms which were accessible to the public; it was highly desirable that the arrangement of the rooms themselves should be as simple as possible. Another important point for consideration was the amount of space that should be allotted to the readers, for that would determine the size of the building. His own opinion was that nothing under 15 square ft. should be allowed for each reader in every large reading-room; a smaller amount of space per reader would be found inconvenient. The question of ventilation was also one of very great importance. These libraries were used by all sorts of people, and when the rooms were very crowded, especially on Saturday nights and in wet and damp weather, the atmosphere became almost unbearable unless there was efficient ventilation. Another important point was that of the lighting of these rooms. He was of opinion that the windows should be as high in the walls as possible,—at any rate, above the level of the eye, for low windows, looking out into the street, attracted little knots of loungers, who were not wanted, in free libraries. It was also most desirable, in view of the fluctuating numbers of readers in these libraries, that the heating arrangements should be under such control that the temperature of the apartments could be lowered or increased, according as the number of readers increased or diminished. He would not go into the intricate question of fittings, the nature of which would be largely dependent upon circumstances. It would, however, be a desirable thing if they could get a chair which should be noiseless; the pushing forward of chairs of the ordinary type, even on wood block floors, was very annoying to readers. With regard to the reference library, of course that was the part of the library which ought to be the study, and it should therefore be kept the quietest portion of the building, and not made a means of communication with other rooms, nor should it be a large book-store; it was better and more economical of space to keep the books in a book-store rather than in the reference library itself. In conclusion, he begged to move a vote of thanks to Mr. Mountford for his excellent paper.

Mr. Karlake, called upon by the Chairman to make a few remarks, said that Mr. Brydon had touched upon almost all the points about which he had anything to say. But there was one comment he wished to make. Mr. Mountford recommended that the reference-library should be top-lighted, with the book-shelves running round it, separated by a barrier or rail to keep the public from touching the books. In his (the speaker's) opinion, however, a top-lighted room was not a good one, either for sitting or reading in, and the suggested mode of arranging the books round the room was certainly most wasteful of space. Books could be stored in book-stores with much greater advantage and economy of space.

Mr. C. T. Davis, Librarian of the Wandsworth Public Library, said that architects who were called upon to design free libraries should strenuously endeavour to bear in mind that the available income from the rate for supporting such libraries in many cases was so small that economy of maintenance and supervision was most essential. It should be borne in mind, too, that whereas in London the free libraries were managed by boards of Commissioners, not more than nine in number for each parish where the Acts were adopted, in the provinces there were sometimes library committees, numerically much stronger than the board of Commissioners; and it was desirable in such cases to give ample accommoda-

tion for them in the shape of a sufficiently large committee or board-room. There should be as few angles, nooks, and crannies as possible, for such often caused nuisance by harbouring dirt. A few good large, light rooms were better than a great number of little rooms. Architects should keep the walls of the rooms as flat as possible, avoiding the use of projections such as pilasters, whether real or sham, as much as possible, for such projections interfered with the hanging-up of maps or large prints from the illustrated papers. He would strongly urge architects who had to design free libraries to keep the ventilation as good as possible; they wanted ample extractive power for the ventilation of these buildings, and plenty of fresh air. As to gas-lights, he did not like the open burners at all, and he thought that in all cases the fumes of the gas should be carried off by means of ventilating hoods over the burners. It was of importance to place the "indicator" with a good light on both sides,—on the attendants' side as well as on the side which was seen by the public. As to the provision of separate reading-rooms for ladies, it was his opinion that they were not needed; but certain tables in the large general reading-room might be allotted to ladies. If a boys' room is wanted, put it close to the lending library, so that it might be well supervised. The suggested way of keeping the books in the reference library, with an enclosed space in front of them, was wasteful of room. A better way was to keep the books in locked and glazed cases, so that the public could see the backs of the books, but not get at them without the intervention of an attendant. It was a moot question whether sanitary conveniences should be provided in free libraries, except for the use of the staff. It was his experience that conveniences of that kind were greatly abused by the public. If supplied, a check on their improper use might perhaps be provided by means of spring-doors and automatic locks, which could only be opened by dropping a penny in the slit. One important point had been overlooked, viz., the provision of fire-extinguishing apparatus. On every floor should be a good supply of water; if possible, a hydrant. Librarian-ship is a profession, and if the librarian is to live at the library let his rooms be such as would suit a professional man. They should be so sited that the noise from his children,—as all librarians are not bachelors,—may not disturb the readers.

Mr. Quinn, Librarian of the Chelsea Free Library, made some remarks substantially to the same effect as those of Mr. Davis.

Mr. E. R. Farrow said he had much pleasure in seconding the vote of thanks to Mr. Mountford for his excellent paper, as well as to Mr. Appleton for reading it, and to Mr. Brydon and Mr. Karlake for so kindly sending plans in illustration of the subject. From what he had been able to learn in conversation with the librarians of similar public libraries, he thought it was now recognised that separate rooms for women and boys were not necessary or desirable; separate tables for them in the large rooms would suffice.

Mr. A. O. Collard, in supporting the motion, spoke in commendation of the British Museum Reading-room fittings and appliances, although he admitted that things there were done on too costly a scale to be applicable to small local or parish libraries. He thought, however, that top-lighting, as there carried out, was most satisfactory, and was at a loss to understand the objections which had been made to such a mode of lighting. There was no more painful room to read in than that of the Library of the Royal Institute of British Architects, for there one was obliged to sit either facing a strong light, or with his back to the light and his book in shadow.

The Chairman, in putting the vote of thanks to the meeting, said that, as was remarked in the paper, architects had been often severely criticised by librarians for defective arrangements in their buildings; but the librarians seemed to be unaware of the fact that the architects were not always to blame for those defects, which were as often as not due to compliance with the instructions of the Commissioners who built the libraries. With regard to the means of ventilating public reading-rooms, it was, as had been said, a most important matter. He was strongly of opinion that mechanical ventilation was necessary to cope with the state of things sometimes met with in crowded reading-rooms on Saturday evenings,—especially on wet, damp, and steamy Saturday evenings. With the vote of thanks he begged

to couple the names of the librarians, Messrs. Davies and Quinn, who had so kindly attended to give the meeting the benefit of their views on the subject.

The vote of thanks was then put and carried very heartily, and the proceedings terminated.

ARCHITECTURAL ASSOCIATION VISITS:

MR. D'O'LY CARTÉ'S NEW THEATRE.

A LARGE number of members attended the first Seasonal visit of the Architectural Association, on Saturday afternoon, to the new theatre in Cambridge-circus, Shaftesbury-avenue.

Mr. D'O'ly Carté in this case, as previously, has dispensed with the services of a contractor, and partially with those of an architect, for having with Mr. Holloway and his assistants arranged the plan and interior of the new building, he resorted to Mr. T. E. Colcott for the design of the elevations and internal decorations.

The state of the building at present is favourable to an examination of the construction, and its fireproof nature is apparent. It is stated that the auditorium will be constructed and fitted in every part of fireproof material, so that insurance of the building will become unnecessary; but whether the entire absence of wood in the construction and decoration will affect the acoustic properties of the building remains to be seen.

A specimen of a light fireproof door for use in the boxes and elsewhere was shown, the frame being formed of light steel, across which was strained asbestos canvas.

Steel has, with few exceptions, been used throughout. The partitions to boxes, balconies, stairs, have been formed of coke breeze and cement concrete, strengthened, where necessary, with steel bars.

The construction of the roof of the auditorium is peculiar in many respects. The trusses and other members are of steel, the spaces being filled in with coke-breeze concrete. The outside is rendered in Portland cement. It remains to be seen whether this roof will withstand variations of temperature and still remain watertight.

Those roofs which are exposed to view have had lattice nailed to the coke breeze, with a tile covering in the ordinary way.

Each circle is provided with a separate entrance and exit, the former of which can be used as an exit in case of emergency. There are but four boxes to each circle, as at present, a preference is shown by the public for stalls. The theatre is designed to seat about 2,000 people.

The orchestra has been designed to meet the views of Sir Arthur Sullivan, and for this purpose every musician will be placed well in front of the stage, and not underneath it, as has been often done recently.

The width of the proscenium is 34 ft. 6 in., and the depth of the stage 47 ft. 6 in. Sufficient height has been provided over the stage for scenes and curtains to be hoisted entirely above the proscenium, opening without either rolling or folding.

Mr. Holloway and his assistants kindly met the party, and explained the drawings and other matters referring to the structure.

THE LONDON COUNTY COUNCIL.

THE usual weekly meeting of the London County Council was held in the Council Chamber of the Corporation of London, Guildhall, on Tuesday last, Lord Rosebery in the chair.

The Annual Budget and Report.—The Chairman suggested that it should be referred to the Finance Committee to consider the question of preparing the annual budget of the Council, and that the chairman of the various "spending committees" should be asked to draw up estimates of the money they would require during the coming year. If the expenditure of the Council was to be methodised, such a course was absolutely necessary. This was agreed to. The Chairman added that, though they were not required by statute to do so, it would probably be expected, and it would certainly be desirable, that the Council should produce an annual report of their proceedings. He took it that the proper date up to which that report ought to be made was the 31st of March, because the day on which they began, or were supposed to begin, their work was the 1st of April, though accidentally that date was antic-

pated by a few days. Their recognised year began on the 1st of April, both financially and legally, and he therefore suggested that the Council should prepare an annual report, and, as a preliminary to that, that a circular should be sent to the chairmen of the different committees to ask them to forward to the Clerk of the Council statements of the work done by their committees upon which such a report might be based. He hoped that that report would be ready for presentation to the Council at their first meeting in the enlarged Council-chamber at Spring Gardens, on or about the 14th of April. This suggestion was also agreed to.

The Proposed Blackwall Tunnel.—Several members announced that they had petitions to present in reference to the proposed tunnel beneath the Thames at Blackwall, as to which the Bridges Committee presented the following important report:—

"The Thames Tunnel (Blackwall) Act, 1857, and the report of Mr. Wolfe Barry, have had the most anxious and careful consideration of your Committee. For many years the people of the east and south-east of London pressed upon the Metropolitan Board of Works their claim to have provided by the central authority some means of permanent inter-communication commensurate with the important interests on both sides of the river. As far back as August, 1852, Sir Joseph Bazalgette prepared, by order of the Board, a report which deals with the whole subject, going very fully into the question of ferries, bridges, and tunnels; this report concludes with the statement that a tunnel is the only suitable means of effecting a permanent crossing at Blackwall. After much consideration, the Board took the same view. Much time was spent in preparing the details necessary before going to Parliament, and a Bill was promoted in the session of 1857. It was referred to a Committee, when the scheme, which was opposed by railway companies and other owners of property, was supported by some of the ablest engineers of the day, viz. Sir J. Bazalgette, Sir F. Bramwell, and Mr. B. Baker. The Committee reported in favour of the Bill, and it was in due course passed. Specifications were prepared and tenders advertised for, and the action of the Metropolitan Board of Works in accepting in the last month of its existence a contract for this important work, instead of leaving the Council unfettered, will be fresh in the recollection of the Council. Your Committee, on taking up the matter, were placed in considerable difficulty, the Council being without a Chief Engineer, and the advantage of having the same engineer to prepare the specification and carry out a work of this character will be obvious. The technical aspect of the questions arising as to size, boring or borings, practicability of scheme, &c., were, by order of the Council referred to Mr. J. Wolfe Barry, and a copy of his report has been forwarded to each member. Mr. Barry, though suggesting certain modifications, considers a tunnel practicable, but suggests a high-level bridge. Your Committee are of opinion that, as a bridge at this point would have to be of such a height as to admit of all ships passing under it without any alterations in their masts, and as ships with masts 200 ft. above the water are stated to pass at this point, the road of the bridge would have to be at least 210 ft. above Trinity High Water Mark. When the low level of the land on both sides of the river is considered, a bridge of this height is, in the opinion of your Committee, out of the question. They therefore recommend—

"That the Council do proceed with the formation of the tunnel authorised by the Thames Tunnel (Blackwall) Act, 1857,—namely, by three lines of borings, one being for foot-passengers and the other two for vehicular traffic.

The consideration of this report was adjourned for a fortnight, and, on the motion of Councilor Longstaff, it was agreed that in the meantime the Bridges Committee should prepare certain returns as to the cost and results of working of the Woolwich Ferry.

Election of a Chief Engineer.—The Standing Committee presented the following report:—

"We have, in accordance with the resolution of the Council on Tuesday last, the 4th inst., considered, in conference with the other Committees concerned, the best course to be taken for the appointment of a Chief Engineer. It will probably be within the recollection of the Council that, when we recommended the appointment of Mr. Dunscombe, the loss of whose services we greatly regret, we mentioned the names of two other candidates for the office,—viz., Mr. A. R. Binnie and Mr. J. Allison. We

formed at the time a high opinion of Mr. Binnie's qualifications, whilst deeming Mr. Dunscombe to be, on the whole, more fitted, owing to his previous long and general experience in Liverpool, for the position that had to be filled in London. The Council being now under the necessity of making a fresh choice cannot, we think, do better than appoint Mr. Binnie to the office. We accordingly recommend—

"That Mr. A. R. Binnie be appointed Chief Engineer of the Council, at a salary of 1,500*l.* a year, upon the following conditions:—That he do hold his office during the pleasure of the Council; that he be required to give his whole time to the duties of his office, and be not allowed to take any private practice, and that on retirement he shall not be entitled to any superannuation or pension."

On the motion of the Deputy-Chairman (Councilor Haggis), this recommendation was unanimously agreed to. Mr. Binnie shortly afterwards appeared on the dais, and thanked the Council for his appointment.

Mr. Dunscombe.—The Standing Committee also recommended,—

"That the Clerk be instructed to convey to Mr. Dunscombe an expression of regret on the part of the Council that the temporary failure of his health has deprived the Council of services from which it had reason to anticipate much advantage, and the hope that his health may soon be sufficiently restored to enable him to enter upon some fresh sphere of duty."

One over-cautious member of the Council, whose name we forbear to mention, wanted to know "whether it would not be going too far" to pass this recommendation. The Chairman promptly replied that he certainly did not think so, for he thought that Mr. Dunscombe, who had given up a good appointment to enter their service, and was now without any appointment, was entitled to some expression of their sympathy. After this, the recommendation was unanimously carried.

The Architect's Department.—The Standing Committee also presented a report on the re-organisation of the Architect's Department. They recommended its division into two departments,—viz., the "Estates and Valuation Department," of which the Valuer, Mr. A. Young, would be the head; and "The Architect's Department," of which Mr. Blashill, the Superintending Architect, would be the head. In this department, the Committee recommended the formation of a "Parks and Open Spaces Sub-Department." The consideration of this report was postponed.

A Board of Works' Scandal.—The Housing of the Working Classes Committee brought up a long report, stating that they had proceeded upon the resolution of the Council of July 16 last instructing them to institute an inquiry into the rights of the present owners of certain land in Whitecross-street. The history of the matter was as follows:—In 1877 a scheme was undertaken by the Peabody Trustees, under the authority of the Metropolitan Board of Works, known as "The Whitecross-street Improvement Scheme." The costermongers in the district, especially those displaced by the carrying out of the scheme, asked the Board that buildings might be erected which made provision for their goods and barrows. The Board promised that that should be done, in a letter dated March 15, 1877, but that promise was not fulfilled. When the costers discovered this, great discontent was expressed, but it was not until 1887 that an organised agitation commenced. Certain costermongers then met every Wednesday at the coffee-house of Mr. Wells; and Mr. Patrick Lamb, a general dealer, and Mr. Church, a bootmaker, took the lead. Mr. Lamb seemed to have been tacitly accepted as chairman, and a Committee was formed, at the suggestion of Mr. Wells, on the 31st August, but the proceedings were, however, never of a very regular character. After one or two meetings Mr. Wells introduced Mr. Hibbert, a local tobacconist, to act as Secretary to what was called "The Watch Committee of Costermongers," this name being taken from an old committee which had existed in 1877, and of which Lamb and Church had been members. Mr. Hibbert's services were readily accepted, as the members of the Committee were of an uneducated class. A deputation, introduced by Mr. Hibbert, then waited upon Mr. Berry, the representative of their Vestry on the Metropolitan Board of Works, to request his good offices on their behalf; and afterwards deputations waited upon the Board, in order to claim a fulfilment of the promise given in 1877. Mr. Berry took up the matter very energetically, and owing to his action the Board decided on December 23, 1887, to sell to

the Watch Committee a piece of land in Dufferin and Errol-streets for 65*l.*, or twenty-one years' purchase at one penny a foot rental. The value of this land had been variously estimated at 3,000*l.* and upwards. The land, it appeared, was subsequently made over absolutely by the Board to Messrs. Hibbert, Wells, Lamb, and Church, but, it is alleged, without the knowledge or consent of the costermongers on whose behalf those persons professed to be acting. Dwellings of an unsatisfactory character structurally (according to the report of the Council's Valuer), and not giving the requisite accommodation for the costers, had since been erected on the land in question, but the four persons named were now willing to convey the land and buildings to the Council, subject to the mortgage. The cost upon which the Council could acquire the property was stated to be not less than about 10,000*l.*, although the Valuer's report stated that the approximate value of the buildings is only 5,533*l.* 10*s.* 5*d.* The Valuer further reported that he could not advise the Council in any terms to acquire the buildings, as, "owing to their defective quality, a large expenditure would have to be incurred in constant repairs, and nothing could be done to make them satisfactory." The Committee, while expressing their condemnation of the carelessness which had taken place, and by which the property of the ratepayers had been sacrificed, concluded by expressing the hope that opportunity at no distant date might be offered for providing for the costers of the neighbourhood the accommodation of which they stood in need, and which was promised to them. The Committee recommended:—

"That the Standing Committee be instructed to investigate the facts appearing from this report, as affecting the Solicitor's and Architect's departments, and the District Surveyor."

This was agreed to; and subsequently, on the motion of Councilor Benn, it was resolved—

"That, in the opinion of this Council, the claims of the Whitecross-street costermongers, as to re-housing, have never been satisfied, and that it be an instruction to the Housing of the Working Classes Committee to inquire and report to the Council in what way their claims can best be met."

Water Assessments.—After some discussion, it was resolved—

"That in view of the quinquennial re-assessment of property in London which will come into force next year (1891), and the resulting effect which will give the water companies power to exact an increased charge for their supply, this Council instructs its Special Water Committee to immediately take the question into consideration, and report thereon."

Mortuaries and Coroners' Courts.—It was also resolved—

"That all Coroners having jurisdiction within the Administrative County of London be requested to furnish the Council with the number and position of existing Mortuaries and Coroners' Courts in their respective districts, and to inform the Council what further accommodation, either as to Mortuaries or Coroners' Courts, they consider necessary in their districts."

District Surveyors and Cellar Dwellings.—Councilor Davies moved—

"That, as District Surveyors fall in many cases to report to the Council and the local authorities the occupation of underground dwellings, it be an instruction to the Building Act Committee to report to the Council what steps can be taken to ensure the District Surveyors carrying out with greater efficiency their duties with respect to these dwellings."

In the course of the discussion which ensued upon this, Councilor Beachcroft expressed a hope that these duties would ultimately be transferred to the sanitary inspectors. Unfortunately, there were at present only 111 sanitary inspectors throughout the metropolitan area. He hoped to see that number increased three-fold.

The motion was carried, and the Council shortly afterwards adjourned.

Swedish Villas in Brazil.—Last summer the Ekman Snickeri factory, of Stockholm, forwarded four wooden villas to Brazil, and they have attracted so much notice that large orders for others have been received, to be executed during the present winter. This factory has also manufactured the wooden structures for the Swedish section of the great agricultural exhibition to be held in Buenos Ayres, as well as that to contain the Danish dairy, both being Scandinavian in style.

Industrial Exhibition in Constantinople.—An industrial exhibition,—the first ever held in Turkey,—will be opened in Constantinople next spring.

CLERKS OF WORKS' ASSOCIATION OF
GREAT BRITAIN:
ANNUAL DINNER.

The seventh annual dinner of this Association was held on Monday evening last in the Venetian Room of the Holborn Restaurant. Mr. J. Macvicar Anderson, Vice-President of the Royal Institute of British Architects, occupied the chair, and there was a large attendance of the members and friends of the Association.

The usual loyal and patriotic toasts having been disposed of (Mr. W. Baker, of Portsmouth, responding on behalf of "The Army, Navy, and Reserve Forces").

Mr. J. H. Smith proposed "The Architects and Surveyors," coupled with the names of Mr. Ralph Nevill, F.S.A., and Mr. J. Gandy.

Mr. Ralph Nevill, in responding, expressed his sense of the value of the services of clerks of works, a body of men, however, whom he had not employed so largely as he could have wished, for a great deal of his practice had been in the country, where, with the help of a good horse, an architect was able to do a good deal in the way of inspecting the progress of his works. During his early experiences of the profession he had acted as clerk of works under his old master, Sir Gilbert Scott, and on another occasion he had also, for the same master, taken upon himself the work of a builder as well, paying the men in addition to supervising their work. No work that he had ever done taught him so much as he learnt in following those occupations. Young architects must not esteem such work too lightly; let them by all means be prepared to do it, and first make themselves masters of the principles of construction, and learn how to take out quantities; men who mastered all such practical matters as these would have all the more satisfaction in turning to the art-side of their profession, which they would feel themselves able to do when they had able lieutenants in the shape of clerks of works, on whom they could lean, and lean heavily. He recollected the thorough coincidence which Sir Gilbert Scott reposed in his clerks of works, and the cordial friendship which Sir Gilbert always felt towards them. Speaking of quantities, he hoped the day would come, and before very long, when the bill of quantities would be made the basis of the contract. When that wished-for time arrived, the importance and value of the services of the clerk of works would be somewhat enhanced, for in many works the final measuring-up of the work, with a view to the settlement of accounts, might very well and very properly be done by the clerk of works. In conclusion, Mr. Nevill said he thought that there was a brilliant future for English architecture. Year by year young men, having received their professional education in London, distributed themselves over the country and settled down to practice, helping to build up what he thought would prove to be one of the finest schools of architecture that had ever been seen.

Mr. J. Gandy also briefly responded to the toast, speaking very highly of his experiences of the courtesy and ability of clerks of works.

The Chairman, in proposing the toast of the evening, "The Clerks of Works' Association of Great Britain," said that it was with very great pleasure indeed that he occupied the chair that evening, for he felt that architects were very largely dependent upon clerks of works. Now, inasmuch as he saw by the constitution of the Association that its objects were to advance the general knowledge and capabilities of its members, and to maintain their respectability and integrity, it followed that architects ought to take the greatest possible interest in encouraging the Association, and in doing all they could to promote its success and efficiency. Time was when the clerk of works, as we now understood the term, was little known or little required. In what were called by some people "the good old times" the architect, if he attained repute at all, only attained a local repute, owing to the slightness of the means of communication between one part of the country and another. The venerable shrines which had come down to our days in the shape of those grand old cathedrals and parish churches which constituted the greatest legacy which could have been left to us, and for which we felt such deep and natural affection, were in many cases the work of a single architect, and clerk of works concentrated in one individual. What a grand occupation it must have been to have had the whole control of the erection of such buildings, without being troubled by the crochets of clients, and without having one's ideas limited on the score of expense,—to have been able to have resided always upon one's building, and to have been able to design its mouldings on the spot, with special reference to the positions they were to occupy! What a contrast with the rush and bustle and excitement of the nineteenth century! "Tempora mutantur, et nos mutamur in illis." Times had indeed changed; steam, electricity, and the means of rapid communication had completely banished the old order of things. The architect who now attained any celebrity was not allowed to repose in one neighbourhood; he had to rush north, south, east, and west at the call of his clients. That was a state of things which made it necessary that the

architect should have on each of his works a responsible and capable representative, and hence the necessity for the modern clerk of works. The modern clerk of works, to be of any use, must be efficient and honest, and hence the necessity of an Association membership in which was some guarantee of the possession of those necessary qualifications. To be an efficient clerk of works in the present day meant a great deal. It implied the possession of a not inconsiderable amount of scientific knowledge, and it therefore behoved every clerk of work to avail himself of every opportunity of improving his general and special knowledge. Their success was largely dependent upon their own efforts to improve the facilities with which they were endowed. The really stupid people in the world were not so much those who were innately stupid as those who, not being innately stupid, were unmindful of the importance of cultivating their natural faculties. In illustration of this and other points in his speech, the Chairman narrated very pleasantly one or two legends of Classic mythology. Although, he said, it might have been supposed that he had a hundred eyes, would have made a remarkably efficient clerk of works, the story showed that he was eventually caught napping. In conclusion, the Chairman coupled with the toast the name of Mr. Linn Dillon, the President of the Association, who made a very able speech in responding.

The other toasts were "The Honorary Treasurer (Mr. John Oldrid Scott)," proposed by Mr. J. Brady, Editor of the Association's *Journal*, and replied to, in the absence of Mr. Scott, by Mr. P. J. King; "The Worshipful Company of Carpenters," proposed by Mr. F. Dashwood, the Hon. Secretary of the Association, in a characteristically racy speech, and responded to by Mr. Banister Fletcher, Master of the Carpenters' Company; "The President, Vice-President, and Committee," proposed by Mr. Alexander Ritchie, and responded to by Mr. R. Wheeler; "The Press," proposed by Mr. G. Dalton, and coupled with the name of the representative of the *Builder*; "The Visitors," proposed by Mr. J. Atkinson, and replied to by Mr. H. Studby-Gordon, A.R.I.B.A.; "The Chairman," proposed by Mr. T. Ganang; and "New Members of the Association," proposed by an old member whose name was not announced.

COMPETITIONS.

Dorset County Lunatic Asylum.—We are informed that sixteen designs have been submitted in competition for the enlargement of this Asylum. The Committee of Visitors have appointed Mr. C. H. Howell their professional assessor to advise in the selection. Mr. Howell is the consulting architect to the Commissioners in Lunacy.

Germany.—Among the competitions decided during the last few weeks, the one at Frankfurt-on-the-Maine, for a new extension of the Town Library, intended to hold 300,000 volumes, has been won by Herr Wilhelm Mueller, of that town.—The competition for a garrison church at Straßburg, with sitting room for two thousand soldiers and standing room for another thousand, only enticed twenty-five architects to compete. Several very fair designs were sent in, but the jury did not consider any one of them worth the first prize; two second prizes were won by Messrs. L. Mueller, of Frankfurt, and L. Klincksberg, of Oldenburg; and a third prize by C. Doffen, of Berlin.—The designs for the new Arts and Science Museum at Düsseldorf will be placed before a competent jury on March 15, and it is generally expected in architectural circles that the competition will show some very interesting planning.

ARCHITECTURAL SOCIETIES.

Birmingham Architectural Association.—At a well-attended meeting of this Association, held on the 4th inst., Mr. J. Cotton being in the chair, a paper was read by Mr. Charles E. Bateman, entitled "A Saturday Afternoon in London," in which he showed how it is possible in the time afforded by a Saturday half-holiday to visit and examine examples of every period of architecture, from the earliest Egyptian to English work of the eighteenth century. Mr. Bateman described a number of examples, all within a small area, and pointed out that by a series of visits such as he described a student could readily grasp the sequence of the historical styles of architecture.

* The Carpenters' Company, as Mr. Dashwood explained, allow the Association the use of meeting-rooms at their Hall. On the other hand, as Mr. Banister Fletcher pointed out, Mr. Dillon, Mr. Dashwood, and other members of the Association have co-operated very cordially with the Carpenters' Company in its various efforts for the promotion of technical education in the building trades.

Among the examples described, all of which were illustrated by photographs and engravings, were the Egyptian, Babylonian, Assyrian, Lycian, Greek, and Roman work in the British Museum; the Churches of St. Bartholomew, The Temple, St. Ebbwvalde, Anstin Friars, St. Helen, and St. Sepulchre; and Crosby Hall, Middle Temple Hall, Somerset House, and Whitehall, in each of which were excellent examples of the work of the various periods at which they were erected.—A paper was also read by Mr. Herbert R. Lloyd, A.R.I.B.A., on "Methods of Calculating Strains," in which he pointed out the advantages of the graphic method of calculating strains, and by means of diagrams of girders and roof trusses carrying loads such as have to be frequently supported in modern buildings, demonstrated the readiness with which the strains upon such supports could be calculated, and the accuracy with which the necessary strength of their various parts could be ascertained. At the conclusion of the papers, a hearty vote of thanks was accorded to Messrs. Bateman and Lloyd for the papers they had read, and a resolution was passed asking Mr. Lloyd to take steps for the formation of a class for the study of graphic statics.

Edinburgh Architectural Association.—A meeting of this Association was held on the 6th inst.—Professor G. Baldwin Brown, the President, in the chair. Mr. John Kinross read a paper entitled "Some remarks on the chapter introductory to Ferguson's History of Architecture." The various subjects treated of were uniformity, mass, proportion, and colour in architecture, and the prospects of advance in modern work. With regard to uniformity, the lecturer referred to Princes-street as an example of individuality carried to excess, and while of opinion that in certain streets there could not be too much variety, a street like Princes-street demanded some uniformity in its architecture, if it was to be worthy of its magnificent natural situation. Size was stated to be the first element in architectural grandeur, and one that the system of building commonly adopted in Edinburgh naturally gave; but proportion was insisted on as necessary to give a large building any permanent value. The various attempts by English architects to introduce colour into buildings were referred to, and the fact stated that at least one of the most eminent of them had entirely changed his views on this subject, and had latterly used only such colour as the local stone afforded. Violent contrasts of colour were deprecated, such as the introduction of large masses of red stone amongst grey, or grey amongst red, and various towns referred to where this had been done with an injurious result. The local colour of towns like Aberdeen and Galashiels was referred to, and suggestions made about other methods of using their local stones. The lecturer considered that these plans. The lecturer considered that advance could only be made in course of time after great individual effort, as at present architects could not be got to work on the same lines, but he hoped that in the future there might be greater unity in general work, and consequent advance. Some discussion followed, and at the close the customary vote of thanks was passed.—*Sootsman.*

Sheffield Society of Architects and Surveyors.—The monthly meeting of this Society was held at the School of Art on Tuesday night, Mr. F. P. Fowler, President, presided, and about forty-five members were present. The President read an interesting paper on "The Valuation of Property." He pointed out that, although many people professed to be familiar with the subject in the abstract, it was matter of wonder that there were such wide divergences of opinion amongst surveyors. His own professional life had been spent in mastering the intricacies of the subject, and in dealing with property, especially undeveloped land, he endorsed the wisdom of the old adage, "Never prophesy if you are not sure." He divided his paper into eight separate headings:—1. Agricultural estates; 2. Building land; 3. Town property; 4. Sale shops, &c.; 4. Ground rents; 5. Manufacturing and trade premises, breweries, &c.; 6. Collieries, ironstone and other mines; 7. Reserve interests and advowsons; and, 8. Sale of properties under compulsory powers. A hearty vote of thanks to the President, moved by Mr. Flockton, seconded by Mr. Innocent and supported by Mr. Winder, sen., Mr. C. Hadfield, and Mr. J. B. Mitchell-Withers, was passed with applause, and it was agreed that the paper should be printed and circulated.

The Secretary announced that papers were forthcoming from Mr. Wike, the Borough Surveyor, and Mr. T. M. Rickman, F.S.S., of London.

ARCHAEOLOGICAL SOCIETIES.

British Archaeological Association.—At the meeting of this Association held on Wednesday, the 6th inst., Mr. Geo. L. Wright, F.S.A., in the chair, it was announced that the Right Hon. the Earl of Carnarvon had, on the invitation of the Council, accepted the office of President for the congress to be held in the autumn at Oxford, and for the following year. It was announced that the office of honorary correspondent had been revived, and the names of a goodly number of correspondents who had been elected were recorded. The Rev. Canon Skelton described a fine coped tomb-head covered with waxon interlaced work, which was found several years ago at Hicking Church, Notts, where it is carefully preserved. Mr. Earle Way exhibited various articles worked in stone, supposed to be weights, found in the bed of a stream at Templeton, near Tavistock. The top stone of a quern found at Belvoir, Notts, was described by the Chairman. Mr. Loftus Brock, F.S.A., exhibited several silver coins of Roman empresses, in fine condition, illustrative of the head-dresses of Roman times. The Rev. Canon Collier, of Chilholton, Hants, exhibited a portion of a massive stone howl found in the locality, and pronounced to be of Romano-British date. The Rev. Mr. Lach-Szymka read a paper on "The Study of the Past in the Present," and referred to various old-world customs, such as the blowing of horns, the waving of torches, passing through or around the fire, &c., which still survive in Cornwall. He also read notes on the recent discovery of a menhir, found built up as old material in the wall of Galval Church, Cornwall. It has a key pattern, and two letters in Roman character, worked in the granite of the county. A paper was then read by Mr. M. Drury, on a supposed Roman causeway at Lincoln. This consists of a deep concrete mass which has been traced beneath the course of the Roman road which still forms the southern approach to Lincoln. The positions of a vast number of Roman discoveries were indicated on a large map, and the finds were described at length.

Royal Archaeological Institute.—On Thursday, the 6th inst., a meeting of this Institute, under the presidency of Mr. T. H. Baylis, Q.C., was held, when Mr. J. L. André read a paper on the antiquities contained in the church at Burton, Sussex. The structure itself is almost devoid of interest, but the church is rich in monumental and other antiquarian features. Mr. André exhibited drawings and rubbings in illustration of his paper. Among the sepulchral monuments, the most interesting were a diminutive effigy of a lady of the latter portion of the fifteenth century, and a brass to Dame Goring, showing her clad in a tabard. This lady was an ancestor of the Goring, father and son, who took part in the seventeenth-century civil wars. Another interesting feature was a wall painting of a female saint attached to a cross saltire, head downwards. Mr. André considered this painting as belonging to the latter half of the fifteenth century.—The Rev. J. C. Cox, LL.D., read a paper on a private seal engraved on amber from old Malton Priory. The seal was found some years ago in a stone coffin in the chancel of old Malton church. The date of this relic was probably of the early part of the thirteenth century. Dr. Cox also exhibited some recent finds from a cave near Buxton.

LECTURES FOR SANITARY INSPECTORS AT THE SANITARY INSTITUTE.

Sir,—The above forthcoming course of lectures, previously announced in your columns, will, no doubt, prove to be an instructive one; although, I for one, consider that the course should not have been restricted to the instruction, and for the special benefit of Sanitary Inspectors alone.

The course should, in my opinion, have had a more extended application, so as to include Medical Officers of Health, and others of our co-workers who play such an important part in the sanitary welfare of the urban and rural sanitary districts.

FREDERIC BOOKER, Sanitary Inspector.

Cowentry, February 10th, 1890.

The "Hercules" Street Cleansing Machine.—Our description of this machine is again unavoidably held over.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—VI.
MAGNETISM (continued).

THE conception that a line of force is a row of electrical particles spinning round with the line as axis, affords simple explanations of the actions of magnets on magnets, magnets on currents, and currents on currents, including the production of electro-motive force in a conductor which is being cut by lines of force.

Let A, B, C (Fig. 14) represent three particles of electricity at rest under whatever the pressure or absolute potential may be in space; if they are now made to revolve about an axis P Q, that is, if they become a portion of a line of force, P, Q, they will, owing to centrifugal force, contract along P Q, and expand in every direction at right-angles to it. Since electricity is elastic, though incompressible, this change of shape and consequent change of pressure in different directions accounts for magnetic force.

Fig. 14.

Fig. 15.

Fig. 15 shows the two cases of attraction and repulsion between the poles of two magnets; in the first case the lines run from one face of a magnet to the other, and the pressure at the points P and Q being diminished, owing to the straining of the electricity between them outwards and sideways, the magnets attract each other; in the second case the lines of force bend outwards so as to present their sides to each other, and in this case the pressure between the faces of the magnets is increased, so that they are pushed away from or repel each other.

A mere inspection of the magnetic field in proximity to a magnet or conductor carrying a current will show whether there is any resultant force tending to move it in one direction more than another.

Fig. 16 shows the section of a conductor passing through the plane of the paper with a current flowing downwards into the paper; its own lines of force combine with those coming from the N-pole of the magnet near it so as to crowd them together on the lower side, hence

the conductor is pushed in the direction indicated by the arrow. Fig. 17 similarly shows the shape of the field near two conductors, in both of which the currents are flowing downwards into the paper; they attract each other.

In fig. 18 the current is reversed in the right-hand wire, with the result that mutual repulsion ensues. These figures explain the well-known facts that parallel currents flowing in the same direction attract and in opposite directions repel one another.

In the year 1831 Faraday discovered the principle of magneto-electric induction—that

Fig. 19.

Fig. 20.

is, the production of electro-motive force when a conductor cuts lines of force. Modern dynamo-electric machinery is the outcome of this discovery, and we have finally to consider how lines of force, by cutting a conductor, can drive electricity along it.

Let C, fig. 19, represent a particle of electricity between two others, M and N; the gear-

ing between them is represented by two driving-hands, and, to help the analogy, the particles may be supposed cylindrical in shape. If M and N become parts of two lines of force, and rotate as indicated by the arrows, the only effect on C will be that it, too, is made to rotate in the same direction. In fig. 20, M is removed. Now if N begins to rotate, or C is brought under the influence of N, already supposed to be in a state of rotation, C has a tendency to move in the direction of the feathered arrow as well as to rotate.

Finally, suppose C to be electricity within a conductor, the hands are destroyed, and we may regard the electricity as in a kind of liquid state within it. If the conductor is constantly moved to the right, so as to be moved into the influence of lines in the position of N and out of the influence of those in the position of M, the N's will have the preponderating effect and will act like paddle-wheels paddling along a current in the direction shown. Clearly, if the motion ceases, the M's will have as much effect as the N's, and the electricity in the conductor will simply spin round without moving bodily forward in a current.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

3,428, Fire-escapes. W. Cooper.

In connexion with a previous patent, this specification describes the use of a brake or bars to control the progress of a chair in which the person is seated, and which is lowered from a bracket near the window in case of fire. The invention is chiefly designed for use in large institutions, hospitals, asylums, &c., or for very lofty buildings. A chair with bars which protect the person seated therein is lowered by means of tackle and controlled by the brake.

4,347, Fireproof Bricks and Structures. J. Homan.

The bricks which are the subject of this patent are supported on main girders, projecting so as to cover the under side of the main girder. These bricks are of exceptional length,—say, 18 in.,—and the ends are notched so that they embrace the lower flange of the girders. Their under surface is by preference made with dove-tailed grooves, so as to form a key for the plaster, and the two sides may be made to incline toward each other so as to form V-shaped grooves to receive and key the concrete. The bricks are perforated, and are laid in the V position and pushed along the girders until each brick touches the last one put in. Floors, walls, and all kinds of structures are made in the same way.

10,070, Door Handles. J. Atherton.

This invention relates to some modification of the ordinary way of fitting the door-knobs to the spindles. The appliance is in two parts, one fitting over the other, after the manner of a collar and a nut. In revolving, the collar causes the nut to revolve with it, but at the same time allows for longitudinal motion. The nut being made to revolve on a conical piece the sections are contracted, and firmly clip the spindle, rendering unnecessary any further fastening of the knob to the handle or spindle.

10,397, Composition or Plaster for Walls. J. B. King.

According to this invention, mineral or calcareous substances are mixed with gelatinous or vegetable substances in a pasty mass which is dried by heat, powdered, and mixed with plaster and with asbestos, and put on as a finishing coat to plaster walls.

13,764, Sash-frames, &c. J. Tall.

The sash-frames which are the subject of this patent are hollowed out in a way specified, and the balance-weights are hollow and weighted with shot or lead. The frame is hinged, and carries sliding-sashes on an outside frame to enable the window to be cleaned, glazed, or painted from the inside of the room, and a bar is provided for supporting the same when open.

13,792, Whitewash and Water-colour Paints. J. J. Carr.

This invention relates to a composition of whitening or colours, mixed or ground together with size, and then dried by heat and again ground, so that when it is to be used it is only mixed with water instead of—as in the usual way—with size.

NEW APPLICATIONS FOR PATENTS.

Jan. 27.—1,379, J. Jenson, Automatic Locks for Gates and Doors.—1,382, H. Sparks, T Squares, &c.—1,418, A. Hammage, Metal Framing for Fireproof Floors and Walls.

MEETINGS.

SATURDAY, FEBRUARY 15.
 Royal Institution.—The Right Hon. Lord Rayleigh, M.A., F.R.S., on "Electricity and Magnetism." 11.3 p.m.
 MONDAY, FEBRUARY 17.
 Royal Institute of British Architects.—Mr. John Slater on "Building Legislation." 8 p.m.
 Royal Academy.—Mr. A. S. Murray on "Sculpture in Greek Temples." 11.8 p.m.
 Leeds and Yorkshire Architectural Society.—Mr. Halsey Ricardo, on "Some of the Conditions of Modern Architecture in Towns." 7.30 p.m.
 Liverpool Architectural Society.—(1) Mr. H. L. Beckwith, F.S.I., on "Quantity Surveying." (2) Miscellaneous Contributions. 7 p.m.
 TUESDAY, FEBRUARY 18.
 Institution of Civil Engineers.—(1) Mr. J. W. Hart on "The Shanghai Water Works." (2) Mr. J. Orange on "The Tystem Water Works, Hong Kong." (3) Mr. J. H. T. Turner on "The Construction of the Yokohama Water-Works." 8 p.m.
 Sanitary Institute (Lectures for Sanitary Inspectors).—Mr. E. C. Roberts, F.S.A., on "Practical Considerations for Sanitary Officers." 8 p.m.
 Society of Arts (Foreign and Colonial Section).—Mr. J. Bentker Heaton, M.P., on "Ocean Penny Postage and Cheap Telegraph Communication between England and all Parts of the Empire and America." 6 p.m.
 WEDNESDAY, FEBRUARY 19.
 Society of Arts.—Professor Sivanus P. Thompson, D.Sc., on "The Organization of Secondary and Technical Education in London." 8 p.m.
 British Archaeological Association.—(1) Mr. G. Patrick on "Wandsworth and Its Ancient Buildings." (2) Mr. M. Drury on "The Roman Station of Lindum." 8 p.m.

Free Lectures to Artisans and others on Matters Connected with Building.—Professor W. H. Corbett on "Modern Sanitation." Carpenters' Hall, London-wall. 8 p.m.
 Civil and Mechanical Engineers' Society.—Mr. A. F. Bruce on "Italian Water Supply." 8 p.m.
 Builders' Foremen and Clerks of Works Institution.—Ordinary Meeting. 8.30 p.m.
 Inventors' Institute.—8 p.m.

THURSDAY, FEBRUARY 20.
 Royal Academy.—Mr. S. Murray on "Sculpture in Greek Temples." 11.8 p.m.
 Institution of Electrical Engineers.—8 p.m.
 Edinburgh Architectural Association.—Mr. H. F. Kerr, on "Ingress and Egress for Public Buildings." 8 p.m.

FRIDAY, FEBRUARY 21.
 Royal Institution.—Mr. S. Bidwell, M.A., F.R.S., on "Magnetic Phenomena." 9 p.m.
 Sanitary Institute (Lectures for Sanitary Inspectors).—Dr. Louis Parkes on "Water Supply, Drinking Water, Pollution of Water." 8 p.m.
 Institution of Civil Engineers (Students' Meeting).—Mr. C. N. Goodall on "Some Types of American Locomotives and their Construction." 7.30 p.m.

SATURDAY, FEBRUARY 22.
 Architectural Association.—Visit to the Imperial Institute, South Kensington.
 Royal Institution.—The Right Hon. Lord Rayleigh, M.A., F.R.S., on "Electricity and Magnetism." 11.3 p.m.
 President Institution of Builders' Foremen and Clerks of Works.—Annual Dinner, Holborn Restaurant. 6.30 p.m.
 Edinburgh Architectural Association.—Visit to Parliament Hall and St. Margaret's Chapel.

Miscellaneous.

"Tiled" Floor-cloth.—The "Scarborough Patent Tiled Floor-cloth Company" send us some specimens of their manufacture, the object of which is to produce a floor-cloth in which the pattern will not become obliterated by use except in the entire wearing out of the material. The surface of the cloth, instead of having merely an application of paint, consists of what are called "tiles" of solid pigment laid on to a backing of stout canvas or cotton and subjected to heavy pressure. In section the cloth is seen to consist of a layer of pigment of nearly equal thickness with the cloth which forms the backing. The obliteration of the original surface of the pigment, by wear, leaves the colour as before, instead of leaving the whitish worn space which is often seen on the portions of a floor-cloth which have received the most traffic, even when the material is still quite sound and substantial regarded as a mere covering. The specimens appear as if they would answer the end intended; and the material is certainly worth attention in this respect.

London and County Banking Company, Limited.—The half-yearly report of this company to December 31 last, presented and adopted at the annual meeting held on the 6th inst., states that after paying interest to customers and all charges, making provision for bad and doubtful debts, allowing £6,532, 12s. 10d. for rebate on bills not due, and transferring 15,000*l.* in reduction of premises, the net profits amount to 189,955*l.* 6s. 4d. This sum, added to 54,641*l.* 17s. 11d., the balance brought forward from last account, produces a total of 244,637*l.* 4s. 8d. The directors recommended the payment of a dividend of 10 per cent. for the half-year, which will absorb 200,000*l.* This will leave a balance of 44,637*l.* 4s. 3d. to be carried to profit and loss new account. The present dividend, added to that paid to June 30, makes 20 per cent. for the year 1889.

The Building Crisis in Rome.—It is stated from Rome that the building and economical crisis which has prevailed in the Italian capital for over a year is becoming very acute. It has been necessary to discontinue nearly all building operations, and the number of failures in the trade is becoming appalling. Thousands of workmen are idle, and disturbances worse than those of last winter are feared.

Proposed Testimonial to Mr. C. Roach Smith.—We learn that at a meeting held some little time since at the rooms of the Society of Antiquaries, it was resolved that subscriptions be invited for the purpose of striking a medal in honour of Mr. Charles Roach Smith, and that the balance of the fund he handed to him, in recognition of his life-long and valuable services in the cause of archaeology.

The Dresden Collections.—The famous art treasures at Dresden are being subjected to a thorough re-arrangement, and a portion of them are to be moved to the Albertinum, an imposing building now being erected for that purpose in the vicinity of Brühl-terrace, and which will shortly be completed. It is expected that the work of re-arranging the collections will be completed in six months.

Certificated Plumbers.—At a meeting held at the University College, Nottingham, on the 6th inst., Professor Garnett, M.A., D.C.L., delivered a lecture on "Sanitary Plumbing," and Sir Philip Magnus presented certificates of registration granted by the Plumbers' Company, London, to a number of masters and operative plumbers in the district. There was a very large attendance, including Mr. Alderman Lindley, J.P. (Chairman of the University College Committee), Mr. S. G. Johnson (Town Clerk), Dr. Boobyer (Medical Officer of Health), Dr. J. White, Principal Clowes, Prof. Heaton, Councillors Sutton and Wright, and numerous representatives of each section of the plumbing trade. Sir Philip Magnus, in presenting the certificates, said that the Plumbers' Company had entered upon a very important work in their system of registration, which had taken deep root, and was now flourishing in very many of the principal towns of England, Wales, Scotland, and Ireland. It was intended to place on a register the names of those plumbers who were capable of conscientiously and intelligently performing their work. He thought it quite as important to register plumbers as to register medical men, for plumbing, if properly carried out, had the effect of preventing disease, which was, after all, better than curing it. But it was perfectly useless to establish a register for qualified plumbers unless the plumbers were also provided with facilities for qualifying themselves. There was scarcely any art which touched so many branches of science as the plumber's art did. Prof. Garnett had shown its dependence upon a knowledge of geometry, chemistry, physics, and mechanics, and, perhaps, to some extent, a knowledge of electricity. It was not for a moment expected that plumbers could become professors of all these different branches of science, but what was wanted was that each plumber should know so much of them as to enable him to deal in an independent and intelligent manner with the difficulties of his craft. At the present moment they were seriously engaged in working out a systematic and progressive course of instruction for apprentices and other plumbers. He was sure they would succeed. Nothing could be more successful than the organisation of plumbing classes had been throughout the country during the past few years. In the session 1885-6 there were 312 plumbers students in these classes; in the following year the number increased to 403; in the year after to 695; and in the year 1888-9 to 1,043; while during the present session no less than 1,217 student plumbers were receiving efficient instruction in the technical and theoretical branches of their craft. He ascribed this success mainly to the fact that the workmen had taken the greatest possible interest in the movement, and both the masters and the operatives were fully alive to the great importance of technical education.

Obituary: Mr. J. T. McCulloch.—The death is announced of Mr. John Thompson McCulloch, a well-known architectural sculptor. Mr. McCulloch has fallen a victim to bronchitis, following an attack of influenza. From his studio at Kennington, where he had a large staff of workmen, Mr. McCulloch—who has died at the early age of forty-seven—has sent out some very good specimens of English architectural sculpture. The following may be mentioned among the important works for which he has executed the carving within the last twelve years, viz., restoration of the quadrangle at Christ Church, Oxford; restoration at the Bodleian Library; carvings at the Queen's Hall and the Library of the People's Palace; carvings at the Edinburgh Public Library; carvings at the Laboratory, Cambridge; Pembroke College; and at the Market, Sheffield. Mr. McCulloch did a great deal of work for the Duke of Norfolk and the Marquis of Bute, and carried out many designs for Mr. E. R. Rohnson. At the time of his death he was engaged on some important works at St. George's Cathedral, Southwark. Mr. McCulloch's unfinished work will be carried out by his son.

The Castle of Chillon.—The *Allg. Schweizerische Zeitung* states that the Waadtland Society, formed for the restoration of the Castle of Chillon, on the Lake of Geneva, and rendered famous by Byron, now considers that sufficient funds have been collected to commence the work. An architect fully conversant with Mediaeval architecture is to be selected, whereupon his plans are to be submitted to a jury of experts.

LONDON.—For proposed alterations, new fittings, and repairs to the Duke of York's public-house, Victoria-street, S.W., for Messrs. Sidney Stone, Messrs. Saville & Martin, architects, 86 and 87, Strand, W.C. Quantities supplied.—

Table with 2 columns: Name and Amount. Includes Patman & Fotheringham (£3,654 0 0), Ward & Lambie (3,547 0 0), C. Ansell (3,333 0 0), H. Burnian & Sons (3,195 0 0), T. Champell (accepted) (3,059 0 0), T. Gregory & Co. (3,057 0 0), E. Toms (3,028 0 0), Hoild & Brand (2,987 0 0), J. Beale (2,950 0 0).

LONDON.—For alterations, sanitary work, drainage, re-decoration, and building of new billiard-room, at 9, St. James's-square, W., for the Committee of the Portland Club.—

Table with 2 columns: Name and Amount. Includes Colls & Sons (£2,651 0 0), Patman & Fotheringham (1,871 0 0), F. G. Davis, 54, Theobald's-road (1,775 0 0).

LONDON.—For alterations, &c., at the "Kenilworth Castle" public-house, New North-road, N., for Mr. R. Howland, Messrs. Birk & Walters, architects, 64, Seymour-place, Bryanston-square.—

Table with 2 columns: Name and Amount. Includes Burman & Sons (£1,700 0 0), Todd (1,679 0 0), Goodall (1,676 0 0), Toms (1,668 0 0), Timson & Son (1,648 0 0), Deering & Son (1,627 0 0), Moore (1,590 0 0).

LONDON.—For reinstating business premises after fire at Nos. 228 and 269, Edgware-road, and 21, Chapel-street, for Mr. Joseph Hinton, Messrs. New & Son, architects, 62, George-street, Portman-square.—

Table with 2 columns: Name and Amount. Includes Goodchild (£384 16 7), Beckland (322 0 0), Marks (294 0 0), Tennent (235 18 0), G. Godson & Sons, Kilburn (accepted) (214 0 0).

LONDON.—For road-making and paving work, East End-road, in the parish of Fulham. Mr W. Sykes, New Streets Surveyor.—

Table with 2 columns: Name and Amount. Includes Atkins, Kingston-on-Thames (£346 0 0), Hes, Wimbledon (795 0 0), Coat, Hammersmith (776 0 0), Adams, Kingsland (772 0 0), Tones & Wimpey, Hammersmith (749 0 0), Nowell & Robson, Kensington (729 0 0), Neave & Son, Paddington (689 0 0), Nash, Fulham (679 0 0).

LONDON.—For road-making and paving works, Broughton-road, in the Parish of Fulham. Mr W. Sykes, New Streets Surveyor.—

Table with 2 columns: Name and Amount. Includes Hes, Wimbledon (£380 0 0), Nash, Fulham (347 0 0), Tones & Wimpey, Hammersmith (258 0 0), Nowell & Robson, Kensington (252 0 0), Atkins, Kingston-on-Thames (250 0 0), Adams, Kingsland (245 0 0), Coat, Hammersmith (203 0 0), Neave & Son, Paddington (198 0 0).

LONDON.—For alterations and additions to No. 13, Eagle-street, Holborn, W.C. Mr. H. Huntly-Gordon, architect, 123, Cannon-street, E.C.—

Table with 2 columns: Name and Amount. Includes Gower & Sons (£164 0 0), F. Hudson (123 0 0), T. Sobey (124 15 0), Kirby & Chase (accepted) (104 5 0).

LONDON.—For alterations and decorative repairs to Block B, 6, Albany-chambers, Piccadilly. Mr. W. H. Huntly-Gordon, architect, 123, Cannon-street.—

Table with 2 columns: Name and Amount. Includes Kirby & Chase (accepted) (By schedule).

LONDON.—For the erection of four houses in College-road, Catford, for Mr. H. Stanley. Messrs. Williams & Hopton, architects.—

Table with 2 columns: Name and Amount. Includes Geo. Weaver, Bromley, Kent (accepted) (£2,875 0 0).

LYDDINGTON.—For the restoration of Lyddington Church, near Oakham. Mr. J. E. Traylen, architect, Stamford: Diocesan Surveyor for Peterborough. Quantities by the architect:—

Table with 2 columns: Name and Amount. Includes Roberts Bros., Stamford (£1,197 0 0), Thompson, Peterborough (1,182 0 0), Law & King, Lutterworth (1,155 0 0), Storey, Bourne (1,075 0 0), Herbert Bros., Leicester (963 0 0), T. F. Halliday, Stamford (926 0 0), J. Halliday, Clifton (959 0 0), Roberts & Son, Weedon (814 0 0).

SLOUGH (Bucks).—For alterations and additions to Tetsworth House, Slough, for forming a new system of drainage and water supply, and for certain decorative repairs, &c. Mr. H. Huntly-Gordon, architect, 123, Cannon-street, E.C.—

Table with 2 columns: Name and Amount. Includes H. Tuten & Sons, London (£1,550 0 0), Deverill, Slough (1,300 0 0), Barker & Co., London (1,187 0 0).

WIMBLEDON.—For erecting a carved pine fitting for drawing-room, "Ferri-ide," Wimbledon, for Mr. J. D. Harrington. Mr. Jas. A. Stonehouse, architect.—

Table with 2 columns: Name and Amount. Includes C. Hindley & Sons (accepted) (£290 0 0).

SUBSCRIBERS IN LONDON AND THE SUBURBS, by prepaying at the Publishing Office, 19s. per annum (or 4s. 6d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

TERMS OF SUBSCRIPTION. "THE BUILDER" is supplied direct from the Office residents in any part of the United Kingdom at the rate of 19s. per annum.

TO CORRESPONDENTS. F. B.—C. L.—T. B. B.—"A Constant Reader" (as to the first question, write to the Secretary of the Building Institute, 71a, Margaret-street, W. As to the second, we cannot advise).

LETTERS OR COMMUNICATIONS (beyond mere news-items) which have been duplicated for other journals, are NOT DESIRED. All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

Masonry Construction.*

"The first cost of masonry should be its only cost. Though superstructures decay and drift away, though embankments should crumble and wash out, masonry should stand as one great mass of solid rock, firm and enduring."

THIS may sound very fine; "decay and drift away" rhyme nicely; but, in an absolute sense, nothing is enduring. Endurance is comparative and variable, dependent on climate,

physical causes, and so on. Nor do we quite see why the superstructures especially should decay and drift away, as they are frequently structures of masonry. But, whether they be "super" or "sub," we are entirely in accord with the sentiments of the anonymous author of the lines above quoted in that masonry should be firm and enduring.

Those lines are the text on which Professor Baker has built up his very interesting "Sermon on Stones." He has given us from Illinois a work of great value, and has been equally happy in the selection of his details, and in the method with which he has placed his knowledge at the disposal of his students, amongst whom we believe he may reckon many on both sides of the Atlantic. The work, 552 pages in length, is divided into four parts:—

- Part I. Description and Characteristics of the Materials.
 - „ II. Methods of Preparing and Using the Materials.
 - „ III. Foundations.
 - „ IV. Masonry Structures.
- And an Appendix.

These parts are subdivided into chapters, the chapters into articles, the articles into numbered paragraphs, and the numbered into unnumbered paragraphs. It is, consequently, very easy, with the further assistance of a good "Table of Contents" and an index (not, perhaps, quite as copious as might have been), to find our way to any particular point in a particular branch of the subject on which information may be desired.

In the very first article of the book the author at once throws down a challenge

which we are not loth to accept. He arranges the merits of good building stone in the following order, and also gives them a space in his book proportioned to the order of merit which seems best to him:—

1. Cheapness.
2. Durability.
3. Strength.
4. Beauty.

It would have been better to have dispensed with any such statement of priority of importance. In the four lines he devotes to beauty, he says that it is "an element of more importance to the architect than to the engineer," and his ideas of what is beautiful appear to be comprised within the expression, "The stone should have a durable and pleasing colour." Beauty of form and of details seem to him almost necessarily excluded from the purview of the civil engineer, and to be confined to the consideration of the architect; but we have always held that these four cardinal merits should receive equal consideration at the hands of civil engineers and their employers. What merit is there in a structure being executed at a low cost if it is neither durable, strong, nor beautiful? It is not cheap at all at such a price. Nor is it cheap if either of these three factors is made to take an inferior position. There are many cases in which durability, or strength, or beauty must indubitably be of considerably greater importance than mere lowness of cost. There is no word perhaps in the English (or the American?) language so much misinterpreted as the word "cheap."

It is somewhat unfortunate that the author has committed himself to the remark that "it seems questionable whether the Parliament House in London can be made to endure as long as a timber building would stand, so great is the effect of the gases of the atmosphere upon the stone." A good deal of nonsense has been written about this matter of the decay of the stone in the Houses of Parliament. The decay is very superficial, and no difficulty whatever is experienced in restoring or renewing the decayed surfaces. We are all aware now that a better selection might have been made of the stone for that important edifice, but there is no occasion to despair of the endurance of the structure on account of the stone which has been used.

Most of the author's observations relating to the tests of building stones are full of interest, and we heartily endorse the extract in paragraph 19 from the "Report on the

Quarry Industry, U.S.A., vol. x," as follows:—

"Hardly any department of technical science is so much neglected as that which embraces the study of the nature of stone; and all the varied resources of lithology in chemical, microscopical, and physical methods of investigation, wonderfully developed within the last quarter of a century, have never yet been properly applied to the selection and protection of stone used for building purposes."

One of the most difficult tests to carry out satisfactorily is that which is to determine the tensile strength of a briquette of cement. The difficulties lie mainly in two directions: one being to get the briquette properly prepared, the other to get it made the right shape. As regards the first of these points, we have known cases where the contractor's foreman has been quite unable to gauge cement so as fulfil the condition specified regarding the strain per square inch of section which it should bear, whilst the employer's clerk of works has, by superior skill in gauging, made briquettes from the contractor's cement to stand the strain readily, and thereby enabled himself to avoid the unpleasantness of having to reject passably strong cement. This point was very forcibly commented on not long since by Mr. W. Y. Dent,* who speaks of it as "a sleight-of-hand that can only be acquired by practice." Professor Baker gives us the various modes specified in Germany, England, Austria, France, and America for testing tensile strength. The Germans attach a greater value to the tests with cement mortar than with the neat cement, the mortar being usually mixed in the proportion of one cement to three sand, both the hand-mixed and the machine-mixed mortars being used. The French particularly specify that sea-water should be used for admixture with the mortar, and that both the air and the water should be maintained at a uniform temperature of from 59 deg. to 64 deg. during the continuance of the experiments, twelve parts (by weight) of water being used to 100 parts of cement and sand combined. With them, as with the Germans, and particularly with the Americans, great stress is laid on the excellence of the sand used for testing, crushed quartz being generally recommended of a size that will pass a sieve of from 300 to 400 meshes to the square inch, and be caught by one of about 800 or 900 meshes to the square inch. It is well, doubtless, that tests

* A Treatise on Masonry Construction, by Ira O. Baker, C.E., Professor of Civil Engineering, University of Illinois. (New York: J. Wiley & Sons; London: Tribner & Co.)

* Lecture on Building Materials. S. M. E. Chatham 1888.

should be carried out with specially prepared sand to show what cement can do; but what we really want to know when we are building is the strength of the mortar we are going to use in a particular structure, and not especially the strength of mortar containing sand which we are not going to use. The shape of briquette recommended by the Committee of the American Society of Civil Engineers may be described as very similar to that of the ladies' corsets so much illustrated in some newspapers, and is a slight modification of the briquette adopted by our Board of Works.

In the chapter on mortar, the author enlarges on the subject of mortars in which lime and cement are jointly used, and on the advantage in some cases of mixing slow and quick-setting cements together. He strongly recommends that "lime should be reduced to a paste before being added to the cement." Of course the cost of the mortar is a good deal reduced, but you do not get equal strength. He adds that "the mortar for the 'ordinary brickwork' of the United States public buildings is composed of 'one cement, one lime, and two of sand.'" The relative tensile strengths of mortars of this description, and also of cement mortars, are illustrated with admirable simplicity by means of diagrams with graduated scales, vertically for tensile strength in pounds, and horizontally for periods of time. The same kind of diagram is also advantageously used to show the transverse strength of concretes of various compositions, except that in this case the vertical scale represents the modulus of rupture in pounds per square inch, and the horizontal scale the proportion of cement used. Curved lines at varying heights on the diagram represent the several ages of the concretes tested.

The author exercises his usual care and accuracy in the observations he makes on the effect of the admixtures of sugar and of salt with mortar. He considers that the best qualities of Portland cement derive no great advantage from being combined with sugar; that Rosendale (or magnesian) cement, mixed with from one-eighth to one-fourth per cent. of sugar, gains about 20 per cent. in tensile strength; and that lime mortar gains about 50 per cent. in tensile strength when the weight of sugar added is about 10 per cent. of the weight of the lime. The practice in India is to add 1 lb. of the coarsest sugar to a gallon of water, and he adds—

"It is better to dissolve the sugar in the water than to mix it dry with the lime, since some limes in slaking burn the sugar, which blackens the mortar and destroys its strength."

As regards salt, he considers that, with ordinary and magnesian cement mortars, work can be carried on in frosty weather if salt be added to the water with which it is mixed, the rule usually adopted being as follows:—

"Dissolve 1 lb. of salt in 18 gallons of water when the temperature is at 32 deg., and add 1 oz. of salt for every degree below freezing point."

He considers that the addition of salt to Portland cement mortar does not seem to do either good or harm, and that mortar composed of one part Portland cement to three parts of sand is entirely uninjured by freezing or thawing; this is accounted for by estimating that the expansive force of water in freezing is less than the strength of Portland, but greater than that of Rosendale cement.

We have observed with surprise the very scanty mention the author makes of silenitic cement and silenitic mortar, merely alluding to it in a casual way, as follows:—"The addition of plaster of Paris to common cement is the special feature of silenitic cement,"—a description of that valuable material which is neither sufficient nor sufficiently accurate, and is an omission which is scarcely covered by the observation in the Preface that "it is neither wise nor possible to give in a single volume minute details." It is possible, however, that silenitic mortar is not much used yet in America.

Great stress is laid (and, in our opinion, very rightly) on the character and chemical composition of the material which cements

together the particles of which a stone is mainly composed, called respectively "matrix" and "aggregate" when applied to concrete. This is a matter of extreme importance, but it is too often overlooked, especially in varieties of stone apparently hard, such as some of the igneous rocks, many of the limestones, and several of the grits.

Dealing with the pressures on existing masonry structures, the author gives much valuable information respecting the permanent loads on several English and American bridges, and records his final opinion of safe loads as follows:—

Concrete.....	from 5 to 15 tons per sq. foot.
Rubble	" 10 " 15 " "
Squared Stone ..	" 15 " 20 " "
Limestone Ashlar ..	" 20 " 25 " "
Granite Ashlar ..	" 30 " 30 " "

But he is especially interesting in the paragraph relating to the importance of the mortar as affecting the strength of masonry, and shows how completely all theories of strength may be upset by the quality and quantity of the mortar:—

"Experiments made upon brick piers 12 in. square and from 2 ft. to 16 ft. high, laid in mortar composed of one volume Portland cement and two sand, show that the strength of the masonry is only about one-sixth the strength of the brick. An increase of 50 per cent. in the strength of the brick produced no appreciable effect on the strength of the masonry; but the substitution of cement mortar (one Portland and two sand) for lime mortar (one lime and three sand), increased the strength of the masonry 70 per cent."

Although it does not materially affect the point of the argument, there is, evidently, a little slip in the passage which has been quoted, for, on referring to the table giving the details of the experiments on brick piers, it is evident that the author should have used the word *decreased* in place of *increased*; and, in place of a gain of 70 per cent., it should have been put as a loss of 60 per cent. in using lime in place of cement in the mortar. Moreover, whilst the brick masonry with cement mortar was one-sixth, with lime mortar it was only *one-tenth* of the compressive strength of the bricks. The description of lime is not stated.

The thickness of mortar in the joints of the best ashlar masonry is especially noticed,—public buildings in cities $\frac{1}{2}$ of an inch, bridge piers, abutments, and large arches from $\frac{3}{4}$ to $\frac{1}{2}$ of an inch, smaller masonry $\frac{1}{4}$ to 1 inch in thickness, and he adds, "the less mortar used, the stronger the wall, therefore the thinner the joints and the larger the blocks, the stronger the masonry, provided the surfaces of the stones do not come in contact." We have in our mind's eye the walls still standing at Samos, in Cephalaria, thousands of years old, though with no roof to shelter them, and other ancient testimonials of skill.

In that part of the work relating to foundations we have a very complete and almost exhaustive treatise. The author truly says,—

"Probably no branch of the engineer's art requires more ability and skill than the construction of foundations. . . . The decision as to what general method of procedure will probably be best in any particular case is a question that can be decided with reasonable certainty only after long experience in this branch of engineering. . . . The experienced engineer, even with all the information which he can derive from the works of others, finds occasion for the use of all his knowledge and best common sense."

Certainly; but after this grave warning it is rather startling to the student or the novice to be told that "it is unpardonable that any liability to danger or loss should exist from the imperfect comprehension of a subject of such vital importance."

Who is there amongst us who has had much to do with the design and execution of engineering and building works, that has not had his judgment upset in this respect some time or other in the course of his career? Unfortunately, our misdeeds are too apparent when we have erred. The doctor *may* kill his patient without his blunder being detected, but we cannot kill ours. We may putty up cracks, but they *will* widen and widen, until the inevitable underpinning has to done, at a

pretty penny of cost to someone. But we do not expect to remain unpunished.

The observations on foundations on clayey, sandy, and semi-liquid soils are well worth attention, as also those on "improving the bearing-power of the soil," which the author divides under four heads:—(1) by increasing the depth of the foundation; (2) by draining the site; (3) by compacting (?) the soil; or (4) by adding a layer of sand. The mode of dealing with some troublesome springs in laying the foundation of the dry dock at the Brooklyn Navy Yard is given *in extenso*, but we will not repeat the account of all the rough-and-ready remedies they tried, until at last they hit off one which was successful. A few pages further on we find an interesting collection of portraits of our old enemies, the cracks due to insecure foundations.

The author presents us with the equations and formulae (aided by diagrams) which he considers most suitable for calculating the extra pressure temporarily brought to bear on certain points of structure, such as the edge of the base of a tall column or chimney, by the force of wind, and his observations on this matter are well worthy of our readers' attention. "If," he says, "the maximum pressure exceeds or is dangerously near the ultimate strength of the soil, the base must be widened."

Over and over again in the course of this book valuable data of work executed are given, and in that part of the work devoted to pile foundations for masonry we have a good example of work with screw piles. "For depths of from 15 to 20 ft., an average of 4 to 8 ft. per day is good work for wholly hand labour."

We have next a close examination of the relative merits of the two principal methods in operation for driving piles,—the steam hammer and the drop hammer,—with an exposition of the disadvantages of the gunpowder driver. After a lucid description of the mode of sinking piles by means of the water-jet, the author compares the respective capabilities of the water-jet and the hammer, and shows that they can often be advantageously used together, especially in stiff clay.

There is a necessary severity displayed in the remarks on the variable results obtained from the different formulae (which are subdivided by the author into *rational* and *empirical* formulae) for calculating the supporting power of piles." He says that—

"Many engineers, instead of inquiring into the relative merits of the different formulae, take an average of all the formulae they can find, and feel that they have a result based on the combined wisdom of the profession."

The whole of the chapter relating to this point is well worth careful study, and bears the stamp of having been investigated very thoroughly. The author is of opinion that "the deduction of a rational formula for the supporting power of a pile is not, strictly, an appropriate subject for mathematical investigation, as the conditions cannot be expressed with mathematical precision." But he proceeds to argue out the whole matter, laying very special stress on the value of the accurate measurement of the *last blow*, and the necessity for adding off the head of the test pile, so as to present a sound and solid surface for the last, or test, blow of the hammer.

The equation that he works out to be the most reliable one to be used in practice is—

$$P = 100 (\sqrt{wh + 50d^2} - 50d).$$

P is the pressure in tons, which will just move the pile the very small distance d , i.e., the supporting power.

d " " penetration of the pile, i.e., the distance the pile is moved by the last blow, in feet; to be ascertained by measuring the movement of a point 2 ft. or 3 ft. below the head.

w " " weight of the ram, in tons.

He admits that, after all, it is only approximate, and is based mainly on the average co-efficients of elasticity of the ram and the pile, but that "probably the error occasioned by the approximations is not material."

Weisbach and Rankine's rational formulae are given and examined, and, amongst

empirical formula, those of Beaufoy, Nylstrom, Mason, Sander, Trautwine, and McAulpine are criticised, and rejected for that evolved by the author. He then, as in most parts of this excellent work, compares theory with practice, and gives a few results of actual measurements taken, and of recorded safe loads, as follows:—

- Piles driven 32 ft. into sand sustain 20 tons each.
- Piles driven 28 ft. into sand sustain 13½ tons each.
- Piles driven 16 ft. into alluvial mud sustain 20 to 25 tons each.
- Piles driven 30 to 40 ft. into sand sustain 70 tons each.

The chapter on "Foundations under Water" contains in Article I an admirably clear and instructive section of an ordinary coffer-dam, and a few words in the next page explains the reason why puddle is improved by an admixture of gravel, as follows:—

"With pure clay, if a thread of water ever so small finds a passage under or through the puddle, it will steadily wear a larger opening. On the other hand, with gravelly clay, if the water should wash out the clay or fine sand, the larger particles will fall into the space and intercept first the coarser sand and next the particles of loam which are drifting in the current of water; and thus the whole mass puddles itself better than the engineer could do with his own hands. An embankment of gravel is comparatively safe, and becomes tighter every day. While a clay embankment may be tighter at first than a gravelly one, it is always liable to breakage."

Timber is much more freely used for subaqueous foundations for masonry in America than in Europe, and the work consequently contains far more explicit instructions than usual about cribs and crib work, and (as previously noted) about piles, with several important examples of executed work, including that for the Poughkeepsie Bridge (which crosses the Hudson about 75 miles above New York), a few notes of which will be of interest:—

"The crib for the largest of the four piers is 100 ft. long, 60 ft. wide at the bottom and 40 ft. at the top, and 104 ft. high. It was sunk through 53 ft. of water, 20 ft. of mud, 45 ft. of clay and sand, and 17 ft. of sand and gravel. It rests at 134 ft. below high water, upon a bed of gravel 16 ft. thick, overlying bedrock. The timber work is 100 ft. high, including the floor of the caisson, and extends to 14 ft. below high water (7 ft. below low water) at which point the masonry commences and rises 39 ft. On the top of the masonry a steel tower 100 ft. high is erected. The masonry in plan is 25 by 87 ft., and has nearly vertical faces. The lower chord of the channel span is 130 ft. and the rail is 212 ft. above high water. The crib contains 2½ million ft. of timber (board measure) and 350 tons of wrought iron."

The author particularly emphasises the fact that timber, when *always* wet, is as durable as masonry, "and," he adds, "ordinarily there is not much difference in cost between timber and stone."

Not the least valuable part of this exhaustive work is that devoted to the pneumatic processes for forming foundations, and the conclusions at which the author ultimately arrives are that,—

"Except in very shallow or very deep water, the compressed-air process has almost entirely superseded all others. The following are some of the advantages of this method:—1. It is reliable, since there is no danger of the caissons being stopped before reaching the desired depth by sunken logs, boulders [sic] "boulders" usually, " &c., or by excessive friction, as in dredging through tubes or shafts in cribs. 2. It can be used regardless of the kind of soil overlying the rock or ultimate foundation. 3. It is comparatively rapid, since the sinking of the caisson and the building up of the pier go on at the same time. 4. It is comparatively economical, since the weight added in sinking is a part of the foundation, and is permanent, and the removal of the material by blowing out or by pumping is as uniform and rapid at one depth as at another, the cost only being increased somewhat by the greater depth. 5. This method allows ample opportunity to examine the ultimate foundation, to level the bottom and remove any disintegrated rock. 6. Since the rock can be laid bare and be thoroughly washed, the concrete can be commenced upon a perfectly clean surface, and hence there need be no question as to the stability of the foundation."

In "Masonry Dams" we have an extremely interesting and carefully-prepared chapter. The author divides dams into two types,—

arch dams and gravity dams; but in consequence of the rare instances in which dams have been constructed arched in plan (there being only two instances known to him), he very properly devotes nearly the whole of his remarks to the other ordinary type. Rankine, Krantz, and Cain's works are frequently referred to. He says that "the profiles of most of the high masonry dams of the world are exceedingly extravagant, and hence it is not worth while to give examples." He gives, however, a maximum section of the great dam proposed for Quaker Bridge, a structure of vast dimensions,—e.g., width of base, 216 ft.; ditto of top, 22 ft. The full height of the masonry structure from the bottom of the foundation to the top of the parapet wall is 277 ft., of which 99 ft. is below the ordinary river bed. The depth of water at the back of this dam is to be 164 ft. The sole of the foundation is secured from sliding by being sunk well below the level of the bed-rock, and is given extra security on this account by means of two longitudinal keys, each 10 ft. square in section, and placed respectively 45 ft. from the toe and heel of the dam.

After discussing the merits of the two types, the author concludes with the opinion that a gravity dam should be built in the form of an arch, i.e., with both crest and toe curved, but that whilst the arch form gives additional safety, "the vertical cross-section should be so proportioned as to resist the water pressure by the weight of the masonry alone." If this is correct, it is manifest that a very slightly-curved dam is the best. He states that the maximum pressure on rubble masonry in cement mortar in some of the great dams of the world is from 11 to 14 tons per square foot. That at the Quaker Bridge dam will be 16.6 tons per square foot. After going through a variety of equations, he gives utterance here, as he does elsewhere in the work, to the contempt which he scarcely desires to conceal for mathematical calculations. He says:—

"There are a number of unknown and unknowable factors, as the weight of the stone, the quality of the mortar, the character of the foundations, the quality of the masonry, the hydrostatic pressure under the mass, the amount of elastic yielding, the force of the waves and of the ice, which have more to do with the ultimate stability of a dam than the mathematically exact profile."

Some remarks on "Rock Fill Dams" are worth perusing; but we drift naturally after "Dams" into "Retaining Walls"; and again, after analysing the theories of Weyrauch, Coulomb, Rankine, &c., he prefers to accept the empirical rules of Mr. Benjamin Baker and General Fanshawe, and gives his reasons for considering the tables of computations for the thickness of retaining-walls to be of but little practical value.

We should like to have seen more space devoted to that branch of the subject relating to the ruin of retaining walls by water at their backs. Looking to some recent misfortunes in the South of England and elsewhere from this cause, it is evident that we want some more light shed on it. So far as they go, the author's observations on this point are most sensible, but there is a quaintness in his suggestion that "one way of making provision to resist the additional pressure which may arise from such saturation is to calculate the requisite thickness of wall as if the earth were a fluid." What sort of fluid does the author refer to? A ton of water has a measurement of about 36 cubic feet, a ton of mould about 33, clay 28, and sand 22 feet. Consequently all dry earths exercise a greater thrust than still water. We apprehend that some other mode of calculation would be necessary in such a case. A few words (less than half a page) are given to "Relieving Arches," but not one word to "Counterforts," notwithstanding the immense importance of a right comprehension of this part of the art of preventing walls from being ruined.

That considerable portion of the work which relates to bridges,—their abutments, piers, and arches,—is a mine of wealth to the student, whether old or young, abounding alike in each part with the theories of

experts, with records of actual work and known arches, with tables of contents, and with specifications. We can do no more now than recommend to every one the perusal of these chapters, as also that on culverts; but before concluding we present this extract about arches, which shows so clearly the practical nature of the author's mind:—

"Every theory of the arch requires certain fundamental assumptions, and hence the best theory is only an approximation. . . . The stability of a masonry arch does not admit of exact mathematical solution, but is to some extent an indeterminate problem. . . . Considered practically, the designing of a masonry arch is greatly simplified by the many examples furnished by existing structures which afford incontrovertible evidence of their stability by safely fulfilling their intended duties, to say nothing of the history of those structures which have failed, and thus supplied negative evidence of great value. . . . Theory should be interpreted by experience; but the experience should be studied by the light of the best theory available."

Consistently with his opinion respecting the importance of the factor of *cheapness*, the author has supplied in every part of his work records of cost as well as estimates. They are worked out in dollars and cents, and are based on prices for labour and materials to which we are not accustomed in England. Any one who desires could, of course, with a little trouble, compare them and reduce them to the coinage of England or any other country, and no doubt they are valuable in some measure. A somewhat important omission in the work is that of masonry in lighthouses, but of course we could scarcely expect that everything should be included.

In conclusion, let us see whether the author has borne out in his work the claims, or most of the claims, he has made in the preface, viz., that common theories have been compared with the results of actual practice, that principles and methods have been developed, that the subject would be presented clearly and concisely, that it would prove useful to the man of experience, and that no pains have been spared in verifying data and checking results. If each and all of these have been fulfilled, as we consider they have, there can be but one verdict possible.

The author has, however, slightly overstepped the mark when he claims that nearly all the matter is believed to be entirely new. Much is new, undoubtedly; and the Professor must accept our grateful thanks for all that is new; but the work must necessarily, and does, contain a great mass of information which is not new at all. Most of it is worth repeating, but still it is not new, and the claim so far as that,—a really minor point,—is concerned cannot be admitted.

But we close the book with the feeling of satisfaction which always comes over the mind when one has had the privilege of perusing the work of a master hand. Professor Baker's is unquestionably the most complete and the most useful work which has ever yet been published in the English language on masonry construction.

NOTES.

LORD BALFOUR OF BURLEIGH made an important statement last week as to the course of procedure in the Railway Rates inquiry. The Board of Trade, it appears, are determined to endeavour to bring a Bill (or report, as may be found necessary) before Parliament this session; and, with this end in view, they desire that the number of witnesses be considerably reduced, so that the Court may visit Edinburgh in March, and Dublin in April. Although such a large proportion of the objections have been abandoned, the number of witnesses still tendering themselves for examination is far too large to admit of any hope of this programme being carried out if all are to be heard. It is, therefore, very desirable that Lord Balfour's proposal should, as far as practicable, be adopted. Mr. Balfour Browne may be trusted to keep back no really essential evidence. The views expressed by

Mr. Marshall Stevens as to the effect produced on the companies' profits by high prices for material and labour (to which we alluded last week) were fully borne out by the evidence of a Newcastle witness. Statistics were put in relating to the North-Eastern company, showing that in 1873, when the price of iron and coal touched the highest figure known in modern history, this Company paid their highest dividend, while subsequent dividends have fluctuated very much in sympathy with the variations in the price of these materials. Complaint has been made that the companies do not go far enough in the direction of low rates for quantities. It would, doubtless, be very beneficial for trade if this principle, already recognised, were extended; but at whatever figure the maximum rates are eventually fixed, the exigencies of trade will always exert an influence in this direction, and the companies will find it to their own advantage thus to assist in the extension of business. The desire to limit the companies' power is, of course, due to the fear that these considerations will not restrain them from exacting the "pound of flesh" in the case of traffic passing between non-competitive points, to the destruction, perhaps, of struggling industries. There has been abundant evidence given during the present inquiry to show that this is a real danger.

THE Council of the Surveyors' Institution has issued a statement of reasons against the application of the "Betterment" principle of rating in regard to the Strand improvements. The ground of opposition of the Institution is mainly based on the principle that most public improvements, and this one in particular, do not operate solely in the appreciation of property, but draw along with them the depreciation of other property; and that therefore a compensation out of public money must often be called for which would balance the increase of rates on account of "appreciation" (a long-established expression which is certainly to be preferred to the clumsy invention, "betterment"). The general principle, as well as the specific application of it in the case of the Strand improvements, is put thus by the Surveyors' Institution:—

"If the appreciation of contiguous property by a public improvement be matter for special taxation, the depreciation of neighbouring property by the same improvement should be matter for compensation. If the public has rights it has also liabilities. The supposed appreciation (or "betterment"), the value of which it is desired to intercept, will proceed from an anticipated increase of trade, and consequently of rentals. But this, in the great majority of cases, would only be obtained to the detriment of some other localities, from which such increased trade and such increase of rents would be diverted. Therefore, in such cases the whole, and in any case the greater part, of any charge or rate which the County Council might succeed in apportioning upon the various parties interested in the properties appreciated should, as a matter of justice, be afterwards distributed by that body among those interested in the depreciated properties; this distribution may be regarded as impossible in practice.

The element of depreciation is obviously present in the Strand scheme. For several hundred yards the southern side of the Strand enjoys at present a virtual monopoly of the traffic, which means the trade. The widening of the street, and the creation of a rival frontage on the north side, means at the least an equal division of traffic between the two sides of the thoroughfare. It means, indeed, more than this, for upon the new sites will no doubt be erected more attractive premises, comparing favourably with many of the old and cramped houses on the south side. There is no proposal to compensate the south side for a depreciation so manifest and so certain to ensue, but on the contrary to make either owners, lessees, or occupiers pay for the so-called "betterment."

In regard to the general idea that appreciation of one portion of property affected often draws with it depreciation in regard to another, we believe the Council of the Surveyors' Institution are quite correct in their views, and that this side of the subject is one which has escaped notice and demands consideration; but we feel some doubt as to whether their illustration in reference to the effect of the Strand improvements

on the property on the south side is quite a valid one. We should be disposed to say that the widening of the Strand and the other alterations which will make this portion of it more central, spacious, and accessible, must inevitably appreciate in a positive degree the property on the south side, though relatively the new site on the north side may enjoy the higher proportion of appreciation.

WE recently referred to a protest by leading Swedish architects against competition jury decisions of late in Sweden, and the document has now been published. The following is a *résumé*:—The protest first draws attention to one made by two architects in the late competition for the new House of Parliament, which was silently ignored by the authorities, and the undersigned therefore wish to endorse the same as fully justified. Complaint is made that architects observe all the conditions laid down in the programme, but that juries are far from doing so. Four instances are cited since 1886. Thus in a recent competition for a large palace, in Stockholm, it was expressly stipulated in the programme that the style was to be German or Italian Renaissance, and that there was to be no tower, and nevertheless the jury awarded the first prize to the only design sent in, with a tower, and in a style quite different from what the conditions required. In the competition for the new church at Sundsvall it was expressly stipulated that the cost should in no case exceed 250,000 kronor, and still the first prize is awarded to a design calculated to cost 440,000 kronor, and the second prize to one estimated at 475,000 kronor, although there were several estimates within the cost stipulated. In the competition for the new House of Parliament the second prize has been awarded to an architect who has entirely neglected the instructions as to the nature and execution of the designs to be sent in, as well as the position of the building on the site. The complainants ascribe this state of things to the faulty and careless drawing-up of the instructions, and predict that if not remedied the leading Swedish architects will abstain from competing when the awards are so unjust. The protest has attracted much notice in Sweden, on account of the position of the signatories.

A LONG and important letter on the subject of electric lighting appeared in the *Times* of Monday, from Colonel Flood Page; a letter written partly in pursuance of a request made to the writer, along with Mr. Crompton and the Earl of Crawford, by the Electrical Committee of the London Chamber of Commerce, to give some expression of opinion in the press in regard to the extent of danger of fire from electric lighting. Colonel Page's letter is mainly devoted to arguing that any such danger is more to be apprehended from bad and unscientific installation than from the conditions of electric lighting when properly carried out. Admitting that the percentage of electric lights in use is but a small one at present in comparison with other forms of lamp, it is nevertheless significant to note that during the last three years there has been an annual average of 565 fires in London owing their origin to lamps, gas, or candles, while there have only been in that period four fires attributable to electric lighting, and of these the last one (that in Grosvenor-square) arose from an installation which was pronounced by the most accomplished of experts as being radically bad and not in accordance with any fire insurance rules whatsoever. In conclusion, Colonel Flood Page says:—

"I think that the public may rest assured that while the employment of electric lighting does not altogether get rid of the liability to accidents which is inherent in everything human, and which at present reaches a most serious percentage in the case of all ordinary artificial illuminants, yet it tends to reduce the risk to a *minima*, far below the chances of fire from candles, oil and gas. The extent of the security is, however, in exact proportion to the skill and care exercised by those who wire the house; while cheap work is fit nearly every department of life poor and bad, in wiring for electric light it is simply fatal. I am

confident that when a competent electrical firm is employed, and a fair price paid for the wiring, &c., of a house; when a consulting electrical engineer, or a competent fire insurance expert is called in to report upon the work before it is paid for, that those who introduce electric light into their houses may enjoy amongst other advantages a sense of security from fire not to be attained by any other means of lighting their houses. I venture to suggest that every householder whose house has been wired by any one not an electrical engineer should call upon the office in which his house is insured, or if uninsured upon an electrical engineer, to inspect and report upon the electrical apparatus which has been fixed in his house; and to those who are at present thinking of having their houses wired I would suggest that they should entrust the work to some electrical firm of known standing."

ARRANGEMENTS are progressing for the holding of an international exhibition in Berlin in 1892. The Polytechnical Society has wisely decided not to construct an imitation of the Eiffel Tower, as such an engineering undertaking would now have but little novelty, and as a technical achievement be far eclipsed by the Forth Bridge.

IN regard to the subject of technical education, it may of interest to note that, according to an official Berlin contemporary, Germany has at present eight technical colleges ranking parallel to the universities. A total of 4,821 persons (or 381 more than last year) are this winter being benefited by the instruction given at these institutions, and of this number 3,372 are matriculated students. Of the eight colleges, Berlin, with 1,457 names, is by far the largest, Munich coming next with 844, and then Karlsruhe 524, Stuttgart 465, Hanover 420, Dresden 380, Darmstadt 275, Brunswick 241, and Aachen 215. Of a total of 757 names entered for "architecture," 435 fell to Berlin, whilst Brunswick has only 13 and Aachen 25 in this division.

IT would appear certain that the recently reported case of the Ravensthorpe Local Board v. Hinchcliffe renders necessary an amendment of section 156 of the Public Health Act, 1875. That section states that "it shall not be lawful in any urban district, without the written consent of the urban authority, to erect or bring forward any house or building in any street beyond the front main wall of the house or building on either side thereof in the same street." It is unnecessary to state in detail the facts of the above case; it is sufficient to say that Hinchcliffe began to build the front main wall of his house 6 ft. beyond what the Local Board alleged was the front main wall of the adjoining house; this was, in fact, only the beginning of such wall, since it was only five inches above the ground. The court decided that there was no "house or building" within the meaning of the Act, only some beginnings of walls. Therefore there had been no infringement of the Act. But it is clear that if this decision were to be acted on, persons might make what should be a street with a regular level of houses, a street of the most extraordinary kind. It is equally clear, therefore, that this section should be altered by authority of Parliament so as to meet such a difficulty as occurred in this case.

DR. PARSONS'S report to the Local Government Board (dated January 21) on the prevalence of enteric fever in the Bedlington Urban Sanitary District, suggests a danger to tenants of small rural property which has not been often noticed before, and perhaps does not exist in many places, in regard to the process of emptying privy middens. This is done by contractors under the Local Board; but it is observed that—

"The contractors are only expected to get out the contents of these cists, alongside of which a cart can be brought. In other places, as where the asphalt is in a yard approached by a narrow entry, it is deemed to be the occupier's duty to get out the contents, and wheel them into the street to be fetched away by the contractor's cart. This practice is objectionable, as imposing an offensive and dangerous duty upon a number of individuals, some

of whom will probably be susceptible to injurious effects, instead of its being undertaken by persons who, being insured to it, are not likely to suffer. Another objection is that the tenant gets out the stuff at such time as may suit him, and it sometimes remains many hours in the street awaiting removal by the contractor."

It is not surprising to learn that the first patient who was attacked by the "fever" attributed the illness to his having a few days before emptied the privy-midden and wheeled the contents into the street for removal. Another evil to which Dr. Parsons drew special attention was the frequently filthy and unhealthy state of unpaved yards and back streets, which were found "littered with refuse through the carelessness of the tenants, and worn into holes full of mud and foul water." A good deal of this may be directly the fault of the tenants, but people of this class eminently need sanitary guidance and instruction.

THERE is, it seems, in Manchester and Salford, and has been for nearly thirty years, a Society known as "The Manchester and Salford Ladies' Sanitary Association." The Mayoress of Manchester gave an entertainment in aid of it about a week ago, and the Mayor took occasion to describe the work of the Society, which has for its object the improvement of the conditions of life among the people dwelling in the slums. The lady-members are not exactly amateur sanitary inspectors, reporting nuisances and so forth, but rather teachers seeking to instil into the minds of the very poor elementary lessons on health, such as the value of cleanliness, fresh air, the good cooking of plain food, and the evils of their opposites. Leaflets on such subjects as these are distributed, and sixteen mission-women, each of whom lives in the district of which she has charge, inculcate the same lessons; evening classes and amusements form part of the programme, and every summer hundreds of children are sent into the country for three weeks' fresh air. How beneficial such a Society may be to the general health of a district is difficult to estimate, but it is well known that the gross ignorance of the masses of the people respecting simple sanitary and sanitary laws is one great obstacle in the way of general improvement. The apathy with which Boards of Guardians in rural districts, and many Local Boards, regard sanitary reforms, is the result of the same ignorance of the simple laws of health. Dr. Page and Dr. Parsons would not have so many dreadful nuisances to report if there were more such Associations in the country for simply drawing the attention of ignorant people to the first conditions of healthful existence.

AN excellent and interesting example of road-mending on scientific principles may now be seen on the main road in the neighbourhood of Kensington. At great expense to the ratepayers, the old macadam was taken up and wood pavement was laid down. Like all mundane things, this pavement has begun to show signs of wear and tear, and ruts, not inferior to those which used to find their way into the macadam, have made their appearance. Into these ruts, harrow-loads of stones and rubble are being emptied. The result is certain. The wood becomes disintegrated and broken up, dust in dry weather becomes more abundant than ever, and mud in wet weather covers the wood surface to a much greater extent than hitherto. Such mending hastens the destruction of the wood pavement. But of one thing there can be no doubt, that if wood pavement is to be used where much traffic is found, it must be laid in a manner to exist without ruts longer than it does at present. But if it is laid down, it should be repaired in a proper manner. To set to work as the Kensington Vestry are doing is only to make matters worse.

THE report of the Special Commissioners appointed by Lord Lothian to inquire into the causes of the Templeton mill disaster

has been issued, and is of a somewhat unexpected character as compared with the evidence previously given. We defer the consideration of it in detail.

"AN Edinburgh Contract of 1754" was the title of an exceedingly interesting paper read by Mr. T. M. Rickman before the members of the Institute of Builders on the 13th inst. The contract referred to was that for the "Exchange," a large block of buildings which covers the site on which it was proposed a year or two ago to erect new Municipal Buildings. Mr. Rickman said that a year ago he purchased a small octavo volume entitled "Contract of Agreement for building an Exchange in the City of Edinburgh, between the Magistrates and Town-Council and the Tradesmen," printed in 1754, which referred to this building. The book contained nine pages of "The Contents," an interesting and elaborate piece of typography; an elevation and a plan of the building; the agreement, including a specification of sixty pages, and an appendix of twenty-seven pages, "containing estimates of the particular pieces of work in the Exchange," comprising the quantities for the whole building. The agreement appeared to Mr. Rickman singular, and one so complicated that it was likely there would be variations in carrying it out, and adjustments necessary in its final settlement. He had endeavoured to investigate what was the outcome of this agreement, but he regretted to say that to a great extent he had been unsuccessful. He had, however, gleaned some information respecting its issue, which he laid before the meeting, as throwing some light on the subject of building contracts, on the system in vogue in Scotland 130 years ago, and, incidentally, on a variety of matters with which it is the business of builders and architects to come in contact in our daily avocations.

THE London Geological Field Class, which has for its object the systematic study of the geology of the London district, is to be congratulated on having obtained the use of the Lecture Theatre of Gresham College for its winter lectures (mainly through the good offices, we believe, of Mr. T. E. Knightley); and the Gresham Committee are to be congratulated no less on having found a new way in which their building can be utilised. The lecture theatre is not by any means an ideal one for use by day, as the strong light from the windows at the back of the lecturer's table prevents his diagrams and his features from being clearly seen by his audience. But where is the learned society's or philosophical institution's lecture-theatre that even approaches the ideal in convenience and safety? Not to pursue this subject, we will only add that the first of a course of four lectures was delivered to the members of the Field Class on Saturday last by Professor H. G. Seeley, F.R.S., "On the Tertiary Rocks on which London stands." Professor Seeley is master of his subject, and his first lecture was exceedingly interesting.

THE first number of a monthly magazine, entitled the *Parents' Review*, which is said to be specially written "to aid parents in their great function of training character," contains an article by Mr. E. C. Robins, on "The Profession of Architecture," which is apparently the first of a series of papers under the general heading "Our Sons," and gives, very briskly indeed, an account of the modern architect and his work. Mr. Robins's answer to the question, "What is an architect?" is especially good. "The 'born' architect is a man of poetic temperament, of creative imagination, and of artistic taste and judgment; coupled with seeing eyes and deft hands, he must have scientific accuracy and constructive power; he is at once a designer, a builder, a man of culture, and a man of business. It is more difficult to define what it is unnecessary for him to know than to expound what he may advantageously acquire. He might be an engineer if he were not an architect; but because he is an architect he should be an

artist and engineer combined. . . . We may define an architect as a *scientific artist*." He then points out the difference between an architect and a builder, and states that "five years is the usual term of apprenticeship; but three years is sufficient if preceded by a two years' course at a technical college." Speaking of the new system of Examinations inaugurated by the Institute of Architects, Mr. Robins enumerates: 1st, the *preliminary*, for youths in the opening years of their pupilage; 2nd, the *intermediate*, for pupils nearing the end of their term; 3rd, the final examination, for young architects who have completed their articles, commenced practice, "and are desirous of becoming Associates of the Institute as the only worthy mode of 'registration,' while endeavouring to make their independent way in the profession." A list of the Institute's annual prizes concludes the article. Mr. Robins does not give any opinion as to whether the present state of the profession holds out much hope of success to youths; and that, we take it, is just the one piece of information which "parents" would like to have. His advice is contained in these words: "If there is no love for art for its own sake, in any of its various phases,—no fancy for things beautiful,—do not make your son an architect." "*Hoc fecit Nykholm*," in the same magazine, is a very picturesque article on the great fourteenth-century architect.

IN a communication addressed to *Notes and Queries*, apropos of St. John's Church, Clerkenwell, Mr. H. W. Fincham seems to determine a question for which diverse criticisms are given by two local historians whom he cites: Pinks and Cromwell. About midway up in the central east window of the present church is fixed a pane of stained glass, bearing a coat-of-arms thus—gules, a chevron or between three combs, on a chief argent, a cross gules. The red cross has been generally taken to denote the old Priory. Having climbed up the scaffolding,—the church's interior being now in course of repair,—Mr. Fincham finds that "upon a narrow band of glass surrounding the coat is inscribed, in beautifully-drawn late Gothic characters: 'Robertus Botyll Pryor: Elect AD 1439 Resign 1469.'" He conjectures that this pane, 15½ in. by 10½ in., may be part of the original filling of the window, or may have been removed into its present position; for the surrounding glass is later in date, from another part of the priory. The removal of the flooring and dado brings to light the bases of some pillars of the earlier church, and, in the southern wall, a pointed doorway, together with portions of ashlar masonry marked with diagonal tool marks in good preservation. It is stated that these remains will henceforth be left exposed to sight. This church was originally consecrated in 1185, by Heraclius, patriarch of Jerusalem; who, in that same year, performed the same function for the Knights Templars' round church, dedicated to St. Mary. It is drawn in one of the three views, by Hollar, of the Hospital of St. John of Jerusalem. In the Guildhall Library is a copy of Vertue's print, showing it as seen from the south, taken from a Cottonian MS. The Order was dissolved by an Act of 32 Henry VIII., c. 24. We adverted to the repairs of the interior of the church in our columns of April 16, 1887.

AT Messrs. Dowdeswell's gallery in New Bond-street is a large collection of pictures and drawings, by Mr. Yeend King, Mr. J. M. Bromley, and Mr. J. M. Macintosh, in illustration of Berkshire scenery. The bulk of the collection is not of very high interest, but the paintings by Mr. King of some of the street scenes in the small towns and villages have very high merit as paintings of architectural subjects, especially "Thatcham," "Shrivenham," "Abingdon Bridge" (95, 96, and 97), and "Lambourne" (102); also a large painting of the "Water Bridge, Newbury," with its picturesque groups of buildings on either side

men appreciate the advantages of the fine arts. And it is important in other respects, for such owners usually have more wealth at their disposal than private persons, the buildings are mostly on a larger scale, and in more frequented parts of the town. Such adornments, too, attract the dwellers in our colonies, and foreigners, and the adornments themselves are a voucher for the cultivation of the nation. In certain respects this adornment is even more important in private houses, not only because there are more private than public buildings, but because if each dweller be cultivated the whole body of the people must be.

The two great material obstacles to painting and sculpture in private houses are the leasehold system, and the expense. On this latter subject two remarks may be made. First, that, even taking the present costliness of painting and sculpture, something might still be effected by leaving out the bad ornament, too often diffused over the whole front, and replacing it by excellent sculpture concentrated on a few important places; secondly, there must be an inevitable fall in the price of good work when so many thousand students are being educated for nothing, or next to nothing.

It is only advertising to a trisium to say that human progress is due to the gradual perfecting of what has gone before, for if this were not the case we might look for new creations in every art and science from savages who have not as yet learned the use of fire. Yet, no one would expect a more perfect steam-engine, a deeper treatise on mathematics, a finer picture, or a nobler building than we now have, from such savages. Even if we were told that such a thing had happened we should not believe it.

At Pompeii we see the remains of a complete system of coloured decoration, possibly the oldest on a large scale that still exists; there are, it is true, small painted chambers that are much older, the tomb of the Lucumo at Veii, and others; and, if we could be sure that the colouring of the Egyptian temples was the original colouring, that might be older still than the tomb of the Lucumo, but we know the colouring at Pompeii cannot be later than the year 79 A.D., when it was destroyed, in the days of Titus. This was the second best period for all the fine arts in the Roman Empire. During the reigns of the Flavian, Ulpian, Elitian, and Antonine families, literature and the visual fine arts flourished, and arrived at a perfection only exceeded at the end of the Republic, usually called the Augustan era.

It is true that Pompeii was only a little watering-place, and we cannot expect to find the arts there in the perfection they had attained in the great cities of the Empire, much less in Rome.

Pompeii only gives us a glimpse of the system. This would be valuable enough under any circumstances, but it is invaluable now when we can get nothing, or next to nothing, else.

The Romans were evidently great admirers of colour. In their public and magnificent private buildings colour was mainly got by veneering* the walls with beautifully coloured marbles, to obtain which every part of the known world was ransacked; one of the marbles, a sort of dirty yellow, called Astracian, is said to have come from Agra in India; we know, too, that the mere apposition of beautifully coloured and contrasting marbles was not enough to satisfy the eyes of the Roman, and to attest their magnificence, for the marble was often inlaid. Statius describes the purple synnadio as inlaid with Giallo Antico, and Seneca speaks of porphyry or Egyptian serpentine ornamented with the same marble. Very few quarries of beautifully coloured and figured marbles have been large enough for the great monolithic columns the Romans used, so the shafts had to be of Estelle, Parian, Carrara, grey Greek marble, of Giallo Antico, or Pavonazzetto, or else the shafts were of red or grey granite or of porphyry. I do not know if monolithic columns of the black Lucullean marble were to be got of the largest size. Pliny merely says there were 360 columns, 38 ft. long, at the temporary Theatre of Scarrus ("Nat. Hist.," XXXVI, cap. 24), which were afterwards removed to his house. The capitals and bases of columns, where Parian marble was not thought good enough, were of gilded bronze, and often the girders and roof-tiles were of the same metal. The doors of the temples at least were adorned with gifts and garlands and with stuffs embroidered with gold.

* The proper word is *finishing*, from a German word meaning to inlay, borrowed by the French, and again from the French by the Germans. *Veneering* is used in Sir William Gell's "Pompeiana" and in Duclos.

*Drawing of one half of the Mosaic Floor of the Prothyrum of a Pompeian House.
By Mr. A. M. Poynter.*

as we read in it the story of Psyche by Apuleius (Apuleius, Lib. VI.), and probably the columns and walls of the front of temples had embroidered bangings and festoons.

Originally the ceilings, vaults, and upper parts of walls were adorned with embossed plaster, painted and gilt, but, after the introduction of glass mosaic, the remaining part of the walls and the vaults were mostly covered with ornament or figures executed in it (Pliny "Nat. Hist.," Lib. XXXVI, cap. 14). We cannot now tell if the glass story of Scarrus's theatre was covered with slabs of cast glass, and the column shafts made of cylinders of it, or whether the whole was merely in mosaic (Pliny "Nat. Hist.," Lib. XXXVI, cap. 24). Columns covered with glass mosaic in patterns have been found at Pompeii, but it is thought by many antiquarians that this glass story was of cast glass. If to these magnificent decorations you add the floors of precious stones, the doors of carved ivory, of embossed and damascened bronze, or of beautiful woods inlaid, you have a splendidly coloured effect, and all the adjuncts were equally splendid. Arms and armour were embossed with sculpture and damascened with gold and silver, and often enriched with gems; the dresses were crimson, scarlet, purple, blue, green, yellow, grey, and white, and mostly embroidered; the couch covers were embroidered in gold and colours; there were gold and silver tissues, splendidly coloured curtains and carpets, not to mention furs; garlands and festoons of flowers, and shrubs and plants in pots; so I think you must admit that most buildings exhibited a most gorgeous display of colour, not to speak of the troops of slaves of all colours that enlivened the scene; and that this taste for colour was not a mere accident dependent on the use of costly materials, but was desired by the people, may be judged of from this, that whenever the walls were plastered the Romans painted them both inside and out.

Rome towards the end of the Republic was the one city from which the mandates of the Senate issued to the world, and must, therefore, have been thronged with the ambassadors of nations and their suites, with deputations from numberless cities, as well as with crowds of foreigners who had merely come to see what Rome and the Romans were like. It had too suddenly become possessed of the hoarded treasures of the world, and of an immense annual revenue from the tributes of the conquered. In consequence, it had become the emporium of the earth, to which all the talent, as well as all the choice commodities, of the world gravitated. The people were no longer the rude husbandmen who could only fight, speak, and make laws, but the better class at least had become cultured, so far as culture is consistent with trained ferocity and the absence of humanity. They read and spoke and wrote Greek, and were much employed in translating and imitating the masterpieces of Greek literature, and in learning Greek science, and eventually they were trying to rival both.

Many of them learned to draw and to model, some even learned to play on an instrument, and nearly all professed to be connoisseurs in painting and sculpture, architecture, and articles of vertu. Their public buildings were crowded with the masterpieces of the Greek chisel,—in Scarrus's temporary theatre there were three thousand bronze statues,—and the best easel pictures of the Greeks were in their temples, not to speak of those in private houses. As far as wealth could purchase talent they had the best, for the Romans had no notion of being outdone, even in the visual fine arts, by the nations they had conquered, and they also wished to see the great achievements of their arms recorded.

It is, perhaps, hardly necessary to mention that mere wealth can but buy what is to be had; it has but little stimulating effect on the transcendental faculties, and does not produce a medium or a surrounding in which genius naturally springs up; it is only when the arts are passionately admired that they arrive at perfection. I fancy all nations and all epochs get what they really and ardently desire. The Greeks adored beauty in every form, and they got it; the Romans adored valour and strategy, eloquence and statesmanship, law and order, and they got them; but the slaves who merely administered to their ostentation, or heguled their idle moments, they thought were only worthy of a pat on the head or a bandsome present. Amongst these slaves were the painters, sculptors, architects, musicians and singers. Old Pliny had wit enough to see that when the artist's highest object was wealth the art be practised necessarily declined; but he did not see that this desire for wealth amongst the artists was only the effect of their surroundings: high poetry only comes from a noble society when every fibre has been strung by passionate emotion. In the present day we have plenty of great natural philosophers, because the people love natural science, and a vast proportion of them know something about it, and passionately admire the great masters of it. These masters may be otherwise obscure, and only just above poverty; but they know the very mention of their names, through the wide realms where English is spoken, will evoke feelings of pride and a thrill of emotion. The feeling for architects in the present day, and the admiration for their works, reminds me of Milton's,—

— "Sent
With his industrious crew to build in Hell."

In the middle period of the Roman Republic there seemed likely to be a chance of painting being considered as a generous art, for some distinguished men in Rome practised it.

As early as 303 B.C., C. Fabius Pictor painted the Temple of Salus, on the Quirinal, and these paintings remained until the Temple was burnt in the reign of Claudius (41-54 A.D.), and his pictures were admired by the critics of the Augustan age. Pliny also tells us that Pacuvius, the poet (220 to 130 B.C.), painted the Temple of Hercules, in the Cattle Market

(Forum Boarium). About the same time P. C. Æmilius Scipio Africanus, the son of Æmilius Paulus, studied painting and sculpture, though painting subsequently seemed not to have been recognised as a generous art, and we hear no more of men of noble family practising it publicly. We have every reason, however, to believe that subject-pictures were as common in houses during the Empire as they were in the Middle Ages.

In Trimalchio's villa we read of painted subjects, past the porter's lodge, probably painted on the walls of the Prothyrum; others on the walls of the portico, probably the atrium, for it is the atriensis who explains them; and not far from them is the dining-room.

Many of the pictures at Pompeii are supposed to be indifferent copies of well-known subjects by the greatest Greek artists, and it is interesting, even if it be not useful, to architects to see how wall pictures were made into an integral part of the decoration; triptychs and framed pictures were hung on the walls just as they are now.

Three favourite schemes seem to have been adopted for the general decoration: the first, and ugliest, was to paint some doors, fill up the parts between with paintings of slabs of marble of different colours to paint a string, and some panels of plain colour above the marble, or to paint a row of full-sized columns or pilasters and fill in between with bordered panels of plain colour, or of imitation marble, and sometimes to paint festoons hanging from column to column. The second scheme was to divide the space, if comparatively narrow, into three vertical divisions with a wide centre and narrow sides, or, if wide, into alternate divisions of narrow and wide spaces, to make a dado line and panel it and the wall above, and to put some slight ornament in the panels or on their borders, and this was usually in monochrome. Still, there are rooms that are treated in a similar way and coloured; the narrow divisions are sometimes not panelled, but have a candelabrum in them, while the larger spaces are panelled, and have birds or figures in the middle, a few rooms are found that are merely panelled, and are without any other ornament than the lines forming the panels, the dado, the frieze, and the cornice.

The third and most usual plan was to divide the height into three unequal parts horizontally, to make the bottom part a dado, to make the middle piece the wall, and above that to make the painting represent the open air, or a wall with open windows in it. Very slight columns that divide the length of the room were put on the dado, or podium. It was customary to put large and important pictures on the back of a shrine, the front painted columns, supporting the roof of it, standing forward; to put some other slight columns, candelabra, or slight narrow structures at intervals, and to panel between them, the centre of the panel being often enriched by a floating figure or a bird. Occasionally, a small framed picture is put in some of the panels, to look as if it were hanging on the wall.

A favourite device, instead of panelling, is to put a light column where the divisions of the panels would be, and let it run up above the part representing the wall, and support one end of an entablature, which is supported at the other end by a column outside the wall.

In the house of Spurius Misor the dado is black with lilac lines, one above the skirting and one half-way up the dado, crossed by vertical lines under the centre of the columns; at the crossing there is a square, and a lozenge coloured mask in the middle, and a lozenge with a patera on the middle line between the two squares. The skirting is grey, put with black marble streaked with grey, put with the streaks slanting, and in each alternate piece the opposite way. The wall above the dado has a frieze above and a wide band below; in the middle is a picture of a huntsman and a dead fawn and a priestess; this picture is on the back wall of the shrine, the front is supported by two slight white columns with coloured hands, and at four places garlands are wound round the columns and carried up diagonally to the next band. The shallow entablature of the shrine is panelled with square panels, whose borders are green and pale plum colour, with the centres and two end panels bordered with white; the centres of the panels are dull orange and plum colour alternately, with patterns in white and green. The soffit of the top is a yellowish brown and coffered, meant for wood. All

round the picture is a framework of black with white end lilac lines, and the band above the dado before-mentioned is a dull orange at the sides and purple under the picture, separated at the top by one broad stripe of green next the black, and white below. In the band under the picture are birds and fruit; under the sides are vases and a volume. The side panels are a deep, dull red, with a small Cupid in natural colours in the middle; a border of about one-ninth of the whole width is formed by five lines, and on the centre line are squares and circles alternately, filled with green, with white ornaments on them. The frieze above is black, with a goose, a basket of fruit, a sistrum, and a bottle in natural colours, and this is separated from the red by an orange and green band; above the black frieze is a bluish cornice with red and orange lines; above this the wall is a creamy white, with light buildings, birds, and sprigs of foliage in light colours.

It is of no use talking about form or colour, for these cannot be described in words, but must be shown with the pencil or the brush; but I may say that the invention displayed is marvellous—plants and flowers, garlands and panels, beasts, birds, and chimeras, scroll-work and figures, are used in profusion, and are mostly confined to borders, the panels being mostly of one uniform plain colour. Though it is hardly necessary to say much of Pompeian decoration, as it is so well known, I may mention that the painted rooms found on the Palatine are in the same style, and from similar chambers found elsewhere most subsequent classic decoration has been taken.

The paintings on the walls of the Loggia at the Vatican are believed to have been taken by Raphael and his pupils from some underground Roman chambers that were excavated and filled in again, or if they were not copied, they were paraphrased. In Roman days this style was universal: we find the same sort of thing chased in silver, in the treasure of Hildesheim. This decoration is supposed to have been invented by the Greeks of Asia Minor—Vitruvius speaks of some executed at Tralles by Apaturus of Alabastra (Vit. Lib. VII, c. 5, p. 5),—and the idea of it may have been suggested by the tents and marquees formed of embroidered stuffs. "Attalike Vestes" were celebrated; *i.e.*, stuffs embroidered with gold at Pergamum, as well as Babylonian and Alexandrian work, which were in colours.

At Trimalchio's feast, during the interval between the courses, fresh covers are spread on the couches, "on which were embroidered the nets, the ambush men with their hunting spears, and the whole apparatus of a hunt" (Pet. Sat., cap. 40). We do not know whether this was a piece of Roman work or not, but these hunting scenes have been common subjects of Indian embroidery from the earliest historic times, and are known as wild-beast patterns.

The use of this sort of arabesque that is met with at Pompeii called down the indignation of Vitruvius; he says (Lib. VII, cap. 5, p. 3), after speaking of paintings representing persons, animals, places, or things:—"Those examples, however, which the ancients adopted from real objects, are now disapproved of in consequence of our depraved taste. For monstrosities are painted on the plaster instead of well-marked copies of definite objects; thus reeds are put in the place of columns; in the place of pediments, little striped grappels with crisped leaves and delicate volutes, and also candelabra, supporting the representations of little temples, above the roofs of which are delicate scrolled stalks rising out of roots, and most of them having little images seated upon them, against all reason; and quite as irrationally also, flowers springing out of their stalks, and having little images half issuing out of them, some with men's, half with beasts' heads. But these things neither are, nor can be, produced, nor ever have been. Thus our new taste has brought us to this point,—that through the inefficiency of bad criticism the excellencies of the arts have shut their eyes for the time. How is it possible for a reed to carry a roof, or a candelabrum a little temple and the ornaments of a pediment, or so tender and soft a stalk to carry a seated image, or to produce flowers and half-figures partly sticking out of roots and stalks? Nevertheless, men, on seeing these falsities, do not condemn them, but are delighted, and never think whether any of them could or could not exist. Minds, however, that are obscured by infirmity of judgment have not the power of testing what is possible, consistently with the authority and

reason of grace; for neither ought pictures to be approved of, which have no resemblance to reality; nor even if they are rendered elegant by their art, ought the judgment about them to be on that account favourable, unless they rest on sound reasons of argument, set forth without self-contradiction."

My translation of this crabbish passage may not be correct, but I got it revised by Professor Middleton and Mr. Holmes, of Pembroke College and St. George's Hospital. What sort of decoration these "harpagineti striati cum crispis follis et volutis teneris," translated as "little striped grappels, with crisped leaves and delicate volutes," may be meant for, I cannot say. The editors of the "Fitture Antiche d'Ercolano" (1757) believe them to be shown in a wall decoration. There is a small open circular Ionic temple, and above the cornice of it are uprights projecting at an angle, with staff between, in the upper fringe of which there are two volutes and an upright stem that might possibly be taken for grappels; we do not, however, see either the striping or the crisped leaves.

We being accustomed to the immense strength of iron and steel, are not so much shocked with the apparent weakness of these supports as Villivius was. They were, doubtless, sufficiently ridiculous in his day. Possibly the notion of such very slight structures originated in the temporary buildings of bamboo used in Eastern festivals; such buildings were probably adorned with flowers, branches of shrubs, sprigs of creepers, ribands and feathers, adorned and hung with balls and little painted tablets.

Pliny describes much of the Pompeian painting as follows ("Nat. Hist." Lib. XXXV, cap. 37):—

"Ludius too, who lived in the time of the late Emperor Augustus, must not be allowed to pass without some notice; for he was the first to introduce the fashion of covering the walls of our houses with most pleasing landscapes, representing villas, porticoes, ornamental gardening, woods, groves, hills, fish-ponds, canals, rivers, sea-shores, and anything else one could desire; varied with figures of persons walking, sailing, or proceeding to their villas, on asses or in carriages. Then, too, there are others to be seen fishing, fowling, or gathering in the vintage. In some of his decorations there are fine villas to be seen, and roads to them across the marshes, with women making hargains to be carried across on men's shoulders, who move along, slipping at every step and tottering beneath their load; with numberless other subjects of a similar nature, redolent of mirth and of the most amusing ingenuity. It was this artist, too, who first decorated our uncovered edifices with representations of maritime cities, a subject which produces a most pleasing effect, and at a very trifling expense."

In some of the old Basilicas at Rome, in St. Mark's at Venice, in Monreale at Palermo, in San Vitale, and in other churches and tombs at Ravenna, we see what must have been the effect of colour in Roman buildings when it was wholly obtained by marble and by marble and glass mosaic, but it is mainly from Pompeii that we see what magnificence can be got by painted decoration. There are, it is true, Pompeian examples of light coloring where the grounds are white or of very light tones, and the best of these are interesting enough and pleasant as a change; but by far the most magnificent instances are where black, dull scarlet, deep crimson, purple, deep orange, and green, form the principal masses of colour. In the house of L. Ceclilius Jucundus, the skirting is high and of a uniform plain green, very like green oxide of chromium, the dado black, the panels a dull scarlet, the frames to the panels of black, and the columns, narrow borders, strings, and the parts which are supposed to show to the open air, of a creamy white. The black dado is enlivened with coloured narrow panels under the columns, and between these light thyrsi are suspended in slanting lines from the top, and are tied on to flags projecting from the panels; flower scrolls grow up from the bottom, and support each of the thyrsi in the middle, and from the point where these last are tied together a tambourine with strings depends; in another part of the dado a lute-shaped piece comes from the bottom in the centre, from the top of which branches of foliage come out and support the sloping thyrsi, and on these last are hung Pandean pipes and a brass dish; the white string above is ornamented at intervals with green and orange; the black band above it, has red panels near the columns, with a nar-

rower orange-coloured panel in the middle. Between the red panels there are projections on either hand, like a signboard, painted in green and purple and ornamented with white; on scrolls at the angles of the lower part of the centre panel swans are perched, holding festoons in their beaks, on which are peacocks. Above, is a yellow string ornamented with a pattern in green and plum colour. Under the centre picture is a black band, with scrollwork in colours, with elephants' and rams' heads growing out of the flowers, and cheetahs as the scrolls; the white borders have orange, green, and plum-coloured panels of various shapes with heads on them, and ornaments between. The white columns are banded with coloured and ornamented bands, and the two deep bands on them are enriched in the middle, with oval plaques with pendent ear-rings between them. From the large imbricated columns scrolls spring out at intervals, or else the columns are supposed to stand in front of fanciful panels on the ground, and on or within each scroll are goats, deer and birds, and a fawn being devoured by a chimera* or some winged monster. The plain red panels are separated from the outer black borders by a band of yellow network, from which grow star-shaped flowers that bend over on the black; the black is banded twice in its height with plum-coloured bands, on each of which is a beast or bird. In the middle of the upright yellow network a scroll, with flowers and fruit at the end, comes forward on to the black, on which are a griffin and a sphinx; the ground work from these to the red is filled with green and plum colour, which is bordered by a yellow line that forms a segment projecting into the red. It would be endless to describe it all, and I have only gone so far to show you how the colours were broken up, and to show the infinite pains that have been taken to make every part interesting.

Whatever may be said against the taste of the Romans in form, I think every one with a passion for colour must allow that they had a pronounced taste for dignified colour. Merely to read of the colours would give a notion that the effect of them was staring, tawdry, and vulgar, but when seen, all that reads like violent contrasts are so skillfully arranged, proportioned, and toned down by art, that the effect is a superb magnificence.

Since Roman times there have been many superb schemes of decoration, some of the Saracenic for instance, and some of the Moorish. I do not know anything that looks more lovely, and is more entrancing for a short time, than the carved and painted plaster-work of the Alhambra, for, as you shift your position, the different planes of colour come out and produce beautiful varieties of tone and tint and fresh patterns; but at last you weary of this, and there is nothing else to arrest the attention, or rather everything is calculated to turn it in other directions. Nothing at the first view is so likely to attract attention as superhuman complexity, but nothing one so soon sickens of; no one can long delight in interlacing lines, commonplace shapes indefinitely repeated, and coarse carving. In Pompeian work we see a profusion of invention that is quite marvellous, and a beauty of form and colour that makes one linger over each bit when one is satiated with the general effect, though I presume it was mostly done off-hand by provincial artists. These very heads of men and animals that grow out of flowers and so disgusted Vitruvius, charm one by their unexpectedness. And we find fawns and goats, lions, tigers, leopards, and cheetahs, owls, eagles, chimeras, and sphinxes perched on every scroll just as you see goats planted on isolated pinnacles in a rocky country; geese and swans bold up strings and ribands, festoons, or necklaces in their beaks; peacocks, golden pheasants and parrots perch on poles or peck at festoons. Masks, lyres, satira, flutes, and trumpets, are interspersed with baskets of fruit and flowers; fauna, onpids, and satyra dance on tight-ropes, and wherever there is a spare place a little picture is introduced. Genii, onpids, bacchantes, dancing, and music girls float in the panels; natural flowers grow from the skirting up the dado. Friezes are painted with subjects, sometimes with comic ones, and almost every vessel in household use is utilised for ornament. In some of the subsidiary pictures all sorts of trades and occupa-

tions are painted, and these are diversified with landscape or architectural subjects. The main pictures are mostly illustrations of subjects from the Iliad, the Odyssey, the tragic poets, or from old Greek stories. The latest subject shown is the onslaught of Alexander the Great and the flight of Darins at the battle of Issus, in the celebrated mosaic at the House of the Faun. Every hint culled from the curls of creepers, the growth of plants, and from the shapes of flowers was used in the ornament. Necklaces, ear-rings, medallions, and hair-pins were used amongst the ornament, as well as garlands, fillets, thyrsi, feathers, tablets, standards, arms and armour, chased plate, and coffers. The ornaments in colour on glass vessels and on pottery are brought in, here and there gardens with their structures in trellis-work, and garden pavilions are introduced as ornaments on bands or on borders of plain colour.

Never since the days of Pompeii has anything of equal inventiveness and artist's excellence come down to us, with the exception of the paraphrases executed by the Italian artists of the fifteenth and sixteenth centuries. Such decoration can only be carried out where there is enormous wealth, as in the latter times of the Republic, in the days of Augustus, and in those of the early Emperors who succeeded him, or where there is a superabundance of highly-skilled talent, as in the days of the Italian Renaissance. The majolica plates, for instance, now worth their weight in gold, were often painted by first-rate artists who were out at elbows, or who had to escape from the towns they were working, for a shilling or two a dozen, to get a dinner with, while they were waiting for better-paid employment; a few eminent painters have done such work in their own houses for their own delight, as Mr. L'Alma Tadema did in his late house.

If we have such fine work in a little country town, what must have been the work in the most sumptuous rooms of Nero's Golden House on which he squandered all the wealth hoarded by Tiberius, and a good part of the State revenue? Monster as Nero was, there can be little doubt that he was a cultivated connoisseur of the Fine Arts, though singing and music seem to have been his most favoured diversions.

Few of the enormously wealthy men of the day have either the taste, patriotism, or open-handedness to have a few of their state rooms decorated in colour by first-rate artists. Although it is important to keep up the finest possible race of horses, and of dogs, and to practise hospitality, the unconscionable sums squandered on horse-racing, hunting, banquets, equipages, and servants, leave nothing for the encouragement of men of letters, men of science, or of artists. Many writers have said that there would be plenty of Virgils, Horaces, and Livys even now, if Mæcenæ could again be brought to life. The Government and the municipalities are far from comprehending the feelings of the working-classes, who would only be too glad to see the public buildings more imposing, and of more magnificent materials, and see them decorated with first-rate painting and sculpture, even though they had to pay another $\frac{1}{2}$ d. in the pound. They at least like to see, as well as to feel, the greatness of their country. The few fine rooms that we do see are mostly done for men with very moderate incomes, who love artistic work, and, like the Italian Cardinals, who enriched Italy with palaces, dine on five shillings a day to have money to spend on adorning their houses.

BUILDING LEGISLATION:

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The eighth ordinary general meeting of this Institute for the present session took place on Monday evening last, Mr. Arthur Cates (Vice-President) in the chair.

The Chairman stated that the President had been invalided by the prevailing epidemic, and obliged to go to the Spanish coast to recruit his health. He hoped the President would return with renewed health and vigour.

The Chairman announced that a Preliminary Examination would be held on March 11 and 12. Forty-two candidates had applied to be admitted to this examination. Of these, seventeen, having satisfied the Board of Examiners, had been exempted, and would at once be registered as Probationers of the Insti-

tute. The remaining twenty-five, with the twenty who were relegated to their studies at the last examination, would come up for examination on March 11 and 12, at London, Bristol, and Manchester, the societies at the two latter places having agreed to hold examinations for the candidates resident in those districts.

Mr. John Slater, B.A., then read a paper on "Building Legislation," of which the following is an abstract:—The author said he considered the subject of the greatest practical interest, and that as our great cities were getting greater and more populous year by year, so its importance also increased,—although, speaking generally, it was regarded with apathy by the public at large. Having given statistics showing the enormous and rapid increase of the population of Greater London during the present century,—which increase was almost as great in the manufacturing districts of Lancashire and Yorkshire,—Mr. Slater asked whether the building regulations now in force, not only in the metropolis, but also in the majority of our great cities, were suitable and sufficient for the necessities of the present day. He thought not; and considered that the metropolis ought to have a Building Act which would be a model for other towns. For many years the Roman law, of which nearly all our laws were developments or modifications, referred only to landed property, and not to houses; but about 202 B.C. the population of Rome increased rapidly, and from that period dated laws relating to buildings, and (1) the institution of the party-wall, with its rights and obligations on the owners on each side thereof; (2) regulations as to carrying off rain-water; and (3) rights of light and prospect. Both in Roman and Byzantine regulations powers were found to control the height of buildings. The earliest regulations in the metropolis were *Fito-Aiywina* Acts of Building, passed in the first year of Richard I., exactly 700 years ago, the general intention of which was very similar to that of the present Building Act. The author then gave some interesting quotations from these regulations, which were to be found in the *Liber Albus* of the City of London, compiled in 1419 by John Carpenter, the Town Clerk. He then briefly referred to several Acts, down to that of 1844, which though manifestly imperfect, was in many of its provisions superior to the 1855 Act. (1) It provided a special court of appeal; (2) it placed the buildings, which were now entirely exempted from all superintendence, under special supervision; (3) the regulations as to carrying out work to any party structure were less likely to lead to dispute than in the existing Act; (4) it contained regulations as to drainage and as to width of streets, which certainly ought to be comprised in any Building Act; and (5) it contained better and more complete regulations as to footings of walls than the present Act or by-laws. There were at present no fewer than fourteen separate Acts in force in the metropolis, while the County Council were promoting a Barking Creek Bill, containing other amendments affecting building law. It was essential that all regulations as to streets and buildings should be codified and embodied in a single document, and that piecemeal legislation should cease. The Act should regulate the width, construction, sewerage, and gradient of all new streets, the line of frontage of the houses, and should provide for a sufficient number of adequate open spaces. It should define clearly the difference between public and private buildings; should exercise control over the situation and construction of the former, and the means of ingress and egress. To secure the prevention of fire, due stability, and healthiness in all buildings, it should control the site; the construction of foundations, walls, floors, roofs, and chimneys; the drainage; the amount of space about a building; and the height of the building in connexion with its position. It should provide an executive for carrying out its provisions, and a special court of appeal for all disputed matters. Regulations as to noxious trades, infectious diseases, common lodging-houses, &c., should be relegated to a special sanitary code, as in New York.

Mr. Slater then dealt at considerable length with the foregoing points one by one. The present regulation as to the width of new streets—that they shall be at least 40 ft. wide—was not sufficient; for a much-used thoroughfare there should be a carriage-way not less than 42 ft. The definition of a public building should be as wide as possible, and none

* The Classic chimera had the head of a lion, the body of a goat, the tail of a dragon, and vomited fire.

should be allowed to be erected with a frontage to one street only. The Manchester new draft Bill contained many improvements, and be congratulated the Manchester Society of Architects upon the result of their representations to the Corporation. The restriction as to cubical contents was unnecessary as a hard-and-fast rule, and there ought to be a discretionary power of allowing larger buildings to be erected, if the authorities were satisfied with their construction. With the increased knowledge of the behaviour of stone and iron under heat, it was absolutely criminal to allow stone staircases carried on unprotected iron supports in buildings used as flats; and, in fact, all the provisions as to fire-resisting construction needed remodelling. The securing of due stability was an important point, and perhaps the most crying defect in the Buildings Acts was that the controlling officers had no power whatever over the materials used other than bricks and mortar. It would not be difficult to frame a schedule which should stipulate, for instance, that lead for gutters should be of not less than, say, 5 lbs. per foot super.; that zinc should be not less than 16 ozs., &c. It was also time that some regulations as to the use of iron in buildings should be laid down—such as, for instance, the minimum depth of a girder spanning a certain opening. If such details were not to be provided for, then the superintending officials should be empowered to satisfy themselves as to the stability in each individual case, and be made responsible. With regard to drainage, he thought the sanitary officers of the various vestries did their duty well; but he considered a divided control unwise, and that the same officer should be responsible for both the erection of the building and its sanitation. Provision should be made for underground rooms being, to a certain extent, protected from the damp, either by the walls being built in cement or by forming a dry area. The close juxtaposition of the houses was a great evil in large cities, and a regulation prescribing a minimum distance between the backs of all houses, large or small, was most urgently needed. The existing provision was positively ridiculous, because it simply prescribed the area of the open space in the rear of a building. The minimum depth of that open space should depend on the height of the house, and should be at least equal to it. In the case of buildings facing public streets, the width of the street should govern the height of the house as a general rule, as in Paris, in nearly every city of the German Empire, and in Sweden. In the last-mentioned country streets 32 ft. wide and less might have houses 43 ft. high; up to 44 ft., houses 54–56 ft. high; and streets about 44 ft. might have houses 66 ft. high. Such stipulation was eminently reasonable, but power should be given to relax the rule in certain cases, provided the construction satisfied the controlling officer of the Building Department as to fire resistance, stability, &c. In order to avoid a monotonous skyline a clause might be framed to the effect that if the front of a building be carried up as a gable, then the limit should apply not to the apex, but to half-way up the gable. The regulation of the relations between adjoining owners as to works to party structures was then dealt with, and reference made to the 1844 Building Act, which had a very wise provision, under which, if the adjoining owner did not give his consent, the matter was referred to the District Surveyor, who was required to report on the matter to the court of appeal. With reference to light and air, a clause to the effect that a building owner should give notice of rebuilding to all parties who could be affected, and their surveyors empowered to investigate the matter and to decide by a majority whether the building would injure any one, and, if so, the compensation to be paid, or to absolutely veto the proposed rebuilding, would be an immense gain to a Building Act in a large city.

Even with a liberally-conceived, comprehensive Building Act, well drawn and lucid in its provisions, disputes would certainly arise. To whom were these to be referred? The great desideratum was that machinery for enforcing the law should be simple, direct, efficient, and inexpensive, and that there should be uniformity of procedure. At present it was precisely the reverse; and a special tribunal should be created fit to deal with building disputes. Having quoted clause 80 of the 1844 Building Act, Mr. Slater referred to a report of the late Mr. Justice Mellor and the late Mr. Joseph

Gwilt, who recommended that a tribunal should be constituted, consisting of two persons, one belonging to the legal and one to the architectural profession; and he believed, if due care were exercised in the selection of the individuals, this would form a very strong court. Referring to the administration of a Building Act, he considered a body like the District Surveyors should jealously guard against abuses; but there could be little doubt that abuses had crept in. If it were true that one District Surveyor had held office for years after he was totally unable to climb a ladder, his duties being done by a clerk—if it were a fact that another found two hours a week sufficient for the personal administration of a large district, nineteen-twentieths of the work again being done by a clerk—it was truly a state of things certainly not contemplated by the framers of the Building Act, and it was no wonder that the office had fallen somewhat into disrepute in the eyes of the County Council. But the greatest defect was incidental to the Act itself; it did not allow the District Surveyors to exercise the slightest discretion, or to take the least responsibility beyond seeing that the bare letter of the law was insisted upon. Many surveyors felt in a great deal of trouble, when they saw this insistence would inflict undoubted hardship, in order to minimise that hardship; but others would never hudge an inch from the *littera scripta*. If the surveyors were armed with discretionary powers, to be exercised on their own responsibility, they would always take care to have good reasons both for permissions and refusals; and such an alteration in the law would surely be welcome to all. In conclusion, Mr. Slater said the London County Council had not yet given due attention to the reform of the Building Acts; but it was essentially a matter for the Municipal Parliament to take up; and he looked forward confidently to the day—in the not far-distant future—when this great metropolis would be administered in accordance with the regulations of a model Building Act, and when London, in addition to being the largest, would be in a fair way to become (as she easily might) the best arranged, best built, most sanitary, and generally most magnificent city in the world.

The Chairman, in inviting discussion on Mr. Slater's paper, said that as he believed several gentlemen wished to speak at great length, and as the time at their disposal was rather short, they would not be able to conclude the discussion that evening. He therefore thought it would be well to adjourn the discussion at the close of the meeting to the 3rd of March.

Mr. E. C. Robins said that the paper was one of great interest to those who were endeavouring to do their duty to the public at the present time. He agreed with a great deal that Mr. Slater had said, and the question of the heights of buildings was one which had always had attractions for him. He believed London was suffering from a plethora of buildings by no means suited to the position in which they were found, and which were getting out of all scale. Another important question, too, was that of air-space, and the building in Broadhurst-gardens, referred to by Mr. Slater, were a case in point. In a great city like London it was difficult to lay down hard and fast rules, but if they got a set of principles recognised by a body constituted for that purpose, it could not fail to effect a great improvement in the Building Act. There ought to be a consolidation of the Sanitary as well as of the Buildings Acts, and instead of permissive clauses, allowing public bodies to do certain things, there should be done. The independence and the proper qualification of sanitary officers was especially needed.

Mr. Henry Dawson said he rose because he could see there was a very urgent necessity for some action being taken on account, not of the committed acts of the County Council, but on account of their omissions. He referred to a most important announcement they had made—he did not say officially, although it was in some respects what might be called official—that they did not intend in future to exercise the power given them under the Metropolitan Building Act of 1855—to allow any excess of openings over solids in external walls giving light to buildings, and that they would not allow any departure from the strict letter of the 13th Section.

The Chairman: Which says that the openings shall not exceed one-half.

Mr. Dawson continued that the 13th Section of the old Act required that the openings in any external wall should not exceed the area of the solids. In cities like London, Glasgow, or Edinburgh, the areas, limited not only sometimes in front, but at the rear of the buildings, made it positively necessary that the openings should exceed the area of the solids. The County Council, in their supposed wisdom—but what he would rather call their ignorance—had put it forth that they did not intend in future that the external walls should have openings in them greater in superficial area than half of the entire elevation. Now that would really be a serious hindrance to all building, and he did not know any body so well fitted as that Institute to take urgent measures, in connexion with other bodies, before Parliament or otherwise, if the County Council persisted in their attitude on this question. They ought to be allowed to have the openings of any size, so long as the construction should be declared sufficient to carry the weights intended to be carried. In a city like London, the access of light to buildings was the one essential thing, not merely for health, but for the purpose of carrying on trades and manufactures of various kinds. He was aware that this subject was under the consideration of the Council Standing Committee of the Institute, and provided that they were really proposing to do something practical in the matter, he did not desire to push it any more than was necessary. But he would most earnestly urge upon the Council of the Institute that they should certainly put their shoulders to the wheel and insist that such a ridiculous clause as section 13 should no longer be insisted upon where not necessary. He was glad that the discussion on the paper was to be postponed until March 3, but this matter should not be left even until then. Some protest should be made in regard to the Bill of the County Council, and to obtain some provision which would prevent the necessity for insisting upon the clause he had referred to.

Mr. Charles Fowler proposed a vote of thanks to Mr. Slater for his excellent paper, which he considered very opportune when the London County Council were making certain propositions for the amendment of the existing Building Acts. It gave them the opportunity of making representations to the London County Council as to what their views might be, which in itself was an advantage. He had marked a few matters which Mr. Slater had mentioned in his paper. Mr. Slater had stated that the first time when Building Surveyors, now termed District Surveyors, were appointed was under the Act of George III., but he (the speaker) had always understood that the Act of Charles II. appointed Building Surveyors in London. As architects they would all agree that the regulation of the height of buildings in streets was most desirable. They might certainly differ as to the proportions of the height to the width of the streets, but they would all agree that it should be regulated.

There was at present a certain number of regulations, only applicable, however, to new streets, and power was vested in the old Metropolitan Board of Works, whose authority had been transferred to the London County Council, to exercise a discretionary power, though some might imagine that they had not exercised it wisely in regard to Northumberland-avenue. It appeared from Mr. Slater's paper that the Romans thought it a desirable thing to regulate the height of buildings, and we had, therefore, excellent authority for following in the steps of such a very practical people. Mr. Slater had mentioned the Act of Charles II., in which buildings were classed by rates, as was the case up to the time of the present Act, when the rates of buildings were superseeded with reference to the heights and lengths of walls. Mr. Slater seemed to think that the regulations with regard to party structures in the Act of 1814, which was superseded in 1856, were better in one respect than those which now existed. He also seemed to think that they led to less litigation, and that such matters were more easily settled in former days. He (the speaker) confessed he was not old enough to have acted under the old Act for a sufficient length of time to have had experience of the advantage of the regulations, but he should think the reverse was the case. It did not seem to him desirable to refer those questions, arising between adjoining owners, to the District Surveyor, but rather that they

should be left to a sort of civil settlement by each adjoining owner appointing a person to represent him, they, of course, appointing an umpire in case they did not agree. He confessed that, notwithstanding occasional failures, it appeared to him that the present method for settling party-wall cases was very good, and he fancied it could hardly be improved upon. Mr. Slater, in another part of his paper, had referred to a special tribunal, and most of them would think that such a tribunal would be an exceedingly desirable thing if they could get it. It was one of those things, however, which the House of Commons had the very greatest objection to, and certainly in the case of the Building Act their objection did appear to be warranted, because it was notorious that the Official Referees under the late Building Act were anything but successful. If they could get the principle admitted,—if the House of Commons would admit the principle,—then the questions might be discussed. He ventured to think that what Mr. Slater suggested, and what was suggested under the former Act, by those gentlemen who had to report, was not what he should have thought most likely to be successful. The architects would require a legal person to formulate their decisions, and he should have thought, if there had been a judge appointed with two professional architects as assessors, that would be more likely to work than having one of each profession, who, if they differed, would have great difficulty in settling the case. He considered that two architects, acting as assessors to a barrister, sitting as a judge, would be more likely to form a successful tribunal, and one which would commend itself to the whole of the profession. The subject of giving discretion to the County Council, who should have certain powers under the Act, was one of very great difficulty. If the powers of the County Council were qualified by the necessity of giving some reason for their decisions in certain cases, the result would no doubt be better. A body invested with so much discretionary power, which could be exercised by the majority of those attending, was a very dangerous tribunal indeed. But, if the Council had to give reasons or allowing or disallowing certain things, it would bring itself under the control of public opinion, as far as those decisions became public, and in that way any tendency to abuse which might arise would be very much checked. He considered the discretionary power in a great many things could be safely vested in the London County Council, subject to certain restrictions. Mr. Slater had slightly touched upon the regulation of other matters in the Building Act besides the mere thickness of walls. He was sorry to say that he had not sufficient time to look up some of the Provincial Acts, particularly that applying to Liverpool. That Act, he always understood, was framed under the advice of the late Sir William Tite, and he believed that it contained certain schedules with reference to the thickness of joists, girders, and so on. Those schedules appeared to work very well, and they might to a certain extent be embodied in a Metropolitan Building Act. The difficulty was very great in framing such schedules, but with competent advisers it might be done. In the case of iron girders certain weights per foot run might be assigned to certain spans, and if the regulations were framed under competent advice, he could quite imagine it could be done with advantage. With regard to officials to carry out the regulations of the Building Act, Mr. Slater had complimented the District Surveyors a good deal, by suggesting that discretionary powers should be given them in a great many instances. He was afraid, however, that many people were much averse to giving officials personages very considerable discretionary powers. They seemed to have a tendency to distrust the discretion of individuals; but he believed that to give a competent and reliable set of officials discretionary powers would be a great advantage.

Professor Kerr hoped that at the adjourned meeting, on March 3, the questions before them would be thoroughly discussed. He would only at present draw attention to one very excellent institution, which seemed to have been rather overlooked by Mr. Slater, namely, the District Surveyors' Association, which was, practically, a court of private appeal in all matters referring to the Building Act, and he could testify, was one of the most useful institutions the profession possessed. The

gentlemen composing it were associated together for the purpose of avoiding everything like a stumbling-block to the efficient performance of their duties as servants of the public. Consequently, when any one had a difficulty with a District Surveyor, he should always ask him to refer it,—and he was bound to do so—to the District Surveyors' Association. A committee would be found there composed of very intelligent men, and they gave their very best attention to all disputed matters submitted to them. If his opinion was worth anything, it might be taken as an assurance that any question which was submitted to that very large committee would be treated in a fair and reasonable spirit. He therefore hoped that in the coming discussion due weight would be given to the existence of that body, as a means of settling disputes without going to the magistrate. He had also always been in favour of the late Metropolitan Board of Works, and now of its successor the London County Council, usurping authority if they did not possess it, in order to get over such difficulties as must constantly occur in the administration of the Building Act. He did not believe that any court of law would object to Mr. Blashill being indirectly vested with power to give his decision upon many questions in dispute, which would be thus intercepted on their way to the Law Courts.

The Chairman: I understand you will take part in the discussion at the adjourned meeting?

Professor Kerr: Yes.

Mr. Edwin T. Hall said that the Practice Standing Committee of the Institute had those matters very fully before them. They had had a Sub-committee dealing twice with the subject already, and he held in his hand a draft document which contained some seventy suggestions for the amendment of the Building Act, and it was probable that on the following day the Committee might authorise the publication of this document in the Institute's *Journal of Proceedings*, as a text to bring the subject to the notice of members. He hoped that every member of the Institute would forward to this Committee any suggestions they might have to make in regard to difficulties they had experienced and as to amendments which they desired to see adopted. These would be taken into consideration at once. He might say that the Practice Standing Committee had received the greatest assistance from the District Surveyors' Association, on more than one occasion, in dealing with matters connected with the Metropolitan Building Act.

The Chairman said he thought it was very desirable that the suggestions referred to should be printed in the *Journal of Proceedings* to be issued on the following Thursday.

Mr. Hall replied that no doubt they would be ready for publication.

The Chairman said he also considered that Mr. Slater's paper should form the foundation of action by the Institute on the matter before them. It might be in the knowledge of the members that the President of the Local Government Board had under consideration a Bill for the consolidation of all the sanitary legislation of the metropolis. That was announced in the Queen's Speech, and there was one section of the legislation, to which Mr. Slater had alluded, now under consideration. Therefore the present would be an opportune moment for bringing before the notice of the Government the absolute necessity for some legislation for building, on the lines suggested by Mr. Slater.

Mr. D. T. Hall said that, incomplete as was the text he had referred to, it would pave the way for a good discussion at the adjourned meeting, and if members would communicate their suggestions to the Committee it would enable them to prepare a document more or less complete, which would be of great service to the London County Council and the public generally.

The Chairman remarked that, if the suggestions could not be published in the *Journal of Proceedings* that week, he believed it would be well to send them round to the members in a printed form.

Professor T. Roger Smith moved that Mr. Slater's paper should be printed and circulated amongst the members before the next meeting.

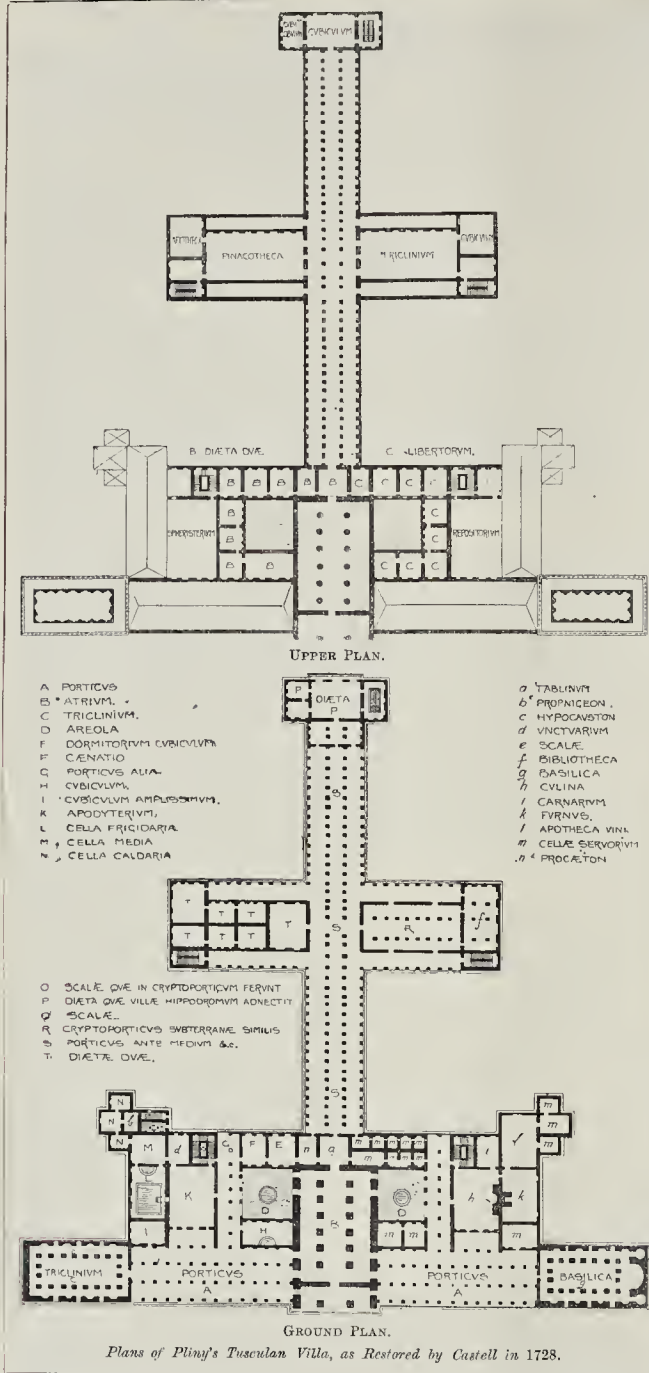

Mr. Rickman seconded the motion, which was unanimously agreed to.

Mr. Hall moved the adjournment of the debate to the 3rd of March, and the meeting then stood adjourned.

PLINY'S TUSCULAN VILLA.

WE anjoin the plans of Pliny's Tusculan villa as restored by Castell (1728), and given as illustrations to Professor Aitchison's second Royal Academy lecture. The following is Pliny's description (translated by the Rev. F. T. Bosanquet), which, as before observed, we withheld from giving in its place in the lecture till we could have opportunity of giving the plans along with it:—

"The greater part of the house has a southern aspect, and seems to invite the afternoon sun in summer (but rather earlier in the winter) into a broad and proportionately long portico (Porticum Latum), consisting of several rooms, particularly a court (Atrium) of antique fashion. In front of the portico is a sort of terrace (Xystus), edged with box and shrubs, cut into different shapes. You descend from the terrace by an easy slope adorned with the figures of animals in box, facing each other, to a lawn overgrown with the soft— I had almost said the liquid acanthus; this is surrounded by a walk enclosed with evergreens, shaped into a variety of forms. Beyond it is the gestatio, laid out in the form of a circus running round the multiform box-edge, and the dwarf trees, which are cut quite close. The whole is fenced in with a wall completely covered by box cut into steps, all the way up to the top. On the outside of the wall lies a meadow that owes as many beauties to nature as all I have been describing *within* does to art; at the end of which are open plain and numerous other meadows and copses. From the extremity of the portico, a large dining-room (Triclinium) runs out, opening upon one end of the terrace; while from the windows there is a very extensive view over the meadows up into the country, and from these you also see the terrace and the projecting wing of the house, together with the woods enclosing the adjacent hippodrome. Almost opposite the centre of the portico, and rather to the back, stands a summer-house (Dieta), enclosing a small area shaded by four plane-trees, in the midst of which rises a marble fountain (Labrum), which gently plays upon the roots of the plane-trees and upon the grass plots underneath them. This summer-house has a bedroom (Dormitorium cubiculum) in it, free from every sort of noise, and which the light itself cannot penetrate, together with a common dining-room (Cenatio) I use when I have none but intimate friends with me. A second portico looks upon this little area, and has the same view as the other I have just been describing. There is, besides, another room, which, being situate close to the nearest plane-tree, enjoys a constant shade and green. Its sides are encrusted with carved marble up to the ceiling (podio tenus), while above the marble a foliage is painted with birds among the branches, which has an effect altogether as agreeable as that of the carving, at the foot of which a little fountain, playing through several small pipes into a vase (Crater) encloses, produces a most pleasing murmur. From a corner of the portico you enter a very large bed-chamber (Cubiculum) opposite the large dining-room (Triclinium), which from some of its windows has a view of the terrace, and from others of the meadow, as those in the front look upon a cascade, which entertains at once both the eye and the ear, for the water, dashing from a great height, foams over the marble basin which receives it below. This room is extremely warm in winter, lying much exposed to the sun, and on a cloudy day the heat of the adjoining stove (Hypocaustum) very well supplies its absence. Leaving this room you pass through a good-sized pleasant undressing room (Apodyterium) into the cold-bath room, in which is a large, gloomy bath; but if you are inclined to swim more at large, or, in warmer water, in the middle of the area stands a wide basin for that purpose, and near it a reservoir from which you may be supplied with cold water to brace yourself again, if you should find you are too much relaxed by the warm. Adjoining the cold bath is one of a medium degree of heat, which enjoys the kindly warmth of the sun, but not so intensely as the hot bath, which projects farther. This last consists of three several compartments, each of different degrees of heat; the two former lie open to the full sun; the latter, though not much exposed to its heat, receives an equal share of its light. Over the undressing-room is built the tennis-court, which admits of different kinds of games, and different

sets of players. Not far from the baths is the staircase (Scala), leading to the enclosed portico (Cryptoportions), three rooms (Dietae) intervening. One of these looks out upon the little area with the four plane-trees round it; the other upon the meadows, and from the third you have a view of several vineyards, so that each has a different one, and looks toward a different point of the heavens. At the upper end of the enclosed portico, and, indeed, taken off from it, is a room (Cnbiolum) that looks

out upon the hippodrome, the vineyards, and the mountains; adjoining is a room (Cnbiolum) which has a full exposure to the sun, especially in winter, and out of which runs another (Dieta) connecting the hippodrome with the house. This forms the front. On the sunny side rises an enclosed portico, which not only looks out upon the vineyards, but seems almost to touch them. From the middle of this portico you enter a dining-room (Triclinium) cooled by the wholesome breezes

from the Apennine valleys; from the windows behind, which are extremely large, there is a close view of the vineyards, and from the folding-doors, through the summer portico (Cryptoportions). Along that side of the dining-room where there are no windows, runs a private staircase for greater convenience in serving up when I give an entertainment. At the farther end is a sleeping-room (Cnbiolum), with a look out upon the vineyards, and (what is equally agreeable) the portico underneath this room is an enclosed portico, resembling a grove, which, enjoying in the midst of summer heats its own natural coolness, neither admits nor wants external air. After you have passed both these porticoes (Cryptoportions), at the end of the dining-room stands " (this is hardly a translation, Pliny says "begins the portico") "a third, which, according as the day is more or less advanced, serves either for winter or summer use. It leads to two different apartments (Dietae), one containing four chambers, the other three, which enjoy by turns both sun and shade." I have omitted the east summer-house.

Houses are built not only to protect people from the inclemency of the weather, but to afford conveniences for the avocations they pursue, and for the recreations they indulge in; so there is no need of apology for giving the account of how Pliny passed his time there.

Illustrations.

ILLUSTRATIONS OF CAMBRIDGE.

WE give in this number reproductions in ink-photo of two of Mr. Fulleylove's charming series of water-colours of Cambridge which, as before noticed, are now being exhibited at the Fine Art Society's Galleries. These of course do not convey the charm of colour which belongs to many of these drawings, to none more than to that of "The Conduit" which is such a well-known object in the centre of the great court of Trinity College. Architecturally perhaps "Wren's Bridge," giving access to John's College from "the backs," is the more interesting; with the gate and gate-piers it forms an effective contrast, in its quiet stateliness of effect, with the more homely and domestic character of the residential buildings. It is curious to see the Gothic feature of the sloped set-off in the bridge buttresses, introduced here for practical reasons as the easiest way of connecting the necessary cut-water form, on the up-stream side of the pier, with the pilaster above.

WREXHAM CHURCH TOWER.

THE peculiar interest of the fine tower at Wrexham (which we may observe is not actually in Shropshire as stated in the plate title, but in Denbighshire, though not far from the Shropshire border) consists in the fact that in style, proportion, and general architectural treatment it is essentially a Somersetshire Tower which has found its way north by some accident, and acts as a surprise in this respect to the architectural traveller and sketcher, who is not expecting to meet anything of this character on the north-east border of Wales. Whether there was any local reason, any connexion with Somersetshire at the time, to account for this, there is no record.

Mr. Arnold Mitchell's drawing reproduces very faithfully the design and architectural effect of this interesting tower.

CHISWICK PARISH CHURCH.

THE window to-day illustrated is the centre one of three on the N. side of Chiswick Parish Church, the design of which was required to illustrate the building of Solomon's Temple.

Centre window.
David with plan of Temple. } Through the base of Solomon with model of Temple. } the four lights a small processional subject of the dedication of the Temple.
Hiram, King of Tyre. } }
The Chief Priest (Zadok). } Solomon. The Elders of Israel. }
The bearers of the ark and a band of choristers. }

The first and third windows are designed to complete the scheme. SHRIGLEY & HUNT.

Wrexham Tower:
from the South

WREXHAM TOWER, SHROPSHIRE.—FROM A DRAWING BY MR. ARNOLD B. MITCHELL, A.R.I.B.A.

PHOTO LITHO. SIMMONS & CO. 22, HANBURY PLACE, LONDON, E.C.

PLAN OF THE PALACE OF THE CÆSARS.

These are reproduced, by permission, from the measured plan and restoration by M. Deglaine, one of the most talented and distinguished of the younger generation of French archaeological architects, originally published in the *Moniteur des Architectes*. They are given here in order to illustrate Professor Atchison's Royal Academy lectures on Roman Architecture.

They are specially referred to in the fifth lecture, which will be published in our next, when we will give some further plans in illustration of the subject.

ON SOME TYPICAL GREEK BUILDINGS.*

I am glad to believe that an increasing number of English architectural students are showing their interest in Greek work by visiting the country and examining the remains of the buildings in their original place, and I only hope that this paper may have some influence in increasing this number. I am sure that any one who does so will gain very valuable lessons, even though he may never care, or have the opportunity, to erect a modern building in either of the Greek styles. There never has been a period since the time, some two centuries ago, when the Parthenon still stood practically complete, when a visit to Greece would so well repay the architectural student. Archaeological societies—Greek, French, German,—have, with infinite care and pains, and at great expense, laid open buildings for decades, if not centuries, buried and unknown, and full of instructive points; and equally important excavations have been carried on by Dr. Schliemann in his private capacity.

It may not be out of place here to say that Athens cannot be considered now an out-of-the-way place to visit. There are several routes; the one I myself prefer is *via* Marseilles, and by this route travelling expenses out and back need not amount to more than 20*l.*, nor the time occupied in travel exceed about eleven days. Athens, itself and alone, is well worth a visit, though, of course, when once there, it seems desirable if possible to see at least two or three of the other sites; and any student going out properly accredited will find every facility put in his way for pursuing his studies both by the Greek archaeological officials and by the Directors of the English and American Schools. Any one acquainted with German will receive equal consideration from the Director of the German School, who has no equal in the practical acquaintance with the buildings themselves, except Mr. Penrose.

It seemed to me, in selecting a subject for this paper, that it would be better to take a few characteristic buildings, and examine them in detail and with some care, rather than to visit hurriedly a large number of sites.

I propose to refer briefly to three buildings which we may take as representing the domestic, secular, and sacred architecture of the Greeks, viz.,—the Palace at Tiryns, the Propylæa, and the Erechtheion of the Athenian Acropolis. The last of these is also a wonderfully beautiful example of the use of the Ionic order, while the second illustrates the very best period of the Doric order, and all three are specimens of the magnificence and freedom of Greek planning. And I may, perhaps, confess that the possibility of adequately illustrating them to you, either by means of photographs or diagrams, had its influence upon the selection of these buildings for our purpose. At the same time, I shall not scruple to show you a few photographs of other buildings, which may assist us to understand them more completely.

Of the three buildings which we are to consider, by far the oldest is the Palace at Tiryns, though six years ago its existence was unknown, and, by most people at least, undreamt of. It is, perhaps, therefore suitable that we should consider it in the first place, more especially as we shall discover in it the beginnings of much of the later Greek art and architecture.

The citadel of Tiryns occupies a magnificent position near the sea, overlooking the Bay of Nafplia. The rock rises abruptly out of the level plain, and nowhere is there any eminence that, in the days before artillery was introduced, could command it. The natural features of the rock were seized upon by the Greeks, and form the key to its fortifications, which were adapted to it with great skill; they are said to be the

most massive of their kind in Greece, and possess several points of great interest. But we must not linger over them, and I can only refer any student who wishes a more detailed account of the walls or the palace to Dr. Dorpfeld's account of them contained in chap. v. of Dr. Schliemann's "Tiryns."

Suffice it to say that, owing to the form of the rock, three more or less separate forts existed within the outer ramparts,—the lower, the middle, and the highest,—and that crowning the last, and occupying the greater part of it, stood the king's palace. The materials used in its construction,—clay, either beaten hard or used as mortar or cement, or as sun-dried bricks; lime, and wood; while in the decoration of its surface, plaster covered with coloured decoration, carved alabaster, and almost certainly bronze plates, were employed. The plan of this fortress-palace, though not perfectly preserved, approaches being so, and is far less incomplete than the palaces at Mycenæ or Troy, or the fragments of Erechtheus's palace on the Athenian Acropolis, and all three have many points of similarity both in plan and construction.

At Tiryns, having passed through the fortress-wall, not an easy matter in the old days for any but a friend, we approach the outer gate of the palace. This gives admittance to a large open space, devoid of building. After traversing this we reach the outer or great Propylæum, with an outer and an inner portico, the forerunner in every essential particular of the great Propylæa at Athens, and of many others. Each portico takes the form of a distyle in antis, while the wall of the gate is pierced by a single opening in the centre, whose great folding-doors stood, not between the jambs, but inside them, and their bronze-covered pivots worked in circular holes cut in the stone of the threshold, which was much wider than the wall. From the inner portico a door admits the visitor to a long winding passage leading to the women's apartments, and just beyond the portico a short passage gives a side entrance to the court of the men's apartments. This Propylæum gives direct admission to a large outer court of irregular form; the buildings enclosing it to the south and west have been either largely obliterated by later buildings, or slipped down the hill with the line of fortification, which gave way here. On the north side they are more perfect, and it is possible to trace distinctly the line of the small Propylæum giving access to the court of the men's apartments. This gateway was similar to the great Propylæum, having an outer and inner portico, and the gate-wall was provided with folding-doors. The court-yard to which this gave admission was large, about 65 ft. by 50 ft., clear of the porticoes which surrounded it on three sides, the east, south, and west; this court was paved, and so also was the outer one already referred to, with concrete and laid so as to clear itself of water. Nearly in the centre of the south side was placed the great altar of Zeus, which is on the axial line of the vestibule which occupied the greater part of the north side of the court. The front of this vestibule took the form of a temple in antis, and was raised on two steps, forming a stylobate. The bases of the two columns and of the ante remain; these below the ground level are of irregular form, but above they are carefully squared to the line of the wall. This also is the usual treatment of the thresholds here, but at Mycenæ they are squared throughout. The bases of the ante have their tops rebated and drilled with a series of holes for wooden dowels. In general the base stones at Tiryns are from 18 in. to 2 ft. high. The upper part of the ante was formed of timber beams placed in juxtaposition side by side, and dowelled to the base, and probably to each other; and these would carry the ends of the lintels, probably formed in a similar way of more than one piece, as was the case later with the great stone architraves of the Parthenon and other temples. The side walls of this vestibule were decorated with slabs of alabaster, richly carved and inlaid with glass. Three pairs of doors hung folding between the jambs gave access to an ante-chamber, from which an opening, not, however, provided with a door, led to the megaron, or principal men's apartment, which was over 30 ft. wide and nearly 40 ft. deep. In the centre are the bases for four wooden pillars which helped to carry the roof, and between them are traces of the large circular clay hearth, found in much

greater perfection in Mycenæ; the floor of the

hall was of concrete, ornamented with a rectangular pattern in incised lines. Of course any restoration of elevations or sections is somewhat uncertain. The walls in the upper parts were of perishable materials—wood and sun-dried bricks—and these fell an easy prey to the fire which destroyed the Temple. The roof was almost certainly flat, and made of clay on a layer of rushes, and the room may have been lighted either by openings in the walls or by having a portion of the roof raised as a simple clear-story or central lantern. From the ante-chamber access is also obtained to the bath-room, which could also be reached from the men's court. The floor of this room was formed by one single stone, sunk and polished and drilled with dowel-holes for a wood lining to the room, and was provided with a movable terracotta bath and with a drain; this bath adjoins a long and winding corridor, out of which several rooms, whose exact purpose it is difficult to determine, opened. It also led to the staircase to the middle fortress, and eventually to the women's apartments, and may have been intended for the use of servants or slaves.

The women's apartments, in general arrangement, closely copy the men's, but they are smaller, and the two sets have no direct communication. The long passage from the inner portico of the great Propylæum gives access through a stoa on its west side to an open court; this communicated directly with the inner court of the women, which had stoa on its east, and on part of its north side. The rest of the north side was occupied with the vestibule to the women's hall, and with the entrance to the corridor which ran round them. This court was drained into the channel from the bath, already referred to, which was formed of rectangular terra-cotta channel pipes which fitted into each other.

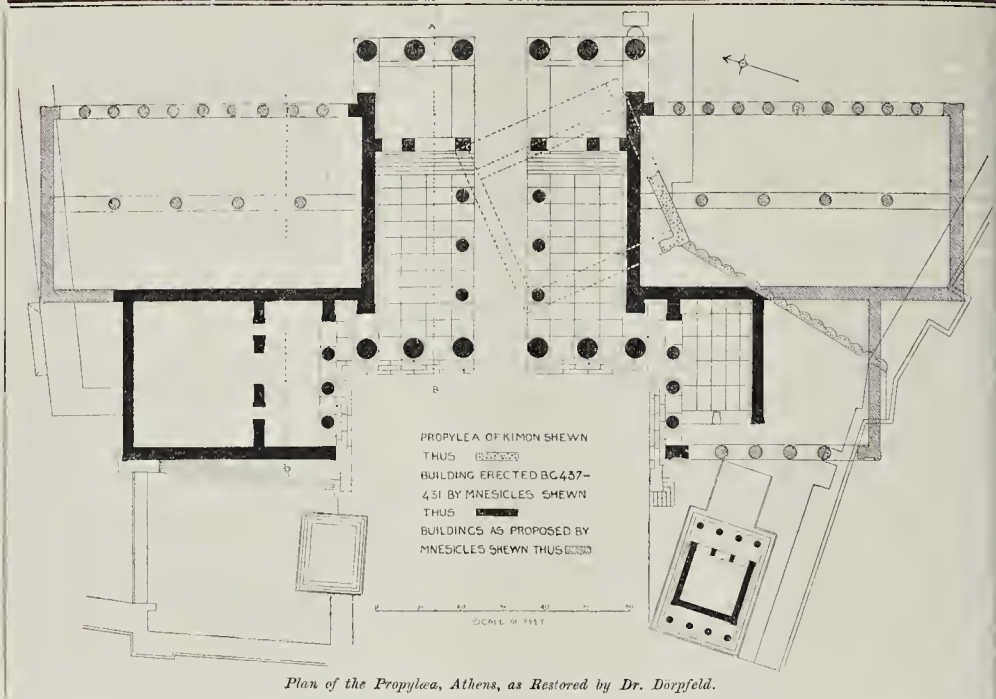

The south side of the vestibule is quite open; the span is about 18 ft., and therefore a lintel would not require intermediate support. This vestibule is nearly square; east and west doors lead into the surrounding corridor, and on the north side a single door, about 5 ft. 3 in. wide, leads to the women's hall; this door is of special interest, for in the pivot-hole the great bronze pivot was actually found. In the centre of the hall there seems to have been a square hearth. East of this hall are several well-defined rooms, grouped together, and only accessible from the surrounding corridor; they probably comprised the King and Queen's sleeping-chamber, with a vestibule, while a small passage gives access to inner rooms, which formed the treasury and armoury; south of this passage is probably the position of the staircase leading to the roof.

A few other rooms are accessible directly from the women's outer court; their exact purpose cannot be at all definitely fixed, but the most important rooms of the palace have been passed in review, and there is but little question as to their identification.

To refer to a few general particulars as to construction, &c., the walls of these rooms stand, for a height mostly of from 1 ft. 6 in. to 3 ft., the lower portions being constructed of stone; above this height the walls seem to have been constructed of timber and sun-dried bricks, and were usually from 2 ft. 6 in. to 4 ft. 6 in. thick. Both the upper and lower parts of the walls, external as well as internal, were coated with clay and then lime plaster; the latter was painted in various colours, subjects being introduced as well as geometrical patterns. The ante, as we have seen, had usually solid stone bases, the upper parts being formed of massive timbers forming an end to the wall. It is probable that these timbers, and also the wooden columns of the porticoes and the megaron, were encased with bronze plates; fragments of such plates belonging to a column were found at Mycenæ, and it is supposed that the interior of the vast chamber known as the Treasury of Atreus was extensively, if not entirely, lined with a similar skin of bronze.

The thresholds were, with one or two exceptions, of stone, of irregular form, but all, excepting a broad central band, which was carefully worked to the width of the wall and stood slightly above the finished floor-level, was worked down so as to allow the floor to be carried up to the wall-line evenly throughout. The roofs were probably flat, formed of massive timbers, which carried, as already stated, reeds, and above them clay; this forms a heavy but good roof if well looked after during the wet season, and is still in general use throughout the East. There may have been an upper story

*From a paper by Mr. R. Eusey Smith, A.R.I.B.A., read before the Architectural Association on the 14th inst., as elsewhere mentioned.

Plan of the Propylea, Athens, as Restored by Dr. Dörpfeld.

over a good portion of it; at any rate, it is probable that there would be at least summer sleeping apartments.

This is one of the earliest Greek buildings of which we have any extensive remains, and belongs, probably, to the sixth century B.C., or possibly an earlier date even. It was certainly finally destroyed in the early part of the fifth century, but the Mycenaean palace, which is of later rather than earlier construction, certainly cannot be later than the eighth century. We have thus a not incomplete idea of a palace of an early Greek king, and are able, in conjunction with the discoveries in the Mycenaean tombs, to form some idea of the splendour of their homes. They were essentially warriors, and probably there was little in the way of what we should consider luxury in their manner of living, but their fortresses and palaces were magnificently constructed, and the latter richly adorned, and their armour and weapons and utensils were often of precious material and most delicate and graceful workmanship.

But, apart from the interest that attaches to whatever may help us to realise the life of the old Greek heroes, of whom we have all heard or read, this palace possesses a very genuine architectural interest, for in it we find evidence of the origin of much that we shall encounter in our study of the later marble architecture; and here already the difficulties of a trabecated system of architecture have been encountered and overcome. In the megaron of the men, for instance, we have an arrangement almost exactly repeated in the episthodomus of the Parthenon. Here, too, we perceive the constructional *raison d'être* of the anta, which was repeated in the early stone and marble architecture, but which ceased to have any real purpose, other than an artistic one, in those buildings which were entirely constructed of marble, and where this feature becomes purely ornamental. We detect, also, the fondness of the Greeks for colonnades or porticoes, a necessity, indeed, of the climate. The system of decorating walls with bronze plates may suggest an origin for the great friezes of later days. We notice, too, great facility in adapting the plan to the limits of the site and to its special requirements, and the importance they attached to a magnificent and stately approach to an important building.

If we endeavour for a moment to realise the effect produced on a visitor to the Palace in all its glory we cannot imagine it to have been otherwise than a striking and grand one, for

which the plan seems eminently adapted. The angle at which the great Propyleum is set to the little one would bring the latter at once into view in passing through the entrance-door; it would, moreover, produce a pleasing variety in shade effects, a point which the Greeks seem to have studied with the utmost care, and notably so in the arrangement of the buildings on the Athenian Acropolis. The outer court itself was probably in some way shaped up, as suggested by its outline now appears; and the small Propyleum led on thence to the Court, with its colonnades casting deep and welcome shadows, and through the pillars of the vestibule and the triple doors of the ante-room to the dimly-lit megaron itself. The whole was rich with colour, alabaster, and bronze, and probably further beautified with splendid textiles. The women's apartments would produce somewhat the same effect on a smaller scale. Of the proportions in elevation it is not safe to speak, but, at any rate, the important rooms, as far as planning is concerned, seem well considered and grouped, and at least to approach nearly to the simple relative proportions so markedly employed later.

No better example of their delight in lavish expenditure of thought and labour over the erection of an imposing portal can be brought forward than the Propylea at Athens, yet this is but an elaboration of the principle contained in the Propyleum at Tiryns, carried out on a magnificent scale and with the very finest materials and workmanship.

The word Propylea means simply "before the gateways," and signifies the colonnade of the entrance either to a sacred precinct, or, as in the case under consideration, to a fortress or some other enclosure. Other examples may be found at Eleusis, Argina, Epidaurus, &c., but none equalled in magnificence that at Athens.

The older gateway of Kimon, of which remains exist, was on a more modest scale, and was partly built of limestone faced with marble slabs or stucco, and with marble antae, and probably columns. The present building was commenced the year following that in which the Parthenon was dedicated, when mechanical skill and mathematical science had reached the utmost perfection, and was planned on a truly magnificent scale. The entire scheme was never carried out; what the true cause of its being abandoned may have been is not quite certain, and does not greatly matter to us, but the Peloponnesian War brought work to a final standstill in 431 B.C., and at this time no por-

tion of the building was finished, and much of it not commenced, or up to foundation level only.

The line of the wall of marble which contains the actual gateways is approximately north and south, and to the west and east were two great hexastyle porticoes; the western one is very deep, and is flanked on either hand by less important porticoes with buildings behind. Somewhat similar but more extensive buildings were designed to flank the eastern portico, but were never carried out, though traces showing the starting and position of them remain. The site presented great difficulties—it was irregular, uneven, and with a very rapid fall to the west—but so skilfully were the very difficulties turned to account, and so admirably does the building fit its site, that they may readily be overlooked; and the whole design is so natural and straightforward that the effect produced on the mind seems to be, that it could hardly have been treated differently.

I have given a brief outline of the original scheme, which will be readily understood from the plan.* I wish now to describe briefly the portions coloured black, those that were actually erected, and which still remain more or less complete. They comprise, briefly, the wall of the gateways; the east and west porticoes, both imperfect, the north-west wing, complete, except for the roof, and a small part of the south-west wing.

A magnificent flight of steps, flanking the approach for chariots, must have led up from the entrance below the temple of Nike to the level of the western or outer portico, which stands on a stylobate of four steps; but this approach no longer exists, and the steps now *in situ* are quite modern. The Doric portico, with a wide intercolumniation in the centre, was surmounted by a pediment, while the two lines of slender Ionic columns behind each supported an immense architrave in a single block, extending the full depth of the portico; the beam is partially hollowed out, to reduce its weight. The wall containing the gates, and which stood on a lofty stylobate of five steps, is pierced by five openings, which were originally filled with

* The diagram from which our illustration is taken was enlarged from the small plan by Dr. Dörpfeld in the *Mittheilungen der German Archaeological Institute at Athens*, Vol. X., 1885. The plan of those portions of the building actually existing was corrected from Mr. Penrose's plan in his "Principles of Athenian Architecture," and in a few details from dimensions taken by Mr. R. Eisey Smith.

bronze doors: the central one (the largest) would be used by the Panathenaic procession, the two smaller side-doors being of comparatively small dimensions. The side walls of this portico undoubtedly had low seats running their whole length, and this would form a magnificent and convenient place of meeting and discussion. The eastern, or inner, portico had a similar elevation to the western, but the columns were raised on a continuous square plinth or stylobate.

The north-west chamber is fairly complete: its west wall stands on an earlier foundation in a different line, and to this the new work has been very cleverly adapted. This chamber is entirely enclosed by walls, the southern one being pierced with openings for a door and two windows, and having a portico of three columns further to the south. It is worthy of remark that the doorway does not come centrally with an intercolumniation. The columns of this portico were also of the Doric order, but on a very much smaller scale than those of the great porticoes. The roof to this wing was hipped, and, as usual, flat in pitch.

The opposite wing to this was never completed, but there is sufficient to show that the original design of this wing, while balancing the other in its total mass, differed widely in its plan, and no doubt in its uses. You will see, from a glance at the plan, that the portico here which exists, is similar in elevation to the opposite one, but is much deeper; and that the chamber, instead of being enclosed, and approached by a door, is open on its west side to another portico, whose columns occupy the line of the west wall of the corresponding wing. I wish to avoid touching on anything that may be considered merely of archaeological rather than of architectural interest, but I think it may be well to briefly refer to the reasons for the restoration of the original plan of this wing, which most certainly was never completed, and this will render necessary an allusion to an earlier epoch in the history of Greek architecture; but for this purpose we need not leave the present building, but merely consider the Propylæa of Kimon.

As was the case with many of the Greek buildings erected later than very archaic times, when marble was hardly used, but previous to the magnificent epoch of Pericles, when lavish expenditure was made, and marble used exclusively for the finest work, this earlier Propylæa was constructed partly of fine limestone and partly of marble. The walls were constructed of the former, but they were terminated, at least when they were in a line with a range of marble shafts, with blocks of marble forming the well-known antæ. These projected beyond the line of the wall, so as to stop the marble or plaster casing which was applied to the rougher material, and the width of the antæ was proportioned to the diameter of the column in connection with which it stood. We have seen instances at Tiryns of a still earlier treatment in wood, but very similar in purpose.

When buildings were entirely constructed of marble, the feature was copied in it, just as in earlier days we find the features of timber construction copied in stone, and observe the way in which it was adapted to various positions. Where it forms the termination to a wall in line with a range of columns, it has a broad face and narrow sides. But where it terminates a wall at right angles to a line of columns we have two broad faces and one narrow one. Bearing this in mind, let us examine the remains we have of the south-west wing, and see what they teach us. I should remark here that the pier occupying the angle between the north and west porticoes is not now *in situ*, but was until a few years ago. The blocks of which it was composed are close at hand. The plan of this pier clearly seems to point to the fact of its having formed an angle pier between two porticoes, for we find a broad face to come next a column, another broad face forming the termination of a wall, and with a narrow return, and then after a very short bit of wall we have another antæ, very clearly pointing to a line of columns running in a direction at right angles to the first portico. If we use now an intercolumniation identical with the north portico, in our attempt to construct the west one, the second column comes, as it should do, exactly opposite the antæ of the existing wall, and with four columns in all, this allows of an angle pier at the south-west angle similar to the one from which we set out. As this west portico was never built, a makeshift had to be adopted, and the small pier, of an entirely irregular and un-

usual form, was introduced to carry the architrave running from the end of the existing wall to the westernmost column of the existing portico, but in an irregular line.

I have dwelt on some length on this point firstly because it seems to me not unimportant to feel tolerably certain of any restoration that may be attempted of this building, which, without doubt, was second only to the Parthenon in hearty and in reputation amongst the Greeks; and secondly,—and this is to us of even more importance perhaps,—because it seems to me to be an instance of the care and thought that should be devoted to any building, whether Greek or Roman or Gothic, that it may fall to the lot of any one of us to restore, either on paper or in actual practice. As regards myself, I can only say that I cannot recall any single lecture or paper that I have heard or read that impressed me more and gave me a clearer idea of the method to be pursued in the examination of existing architectural buildings, and the importance of not disregarding the least bit of evidence, however apparently trivial, than the lecture I heard Dr. Dörpfeld deliver on the subject of the Propylæa on the spot, where he could point out each point as he referred to it. To that lecture I am largely indebted for a great part of any knowledge I possess of the building. The general surface of the walls seems to have been left unfinished, though this was not the case with the columns, and I may refer again to it when the lantern slides are thrown upon the screen, as also to the method of working the drums of the columns, which I recollect Mr. Penrose explaining here some years ago, and which I hope to be able to show you. The full-size mouldings shown on the walls were taken by my friend, Mr. Schultz, during the year I was in Athens. They strike one rather, I think, as being small in character and especially small in projection; were they executed in a coarse material and placed under the dull skies and smoky atmosphere of London they would, probably, not be very effective, but in the pure air of Greece the sun casts shadows as sharp and clear as possible, and every line tells, and the delicate material allows of very delicate treatment.

The Doric order, drawn to a small scale, is sometimes apt to look excessively severe, and possibly uninteresting. The same may, perhaps, be said of various reproductions of it in stone. It is, however, a different matter when you see it executed in marble, with perfectly true and sharp lines, and, as a result, perfectly true and delicate shadows. Even as a ruin the Propylæa produces an almost inexpressible effect of grandeur and magnificence. Turning round from under the Nike bastion one comes full upon it from below, and one can realise the object of the deep portico on the west side, for nearly the whole of its richly-decorated soffit, when it still existed, would have appeared at once to an old Greek visiting it; while the great pediment of the central portico would have towered above the hipped roofs of the wings. The break in the roof-level, which on a section seems unsightly, would from no point have been visible, except at such a distance as to be unobjectionable. One can nowadays sit down near the commencement of the steps under the shade of the bastion, and watch the sun, as it creeps round gradually, bring out new lines of light, and cast fresh shadows and deepen existing ones; and when all this took place, with the gloomy depths of the great portico and its gorgeous roof for a background, it must have been, indeed, a sight for gods and men.

Finally, we will make a short inspection of the Erechtheion, and though it is not from many points of view the most typical temple to have selected, it is a very interesting example of the variety and hearty that may be introduced into a Greek religious building, and further, it is a beautiful example of the Ionic order. Another reason which, I think, alone would justify me in its selection, is that when you have obtained some idea of the plan and elevations of the building, any of you who care to do so may examine for yourselves, and within a mile of this room, almost every detail of it. In the British Museum, between the Parthenon marbles and the new Phigaleian room, a great many fragments are collected together—an entire column, including cap and base, from the east portico,—the only column missing from the exterior of the building,—large portions of the architrave and cornice, and various smaller details. One or two fragments from the Propylæa, including a cap,—badly placed, how-

ever,—and the drum of a column and part of an architrave, may be seen in the same room.

Mr. J. Ferguson read a paper on this building before the Royal Institute of British Architects on February 14, 1876, but he confined his attention principally to the elucidation of the difficulties in connection with the arrangement of the interior. I dare say many of you know the paper; it is very learned, and seems to have proved his point, but I wish only just to refer to this interior which is destroyed, to show its effect on the existing exterior. It was divided internally, says Mr. Ferguson,—whose restoration has been, I believe, generally accepted,—by a cross wall into two distinct temples; the eastern one at the higher level was dedicated to Erechtheus, and the western, much lower, to Athene Polias, and this latter was the most sacred shrine on the whole Acropolis.

This arrangement naturally affects the exterior very largely. The position chosen for its erection is just at the point where the Acropolis rock commences to fall away rapidly. At the east end we find a hexastyle portico standing on a stylobate of three steps, with its architrave in position, and it would be complete but for the removal of the north-east column to the British Museum. Portions of the frieze of black marble also exist. The south wall remains throughout its whole length, but not to its full height. The stylobate and the base moulding of the antæ are continued; and, as usual, the first course of stone is very much deeper than any of the others. At the west end of this wall is situated the Caryatid portico, with six female figures, and these, though at a glance almost identical, reveal a great variety in their treatment as regards detail; to this point a uniform level has been maintained, but this portico is founded on the stylobate of a large early temple, and below it there is a sudden drop to the ground-level. The west façade had a blank wall for nearly half its height, with a plain central doorway; above this, the wall had attached columns, and was pierced with windows.

The north wall extends far enough beyond the west wall to obtain a doorway in it entirely outside the building, giving access to a courtyard to the west of the building, and entered from the great north portico; beside it is the principal doorway. This tetrastyle portico has six columns in all, and still retains part of its coffered ceiling; its floor level corresponds to that of the western doorway. The north wall is complete as regards its length, and at some point an external flight of steps between the building and the Acropolis wall must have led up to the higher level.

Sadly ruined as this building is, we are enabled to obtain a very fair idea of its general effect; from whatever point of view it is seen there is a charming variety of grouping and outline, and it is hardly possible to find a view in which at least two of the porticoes are not visible. Added to the hearty of outline, the delicate mouldings and the exquisite carving, which though employed with no niggard hand is concentrated on certain points, must have given the complete building an air of wonderful delicacy and refinement, and this was no doubt heightened by an extensive use of colour.

We have now considered more or less briefly each of the three buildings I proposed to describe to you. In the first case we had to confine our attention mainly to the plan and observe its clever grouping and variety of line, with the early promise of future development. The other two examples belong to the very best period of Greek art, and as regards style no more perfect examples of the Doric and Ionic orders are to be found, and it is interesting to contrast the two. In each case the materials and workmanship are the same, that is to say, literally the most perfect that it is possible to obtain. The Propylæa owes its impressiveness and dignity, which even in its present ruined state is undeniable, to the most careful grouping of the various parts, and its comparative massiveness, combined with the most accurate and carefully considered proportions of the relative parts and very delicate optical refinements. It is absolutely devoid of carving or sculpture, and there is no trace of such ever having existed; carving indeed was sparingly used in the Doric order, but sculpture was often used in a lavish way, as at the Parthenon; it was almost invariably set in some frame, such as the pediment or metope, and skilfully designed so that the main lines of

the groning should give a contrast to the enclosing lines. In the Ionic order as typified by the Erechtheon we find sculpture comparatively unimportant, though a sculptured frieze is by no means unusual; the carving of long lines of surfaces is, however, adopted; this is no doubt more suited to the slenderer proportion and more delicate effect of the composition. Before closing I should like to try and show you something of the effect produced by these buildings as they stand. Though for architectural purposes, including those of instruction, photography may be, in many ways, inferior to a good set of drawings, I believe no other means is so capable of conveying the effect of a building and its workmanship, even to a trained architect, as a good photograph, thrown on to a large screen, with the aid of a lantern. (Nearly thirty views were then shown on the screen and explained by the lecturer.)

[We must defer our report of the discussion until next week.]

FREE LECTURES TO ARTISANS AT CARPENTERS' HALL:

MR. BANISTER FLETCHER ON "THE ARCHITECTURE OF THE WORLD IN ALL AGES."

The first of this year's series of free lectures to artisans and others on matters connected with building, under the auspices of the Worshipful Company of Carpenters, was delivered on Wednesday, the 5th inst., by Mr. Banister Fletcher, J.P., F.R.I.B.A., Master of the Company, as already briefly mentioned. Sir John Lubbock, F.R.S., presided, and there was a large attendance.

Mr. Banister Fletcher, in his introductory remarks, referred to the necessity for art-training, and quoted a remark made by Mr. T. G. Jackson, M.A., at the Art-Congress at Liverpool in 1888, "that architects should train public taste." Asking the question, "What is Architecture?" the lecturer answered it by giving the following short definition:—"Architecture is the art of constructing buildings upon scientific principles with proportion and beauty." After quoting the late Mr. E. M. Barry's definition of architecture,—"a useful art as well as a fine art"—the lecturer proceeded to trace the history of the human habitation from the earliest times, quoting from Viollet-le-Duc and Gwilt, and pointing to enlarged copies of illustrations from the works of those writers in elucidation of his remarks. He next treated of the rock-cut cave dwellings and temples of India and Asia Minor. Passing on, he briefly and rapidly referred to the varied and characteristic forms of Egyptian, Assyrian, Hindu, Chinese, and Mexican architecture, and then described the main features of Greek and Roman architecture. Next came a description of Sarcenic architecture, with its developments in Syria, Persia, India, Turkey, and Spain. The lecturer then briefly treated of Romanesque, Gothic, and Renaissance work, and concluded by alluding to modern revivals. This is but an outline of the lecture, which covered so very wide a field, and necessarily extended to such length, that we cannot print it *in extenso*, having regard to the many other claims on our space just now. We give, however, the lecturer's concluding remarks: "In dealing with this vast subject to-night, I have treated it more as a short and concise history, from a superficial point of view, rather than as an architectural history dealing with the details; for it is too vast and great a subject to be so dealt with in a single lecture. But I have endeavoured to place before you the very many different types of architecture, showing how they each arose, and the reason for the fresh forms. I would again remind you that each type was the outcome of some distinct impulse. We have had in this country during this century a great impulse. I refer to steam and electricity. Compare the result of their introduction on ship-building with the result of their operation on architecture. In shipping they have created a new style: in architecture they have done practically *nil*. We have, it is true, large viaducts and lofty buildings, large hotels and termini, but there is no peculiar style. We meet to-day with Gothic, Greek, Moorish, &c. Surely there must be some reason for these incongruities? I think you will agree with me, it is due not only to a want of artistic feeling on the part of a people, but also to the great competition of the age, in which all join in striving to turn in as great a result as possible out of the least outlay of intellect or money. Much has of late years been done by city companies and kindred

institutions to educate the people, and to endeavor to create an artistic feeling, but much remains for us to do. As an illustration of what has been accomplished in a minor department, I would mention stage scenery. Compare it with that of thirty years ago, and the great improvement will be at once seen. Managers, ever quick to suit the taste of the public, have realised the necessity. In conclusion, I hope that this evening has been a pleasant one,—that the time spent among the glorious works of the past has given us elevating thoughts, an earnest desire to cultivate our taste, a longing for and power to appreciate the beautiful and good, and determined us, as far as in us lies, to make our buildings more architectresque and our homes more artistic."

PROFESSOR ROGER SMITH ON DRAWING: GEOMETRICAL AND PERSPECTIVE.

The second lecture of the series was delivered on Wednesday, the 12th inst., by Prof. T. Roger Smith, F.R.I.B.A., who observed at the outset that drawing was becoming more and more one of the "matters relating to building." Every difficult piece of construction was worked out on paper. Our contracts were arranged, our estimates were made on the basis of plans and drawings, and these were consulted every hour during the progress of any important building; while the deposit of plans of sites, drains, and buildings, which modern laws and by-laws so often rendered necessary, had made it requisite to prepare copies, in duplicate or triplicate, of plans of almost every building, even the smallest. This was the case far more now than it was when the lecturer first began to become familiar with building matters, and very far more than it could possibly have been a century back; while, before the use of paper had superseded parchment, or even before the time when paper was obtainable in large sheets, drawings were a rare luxury. No one could do much building work who could not read a drawing with facility, while no one could hope to rise to any position of responsibility in connexion with buildings who could not make a tolerable drawing of anything that he had to deal with. Even those the nature of whose work made it unlikely that they would be called upon to make drawings, would do well to learn to draw, in order that they might be able to understand and make use of working drawings. The phrase which he had just made use of, viz., "reading drawings," was constantly employed, and was very significant. To one man a drawing conveyed information, just as a book in a language he understood would do; to another man a drawing was as much a puzzle as a book in a language which he had not learnt; and the man who could not understand the drawings for a building was unavoidably shut out from much important employment in connection with it, for which he might in other respects be quite fitted. Now, there was no way of learning to read surer than learning to write,—no way of learning to read drawings surer than learning to make them. That alone ought to give draughtsmanship great importance to the members of an audience like the present. The subject naturally split itself into two divisions, and he had attempted to mark them by the use of the two words, Geometrical and Perspective, in the title. Geometrical drawing represented things as they were, and not as they were. Perspective drawing represented things as they appeared to the eye, and not as they were. That sounded like a paradox, but it was the simple truth, and the paradox, if there was one, rested upon the singular circumstance that our sight, from which we derived almost all our notions of solid things, rarely, if ever, let us see them as they were, but almost always modified or distorted them in a manner which they would recognise the moment it is pointed out to them. On this head the lecturer continued:—"Go into a great building with an open roof,—say, for example, Westminster Hall,—and look up at the trusses another,—or, at any rate, you see a portion of each past those nearer to you, and each one as you look up at it appears below the one on this side of it, and smaller. The trusses appear to be diminished and lowered by distance, and in drawing such an interior in perspective, the draughtsman would put in each truss lower and smaller as it recedes from the eye. In real truth, however, as has just been said, the trusses are equal in size and all on a level, and

were the draughtsman showing the interior of Westminster Hall on a geometrical drawing, he would draw the trusses all of a size and all at the same level (in such a drawing as, for example, a longitudinal section). Take a geometrical elevation of St. Paul's Cathedral, and look at the relative positions of the great west portico and the dome. The geometrical elevation will show you what is the fact: that the dome is exactly behind the portico, so that a line which divides the portico into two halves, and cuts through the apex of the pediment, if produced, would divide the dome into two halves. Go to the building itself, and you will find that though when you are exactly opposite the two features are in the same relation to one another, the moment you move to the right the dome appears to move to the right also, and the apex, or point of the pediment, begins at once to move towards the left of the dome, so that a person taking a view of the cathedral from a point where the front and flank are both visible—for example, from the south-west angle of the churchyard—must represent it with this pediment towards the left and the dome towards the right. Perspective drawings, then, mean drawings of objects as the eyes see them, including, if you will, other things than buildings, though to buildings we shall chiefly confine our attention. Geometrical drawings mean drawings which represent the actual shapes and arrangement of things, but represent them as we never exactly see them, but only as we know them to be—just in the same way as a map represents a country, a town, or an estate—not as we see it from some neighbouring eminence, but mapped out to scale. The foundation of all geometrical drawing is the use of a scale and the power of measurement.

We regret that we have not space to give the whole of the lecture, but we quote the concluding portion of it:—

Perspective drawing may be made one of the most difficult and perplexing subjects, and it figures as such a subject in most books. I strongly advise those who wish to learn it to get personal instruction, and that over a drawing-board. You may probably find instruction in a class, where the teacher is practical, which will answer the purpose; but the best method is, after a very little study of the principles, to begin a drawing under the guidance of some one who is familiar with this sort of work. You will find it quite as difficult to learn perspective drawing by a book alone as to learn in the same manner to ride on horseback, or to play at cricket. It was stated early in the lecture that perspective has to do with other things besides buildings with straight walls and roofs. See a line of scenery, straight, well set up, and perfectly in line. They look like a wall, and if you drew them you would draw them as a wall. Let the word be given to fall out, and the wall dissolves, but the men of whom it is composed, though they have dissolved into irregular groups, are just as much influenced by the laws of perspective as before, and their apparent size is just as much diminished if they are at the remote part of the parade ground as it was when they were at the remote end of a formal line. In drawing or painting the human figure, and in other artistic work, what is called foreshortening, which is one of the sources of artistic effect, is very much practised. This is perspective. Represent a man with his arm stretched out across the picture like a signpost, and you have a hold figure not very difficult to draw; but let him swing his arm round and point right at the spectator, or nearly at him, and you tax the resources of the most skilful draughtsman to render correctly on paper the effect which this attitude produces on the spectator. Foreshortening, or in other words the perspective of the human figure, needs much practice to manage it well. Another use of the word perspective is to be found in the months of those who discuss paintings, especially landscapes. I refer to aerial perspective, for which phrase might be substituted "effects of atmosphere." Here is no longer any question of outline, but of those sobering effects, due to the distance of an object, which rob its outlines of sharpness, its colouring of contrast, and hide much of its detail, and harmonise and blend together things that would be distinct and separate were the object nearer to the spectator. This is not, properly speaking, an effect of distance, and it seems to have acquired a name which gives it some claim to mention

when perspective is being considered. In taking leave of the subject, I wish to come back from any reference to the painter, or even the perspective draughtsman, to the sort of drawing which is more immediately the concern of most of us. I strongly recommend any who do not draw to make an attempt to learn. It is like acquiring a new language. After you have been practising drawing for a time, every drawing that comes into your hands has a new meaning for you, just as when you have done exercises in a foreign language for a time you begin to find that books in that language cease to be impenetrable mysteries to you, and find a voice with which to address you. When you get further, and are able to make good, useful drawings of intended works, you begin to feel like the man who has mastered a foreign tongue sufficiently to be able to speak in it; and it is not alone the sense of a new power which is desirable, valuable though that may be, but that power makes you a more useful man, and a more valuable man on a building, in whatever capacity you may be engaged, and will give you more certainty of employment and better prospects of good pay. Only let me urge on those who learn to draw to fix it in their minds that they must draw *well*. Your work, whether simple or otherwise, should be clear, vigorous, distinct, free from blunders, executed with a clean line, true to scale, and, in short, good in quality.

The third of this series of lectures was delivered at the Carpenters' Hall on Wednesday evening last, by Professor W. H. Corfield, M.A., M.D., his subject being "Modern Sanitation." Mr. Joseph Preston presided, and there was again a very large attendance.

THE LONDON COUNTY COUNCIL.

The usual weekly meeting of this Council was held on Tuesday last, in the Council Chamber of the Corporation of London, Guildhall. Sir John Lubbock, the Vice-Chairman, presided, in the absence of Lord Rosebery.

The Architect's Department.—The first part of the Standing Committee's Report on this department was then considered. This part of the Report was as follows:—

"We have to report that we have just concluded an inquiry into the staff and the general arrangements of the Architect's department, an inquiry which was rendered necessary by various circumstances, but particularly by the taking away from that department the work of valuation, and the constitution of a separate office of Valuer. The arrangements to be made have been carefully considered by a Sub-Committee appointed by us for the purpose, and their suggestions have been thoroughly re-considered by us. Our first recommendation is:—

(1) That the two departments be named respectively the Architect's Department and the Estates and Valuation Department.

Estates and Valuation Department.
The principal duties of this department will be the following:—
Prepare plans and estimates of cost of improvement schemes, and support such schemes before Parliamentary Committees.

Assist in the preparation of Parliamentary plans, when required.

Survey and prepare plans in detail of land and buildings to be purchased.

Value for compensation, and conduct negotiations for purchase, and give evidence.

Advise on the value of local improvements on applications for loans or contributions.

Value for reserve rents and prices for surplus property.

Advise on the assessments for rating of property belonging to the Council, and (with the assistance of the Solicitor when necessary) conduct all objections and appeals against assessments.

Examine the valuation-lists of the several parishes as prepared under the Valuation (Metropolis) Act, and support objections with a view of promoting uniformity of practice amongst Assessment Committees as will secure a fair basis of contribution to Metropolitan rates between one parish and another.

Value Government property with reference to the contributions made in lieu of rates in respect of such property.

Keep a register of the Council's property.

Manage the property taken for improvements, but not collect the rents.

Superintend the execution by the general works contractors of repairs and general works incidental to such property.

Deal with the Council's lands and buildings, valuing, plotting, letting, sales by auction, or otherwise.

Report periodically to the Corporate Property Committee, the Improvements Committee, the Local Government and Taxation Committee, and to any other Committees as required.

We recommend, —

(2) That the foregoing be approved as a general outline of the duties of the new department, it being

understood that the full duties comprise such as are required by any of the Committees associated with the department and approval of the Council.

In connexion with the interest of the Council in the proper working of the Valuation (Metropolis) Act, we have ascertained that a large percentage of the forms of return sent out by the local authorities are not returned, and, although in some parishes such non-return is taken as ground for increasing an assessment, this course is not generally approved. We believe that one excuse for many returns not being made would be removed, and the business generally expedited, if the return forms were allowed to pass through the post free, and, as the valuations made are made solely at the expense of the local rates, although used for imperial as well as local taxation purposes, we recommend, —

(3) That her Majesty's Government be requested to allow the return to be sent to the local authorities through the post free.

The Staff of the Estates and Valuation Department would be as follows:—

Principal Officer: The Valuer.—Mr. A. Young, Salary, 1,000*l.* a year.

Chief Professional Assistant: The Assistant Valuer. Duties.—To assist the Valuer in professional work as required, and in his absence to undertake his duties and responsibilities. Mr. E. J. Harper, service eleven years. Present salary, 428*0* a year.

We recommend —

(4) That Mr. Harper be appointed Assistant Valuer, at 350*l.* a year.

Chief Clerk: Duties.—To control clerical work of the department; examine accounts, prepare reports, indices, &c., conduct correspondence, and be generally responsible for the indoor work of the department. Mr. W. Garnsey, who has been seventeen years in the service, and is now in receipt of 430*0* a year, the maximum of his class.

We recommend —

(5) That Mr. Garnsey be appointed chief clerk at a salary of 350*0* a year.

First Class Officer: Mr. F. W. Cook.—Salary, 187*10s.* Service, eleven years.

We recommend —

(6) That Mr. Cook be placed in the first class, at the commencing salary of the class, 200*0* per annum.

Six Second-Class Officers.—Mr. A. Maddox, inspector of tenement property. Attends to changes of tenancy, valuation of fixtures, notices to quit, &c. He has been in the service eleven years, and is a very useful and experienced man. Present salary 43 per week.

We recommend —

(7) That Mr. Maddox be placed at the top of the second-class at 200*0* a year.

Messrs. F. J. Ruddle, H. Ainsworth, W. A. Webb, and F. Littlewood, are surveyors who have entered the service during the past two years. They have proved themselves good officers, and have been paid 3*l.* 3*s.* per week.

We recommend —

(8) That Messrs. Ruddle, Ainsworth, W. A. Webb, and Littlewood, be placed in the second-class at the commencing salary of 102*10s.* each.

There is a vacancy for an additional land surveyor, whose employment was authorised by the Council on August 2 last, but who has not yet been appointed owing to want of accommodation.

These recommendations were all agreed to, although amendments were moved to the effect that the Valuation work proper (the valuation of property which the Council might seek to acquire) should be kept distinct from the management of the Council's estates, another officer appointed for the last-named work. It was also urged that the salary proposed to be given to the Valuer was inadequate.

Green-street, Leicester-square.—On the recommendation of the Improvements Committee, it was resolved, after a long discussion,

"That the consent of the Council be given to the acquisition by the Vestry of St. Martin-in-the-Fields of the land now vacant in Green-street, including the site of the corner house, called No. 31, Leicester-square the demolition of which is only awaiting the resolution of the Council, for the purpose of adding to the public way so much thereof as may be arranged by the Council, and that the Council do, upon the usual conditions and subject to an estimate being submitted to the Council by the Finance Committee, as required by the statute, contribute three-fourths of the cost, after deducting the recompense; and that the Solicitor be instructed to prepare an agreement with the Vestry for carrying the arrangement into effect."

After transacting other business, the Council adjourned.

ARCHITECTURAL SOCIETIES.

The Architectural Association.—The ordinary fortnightly meeting of this Association was held on Friday, the 14th inst., Mr. Leonard Stokes, President, in the chair. The minutes of the previous meeting having been read and confirmed, Mr. E. S. Gale (Hon. Secretary) announced that the second sessional visit would take place this Saturday, February 22, to the Imperial Institute, South Kensington, when Mr. Colicutt had kindly volunteered to meet the party. Mr. Gale also proposed a vote of thanks to the various gentlemen who facilitated their visit to Mr. D'Oyly Carte's new theatre, in Cambridge-circus, on the 8th inst., specially mentioning Mr. D'Oyly Carte, Mr. T. E. Colicutt, and Mr. Holloway and his assistants. Mr. F. R. Farrow (Hon. Secretary) announced that he had received an appeal from the secretary of the committee for the restoration of the tower of the Church of St. Mary Magdalene, Chewton Mendip, Somerset, which it is proposed to restore under the supervision of Mr. J. D. Sedding as architect, Mr. R. Eley Smith then read a paper on "Some Typical Greek Buildings," the greater part of which we print in other columns.

Liverpool Architectural Society.—On Monday evening a special meeting of this Society was held in the Royal Institution, Colquitt-street, Mr. T. M. Reade presiding. The principal item of the proceedings was a paper by Mr. H. L. Beckwith, F.S.I., on "Quantity Surveying." Speaking of the importance of quantity surveying as compared with the position it had held some years ago, he said it had now come to be a recognised profession by itself, especially in London. In these days of competition, speed was of very great importance, and it was most important that the quantities should be so described that the contractor, in running through the items, should have no difficulty in at once assigning the proper value to them.

Manchester Architectural Association.—At the ordinary meeting, held at the Diocesan Building on Tuesday last, Mr. J. H. Woodhouse, President, in the chair, Mr. F. R. Farrow, A.R.L.B.A., read a paper on "The Ventilation of Public Buildings," which he treated in a most exhaustive manner. A vote of thanks, proposed by Mr. Mould, seconded by Mr. Booth, and supported by Messrs. Hodgson, Stelfox, Hinde, and Willoughby, terminated the meeting.

CAST-IRON COLUMNS.

SIR.—Will one of your readers kindly tell me how "in practice" the dimensions of a hollow cast-iron pillar are calculated, "without the use of tables," the height and load being given.

The formula $W = 42 \frac{a^{3.5} - d^{3.5}}{l^{1.6}}$ seems only adapted to checking estimated dimensions, and then a table of logarithms is necessary.

GREENWELL.

* * * "Greenwell" is referred to the four articles upon "Pillars" which formed our Student's Column ("Iron") in June, 1888. The formula he quotes is described in article xxv., page 454. In Stoney's standard book, as well as in other works upon the Theory of Stresses in Girders, &c., the powers of diameters ($d^{3.5}$) from 1 to 12, increasing by fractional parts, and also the powers of length ($l^{1.69}$) from 1 to 24 units of length, will be found.

Rankine's formula for the strength of struts and pillars is thus expressed $P = \frac{1}{1 + kl^2}$ in which reference to the above Tables of Powers is not involved. In this formula, which is constructed similar to the well-known Gordon formula: $P = \text{crushing strain in tons per square inch of section, } F = \text{the ultimate crushing strain of a short length of material in tons per square inch} = 35 \text{ for cast-iron, } k = \text{coefficient and for cast-iron} = 0.025 \text{ or } \frac{1}{40}, \text{ for circular section, and } l = \text{length of column divided by the radius of gyration, so that for a solid circular cast-iron section}$

$$P = \frac{F}{1 + \left(\frac{1}{400}\right) \left(\frac{l}{r}\right)^2}$$

and since r , the radius of gyration, = the moment of inertia divided by the mass, if a = the total area, we have

$$\frac{P}{F} = \frac{1}{1 + \left(\frac{1}{400}\right) \frac{a l^2}{I}}$$

This form is useful to apply when the moment of inertia of the section is calculated. In the case of a solid circular section the moment

of inertia = $7854 R^4$, and the area = $7854 D^2$, hence the radius of gyration

$$= \sqrt{\frac{R^4}{4 R^2} = \frac{R}{2} \text{ or } \frac{D}{4}}$$

The formula is an empirical one, but by its means we may thus estimate the proportion of sectional area that a long column must have in proportion to a very short column which has been experimented upon, and which would fail by crushing, independent of flexure. Practical knowledge and experience can alone suggest the most exact diameter to employ, but since there is a liability for the core not to be concentric in casting, there is no harm in erring upon the safe side in large columns. The hollow column of average thickness is preferable to a smaller one of greater thickness, and the latter is also preferable to a solid column, because by enlarging the diameter, increased stiffness is attained with the same quantity of metal. In the case of a hollow column the strength nearly equals the difference between that of two solid columns the diameters of which are equal respectively to the external and internal diameters of the hollow one.

Suppose, for example, we imagine we have to deal with a column 12 in. solid diameter and 80 in. long. If five tons may be allowed as the safe strain in a very short column, how much may be allowed for this column with both ends firmly fixed and bedded with extreme care?

$$r = \frac{12}{4} = 3 \text{ inches.}$$

$$P = \frac{5}{1 + \left(\frac{1}{400}\right)\left(\frac{80}{3}\right)^2} = \frac{5}{1 + \frac{6400}{3600}} = 1.8 \text{ tons}$$

per square inch, and since $\frac{5}{1.8} = 2.78$, it shows that the area required would be at least twice that of a short column where five tons permissible strain could be introduced.

IMPACT LOAD.

SIR,—A rectangular slab of concrete is firmly supported at two opposite sides in the direction of its length, and held firmly as between two girders, while the adjacent opposite edges in the direction of its width are free and unsupported. A weight of $\frac{1}{2}$ cwt., or 5 lb., is allowed to fall upon the centre of the slab, from a height of 9 ft., and it is required to know what dead load, applied passively, would be equivalent to the impulsive load described above.

Can any of your readers give the writer any suggestion on the subject? IMPACT.

AIR CURRENTS IN SEWERS.

SIR,—Referring to the article which appeared in your paper some weeks ago on Mr. W. Santo Crimp's experiments on the movement of air in sewers, I have recently taken observations in the deep headings and completed sewers in the outfall works at Margate, with the result that I find the direction of the air currents is controlled entirely by the wind on the surface. J. WILKINSON.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—VIII.

MAGNETIC TERMS.

IRON and steel play such important parts in the construction of dynamo-electric machinery and other plant used in connexion with electricity supply, that it is necessary, before proceeding further, to define certain terms used in describing the magnetic state and properties of magnetic substances. Until quite recently, magnetism has been very superficially treated in ordinary text-books; anything like an exact study of the subject has been by purely mathematical methods, that is to say, by methods which put certain abstract facts into symbols in such a way that the investigator entirely loses sight of their physical aspect. For mathematical purposes, magnetism is frequently considered to be a fluid capable of acting at a distance, an assumption known to be contrary to the truth, while the all-important lines of force are ignored. Now, however, that magnetism has, owing to the dynamo-machine, become an important factor in modern engineering, entirely new methods of dealing with problems connected with it are being developed. The subject being, then, in a somewhat transitional state, in the explanations of the various expressions which follow the customary definitions are first given, but an endeavour is made to translate explanations involving the idea of a fluid into language involving the idea of lines of force, the probable nature of which has already been discussed.

The definition of unit magnetic pole was given in a previous article. By this definition, it is a pole which produces a field of unit strength at a distance of one centimetre from it; but the locus of points distant one centimetre from a pole is a spherical surface, whose area is 4π square centimetres, hence from a point of unit strength spring 4π lines of force, since there is one line per square centimetre of surface. The poles of a magnet, or solenoid carrying a current, are but centres of force at which the whole of the magnetism may be supposed concentrated, magnetism being then regarded as the agent which produces lines of force; in just the same way the whole of the quantity of matter in a body is frequently supposed concentrated at its centre of gravity. It is, therefore, sometimes convenient to speak of "a quantity of magnetism," and "Unit quantity of Magnetism," as that quantity which produces 4π lines of force. If it is desired to measure the quantity of light coming from a gas flame, the total quantity, or number of rays of light sent out in all directions is measured; a lens may make the amount of light emitted in one direction vastly greater than that sent in another, but it does not change the total quantity of light given by the flame. Similarly the lines of force springing from a magnet may be concentrated in one direction, so as to form a very intense field, or may be distorted in any way; but a given quantity of magnetism can only produce a given number of groups of 4π lines of force.

The Moment of a Magnet (M) is the strength of one of its poles (m) multiplied by the distance (l) between them. That is $M = ml$. The expression "magnetic density" is sometimes applied to the surface of a magnet. The Magnetic Density (D) at any point on the surface of a magnetised mass is the quantity of magnetism per square centimetre at that point,—that is, D is the number of groups of 4π lines that emerge per square centimetre at that point.

The degree to which a body or portion of a body becomes magnetised is called its "intensity of magnetisation."

The Intensity of Magnetisation (I) at any point within a magnetised body is the magnetic moment per unit volume at that point. Let v be the volume of a little cube of cross section s cut from around the point so that an edge is parallel to lines of force, then if M be its moment, $I = \frac{M}{v} = \frac{ml}{s^3} = \frac{m}{s^2}$. Now from the quantity of magnetism m there come $4\pi m$ lines of force, therefore I is the number of groups of 4π lines passing through the point per square centimetre. In the case of a uniformly magnetised bar, I is the number of groups of 4π lines emerging from the magnet divided by the area of the end or cross section.

The various definitions given so far do not involve in any way considerations of the magnetising agent; indeed, in the case of a permanent magnet no such agent exists, for having once become magnetised coercive force keeps the molecules in position. Steel and iron are magnetised by various methods, but they all consist of sending lines of force through the metal by some means or other so as to turn the molecules along them in the desired direction. In the case of steel, and even to a certain extent in the case of soft iron, a blow or continued vibration appears to temporarily loosen the molecules and enables them to turn more readily; just as when examining the shape of a magnetic field by means of filings a tap on the card or surface on which they are placed makes them lie in greater numbers along the lines of force. A piece of soft iron is usually magnetised by placing it within a helix, the whole forming an electro-magnet as soon as the current passes; steel may be magnetised in the same way, or by putting it in front of an electro-magnet. In the two definitions which follow the inducing field may be regarded as that produced by a helix, its strength H being the strength of field within the helix when filled with air only.

When different substances are placed in a magnetic field of a certain strength the intensity of magnetisation induced differs considerably, and depends on the "susceptibility" or "coefficient of magnetisation" of the substance in each case.

Susceptibility (k) } Is the intensity of magnetisation per strength of inducing field.
Coefficient of Magnetisation.

That is $k = \frac{I}{H}$. When the coil was empty H lines per square centimetre passed through

it; the iron having been inserted it became magnetised to the intensity I , and, therefore, added $4\pi I$ lines of force per square centimetre. Hence kH is the quantity of magnetism produced in the metal by the field of strength H , per square centimetre of cross section. Closely allied with the susceptibility is the "permeability," or "co-efficient, of magnetic induction." Permeability (μ) is the ratio (Co-efficient of magnetic induction) between the number of lines of force per square centimetre passing through the metal and the strength of the inducing field. The number of lines of force added per square centimetre has just been shown to be $4\pi I$, so that the total number is $H + 4\pi I$, hence

$$\mu = \frac{H + 4\pi I}{H} = 1 + 4\pi k, \text{ and } k = \frac{\mu - 1}{4\pi}$$

The difference between susceptibility and permeability is roughly this: Susceptibility involves the idea of the metal adding magnetism to the system; permeability that of the metal multiplying the lines in the original field. Either can be calculated from the other by means of the above formulae.

The reader may be reminded that we have adopted the theory that electricity is an incompressible continuous fluid permeating alike all matter and all space, filling it completely. Fluid is not exactly the right word to use, but as there is no right word, "fluid" is used as being the best to be had. Magnetism has been described as portions of this fluid rotating around axes, which form closed curves, threading their way through space and all sorts of materials. Magnetism is measured by the number of these axes or lines of force produced, and the quantity numerically stated by the total number of groups of 4π lines formed. The method of measuring magnetism must not be confounded with that adopted for measuring the strength of a magnetic field, when the number of lines passing through a given area is taken and not the total number of lines in the field. Broadly speaking, then, by a quantity of magnetism we mean a quantity or a number of lines of force.

It is a remarkable fact that when one or two whirls or lines of force is sent into a piece of iron or other magnetic substance it produces a number of other whirls within the mass, which, in turn, are sent out of the substance. This power of multiplying or adding to lines of force, already respectively referred to as permeability and susceptibility, will be discussed more fully in future articles.

The value of μ for air or space is arbitrarily taken as 1. Substances for which the value of μ is greater than 1 are called paramagnetic, or simply magnetic; those for which μ is less than 1 are called diamagnetic.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

116, Cement and Plaster. R. Stone.

The chief point in the process of manufacture which is the subject of this patent consists in treating with petroleum, oil, vitriol, or spirit, the chalky substances of which the cement is composed. By this means the sulphur, an injurious compound in cement, is removed. Several modifications and different parts of mechanism for rolling and grinding the chalky material are incorporated in the same specification.

2,750 and 2,751, Artificial Stone. A. C. Pontou and others.

According to this invention an artificial stone is made by taking fine or coarse aggregates of a silicious nature,—sand, gravels, pebbles, &c.,—and mixing them with a silicious cement composed of silicate of soda or of potash, &c. After the materials are mixed together they are moulded in blocks and subjected to heat, and afterwards staked for use. The second specification relates to the mixing of the substances and the subsequent crystallisation by heat, and claims that artificial stone so prepared may be returned to the moulds without showing any shrinkage or distortion.

6,261, Chimney-pot. F. Meiton.

The chimney-cowl which is the subject of this patent is of octagon shape, and fitted with hanging flaps, which are blown by the wind in such a way as to prevent down-draught, those on the opposite side being open to allow for the escape of smoke.

10,759, Fire-places and Mantel-pieces, &c. E. C. Massey.

This invention is designed to provide open fire-places or grates with fittings of effective appearance and increased radiating power, and the improvements consist in forming upon steel or other metal designs, figures, and ornamentation of porcelain or pottery in flat, relief, or intaglio.

16,774. Carpenters' Pongh and Fillister. H. Madder.

This invention consists in the use of screws passing through the top of the plane into nuts to prevent the sliding bars from slipping when the tool is at work, and the rounding of the forefeet or guide of the plough to prevent jerk whilst ploughing over mortices.

NEW APPLICATIONS FOR PATENTS.

Feb. 3.—1,776, C. Phillips, Metal Dowels.—1,782, R. Ashworth and W. Evans, Self-acting Door-closer.—1,789, T. Thomas, Automatic Flushing Syphon.—1,795, W. Roff, Water-closet.—1,820, H. Gurney, Kilo for Burning Bricks and Tiles.

Feb. 4.—1,829, F. Schmidt, Fittings and Double Windows or Casements.—1,851, J. Stott, Joiner's Tool.—1,900, J. and A. Drexler, Roof Coverings.

Feb. 5.—1,908, R. Wilford, Screw-fastenings for Windows.—1,923, G. Dimmer, Chimney Cowl.—1,934, C. Pihel, Silicious Paving and Building Stone.

Feb. 6.—2,008, R. Eversed and U. Coleman, Flushing Drains, Water-closets, &c.

Feb. 7.—2,020, J. Hatch, Roof Glazing.—2,021, S. and W. Dearden, Stone-sawing Machinery.—2,032, R. Carson, Adjusting and Holding Window-sashes in any desired vertical position.

Feb. 8.—2,077, E. Barlow, Water, Gas, Drain, and other Pipes, and Joints for same.—2,085, A. Hay, Fireproof Doors.

PROVISIONAL SPECIFICATIONS ACCEPTED.

14,177, J. Perry, Sliding and Reversible Casement Window.—20,528, E. Young, Preventing the Rattling and Shaking of Window-sashes.—20,681, A. Myall, Finishing Wood Mouldings.—20,692, J. Couiter, Machine for Dressing Stone, &c.—205, H. Johnson, Window Fasteners.—274, A. Natterer, Electric Bells.—423, W. Silverlock, Ventilating Sewers, &c.—428, A. Wright, Weathered Facing Brick.—711, W. Greenes, Ventilator.—734, W. and J. Rawlings, Syphon Flushing Apparatus for Water Closets.—777, F. Streeter, Water Waste Preventers.—802, J. Harding, Bakers' Ovens.—821, J. and J. Bruce and F. Baker, Shop-window Fittings.—832, G. Hope, Sand Separators.—1,185, C. Hunter, Extracting Cowl.—1,272, T. and H. Moorwood, Canopied Grates and Fire-places.—1,295, C. Shaw, Flushing Apparatus.—1,418, A. and E. Pullman, Fire-grates.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months. 4,432, W. Ingle, Hanging Sliding Window sashes.—5,595, R. Roberts, Prevention of Down Draught in Chimney-pots.—5,644, T. Shouler, Fastenings for Cupboard-doors.—5,846, J. Watkinson and T. Dodd, Gas Brackets, &c.—5,900, H. Legg, Sash-locks.—13,118, A. Clark, Moulding-planes.—18,493, H. Lake, Bricks.—87, D. Hart, Screw-drivers.—257, L. Halliday, Saw-sanges.—258, L. Halliday, Saw-sharpening Machines.—276, A. Boulé, Sash-balances.

MEETINGS.

SATURDAY, FEBRUARY 22.

Architectural Association.—Visit to the Imperial Institute, South Kensington.

Royal Institution.—The Right Hon. Lord Rayleigh, M.A., F.R.S., on "Electricity and Magnetism." II. 3 p.m.

President Institution of Builders' Foremen and Clerks of Works.—Annual Dinner, Holborn Restaurant, 6.30 p.m.

Edinburgh Architectural Association.—Visit to Parliament Hall and St. Margaret's Chapel.

MONDAY, FEBRUARY 24.

Royal Academy.—Mr. A. S. Murray on "Sculpture in Greek Temples." III. 8 p.m.

Surveyors' Institution.—(1) Mr. S. Wood, Q.C., on "The Establishment of a Tribunal for the Trial of Compensation Cases." (2) Resumed discussion on Mr. C. M. Freeman's paper on "Some Suggested Amendments in the Law and Practice of Compensation." 8 p.m.

TUESDAY, FEBRUARY 25.

Institution of Civil Engineers.—Further discussion on the following papers:—(1) "The Shanghai Water-Works," by Mr. J. W. Hart. (2) "The Tyam Water-Works, Hong Kong," by Mr. J. Orange. (3) "The Construction of the Yokohama Water-Works," by Mr. J. H. T. Turner. 8 p.m.

Sanitary Institute (Lectures for Sanitary Inspectors).—Professor H. Robinson, on "Drainage and Construction." 8 p.m.

WEDNESDAY, FEBRUARY 26.

Free Lectures to Artificers and others on Matters Connected with Building.—Professor Armstrong on "The Domestic Fireplace," Carpenters' Hall, London-wall. 8 p.m.

Institution of Civil Engineers.—Students' Visit to the Nine Elms Works of the London and South-Western Railway. 2 p.m.

THURSDAY, FEBRUARY 27.

Institution of Electrical Engineers.—Discussion on the following papers:—(1) "The Theory of Armature Reaction in Dynamos and Motors," by Mr. J. Swinburne. (2) "Some Points in Dynamo and Motor Design," by Mr. W. B. Eason. 8 p.m.

St. Paul's Ecological Society.—Major Heales, F.S.A., on "The Ecological of Denmark." 7.30 p.m.

Society of Arts (London Section).—Mr. W. Sherriff on "The Northern Shan States and the Burma-China Railway." 6 p.m.

FRIDAY, FEBRUARY 28.

Architectural Association.—Mr. W. A. Fife on "Architecture in Oxfordshire." 7.30 p.m.

Royal Academy.—Professor J. H. Middleton on "Florentine Sculpture in the Fourteenth and Fifteenth Centuries." I. 8 p.m.

Sanitary Institute (Lectures for Sanitary Inspectors).—Sir Douglas Galton, F.R.S., on "Ventilation, Measurement of Cubic Space," &c. 8 p.m.

SATURDAY, MARCH 1.

Association of Public Sanitary Inspectors.—Mr. D. Richards on the "Disposal of House Refuse." 6 p.m.

Royal Institution.—The Right Hon. Lord Rayleigh, M.A., F.R.S., on "Electricity and Magnetism." III. 2 p.m.

Miscellaneous.

The Sanitary Assurance Association.—The ninth annual meeting of the members of the Sanitary Assurance Association was held on Monday, the 17th inst., at the offices, No. 5, Argyle-place, W. Sir Joseph Fayrer, K.C.S.I., F.R.S., in the chair. Mr. Joseph Hadley, Secretary, read the annual report, which referred to the work of the Council in promoting the Sanitary Registration of Buildings Bill. To the lectures given by members of the Council on sanitary subjects, and special reference was made to the disclosure of serious sanitary defects in Board Schools and clergy-houses which had been inspected by the Association during the past year. The report concluded as follows:—"Though the important bearing of the work of the Association on the public health is not yet fully appreciated by the general public, the financial statement for the past year proves that the Association is making progress, and that after nine years' experience its work continues to be appreciated. The income for the year was 3987. 8s. 10d., and after meeting all liabilities a balance is carried forward." The Chairman proposed the adoption of the report, and said that the more he saw of the work of the Association and the need for sanitary improvement the more was he interested in its progress, and he expressed a hope that not only might this Association prosper but that others might be formed, so great was the work to be done. Alderman Sir Vincent Kennet-Barrington seconded the adoption of the report, which was supported by Surgeon-General Cornish, Mr. Mark H. Judge, and Mr. Henry Rutherford, and passed unanimously. General Burne, C.B., and Dr. Danford Thomas were re-elected members of the Executive Council, and Sir Joseph Fayrer and Professor T. Rogers Smith, F.R.I.B.A., were re-elected President and Vice-President respectively.

Schools, Leicester.—In a limited competition, confined to local architects, we hear that the Newfoundland School Board have adopted the design of Mr. W. M. Cowdell, of Leicester, for a new school to accommodate 600 children.

Mid-Kent Waterworks.—There are new works being constructed by a company for the purpose of supplying Scotland and West Malling and several villages on the left or west bank of the Medway, between Maidstone and Rochester. The well, which was commenced in July last at Lower Halling, near Rochester, was dug to chalk-water level (12.00 ordnance datum), 50 ft. from the surface, then bored for 315 ft., making a total of 365 ft., at which depth, on Monday last, the 17th inst., water was tapped in the lower greensand. The geological formations passed through were, for the first 140 ft. chalk, then a thin layer of rock, through 220 ft. of gault, and 20 in. of very hard rock into the greensand, which is of a coarse nature. The yield is abundant, as immediately on being tapped it rose to within 37 ft. of the surface, or 13 ft. above chalk-water level, and is estimated to stand at a constant level, pumping over 20,000 gallons per hour.

The bore-hole is lined with 15 in. wrought-iron tubes screwed together in wrought-iron sockets with a steel shoe, and then perforated tube with 5,200 holes 1/4 in. diameter in order to keep the sand from rising. The reservoir, to hold about 200,000 gallons, is built, and only has roof to be put on, and some eight miles of mains are laid. There are several large works, besides a population of about 8,000, to be supplied, and at the request of the West Malling Rural Sanitary Authority, the Company is applying to Parliament this Session for an extension of area, especially on the right or east bank of the River Medway. Mr. Richard Batchelor, of Chatham, who has successfully made six out of the ten borings into the greensand in the county of Kent, was the contractor. Messrs. William Russ, M.Inst. C.E., and Arthur F. Bowker, C.E., F.R.G.S., are the engineers.

The English Iron Trade.—The better feeling in the English iron market which began last week has continued also during the present week, and the outlook would be hopeful if there were not the possibility that the threatened miners' strike may disorganise trade. Although the business done in pig-iron is still chiefly confined to holders of warrants, the fact that better prices have been obtained for them shows which way the tide is turning. The Glasgow warrant-market has been firmer, and there is also more demand for Scotch makers' iron. In the North of England, makers still hold to their former rates, while warrants have gone up 2s. a ton. In Lancashire producers sell very little crude iron, because their quoted prices are still nominally unchanged. In the midland district makers are little inclined to give way. In the north-west, hematite is firmly maintained by makers at its top price, because they are in no need of new orders. Manufactured iron is still quiet, but firmer in price. Steel also is very steady, because of a fair demand. Shipbuilders are booking very little fresh work, but they are fully engaged, and engineers also keep busy, notwithstanding a slight falling-off in the quantity of new work ordering.—Iron.

The Civil and Mechanical Engineers' Society.—At a meeting of this society, held on the 19th inst. (Mr. Henry Adams in the chair), a paper was read by Mr. C. Fairlie Bruce, on "Italian Water Supply." The author briefly described the works at Turin, Milan, Verona, Florence, Leghorn, and Naples, dwelling at greater length on any points of interest involved in them—of these the subterranean service-reservoirs at Capodimonte seemed most striking—they are excavated at a depth of 164 ft. below the surface in the Tugea rock.

Proposed French Exhibition at Earl's Court this Year.—We are informed that at a meeting of the Réunion Commerciale and Industrielle, held at the Palais-Royal, Paris, on the 14th inst., M. Gustave Sandox in the chair, it was unanimously decided to render every assistance in the organisation of the forthcoming French Exhibition, which opens at Earl's Court on May 3. It is stated that some of the most interesting of the attractions of last year's Universal Exhibition in Paris will be shown at Earl's Court.

Architectural Partnership.—Mr. J. F. Wadmore writes from 35, Great St. Helens to say that in consequence of the retirement of his partner, Mr. A. J. Baker (on account of ill health), he has arranged to take his son, Mr. Beauchamp Wadmore, A.R.I.B.A., into partnership, in conjunction with Mr. W. R. Mallett, who has been with the firm for over twenty years. The title of the new firm will be "Wadmore, Wadmore, & Mallett."

Supposed Coalfield in Kent.—For the past two or three years Sir Edward Watkin, the Chairman of the South-Eastern Railway and Channel Tunnel Companies, has been directing his attention to a search for coal at a point on the South-Eastern Railway adjoining the experimental heading for the tunnel. The discovery of a bed of coal is now announced (in the *Times* of February 20) by Mr. Francis Brady, C.E., the engineer-in-chief of the South-Eastern and Channel Tunnel Companies, under whose directions the operations have been conducted. His report says:—

"Coal was reached on Saturday last, the 15th inst., at 1,180 ft. below the surface. It came up mixed with clay and reduced almost to powder by the boring tools. A small quantity of clean bright coal found in the clay was tested by burning and proved to be of good bituminous character. The seam was struck after passing through 20 ft. of clays, grits, and blackish shales belonging to the coal measures, which at this point lie close under the lias, there being only a few intervening beds of sand, limestone, and black clay separating them. The correspondence of the deposits with those found in the Somersetshire coalfield is thus pretty close, the difference consisting in the absence of the red marl at the Shakespeare boring. The lines of bedding in the shale are distinctly horizontal. This is an indication that the coal measures will probably be found at a reasonable depth along the South-Eastern Railway to the westward. I beg to hand you herewith two specimens of the clay containing coal, one taken at 1,180 ft. and the other at 1,182 ft. I also enclose a specimen of clean coal taken to-day at 1,183 ft. 6in. from the surface."

Swimming-Baths, Southampton.—The Corporation of Southampton has decided to erect covered swimming-baths, Turkish baths, and private baths for both sexes, and at their last meeting unanimously adopted the design and scheme as prepared by Mr. W. B. G. Bennett, C.E., the Borough Surveyor, the estimated cost being 7,000*l.* Tenders are to be asked for at once.

(Received too late for insertion last week.)

LONDON.—For alterations to premises, new strong-room, shop front, and interior fittings, at 18, Forchester-road, Baywater, for Mr. E. W. Thompson:—

S. Yardley & Sons (accepted)	£485 0 0
------------------------------	----------

(Received too late for insertion last week.)

LONDON.—For show-cases, counters, and interior fittings for the Army and Navy Co-operative Stores, Limited, Westminster:—

F. Sage & Co.	£892 0 0
Drew & Cadman	873 0 0
S. Yardley & Sons (accepted)	860 0 0

(This list was received too late for insertion last week.)

MILFORD HAVEN (S. Wales).—For pulling down and rebuilding the "Palms" Tavern, Milford Haven, for Mr. J. Vaughan. Messrs. Burtin & Wood, architects, Milford Haven. Quantities by Mr. Henry Bushell, 1, Finsbury-square, E.C.:

Stimmons, Milford Haven	£1,063 4 8
Cole, Milford Haven	657 0 0
William, Milford Haven	645 0 0
Phelps & Co., Milford Haven	558 15 0

MITCHAM.—For alterations and additions to the "Gardener's Arms," Mitcham, for Messrs. Truman, Hambury, & Co. Mr. E. J. Capell, architect:—

Hobbs	£286 0 0
Whitehead & Co.	285 0 0

ORINGTON.—For the erection of the Village Hall at Orington, Kent, for Mr. A. Brown. Mr. St. Pierre Harris, architect and surveyor, 1, Basinghall-street, E.C., and Orington:—

E. Lawrence & Sons, London	£3,755 0 0
H. Smartford & Son, Clapham	4,371 0 0
D. Payne, Bromley	3,329 0 0
Holt & Son, Epsom (accepted)	3,150 0 0

PLAISTOW (Kent).—For alterations to the "Prince Frederick" public-house, Plaistow, Kent, for Messrs. H. & V. Nicholl, Limited. Mr. Albert L. Ouy, architect, 78, High-street, Lewisham:—

C. Robson	£592 0 0
Hoare	500 0 0
Pritchard	493 0 0
Kenard Bros.	450 0 0
Knight	423 0 0
D. Payne, Bromley (accepted)	382 0 0

PLYMOUTH.—For rebuilding premises, No. 14, Cambridge-street, Plymouth, for Mr. J. C. Holland. Mr. Archd. D. Shortridge, architect.—

Palmer	£555 0 0
Debnam	489 0 0
Sweet	454 10 0
May	459 0 0
Laphorne & Goad	430 0 0
Palk & Partridge	422 0 0
Sheppard (accepted)	383 0 0
[All of Plymouth.]	

PLYMOUTH.—For rebuilding premises, No. 35, Frankfort-street, Plymouth, for Mr. J. M. Sercombe. Mr. Archd. D. Shortridge, architect.—

Laphorne & Goad	£249 0 0
Palk & Partridge	438 10 0
Debnam	429 0 0
May	425 0 0
Sheppard (accepted)	376 0 0
[All of Plymouth.]	

PLYMOUTH.—For additions to Mount Pleasant Temperance Hotel, Plymouth, for Mrs. Kernick. Mr. Archd. D. Shortridge, architect.—

Laphorne & Goad	£241 0 0
Finch	409 0 0
Palk & Partridge	429 0 0
Debnam	459 0 0
May	414 0 0
[All of Plymouth.]	

POTTERS BAR (Herts).—For the enlargement of the Vicarage House, Northw. Potters Bar, for the Rev. W. B. Bondage. Messrs. Charles Kirk & Sons, architects, St. Paul's. Quantities supplied by the architects:—

Robert Williams, Barnet	£1,182 0 0
T. & W. Savage, St. Albans	1,055 0 0
John Carron, Barnet	452 10 0
Gabriel Warboys, Bessingbourn	938 0 0
C. Miskin, St. Albans	933 0 0
Road & Son, Grantham (accepted)	925 0 0

ST. LEONARDS-ON-SEA.—For the erection and completion of a private residence, Daner-road, for the Trustees of the Everdell Estate. Mr. Frank H. Humphreys, architect, 6, Trinity-street, Hastings. Quantities by the architect:—

No. 1.	No. 2.	
Eldridge & Crutenden	£5,408	£283
T. Salter	5,320	190
H. E. Crutenden	5,265	186
C. Hughes	5,229	214
A. H. White (accepted)	5,130	260
[All of St. Leonards-on-Sea.]		

* Extra in fitting dining and billiard rooms in oak.

STREATHAM.—For alterations and additions to the "Horse and Groom," Streatham, for Mr. J. Pettigill. Mr. J. C. Reynolds, architect:—

Cox	£2450 0 0
Drew & Cadman	424 0 0
Warne	408 0 0
Farker	380 0 0
Whitehead & Co.	345 0 0
Smith (withdrawn)	317 0 0

WATFORD.—For erecting new stable at Watford, Herts, for Messrs. R. White & Sons. Mr. C. W. Lovett, architect:—

A & W. Garner, Peckham	£500 0 0
Judge, Watford	518 0 0

WICKHAM (Kent).—For alterations and additions to the "Foresters Arms," Wickham-lane, Wickham, Kent, for Messrs. Mitchell & Beasley. Mr. J. O. Cook, architect, Woolwich, S.E. No quantities supplied:—

Battley	£291 0 0
Foreman	115 0 0
J. O. Richardson, Peckham	440 0 0

WOOD GREEN (Middlesex).—For erecting London Provincial Bank, Wood Green, N. Mr. A. R. Barker, architect. Quantities prepared by Messrs. Young & Brown, Henrietta-street, W.C.:—

Landow	£3,632 0 0
Yardley & Sons	3,580 0 0
L. & W. D. Patman	3,440 0 0
Messum	3,279 0 0
Shepherd	3,185 0 0
S. Jerrard	3,080 0 0

[This list was received too late for insertion last week.]
Alterations at the "Kenilworth Castle."—The lowest tender in the list for this job, published in the Builder last week, p. 124, was sent by Messrs. G. Mowar & Son, not by anyone named "Moore." The mistake was not ours.

SUBSCRIBERS IN LONDON AND THE SUBURBS, by prepaying at the Publishing Office, 78, per annum (or 4s. 3d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

The Report on the Glasgow Mill Disaster.

THE report on the causes of what has been known as the Templeton mill disaster at Glasgow, by Col. Malcolm and Mr. Robertson, the Commissioners appointed to inquire into the cause of the fall of the building and report thereon to her Majesty's Secretary for Scotland, is dated January 23 of this year, but does not appear to have been communicated to the press in any way, or the fact of its having been sent in made public, till two or three weeks after that date. The opinion expressed in it as to the main cause of the disaster must be rather a surprise to those who paid attention to the evidence as given at the public inquiry. The opinion we expressed immediately after the disaster was that it was a lesson on the necessity of designing and constructing buildings so as to be safe in process of construction as well as after their completion; that walls 185 ft. long and 70 ft. high without cross walls could not be considered safe against a gale, as long as they remained practically in the form of an empty and unroofed shell; that the floors should have been filled in and completed as the building went up, and that the walls should have been strengthened by buttresses such as would have formed a portion of any Medieval cathedral or other wall of the same length without cross walls. The evidence at the public inquiry, as published in the *Glasgow Herald*, appeared as a whole to justify our previous remark that it was not likely the inquiry would elicit anything which would materially modify the above view as to the cause and moral of the calamity. It came out in the evidence that the back wall, the one furthest from the wind, was built on columns (or rather, as now appears, on H-shaped standards); but though this wall was thus undoubtedly less stable than the front wall, it seemed hardly reasonable to think that the fall of a building from the pressure of a violent blast of wind should result from the weakness of the back wall, which was more or less sheltered from the wind, rather than from that of the front wall which was exposed directly to the full force of the gale.

One fact, however, appears in the final report of the Commissioners which did not

appear in the original evidence of the public inquiry, and which they appear to have arrived at by independent investigation subsequently. The H-stanchions referred to above had spreading bases, 3 ft. by 2 ft., and 1½ in. thick, resting on the concrete footings. The stanchions supported a series of cast-iron lintels 2 ft. wide, on which the back wall was carried. The wall, 66 ft. high above these, was 2 ft. thick in the lower story, and 18 in. in the upper stories, the reduction in thickness being made entirely on the inner side of the wall; the method which would no doubt occur to ninety-nine people in a hundred as the most natural manner of reducing the thickness, at a floor level, instead of letting the reduction show externally. It cannot be said, however, that this was the most reasonable or scientific method of doing it, as the result, of course, would be to bring a major portion of the weight of the wall outside the central line of the beams and stanchions, and to a certain extent injure the equilibrium which it is so doubly important to maintain when a great weight is carried on thin iron supports. The special fact, however to which we have alluded, is that not only were the stanchions tilted over towards the outside (which would naturally be expected when the superstructure fell in that direction) but five of the base-plates were found to be fractured, "the projection on the east or outer side being broken off."

The Commissioners attach great importance to this fact as bearing on the cause of the accident. They evidently regard it not as one of the results of the overturning of the back wall, but as mainly contributing to the catastrophe. The stanchions, they say, were no doubt amply sufficient to bear their load as long as it was stationary, "but as soon as an oblique pressure came upon them, in consequence of even a slight oscillation of the wall above, they were insufficient. The base-plate projecting 6 in. beyond the solid part of the stanchion, without stiffening or gusset pieces, gave way in one-third of them at the time of the accident, and, we believe, contributed materially to the failure." The following is the Commissioners' summary of their view of the manner of the failure:—

"The back wall and the stanchions on which it rested were distinctly the weakest part of the whole building. The westerly gust which prevailed at the time of the accident gave precisely the conditions which would test this part of the structure to the uttermost, and take it at the greatest disadvantage. We must conclude that the weakest part of

the structure, under the conditions existing at the time, was that to which the failure was due, and now we believe we are in a position to submit a correct explanation of the accident.

The first gust caused the whole building to oscillate, an action which is inevitable in a structure of considerable height, and which should not damage a properly designed construction, but this oscillation severely strained the back wall, especially towards the centre of its length, and the oblique pressure which accompanied it fractured one or more of the base plates of the stanchions. The second gust, acting with increased force on the somewhat weakened structure, caused a greater swaying of the building, broke more of the base-plates, and probably tilted some of the stanchions, causing the grinding of the wheels which was observed in the weaving-shed.* The third and strongest gust was probably that which caused the catastrophe. Under its impulse the already weakened wall, deprived of a portion of its effective support by the fracture of the base plates swayed beyond the narrow limits of its stability, and in its fall not only deprived the front wall of the support of the joists, but actually by their connexions assisted to drag it over. The result was the simultaneous collapse of both front and back walls, as already described."

The evidence of witnesses of the catastrophe (not numerous, it may be observed) was clear to the effect that the whole fall was instantaneous, and therefore allowed no room for the theory advanced by one witness that the upper and more solid portion of the front wall, where no flooring-joists had been set, was first blown over upon the joists and so dragged the whole down: a theory improbable in itself, and obviously not in accordance with the ascertainable facts.

The opinion of the Commissioners as set forth in the above quotation is of much interest, and "undoubtedly" suggests a new idea as to the manner in which this deplorable catastrophe was brought about. That it may very possibly have happened in the manner here set forth cannot be denied; but we should think the conclusion drawn is much more open to doubt than the report seems to imply. In the first place, it seems rather a curious way to put it to describe a gale blowing against the west wall of the building as giving "precisely the conditions which would test to the uttermost" the weak portions of the wall on the east side. It is assumed, of course, that a great deal of the wind pressure on the west wall was transmitted to the east wall through the joists; but these did not go into either of

* The axes of the wheels being, we conclude, connected with the stanchions.

† For the sake of brevity we define the two sides as west and east, though they were not precisely facing those points of the compass.

the walls, nor, from the manner in which they appear to have been secured, does it seem probable that they even butted against them, though there was another kind of connexion in the way of tie, to be described presently. The wind may, as we suggested before, have made a kind of swoop into the interior of this great unroofed shell, and so have fairly hurst the walls out, which would account for part of the west wall falling outwards. The east wall, carried on its row of iron sticks, would no doubt have been the readiest to fall; and its faulty construction accounts for the fact of its falling, although not on the side directly exposed to the gale; but we are distinctly of opinion that the west wall fell to the force of the wind, mainly, if not altogether; and as it is unquestionable that this was a strong and very well built wall,—all the witnesses are agreed on that point,—this is, as we before said, the lesson of the disaster: that a long wall strong enough for a covered and floored building may not be strong enough while the building is uncovered and open. Had there been a series of heavy transverse girders built into each wall, and the east wall built as strongly as the west one, we believe both would have mutually supported each other, and the whole have remained standing; but it does not appear that the method of laying the flooring-joists constituted such a tie as to render the two walls either mutually supporting or mutually destructive. There seems to be no kind of proof that the base-plates of the stanchions failed before the fall of the walls; and it appears to us that the stress laid by the Commissioners on the structural weakness of the wall that was on the leeward side of the building, and its effect on the disaster, rests more on assumption than on anything like proof (as they would perhaps admit), and that it tends rather to draw attention aside from the main source of danger, the building of walls of "unlimited" length without sufficient buttresses, and which therefore only become safe against violent winds when the roof, floors, and openings are all closed in.

That it has this tendency to withdraw attention from the main point we see from an article which appeared in a Glasgow paper simultaneously with the publication of part of the report a few days ago, in which, while much is said as to the practical lessons to be drawn from the report, the question of the behaviour of long unsupported walls, as such, is entirely ignored. The Commissioners do not entirely ignore this point; but they merely refer to it in a passing sentence at the close: "It is probable that if the roof, floors, and windows of the building had been completed, no wind pressure which has been observed in this country would have been sufficient to destroy it": almost the very words we used in our comment at the time; and that is the real point of the matter. They add that "it is to be hoped that one result of this disaster will be to ensure that greater attention shall be paid in future to the security of buildings under construction"; a hope which we also expressed, but we also suggested the desirability of building long walls in such a manner as to be stable in themselves, instead of depending on floors, when the floors should rather depend on them.

A great deal was said at the inquiry, a good deal of which was nonsense, in regard to the method of joisting the building and connecting the floors with the walls. The method actually employed was this: the main beams ran longitudinally, parallel with the main walls, and carried on a series of cast-iron columns; the joists were placed transversely, but were not built into the walls, but rested on wall-beams 9 in. by 8 in. supported on stone corbels built into the walls, the beams being anchored into the walls by iron straps. Every third joist crossed the building in a single piece, but how the joists were secured to the wall-beam we do not find precisely stated anywhere; we do not gather that there was anything in the way of straps or ties hindering them to the wall-beam, though the latter was apparently well anchored to the wall. This method of laying the joists

was objected to by some witnesses as unsafe, as not tying the walls together; it was urged that the joists should have been built into the walls. The Commissioners, and we entirely agree with them here, dismiss this objection as frivolous. No better tie would be got by building a number of ordinary joists into a wall than by laying them bearing on a beam or corbels as described; the walls would be to a certain extent weakened and the hold of the joists would amount to nothing of any importance; everyone accustomed to buildings knows what a large proportion of ordinary flooring-joists are quite loose in the walls. Therefore we think the criticisms that were passed about this method of securing the joists were perfectly mistaken and groundless. But we also think that flooring joists so laid, though with the advantage of not weakening the substance of the wall, were quite inefficient as a tie; and one of our reasons for questioning the opinion of the Commissioners as to the manner in which the building fell is just this—that we do not see, for all the information we can get about the fixing of the joists, that the latter had any such connexion with the wall, or rather with the wall-beam, as would enable them to exert any important pull in dragging over a heavy and well-built wall-like what the west wall of the building is described to have been: the joists would have parted from the wall-beam before that. The mistake lay not in this or that way of forming the bearing of the joists, but in the radical error of laying the joists transversely and the girders parallel, instead of the opposite arrangement. Here is a long comparatively narrow building with two walls the long way, without any support or buttressing from cross-walls,—with little or no buttressing of any kind in fact, and it is desired to fix the floors in so as to assist the stability of the whole structure. The theoretical importance of the floors in this respect, under the circumstances, was referred to and recognised again and again in the course of the inquiry. And if this was an object, does it not stand to reason and common sense,—constructional common sense,—that the proper course to take was to fix the large girders transversely, one to each pier, building them into the walls and thus obtaining the important assistance of their mass and weight and strength in connecting the walls together? To neglect this in such case, to lay the main beams longitudinally and only lay the light joists from wall to wall, is a mode of proceeding which seems to us entirely at variance with practical common sense. The Commissioners touch upon this point, but in a remarkably mild manner, and in terms which seem very nearly self-contradictory. In regard to the way in which the floors were actually constructed they say:—

"The mode of supporting the joists at the walls which has been already described was severely commented on by some witnesses, who maintained that the joists should have been carried into the walls. Other witnesses expressed the opinion that the method adopted is superior to the other. This is one of several instances in which experienced practical men have taken diametrically opposite views on points raised in this inquiry. We have no hesitation in expressing our view that the method adopted, which is recommended by most competent authorities, and which certainly leaves the wall stronger than the other does, is to be preferred, and should be adopted in most cases, care being taken to preserve the 'tie' between the front and back walls. This latter point seems in the present case to have received careful consideration, and we have come to the conclusion that the mode of supporting the joists did not in any way contribute to the accident."

We cannot discover any statement in the report or in the published newspaper accounts of the inquiry as to how the joists were connected to the wall, but we agree that the method of supporting them did not contribute to the accident. The report proceeds:—

"An important point raised was as to the most efficient arrangement of the floor-beams in such a building. Here again there was a difference of opinion among experts. We are disposed to agree with those witnesses who held that the best arrange-

ment for the general stability of the building is that the beams should run transversely, so as to connect the front and back walls at every bay and on every floor, rather than those who maintained that a better connexion was secured by placing the joists transversely, as in the case of this mill. The point is one of general interest, but is not of importance in this inquiry, as from the circumstances of the case we have concluded that this point had no material influence in determining the fall of the mill."

Considering the weak construction of the back wall, perhaps this may be so; but if the two walls had been equally well built, though they had been each weaker than the west wall actually was, their mutual stability would have been materially increased by having the main girders built into and connecting them; and we must express surprise that the opinion on this point is given in so doubtful and tentative a manner in the report.

The Commissioners also express in very mild terms the opinion, which many who read the evidence would be disposed to express in much stronger terms, that the inquiry disclosed lamentable inefficiency in the constitution and action of the official building authorities of Glasgow. These consist of a Dean of Guild (who we believe need not necessarily be a man of any expert knowledge in construction at all—he appears to be an ornamental official), a legal assessor, and eight persons called "liners," who are supposed to supply the Dean of Guild with the practical knowledge which he does not possess himself. It appears from the evidence in this case that plans of such a building as the mill in question may be passed by the official authority, though there is no adequate or distinct indication on them of the precise method of construction to be employed; and that one method may be implied and accepted by the authorities on the drawings, and another method employed in construction, without any official interference being aroused. The report says:—

"The plans submitted in this case, which were doubtless in accordance with practice such as are required by law, seem to us of a somewhat meagre description. They were so vague as, *e.g.*, to leave doubtful the mode of supporting the joists, the Court believing by reasonable inference from the plans that one method of construction was intended, while the architect has shown that his intention, though not expressed on the plans, was to adopt a different method, *viz.*, that which was carried out. The plans certainly showed the dimensions and construction of the back wall, which we have considered a material factor in the destruction of the mill, but they did not, and being on a small scale, could not show the details of the iron stanchions, which we have also considered as materially contributing to the disaster.

"Again, in the matter of inspection, it appears that although a different method of supporting the joists was adopted from that which the Court understood that it had approved, and this without the authority of the Court or of any one connected with it, no notice was taken of this important deviation, as it should have been considered, from the approved plans."

The question of building the joists into the walls or not, as we have observed and as the Report admits, was of little practical consequence in the matter; but it is evident that if it had been, the indifference of Dogberry would have been just the same. One of the "liners," indeed (the general "practical" insight of these gentlemen, we may say, comes out delightfully in the evidence), finding that his court was not making a brilliant show in the inquiry, attempted to make capital out of this by saying solemnly, "If when these plans came before us in the Dean of Guild Court, the plans had shown corbels and beams, I for one would never have passed these plans." Unfortunately the decision of the Commissioners that the matter was of no practical importance rather takes the point out of this bit of tardy official virtue.

Another very regrettable feature in the inquiry is touched upon, though lightly and in a somewhat indulgent spirit, by the commissioners *viz.*: the conflict as to responsibility between the architect and mill engineer who were jointly consulted by the building owners. The statement of the latter was that they employed the engineer as a specialist to

make a plan specially adapted for the machinery, driving-gear, supporting pillars, &c., to give the architect information as to these special subjects, the latter being otherwise left to carry out the building as he thought best. There seems to have been room for some misunderstanding between the two as to their respective share in the work. But the architect in his evidence repudiated his client's view entirely, maintaining that he was not responsible for the construction in any way, although he had signed the plans for the Dean of Guild Court; drawing from Colonel Malcolm the very natural remark that he did not know what the value of a signature might be if there was not some responsibility attaching to it. In the progress of the evidence there were further attempts on the part of each professional man to disclaim responsibility and to throw it on the other. In the case of a terrible accident involving serious loss of life, we must say that the spectacle of the two professional men employed each endeavouring to elude responsibility and throw it on the other, is from whatever point of view we regard it, not an edifying one.

Serious blame, however, for the calamity has not been attached to any one concerned, to the extent of direct responsibility for it, still less of criminal negligence. It is a terrible incident in the chapter of accidents, arising from unforeseen and unusual circumstances which were not provided against. But it can hardly now be called an accident if a similar calamity is ever allowed to happen again.

NOTES.

THE Institute of Architects publishes with its last circular an important and suggestive list of points for consideration in regard to building legislation for the County of London. These are grouped under various heads. Among "Definitions" are to be considered "virgin soil," "site" of a building, "centre" of a roadway, "story" of a building; all points on which there are constant misunderstandings. The heading "Erections" which are not to be deemed buildings, but to be under control" promises opportunities for better definition of a building; and under the heading of "Exemptions" it seems to be suggested that there may be some means of escape suggested from a hard-and-fast law which often bears very unfairly or at least inconveniently on the erection of small structures such as greenhouse adjuncts &c. Other headings are "Limits of a Building"; "Walls and Floors," including the consideration of the question of lifts penetrating floors and roofs of separate buildings (a new subject for legislation arising out of modern conditions of life in cities); "Roofs," including "access to roofs"; "Frontage Lines"; "Courts of Appeal"; "District Surveyors," including considerations as to limits of fees; "Light and Air"; "Working of Act"; and "Miscellaneous," under which heading are included considerations in regard to "notice boards and hoardings"; "pilasters and cornices of shop fronts wholly of incombustible materials" (it will probably be for the good of street architecture as well as construction if this subject receives some attention); "direct control of District Surveyors over materials and construction," perhaps one of the most important subjects noted, as in fact the practical efficiency of building legislation largely depends on this.

ALIVELY discussion arose at the Railway Rates Inquiry, last week, out of a demand for certain information on behalf of the cotton trade. Different branches of trade are now submitting their views to the Court. In turn, but points of general interest frequently arise during the hearing of the case of a particular industry. The cotton traders desired to have returns of cotton traffic, showing the tonnage rate per mile independent of terminal charges. The companies at once scented danger, the nature of which Mr. Pope, who is representing the London and North-Western Railway, proceeded to ex-

plain. He commenced by assuring the Court and the traders that the companies wished to deal with them with perfect frankness and courtesy, but confessed to a certain amount of alarm at being called upon to furnish a return "which would be of questionable utility now, and might be available for other purposes hereafter." Mr. Balfour Browne denied in the strongest terms that the traders, in asking for these returns, had any concealed motive, or that they wished to use them for any ulterior purpose. The fear of the companies is that the information given may afterwards be made use of by competitive interests,—notably, the Manchester Ship Canal,—and this suspicion will account for their disinclination to furnish it. The magnitude of the traffic may be gathered from the fact that 500,000 tons are annually sent from Liverpool to Oldham. Several instances were given in which sidings were provided and terminal services performed by the trader, but charged for by the company, and the Court should certainly provide for rebates under such circumstances.

WE referred a fortnight ago to the discussion in the Liverpool Town Council in regard to the continuation of Mr. Stirling Lee's series of sculptured panels for St. George's Hall, and to Mr. P. H. Rathbone's offer to bear the cost of the remaining panels of the series, on condition that they were to remain for at least five years, to give time for a matured public opinion on their merits. The question, as noted at the time, was referred to the Finance Committee, which appears to be (perhaps appropriately enough in these days) the final arbiter in matters of taste. The following extract from the *Liverpool Daily Post* of Saturday last gives the result of the reference:—

"**THE ST. GEORGE'S HALL PANELS.—ACCEPTANCE OF MR. RATHBONE'S OFFER.**—At the ordinary meeting of the Finance Committee yesterday, under the chairmanship of Alderman Radcliffe, the recommendation of the Council referring to them Mr. Rathbone's offer to complete the St. George's Hall panels at his own cost came up for consideration. Mr. Rathbone, in his letter, said that it was not fair to judge the series by the first two panels of Mr. Stirling Lee, and he stipulated that the remaining four should be placed *in situ* for at least five years, after which, if it was decided by the Council that they were not worthy of their place, they could be removed. The designs of Mr. Lee for the new panels were submitted, and were approved of by several members. Mr. J. B. Smith moved that Mr. Rathbone's offer be accepted, and that he be thanked for his munificence. This was seconded by Mr. Holder, Alderman Livingston proposed, and Mr. J. B. Moran seconded an amendment that the Council, having already expressed an adverse opinion on the bas-reliefs, it was not expedient to proceed further in the matter. On a division, four voted for the amendment and seven against. The proposition was then declared carried."

We congratulate both Mr. Stirling Lee and the Liverpool official authorities on the result, and we have little doubt the Committee will discover in the end that they have no reason to regret the decision so tardily arrived at.

AT a meeting of the British School at Athens, on Friday, February 14, Mr. E. A. Gardner read a paper on the technical processes in Greek sculpture, with special reference to a number of unfinished statues which have been found in various degrees of progress, and which are now collected together in the Central Museum at Athens. Mr. Gardner principally concerned himself with the methods of fourth-century sculptors, most of the examples being of that period, but he first noticed a specimen of the early straight-limbed Apollo type, which was found in the quarries at Naxos. This was in the first stage of progress, the figure having been merely rough-d out. He showed how this had been done, much as a beginner would proceed to work at the present time, the sculptor first tracing the lines of the figure on the face and sides of the block and then proceeding to rough out the limbs by cutting off the marble in planes parallel to the face and sides. The surface clearly indicated that this

had been done with a pointed punch. In this connexion Mr. Gardner said that the squareness of the early statues need not necessarily be traced to a wood tradition, and he was not inclined to accept the theory that most of the early *Xoana* were of that material; he showed that the meaning of the word did not imply this, and mentioned several which were known to have been of marble. He argued that roundness rather than squareness of section was characteristic of wood, and he thought that the square appearance of early marble figures might more naturally proceed from the material itself, the rectangular block of marble on which the sculptor set to work. He then proceeded to trace the processes of execution in the fourth century, and the nature of the tools employed, basing his remarks principally on a statue from Rheinea, which showed different degrees of progress on the various portions of the figure, but referring also to the others as he went on. Beginning with the rough marble block, he showed how they first roughly shaped out the figure with a punch driven with a hammer, and not with a pointed axe or hammer, as had sometimes been assumed; how they afterwards dressed down the lines more carefully with a similar but smaller and sharper instrument, and how, when they had got the figure thus blocked out, they proceeded to model the limbs by cutting down the surface gradually with a curved chisel; and he pointed out on the statue small flat cup-shaped sinkings showing the beginning of this process. The general surface was then finely worked over in detail with a claw-shaped chisel, the form of the limbs being carefully worked up, and the folds of the drapery were drilled out with the running bore. He mentioned, as an instance of a different treatment, an early archaic figure from Delos, where the use of the saw could be distinctly traced in the narrow sunk lines of the parallel folds of the straight hanging drapery. He went on to show how the forms of the muscles were afterwards accurately mapped out or outlined, and how the whole figure was again gone over with a finer claw chisel, and finally finished off with a flat one. He had come to the conclusion, from a careful study of these statues, that the sculptor did not work from a finished model, although he may have had a rough study beside him, but rather that he worked quite freely, developing his ideas as he proceeded.

SELEDOM has a town shown so much activity in building as Leipzig has shown recently. The new Booksellers' Exchange, the Conservatoire, the Public Slaughterhouse, and the Workhouse are only just completed; and we find already a large number of other public buildings are nearing their completion. Among these we see an extensive "police headquarters," designed by the architect to the town, "Baudirektor" Hugo Licht, showing highly-interesting elevations and an exceedingly practical plan; an "artisans' school," by the same artist, showing some original detail in the façades; a new "central market," chiefly in iron; an extensive library for the University; and a new building for the "art and science schools," which, although it has very poor elevations, and its interior arrangements are not much better, must, at all events, be mentioned on account of the extent of the building. The competition designs, dispositions, cost, &c., of these buildings, and, above all, of the new Imperial Law Courts (which also are progressing rapidly), certainly have at their time interested the average Leipzig citizen; but never before has the whole community taken such a lively interest in an architectural matter as at present in the "Rathhaus" scheme. There has been much difference of opinion in reference to the demolition of a fine old architectural relic, between architects and lovers of art on the one side, and the ordinary layman on the other. Leipzig may well be proud of having such an interesting and grand old Town-hall as the one built by Hieronymus Lotter

in the middle of the sixteenth century; and yet, now that accommodation is wanting in the old place, a large number of the good burghers seem to have a great desire to pull it down, and to erect in its place and on the sites adjoining an unyielding edifice, containing the offices of the fiscal administration and a town-hall combined. Opposed to this scheme, and backed by the published opinions of the leading architects in Germany,—such as Professor G. Hauberrisser, Regierungs-Baumeister Hoffmann, Oberbaurath v. Schmidt, and Bauath Wallot—we find a design (worked-out and drawn by Herr Reg.-Baumeister H. Solf, according to the ideas and sketches of the above-named town "Baudirektor") which not only saves the old Rathhaus, but also the old Booksellers' Exchange adjoining, and which brings these two buildings very cleverly in connexion with an excellently-planned extension containing all the offices and committee-rooms required. In no way wishing Leipzig to stop its activity in the erection of new public buildings, we certainly in this case hope that the citizens will be satisfied with an extension and a thorough repair of the old Rathhaus; and, seeing that the Town Council contains several members of the architectural profession, we may also hope that these gentlemen, in carrying out work, will unite in the cause of archaeology as far as practical considerations render it possible to do so.

STRASBURG CATHEDRAL is the first German Catholic church in which electric lighting has been applied. It had been feared that this new and strong illumination would spoil the solemn and mysterious effect of the interior, and would at the same time modify the colour effect of the beautiful reddish "Vogesen stone" used in the building; but it has been found that although the groups of incandescent lights attached to the piers and columns certainly light up the latter very brightly, the interior as a whole looks quite as well, if not better, than before. Arc lights have been used outside the building, and these show off the details of the façade exceedingly well.

SOME interesting information which would prove highly valuable to engineers has been recently put before the English-speaking branch of the profession in the "Proceedings of the Institution of Civil Engineers." The town of Cueno, in Italy, has been recently enlarging its water supply, and Mr. G. Ponzio, the engineer in charge of the work, has been largely using cement-made tubes in the formation of an aqueduct. He is loud in the praise of cement for such purposes. It is advantageous in regard to economy, in rapidity of construction, in impermeability, and in facility of adaptation to any form. It also preserves the freshness and purity of the water in a most satisfactory degree. The cost of cement tubes is not more than about 40 per cent. of that of iron pipes. At Cueno the new cement pipes were laid in the open channel which formed the course for the old water supply. There is a fall of 77.8 ft., and the new supply having to be under a pressure due to this head, the tubes having a diameter of 9½ in., the thickness should have been, according to the usual formula, 7½ in. Before constructing his tubes, however, Mr. Ponzio made some experiments in order to determine the correct proportions required, and he found that a thickness of tube of 3.15 in. was amply sufficient. The material used was Casle cement, and the cost was 5s. per yard, including labour; or 6s. 9d. per yard including all contingent charges. During the winter the cement set in twelve hours, but later, when two qualities of cement were blended, the setting was perfect in less than seven hours.

DR. BOHME has communicated to a German publication some details of experiments made with volcanic sand from the Eifel Mountains in Germany, in order to determine its value for making mortar. The

percentage of silica was about 52.0, of alumina 14.0, of lime 11.0, and of magnesia 7.0. The results appear to have been in some instances really remarkable. As compared with the standard sand, it was found that in every case the volcanic sand gave a higher tensile and crushing strength. A mortar composed of one part Portland cement with three parts of standard sand gave a standard strength of 34.15 kilogrammes per square centimetre (485.71 lb. per square inch) when immersed in water for one year, while a similar mortar when made with volcanic sand attained a strength of 50.15 kilogrammes per square centimetre (713.28 lb. per square inch) in the same time. The crushing strength of the same mortars under similar conditions was 320.8 kilogrammes per square centimetre (4,562.66 lb. per square inch), and 499.1 kilogrammes per square centimetre (7,098.58 lb. per square inch) respectively. Mixtures of different varieties of rich lime and volcanic sand were also far superior to mortars made with standard sand. With proportions of sand higher than those stated the superiority of volcanic sand was still more marked, both for cement and lime mortars. In the matter of adhesion and resistance to frost, also, the volcanic sand gave higher results.

MR. HOWORTH asked a question in the House of Commons on Tuesday as to alleged injuries and mutilations to the Beni Hassan tombs in Egypt, mentioning a report that twenty-five names of kings had been erased and the heads of the principal figures abstracted. Sir James Fergusson knew nothing of it, but promised that inquiry should be made of Sir E. Baring. Beni Hassan is too important a chapter in ancient history for dunces to be allowed to erase at their pleasure.

IN regard to Wrexham Tower, of which we published a view last week, a correspondent writes:—"The statement has been ventured that the tower of St. John's, Cardiff, was by the same architect. The Vicar of Wrexham came thence, but the tradition I mention long ante-dates. Having seen the tower of St. John's, I cannot say there is much to compare. Knowing also the tower of Wrexham from a time when all was considered too perfect for restoration, I recollect that one only of the four pinnacles is original, decidedly a Somersetshire feature. Still, Welshmen have a right to be proud of the tower. There are images of saints on three sides, but none on the north. As to the church, there are internal evidences that the clearstory is additional; also the absence of old wood-work may be the saddest evidence of fire. The doorway and window at the end of the north aisle are new compared to the rest. The window-seat alongside the door comes over joint-over-joint work of a doorway now transposed. Access to a gallery, removed at restoration, led to this alteration, and the four-foil panelling beneath the first weather-mould now ornaments the interior. The windows to the last bay of the clearstory, as well as of the aisle, differ from the remainder. The chancel, 'so called,' quite shows that all was chancel until the east window was broken away for the annexation of an insignificant adjunct to a collegiate church."

UNDER appointment of Mr. Justice Stirling, in the suit of Clark v. Clark, the house, No. 14, at the south-western corner of Buckingham-street, Strand, was put up for sale by auction at the Mart, on Tuesday last, and was bought for 10,500l. This freehold property, covering nearly 4,000 ft. superficial, and yielding an aggregate rental of 860l. a year, or, say, 680l. net, stands on the site of a house occupied by Samuel Pepys during the period 1684-1700, and wherein, as their President, he was wont to entertain the members of the Royal Society. Pepys was Secretary to the Admiralty from 1684 to 1688, when Phineas Bowles succeeded him; he was elected P.R.S. in 1684, and held office for two years. In the year 1689 he had for his opposite

neighbour, at No. 15, Peter] the Great. The Buckingham-street of Pepys's day had been built in 1675, after the sale for 30,000l. of York House, together with its grounds, by the second Duke of Buckingham, who removed hence to College-hill, in the City. Of York House, Hollar made a drawing in 1630, whereof Herbert published a print in 1808. Pepys's house can be identified in a plate of Boydell's "Views" (1778); but a better view of it, and of the Czar's lodgings, may be seen in one of the several Thames-side paintings, by James, circa 1756, in, or lately in, the Queen's Presence Chamber, at Hampton Court Palace. When Hatton compiled his "New View of London" (1708), Pepys's house served, as we gather, for the Royal Wardrobe, under the mastership of Ralph, first Duke of Montagu. No. 15 yet remains; No. 14 has been rebuilt. The present house was inhabited by Clarkson Stanfield, R.A., in his earlier career as a scene painter; and, after him, by William Etty, R.A., who, removing hither in or about 1824, resided in it until about fifteen months before his death in his native city, York, on Nov. 13, 1849. We may add that the property has a south frontage of 82 ft. to the private enclosure known as Villiers-wall; and the purchaser is entitled to acquire, by private treaty, the adjacent plot, No. 19, Villiers-street.

THE subject of Westminster Hall was again before the House on Tuesday evening, and the discussion again showed the correctness of our predictions as to what would be thought and said of this piece of archaeological tinkering when completed. This time the carriage drive as well as the staircases came under consideration, and one member observed that "Outside had been provided an extraordinary pit for members' carriages, which recalled the lions' den into which Daniel was thrown. It was a kind of *descensus Averni*, a decline down which no carriage could be driven with safety, and in the shed itself it was almost impossible to turn a carriage round. The shed might do very well for bicycles, tricycles, and wheelbarrows; but it was useless for members' carriages. When two carriages were in a third could enter only by backing down the incline." Mr. Marjoribanks might have read something very like this in the *Builder* before the work was ever carried out, just as all the other objections which are now so violently thought justly made by excited members were made in our columns before any of the work was carried out, and all that Honourable Members have discovered when it is too late they might have discovered before any of the work was done if they had looked for information to those who could give it. Mr. Shaw-Lefevre seems to have abated very much of his former tone of self-satisfaction over the work he did his best to promote, and, after an admission that "there was no doubt great difference of opinion as to the artistic merit of the work done in Westminster Hall" (he has discovered that at last, apparently), contented himself with a mild protest that the money now asked for in "Supply" was only for the purpose of properly laying-out the ground westward of Westminster Hall; and that of course must be done anyhow: so the vote of 2,000l. was agreed to.

ON the same evening, in Supply, the money for the purchase of the land between Prince's-gate and Queen's-gate, from the Commissioners of the Exhibition of 1851, was voted, after a short debate in which the only reasonable objection raised was one in which we rather sympathise, viz.: that before voting large sums for a site and separate new buildings at South Kensington, the original buildings of the South Kensington Museum should be completed. Their incomplete state for so many years is a discredit to the nation.

An "Engineers', Electricians', Builders', and Ironmongers' Exhibition," is announced to be held at the Royal Agricultural Hall, Islington, from March 17 to 29.

LETTER FROM PARIS.

MUCH has been said recently in the Paris press in reference to a supposed new masterpiece by Rembrandt discovered at Pecq, a little town near St. Germain, and which a well-known dealer had purchased for some millions of francs, at a sale of effects of the deceased owner. It was also reported that the new possessor of the picture (of which the subject is "Abraham at table with the Angels"), from motives of patriotism, had refused most advantageous offers for it in order to give the State the option of purchasing it for the Louvre. As, however, the manufacture of "old masters" is at present carried on more extensively than ever in Paris (there was an exhibition very recently, at the Georges Petit Gallery, of a whole set of fictitious Raphael cartoons purporting to have been found in Russia, and said to be far superior to those of Hampton Court!), the artists and the more enlightened portion of the public did not take much interest in this "discovery" of a new Rembrandt, though, as may easily be imagined no pains have been spared to get up an excitement about it. This attitude of scepticism appears to be now justified, as in the opinion of such judges as M. Gérôme and M. Bonnat the picture, though signed and dated, is of very unequal and in part of very bad execution, and cannot be regarded as genuine. M. Bonnat, it may be said, is a kind of expert in regard to Rembrandt, of whose drawings he possesses a remarkable collection. The Louvre is already rich in undoubted Rembrandts, and is not likely to consider any offer for the purchase of a doubtful example.

It is to be hoped that the State will also decline the offer of Manet's "Olympia," which it appears was purchased by the subscription of some artists and amateurs (as noted in our last letter) with the object of presenting it as a gift to the Louvre. Manet was no doubt a remarkable artist in his way, and exercised a great influence on the modern school; but if he is to be represented in the national collection (which seems rather premature) it should at all events be by some work less eccentric than the "Olympia"; though as the picture is offered by persons of considerable position in Paris, there may no doubt be some hesitation about declining it under the circumstances.

At the Hôtel de Ville the second competition for the decoration of the "Siège de Paris" room has just been decided. Five artists were selected to compete again with studies of a portion of each design, the size of the ultimate execution. M. Arus selected a sad enough incident in the combat of Buzenval, M. Adolphe Binet has also chosen a military subject, a battery of artillery; MM. Baudouin and Delance have, on the contrary, painted the sufferings and dangers of the population in Paris during the Siege; while MM. Gilibert and Dupray, who are collaborators in one design, have illustrated the scene of the despatch of one of the balloons which was to convey information of the state of Paris to the provinces. The fine colour of M. Binet's work, and the animation of his figures, captivated the judges from the first, and they have commissioned him to execute the work. M. Arus receives a premium of 4,000 francs, and each of the other competitors 3,000; 80,000 francs has been voted for the execution of the work.

The Committee for the decoration of the Hôtel de Ville has received with great satisfaction the series of sketches by M. Galland for the decoration of the gallery adjoining and parallel with the three Salons à arcades. M. Galland, who has in this scheme fifteen small cupolas, and two pediments to decorate, has elaborated a scheme in which the principal trades of Paris are typified. The artist has been working at this scheme for three years; and as he will be able to commence the work this month, this piece of decoration, on which 120,000 francs will be expended,* may be expected to be completed at the close of the year.

What specially characterises the work of M. Galland is the respect he observes for the lines and details of the architecture,—a matter greatly neglected by many decorators of the present day, and the committee has become painfully aware through many of the sketches of schemes submitted to them; and the process of dividing up the decoration of many of the rooms among

several artists is not likely to improve matters in this respect, as there can be no *ensemble*, no prevailing motive or principle, among several decorators working each in his own way in various portions of the same apartment.

The twelfth exhibition of the "Aquarellistes" represents artists belonging to both the sections into which the Salon disensions have divided the art-world of Paris. Among the best works exhibited are those of MM. Clairin, Duez, Roger Jourdain, and Maurice Leloir, the Spanish scenes of M. Worms, the remarkable drawings by M. Zuber, the illustration designs of M. Boutet and M. Monvel, the flower-paintings of M. Eugène Morand & Co. M. Vibert has this year abandoned his eternal cardinals for a scene in which he represents himself as a "Médecin malade." M. Besnard, talented as he is, exhibits water-colours the colour quality of which becomes more and more incomprehensible. On the other hand his designs for windows for the "Ecole de Pharmacie" are very interesting.

The new Salon, which is now currently recognised as the "Salon Meissonier," in distinction from the "Salon Bouguereau," has been definitely accorded the use of the Palais des Beaux-Arts for its first exhibition to open on the 15th of May. The bureau of the new Society is constituted as follows:

President—M. Meissonier.
Vice-President—M. Puvion de Chavannes.
Presidents of Sections—Painting, M. Carolus Duran; Sculpture, M. Dalou; Engraving, M. Braquemond.
Secretaries—MM. Billote and Jean Béraud.
Sub-Committee of Painting—MM. Daguau-Bouveret, Lhermitte, Cazin, Gervex, Renouard, Baron, Courtois, Guignard, Besnard, Duez.
Sub-Committee of Sculpture—MM. Rodin, A. Lenoir, and Desbois.

The old Salon will retain its old quarters at the Palais d'Industrie, but important modifications are being made in its regulations: the "exempts" are to be suppressed, and all exhibitors are to pass the ordeal of the jury. The rule which limits each exhibitor to two works, however, remains in force.

A committee presided over by M. Jules Comte, Directeur des Bâtimens Civils, has decided to institute a general return of the examples of tapestry which form part of the "Mobiliier national." There are about 600 pieces in the Paris stores of this department, to which it is proposed to add those which are now scattered about in various localities in the provinces, in the palaces at Pau, Versailles, Fontainebleau, and Compiègne, &c. Including the textiles lent to the different embassies of France, there is probably a total of 1,100 examples of tapestry of the first order, and which would form when united a splendid collection. As soon as the inventory is complete, the Gobelins establishment will be charged with the repair of the specimens which are mutilated or damaged, after which the finest examples will be selected for a museum of tapestry to be established at Paris, which will enable the public to become acquainted with artistic treasures of the existence of which it is at present almost in ignorance.

The monument to Paul Baudry, of which we have already given a description, has just been inaugurated at Père-la-Chaise. M. Bartholdi has just completed the model for a monument to Gambetta which a group of inhabitants of Alsace-Lorraine are about to erect near his memory at Avray; it will be placed near the house in which he died. The whole monument will be about 15 metres high: at the foot will be two groups representing Alsace and Lorraine taking refuge at the altar of "La Patrie." At the summit of the monument will be the figure of Gambetta standing and holding the tricolour flag, which he is supposed to have saved, but with the flagstaff broken. It is stated also that M. Bartholdi has for a long time past had a scheme for a monument to be erected on the Place St. Pierre, at Montmartre, to commemorate the services of the aéronauts during the Siege of Paris, but the difficulty was to manage the balloon so as to give it importance in the design. His last idea is that the balloon should be represented by a great globe of thick polished glass which would contain a powerful electric lamp to light the Place St. Pierre. The monument, if it is ever really executed, will certainly be one of the curiosities of Paris, though it may be doubted whether the effect will be as satisfactory as surprising. M. Bartholdi, who has made a kind of speciality of "original" monuments, has not been always very happy in his originalities,

witness the bronze lion on the Place Denfert-Rocherau; and he might contrive to symbolise the aéronauts by something more capable of decorative treatment than a balloon.

While on the subject of colossal monuments we may mention the crusade that has been preached by the Bishop of Verdun in favour of Jeanne d'Arc, in whose honour a great national subscription is proposed for a colossal monument at Vaucouleurs. The pedestal of this monument is to be nothing less than a representation of a Medieval chateau, flanked by four solid towers, and fortified with machicolations, battlements, a drawbridge, &c., all constructed according to the rules of ancient military architecture. The chateau will be dominated by a *donjon* raised at least 40 metres higher, on the summit of which will be placed a colossal group representing Jeanne d'Arc on horseback led by two armed men. Such a scheme will demand money of course, and the Bishop of Verdun commenced on a recent Sunday a series of preachments and collections in the Madeleine in furtherance of this object, which he proposes to continue in a tour through France. The project has, however, been much opposed, as there has already been commenced an important monument at Domrémy, the birth-place of the heroine, designed by M. Paul Scäille; and a commemorative group of sculpture, now nearly finished, was commissioned in 1880 from M. Allar. This monument was interrupted in 1884 for want of funds, and 350,000 francs are still required to complete it. The success of the Bishop of Verdun's appeal would therefore probably prevent, for an indefinite time, the completion of the Domrémy monument.

The Institut de France has received an important legacy from the late M. Piot, a learned collector of works of art, who has left the bulk of his fortune to the Académie des Inscriptions et Belles Lettres. The Fine Arts section is also left an annuity of 2,000 francs, intended to be bestowed alternately on a painter and a sculptor. The Louvre has also benefited by M. Piot's will, and among other objects receives a picture by Raphael and a terra-cotta by Donatello.

Each member of the Institut has received recently a copy of a medal presented to the Duc d'Aumale in commemoration of his gift of Chantilly. The medal is a remarkable and artistic work of M. Chaplain, bearing on the obverse the profile of the Duc d'Aumale and on the reverse a view of the Chateau of Chantilly.

The question, long discussed, as to a diploma for architects has entered on a new phase; and, on the proposition of M. Charles Garnier, as President of the Société Centrale, the Government has appointed a Commission charged to make a study of the legal conditions under which the profession of architecture is exercised, the system of studies by which entry is gained to the profession, and the nature of existing diplomas of any kind in sanction of these studies. A scheme of questions prepared by the Société Centrale, and which deals with both the practical and theoretical side of the question, has been submitted to this Commission, which held its first meeting on February 11, under the presidency of M. Larroumet, Directeur des Beaux-Arts.

At the Ecole des Beaux-Arts, the Jury of Architecture, under the presidency of M. Ginain, has considered the forty-four designs sent in competition for the "Edmond Lahare" prize, of which the subject was "Le Siège d'une Grande Commandement Militaire," a very fine and one would think an inspiring subject. The prize has been decreed to M. Despradelle, pupil of M. Pascal; and "mentions" to M. Eustache, pupil of M. Ginain; M. Heubès, pupil of M. Pascal; M. Majon, pupil of M. Guadet; M. Huguet, pupil of M. Blondel; and M. Louvet, pupil of MM. Louvet and Ginain.

The death of a well-known art critic, M. Ernest Chéreau, is to be recorded. He was one of the Inspecteurs des Beaux-Arts under the Empire. He leaves several works on painting of considerable value; among others "L'Art et les artistes modernes en France et en Angleterre;" "La peinture Française au XIX^{ème} Siècle;" "Les Nations Rivalises dans l'Art." We have also to notice the death of M. Duruy, one of the many architectural engravers who worked on the *Revue Générale de l'Architecture* and on the *Motifs Historiques* of M. César Daly. For some years past, however, M. Duruy had entirely devoted himself to the work for the large Dictionnaire for the Académie Française.

* 4,800, on the decoration of one corridor of a great public building. What a satire on the ways of our English State and municipal authorities regard to art: what a chorus of indignation would arise from "economic" members if such a proposition were made at Westminster or Spring-gardens!—Ed.

ROMAN ARCHITECTURE.*
BY PROFESSOR AITCHISON, A.R.A.

Palaces.

I THOUGHT I might as well say a few words on the Imperial Palaces of the Romans, as they are the most glorified form of houses. They were vast in size, their rooms were large and sometimes colossal, and designed to be worthy of the magnificence of the Masters of the World, with the exception of the Palace of Augustus, which was small in extent, and whose rooms were modest in size. If we were fortunate enough to have the plan of Nero's Golden House, it would, I think, be the plan of the largest palace in the world.

The plans of some of the palaces show great ingenuity, and there is an evident desire to make the State-rooms, of those built after the days of Augustus, as magnificent as possible, by grandeur of size, by ornamental shapes, and by sumptuous decoration.

The scraps of precious marbles, and of carving, would show how magnificent their linings were, both inside and out, even if we were without express statements of their sumptuousness in the Roman writers.

Beyond their plans, the costly fragments, and the loose descriptions of their magnificence, all is darkness,—a darkness, too, hitherto impenetrable to our eyes and our researches. Pliny's letters, through the studied elegance of their language, have come down to us, and in them we find a rough description of two of his villas, and thus know something of the arrangement and use of the rooms. We get, too, a glimpse of the decoration of one room, with its carved marble dado, and its painting of birds and foliage above.

In the palaces, alas! we know nothing of the uses of the rooms—we can but guess at the uses of a few; and the historians merely speak of the gold, ivory, and mother-of-pearl, of the costly marbles and gems lavished on the interior of Nero's. Here and there amongst the ruins the painted decoration of some upper-servants' rooms have been found, which are just enough to whet our appetite for the lost magnificence of the master's halls. We can scarcely imagine that it never entered the head of a court-painter, usher, or chamberlain to write a book on the arrangement and adornment of the Court; but it is not common for such persons to acquire a style that will make their hook a treasured possession when the ceremonies have ceased and the palace is in ruins. Such descriptions are generally slipshod and bombastic, and soon find their predestined end at the hands of the pastycook, the grocer, the hutterman, or the stoker. A dining-room, baths, fountain-rooms, and some of the meanest offices proclaim their use, but to find out the destination of the bulk of the rooms seems to defy our attempts, as we neither know the officers employed, nor the usual ceremonial, so that each room can only be described as a fine large oval, circular, square, or oblong room, with columns, niches, recesses, or windows. The value of the architect's and sculptor's work is, however, not wholly lost to posterity; we can often trace the plan, when excavations are made, even when the structure has been pulled down, from the bottom of the walls being mostly covered by rubbish, which has by concealing them prevented their total destruction, and can thus judge of the architect's skill in planning, and of the elegance or coarseness of his moldings. A few scraps may reveal to us the sculptor's genius, skill, care, and knowledge; but it is only through exquisite verbal descriptions that the past can be sufficiently preserved to enable us to re-create and re-people it.—I say exquisite verbal description, for if it be not exquisite it perishes too, so true is Horace's remark:—

"Many, many have lived, who were vallant in fight,
Before Agamemnon; but all have gone down,
Unwept and unknown, in the darkness of night,
For lack of a poet to hymn their renown."

The first of the Royal palaces, after the Republic, was that of Augustus, on the Palatine. We know from Suetonius that he first bought the house of Hortensius, the orator, and used it for his residence. (Suet., "Aug.," 72.)

We also read that his house on the Palatine was burnt down and rebuilt by the sub-

* Being the fifth Royal Academy Lecture on Architecture this session, delivered on Monday, February 10, (For the four previous lectures, see the *Builder* for Feb. 1, 8, 15, and 22 respectively.)
† Hor., *Lib. IV.*, ode 9, canto 7. Sir T. Martin's translation.

scriptions of the veteran soldiers, the judges, the tribes, and the people ("Aug.," 57); but whether it was the same house of Hortensius we do not know. Still I think that if that which is called the house of Augustus were his, it must have been built or rebuilt for a palace, as so many of the rooms are evidently designed for State purposes. I think, in fairness to this autocrat, we ought to admit that he had some public virtue. Suetonius ("Aug.," 21) says:—"By the character which he thus acquired, for virtue and moderation, he induced even the Indians and Scythians, nations before known to the Romans by report only, to solicit his friendship;" and as Lucian makes Dionysius, the Sicilian tyrant, get off from being tied to the back of the Chimera through Aristippus "alleging that he had been ready and judicious in his pecuniary gifts to several men of learning" (Lucian's dialogues, "Menippus"; or, the Oracle of the Dead), we also should make some allowance for the patron of Horace, Virgil, and Livy, and for the rule of a despot that allowed the works of Sallust, Ovid, Tibullus, Propertius, and Cornelius Nepos to be published. But whether we condemn him as a tyrant who riveted the chains of slavery on the Roman people, or absolve him by saying the time had come when Rome was unable to govern itself, we must allow he had a williness and astuteness that were almost superhuman, which induced him to show as little arrogance and ostentation as possible. With this object in view, he made his palace small in size and of common materials, so that it by no means equaled in magnificence the greatest houses of the nobles. The space covered on the ground-floor was but about 253 ft. wide by 213 ft. deep, but it was about as deep as wide on the first floor, viz., about 252 ft., or more, where its front was on the higher ground. Its south front is not half the length of that of Diocletian's, 592 ft.; it is less than Blenheim, which is 323 ft.; and less than Castle Howard, which is 292 ft. On the ground-floor it consists of an entrance corridor, from a street at the side of the Circus Maximus, leading into a peristyle. At the opposite end, next the peristyle, are three rooms of unique shape, and with all the characteristics of Byzantine work, and the only light they get, except through the doors, is from circular openings through their vaults into the rooms above; the two side rooms are octagons, with four semicircular niches on the slanted sides, and three oblong recesses, with a niche at the back of each on the three square sides, the fourth side being the door. These two halls look like audience chambers; the centre one is called by Guattani the Chalcedicum, and is supposed to have been used by Augustus when hearing cases. The Chalcedicum seems to be a square vaulted chamber, with a large semicircular niche on the right and left sides, and an oblong recess with a niche at the back, opposite the door. On each side of the niches are passages, the front one leading right across that end of the building to an open court on one side, intercepted only by the two other halls, which are entered through their niches; the passages on the further side of the niches in the Chalcedicum lead into a suite of three rooms with closets at each end. If you consider that each passage had a curtain where it abutted on to the Chalcedicum, you will understand that no arrangement could be more safe or convenient; the two back rooms next the passage could be filled with guards, and another with such lawyers or friends as he might wish to consult, and he could slip through the curtains, enter these back rooms, or he could go into either of the halls on each side, by the front passage, or to his private apartments, either on the ground or first floor, as there are staircases by the sides of the open courts. The two flanks of the peristyle contained the rooms belonging to the baths, an open court, and perhaps other rooms,—certainly one large room on each side, nearly of the proportion of a Triclinium, shown by Guattani without window or door openings; so that we are led to the conclusion that the walls were destroyed to the level of the ground when the Abbé Rancourell had the palace excavated. The whole plan is perfectly symmetrical on a centre line drawn through the centre of the entrance to the centre of the Chalcedicum. Taking, therefore, the front on one side of the entrance, we find, adjoining the peristyle to the south, two oblong rooms with the corners cut off, separated by an oval room at right angles to them, whose semicircular ends project beyond the width of the former rooms, thus form-

ing a sort of Greek cross. Towards the front are two circular chambers, with passages round two of their sides, that communicate with the front and the oblong chambers before mentioned; between the passages of the circular chambers, the oval room, and the front, is a small oblong room. There are no rooms that would answer to the ordinary dining-room (Triclinium), except the two on the flanks before mentioned, which are shown without either door or window openings.

Augustus was a spare eater, and may have preferred a circular dining-room, only admitting of eight persons at the most; but this could not have been the case when he had the fancy-dress supper-party representing the twelve gods and goddesses of Olympus, where he played Apollo. He may, and probably did, dine on the first floor. We also know that the Empress Livia passed some of her time spinning amongst her maids; and his sister and two grand-daughters, who probably passed much of their time in the palace, used to spin too.

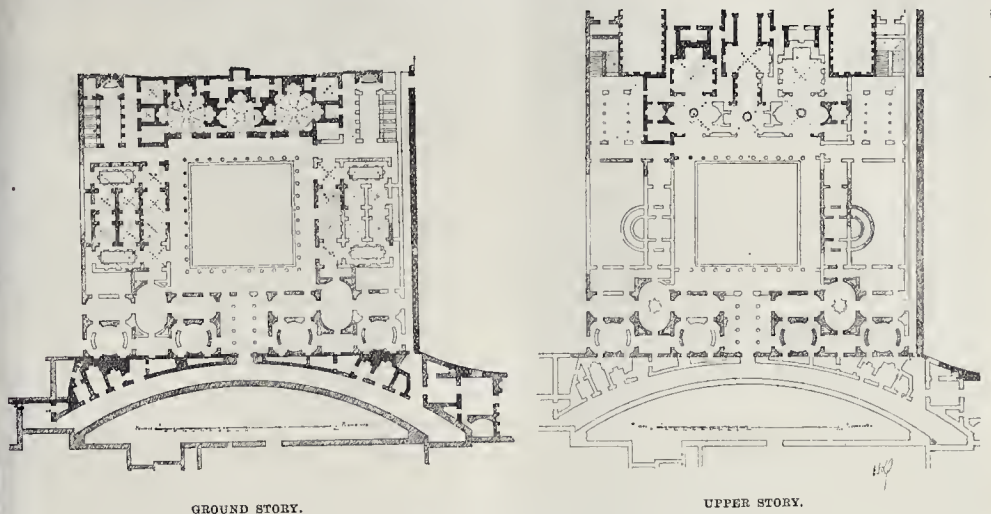

Suetonius ("Aug.," 7) tells us, "He seldom wore any garments, but what were made by the hands of his wife, sister, daughter, and grand-daughters." So there must, one would fancy, have been rooms for weaving, fulling, and dyeing, not to speak of the rooms where he dictated to his secretary, his workshop, or museum (Suet. "Aug.," 72), the rooms where his grandsons, his own philosopher, and his grandsons' tutors lived, and the kitchens and pantries; not to speak of the rooms for the chamberlain's pages, ushers, and guards.

On the first-floor the palace was entered from the north, i.e., from what was the back on the ground-floor; the two staircases from the ground-floor land there. The back part above corresponds precisely with the rooms of the front part below. On the flank there are only two narrow oblong rooms, and one of moderate size, with a semicircular end projecting in front of the former rooms, with an outside passage all round it.

The back part below, as I said before, becomes the front above, entered from the back of the grounds of the Temple of Vesta, and it seems thus laid out.—First, there was a lobby with two calls on either side, probably for porters or guards; the lobby led into a small Atrium with a small Tablinum at the back, opening on to a room over the Chalcedicum, and possibly two small Triclinia to the right and left, with passages and an ample space between for guards, servants, and for serving tables, the ends of the Triclinia opening out on to two rooms, if I may so call them, over the halls of audience beneath. Nowadays we should fancy them to be rooms adorned with flowers and shrubs, because they could not well have been used for much traffic, seeing there were marble gratings in the middle, some 6 ft. in diameter. It is possible that the Triclinia were so small because these end rooms served for the mountebanks or buffoons to perform in. Suetonius says ("Aug.," 74) he "introduced buffoons and stage players, or even low performers from the circus, and very often itinerant humorists, to enliven the company."

The plans given are enlarged from those by Guattani. In 1775, the Abbé Rancourell discovered these remains and had them excavated, and the plans taken by the architect Barbani, from whom Guattani had them, and published them in his "Monumenti Antichi Inediti" (1784-5). The Abbé was very jealous of any one seeing the ruins, much less taking dimensions; but Guattani says Piranesi paid some of his people to take them at night, at the risk of their lives, for fierce dogs were kept there as well as watchmen; and I believe Piranesi published plans which M. Deglaine has accepted, but they differ somewhat from Guattani's. From Guattani's statement, the architect Barbani, who could measure and plot them at his ease, is much more likely to be correct than Piranesi's people, who had to get them by stealth.

When the Italian Government has this palace re-excavated, we shall know which plan is right, for after the Abbé had had the palace excavated, he had it filled in again. The site had been previously searched by the Spada family, who found there the antiquities still adorning their palace; but the former search must either have been superficial or incomplete, for the Abbé found the Apollo Sauroctonos, now in the Vatican Museum, two statues of Leda, one of which is in England, a head in metal, other heads, busts, and parts of figures, as well as numerous fragments of capitals, cornices, friezes, &c.

GROUND STORY.

UPPER STORY.

Plans of the Palace of Augustus on the Palatine: after Piranesi.

(Reproduced from the Gazette Archéologique.)

On the ground in front of the palace, on the first floor, Augustus constructed a vast portico with upwards of fifty fluted columns of Giallo Antico, and enriched the portico with statues of the Danaïdes between the columns, and in front of the columns with fifty equestrian statues of the sons of Egyptus the husbands of the Danaïdes, all of whom were killed by their wives, with the exception of Lynceus the husband of Hypermetra, who succeeded Danaus as King of Argos. Although these murders are said to have been condoned, the poets make the Danaïdes condemned to draw water in leaky vessels after they had crossed the Styx.

At the north end of this portico, Augustus built and dedicated a temple to Apollo, commonly called the Palatiae Apollo, on a spot that had been struck by lightning. Once before, when in Spain, he had escaped, when the slave who carried a torch before his litter was killed by lightning, and in consequence he dedicated a temple to Apollo Tonans. (Suet., "Aug." 29.)

The Sibylline books were kept by Augustus's orders in two gilt coffers in the pedestal of the statue of the Palatiae Apollo, according to Suetonius, ("Aug." 31), though the originals were burnt when the Temple of Jupiter Capitolinus was destroyed in the wars between Marius and Sulla, but fresh copies were obtained from Greece, Italy, and Asia Minor. Between this temple and the palace was a circular temple to Vesta, which only projected enough to break the peristyle surrounding the Temple of Apollo; there are grounds to the Temple of Vesta, as well as a grove, and a house for the Vestals, and to the right of it, and nearly in a line with the portico of the Temple of Apollo, was the celebrated library of Augustus, called the Apollinean Library, filled with the Greek and Latin authors, and where the Senate occasionally met.

Tiberius built a palace to the left or west of that of Augustus, and, according to M. Deglaine, considerably to the north of the north front of Augustus's Palace, so as to avoid the houses of Livia and Germanicus and the Temple of Jupiter Victor. In the grounds at the front of this temple, which faces the south, Tiberius seems to have built his libraries, with peristyles at the back of them, which abut on the flank of Augustus's Palace. I may here remark that Thon's, Canina's, and M. Deglaine's plans so greatly differ from one another that they cannot be reconciled. My description is from M. Deglaine's plan, which is from the latest excavations.*

To the north of the Palace of Tiberius, and

* This plan was given as a lithograph in the last number of the Builder.

extending beyond it to the east and west, Caligula built his palace, and there was a passage to the north of the house of Livia that ran along the east side of the Palace of Tiberius, in which the demented tyrant, Caligula, is supposed to have been killed; subsequently Nero built his Golden House nearly from the Circus Maximus at the south end, to the Quirinal Hill at the north. Some of the lower chambers of his palace are under the Theatridion of Titus's Baths. Vespasian built the Colosseum on a part of the Golden House; and a part of it was seemingly demolished to make room for the Basilica of Maxentius—at least it is so shown in Pirro Ligorio's drawings, and it extended eastwards to the ground in front of the Coelian Hill.

A plan of the former palaces and some of Nero's Golden House is given in C. Thon and Ballan's work on the Palace of the Caesars (Fol. Rome, 1823, with text in 8vo.) and in Canina's plan of Ancient Rome.

When my old friend, M. C. Lucas, the well-known French architect, heard I was going to touch on the palaces of the Caesars, he was kind enough to mention it to M. A. Levy, the Editor of the "Gazette Archéologique" and "Le Moniteur des Architectes." M. Levy, with that magnanimity which so distinguishes our brothers across the Channel, not only presented me with M. Deglaine's article and plans of the palaces of Augustus and Domitian, but gave me leave to publish the plans, and offered to lend me the plates. As it is entirely through the kindness of these gentlemen that I have been able to give a description of the last discoveries and restorations of the palaces of the Caesars, I take it for granted that I may return your thanks with my own to Monsieur C. Lucas, M. A. Levy, and M. Deglaine.

The palaces of Augustus, Tiberius, Caligula, and Nero being built, the only spaces left were two pieces of ground, the first extending from the grounds of the Temple of Jupiter Stator to the Libraries of Tiberius, and the other from the Library of Augustus to the south front of his palace. From the first plot at the north end a piece had to be left for the grounds of the Temple of Jupiter Stator, and a wide road between it and Tiberius's Palace, as an approach to the back of the Temple of Jupiter Victor. There was thus left an oblong site, extending southwards from the grounds of the Temple of Jupiter Stator to Tiberius's Libraries, and from west to east from the road to the Temple of Jupiter Victor to the enclosures of the temples of the Apollo Palatine and Vesta, and the west flank of Augustus's house.

The second plot was on the east side of Augustus's Palace, extending lengthwise from the Apollinean Library to the Circus Maximus,

and crosswise from the east flank of Augustus's house to a part of Nero's Palace, supposed to have afterwards been restored by Septimius Severus. On the first-mentioned plot Domitian built some State-rooms; in the middle was a large open peristyle, to the north was a magnificent hall, called by M. Deglaine the Tablinum, and by Professor Middleton the Throne-room. It is divided lengthwise into five bays by six columns, with piers at the back of each column, forming recesses, and at the back of each recess is a square niche; the ends are divided into three bays by four columns; at the north end is an entrance to the middle, and a recess on either side the doorway. At the south is a flat apse in the middle, and two doors on either side; in the apse the Emperor is supposed to have sat on his throne; to the left is a Basilica, where it is supposed he gave judgment; and at the back of it a passage, staircase, and small room.

On the right of the Tablinum is a Lararium, or private chapel, a staircase, and a room nearly square. The east side of the peristyle touches the wall of the grove of Vesta; to the left or west side are a series of five rooms, a circular one in the middle, with semi-circular rooms at either end of it, and at each of the extreme ends is a shallow oblong room, also with one semi-circular end; the semi-circles do not touch one another, but are joined by a wide passage forming an oblong recess to each semi-circle. You see by the plan that there are spaces between the outer walls and the semi-circles which are formed into four rooms or recesses in the shape of lunettes. At the south end of the peristyle is a magnificent Triclinium or dining-room, with a Nymphaeum, or fountain room, on either side, and at the back of the western Nymphaeum a few small rooms.

You at once see the change that had come over the people and the Emperor. Augustus tried to avoid ostentation, and to house himself and family modestly. Tiberius, when he was made Emperor, said he had a wolf by the ears. Nero himself is supposed to have perished through building such an enormous palace; but Domitian built four or five State rooms on a site that is bigger than that of Augustus's Palace: the Throne room, about 115 ft. by 89 ft., would nearly occupy a fourth of Augustus's Palace; and you must remember that Domitian had all the other palaces for habitation as well.

On the other plot Domitian built a Stadium with a large apse or hemicycle in the middle, in which he probably sat. He seems, like Nero, to have been passionately fond of the games, and is reported by Suetonius to have had girls run for prizes. There are some small rooms at the south end, as well as at the back of the

hemicycle. The latter are said to be the *Therma* connected with the Stadium. Domitian also made a curved portico to screen the south front of Augustus's Palace. The magnificence of his palace was such that when Plutarch describes the Temple of Jupiter Capitolinus, rebuilt by Domitian, he says:—"But, after admiring the magnificence of the Capitol, if anyone was to go and see a gallery, a hall, or bath, or the apartments of the women in Domitian's Palace, what is said by Epicharmus of a prodigal,—

'Your lavish'd stores speak not the liberal mind,
But the disease of giving;'

he might apply to Domitian in some such manner as this:—*Neither pity nor magnificence appears in your expense; you have the disease of building; like Midas of old, you would turn everything to gold and marble.*" (Plutarch's "Publicola." Langhorne's Tran., 8vo. Lond., 1801.)

According to Martial, Rabirius was the architect of Domitian's Palace, which was called the *Parthasian*, because it was supposed to be on the site of the palace built by Evander, the Arcadian or Parthasian, when he emigrated to Italy and became a king.

Looking at the generality of Roman buildings, it seems unlikely that this palace was so enormously high, but the diseased vanity of tyrants makes them admire the most fulsome and absurd flattery, and Martial was quite ready to fool this tyrant to the top of his bent; he meanly revenged himself for his own servility by abusing Domitian after his death, and it is thought by some that Trajan looked upon him with disfavour on account of this marked characteristic of sycophants, and that in consequence he left Rome and died in poverty at his native town of Bithilis in Spain.

This is his epigram (Lib. VIII., 36):—

Smile, Cæsar, at the pyramids' loud fame;
Memphis, no more thy barb'rous wonders name;
Th' Egyptian works reach not the smallest part
Of the Parthasian court's majestic art:
No such illustrious piece the day does show;
Nor Sol In's universal travels know.
Seven vast pavilions, like seven mountains, rise,
Seven vast pavilions, like seven mountains, rise,
Pæon on Ossa could not so the skies;
Thunder and clouds beneath, th' aspiring top
Enters the heavens, and gainst the stars does knock;
The sun salutes it with his early ray,
On highest hills 'tis night, when here 's the day.
Thy palace, 'bove th' Olympian though renown'd,
Unto its lord is not yet equal found. —Anon. 1695.

In front of the building, to the south of the Library of Tiberius, M. Deglane shows a building which he calls the *Pædagogium*, or dwelling of the Court pages, oblong in form, with a slanted side next the *Circus Maximus*. The building consists of a long and narrow peristyle, with four rooms on either side; and, in addition, in the centre of the north side is a hemicycle, and corresponding with it on the south side is a large room with a segmental back. There are corridors at both ends, the west one returning round a part of the south side. At the back of the east corridor are two good-sized rooms, and a large one in the middle of them; and in front of this, to the east, is a deeply-recessed portico opening on to a grand staircase.

The *pædagogus* was originally a trusted slave, to whom the sons, and sometimes the daughters, of the house were given in charge to be taken to and from school and the gymnasium. The main duty of the *pædagogus* was to keep them out of mischief; he was the same sort of person in Roman times as the tutor was here in the last century, whom Horace Walpole irreverently called a "bear leader." We read about the *pædagogus* in the "Bacchides" of Plautus; but under the Emperors the court-pages were the sons of freedmen citizens.

It got to be a fashion amongst the great to choose their pages, who were mostly slaves, for their beauty, and to dress them in the most magnificent manner.

Pliny (N. H. Lib. XXXIII., cap. 12), in speaking of gold with which the women bedizen themselves, says:—"Much more becomingly do we accord this distinction to our pages, and the adorned beauty of these youths has quite changed the features of our public baths." We read in Pliny the Younger (Lib. VII., lit. 27) that the pages had an apartment to themselves in great houses called the *Pædagogium*; in telling us of Roman strip rapping, which then took the form of hair-cutting, and of the ghosts that remind one of a story in the tales of old Japan, he says:—"I have a freedman Marcus, not an illiterate man. As he and his younger brother were lying together in the same bed, he fancied

he saw somebody sitting on the bed moving a pair of shears to his head, and cutting the hair off from the top of it. When it was light, the hair from the top of his head was found to be cut, and the hairs were found lying about. A short time after this, an event of a similar nature gave credit to the former story. A lad was sleeping in the *Pædagogium* with the rest. As he relates, two in white shirts came through the windows and sheared him as he was lying, and returned by the way they came. The day showed that he also had been sheared, and his hair spread about."

Augustus merely assigned places to the *pædagogoi* at the games, immediately behind those of their young masters, but Suetonius speaks of Nero's houses (*Pædagogia*) for pages who were free horn.

The Palace of Diocletian at Spalatro* is one of the few palaces of which any exact outline is left, and if Robert Adam is to be trusted, the outline is pretty clearly defined; some of the towers still remain, as well as the Temple of Jupiter, the Temple of *Esculapius*, a circular hall, and enough of the walls to enable the restoration to be made with fair accuracy. Within the palace walls about half the modern town is enclosed.

Adam gives the width as 592 ft. by a depth of 698, including the angle towers, and about 532 ft. by 638 ft. to the outside of the walls.

To the north is the *Porta Aurea*, or Golden Gate, flanked by two octagon towers, which admits into a sort of guard-room lobby; from this lobby a straight street, about 35 ft. wide, with a covered passage on either side, leads up to the steps of a tetrastyle portico. At right-angles to this, and in the middle of each of the enclosing flank walls, is a street of the same width with the same covered walks, going from the east to the west gate, which are called respectively the *Bronze Gate* (*Porta Ænea*) and the *Iron Gate* (*Porta Ferrea*). All round the inside of the walls up to the *Palæto* itself are a series of cells with a covered walk in front of them, probably barracks for his guards, with a pair of staircases by each gate to lead to the ramparts. [See Lithograph plan.]

Illyria and Dalmatia were notorious for piracy, and nothing could have offered a greater temptation than an emperor's palace to plunder, with beautiful women and handsome pages to be sold in the slave-markets, had not the Palace been well garrisoned.

In the two islands to the north, formed by the crossing of the streets, are two large blocks of buildings, detached from the covered walk of the harracks by open streets about 30 ft. wide, their southern walls form the back of the covered walks to the cross streets, and their eastern and western of the main street, near the *Porta Anrea*.

To the south of the cross streets are two open squares, walled in on three sides, and screened off next the street by an arched colonnade to each. In the area of the east square is the octagon temple of Jupiter, and in the west square is a small temple to *Esculapius*;—at least, these are the names given them by Adam.

Severus Alexander, who lived some sixty years before Diocletian, had two private chapels in his palace: one dedicated to the Virtues and the other to the Talents. In the first he put statues to Alexander the Great, Abraham, Orpheus, Apollonius of Tyana, and Jesus Christ.

In the other he had statues of Achilles, Cicero, Virgil, and of other famous men, and offered sacrifices to them every day.

From the portico before-mentioned the body of the palace is entered by a doorway in the centre of the back wall of the portico, and leads into a circular chamber about 38 ft. in diameter, with four niches from which you enter a hall (possibly) of audience, about 98 ft. long, by 80 ft. wide, but divided into a nave and two aisles by six columns, leaving the nave about 45 ft. wide. Opposite the entrance is a door to the enclosed portico or cloister facing the sea; in the upper or north corners are two closets about 12 ft. square, and the same spaces are cut off at the south or lower end, and contain circular staircases. In each side of the hall, near the upper end, is a doorway leading to a passage which communicates with the other rooms of the palace; this hall was probably an Egyptian one, as it has no windows. Just as in the house of Augustus, each side of the Palace to the right and

* It is now spelt Spalato, but I give the name from Robert Adam's "Ruins of the Palace of the Emperor Diocletian at Spalatro in Dalmatia." (Fol. 1764.)

left of the great hall, is exactly alike, and leads one to believe that one side was devoted to the ex-Empress and her suite, for there is a suite of bath-rooms on each side.

In his restoration, Adam shows four doors to each of these passages, one to the great hall, one opposite into a long room without windows, one at the north end, opening into a square room, and one at the south end into a hall parallel with the sea, about 88 ft. by 59 ft. The first square room to the north communicates with similar square room to the west, both of these rooms having openings 26 ft. wide into the court of the Temple of *Esculapius*, and this court was probably a garden. After Diocletian's abdication, Maximianus, his former partner in the Empire, tried to persuade him to resume the reins. His celebrated reply is well known:—"You should see the vegetables I grow in my own garden, cultivated with my own hands, and you would not talk to me of empire." And he also said, "An honest, cautious, and excellent Emperor is sold."

The room into which the south end of the passage leads seems to be another Egyptian Hall, for Adam shows it without windows, though I am inclined to think the room from which the passage is cut off must have been an open court. At the south end of the last is one door leading into a large oblong peristyle, with a large apse to the north end, which Adam supposes to be the swimming-bath; but which bears a strong resemblance to the *sterquilinum* of the house of Augustus, beyond this are two rooms 31 ft. and 25 ft. wide, and 64 ft. long, which Adam calls the *spheristerium*, and *comatio*. At the back of them, beginning at the west and working east, there is a passage, five rooms, and a staircase; the first room from the passage is trefoil shaped, which he calls Diocletian's bed-room, and the other four rooms baths.

We must thank Adam for what he did, not blame him for what he possibly could not do. Probably additional information could be obtained if the Emperor of Austria would be at the expense of excavating, and put the work into the hands of some of his learned architects; at any rate they should find the hanging floors of the bath-rooms, probably the fine and water-pipes; but as it is the rooms are arbitrarily named, I may here say that in this, as in the house of Augustus, the repetition of the halls and baths certainly points to male and female sides of the house.

Nothing remains now but to examine the two blocks of buildings in the North-East and North-West Islands; the remains of the North-West show an open peristyle with two long galleries on the east and west sides and two short ones at the north and south ends. Adam, in his restoration, calls it "Gynæceum, Textorium, seu Conclave, apartments for matrons and young women," literally the women's apartment, the weaver's shop, or the cage.

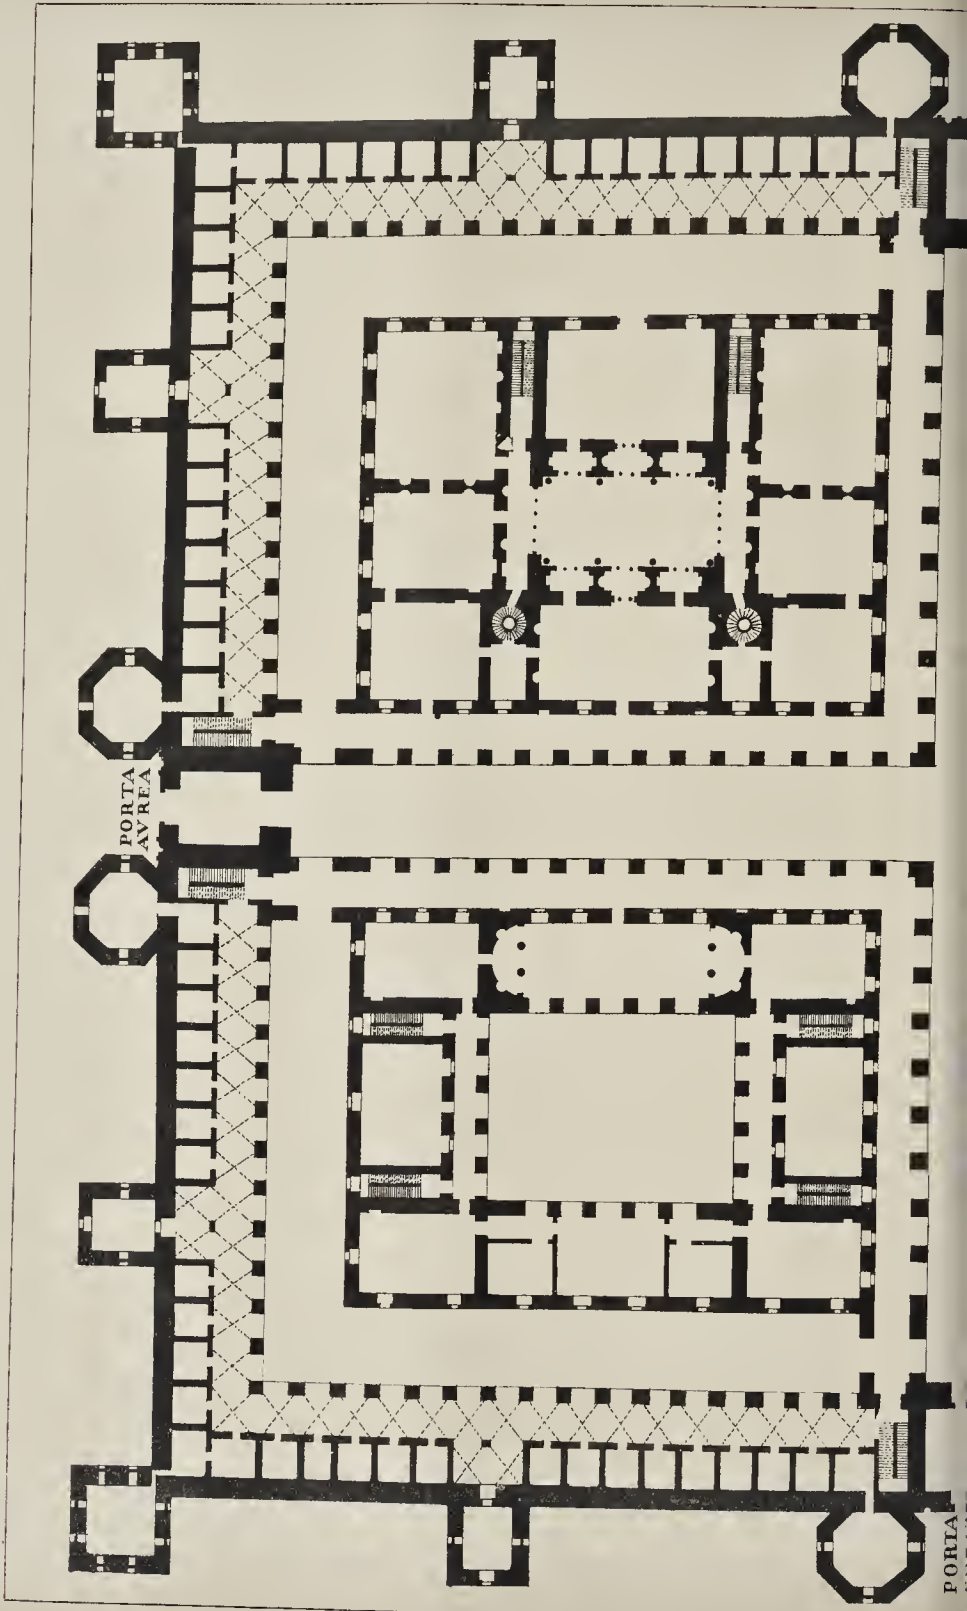

The one in the North-East Island he calls the *Alceum*, or apartments for courtesans. Diocletian had his palace in 303, abdicated in 305, and died in 313. As he was unable to protect his daughter Valeria, the widow of Galerius, from being banished to the deserts of Syria by Licinius, I fear his courtiers, if he had any, were merely dependents, and it is possible it was the *Pædagogium* or the *Hospitium*.

It was customary for the wealthy to have an *Hospitium*, or part of the house set apart for the lodging and entertainment of foreigners who had rights of hospitality with them. We know something about it in the Greek house of from Vitruvius (Lib. VI., cap. 7, p. 4), but nothing about it in the Roman house, except from stray passages in the Classics. When Trimalchio at his dinner-party describes his house he mentions this part. His description is as follows:—"I built this house. As you know, it was a cottage, now it is a temple; it has four dining-rooms, twenty rooms, two marble porticoes, above a series of many cells, a bedroom in which I sleep, the dwelling-place of this viper (his wife), an excellent porter's box, the guests' quarters (*Hospitium*) take a hundred guests. In short, Scæurus, when he comes here, is never unwilling to put up; yet he has by the sea his paternal guest-chambers, and there are many other parts, which I will show you." (Pet. Sat., cap. 77.) This *Alceum* Alcuicornus may have been the guests' quarters; and, as we are absolutely ignorant of how the guests were accommodated, it may be that they were lodged in a kind of barrack.

This block has also an open peristyle in the middle, three rooms to the north, and three to the south, a room on either side of the peri-

PLAN OF DIOCLETIAN'S PALACE AT SPALATO

284-313 A.D.

(In Illustration of Professor Aitchison's Lectures.)

yle to the east and west; two passages with arcades at each end, the west ones circular, and two closets, 14 ft. by 6 ft., to the west. The dam makes the peristyle like the *Tepidarium* of a bath.

The plan of this palace is a commonplace, and, as far as we can judge without knowing to what purpose the buildings to the northeast and north-west islands were devoted, not particularly convenient.

The square hall to the south-east, too, cannot have had much light, as its window is within 1 ft. of the portico surrounding the Temple of Jupiter, unless, indeed, the room shown at the back was an open court. The architectural proportions are generally odious, the mouldings are coarse and commonplace, and the floral sculpture is hardly equal to the productions of the commonest plasterer of Drury-lane; but, for all this, Diocletian's palace is one of the most interesting buildings in existence, and the most interesting with hope for the architects of the present day.

In the first place, we see the work of independent thought in many parts of the building, quite as strongly as its want of taste. In the entrance portico the architect wanted a central entrance, so he bent the whole entablature into a semicircular arch, resting on the two central columns. He wanted to hide the temple as little as possible by the screens, and so made the arches spring directly from the capitals of the columns. He wanted to ornament the upper piece over the doorway of the *Porta Aurea*, between the two towers, and put an arcade resting on columns that were carried by corbels; and lastly, he wanted to build a dome without centering. Why it is so encouraging to the architects of the present day is readily explained: it shows that to however low a state architecture has fallen, the seeds of a new style may be planted so soon as men begin to think for themselves, and to act boldly and logically on their convictions; for here we see an architect who was halting between two opinions, who adhered to his precedents so long as he could do so without damage to the effects he wanted, but who boldly threw them aside when they interfered with his conceptions. This palace is the halfway house between the Hellenistic architecture of Rome and the Roman architecture of Byzantium, when it was freed from the trammels of a style that did not suit its constructional advance.

SCULPTURE ON GREEK TEMPLES.—I.

ROYAL ACADEMY LECTURES.

MR. A. S. MURRAY, Keeper of Greek and Roman Antiquities in the British Museum, delivered the first of a course of three lectures on "Sculpture on Greek Temples" at the Royal Academy on the evening of Monday, Feb. 17.

Mr. Murray commenced by quoting a passage from the play of *Ion*, by Euripides, to show that usually the sculpture on a Greek temple was disposed in the pediments, metopes, and frieze. But there were some important exceptions to that rule. There were columns which, instead of being merely fluted, were partly sculptured. It happened that the only examples of sculptured columns, known either from ancient literature or from actual remains, were those of the Temple of Diana at Ephesus. The site of that temple was some years ago largely, though not completely, explored by Mr. J. T. Wood, at the instance of the British Museum. Among much that rewarded his unrewarded labours, the first thing that attracted general attention was the large sculptured drum of a column, now to be seen in the British Museum, with other parts of similarly sculptured drums. These sculptured drums had belonged to the last temple of Diana,—the one which was erected in the time of Alexander the Great, and which lasted down into Christian times. It was a building of immense size, great wealth, and a source of much profit to the citizens of Ephesus at various periods of its history. The character of the sculptured drum referred to was sufficient to determine its date; besides, we had the statement of a Roman writer that a certain number of the columns of that temple had been sculptured,—*columnæ celsæ*, as he called them. It was supposed that these sculptured columns had been placed in the front and at the back of the temple. But points of more interest, perhaps, were—(1) how and up ere they sculptured? and (2) on what sort of base did they stand? With regard to the first question we had a certain amount of

evidence on a coin of Ephesus, which gave a view of the front of the temple. That coin was quite clear and explicit on the point that the columns were sculptured only on the lowermost drum; but in view of the diversity which existed among the pieces brought to the British Museum, it had been argued that the sculptures had reached higher up the column, though it was not easy for us to reconcile our tastes to such a prospect. One would rather suppose that among the sculptured columns there had been some difference of dimension. That was not impossible, and in that event the different sizes of the sculptured fragments would be accounted for. Then came the question of the base. We possessed in the Museum a number of square sculptured blocks from Ephesus. On the top surfaces of these blocks a circular bed had been made to receive, evidently, the base of a column; and it was a singular fact that these circular beds were just the size to receive the columns of the temple. If four of these square blocks were placed back to back, so as to form a cube, and if on the top of them were set the large sculptured drum, it would be found that the latter fitted on to the prepared bed. But the effect was questionable. The square blocks were sculptured in very high relief, and when they were immediately surmounted by a sculptured drum in comparatively low relief, there was a striking effect of conflict and confusion, in an artistic sense. To some extent that effect would be lessened by interposing between the two sets of sculptures a simple architectural base, as the late Mr. James Ferguson proposed. But even then it was doubtful if the result would be nearly satisfactory, and on the whole, perhaps, a sculptured column would be better without a sculptured base to stand on. Since Mr. Wood's discoveries at Ephesus we had become acquainted with the results of the German excavations at Pergamon, which was not far from Ephesus. The sculptures there found were of a later date, but they agreed with those of Ephesus in having an equally strong tendency towards the colossal. They included a large series of colossal reliefs, above which rested an extensive colonnade with fluted columns of the Ionic order. A glance at the German publication illustrating the remains at Pergamon would show that that extensive sculptured base, supporting a long colonnade of simple fluted columns, had an admirable effect. Guided by it, he (the lecturer) some time ago tried the experiment in the Museum of placing above two of the square sculptured blocks a cast from a simple fluted column found by Mr. Wood on the site of the temple at Ephesus. It fitted excellently, and so far as he had learnt the opinion of competent judges, the effect artistically met with general approbation. Reverting to the sculptured drum from Ephesus, the subject represented was believed to be Alcestis being led to the lower world by Thanatos, the god of death, and by Hermes, the guide of souls on their journey thither. The youthful figure on the left was not exactly what we expected in Thanatos, and yet it was not altogether unsuitable. But no better explanation of the subject had yet been found. As regarded the sculpture itself, the lecturer said he hesitated to say that he was no great admirer of it; but it was necessary to give an opinion, because some authorities, entitled to every respect, had expressed themselves otherwise. They appeared to have been influenced by the tradition that one of the columns of the temple had been sculptured by no less an artist than Scopas. But even if that tradition had been quite explicit, which it was not, it would not follow that Mr. Wood had found that particular column; the chances were rather the other way. Nevertheless, a distinguished German was prepared to recognise in that sculptured drum, if not the work of Scopas, at least the influence which his presence in Ephesus was likely to exercise, supposing he had been in Ephesus. That was an easy way of arguing, and it might mean much or it might mean little. But we were fortunate in knowing the style of Scopas from several fragments that had survived, and we could see that it was immeasurably above that of the Ephesian drum. We had, on the one hand, two mutilated heads from the sculpture of a temple by him at Tegea, in Arcadia; of these, casts were to be seen in the British Museum. On the other hand, we also possessed in the Museum part of a marble frieze, representing a charioteer, which belonged to the Mausoleum at Halicarnassus, and which, it was generally felt, must be part of the

work of Scopas on that monument. With these limited materials it might seem that we had too little to furnish an adequate notion of his style; but it was to be remembered that what was known of him generally pointed to a peculiar gift, which would show itself best of all in the faces of his figures. It happened that in these surviving sculptures the heads were remarkable for the excellence with which they rendered a particular type of youth which Nature employed when she desired to reveal in the face some permanent mood or pathos in the soul. So far as the general conception of such a type of youth was concerned, that might be said to have been attained some time before Scopas in the heads of many of the youths on the Parthenon frieze. The tendency of Scopas was to develop that type throughout the whole structure of the face and head. It was a task requiring the utmost refinement of observation and delicacy of execution, side by side with a preservation of all that was essential to strength and power. In one of the heads from Tegea, and in the charioteer from the Mausoleum, the throat was strongly marked, and stood out in contrast to the softness of the cheek and the almost pathetic expression of the eye and its socket. In the other head from Tegea there was a pervading pathos combined with the greatest refinement of execution, as in the eye, cheek, nostril, and mouth. The lips were marked along the inner edge with an incised line, as in bronze sculpture. When we attempted to compare these fragments of the work of Scopas with the sculptured drum from Ephesus, we were met at first by the negligence of execution which pervaded the Ephesian sculpture. On mere negligence of execution one would not lay any great stress (that was a failing that might be accounted for in many ways), provided the work altogether was of a high character of conception. But he (the lecturer) could see no such high character of conception in the Ephesian sculpture. The draped figure of Alcestis in the middle of the group was little more than a study of drapery,—like many of the terra-cotta figures from Tanagra, but hardly so fine as some of them. The faces and nude forms of Hermes and Thanatos had nothing to raise them above the level of the work of a well-trained sculptor in the latter part of the fourth century B.C. No doubt there was considerable difficulty attendant on sculpture on a round surface. In that respect the sculptor had displayed a good deal of talent, and was entitled to full credit for it. Before leaving the Temple of Diana at Ephesus, the lecturer discussed the sculpture on the huge square blocks, which, as, before stated, in very high relief. Mr. Wood had assigned these blocks to the frieze of the temple, but there were several insuperable obstacles to their location there, not the least being the fact that among these blocks there were at least five corner-stones, whereas a Greek temple was content with four corner-stones in the frieze. For purely ocular purposes one would gladly place these very high reliefs very high in the building. But it was quite certain that they were placed low down, and that they supported columns. Some defence would be looked for of that proceeding of giving very high relief low down, on the level of the eye, or nearly so. Such defence, he thought, was to be found in the fact that the base of a large temple like that of Ephesus must at the first sight have conveyed an impression of vast solidity and strength, and if the artist or architect must have sculpture on it, he had no choice but to give his sculpture very high, strong relief; and having decided on that, what could he do better than choose for the subject of his sculptures the labours of Herakles, the strongest of all Greek heroes? If sentiment could help him, it was there in abundance. The lecturer said he need not describe the various labours of Herakles represented in those reliefs, but the fact was worth bearing in mind that on the part of the temple at Ephesus, where an impression of the greatest possible solidity and strength was necessary, we found sculptured the labours of Herakles in high, powerful relief.

The lecturer next went on to speak of some earlier sculptured fragments (including parts of columns) found at Ephesus, belonging to the temple which was burnt down by Hierostratos. An artistic peculiarity of this temple was that the cimatium of the cornice was sculptured, not with a plant ornament, as in the later temple and in most others, but with groups of figures, in low and delicate relief, between the

lions' heads which served to carry the rain from the roof. The lecturer then directed attention to the figures called Telamones or Atlantes, which were employed in the Greek Temple of Zeus at Agrigento, in Sicily, and, in conclusion, referred to the Caryatides of the Erechtheion at Athens as forming another notable exception to the general rule as to the situation of sculpture on Greek temples.

[We hope to give reports of the second and third lectures in our next.]

COMPETITION DESIGN FOR NEW YORK CATHEDRAL.

THIS is a design submitted in the competition for the proposed cathedral at New York, by Mr. R. W. Gibson, an English architect, who has migrated to and settled in New York.

As will be seen from the drawings, the design is purely Mediæval in plan and architectural character, but of an unusually rich type. We understand that there was an impression among the competitors that the promoters of the competition wished for what may be called an ecclesiastical design; an impression which appears to have been to some extent a mistaken one, but which may be taken to justify the adoption of the purely Mediæval type by competitors, as it would be of no use to offer people in a competition what they did not want. The result of the competition appears to have shown that the promoters have more modern views than was anticipated. If so, we think they are in the right, and that a leading city in the new world should endeavor to strike out a new type of cathedral. But this does not alter the fact that Mr. Gibson's design is a fine and rich architectural conception on the model of a Mediæval cathedral.

We understand from the architect that he forwarded us a detailed description of his design, but this has unfortunately not reached us, and we can only therefore leave the design to speak for itself.

CENTRAL TOWER AND CHAPTER-HOUSE, LINCOLN.

The illustrations of these well-known features of one of the finest and at the same time most finished and artistic in style of the English cathedrals, are from the set of sketches by Mr. John Begg which have gained for him this year the Pugin Travelling Studentship of the Institute of Architects.

PLAN OF DIOCLETIAN'S PALACE AT SPALATO.

This plan, giving the palace as restored by Robert Adam, is reproduced from one of the diagrams illustrating Professor Altchison's fifth Royal Academy lecture on "Roman Architecture," and is referred to and described in that lecture, which we print in full in our columns.

The English Iron Trade—The English iron market has had another relapse this week, mainly the result of the speculative influences which have been upsetting the ordinary conditions of trade during the past month. There is, on the contrary, less apprehension of a disturbance of business from a general miners' strike, as there is some prospect—which, we trust, will not be falsified by subsequent events—of a peaceable settlement of the pending dispute. The pig-iron trade is especially affected by speculation. The Glasgow warrant market has been flat, and the effect has been to further depreciate Scotch makers' iron. In the north-west also makers have reduced their quotations of mixed numbers of Bessemer iron by 2s. a ton. In the latter district, as well as in the north of England, the difference between warrant prices and those quoted by makers is still about 6s. to 7s. a ton, and for hematites as much as 10s. The southern pig-iron markets are likewise weaker. This tendency is less pronounced in finished iron and steel; nevertheless, prices have given way to some extent, without, however, interfering with their general steadiness. The orders booked for new ships are still scarce, and engineers are beginning to report a similar experience.—*Trom*

THE ARCHITECTURAL ASSOCIATION: SOME TYPICAL GREEK BUILDINGS.

IN the course of the discussion which followed Mr. R. Elsey Smith's paper on this subject,* Mr. Stannus, in moving a vote of thanks to Mr. Elsey Smith for his interesting paper, said that Mr. Smith was to be congratulated upon the good use which he had made of his opportunity as Greek Travelling Student of the Institute. He was to be envied for the opportunity he had had of visiting Athens, as well as commended for the good use he had made of his time, and they could not sufficiently thank him for the trouble he had taken in so generously bringing before them some of the results of his visit. He thought Mr. Smith had done well to confine his attention to two or three typical buildings. The plan of the Propylæa at Athens† was an exceedingly interesting one, and Mr. Smith had been able to lay before them the newest lights on the subject, thanks to the kindness of Dr. Dörpfeld. The manner in which Mr. Smith had explained the beautiful and exceedingly complex plan of the Erechtheion was very instructive. That and the other buildings on the Acropolis at Athens furnished together an admirable illustration of the elasticity of the Greek style. People had long had an idea that in Greek architecture everything must be rectangular or on one axial line, and that everything must be on the same level. The light which had been thrown on the buildings of the Acropolis of late years had dispelled that idea. He need not remark on the admirable refinement of detail which characterised the Greek work; but strong as might be our admiration for it, it did not follow that it would bear exact reproduction in this country. The delicacy of Greek work was not suited either to our duller climate or to the coarser materials in which we built. Dr. Temple (now Bishop of London), in one of the essays which appeared in "Essays and Reviews" many years ago, referring to the early Christians, said that we should do, not what they did, but as they did. Similarly he would say with regard to Greek architecture, that we were not called upon to do what they did (and if we were called upon we could not do it), but we ought to strive to work in their spirit. In conclusion, Mr. Stannus spoke highly of the admirable way in which the paper had been illustrated by drawings and photographs hung on the walls, and by photographic lantern-slides thrown on to a screen.

Mr. H. O. Crosswell seconded the vote of thanks, and also expressed his appreciation of the way in which the paper had been illustrated.

Mr. Owen Fleming said that the plan of the Palace of Tiryns was exceedingly interesting as a specimen of the domestic architecture of the ancient Greeks, a subject in which there was a great deal of latent interest. In the writings of Homer we found the palaces of the kings and primitive heroes described fairly fully, although, no doubt, with some poetical licence. A study of Homer in conjunction with the plan of the Palace of Tiryns suggested many interesting questions. He cordially supported the vote of thanks to Mr. Elsey Smith.

Professor Roger Smith said the subject was one of great, and he was happy to think, of increasing interest. It was very satisfactory to see that more and more attention was being paid to Greek architecture, and that mainly because of the extraordinary thoroughness and completeness with which all kinds of Greek buildings were executed. As had been said by Mr. Stannus, we did not want to do Greek work at the present day; and if we did we could not do it. The circumstances were different,—we had not the marble and we had not the Greek sky over our heads, and if we had both those things, the circumstances of to-day were quite different. The extraordinary accuracy and beauty of Greek work, and the pains taken with every detail of it, the attention which was paid to proportion and to every other matter, was remarkable, and full of instruction for us in the present day. There were one or two curious points about the plan of the palace of Tiryns. He was glad to hear the inquiry which had been made about domestic Greek architecture, but this palace was really the first perfect bit of it that had been revealed. There was, he hoped, a good deal more to be learnt from it yet, not merely from

the study of Homer, but from actual buildings, some of which possibly remained to be discovered. At present we had in the palace of Tiryns the only complete example of a Greek domestic building. It was interesting to see how completely the old Greeks separated the men's from the women's parts of the house. Another point to which he would allude was the plan of the Acropolis, which showed that the Greeks were by no means slavishly addicted to placing their buildings at the same angle to one another. It was only necessary to glance at the plan of the Erechtheion to see that regularity was not even adhered to in a single building.

Mr. F. R. Farrow, in supporting the vote of thanks, said that Mr. Smith had practically put before them the results of the most modern investigations of the German and other archaeologists who had done so much to throw light upon questions of Greek archaeology.

The Chairman, in putting the vote of thanks, said that like some former speakers in the discussion, he had not been to Greece, and therefore he could not judge of the effect of these marvellous buildings, although one might realise their effect to a very great extent from the excellent photographs which had been thrown on the screen that evening. Although those enlarged photographs gave them an excellent idea of the general appearance of the buildings, yet they were devoid of that beauty and colour which made them such beautiful objects to look upon even in their ruin. He had, however, been to Sicily a few years ago, and there he saw some remains of Greek temples, which, although very fine, were constructed of a rather coarse yellowish sandstone, not altogether satisfying to the eye. Still the effect was very fine, and having seen the Greek architecture of Sicily he could very well understand how fine must be the appearance of the work in Greece. He was glad to hear Mr. Stannus refer to the fact that Greek architects were not necessarily rigid in their lines, and not tied down to hard and fast rules. The Greeks, who were naturally artists, did practically what they liked, and they could not help doing the right thing. He quite agreed with what had been said as to Greek work. We should study it and learn from it without seeking to directly imitate it; we should rather work in the spirit of the style than attempt to follow it in the letter.

The vote of thanks having been carried by acclamation, Mr. R. Elsey Smith briefly replied, and the meeting terminated.

THE ARCHITECTURAL ASSOCIATION VISITS:

THE IMPERIAL INSTITUTE.

The second seasonal visit of the Architectural Association was made on Saturday afternoon to the Imperial Institute, Exhibition-road, South Kensington, and was attended by a large number of members.

The party was received by Mr. T. E. Collcutt, the architect, who, in addition to pointing out the main features of the structure, gave an interesting description of a series of careful tests which had been applied to the different materials employed.

The building, at present confined to the front block, has not been raised much above the level of the first floor, but the inspection of the detail, and the careful workmanship of the Hopton Wood stone internal dressings, excited much interest.

The foundations have been taken down to a stratum of blue clay found at a depth varying from 12 ft. to 26 ft. below the level of the site. The footings and the walls of the ground floor have been built of London stocks and Portland cement mortar, but Jennings's Parkstone wire-net bricks have been used in the body of the central tower, and of those piers which sustain much weight. Portland stone is being used in the elevations.

Official Architecture in Prussia.—According to an official notice, the Prussian Government has, during the year 1888, had the superintendence of the erection or alteration of 503 buildings. Of these works, 44 were churches and 33 vicarages, 96 elementary and 8 high-class schools, 33 buildings belonging to the University system, 8 for scientific collections, and 3 to be used as hospitals; the government and administration required 10 new homes, the town and provincial law courts numbered 22, and 19 prisons had to be taken in hand.

COMPETITION DESIGN FOR NEW YORK CATHEDRAL.—MR. R. W. GIBSON, ARCHITECT.
PERSPECTIVE VIEW

THE LONDON COUNTY COUNCIL.

The usual weekly meeting of this Council was held on Tuesday afternoon in the Council Chamber of the Corporation of London, Guildhall, Lord Rosebery in the chair.

The Proposed Blackwall Tunnel.—The Bridges Committee presented the following report:—“The Thames Tunnel (Blackwall) Act, 1857, and the report of Mr. Wolfe Barry have had the most anxious and careful consideration of your Committee. For many years the people of the east and south-east of London pressed upon the Metropolitan Board of Works their claim to have provided by the central authority some means of permanent inter-communication commensurate with the important interests on both sides of the river. As far back as August, 1852, Sir Joseph Bazalgette prepared, by order of the Board, a report which deals with the whole subject, going very fully into the question of ferries, bridges, and tunnels: this report concludes with the statement that a tunnel is the only suitable means of effecting a permanent crossing at Blackwall. After much consideration, the Board took the same view. Much time was spent in preparing the details necessary before going to Parliament, and a Bill was promoted in the session of 1857. It was referred to a Committee, when the scheme, which was opposed by railway companies and other owners of property, was supported by some of the ablest engineers of the day, viz., Sir J. Bazalgette, Sir F. Bramwell, and Mr. B. Baker. The Committee reported in favour of the Bill, and it was in due course passed. Specifications were prepared and tenders advertised for, and the action of the Metropolitan Board of Works in accepting in the last month of its existence a contract for this important work, instead of leaving the Council unfettered, will be fresh in the recollection of the Council. Your Committee on taking up the matter were placed in considerable difficulty, the Council being without a Chief Engineer, and the advantage of having the same engineer to prepare the specifications and carry out a work of this character will be obvious. The technical aspect of the questions arising as to size, boring or borings, practicability of scheme, &c., were by order of the Council referred to Mr. J. Wolfe Barry, and a copy of his report has been forwarded to each member. Mr. Barry, though suggesting certain modifications, considers a tunnel practicable, but suggests a high-level bridge. Your Committee are of opinion that, as a bridge at this point would have to be of such a height as to admit of all ships passing under it without any alterations in their masts, and as ships with masts 200 ft. above the water are stated to pass at this point, the road of the bridge would have to be at least 210 ft. above Trinity High Water Mark. When the low level of the land on both sides of the river is considered, a bridge of this height is, in the opinion of your Committee, out of the question. They therefore recommend—

(a) That the Council do proceed with the formation of the tunnel authorised by the Thames Tunnel (Blackwall) Act, 1857.

(b) That the Bridges Committee be authorised to nominate an engineer of experience in tunnelling with a pneumatic shield, to prepare the necessary plans and specifications for carrying out the works, submitting the whole to the Council.

The adoption of this report was moved by Mr. O. W. Osborn, Chairman of the Bridges Committee.

Mr. Arthur Arnold moved, as an amendment—

“That the Council doth disagree with the recommendation of the Committee, and is of opinion that the report of Mr. Barry should be adopted so far as it is opposed to the construction of a tunnel at Blackwall, and that the best efforts of the Council should be directed to providing such other means of communication as may appear most desirable.”

After a long discussion, in the course of which opinions strongly adverse to the tunnel scheme were quoted as having been given by Mr. Wolfe Barry, General Sir Andrew Clarke, R.E., and other engineers (not on account of engineering difficulties, but on account of the ill-chosen site of the tunnel and its necessarily long approaches), it was agreed to adjourn the further consideration of the subject to a special sitting to be held on Friday next, March 7. We may add that in the course of the discussion an extension of the ferry service, as now working at Woolwich, was advocated.

Having transacted other business, the Council adjourned.

SURVEYORSHIPS.

London (St. Martin's-in-the-Fields).—Mr. Charles Mason, Assoc. Inst. C.E., Assistant Borough Surveyor of Leicester, was last week unanimously elected Surveyor to the Vestry of St. Martin's-in-the-Fields, Westminster. There were eighty-five applicants for the appointment who were reduced to the following eight for the final, viz., Mr. Mason (Leicester); Mr. Monson, St. James' Vestry, Westminster; Mr. Waddington, Assistant-Surveyor to the Islington Vestry; Mr. Wright, Assistant-Surveyor to the Battersea Vestry; Mr. Garthwaite, Engineer's Office, Corporation of London; Mr. Burgess, Stockton-on-Tees; Mr. Dickenson, York; and the Assistant-Surveyor, St. George's, Hanover-square.

Wimbledon.—At a meeting of the Wimbledon Local Board, held on the 19th ult., Mr. O. H. Cooper, A.M.I.C.E., Assistant-Surveyor, was appointed Surveyor, in the place of Mr. William Santo Crimp, who lately obtained the Assistant-Engineership to the London County Council.

THE CENTRAL ASSOCIATION OF MASTER BUILDERS OF LONDON.

The eighteenth annual meeting of this Association was held at the offices, 31 and 32, Bedford-street, Strand, W.C., on Wednesday, the 26th February, Mr. J. T. Chappell, President, in the chair.

The Secretary, Mr. E. S. Henshaw, read the following report:—

“The Committee have the pleasure to place before the members their Eighteenth Annual Report.

It will be remembered that the last annual general meeting the President, Mr. Jno. T. Chappell, and the then Past-President, Mr. H. H. Bartlett, were requested to confer with the solicitor, and if considered advisable by them to take the necessary action with reference to the Classification and Schedules of Rates and Charges proposed by the railway companies under the Railway and Canal Traffic Act (1888), and lodged by them with the Board of Trade.

A Commission was appointed by the Board of Trade to hear any objections on behalf of traders to the propositions of the railway companies. As the statements prepared by the President showed that these propositions injuriously affected the building trade, the Committee employed an expert, who drew up formal objections and prepared elaborate tables, showing the enormous increase which the railway companies were asking the powers to enable them to charge for the carriage of building materials and plant: in some cases the proposed increase on the present rate being as much as from 200 to 300 per cent.

In addition to the individual opposition of this Association, the Committee are also opposing the railway companies through the Mansion House United Association on railway rates.

The Board of Trade having issued a circular asking objectors and the railway companies to meet and endeavour to come to some arrangement which would be satisfactory to both parties, the Secretary met them, but without any satisfactory result.

The expenses incurred are very heavy, and a special fund has been started by the Committee to meet this increased expenditure, and the Committee trust the members of the Association will respond liberally, so that the general funds will not have to be encroached upon.

Prints of the tables prepared by the Association in support of their case, and giving much information upon the present powers of the various companies running into London, can be obtained at the office of the Association.

Early in the year the Committee had to consider the action of the London County Council (Main Drainage Committee) in proposing to fine a member of this Association 500*l.* for sub-letting brickwork. The firm attended to be fined by the London County Council, when the Committee's report was read, and the Chairman of the firm, and the matter has since been allowed to drop by the London County Council.

During the autumn demands were made by the navies employed by three firms of contractors for an advance of wages of 5*d.* per hour, but on being told their demands could not be acceded to, and that any dissatisfied men could go to the office and receive their money, the men, after a short interval, returned to work.

Notices have been received from different branches of operatives in the Provinces, viz., Birmingham, Bradford, Liverpool, Leeds, Edinburgh, Bristol, &c., for a rise in the rate of wages, and other matters.

The attention of the Committee having been directed to the recent Act of Parliament for the rating of hoardings, which empowers each parish to make its own regulations, the Committee felt it was a matter that must be dealt with, in each case, by the individual alderman.

The Committee have to announce that the Home Secretary has given notice of his intention to introduce into the House of Commons a Bill to amend and consolidate the law relating to the Liability of Employers for Injury to their Workmen. The Committee presume that this Bill will be drafted on the lines of the Bill introduced previously, and, if passed into law, will add very much to the liability of employers. The Committee therefore, think it right to impress upon all members of the trade the desirability of effecting insurances against these risks with the Builders' Accident Insurance, Limited.

In accordance with the rules of the Association, the President, Mr. Jno. T. Chappell, becomes an Honorary Vice-President; and four members of the Committee—viz., Messrs. Wm. Downs, John Marsland, Geo. Wall,

and John Woodward, retire—Mr. Wm. Downs and Mr. Geo. Wall being eligible for re-election.”

The Chairman moved that the report and accounts he received and adopted, and the resolution having been seconded was carried unanimously.

Mr. J. Howard Colls was then elected President; Mr. Downs and Mr. Geo. Wall were re-elected, and Mr. G. J. Lyall and Mr. R. Thorn were elected, members of the Committee. Messrs. G. Williams and H. S. Foster were elected auditors.

A vote of thanks to Mr. Jno. T. Chappell for his services as President for the past year concluded the proceedings, after various matters with regard to the trade had been fully discussed.

PROVIDENT INSTITUTION OF BUILDERS' FOREMEN AND CLERKS OF WORKS: ANNUAL DINNER.

The annual dinner of this old-established Institution was held on Saturday last, at the Holborn Restaurant, under the chairmanship of Alderman Sir James Clarke Lawrence, Bart. There were more than 300 members and friends of the Institution present. The usual loyal and patriotic toasts having been given (Mr. George Barr, jun., replying on behalf of “The Reserve Forces”).

The Chairman, in proposing the toast of the evening, “Success to the Provident Institution of Builders' Foremen and Clerks of Works,” said it was hardly necessary to say a word to commend the claims of the Institution to the sympathy and support of those whom he saw around him. Was there any one present who did not know how precarious was the life of a builder's foreman or a clerk of works? Where, then, would be found a stronger desire or a deeper determination to support an institution which ministered to the needs of old and infirm members of those callings, or of their widows and families? He had been looking through the report, and one thing that struck him was the great amount of good they had been able to accomplish. He had known the Institution for a great many years, and he most cordially commended it to the support of all who were connected with the building trade. With the toast (which was warmly received) he coupled the name of Mr. J. W. H. Bedford, the honorary secretary.

Mr. Bedford, in responding, gave some particulars of the working of the Institution. He stated that a member's subscription was only 2*l.* per annum. With that limited subscription, however, they never could have done what they had during the last fifty years. They had to thank the master builders (and none more so than those who, father and sons, bore the honours of the name of Lawrence), the builders' merchants, and others. The Institution now dispensed about 300*l.* a year in pensions.

Mr. Grooms, in proposing “The Governor, Trustees, Donors, and Honorary Subscribers” spoke in warm terms of the great services which had been rendered to the Institution by those gentlemen, and especially by the Governor, Mr. George Plucknett, J.P., whose name was associated with the toast.

Mr. Geo. Plucknett, J.P., in responding, said that he could bear testimony to the admirable and economical way in which the affairs of the Institution were managed. There were hardly any expenses connected with its management, the officers being honorary, and doing their work well.

The Chairman next proposed “The Architects and Surveyors,” who were of all men the most capable of judging of the value of the services of the clerk of works and builder's foreman. He spoke of the interest which many architects and surveyors evinced in the status and prosperity of building trade employees, and urged his hearers to do all they could to take advantage of the means of improved technical education now open to them. Alluding to the lectures now in course of delivery at Carpenters' Hall, he spoke in highly complimentary terms of the lecture given there a few days ago by Professor Roger Smith on “Drawing.” He had never heard that subject, in relation to the needs of building artisans, so well treated of in a lecture, and he could only say that Professor Roger Smith was proving himself a worthy successor of the late Professor Donaldson in the Chair of Architecture at University College, London. As a personal matter, he (the Chairman) was proud to have been amongst the first of the late Professor Donaldson's pupils at University College, some forty years or more ago.

Mr. H. Percy Monckton, F.R.I.B.A., replied on behalf of “The Architects,” and Mr. W. H. Strudwick on behalf of “The Surveyors.”

Mr. Alexander Ritchie, in a humorous speech, proposed “The Builders,” coupled with the name of Mr. Hall, of the firm of Hall, Beddall, & Co., successors to Messrs. William Lawrence & Sons, of which firm the Chairman was a member.

Mr. Hall, in replying, said that he was specially pleased to be allowed to speak on that occasion, for if it had not been for the magnificent liberality of Sir James Clarke Lawrence and his brothers, he

(Mr. Hall) would most probably not have been there in the capacity of a master-builder that evening.

The other toasts were "The Chairman" (proposed by Mr. Bedford), "The Press" (proposed from the chair and coupled with the name of the representative of the *Builder*), and "The Visitors," proposed by Mr. Stapleton, and coupled with the name of Mr. James Adams.

During the evening the Financial Secretary, Mr. J. Merifield, announced donations and subscriptions to the amount of between 50*l.* and 60*l.*

A CLAIM ON A BILL OF EXTRAS:

SMITH R. KIRK AND RANDALL.

THIS case, heard in the Brompton County Court on Tuesday last, was of some interest. It had been remitted from the High Court, and was a claim for 49*l.* 5*s.* 6*d.*, for goods supplied. The point raised was as to a builder's liability to pay to specially-empowered tradesmen money ordered by the architect to be included in the bill of extras, and so included by the quantity surveyor.

The case arose out of the erection of the Kensington Public Baths, of which Mr. Thomas Verity was the architect, and Messrs. Kirk & Randall the builders. The plaintiffs were Messrs. C. Smith & Sons, lock manufacturers, &c.

It was shown by the evidence of Mr. Verity and of Mr. F. H. A. Hardesty that the amount in dispute was inserted in the bill of extras, and that the amount had been paid by the Baths Commissioners to Messrs. Kirk & Randall, having been included in a lump sum of 2,500*l.* paid in final settlement of the contractors' account. That amount was arrived at on the basis of a bill of extras and variations, the items of which had been jointly agreed to by Mr. F. H. A. Hardesty, the quantity surveyor acting on behalf of the Commissioners, and Mr. Sydney Batstone, a surveyor appointed by the builders to watch their interests in the measuring-up of the work and the final adjustment of the account.

For the defence it was contended that the architect had exceeded his authority under the contract.

His Honour, Judge Stonor, gave judgment in favour of the plaintiffs for the amount of their claim, with costs. He held that, in pursuance of the contract, Mr. Verity had power to order the goods, and did order them; that the amount being included in the accounts prepared by Mr. Hardesty on behalf of the Commissioners, and Mr. Batstone on behalf of the defendants, the latter must be held to have had knowledge constructively that it was so included; and that, not having repudiated it when they agreed to a settlement with the Commissioners and gave a receipt in discharge of all claims, they were liable.

INSANITARY CONDITION OF A RESIDENCE IN WEST HAMPTSTEAD.

SIR,—My attention has been directed to your "Note" in last week's *Builder*, with reference to the above, and as the "Independent Surveyor" who was called in permit me to say that the statement made in Mr. Tonge's letter to the *Times* of the 10th inst. was perfectly correct, and that the passage to the main drain (or sewer) was blocked at the time of my visit to the house, and, judging from the accumulation of deposit in the drain, I should say it had been blocked for a considerable time.

Chokages of this kind, under certain circumstances, can occur without being known to the tenant and without being visible at the surface, and, incredible as it may appear, on being called in to examine the drainage system of a large house in South Kensington a short time ago, in which there were two cases of typhoid fever, not only was the outlet to the sewer blocked, but the whole drain—a nine inch one—was full-up with decomposing sewage from end to end, and in addition, the soil surrounding the drain was blackened to the extent of about three feet on either side of it and from two feet to two feet six inches in depth. The pipes had been laid dry, i.e., without any form of jointing material, and after the occurrence of the chokage the liquid sewage passed away into the gravel soil, and the solids remained behind, as before stated.

There was absolutely no evidence of all this on the surface, and but for the outbreak of fever the sewage might have gone on accumulating under the house to this day without the tenant being aware of it.

I am pleased to note from recent reports that the Local Sanitary Inspectors, as a body, are making a move to weed out the incompetent men from their ranks, of whom, alas! there are at present by far too many. Within the past twelve months no less than three cases similar to that of Mr. Tonge's have come under my direct notice, where Sanitary Inspectors have shown gross ignorance and incompetence in dealing with drainage matters, and this in London too, "the least badly-drained metropolis in the world."

N. P. JASPER, Assoc. M.Inst.C.E.

LECTURES FOR SANITARY INSPECTORS AT THE SANITARY INSTITUTE.

SIR,—Referring to Mr. Booker's well-meant letter in your issue of the 15th Feb., I should like to point out that hitherto no lecturers have, as a rule, departed at the twelve or thirteen hours in all devoted to them is insufficient. It would, therefore, seem impossible to make the lectures of more extended application without seriously injuring their present special usefulness. On the other hand it seems to me that the Sanitary Institute would greatly extend its usefulness, and promote the objects which are dear to it, by granting certificates to candidates other than Sanitary Inspectors, and confining the examination of such candidates to those subjects (varying, of course, according to the offices held, or trades pursued) in which they desire to obtain certificates of sanitary knowledge and proficiency.

I put in a plan that the Sanitary Institute should grant certificates to builders who show a sufficiently perfect knowledge of the sanitary branches of their trade, without asking them to pass through the whole of the subjects special to inspectors of nuisances, many of which subjects are entirely outside the builders' sphere and trade, and which might easily be replaced by the knowledge of sanitary building construction and the methods by laws relating thereto. It seems strange, whilst the registration of plumbers, masters and men, is progressing slowly but surely, that the registered plumber is oftentimes under a misapprehension (not that the much-maligned builder) whose orders, whether sanitary or unsanitary, he must implicitly carry out, and yet that the master cannot obtain the Institute's sanitary certificate without coaching himself up in the multifarious duties of an inspector of nuisances.

Doubtless besides builders there are others who are desirous of obtaining the Institute's sanitary certificate, and surely the Sanitary Institute cannot better promote its objects than in creating, fostering, and satisfying the demand for such certificates which must eventually and certainly result in the diffusion of sanitary knowledge amongst all classes; until which time the Sanitary Inspector, with all his learning and perseverance, will find his hands greatly tied.

February 19, 1890.

VALVES TO FRESH-AIR INLETS.

SIR,—I noticed in the course of his interesting and valuable lecture on "Modern Sanitation," at Carpenters' Hall, on Wednesday last, Dr. Corfield touched on the question of "valve" or "no valve" to fresh-air inlets to drains. He appears most decided in his opinion that they are useless and radically wrong, and in the course of his remarks said:—"When you find a valve on a fresh-air inlet you may depend that the man who carries out the work had not sufficient confidence in the arrangements to be certain that what intended as an inlet would not at some time or other become an outlet."

With all due deference to Dr. Corfield's opinion, I think he is putting it rather strongly when he says this, and I would ask him whether he has sufficient confidence in any of the works he has superintended to enable him to say, "That inlet will never become an outlet?"

For my own part, I do not consider it of vital importance whether a valve is provided or not; but the fact remains that every time a good flush is sent down the drain it acts as a piston and forces the gases and air in the drain before it, and if there is no valve on the inlet that is where they will make their exit.

But, as I have just hinted, the quantity being so small, and in a properly-ventilated drain the gases having no opportunity of becoming dangerous, I do not consider a valve absolutely necessary, although I still hold that in some situations it may be desirable to prevent the exit of anything through the inlet. Therefore, I do not consider, because a man takes a precaution which in some cases may be necessary, that it shows a want of confidence in his work, for with the best design and workmanship, natural laws will at times cause the gases and air in a drain to seek to escape through the first air-inlet, and I challenge Dr. Corfield or any one else to refute this.

HARRY G. ASSITER.

Free Lectures to Artisans at Carpenters' Hall.—The third of the present series of free lectures to artisans and others in matters connected with building, under the auspices of the Carpenters' Company, was delivered on Wednesday, the 19th ult., by Professor W. H. Corfield, M.A., M.D., his subject being "Modern Sanitation." Mr. Joseph Preston presided, and there was a large attendance. The fourth lecture of the series was delivered to a large audience on Wednesday evening last by Professor Armstrong, Ph.D., F.R.S., his subject being "The Domestic Fireplace." Mr. Charles Barry, F.S.A., F.R.I.B.A., presided. We hold over our reports of these two lectures.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—IX. MAGNETIC CIRCUIT.

THE rapid development of dynamo-electric machinery soon rendered it necessary that the number of lines of force or flux traversing any part of a machine should be determined, if possible, by methods as easy to use as Ohm's law for the determination of the current flowing in any part of an electric circuit. Electrical engineers, finding the means employed by mathematicians unsuited to their wants, have returned to and extended Faraday's way of attacking the problem.

Faraday described everything he treated with such minuteness of detail that want of space prevents our giving his ideas in his own words, but the two following quotations from his "Experimental Researches in Electricity" will show his general methods sufficiently for the purpose.

Under *Magnetic Conduction* he wrote, in 1850, "I will now endeavour to consider what the influence is which paramagnetic and diamagnetic bodies, viewed as conductors, exert upon the lines of force in a magnetic field." And again, under *Analogy between the magnet and a voltaic battery*, "The magnet with its surrounding [field of force*], may be considered as analogous in its condition to a voltaic battery immersed in water or any other electrolyte; or to a gynomotus or torpedo, at the moment when these creatures, at their own will, fill the surrounding fluid with lines of electric force." Within the last few years the idea of conceiving a magnet or helix carrying a current as a magnetic battery, and anything through which lines of force pass as a magnetic conductor, has become all but universal among electrical engineers.

In the case of a simple electrical circuit, fig. 21, consisting of a battery B, where an E.M.F. E is driving a current through a circuit of total resistance R, if C is the current flowing, then $C = \frac{E}{R}$. Again, if between the points O and Q

in the external circuit a second conductor be placed, it is easy to calculate how it will modify the resistance of the whole circuit, and also what proportion of the whole current given by the battery flows from O to Q by way of either of the two branches O P Q and O Q. When the dimensions of an electrical conductor and the specific resistance of the substance of which it is made are known, it is easy to calculate its resistance, unless mathematical difficulties are introduced owing to its shape being complex. By the specific resistance of a substance is meant:—The resistance of a cube of the substance whose edge is one centimetre in length, the direction of the current being perpendicular to a face. Under ordinary circumstances conductors are of uniform cross section. For such a conductor let:—R=the resistance, ρ =the specific resistance of the substance of which it is made, l=length, s=the cross section, then:—

$$R = \frac{l}{\rho s} \quad (1)$$

By the length of the conductor is meant the length measured in the direction of the current, and similarly the cross section is taken at right-angles to this direction at each point. Clearly, the resistance of a particular conductor differs according to the direction in which the current is sent through it, the resistance offered to a current by the conductor in fig. 23 is much greater when the flow is from the face A to B

* Faraday uses the expression "spheroidal of power," the meaning of the word spheroidal having been previously explained in a note which it does not seem necessary to reproduce here.

than when it is from P to Q. Ohm's law and its consequences, however, are too well known to need recapitulation here, and the above

Fig. 23.

facts have merely been recalled for the sake of analogy in considering the magnetic circuit.

Figs. 21 and 22 may now be compared as two very simple cases of electric and magnetic circuits; B is a voltaic cell, having a certain electro-motive force which will, if a closed path of electrical conductors lead through it, produce a current in such path whose value can be calculated by Ohm's law, if the E.M.F. of the cell and the resistance of the circuit are known. H is a helix, carrying a certain current of A amperes, and produces lines of force whose number depends upon the media through which they pass. The number of lines passing by any path is, as already stated, called the flux through that path, and just as a voltaic cell can, by virtue of its electro-motive force (E.M.F.), send a current through an electrical conductor, so can a helix by virtue of its magneto-motive force (M.M.F.) send a flux through a magnetic conductor.

Flux is, therefore, the analogue of current, though it must at once become apparent that a flux is a more difficult thing to control than a current. A current may be entirely stopped by placing an insulator across its path; but lines of force can go through every known substance,—there is no such thing as a magnetic insulator,—and hence the regulation of a magnetic flux presents the difficulties that would be presented by an electric current if no substance could be found to insulate a charge of electricity properly. The meanings of such expressions as electro-motive force have already been given in former articles; how those explanations can be made to apply equally well to the corresponding ones applied to magnetism may be seen by the following definition of electric and magnetic potential, it being noted that as the definition applies to the "absolute" units. As the potential of the earth is unknown, and by the potential at a point is meant the difference between its potential and the earth's, difference of potential is alone defined.

The difference of { electric } potential between two points is the number of ergs of work that would be done in moving unit

{ quantity of positive electricity } from one point to the other. The various units used in the magnetic circuit have not been long enough in every-day use to have been given names corresponding to the ampere, volt, and ohm, and the expressions used are, therefore, verbose.

Various kinds of apparatus are employed for producing electro-motive force, but for the production of magneto-motive force a helix, as in fig. 22, is practically the only device used, and its M.M.F. can be readily calculated. Let A = current in amperes flowing through the helix, n = number of turns of wire and M = the M.M.F. produced:—

$$M = \frac{4\pi n A}{10} \quad (ii)$$

The quantity nA is called the number of ampere-turns in the coil, for as the other parts of the expression consist of constants, the M.M.F. of a helix depends upon the ampere-turns, and not upon either the current or number of turns alone.

Ohm's law, as applied to the electric circuit, may be regarded as a definition of electrical resistance. We will, therefore, take Ohm's law and apply it to the magnetic circuit, to define magnetic resistance. In fig. 22, suppose the anchor ring, O' P' Q', which forms the circuit under consideration, to be made of the best soft iron; as specimens of this metal may be taken whose specific magnetic resistance is only a few ten-thousandths that of air, we shall regard air as relatively speaking a magnetic insulator, and consider that the whole flux passes through the magnetically insulated anchor ring. Let l = mean length of ring, s = cross section. M = M.M.F. of helix.

If the ring contained air alone, the specific

magnetic resistance of air being taken as 1 then F_a, the flux through the air, would be by Ohm's law:—

$$F_a = \frac{M}{\left(\frac{l}{s}\right)} \quad (iii)$$

If, however, the air-ring is replaced by the iron-ring, whose permeability is μ, the flux F will be μ-times as great; M has not changed, hence the resistance of the circuit has fallen to $\frac{1}{\mu}$ -th its former value, and

$$F = \frac{M}{\left(\frac{l}{\mu s}\right)} \quad (iv)$$

If the expression $\left(\frac{l}{\mu s}\right)$ for the magnetic resistance be compared with $\left(\rho \frac{l}{s}\right)$ given in equation (i), it will be seen that $\frac{1}{\mu}$ is the specific magnetic resistance of the sample of iron used, so that permeability and magnetic conductivity mean the same thing.

In addition to the difficulty of applying Ohm's law to the magnetic circuit, arising from the fact that even air is a magnetic conductor, and hence that what may be called leakage of flux, corresponding to leakage of current in an imperfectly insulated electric circuit, takes place; there is the very serious difficulty that while ρ remains constant no matter what current is passing, so long as the temperature of the body remains constant, μ varies in a very complicated way with the flux, and this variation in the case of iron must next be considered.

Books.

Electric Light, its Production and Use. Embodying Plain Directions for the Treatment of Dynamo-Electric Machines, Batteries, Accumulators, and Electric Lamps. By JOHN W. URQHART. Third edition. London: Crossly Lockwood & Son. 1890.

THE first edition of this work appeared in 1880, and although a considerable amount of new matter has since been added, it is typical of the books which used to be written about the electric light in its early days. After giving a brief account of the first production of the voltaic arc, and defining the ordinary electrical units, the author expresses his opinion that, "As a source of electricity for permanent electric lighting the voltaic battery is, in our opinion, practically useless," and then proceeds to describe with much detail the "construction of batteries," and many of the well-known forms of cells. The accounts of the Lalande and Upward batteries, however, from which so much was at one time expected, will be read by many with interest. The descriptions of the development of accumulators give a good idea of what has been done in this direction; but the data, evidently furnished by manufacturers of secondary cells, are misleading in the extreme. Mr. Urqhart states that if a cell is discharged slowly its "efficiency" may be as high as 95 per cent. Probably the author means that 95 per cent. of the ampere-hours put into a cell can be got out again, but surely the fallacy of measuring the so-called "efficiency" of a cell by this means has been pointed out often enough.

A few words upon thermo-electric batteries bring the writer to the subject of dynamo-electric machinery. About two-thirds of the plant described is altogether antiquated, and never met with nowadays. "Antiquated" may seem a strong word to apply to apparatus that was used eight or ten years ago, but it must be remembered, so rapid has been the progress of the electric light, that dynamo-machines and lamps which were new inventions in 1880 are now wholly superseded. The hints given for the "Treatment of the Dynamo," are practical, and may be read with advantage by those likely to have charge of an electric light installation. Transformers and meters are dismissed with fifteen pages. Apparently Mr. Urqhart has never heard of the Ferranti transformer, used by the largest electricity supply company in the world, nor of the Lowrie-Hall transformer, used by all the House-to-House companies. Among arc lamps it is almost needless to

say, after the general idea which has been given of the contents of the book, that the Serrin, Duboscq, Wallace-Farmer, and other extinct varieties are all fully illustrated and described, as well as the candles of Jablochhoff, Wilde, Jamin, and others.

We sincerely trust that no young wireman will take Mr. Urqhart seriously when he states that "cotton-covered wire Nos. 12 or 14 B. W. G. is frequently used for conducting branches for groups of incandescent lamps," although it is only fair to the author to say that some of the fire insurance offices had reason to know that such acts were perpetrated before the days of the "Phoenix Rules."

Criticism on our final extract from this interesting work is unnecessary:—

"The Ferranti system employs high tension alternating currents, and as these mains are intended to be used for conveying electricity to Central London from the large generating station at Deptford, where the Ferranti system is exclusively employed, it is probable that at a pressure of over a million volts (sic), such a main will be utilised to convey currents to feed many thousands of lamps."

The Science of Metrology; or, Natural Weights and Measures. A Challenge to the Metric System. By the Hon. E. NOEL, London: Edward Stanford. 1889.

METROLOGY is the "science of measuring," and deals, as the author reminds us, with "measures of all sorts." The author, in challenging the advocates of the metric system, endeavors to show, in a clever and systematic manner, that, "by very little alteration and by a little amending, the existing English measures can be welded into a system scientifically as well as practically superior to the metric," and, at the end of the book, he provides tables and diagrams to completely illustrate his object. The number "ten" having only two divisors, 2 and 5, one of which gives a fraction of one-fifth, a proportion very seldom used, he argues that duodecimals are superior to decimals, and suggests how duodecimal sub-division may be applied to decimal notation. The metre, the basic standard of length, is supposed to be the ten-millionth part of a quadrant of the meridian passing through Paris. He recommends the adoption of the earth's semi-axis as a better base to start from than a line drawn from the North Pole to Paris and prolonged to the Equator, and suggests making the standard "foot" measure the twenty-millionth part of the earth's semi-axis, i.e., of the earth's polar radius, or half the polar axis on which it revolves. The most commonly-used rule in England being a 2-ft. rule, he would convert it into an "all" rule of about 25 in. in length, and he shows how all the measures he proposes bear a definite proportion one to another, and become applicable both to surface and to cubic measures. The acre not being an exact measure of a square, he shows how by his system the standard square unit would not possess this objection, and argues that the Government, in adopting the scale of 7920, "unwittingly forecast the coming of an improved and scientific system of measures." The real reason, we would remind him, is because this scale one square inch practically represents an acre. He applies his system to the readings of a thermometer, barometer, geometry, and coinage. We admire his efforts to defend the duodecimal system, but we think it is not likely to be amended in the ingenious manner proposed in this interesting manual.

Theoretical Mechanics. By J. EDWARD TAYLOR, M.A. Lond. London: Longmans, Green, & Co.

THIS is an elementary book, which is designed to be "specially helpful to those who are reading on the lines of the Science and Art Department Syllabus for the elementary stage;" and to be "sufficient for the requirements of the London University Matriculation examination in this subject." In these respects the author has undoubtedly been successful.

Mr. Taylor, — who, it should be stated, is head master of the Sheffield Central Higher Grade and Science School, — begins with a chapter on motion, and goes right back to the commencement of things, starting with the most elementary propositions. This plan he follows throughout the book, and no doubt it is necessary in a work designed for beginners and those not of mature age. There is really not much to criticise in a book of this description. The author does not attempt any literary embellishment.

We meet with the old familiar examples by which mechanical propositions are usually illustrated, a good feature being the examples for exercise at the end of the chapters.

The Ancient Laws of Wales. Viewed especially in regard to the light they throw upon the origin of some English institutions. By the late HUBERT LEWIS, B.A. Edited by J. E. Lloyd, M.A. London: Elliot Stock. 1889.

This is a work full of information, and marked by much erudition; but it is impossible for us to notice it in detail, as it is scarcely within the scope of this journal. It is a book which is, however, deserving of notice, because it is one of that class which, while it is of historic and permanent value, does not meet with that popular reception which much more ephemeral works receive. Here is an extract which will exemplify the character of the work: "There is good reason to believe that one sense in which the word 'maenor' was used was that of a castle or superior mansion, wholly or partially of stone or brick, or having a stone or brick wall enclosing its precincts" (p. 141). A few pages further it is shown that the maenor or "manerium" the manor, became synonymous with the district around the Castle. In this way we trace the English manor of the Middle Ages to a British origin. Hitherto legal writers have given the derivation of manor as the Latin word manendo, or the French mesner. This is merely fancy, and in the book before us we seem to have the true derivation. The fact is that the authoritative writers on English law, such as Coke and Blackstone, are of little weight in regard to many points, which can only be elucidated by writers who will treat the subject in a scientific manner.

How to Appeal against Your Rates in the Metropolis. By A. D. LAWRIE, Barrister. Second Edition. 1890.

This is a convenient little handbook. We should, however, scarcely notice the second edition of so small a work were it not that we are nearing the time for the quinquennial valuation of the metropolis. While, however, the procedure in regard to rating appeals in London and the general principles of rating are clearly and shortly stated, we should not recommend any one to go very far in an appeal without competent professional advice. On the other hand, a person reading this work will be in a better position to consider whether or not he shall rest satisfied with the manner in which his property is assessed.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

1,577, Sliding Windows. A. F. M. Yoniton. According to this invention, near the top of the inner face of the sash-stile of the bottom sash, as convenient, there are affixed plates containing slots, and to the frame of the window are attached block-plates, or vice versa, or sliding-pins or pivots are fixed, and when any of the improved methods of fixing or swinging the sashes are adopted, the sash (after temporarily removing the inside beads) and raising it to the height required, may be swung inwards from the bottom for outside cleaning from within the room. Into each face of the outside lining opposite the side of the frame at any convenient height is placed a projecting screw or pivot as an axis upon which the top sash may turn inwards by means of projecting hooks, affixed to the top-rail or outside face of sash-stiles, the parting-beads having been temporarily removed or hinged back flush with the pulley-stops.

2,795, Mixing Concrete. J. Stansfield. In a revolving circular pan or vessel similar to a pug-mill the material is mixed; but by this invention an addition is made to the ordinary mechanism in the shape of plates formed and curved like a ploughshare. The revolution of the pan forces the concrete against the plater, which turn it over and mix it.

2,862, Improvements in Water-closets. C. W. Durham (New York).

According to this invention, the lower portion of the water-closet bowl or pan is fitted with a screw-thread, which enables it to be fixed in the pipe itself with or without an intervening trap of O or half O form.

4,946, Bricks. R. R. Cluniss.

The improvement which is the subject of this patent consists in forming a series of studs or projecting pieces on one side, while upon the opposite side a corresponding number of indentations

are made. These studs and indentations are so arranged that the studs of one course will fit into the indentations of the next in order, according to any determined bond, so that a complete tie may be secured. Very little mortar is required, and the expense of manufacture is not greater than that of ordinary pressed brick.

4,947, Drain-pipe Joints. R. R. Cluniss.

By this invention an inward bevel is formed around the edge of the socket at one end of the pipe section, and a flange or collar is fixed at the other end of the pipe, the end of the pipe being roughly bevelled. The cementing material being roughly laid therein, the flanged end of the pipe next in order is forced therein until the bevelled end of the pipe comes in contact with the pipe end inside the socket, the shoulder comes in contact with the outer edge of the socket, and the expressed cement being cut off by the bevelling a complete and closed joint is made.

19,744, Decorating Tiles, Bricks, &c. G. A. Marsden.

According to this invention, lace or such like textile fabrics are put into the mould from which the brick or tile is made, or stencils or similar means are used, to produce a relief or indented surface; this gives a design in raised or intaglio to the face of the bricks or tiles.

NEW APPLICATIONS FOR PATENTS.

Feb. 11.—2,169, W. Barnes, Joiners' Cramp.—2,190, E. Johnson, Open Stoves or Fire-grates.—2,223 and 2,224, J. E. Rendle, Glass Roofing.—2,230, H. Lake, Excavators and Elevators.—2,233, H. Lake, Window Sashes and Frames.—2,240, H. Loftie, Wood Augers.

Feb. 12.—2,256, J. Robbins, Water-pipes, &c.—2,259, M. Chapman, Double-action Lock.—2,263, W. Heywood, Glazing and Roofing Buildings.

Feb. 13.—2,320, S. Denison and Others, Tile and Brick-pressing Machines.—2,321, S. Denison and Others, Brick-pressing Machines.—2,323, F. Bosshardt, Gabled Roofs.—2,346, T. Kemp, Testing Drains.—2,371, C. Edwards, Manufacture of certain kinds of Brick and Fire-clay Substitutes.—2,387, J. Pollock, Window-sash Regulator.

Feb. 14.—2,394, E. Field and F. Andrew, Door-knobs, &c.—2,397, W. Blackband and H. Lunn, Securing Door and other Knobs to Spindles.—2,400, T. Helliwell, Glazing Bar or Astragal for Supporting Sheets of Glass, Zinc, &c.—2,445, A. Osborne, Heads of Screws.

Feb. 15.—2,473, J. Bennison, Chimneys or Flues of Fireplaces.—2,508, B. Westerdahl, Plasterers' Lathing.—2,509, J. Guttman, Stocks for Boring-bits.

PROVISIONAL SPECIFICATIONS ACCEPTED.

16,016, D. Knowles and E. Raybone, Sash Fasteners.—19,825, G. Verity and J. Thomas, Raising and Lowering Sliding Doors.—20,175, B. Pybus, Door Closing Apparatus.—20,518, W. Eckerley, Water Waste Prevention Cisterns for W.C.'s.—20,814, J. Tudberry, Drying Bricks.—137, J. Lyon, Glazing Greenhouses, &c.—311, S. Rogers, Water Waste Preventer and Regulator.—723, W. Thompson, Window Fasteners.—746, F. Fawthorpe, Sash Bars and Glazing Holding Devices for Roofs, &c.—949, C. Szklia, Fastenings for Doors.—974, E. Ingham, Draught Preventers for Doors.—1,020, T. Reed, Water Taps.—1,115, N. Proctor and others, Brick-making Machines.—1,153, C. Danbelligh, Window Sashes.—1,176, W. Sinclair, Cementing Iron Rails to Stone Kerbing, &c.—1,178, W. Sinclair, Water-proofing and Preserving Composition for Stone.—1,190, H. Lake, Valves for Flushing Tanks and Cisterns.—1,346, W. Sugg, Ventilating, 1,978, R. Jewell, Fire Grates.—1,639, A. Deydon, Stove.—1,634, M. Farington, Lime.—1,671, W. Curtis, Window Sash Fasteners, &c.—1,678, C. Sansom, Fire-grates or Stoves.—1,755, A. Tomkins, Slow Combustion Stoves.—1,760, J. Taylor Ventilators, Cows, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months.

2,688, W. Defries and N. Feeney, Hinges.—5,748, J. Willing, Fixing Letters and Devices to Facias, &c.—5,790, W. Emden, Drain-pipe Joints.—6,310, J. Sibson, Tombstones, &c.—15,364, W. Thompson, Grinding Machines for Frame and other Saws.—16,519, W. Minns, Cutting Window lead for Glaziers' use in the manner of Stained-glass Windows.—20,712, B. White and A. Boyd, Brick-making Machines.—256, A. Halliday, Saw-sharpening Machines.—671, A. Clark, Cutting Stone.—675, C. Stillwell and A. Thayer, Square and Level.

Value of Land at Cricklewood.—On Monday evening last Messrs. Baker & Sons, of Queen Victoria-street, held a sale of freehold building land, known as the "Oaklands Park Estate," opposite the "Crown" Hotel, Cricklewood. We understand that the whole of the plots offered were sold, at a total of 7,000*l.*, being at the rate of about 3,000*l.* per acre.

RECENT SALES OF PROPERTY:

ESTATE EXCHANGE REPORT.

FEB. 17.—By G. A. WILKINSON. Portland-place—No. 11, called "Langham House," f. £14,200. By ROGERS, CHAPMAN, & THOMAS. Belgravia—10, Lower Belgrave-street, u.t. 21 yrs., g.r. £20, r. £130 p.a. 1,000. [Contractions used in these lists.—F.g.r. for freehold ground rent; l.g.r. for leasehold ground rent; l.g.r. for improved ground rent; g.r. for ground rent; p. for rent; f. for freehold; c. for copyhold; l. for leasehold; c.r. for estimated rental; u.t. for unexpired term; p.a. for per annum; yrs. for years; s. for street; rd. for road; sq. for square; pl. for place; ter. for terrace; yd. for yard, &c.]

MEETINGS.

SATURDAY, MARCH 1. Association of Public Sanitary Inspectors.—Mr. D. Richards on "The Removal and Disposal of House Refuse in London." 6 p.m. Royal Institution.—The Right Hon. Lord Rayleigh, M.P., F.R.S., on "Electricity and Magnetism." 11. 3 p.m. MONDAY, MARCH 3. Royal Institute of British Architects.—Special general meeting for members only; followed by a business general meeting for members only, to continue the discussion of Mr. John Slater's paper on "Building Legislation." 8 p.m. Royal Academy.—Professor J. H. Middleton on "Flourishing Architecture in the Fourteenth and Fifteenth Centuries." 11. 8 p.m. Society of Engineers.—Mr. R. H. Tweddell on "The Application of Water Pressure to Machine Tools and Appliances." 7.30 p.m.

Royal Institution.—General Monthly Meeting, 5 p.m.
Clerks of Works' Association (Carpenters' Hall).—Mr. T. Edmond on "Lighthouse Construction," 8 p.m.
Edinburgh Architectural Society.—Mr. J. M. Hay on "The Decorative Panels of St. George's Hall," 7 p.m.
Leeds and Yorkshire Architectural Society.—Mr. M. Macarney, B.A., on "The Revival of Applied Art," 7.30 p.m.

TUESDAY, MARCH 4.

Institution of Civil Engineers.—(1) Mr. C. O. Burgess on "The Hawkesbury Bridge, New South Wales," (2) Mr. F. T. G. Walton on "The Construction of the Buffin Bridge over the Ganges at Benares," (3) Mr. G. E. W. Cruttwell on "The New Blackfriars Bridge on the London, Chatham, and Dover Railway," 8 p.m.
Sanitary Institute (Lectures for Sanitary Inspectors).—Professor W. H. Corfield, M.A., on "Sanitary Appliances," 8 p.m.
Society of Biblical Archaeology.—(1) Dr. J. H. Gladstone, F.R.S., on "The Bronze and Copper of Ancient Egypt and Assyria," (2) Mr. E. B. Taylor, F.R.S., on "The Winged Figures of the Assyrian Monuments and the Artificial Fertilisation of the Date-Palm," 8 p.m.
Builders' Clerks' Benevolent Institution.—Annual General Meeting, 7.30 p.m.
Glasgow Architectural Association.—Annual General Business Meeting.

WEDNESDAY, MARCH 5.

British Archaeological Association.—Mr. J. Romilly Allen, F.S.A. (Scot.), on "The Early Sculptured Stones of the West Riding of Yorkshire," 8 p.m.
Architects' and Artisans' and others on Matters Connected with Building.—Professor A. B. W. Kennedy on "The Forth Bridge," Carpenters' Hall, London-wall, 8 p.m.
Civil and Mechanical Engineers' Society.—Mr. E. Lucas on "Fresco Cement," 7 p.m.
Surveyors and Auctioneers' Clerks' Provident Association.—Annual General Meeting.—Auction Mart, Tokenhouse-yard, 4.30 p.m.
Society of Arts.—Mr. J. Tripplin on "Recent Progress in British Watch and Clock Making," 8 p.m.

THURSDAY, MARCH 6.

Royal Archaeological Institute.—(1) Mr. J. P. Harrison on "Anglo-Norman Ornament Compared with Designs in Anglo-Saxon MSS.," (2) Mr. A. Oliver on "A Brass at Newbury," 4.30 p.m.
Liverpool Architectural Society.—A dinner will be given at the "Bear's Paw," Lord-street, 6.30 p.m.

FRIDAY, MARCH 7.

Royal Academy.—Professor J. H. Middleton on "Florentine Sculpture in the Fourteenth and Fifteenth Centuries," III, 8 p.m.
Sanitary Institute (Lectures for Sanitary Inspectors).—Mr. C. Jones on "Scavenging, Disposal of refuse and sewage," 8 p.m.

SATURDAY, MARCH 8.

Royal Institution.—The Right Hon. Lord Rayleigh, M.A., F.R.S., on "Electricity and Magnetism," IV, 3 p.m.
Edinburgh Architectural Association.—Visit to Free Library and Old University Buildings.

Miscellaneous.

Competitions: Germany.—Looking at the list of competitions decided during the last fortnight, we find that the one at Langensalza for a new school-house (with eighteen large class-rooms), which had enticed as many as one hundred architects to compete, has been won by Herr Reg. Baumeister F. Wendorf, who is at present attached to the staff of a well-known Imperial "Baubureau" at Leipzig. This is the third time,* and in quick succession that this artist, who may well be termed a "school specialist," has come out first in competitions for this class of buildings, and that in spite of the large number of rivals. Twenty-two designs were sent in for the new Trinity Church at Dresden; here, as at Strassburg,† the jury did not consider themselves entitled to award the first prize. The second one (£100) was won by Messrs. Abesser & Kröger of Berlin, and the third (£50) by Herr Schramm of Dresden.

Workman's Barracks.—On the works for the Baltic Canal, now being executed in North Germany, the unmarried workmen are required to live in barrack-huts especially erected for them. These are all built under Government control and supervision. They are constructed of timber, boarded inside and out. The minimum cubic contents per bed was fixed by the Government Sanitary Department at 12 cubic metres. The apartments are in all cases warmed and ventilated, and latrines are placed so as to be accessible to the living-rooms and dormitories, but not in contact with them; they must be supplied with water. The cost of each barrack-dormitory for 100 workpeople is approximately 700*l.*; living-rooms, dining-hall, and premises for staff, 1,000*l.*; latrine, 50*l.*; door-keeper's hut, 15*l.*; and dust-bole, 12*l.* 10*s.* There are also two hospitals, each with twenty beds.

Public Works in New York.—The report of Mr. T. F. Gilroy, Commissioner of Public Works of New York, states that 4,353,000 dols. were expended during 1889. In extending and improving the distribution of water, 18.93 miles of additional water mains were laid. The system for distributing the water supply of New York now includes 657.19 miles of mains, with 6,760 stopcocks and 8,420 fire hydrants. During the year, 1,659 additional water meters were placed, making a total of 19,870 now in use. The average daily consumption of water through meters is 37,483,300 gallons. Work is in progress for a canal and tunnel to divert the water of the Byram River into the Bronx River, by which the water supply from that source will be increased by 6,000,000 gallons a day. In the extension and improvement of the New York sewerage system, 28,273 lineal feet of sewers, 1,274 lineal feet of culverts, and forty-six receiving mains were constructed, and the sewerage system on Manhattan Island now comprises 433.73 miles of sewers, with 5,209 receiving basins.

Public Works Officials, Berlin.—All officials attached to or under the control of the Architectural, Surveying, Civil and Railway Engineering, and the Administrative Departments of the Prussian Ministry of Public Works have received notice that they will henceforth be required to wear uniform on all official occasions; and the new designs for the uniforms have been published. The "order" distinguishes "gala uniform" and "ordinary service uniform," the former requiring the old Brandenburg frock-coat, white casemere trousers and waistcoat, cocked hat, and a light sword in white leather sheath. The "service uniform" will resemble the attire worn by the German officers of line regiments, herring that dark grey trousers will take the place of blue ones, and that a sword of the old pattern will be worn in a black leather sheath. Members of the architectural department can be recognised by a cocarde containing a triangle, compass, and plumb-line, surmounted by a crown.

Berlin Town-hall.—The large assembly-room of the Berlin Town-hall has, owing to the great number of evenings it has been used since its erection, and also partly in consequence of the fire that occurred at the Red Cross Bazaar last December, been so blackened with dust and soot that the Committee in charge have proposed an entire cleansing and redecoration of the interior. Owing to want of funds, the ball has in reality never been properly completed, and it is now proposed that the original ideas of the architect (Barath Waesemann) should be carried out, and, besides the redecoration proper, that the walls should be adorned with frescoes referring to Berlin life (after the sketches of Prof. August v. Heyden). Barath Blankenstein, the City Architect, who is professional adviser to the Committee, strongly recommends the electric lighting of the assembly-room, and also some alterations in the hot-water coils. He estimates the total cost of the proposed improvements at 2,400*l.*

Oundle Sewerage.—The Commissioners of Oundle held a special meeting on the 17th ult. to consider plans submitted by Mr. W. H. Radford, C.E., of Nottingham, for the sewage disposal of the town. The engineer explained that he proposed to purify the sewage in duplicate precipitation and filtration tanks, the chemicals and filtering medium being supplied by the International Sewage Purification Company. The sewage mud would be pumped on to air-drying pits by means of a small circular windmill. The whole of the town sewage would be delivered to this site by various new pipe-sewers, the sewage of one low-lying locality being pumped into a high-level sewer by a small compressed-air pump placed under the street and supplied with compressed air through a pipe from the new waterworks engine. The Commissioners decided to carry out the scheme in its entirety.

Trade Smoking Concert.—The Mutual Cycling Club (in connection with Messrs. Colls & Sons' office staff) gave a very successful smoking concert at the Surrey Masonic Hall on February 20. Mr. J. Howard Colls occupied the chair, supported by Mr. William Colls, Mr. Ellis Marsland, and a large number of visitors connected with the building trade.

The Norwegian Pottery Industry.—The Norwegian pottery industry—a new one—is progressing, there being exported last year 45,000 kilos against 26,000 kilos in 1888. Most of the manufacture is sold in this country.

Edinburgh Architectural Association.—A meeting of the Edinburgh Architectural Association was held on the 20th ult., in the hall, 42, George-street, Professor Baldwin Brown in the chair. Mr. Henry F. Kerr read a paper on "Ingress and Egress for Public Buildings," a subject which, he said, had only in recent years met with any serious and sustained consideration. To render panic among an audience impossible or innocuous, he emphasised the necessity of passages, staircases, and doors being of such ample width as to allow the building to be emptied speedily. All exits should be always used, and individually they should be of such capacity as to visibly recommend themselves to the audience. The Glasgow scheme of enlarging the exits for the upper floors was, Mr. Kerr thought, to be recommended. A plurality of exits for each block should in all cases be insisted on, and the exit capacity of the seat rows should also be attended to. Stairs for ascent and descent ought not to be of less width than the corridors between them and the auditorium, or wider than the corridors between them and the exterior. They should be provided with a hand-rail on both sides, and where six or more feet in width should also have a hand-rail in the centre. The straight stair was open to objection if of any length, the square and the newel square,—when doubled on itself,—being the safest forms. It was desirable always, in the interests of safety, to reduce the number of steps required for access to the various parts of a building, as the danger was generally speaking in proportion to the number of steps to be traversed. Hence the object in sinking the pit in theatres below the street-level, to reduce the height from the street to the gallery, and hence also the merit of Mr. Barrow's plan, which placed the gallery outlets at the level of the lowest seats in place of at the level of the highest. He recommended that all exit doors should be conspicuously marked as such, so that the audience might not use a door which did not lead to the outside of the building. Doors should open outward or swing either way, and should not be secured except by some fastening which yielded automatically to pressure from within. Corridors and stairs should be kept clear of all obstructions, barriers being rarely if ever admissible. Mr. Kerr was cordially thanked for his paper, which was illustrated by plans, diagrams, and models.

The Plumbers' Company and the Education and Registration of Plumbers.—We understand that the freedom of the Plumbers' Company has been conferred upon Mr. Edward James Jarvis, operative plumber, of Plymouth, on account of his having passed the Company's Examination in Honours.—On the 19th ult. a deputation of the Governors of the University College for North Wales waited upon the Court of the Plumbers' Company at the Guildhall for the purpose of explaining their system of technical education, and urging the claims of their institution. The deputation, which consisted of Mr. Ratbone, M.P., Mr. Roberts, M.P., Mr. Lewis, M.P., Mr. Darlishire, B.A., J.P. (London University), and Prof. Gray, was introduced by the Right Hon. G. Osborne Morgan, M.P., Vice-President. Mr. Morgan, in addressing the Court, said it was hoped that some of the aid the Company had so generously extended to struggling institutions would be bestowed upon their College at Bangor, which devoted all its energies to promoting thoroughly scientific and technical instruction, and, during its five years' existence, had established branches in all the principal towns of North Wales. Prof. Gray gave details of the work done by the College, and the public support accorded thereto. Mr. Rathbone and Mr. Darlishire also addressed the Court. The Master of the Plumbers' Company (Mr. W. H. Bishop), in reply, said he could only say that the Company's resources were taxed to the utmost, and the Court were therefore unable to offer any immediate financial assistance; but they would consider what steps might best be taken to include the University College for North Wales in their scheme now in course of preparation, by which the necessary funds might be provided for carrying out a complete educational system in all parts of the kingdom.

Black Granite.—Black granite is now being quarried on the lake Vetterin, in Sweden, which is then cut and polished into various architectural ornaments at Varberg, whence they are exported to England, Germany, Denmark, &c. The stone is very handsome when polished. Some 100 men are employed here.

* Emden and Mannheim, both times first prize.
 † See *Builder*, Feb. 15 last.

British Archaeological Association.—The last meeting was held on Wednesday, Feb. 19, Mr. J. W. Grover, F.S.A., in the chair. A curious example of bookbinding, formed of an ancient illuminated MS. on a sixteenth-century book, was exhibited by Mr. Loftus Brock, F.S.A. Mr. A. Oliver produced a rubbing of the remarkable brass in the possession of the Surrey Archaeological Society, supposed to have been brought from Netley Abbey. Two figures are represented on it,—the field being occupied by a diaper of cresets in flame. Mr. C. H. Compton pointed out reasons for discrediting the belief that the cresets were intended for the badge of the Compton family, as had been supposed. Mr. G. R. Wright, F.S.A., read a description of the creset stone in the recently-destroyed church at Lewanick, Cornwall. It consists of a circular granite cap in which are holes for seven candles. References were given to many other similar objects, while their use was attested by quotation from the Record of Durham. A paper was then read by Mr. G. Patrick on the antiquities of Wandswoth.

Royal Victoria Hall, Waterloo Bridge-road, S.E.—The following science lectures will be given at the above Hall during March:—March 4, "Geology in the Streets of London," by Mr. F. W. Rudler. March 11, "The Infinitely Great and the Infinitely Little," by Dr. Dallinger. March 18, "Australia," by Prof. Beare. March 25, "Rome," by Mr. W. North.

New Post-Office, Geneva.—A new chief post-office is to be erected on the site in the Rue de Monthlanc acquired some time ago for this purpose by the Postal authorities. The cost of the building, which is to be carried out in accordance with the designs of the Brothers Camoletti, is estimated at 1,500,000 francs, or nearly 60,000*l.*

The Stockholm Building Trade.—Last year 188 new houses were erected in Stockholm, containing 7,196 rooms, of which 104 were passed by the City Building Board. In 1888 the number of new houses was 128, with 4,736 rooms, of which 123 were passed. This shows a great falling-off in building operations in late years.

Royal Society of Painter-Etchers.—The following gentlemen have been elected Associates of this Society,—viz., Messrs. A. W. Hayes, W. Boucher, C. F. Robinson, and F. S. Walker.

Bottrill & Son, Reading.....	4,305 0 0 .. 130 0 0
Gregory & Co.....	4,287 0 0 .. 145 0 0
W. P. Rice.....	4,197 0 0 .. 131 0 0
R. Fink, Milford.....	4,153 0 0 .. 112 0 0
Patison.....	4,109 0 0 .. 121 0 0
P. Peters, Horsham.....	3,937 0 0 .. 124 18 0
G. Box.....	3,918 0 0 .. 114 0 0

MACCLESFIELD.—For alterations and additions to the Theatre Royal, Mill-street, Macclesfield, for General Booth, Mr. J. Williams Dunford, architect and surveyor, 101, Queen Victoria-street, E.C. :-
 G. Roylance, Macclesfield £1,150 0 0
 W. W. Gladwell, Macclesfield 1,000 0 0
 Weale & Co., Ludlow 900 0 0
 Martin & Barclay, Battersea* 517 0 0
 * Accepted.

NEWCASTLE-ON-TYNE.—For the erection and completion of Citadel, accommodating 3,600 persons, for General Booth, in Westgate-road, Newcastle-on-Tyne. Mr. J. Williams Dunford, 101, Queen Victoria-street, London, E.C. :-
 Lowry, Newcastle £3,657 0 0
 Coxhead, Leytonstone 3,497 0 0
 Middlemiss Bros., Newcastle* 3,125 0 0
 * Accepted.

POTTON.—For the erection and completion of Salvation Army Fort in Potton, for General Booth, Mr. J. Williams Dunford, architect and surveyor, 101, Queen Victoria-street, E.C. :-
 J. Smith, Bedford 547 0 0
 Haywood & Son, Bedford 375 0 0
 H. Walker, Bedford 319 0 0
 J. Ramsford, Potton 286 10 0
 S. Woodman, Potton 285 0 0
 Edwood & Son, Sandy 235 0 0
 L. Jarvis, Banbury (accepted) 228 0 0

PRESTON (Lancs.).—For pulling down and rebuilding Mission-room, Rugged School, &c., Leeming-street, Preston, for Rev. E. Over, Mr. Thomas W. Weaver, architect, Preston :-
 George Lucas (accepted) £408 0 0

PRESTON (Lancs.).—For pulling down and rebuilding "The Gaulthorn Inn," Porter-street, Preston, for Messrs. Beardsworth & Whalley, Little Harwood Brewery, Blackburn. Mr. Thomas W. Weaver, architect, Preston. Quantities supplied by the architect :-
 John Walmaley £1,420 0 0
 Charles Walker 1,115 13 0
 Thomas Croft 1,007 11 0
 David Tullis & Son 1,057 0 0
 John Cartmell (accepted) 1,054 0 0
 [All of Preston.]

SIDMOUTH.—For the erection of a new Cottage Hospital, Sidmouth, South Devon. Mr. Walter F. Cave, architect, 2, George-street, Portman-square, W. :-
 R. W. & J. Skinner, Sidmouth, £1,708 10 0
 W. Grainger, Chiddingfold 1,330 0 0 £20 0 0
 E. Carnell, Ottery St. Mary 1,330 0 0 37 0 0
 Turner & Skinner, Honiton 1,250 0 0 33 0 0

TUNBRIDGE WELLS.—For additions to Salvation Army Fortress, Tunbridge Wells, for General Booth, J. Williams Dunford, architect and surveyor, 101, Queen Victoria-street, E.C. :-
 G. Givver, Gordon-road £268 0 0
 Beale & Sons, Frant-road 254 0 0
 T. Stabridge, Newington-road 209 0 0
 J. Jarvis, Grove Hill-road* 193 0 0
 White & Humphrey, Park-street 187 0 0
 [All of Tunbridge Wells.]
 * Accepted.

WOOD GREEN.—For the erection and completion of Salvation Army Citadel at Wood Green, for General Booth, Mr. J. Williams Dunford, architect and surveyor, 101, Queen Victoria-street, E.C. :-
 Brown & Sweetland, New Southgate £2,050 0 0
 Martin & Barclay, Battersea 1,469 0 0
 E. J. Coxhead, Leytonstone 1,373 0 0
 E. Jarvis, Banbury 1,225 0 0
 Edwood & Sons, Sandy (accepted) 1,200 0 0

SUBSCRIBERS IN LONDON AND THE SUBURBS, by prepaying at the Publishing Office, 15s. per annum (or 4s. 9d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

TERMS OF SUBSCRIPTION.
 "THE BUILDER" is supplied twice from the Office to residents in any part of the United Kingdom at the rate of 19s. per annum *Postpaid*. To all parts of Europe, America, Australia, and New Zealand, &c. per annum 27s. India, China, Ceylon, &c. 30s. per annum. Remittances payable to DOUGLAS FOURDRINIER, Cashier, No. 46, Catherine-street, W.C.

TO CORRESPONDENTS.
 1). C. A.—S. M. (we cannot insert detailed accounts of entertainments of that kind. They are of no public interest).—T. W. A. (too late).—A. & C. H. (too late).—E. A. (sent too late).—G. St. F. H. (too late).—H. R. (next week).
 All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, not necessarily for publication. We are compelled to decline publishing out books and giving addresses. Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors.
 We cannot undertake to return rejected communications.
 Letters or communications (beyond mere news items) which have been duplicated for other journals, are NOT DESIRED.
 All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.

Registered Telegraphic Address, "THE BUILDER, LONDON."

CHARGES FOR ADVERTISEMENTS.

SITUATIONS VACANT, PARTNERSHIPS, APRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS.
 Six lines (about fifty words) or under 4s. 6d.
 Each additional line (about ten words) 0s. 6d.
 Terms for Series of Trade Advertisements, also for Special Advertisements on front cover of Competition, Contracts, & Sales by Auction, &c., may be obtained on application to the Publisher.

SITUATIONS WANTED.
 FOUR Lines (about thirty words) or under 2s. 6d.
 Each additional line (about ten words) 0s. 6d.

PREPARATION IS ABSOLUTELY NECESSARY.
 * * * Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to DOUGLAS FOURDRINIER, Publisher, Addressed to No. 46, Catherine-street, W.C.

Advertisements for the current week's issue must reach the office before THREE o'clock on FRIDAY, but those intended for the front Page should be in by the same hour on WEDNESDAY.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS.

MENTIONS OR ORDERS TO DISCONTINUE same must reach the Office before TEN o'clock on WEDNESDAY morning.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that all the latter OFFICES should be sent to the Office.

PERSONS Advertising in "The Builder" may have Replies addressed to the Office, 46, Catherine-street, Covent Garden, W.C. free of charge. Letters will be forwarded if addressed in envelopes are sent, together with sufficient stamps to cover the postage.

AN EDITION Printed on THIN PAPER, for FOREIGN and COLONIAL CIRCULATION, is issued every week.

Now ready, **READING CASES,** NINEPENCE EACH. (By post (carefully packed), 1s.)

The Discovery of Coal in Kent.

THE Ruskinian "cult" must have been greatly shocked by the discovery of coal between Dover and Folkestone, in a boring at the works of the Channel Tunnel Company during the past few weeks.

It would not be at all surprising if "the master" himself were to present us with an indignation paragraph on the subject, for has he not already said in "King's Treasures," "If . . . you could double your income or quadruple it by digging a coal-shaft in the middle of the lawn, and turning the flower-beds into heaps of coke—would you do it? I hope not. I can tell you you would be wrong if you did, though it gave you income sixty-fold instead of fourfold. Yet this is what you are doing with all England!" Already, on nearly all sides, we hear unfavourable comments as to the prospects of the "fair county of Kent" being turned into a "black country," and it may not be uninteresting, on these and on other grounds, to inquire into the nature of the evidence which has been mainly instrumental in producing the scare.

At a point on the South-Eastern Railway adjoining the experimental heading for the proposed Channel Tunnel, a deep boring has, for some time past, been in progress, with the object of investigating the deep-seated geological structure, and especially to learn if coal exists within reasonable limits of depth; and Mr. Francis Brady, C.E., Engineer of the Railway and Tunnel Companies alluded to, reported that on February 15th coal was reached at a depth of 1,180 ft. below the surface, and it was proved to be of good bituminous character. The seam was struck after passing through 20 ft. of clays, grits, and blackish shales belonging to the Coal-measure series, and it is known that the lines of bedding in the shale are distinctly horizontal. Specimens of coal were also taken at 1,182 ft. and 1,183½ ft. from the surface—so ran the official announcement. We are able to add, on good authority, that fossil plants were also discovered which, when duly investigated, will no doubt go far to fix the exact horizon in the Carboniferous formation to which the coal-seam belongs, and so

enable us to more safely predict the probable depth of additional seams.

This is unquestionably an important discovery; but before indulging in visionary illusions of the prospect of obtaining coal at the proverbial "eighteen-pence per ton," let us critically examine the value of the evidence bearing on the point. We know that, so far, the coal has been proved to be of good quality, but we require further information to enable us to solve the problems as to whether the seam discovered is associated with others, and, if so, what are their nature, thickness, and depth from the surface, as well as their extent and development underground.

These questions can only be answered by analogy, and the only one that admits of an easy off-hand solution is the consideration of the depth of the seams (assuming more than one to exist) from the surface. Since the discovery, doubts have been expressed as to the commercial results of working a coal-field at such a depth,—such remarks, as usual, emanating from irresponsible persons. A very elementary acquaintance with coal-mining shows how groundless are such fears, for the depth is well within the mining limit. At the Rose Bridge coal-pit, near Wigan, the shaft is nearly 2,500 ft. deep; in Hainault, coal is being worked at the depth of 2,800 ft., and one pit even goes down to 3,411 ft. The chief element in determining the limit within which coal may be won is the increase of temperature which accompanies increase of depth. The thermometer rises 1 deg. in about every 60 ft. of descent for the first 1,800 feet, and the ratio then increases, and it is calculated that at 3,420 ft. the temperature of the air in the mine equals that of the blood. From experience in deep mines, Sir W. W. Smyth is of opinion that the difficulty of temperature may, by due appliances, be overcome for even a greater depth than 4,000 ft. There need, therefore, be no fear but that, if other coal-seams exist anywhere near the one already discovered near Dover, they could be won in the ordinary way.

In regard to the other questions, it may be at once admitted that they can only be answered theoretically, but the theory in this case is accompanied by very strong probability. The mere fact that coal would be found in south-eastern England, and near the spot where it has actually been proved to exist, was predicted by geologists a long time ago. Mr. Godwin-Austen nearly forty years since gave several reasons for his belief in, which

belief was also shared by Professor Prestwich and other well-known geologists. The geological world, therefore, is not surprised at the discovery, though eagerly waiting further results. Certain eminent geologists, however, and amongst them the late Sir Roderick Murchison, were of opinion that, although Carboniferous and other Palaeozoic rocks might be met with at great depth in the south-east of England, no coal-field would be found to exist; and from an intimate knowledge of the facts (strengthened by recent research on the Continent) on which this opinion is based, we are bound to say that great deference must be paid to it. To find coal is one thing, but to find it in payable quantities is quite another.

It may be premised that the argument for the extent of the coal measures under our south-eastern counties rests, in short, on the fact that a line of coal-fields runs from Westphalia through the south of Belgium and French Flanders into the Boulonnais, and that these fields present a most striking analogy with the Somersetshire and South-Wales coal-fields, which trend in the same direction. In order that the non-geological reader may appreciate the whole question, we may say something respecting the occurrence of the strata concerned in the matter.

The rocks in the region in question, when all are present and in order, are superimposed as follows:—

Palaeozoic	}	Carboniferous.
		Devonian.
		Silurian.
		Cambrian.

Thus, normally, the Carboniferous beds (including the coal-measures and carboniferous limestone, &c.) lie on the Devonian, and this in turn on the Silurian, and so on. It will be readily seen that under these conditions, if the boring tool reaches the Devonian or other beds under the coal-measures, without passing through these latter, we ought not to expect to find coal at the spot. The general order of succession of the beds is absolutely proved, and does not admit of the slightest discussion—we know, not only from the stratigraphical relations they bear to each other, but from their included fossils, that of these beds the Cambrian is the oldest, and the Carboniferous the youngest. Now, certain of these beds have frequently been met with in borings of great depth in and around the London basin, but hitherto no coal seam has been discovered. At Messrs. Meux & Co.'s Brewery, Tottenham

Court-road, the Devonian was reached at 1,066 ft. from the surface, and bored into 80 ft.; at the New River Co.'s boring at Cheshunt (Tarrford) the same horizon was found at 950 ft., and was pierced 30 ft. The geological age of the lowest beds found down to 1,445 ft. in the Richmond boring, which mainly consisted of red marl and sandstone, is not definitely known, in the absence of fossils, but, from the circumstance that small pieces of anthracite were found, it is inferred that the coal measures are not far from the site. It should be remembered, however, that this anthracitic matter was found above the red sandstone beds alluded to, so that this evidence does not preclude the possibility of the latter being of Devonian age. From an inspection of some of the cores brought up in boring, we incline to the opinion of Professor Judd (though not quite from the same reason) that they are younger than the Carboniferous beds. The sandstone does not seem to be sufficiently altered to present the normal appearance of those Devonian beds with which it ought to be compared, whilst in lithological character it very closely resembles the New Red Sandstone, which is younger than the Carboniferous. It is much to be regretted that this and the borings at Crossness, near Erith, which finished at 1,060 ft.; at Kentish-town, which went down to 1,302 ft.; and at Streatham, 1,120 ft., all of which left off in rock of a similar character, were not driven deeper; for, if the coal-measures exist under those spots, they would almost certainly have been reached. In any case, the experiment was well worth trying. At Ware (New River Company's works), in Hertfordshire, at about 796 ft. from the surface, Silurian beds were found and pierced for 35 ft.; whilst at Harwich, Carboniferous beds were met with at 1,030 ft., but the presence of the fossils known as *Posidonomyæ* showed the horizon to be lower than the coal-measures.

Many other deep borings have been made, but the evidence afforded by them does not immediately concern the subject in hand. We may, however, allude to the deep Sub-Wealden boring, near Battle, which is of a negative character, as it attained a depth of nearly 2,000 feet, ending in rocks of middle oolite, which are very much younger in age than the Carboniferous. This experiment shows that it is not advisable to search for coal in that part of Sussex. The oft-repeated question as to whether coal exists under London is, therefore, not yet definitely settled. Indeed, we are of opinion that none of the evidence obtained from the above-mentioned borings in the London district,—not even in those instances where pre-Carboniferous rocks are proved,—is *per se* absolutely conclusive as to the presence or absence of the coal-measures; for although the super-position of the divisions of the strata, alluded to in the earlier part of the article, holds good as a very general rule (indeed, wherever they have been comparatively undisturbed), the contingency of an exception must unfortunately be made in reference to their relative position under south-eastern England. The coal-measures and Palæozoic rocks, stretching in a line through the south of Belgium to the Boulonnais, were involved in the making and elevation of the Ardennes mountains, of which the Somersetshire and South Wales coal-fields and associated rocks are merely the western prolongation. This does not seem to admit of the slightest doubt. Therefore, the old rocks proved in the deep borings, in the south-east of England, are simply the depressed broad axis of the old Ardennes mountains which run underground from the Boulonnais to Somersetshire, being covered by deposits of younger geological age. This being so, there is no reason why the same stratigraphical phenomena should not be exhibited in the depressed portion of the Ardennes axis, as we find in its elevated and exposed portions on the Continent, on the one hand, and in Somersetshire on the other. It is clear, therefore, that in order to get at the true value of the discovery near Dover, we must study the ex-

posed parts, to which we have just referred, and this we will now briefly proceed to do.

The first thing that strikes us is that the great earth movements which resulted in the elevation of the Ardennes, have considerably fractured and dislocated most of the geological formations concerned, by reason of which the natural order of the beds has been very much upset. In places, hundreds of feet of strata have been completely inverted, whilst "thrust faults" have much disturbed their original positions, the maximum effect of which is that older beds have been forced to occupy a superior position to the coal measures. For example, in the bore-hole of Saint Homme, near Mons, the section is as follows:—

	Mètres.
Tertiary and Cretaceous beds.....	34
{ Silurian shales	78
{ Devonian beds	84½
{ Carboniferous (coal-measures, &c.) reached.	109½

It will be seen that the normal positions of these beds have been completely inverted. This is by no means an isolated example. It is the Mons coalfield that so closely resembles the Somersetshire basin. In both areas, the strata are partly inverted, and the coal-seams much cut up, but especially at Mons. In the latter place, a single seam may be passed through six times in one pit 1,050 ft. deep, and the strata which if flat would be 9 miles broad, are squeezed into a space 7 miles across. At Charleroi, the compression is still greater, a breadth of 8½ miles of flat strata being narrowed to less than half that distance by contortion through lateral compression. To the north of the Mendip Hills (Somersetshire coalfield) the seams of the lower coal-measures are bent quite over, in the Nettlebridge Valley, they are \cap -shaped, slide faults are of common occurrence, and, in fact, the analogy is very complete, not only in regard to the physical disposition of the strata, but to the included fossil plants, in the two areas under discussion. At Ougrée, near Liège, the coal shales are covered by the Devonian, and the same class of structure predominates in the Boulonnais. The question may be asked, in the light of the foregoing facts, whether any one could positively say that, because Silurian or Devonian beds have been found in deep borings in south-east England, the coal-measures do not exist under that region. What is there to show that the older beds are not thrust on to, or inverted over, the coal-measures in that district? We shall see.

Certain evidence tends to show that to the north of the Ardennes, the Palæozoic beds are not so much disturbed, and this throws an important light on the whole question of a Canto-Metropolitan coal-field. The Palæozoic beds, on becoming covered over by newer deposits north of the Ardennes, do not at once plunge very deeply into the earth. At Brussels, Silurian beds are found at depths varying from 63 to 123 metres; at Denderleu they exist at 151 metres; at Ninove and Grammont, Palæozoic strata were met with at 56 and 4675 metres respectively; at Alost, Silurian at 1869 metres; at Menin (near Courtrai), Devonian at 1565 metres; Flobecq, Silurian at 67 metres; Tournai, carboniferous limestone at 151 metres; and at Ostend we get the Silurian at 310 metres. On plotting and sectioning these to scale, it will be found, as we have before explained, that the old Palæozoic surface, now underground, is less disturbed and goes deeper (though not immediately) as it recedes from the outcrop on the northern flank of the Ardennes, and goes northward and westward, and, moreover, that no coal exists at any of these points to the northward of the known productive fields; the borings are so close together (we could quote several others) that this important point is definitely settled. We could show that the same phenomena are presented in Eastern Belgium with reference to the Liège field.

Now to approach the Valenciennes coal-field, for this is a further connecting-link with our

own beds, being nearer to them than the Mons area. The field of Valenciennes thins out, and the coal deteriorates so much that at Bethune it is a mere narrow wedge. In coming nearer the Channel, this poor narrow zone is flanked to the north and south by Devonian rocks, which occur just under the chalk. A "Carte Industrielle du Bassin houiller du Nord de la France" was prepared for the Compagnie des Végnes, showing numerous fruitless trial-bores by speculators. In face of these facts, Sir Roderick Murchison stated his belief that success would not crown any efforts in search of coal on this side of the Straits of Dover; and this argument is so potent that hardly anything short of the actual discovery of a coal-field in Kent or adjacent counties can materially affect it. There seems no doubt whatever, from the continental evidence, that the middle and lower Palæozoic rocks serve to connect the Ardennes axis with the Somerset axis and basin, but the probability of the coal-measures lying on them, or being caught up in folds or inversions underground in the south-east of England, is rather small. The evidence of the London basin borings alluded to, is painfully similar to that obtainable from those cities executed to the north of the productive fields in South Belgium. There is just a bare possibility of a small independent coal-field existing under parts of our south-eastern counties, but that is all; the evidence at present in support of this theory, as we have seen, is not very encouraging.

Meanwhile, Sir Edward Watkin must, of course, follow up the discovery by going on with the work, and we hope that the diameter of the bore-hole is sufficient to enable him to thoroughly probe the matter. Other trial bores are, no doubt, contemplated, and we would suggest that a more favourable result might be obtained by sinking them about ten miles west-south-west of the Channel Tunnel site. The lower Secondary beds will probably be a little thicker there; but the main reason for the suggestion is that the site is more on the line of strike of the Carboniferous beds in the Boulonnais at Ferques, Leulinghen, Locquinghen, and Hardinghen, than is the Channel Tunnel site. This latter seems rather too much to the eastward, and, assuming extension of the coal-measures from the Boulonnais, that seam at present discovered would merely be a representative of the thin northern flank of the field, instead of the thicker and best part of it, which we believe (under the assumptions) would be found at the spot at which we suggest a further experiment being made.

In the meantime, it is to be hoped that both public spirit and private enterprise will raise sufficient funds to definitely prove or disprove the existence of the coal-field. The necessities of a practical and progressive nation will then decide whether or not it is wrong to turn Kent into "heaps of cokes," and increase our incomes "sixtyfold instead of fourfold," in face of the maledictions of Ruskinian sentimentalists.

A HISTORY OF CROMER.*

THE interest recently felt in Cromer through its rehabilitation as a fashionable watering-place, coupled with a desire to do something for the fund for the restoration of the church, seem conjointly to have inspired Mr. Rye with the idea of putting some information as to the history of the place into a handsome quarto volume, printed on special and thick paper and with margins of monumental spaciousness. There is much to be said and learned about the town and district, we surmise, other than what is here included; but the volume contains enough information, apparently trustworthy and carefully prepared, to satisfy those who are not professed archaeologists, and ought to prove of some interest to the many persons who now throng to the decayed little Norfolk

* Cromer, Past and Present (or, an attempt to describe the Parishes of Cromer and Spidpen, and to narrate their history. By Walter Rye. Printed for the benefit of the fund for the restoration of Cromer Church. Jarrold & Sons, Norwich and London; 1889.

coast town for their autumn change and holiday.

"Decayed" may be thought a mistaken word to apply to a town which has not many years since had a new railway run to it, besides the more recent local line ending at "Cromer Beach" terminus, and which has built various new terraces and is entering for the first time on the dignity of a town hall, the new building for which is illustrated in this number. But Mr. Rye,—who, though he dates his preface from Putney, appears from various patronymics in the book to be either in person or in family an old Cromerite—observes that at the present moment the town has absolutely no sort of trade except that one of looking after the comfort and pockets of visitors, which goes on so briskly for about two months out of the twelve. Shipden or Schipeden, which was once the main portion of the town, lies under the sea, and a steamer was wrecked on what was said to be the remains of its church walls the year before last, and which are occasionally visible above water, though not as the author says, "at neap tides," but at low water at spring tides, which is when the tide is lowest.*

"To understand what Cromer was like three or four hundred years ago, one must picture to oneself a great cliff standing much more out to sea than at present, and under it a real harbour with a heavy-timbered pier-head like that now at Gorleston, with rough stone walls clumsily contrived and repaired now and again in an obstinate English fashion, as the incoming sea cut them away from time to time. Quite a fleet of trading-ships and fishing-boats lazily tossing about within the harbour, and a large fishing and outfitting population busy on the shore,—in fact as different a spot from the quiet watering-place of the present day as can well be conceived."

And what was the great spacious church of Cromer built for, with its massive and richly decorated tower, save for a place where many went out and in—for something much more of a town, we may be sure, than now clusters about the two or three little winding lanes which form all that is left of the streets of the old town. In 1358, the author tells us, the "merchants of Cromer" are mentioned (he does not say in what document). He also notes the theory that Cromer is really the buried part of the town and Shipden the present Cromer, for which there seems to be some evidence of a doubtful and uncertain character. In 1425 the place is referred to as "Shipden by Cromer": the form "Shipden alias Cromer" begins about 1452, and the name of Shipden by itself falls out about 1483, but "Cromer alias Shipden" is found for many years afterwards.

The chapter on "The Old Trades and Townsmen" contains much that is interesting, especially in the glimpse we get through old letters and other documents of the constant struggle to keep up the port and make things good against the inroads of the sea. 1551 was a bad year. "Not only had 'the rages and surges of the sea' swallowed up and drowned a number of the great sort of houses, but a great part of the town had by negligence of certain persons been consumed by sudden fire, so that by the length of a whole street it was still not rebuilt;" and a petition for relief was sent up to the Government, with what result does not appear. In the seventeenth century Cromer and the neighbouring coast received a good deal of disagreeable attention from pirates of various kinds, and there was such a chronic state of alarm on the subject that in 1623 Taylor, "the water poet," and his companions, making an innocent boating excursion round the coast and landing at Cromer, were taken in charge on suspicion, their boat considerably damaged, and themselves kept in durance vile till some leading gentlemen of the neighbourhood could be summoned to examine them; who quickly understood the truth, and Sir Austin Palgrave offered them the hospitality of his house a few miles off, where no doubt they ended with a merry

* It is curious how widespread is this popular error that neap tides are the lowest of all. The high tide is lower at neap than at spring, but the low tide is not so low: in other words, the rise and fall in reference to normal level is less.

evening. The whimsical poem in which Taylor relates the adventure, and satirises the absurd alarm and cowardice of the town-folk, is quoted in full, and is in its way very amusing reading. Taylor at the close of the poem heaps coals of fire on the heads of his persecutors by making an appeal to public sympathy in regard to the perilous condition of the town, not from pirates, but from the sea:—

"It is an ancient market-town that stands
Upon a lofty cliff of mouldering sands;
The sea against the cliff doth daily beat,
And every tide into the land doth eat.
The town is poor, unable by expense,
Against the raging sea to make defence;
And every day it eateth further in,
Still waiting, washing down the land doth win,
That if some course be not ta'en speedily,
The town's in danger in the sea to be.
A goodly church stands on these brittle grounds,
Not many fairs in Great Britain's bounds;
And if the sea shall swallow it as some fear,
'Tis not ten thousand pounds the like could rear.
No Christian can behold it but with grief,
And with my heart I wish them quick relief.
So farewell Cromer, I have spoke for thee,
Though you didst much unkindly deal with me."

The present Cromer lighthouse, with its powerful revolving light, well known to visitors as a conspicuous object on the highest point of the fine down between Cromer and Overstrand, was built well inland in consequence of the fate which befell the old one, which it appears was still standing, an old brick circular tower, on the then verge of the cliff, in 1806, "when it slipped into the sea silently one night"; a fate which will probably also before many years befall the old abandoned circular church tower of Stedstrand, three miles eastward, of which a sketch was given in the *Builder* of Sept. 24, 1887.

The book having been produced mainly with the intention of aiding the church restoration fund by its sale, Cromer church naturally occupies a considerable space in it, and is well described historically and architecturally, and illustrated by many engravings of various curious and interesting bits of detail. From this chapter we learn that the recent state of utter ruin of the chancel was consummated by deliberate destruction, in order to save the expense of repairing it; an order for the demolition, for that stated reason, having been given by "Antony, by divine permission Bishop of Norwich," in 1681, and for building up the ends of the nave and aisles with walls. The author adds: "The work of demolition is said to have been completed by gunpowder (I sincerely wish the reverend gentleman had been seated on the mine at the time of its explosion), and the roof screen and loft, if not already down, must have been sacrificed when the chancel arch was blocked up. . . . It was reserved for the authorities in 1840 to put the finishing touch to a century and a half of vandalism; for, to obtain 540 extra sittings, they pulled down the west gallery, and not only built it up again, which was bad enough, but erected two others along the aisles, which was worse." All these were removed in the first restoration some years since, and there is now a grand open lofty nave, a little marred by the rather too slender proportions and poor mouldings of the piers, but the general effect is fine, especially when seen filled with the crowded congregation which musters in the autumn season. The next thing wanted, when the chancel is paid for, is an organ in proportion to the scale of the building, instead of the wheezy little instrument (opened by Beckwith of Norwich, in 1792) which stands in a corner of the nave, and is fairly drowned by the psalm-singing of the congregation.

The restoration of the nave was carried out under the direction of Mr. Brown of Norwich, and by a local builder, Mr. Newman, and seems to have been very well and carefully done internally, and in a very conservative spirit as regards the exterior. The author observes, "the present restoration is supervised by Mr. Blomfield, and the builders are strangers to these parts, which is a pity." Mr. Rye is evidently a Home Ruler in these

matters, and makes one or two other hits at the impropriety, as it appears to him, of having engaged an architect from a distance, instead of one native to the country and acquainted with the local type of flint building: but as he does not appear to be able to lay his finger on any tangible error on Sir Arthur Blomfield's part, we may regard this as only the general grumble of a writer with strong local sympathies. He has however, in spite of these feelings, produced the book before us as a contribution towards the cost of the chancel restoration, and whether or not it has been successful in that respect, it is at all events a record which many of those who know and love the place may be glad to possess.

NOTES.

WE have said so much concerning the Forth Bridge at various stages of its progress that it is hardly necessary now to recapitulate its history, or to do more than offer our congratulations to those most nearly concerned on the successful completion of one of the greatest and boldest engineering projects in the history of the world. Whether the construction of the bridge will repay in a financial sense the outlay upon it may be doubtful, but we are disposed to agree with the opinion we have already seen expressed, that it was worth doing for the sake of glory, and the exhibition of the power of modern engineering to cope with great natural obstacles. Sir John Fowler, we are glad to see, is to be created a Baronet, and Mr. Baker a Knight Commander of the Order of St. Michael and St. George, and Mr. Arrol, the contractor, will be knighted. No one will dispute that all the honours are well earned, far better than some of the similar honours that are bestowed as mere political rewards. Sir John Fowler in his speech at the luncheon did not forget to say a word for the workmen, who as a body deserve all recognition for the courage as well as skill which they have exhibited in carrying out this difficult and risky work. To say that "not one of them had ever knowingly scamped a rivet" may be hardly in accordance with things we have both heard and seen in the progress of the work; but this we suppose is an occasion on which "omnes omnia bona dicere" is a kind of accepted understanding.

WE feel little doubt that the cause of the dreadful railway accident at Carlisle is that which has nearly caused other accidents before now, and which we have always expected would bring about a fatal accident sooner or later: viz., the habit of trusting to the power of the continuous brake over a whole train to pull up in a much shorter space than was formerly necessary, and thereby endeavouring to save time by running fast up to a station and pulling up quickly. This system, to begin with, greatly interferes with the comfort of railway travelling by shaking and jerking the train much more in stoppage than used to be the case; but it is also a constant source of possible danger, which this time seems to have had its effect. The old hand-brakes on tender and guard's van required a considerable distance to pull up a fast train, but they were simple levers which, if examined immediately before starting (as was always the rule on all well-managed railways), might be safely depended on to do their work. The continuous brakes of various kinds, now in use, are much more complicated machines, giving no doubt an immensely-increased chance of safety in an emergency, but also liable to fail occasionally when absolutely wanted. The inquest may elicit some other or additional reason for the accident; but on the face of the facts as so far stated we have little doubt that the real moral of the accident is that engine-drivers should be peremptorily required to allow longer distance for pulling up, regarding the continuous brake not as a means of regularly

pulling up sharp, but as a provision for emergency. Unless this is enforced we shall have other accidents of the same kind.

MR. STANHOPE'S statement in the House of Commons last week, in moving a resolution preparatory to the introduction of his Bill in regard to barracks and the accommodation of troops, must be regarded with mingled mortification and satisfaction, for it is evident from the speech of the Secretary of War that the sanitary state of our barracks has been thoroughly unsatisfactory, and that the progress in sanitary matters, which has generally been noticeable all over the Kingdom, has not taken place in those buildings which are set apart for the accommodation of our troops. The blame for this must be placed on several shoulders: on those who have been at the head of the War Office, on persons in charge of troops at insanitary barracks, and on the country at large, who have preferred to save their money rather than improve the health of their troops: but, of course, the chief blame rests on the Secretary of War, who is morally and officially responsible to the country for the health of its troops. A more naive and unstatesmanlike confession than that of Mr. Campbell-Bannerman, who had been Secretary of War to the late Government, could not have been made; for he stated that he was well aware that the housing of the troops of this country was in a most unsatisfactory state, and had been so "for a series of years." It was, in fact, a confession of official incompetence. Again, Mr. Stanhope stated that so long ago as 1859 the Commission on Barracks and Hospitals reported as to the Galway Barracks "that they are amongst the very worst specimens of public establishments we have ever seen." Yet thirty years have elapsed, and we are only now going to carry out the recommendation of that Commission. But of past mistakes and oversights it profits little to speak; we are now more concerned with the effective improvements of the future. At the same time it is necessary to point out that it will not be sufficient to remedy defects in some places only; the whole barrack accommodation of the United Kingdom and abroad must be overhauled. We say this because in Mr. Stanhope's statement no mention was made of Scotland, and of only four foreign stations; and we can have little doubt that there are lots to be found in other places.

WITH the military details of the scheme above referred to we are not concerned, but, as regards the other parts of it, Mr. Stanhope's statements seem to be fairly satisfactory. As he is going to ask the country to spend over 4,000,000 of money, he has not been satisfied with the opinion of his official advisers. He has consulted "a contractor high in his profession," and Mr. Pilkington, who has had "enormous experience in planning industrial dwellings," who are satisfied with the proposed manner in which the work is to be done. It would have been more satisfactory to the public, however, if the name of this contractor had been stated, and a consultative committee of two or three architects would have had more weight than the opinion of one. It is satisfactory, however, to find that a Sanitary Committee is to be established to supervise the sanitary part of the scheme, and also, in the future, to examine the reports of the sanitary state of the barracks received both at home and abroad; and to make recommendations thereon to the Secretary of State for War; but our satisfaction is somewhat damped on this point when we hear in mind how many reports are made which responsible officials do not act upon, and we have a glaring instance of this in regard to the Galway Barracks, which we have just mentioned. It is unnecessary to particularise the new barracks which are to be built,—which, indeed, Mr. Stanhope did not do fully. There are to be new barracks at Duhlin and somewhere outside of Manchester, also at Portsmouth, Enniskillen, and at Malta. The ques-

tion is yet in a preliminary stage, and as further details are made public it will, no doubt, be necessary to refer to it from time to time. For the present it is sufficient to congratulate the country on the probability that within the next two or three years its troops will be housed as for a long time it has accommodated its paupers, lunatics, and criminals.

THE new edition of the Post Office Guide is far more true to its name than has been the case with previous issues. Not that these have been deficient in information, varied and valuable, but the meaning of some of it was so obscured by "signs and wonders" that only an expert could show the interpretation thereof. These remarks apply more especially to the particulars of the despatch and delivery of mails to and from London, which are now set out most distinctly. Hitherto they have been expressed in a mysterious manner by means of letters and figures (in and out of brackets), the seeker for information on these points being confronted by something closely resembling an algebraic problem. Now, the time of despatch of each mail to and from all the principal offices in the three kingdoms is shown in one column, and the approximate time of delivery in another. This information occupies nearly a hundred pages, in lieu of the half-score pages into which it was before compressed, and is followed by the regulations relating especially to the London district. The latter still presents a somewhat complicated appearance, but is very full and complete, and is set out in a more uniform manner than before. It will be remembered that the January edition of the Guide was burnt at the printers' just as it was ready for delivery; and if Mr. Raikes had all this new matter ready for the New Year's issue, it must have been particularly annoying to him to have had the whole edition destroyed. We notice that the Telegraph Money Order system is now to be extended to all offices transacting Telegraph and Money Order business, so that the experiment,—which has hitherto only been in force between about a dozen places,—has, presumably, been successful.

THE eighth exhibition of the Society of Painter-Etchers at the rooms of the Society of Water-colours is an excellent one as a whole, and contains some works of special character and power. In an architectural journal mention should perhaps be made first of the highly worked and magnificent etchings of buildings by Mr. H. A. Haig, especially the interior of Burgos Cathedral (16), as remarkable for the accuracy and care with which the architectural detail is shown as for the brilliant effect of light and shadow that is realised. There are few architectural etchers who combine breadth of effect with correctness and clearness of detail as we see it here; though it may perhaps be said that the work still remains essentially an architectural drawing, with a certain degree of the artistic limitation suggested by the phrase, "The Patio of the Cloisters, Burgos" (45), is another fine work of the same class. Mr. Slocombe contributes also some large architectural subjects in a somewhat freer and less finished manner (more suitable perhaps for etching), such as "A Canal at Bruges" (91). We should not forget Mr. Haig's fine view of "The Two Bridges, Cuenca" (123), the subject being a remarkably effective one, the contrast of the little half-ruined bridge below and the towering arches of the aqueduct rising above it. In regard to etching, however, our sympathies are much more with the slighter and more freely executed works, which show a great deal by a few lines, which is the special power of etching. Among the best of this class are some of Mr. Frank Short's small works, "A Wintry Blast on the Stourbridge Canal" (20), a dry-point, is quite a little poem in copper-scratching, so bleak and wind-driven is the effect of the whole. Mr. Hugh Paton's "Gourock" (11), Mr. Wilfrid Ball's "After Sundown, Venice" (12), Mr. Percy Robert-

son's "Wet Day, Whithy" (107), Mr. F. Short's "Low Tide, The Evening Star, and Rye's Long Pier Deserted" (97) are other examples of the same kind of work, where "more is meant than meets the eye." Among works aiming at special effects the "Music Party on the Grand Canal, Venice" (114), by Mr. T. C. Farrer, is a remarkable attempt to realise moonlight effect in an etching on a large scale, and very striking and powerful in effect and manner of execution. Among the special things of the exhibition are the strange figure studies by Mr. William Strang; some of them, as "The End" (249) and "A Soup Kitchen" (52) are perhaps as repulsive as they are original; but the one called "Taking the Oath" (34) is a most remarkable study of character in the various heads. Of the original genius of this artist there can be no doubt; it is to be hoped he will not allow it to degenerate into eccentricity, which seems to be rather his danger. A considerable loan collection of Rembrandt's etchings adds another special interest to this year's exhibition.

PARIS GARDEN, known as the King's Manor, as appertaining to its lord and copyholders, formerly lay in St. Saviour's parish, and was famed for its mill, water-courses, pastures, and wild plants. In 1670 nearly all of it was taken for the new parish of Christchurch, as constituted under the will of John Marshall, who had died forty years before. Comprising the ancient hide of Widelife, and covering nearly 100 acres, it had been given in 1113 by one Robert Marmion to the Cluniac monastery at Bermondsey, whence, about fifty years later, it passed to the Knights Templar, who set up a chapel there, and from them to the Knights Hospitaller of St. John. In the early years of the fifteenth century it became a sanctuary for offenders. Ultimately passing to Henry VIII, it was granted as dowry for Jane Seymour. Lord Hunsdon and others, who got the manor from Queen Elizabeth, conveyed the land and manor-house to Thomas Cure, a benefactor to the parish. The manor-house has been identified with the Holland's Leaguer, or Nob's Island, one of the many houses of ill-fame that formerly flourished on Bankside. The moated and castellated "Leaguer," which was kept by one Susan Holland, in 1630, and is illustrated in Wilkinson's "Londina," stood south-westwards of the present Falcon drawing dock. Latterly known as Beggars' Hall, it was pulled down in making the southern approach to Blackfriars Bridge; yet some authorities question the survival of the original building to that time. The Widelife was converted into a sewer, having its outlet by the Barge House-stairs. In a fine bird's-eye view of Bankside, *temp.* Elizabeth, are shown "Gravel-lane [now an arm of Holland-street] leading to St. George's-fields" (of which the site has lately been taken for widening the railway bridge); the "Olde Parris Garden-lane," running from the Cross to the river-side; the way leading to the Manner-house; "Olde Parris Garden"; together with Widelife Mill and the mill-pond, southwards of the once famous "Folken Ine in the Clincke Libertie." Gravel-lane is marked in Horwood's large-scale map as the parish eastern boundary. The mill-pond lay at the elbow of Holland-street.

TWO tenements in Gravel-lane, Southwark, a cottage in White Hart-court, and a plot of land in Broadwall, Stamford-street, Lambeth, were yesterday put up for sale at the Mart. This small property, which is free from quit-rents or fines, is noteworthy as being copyhold of the old Paris Garden Manor, whereof a small slip,—latterly Cuper's Gardens,—yet remains, in position at least, in the public recreation-ground at the southern foot of Blackfriars Bridge. In his "Glossographia" (1681), Blount derives the name of this Manor from one Robert de Paris, *temp.* Richard II. A Close Roll, 15 Rich. II., relates to an order by that Sovereign that London butchers should carry their garbage

and off to a place "juxta domum Roberti de Parys," whence, it appears, the residuum was to be cast into the river. Mr. W. Rendle, the eminent Southwark antiquarian, has stated that he is "inclined to think the Manor may have been first known as Parish or Parysh Garden, becoming at length, about the time of Henry VIII. and Edward VI., Paris Garden, or, indifferently as it was spelt, Paris or Parish." He cites a record of 1420 wherein it appears as Parish Garden; and from another, of fourteen years later,—“*Molendina de Widefete cum Gardino, &c.: vocato Parish-gardin.*”

SOME stained glass which is shortly to be fixed in the great west window of St. John's, Chester, given as a Jubilee Memorial by the Duke of Westminster, has been on view at Mr. E. Frampton's studio. There are three lights filled with figure subjects (numbering twelve in all) dealing with the history of the city and church, and divided from each other by bands of grisaille. Heraldic work has been introduced at the base of each light and on the grisaille work, the shields in the former position bearing the Royal Arms and those of the donor and his wife; while the latter have the arms of the Mayors. The church itself figures in several of the subjects, the warm red sandstone forming a suitable background. Altogether, the contrast between the white of the grisaille and the rich colouring of the figure-subjects seems likely to give a fine effect when fixed, although it is impossible to judge fairly of its effect as seen in the studio in London. The success, however, of the Blake Memorial at St. Margaret's, Westminster, augurs well for this latest addition to St. John's at Chester. The window is to be fixed shortly, and dedicated on Easter Eve.

THE newly-worked marble quarries at Saalburg promise, at a period not far hence, to be the largest of their kind in Germany. The stone-bed, which is of enormous extent, and will take centuries to exhaust, gives a stone of excellent durability as well as of very fine colouring. The works are in good hands, and extensions and improvements are continually being made on a large scale.

ON February 17 a paper on "London Docks and their Construction" was read by Herr Garbe before a company of about eighty members of the "Architekten-verein" of Berlin. Special note was taken of the construction of the sides, lock-walls, &c., of the more modern docks in "beton"; and the lecturer strongly advised the use of this material for similar works in Germany.

THE President of the Union at Oxford has appealed to the life-members, says the *Academy*, for subscriptions to a fund of 2,000*l.* for putting the buildings into thorough repair. The Society's rooms lie between the Corn Market and New Inn Hall, lately incorporated with Balliol College. To this site, since enlarged at various times, the original "Debating Society" removed in 1852. A room for debates was built about four years later; and this in turn was replaced with a larger room, constructed of brick with stone dressings, after the designs of Mr. Waterhouse. The former debating-room was converted into a library. Its frescoes, by Burne Jones, Rossetti, and other artists, are, we are informed, in a sadly decayed condition. The block of buildings comprises, also, the keeper's apartments, a smaller library, a writing-room, newspaper and magazine rooms, lavatories, &c. Our contemporary hints that these attractions are somewhat weakened by the recent luxurious provision on the part of the several college authorities of libraries and undergraduates' common-rooms, together with the increase of various clubs and kindred associations amongst the students themselves.

THE exhibition of pictures of Japan by Mr. Alfred East, at the Fine Art Society's Gallery, is interesting both in an artistic and topographical sense. Mr. East is an artist with a great power of rendering effects of light and colour in landscape, and has produced a number of drawings of great beauty and interest from this point of view, while conveying also a strong impression of reality of representation; and those who have not visited Japan gather from the collection an impression of knowing a good deal more of the character of the landscape and village scenes of the country than before. The village street half covered with umbrellas put down open to dry after a rainstorm (96) is a very characteristic bit of local effect. Among the larger landscapes is a very fine view of Fuji-San (as we are now told to call the mountain) in early morning (22); two scenes showing peculiar effects of light on Lake Biwa (14, 18); "A moist day in a paddy-field" (21); with the white egrets like flying flocks of sunlight over it; "Lotus flowers" (34) and "Lotus pond" (42), the latter a fine study of the crowd of flowers with great leaves expanded in the bright sunlight. "An angry night" (60) is a small but interesting study of a peculiar effect of dull red sky under a roof of dark clouds. The largest painting, "Dawn on the Sacred Mountain" (69) is perhaps not so entirely successful as some of the smaller landscapes, but it is an ambitious and in many respects a fine work.

AN Architectural Students' Association has just been formed in Sunderland, the stated object being, according to the wording of its second Rule, "to provide union among its members, the elevation of the profession of architecture, the general advancement of the study of the art and science of architecture, and the guiding the studies of the members to qualify themselves to pass the progressive examination of the R.I.B.A." This is a step in the right direction, which we hope will be followed by other towns which have not as yet any such Association. The formation of provincial Associations with the special object of working up to the programme of the Institute of Architects is one of the best practical methods of promoting both unity and an adequate educational standard in the profession of architecture.

ROMAN ARCHITECTURE.*

BY PROFESSOR AITCHISON, A.R.A.

THE subjects I have touched on in the preceding lectures are so vast in extent that many courses of lectures might be given on each one, but I thought it would be more useful to devote this last lecture to some general remarks on Architecture, and to a reasoned abstract of the preceding subjects, than to add fresh matter.

Classical archaeology is a fascinating study, as it brings more visibly before us the ways of those from whom we have received the bulk of our civilisation, it opens our eyes to the knowledge we have gained since those times, and also to what we have lost, for, to speak of nothing else, the perfection of form and dignity attained by the ancients has never since been equalled.

We cannot doubt that Vitruvius was acquainted with the canons of Greek art, nor that he has given them in that modified form in which they were used by the Roman architects of his day. We have at least learned from Vitruvius the method of proportioning the parts and disposition of an order by means of the module, and we know that the proportions adopted by the ancient Romans in their orders have been universally approved by mankind ever since, or at least at the most cultivated epochs.

Through Vitruvius architects have not only been impressed with the importance of obtaining harmonic proportions in their buildings, but they have admitted, by constantly seeking such proportions, that to such proportions the æsthetic part of architecture is mainly due. We cannot doubt that these views were adopted by

* Being the sixth and concluding Royal Academy lecture on Architecture this session. Delivered on Thursday, February 13. (For the five previous lectures, see the *Builder* for February 1, 8, 15, 22, and March 1 respectively.)

the Gothic architects, when we have Casarino's scheme for properly proportioning the plan as well as the elevation of a Gothic cathedral. When an accomplished architect says of a building that it is disproportioned, or ill-proportioned, he cannot express a more severe condemnation.

Besides knowing the rules, we want so to educate our eyes to good proportion, that we cannot endure anything ill-proportioned coming from our hands. We should emulate Michael Angelo, and have our compasses in our eye. If my contention be admitted, can any study be more important than that of the antique for training our eye to good proportion?

Unfortunately, most of the ancient Roman buildings are in ruins, so that we can get but little else than the proportions of their plans; but when complete parts still remain, as in the Baths, though stripped of all ornament, we cannot fail to be struck with their majestic proportion.

All must admit that the effect of the Pantheon is unsurpassed, and in this case we have the original building almost complete.

Little more than half a century ago classical archaeology was nearly all that was taught, because it was nearly all that was wanted, and even now, according to V. le Duc, architecture is but archaeology. Still, I think we are now in a somewhat different position; there has been a Gothic eruption since in the way of art, and an engineering irruption in the way of science, and both have modified our views on art. As regards science, the ancients are mere children by the side of our contemporaries; the 1,300 ft. span of the Forth Bridge makes the Pantheon, with its 132 ft. diameter, and the Basilica of Maxentius with its 80 ft. span, look like toys. The Pantheon has, however, stood for 1,900 years, and affects the cultivated visitor of to-day very much as it may have affected a cultivated Roman in the days of Agrippa; while the bridge is but to meet a temporary want.

Though we are so near to Gothic days in point of time, and so far from those of Greece and Rome, yet as regards the main features of our civilisation, and as regards our feelings, thoughts, and habits, the position is reversed. With the fortunate exceptions of our having no slaves and not living on plunder, the Roman manners, customs, and ways of thought are very like our own; we fancy in our reading we are talking or listening to English gentlemen, until we come across some horrible trait of cruelty or inhumanity that almost makes our hair stand on end, but of which the Roman writers thought nothing. Martial mentions, in the lightest way, that at the ensuing games the episode of Mutius Scaevola before Porsenna is to be acted, and the slave who acts Scaevola will burn his right hand off. He remarks that this appears to be a very courageous act, but it is not so, for if he does not do it, he will be put in a pitched dress, and burnt alive.

We sympathise more with what is dignified, graceful, and refined than with what is wonderful and full of savage energy, but wholly wanting in grace and subtle proportion.

Geologists, I believe, draw a line between the condition of the earth before and after the Flood; our line of demarcation as regards a part of our thoughts and habits is drawn at the perfecting of the steam-engine by James Watt. In certain respects the world has been revolutionised by it and our habits, and partly our thoughts, have been revolutionised too. Shortly after the perfection of the steam-engine came the French Revolution, and that has produced a different state of feeling between man and man. There is, in consequence, a certain chaos of feeling on the disparity of the position this age holds in respect to the world behind it among all educated Englishmen, and probably in all Christendom. In certain material directions the old world has almost a ridiculous and contemptible air; time as regards space had not then been annihilated, and work had to be done slowly and laboriously. Ulysses smoothing his door-posts with a bronze adze is almost ludicrous, when we could get them better done in a few minutes by a planing machine; but who amongst us can compare with him in simplicity and dignity? The hulk of a Doric column of the Greeks is ludicrously excessive from a material point of view, but a 4-in. cast-iron column does not raise in any mind a feeling of sublimity and delight. We are, as it were, dragged in two directions; we are elated by the magnificent material achievements of our contemporaries and im-

diate predecessors, and we are humiliated and depressed by the superiority of the ancient thinkers, writers, and artists.

Homer probably appears to us even grander and more unapproachable than he did to his contemporaries. The late James Fergusson was always in a state of indignation because the contemporaries of the inventors of the railway, the steamboat, the telegraph, and steam printing, were not better poets, painters, sculptors, and architects than the Greeks; he was convinced that it was merely due to indolence and wrongheadedness, and from the numerous utterances of the day you may see that this opinion is common.

If there is no poetic feeling at any particular epoch in a nation, there is no poet. If a figure-painter finds no paintable subject of the present time, he falls back on Greek, Roman, or Biblical times. A sculptor can have angels, gods, goddesses, or heroes; he is not confined to swallow-tail coats, chimney-pot hats, and glazed leather boots; but there must generally be new buildings actually fitted to the requirements and exigencies of the present day, and though most people do not care a straw about architecture, they execrate architects, because they do not happen to live in a fine-art epoch. Every despot would like his age to be an eloquent one, forgetting that persuasion or demonstration is useless when he can do what he likes, and that he may even punish plain out-spokenness with imprisonment or death. You cannot have what you want when that want, is merely produced by vanity. You must have the requisite preliminaries, cultivation, surroundings, and admiration before you can get what you say you want. People, as a rule, say they want a new style of architecture. What do they do to get it? Let us take music as a thing people do want: what do they do to get first-rate music? At least one-half of the population above the lowest class, the fairer half, learn it from their childhood. A great part of the male half profess to like it, and often hear some, and a few, outside professional musicians, study it. The encouragement of successful musicians, in a pecuniary sense, is splendid, and the enthusiasm not only exhibited but felt, is unbounded; whether the higher gifts of the composers are equally well remunerated and admired, I do not know.

Most educated people know the difference between a Classic and a Gothic building when they see them, and that is usually the beginning and end of their knowledge. They praise St. Paul's and Westminster Abbey, just as they praise Milton and Shakespeare, because it is the fashion, though they have probably never read the former and have only seen some of the plays of the latter acted. On how few modern buildings do they cast an eye or bestow a thought, for the purpose of appraising their merits or enjoying their beauties; how many passers in Pall Mall stop to admire the Reform Club, and thank God that England produced such a genius as Barry?

Before you can make the first step towards a new style there must be something with which the public is taken; the public must have some strong desire towards one form rather than towards another, or there must be some new structural necessity for some new form, and it must insist on this new form being made beautiful in the way it desires; but as far as I can see there is no more inclination towards one particular form than towards another, and there is no unanimous desire for any particular form of beauty. Directly such a taste showed itself the architects would follow, and then there would be a development; but until such a concurrence of taste exists, it seems to me impossible for a new style to arise; and he it observed that most new styles, except Byzantine, have been created by nations just emerging from barbarism.

Each architect now paraphrases what he likes best,—Greek, Roman, Early or Late Italian Renaissance; French, German, Dutch, Flemish, or Scandinavian Renaissance; Elizabethan, or the various phases of Byzantine, Romanesque, Gothic, and Saracenic.

Great skill in planning, considerable invention, and great taste is often shown in our new buildings; in fact, London is fast becoming the most picturesque modern city in the world; but there can hardly be a concurrence of aim in the architects.

Before this unanimity of taste can take place, the people must love architecture, have some knowledge of its laws, and have a strong desire

to get their views carried out, and he as thankful to the architects who can thus raise their emotions as they are to poets.

It is the admiration of his contemporaries that is the greatest spur to the unwearied striving of the genius, be that genius in what line you please. Next below this, the most desirable things are praise, honour, and wealth. Did any one ever hear of an architect getting anything but abuse? I believe there is only one architectural knight in England, and there are not ten men in London who make a decent living out of architecture. I now speak of those who can make a living out of designing buildings combining beauty with utility, and I do not include the measurers, valuers, surveyors, land and house agents, nor those who build for utility only, without regard to shapeliness.

Architects are not exempt from the effects of the wonders that are being created around them; the faint breathings of the past revolution still stir their veins, and there are signs of a new one:—

"Slowly comes a hungry people, as a lion, creeping higher,
Glances at one that nods and winks behind a slowly dying fire."
Tennyson—"Locksley Hall."
