They, too, want to surpass the past, to stamp their works with the expression of the age, and, if possible, to start such new modifications in architecture as may eventually become a new style; but the question is, how any one of these objects is to be compassed? The age is an inartistic one, where the highest intellects are wholly set on conquering physical difficulties, on superseding human labour, and on the investigation of the laws of Nature—an age which looks on all the arts, and particularly the architectural one, in the same light, that Sir Isaac Newton looked on poetry, as "ingenious nonsense." Much of the building that is done, and much that will be done, must in its main features greatly resemble the past; it will be in stone, in brick, in concrete, in wood, or in lath and plaster. There must be columns and piers, colonnades and arcades, and walls with openings. The openings must be square or oblong, round or oval, with flat, round, elliptical, or pointed tops, and there must be roofs or terraces. The architects should stamp their buildings with the tastes of the day—only, unfortunately, there are none. Directly there is an insistence on buildings being beautiful (and of a new kind of beauty), there is a hope in iron, for iron buildings do now occasionally occur, and must occur more frequently in the future, and there are no examples of iron buildings in the world.

The question is, How are we best to prepare ourselves for the inevitable changes that must take place? Of one thing I am sure, that there can be no improvement so long as men think that any man, any people, or any age has done that which cannot be surpassed, and that all that can be done is to imitate that work. Yet the sole method of surpassing the best that has been, is to imitate it and to paraphrase it, until we can do as well ourselves, and then to advance beyond it.

Since the Egyptians, there have been no such great builders as the Romans, and they, being the masters of a good part of the world known to the ancients, wanted grand public buildings in every large city of their dominions. Consequently, there was a school, or probably many schools, for such buildings; here there is only occasion for two or three in a century.

Even three great public buildings in a century might give much aid to young architects, and to the foremen and workmen employed, they would be schools of architecture if they were in one style, and that style was the chosen one of the people, and by this I mean if the people had developed taste and liking enough in one particular direction; but if one of these public buildings is Classic Roman, another Gothic, and another Early Italian Renaissance, you get no concurrence of opinion and effort, and no means of comparison. There is, too, another consideration—the buildings should be such that the best paintings and sculpture of the present day will harmonise with them. This cannot be the case with Gothic. The best painters and sculptors will put in their best work; but then their work is incongruous with the building; the modern Gothic architects feel this, and when they can, force inferior artists to imitate Gothic images and Gothic gabling.

Considering that our practice is now confined to mansions and private houses, I thought that some notion of the Roman mansions and houses must be both interesting and useful.

Rome itself was in a sunny climate, and all

its southern and eastern possessions were in still warmer climates. Shade was wanted, which was procured by porticoes, and porticoes require columns, and nothing is more beautiful than well-designed porticoes in a sunny climate, with the alternation of bright light and deep shadow. But here, in this misty climate, and in this sooty air, the columns and the shade between them are nearly alike for a great part of the year. Here, it is true, we want shelter, but we also want light, and porticoes are usually most disastrous adjuncts to public buildings, except as porticoes to churches, for they darken the interiors.

One would judge England to be a very poor country, for the riches and pedestals of our public buildings are still without their statues and groups. Remember the three thousand bronze statues Scarus had in his theatre, which was only a temporary one for a month or two's use; and gem engraving is almost extinct, as well as the making of artistic plate. Yet if we can keep up our courage, our vigour of mind and body, our industry and invention, our integrity and virtue, England will gradually become rich, and as wealth is what is saved by self-denial from the surplus industry of mankind, the gaining and preserving it are certainly virtues. Riches themselves, if properly used, seem to me to be an undoubted advantage. As Dr. Johnson so wisely remarked, there have been many treatises on the advantages of poverty, but none on the advantages of riches, as these are self-evident. If we will but use these riches, when we get them, wisely, there is no reason why England should fall; that is, if wisdom, courage, temperance, and justice still remain with us.

I think the creation of beautiful things is not demoralising, so I have had no hesitation in recommending the study of Roman houses, villas, and palaces. In hearing the account of Pliny's villas you see to some extent the requirements of those days,—the choice of views, of sun and shade, of retirement and quiet; and you have the attempts of distinguished architects and antiquarians to re-construct the Laurentine Villa from Pliny's description. You must not even think that the Atrium of the Roman house is not adapted to English wants for one of the great triumphs of Barry at the Reform Club and at Bridgewater House was the utilising of their Atriums by covering them with glass.

Whether it was from modesty or fashion that Pliny said nothing about his servants' housing I know not, but we can only deplore it. The series of cells (Cellatio) on the first-floor, that Trimalchio mentions, was probably the slaves' barracks. We find that Pliny had an apartment for his pages to sleep in, and that there were many of them in the room (Pliny 7, 27). As early as Plautus we find the women's slaves included wardrobe women (Vestisipia), a perfume keeper (Unctor), a cofferer (Auricustos), fan-bearers (Flabellifera), sandal bearers (Sandaligerulo), singing girls (Cantrices), casket keepers (Cistellatrices), messengers (Nuntii), news-carriers (Bennntii) (Plaut. Trinummus, act ii, sc. 1), and it is not likely that these were decreased as Rome became richer. There are inscriptions to the slaves of the Empress Livia,—the maid who combed her lap-dog is called "a Cura Catella"; another put in her earrings and was called "Auricular Ornatix"; another put on her shoes, and was the "Sera Sandalis"; there were the dress-folders and dress-perfumers, the hair-dressers, the hair-parter, the wig-keeper, the mistress of the rouge-pot, and of the powder-puff. But, as I told you before, there were names for upwards of 300 slaves. This affluence of slaves encouraged a passion for every possible convenience. We see how small an advantage was dearly purchased by Pliny in having a gallery built as large as a public one, merely for taking a walk in bad or hot weather. Nero's was a mile long.

The plan of a Roman house seemed so convenient to Palladio that he built the Convent of La Carità at Venice in imitation of one. These are his words:—"The following building is of the Convent of La Carità; where there are the regular Canons in Venice. I have sought to make this house resemble those of the ancients; and therefore I have made there the Corinthian Atrium: which is as long as the diagonal of the square of its width. The wings are two-sevenths of the length, the columns are of the composite order, $3\frac{1}{2}$ ft. thick, and 35 ft. long. The open part in the middle is a third part of the breadth of the Atrium." (What he means

by this I do not understand, unless he alludes to a rain-water tank in the open space.) "Above the columns there is an open terrace on a level with the third order of the cloister, where there are the cells of the friars. Adjoining the Atrium on one side is the Sacristy, girded with a Doric cornice, which carries the vault above; the columns that are seen there support that part of the wall of the cloister which in the part above divides the chambers, or rather the cells, from the gallery. This Sacristy serves for the Tablinum (so they called the place where they put the images of their ancestors). Again, to suit myself, I have placed it on one flank of the Atrium. On the other flank is the place for the Chapter, which answers to the Sacristy. In the part by the church is an oval staircase open in the middle, which is convenient and beautiful. From the Atrium one enters into the cloister, which has three orders or columns, one above the other. The first is Doric; the columns project from the pilasters more than half" (he means from the piers). "The second is the Ionic; the columns are a fifth part less than those of the first; the third is Corinthian, and has the columns a fifth part less than those of the second. In this order in the place of pilasters there is a continuous wall, and in a straight line over the arches of the lower orders are windows" (i.e., in a vertical line from the centres of the arches), "which give light to the entrance of the cells, the vaults of which are made of canes, so that they may not weight the walls. Opposite the Atrium and the cloisters beyond the walk the refectory is found, two squares long, and as high as the bottom of the third order of the cloister; it has a gallery on either hand" (how the refectory and the walk were lit the plans and sections do not show), "and under it is a cellar much after the manner that they make cisterns, in order that the water cannot get into it. On one side it has the kitchen, ovens, poultry-yard, wood-house, laundry, and a pretty garden, and on the other, other places. There are in this building, including rooms for strangers, and other places which serve for different purposes, forty-four rooms and forty-six cells."—(Pall. "I quattro libri dell' Architettura," Venice, 1570. Lib. 2, Cap. 6.)

The plans of the Palace of Augustus are worthy of your attention for many peculiarities. I mentioned before that the audience chambers, or Courts of Appeal, were of a peculiar shape, reminding one of Byzantine work (in Byzantine architecture these curious shapes were adopted to get abutments for domes and vaults); with the exception of the light they got from the outer doors, they seem only to get light from a grating at the top; how the rooms at the back were lit we do not at present know, as they abutted on a hill side, but probably by slanted shafts to the front of the Palace, as was done at Caracalla's baths. On the two flanks, the Peristyle might have been lit from it, as we know nothing of how much of the wall was found, and the back parts might have been lit by skylights; but in the front of the ground-floor circular rooms, if they really were without windows, could only have got a glimmer of light by reflexion from the passages; it is scarcely likely that they had gratings in the floors over them, and we are at a loss to know for what purpose they were used. If there were no upper story, the rooms on the first floor might have been lit by skylights. It has occurred to me that they might be bed-rooms, supposing that bedrooms were ever made circular, and the passages round them were Androns to prevent the inmates being disturbed by the noises of the streets. The street noises of a night seem to have been intolerable,—all the goods traffic being carried on between four p.m. and sunrise; and then, as now, in Italy, traders and copper-smiths began work at midnight.

Seneca's description of the noises of the smith, the sawyer, and the musical instrument maker who tries his flutes and trumpets close to him is amusing. (Senec. Epis. 57, 13.)

I think there must have been a large opening, or several openings, in the wall next the Peristyle at the back of the Tablinum on the first floor, so that when it was wanted there might be a view from the Tablinum across the court.

One must bear in mind that the Temple of Apollo with its porticoes, the Temple of Vesta, the House of the Vestals, and the Grove, were within the Palace grounds, and that the Temple of Apollo was probably used by Augustus and his family as a private chapel.

When Lepidus, who was Pontifex Maximus,

died, Augustus took the office himself, and as he was obliged to live close to the Temple, of which he was the guardian, and the Temple and the house of the Vestals was close to the Via Sacra, he moved the Temple and Virgins close to his palace.

The main hall of the Apollinean Library, if it was the original one, must have been magnificent, being 77 ft. by 56 ft., with its three large apses 37 ft. in diameter, but whether vaulted or not we do not know, and must have been well fitted for the meetings of the Senate, though one wonders how Augustus found them seats. The Senate-house or Curia, rebuilt by Diocletian, is now the Church of St. Adriano, and was drawn by Vitruvius. The state-rooms of Domitian's Palace are on a grand scale, the throne-room 136 ft. by 100 ft., and the dining-room 107 ft. by 95 ft., without including the flat apses. The throne-room may possibly have been vaulted, but the dining-room was certainly not. If there are any sufficient remains of the bases of the columns the whole could be roughly reconstructed, as definite proportions were given to the columns and entablature, and possibly there may be scraps enough left to see what the carved decorations were like.

It is worth noticing how charming the dining-room must have been with one end open to the Peristyle, and with windows or sash-doors down to the ground on either side, so that the guests could see the plants in the conservatories, and both see and hear the plashing fountains.

I read you before Plutarch's remarks on this palace being more superb than the Temple of Jupiter Capitolinus, enriched as this was with the columns plundered by Sulla from the Temple of Jupiter Olympius at Athens.

However great a monster Domitian may have been, he evidently had good taste in architecture, or he would not have employed so able an architect to build his palace. The curved terrace or portico, 244 ft. across, he built in front of Augustus's Palace to overlook the circus maximus, must have been one of the finest sights in Rome.

Martial has many epigrams on Domitian's buildings, one long epigram on the glories of his palace (Lib. VIII., Epig. 36) I gave you in my last lecture; but as all his epigrams to the Emperor are particularly fulsome until his death I have not given them. When Domitian was assassinated he wrote in his Book of Shows (Lib. Spec. 33):—

"How much thy third has wrong'd thee, Flavian race!
"Twere better ne'er to have bred the previous brace."

He has, however, another on the architect of the palace, Rabirius (Lib. VII., Epig. 56, p. 331), as follows:—

"Rabirius model took from heaven to build
Our wondrous Palace, sure; he is so skilled.
For Phidias Jove a worthy fame to rear,
Pisa* must beg him of our Thunderer."

According to Suetonius (Domitian 12), Domitian had exhausted the Exchequer by the expense of his buildings and public spectacles, but beyond this he says nothing of his Palace.

I have said in the lecture on palaces all I have to say about Diocletian's.

On reviewing the plans of these three epochs, the Augustan, the Flavian, and that of Diocletian, we see that there was much more thought and ingenuity bestowed by the architects on the plans in the first epoch than in the two latter.

From the houses at Pompeii there is much information to be picked up in the way of planning, particularly on angular and irregular-shaped pieces of ground, and in construction; much, too, may be learned in the way of monumental-water work, for Pompeii is full of fountains, and you heard from young Pliny what pleasure the Romans took in the tasteful display of water. The whole town was a plastered one, with the exception of some of the public buildings, and from it we see how colour can raise this mean material to the highest position. If there is not much to be learned directly in the way of architecture, there is that which is more valuable, hints and suggestions of treatment, that we may require at any time in our practice. I may instance the Roman Doric columns covered with mosaic, and the way in which the moldings of the bases were arranged to fit them for the application of mosaic.

I think I made it clear before that I was an ardent advocate for making every building a

* Pisa was another name for Olympia (sixteenth century MS.).

shrine of the three visual Fine Arts, and at Pompeii we see them combined; but I go further, and am equally desirous of seeing the household fittings and utensils made as beautiful as possible, so as to harmonise with the architecture, the painting, and the sculpture, as we see that the majority of them do at Pompeii. In one respect I think this heightening of furniture, tools, and utensils is quite as important as the heightening of buildings; for if the smaller things which are devoted to use are beautiful, the seeing them constantly must heighten a taste for beauty in those that use them. Their beauty has, too, additional advantages, for it must cause the makers to be instructed in the art of heightening the useful.

As far as architecture is concerned, it can hardly be expected that this great constructive art can become a necessity for all, nor can be so adequately fitted to its high position, if all the subsidiary constructive arts present nothing to the eye but utilitarian abortion; and when I speak of Architecture I do not mean mere building.

The capitals with figure episodes in them show the sculptor that they can be made more interesting and beautiful by the introduction of the highest form of beauty,—the human form,—and that their ornamentation is not necessarily confined to floral forms.

The painters, too, may see that however badly the subjects may have been painted, there was an evident desire to choose subjects that are fraught with lovely and dignified form, and connected by literary tradition with important and striking events. There seems an inclination in the present day to devote the genius that inspires the figure-painter and the extraordinary skill which has cost him so many long years to acquire, to immortalising events which not infrequently are the most commonplace, and forms that are without dignity or beauty, when they are not absolutely ugly. For example: workmen drinking, oysters gambling, or commonplace episodes in the dressing-rooms of theatres. Surely this entrancing art should preserve for us, and for posterity, the most perfect beauty, the noblest forms, the most delicate and most gorgeous colours, and those actions and expressions which charm the eye or ennoble the soul.

Personally, I am deeply interested in the bringing of constructive ironwork into the pale of architecture. It does have some place even now in modern building, and will, I am convinced, hold a conspicuous place hereafter in countries having a smoggy and misty atmosphere, like our own, and in the narrow streets and frontages of manufacturing towns, where land is dear and light is scarce. I say this without diffidence, although there is so vast a majority of an opposite opinion.

Few architectural students care about solving the scientific problems of ironwork, and are sometimes indignant at being expected to study them, and the aesthetic part they tacitly but resolutely refuse to attempt. The former neglect somewhat lowers, and certainly impoverishes, the profession. The public will have what it wants, and this important constructive branch of the profession falls into the hands of the engineers; but as to the latter, it cuts to the very roots of the art, for if architects show that they cannot deal architecturally with new materials, the art at once sinks to a sort of dilettanti antiquarianism, on a par with heraldry or shooting with the long bow.

The light architectural edifices portrayed on the walls of Pompeii, and in some of the now buried chambers elsewhere, suggest ironwork to us; and though we perhaps cannot adopt any of the forms directly, they give hints for the sort of treatment that might be adopted. There is, however, this observation to be made: at Pompeii the capitals and bases have mostly been treated like the orders,—i.e., proportioned to the diameter of the columns, while they should be proportioned to the height of the columns. The Italian architects, who dispensed with columns on the faces of their buildings, proportioned the crowning cornice to the whole height of the building.

Our architectural comrades in France, with that instinctive artistic perception which belongs to them, utilised these decorations as motives for the coloured ornamentation of cast-iron columns. The use of beautiful colour in buildings is fast becoming a necessity, and we may hope, ere long, to see enamel successfully applied to ironwork.

Before dismissing the subject of what we may learn from the antique, I may mention

their ornamental plastering, which is probably the most beautiful that still remains; there is a freedom, an extreme delicacy, and a look of being done off-hand, that makes it most charming to my eyes; and had not the Romans been of the same opinion they would hardly have classed the ornamental plasterers with the architects, sculptors, and painters.

To the sculptors must be left the decision of whether the Roman plastering or the imitations of it by the Italian artists of the Renaissance bear the palm.

Professor Roger Smith has lent me the photographs of the charming specimens you see before you, some from the tombs on the Via Latina and some from Pompeii.

From the ornamental plastering that I saw, many years ago, in one of the chambers at Hadrian's Villa, for it seems now to be withdrawn from the public gaze, I am convinced that it was hand-modelled on the spot. We have in the present day in England much plaster-work that is very beautiful, but it is almost invariably cast work, and that involves much repetition.

I fear architects are too prone to fall in with the ordinary sweating system, even to chime in with a statement of its principles, when they are but put forward as a feint. Englishmen, as a rule, are patriotic; and if it is pointed out to rich men that it is a patriotic thing to encourage first-rate work, and the revival of artistic work, once even common here, and that neither can be got on those principles, I feel sure that some architects would succeed, and that we should be re-creating a school.

Artistic, however, as the Roman school of plastering was, it did not possess the transcendent merits of Greek art. Greek art aimed at simplicity as the true mark of excellence. This simplicity was not the native simplicity of a rude race, charming as that often is, but the product of the highest cultivation, and we admire it as we do the off-hand work of a great artist, who, with one sweep of his brush, will give a curve not only of perfect beauty, but of exact fitness for its place, and by the addition of a few blobs will make a piece of ornament infinitely more pleasing to an educated eye than the most elaborate work of a second-rate ornamentalist, just as the simplicity of Demosthenes surpasses the ornateness of Cicero. The Greeks used as little ornament as they could, but made what they did use as perfect as possible, so as to have "infinite riches in a little space," putting the ornament too, exactly where it was wanted, and leaving the spectator to wish for more; throwing down, as it were, the gauntlet of challenge, as if the artist had said, "I have done my work, do it better if you can"; while as a rule the Roman work was overloaded with ornament, though it seems to me that it was less overloaded in their plastering than in their stonework. The Romans desired magnificence, the Greeks, art. I mention this lest you should think that the highest Roman standard cannot be surpassed.

Besides the important facts that the remains of Roman architecture are so numerous, and that Roman architecture was the mother of Byzantine, Romanesque, Saracenic, and Renaissance, the architecture of that great people is not without artistic merits of its own. It certainly attained dignity and magnificence, and occasionally the combination of size, proportion, and skilful lighting made some of its works sublime, as we see in the interior of the Pantheon, and in some of the ruins of the palaces and baths. Though it may appear rather paradoxical to say so, looking at the achievements of the present day; yet I cannot help thinking that the architects of Christendom have not as yet absolutely mastered architecture so as to be able to shape every new requirement and every new material that comes before them into a perfect architectural whole, different from the past, and yet equal or superior to it; for I cannot think that the want of a universal style is the fault of the architects. Capitalism as originality is, there is too much evidence in England of a desire for quaintness, oddness, and variety at any cost; after due harmonic proportion, without which the best architecture can only reach a secondary grade. The highest aim is to produce exquisiteness, majesty, or sublimity in buildings, and this can never be done until the art of proportion has been thoroughly mastered, and the architect makes architecture his expression of worship. This last phrase has been so much abused as to be equivalent not only to the,

religious devotion to an art, but to the abandonment of all the rules of morality as well; it is not, however, by brutalising ourselves by vice that we can attain the highest excellence, but by purifying ourselves by the practice of the virtues. We must first learn the elements of the supremely difficult and complex profession that we follow, more varied in its requirements than any other. We must not only study the great creations of the past, but endeavour to extort from them the secrets of their success; we must spare no pains in what we do, we must have an unselfish desire to see architecture soar to a perfection not hitherto attained, before we can even hope to equal the great masterpieces of antiquity, much less to surpass them. The very thought of surpassing all that has been done before raises a glow of generous emotion in the bosom of every architect, and no one can say when the time may come that people's eyes will be opened, and this master art again take the foremost place in the desires and admiration of the English-speaking race.

SCULPTURE ON GREEK TEMPLES.—II.

ROYAL ACADEMY LECTURES.

MR. A. S. MURRAY, of the British Museum, delivered his second lecture* on this subject on the 20th ult.

The lecturer commenced by remarking that in a Greek temple the most striking feature was the pediment by which it was crowned. Having shown how the triangular shape of the temple pediment grew naturally out of the exigencies of roofing, he proceeded to speak of the sculptures in such of them as had survived. Of existing pediments we had three conspicuous examples: the pediments of Ægina, of Olympia, and of the Parthenon at Athens. But firstly, he would draw attention to certain small pediments which were found on the Acropolis at Athens during the recent excavations, and which, being older than the others, would be of interest as illustrating almost a first effort to obtain a composition fitted for a triangular space. These pediments had belonged when the Persians sacked Athens. The sculptures were in relief on the back of the pediment, the material being a sort of limestone, known as *poros*. A very free use had been made of bright colours, blue and red, which would be attractive in a rude early age. In one pediment the scene illustrated was that of Herakles slaying the Lernaean Hydra, a huge serpent with innumerable heads. This was on the right; on the left was the faithful companion of Herakles, Iolaos, standing ready with the chariot to bear Herakles off victorious. Fragmentary as the sculpture was, it showed that the sculptor had made at least one good observation in regard to the horses. The Lernaean marshes, where the incident took place, were, to this day, thick with runnels of clear, glittering water. No horse could stand there without lowering his head to drink, and that was precisely what the sculptor needed, to get the heads of his horses down into the contracting part of the pediment. The huge crag that filled in the angle had also a part in the legend, for while Herakles was still engaged with the Hydra the crag moved forward and seized his heel. The opposite angle of the pediment had been destroyed, but doubtless it was filled in by the lessening coils of the Hydra. As regarded composition, it was interesting to compare the chariot of Herakles, facing the angle, with the chariots of the later pediments of Olympia and the Parthenon, which faced the centre. In the west pediment of the Parthenon the horses, rearing towards the centre, represented the perfection of grouping, where chariots were concerned; while the small archaic pediment in question, with its chariot turned away from the centre, belonged to a stage of art when sculpture was hardly equal to the difficult task of representing rearing horses; indeed, it was a century later before art was sufficiently master of its powers to render a group of fiery horses. Similarly, in the east pediment of Olympia, though the horses were not rearing, their heads were turned towards the centre,—a departure from the archaic manner and an improvement in composition. The archaic manner had, however, the advantage that the sense was perfectly clear; the chariot was waiting to

carry off Herakles when he had slain the Hydra. But as to the west pediment of the Parthenon, what troubles had we not had with the chariots facing the centre when the positions should have been reversed, according to our notions of the incident. We were told that in that incident the victory was won by Athene, and had her chariot been turned away from the centre, we could have understood the matter easily. But the great Greek sculptors apparently cared more for their art than for telling their story clearly enough for modern intelligence. The sculptor of the archaic pediment was more explicit: he wanted to tell his story. In the other archaic pediment, Herakles was represented, on the left, in the act of slaying a huge snake, possibly the Echidna, whose body seemed to be encircling itself out of the corner in which it had been lying. While, however, the serpent seemed to come out of a dark hole, Herakles equally appeared to advance from the broad light. By slaying the monster he illustrated one of those conflicts of the powers of light and darkness which played, or seemed to play, so large a part in Greek mythology. But in this pediment Herakles occupied a secondary position. His slaughter of the serpent paled beside the deed of his father Zeus, who slew the triple monster, Typhon, and buried him in the Serbonian marshes. On the right-hand side of the pediment we saw Zeus in the act of hurling his thunderbolt at the grotesque monster, whose tail coiled away into the angle. The sculpture of Typhon was very rude and very highly-coloured. Such work could not be much later than 700 B.C. In this pediment, equally with the other, the sculptor had followed an order of composition in which the action moved from the centre towards the angles; and it would be interesting to know whether the same was in general the archaic order as compared with the later compositions of Ægina, Olympia, and the Parthenon, where the movement was from the angles to the centre. At present we had not sufficient evidence on that point. In any case it was a splendid change from the archaic manner to the centralising of later times. The centre of the pediment then became the centre of action,—the place of highest dignity. From each side approached figures of ever-increasing importance in the scene. The great difficulty that remained was the filling-up of the angles with figures appropriate to the scene. In the pediments of the temple of Ægina the extreme angles were filled up by wounded men who had yet strength to raise themselves a little,—just enough to fill the increasing space of the pediment. Next to them came archers, who knelt on one knee to draw their bows; and so by a regularly increasing set of perfectly natural attitudes the centre of the incident was approached, and we looked for the incident which was to form the keystone, so to speak, of the angles to the centre. The centre was a wounded hero fallen to the ground; he had evidently been a leader in the fight, for while the opponents were eager to despoil him of his armour in the old Homeric manner, his friends made a desperate effort to save him. Meantime, in the very centre of the pediment, and directly behind the fallen hero, appeared the goddess Athene, visible to us, but probably invisible to the actual combatants, but in any case come to turn the scales of battle. So far as the indications of costume went, the battle was between Greeks and Trojans. Such was a brief outline of the composition of the Ægina pediments. These sculptures were worth careful study. They were, of course, archaic, and were certainly not exhibiting the perfect freedom of form which we saw in the pediment sculptures of the Parthenon, and in subsequent sculpture; but they evinced the faithfulness with which the sculptor had observed the details of his forms, and the precision with which he had rendered them. There was abundance of reason to give him credit for recognising those many modifications of form which were necessary for a composition in which the various groups, though sculptured in the round, had yet in a measure to appear as in relief. He had to find a medium between the flatness of relief and the full roundness of a statue. In point of date the Æginetan sculptures stood about midway between the very archaic pediments before described, and the pediments of Olympia. Looking at the sculpture of the east pediment at Olympia, the first observation which suggested itself was that the sculpture, though manifestly later than that of Ægina, had gone back in a great measure to the older principle of relief.

* For report of the first lecture see *Builder* for last week, p. 155.

But it was to be observed that the parts which were worked in relief had not, except in the case of the horses, been sculptured on the true principle of relief, which aimed at presenting to the front the greatest possible extent of the figure or figures. In the Olympian pediments the figures were, in a number of cases, sculptured on a background, and in that sense they were reliefs; but for the rest the projection was enough to make them look like actual statues in the round, and as such they were generally considered. Having discussed at some length the question of the subject and the arrangement of the figures in the east pediment at Olympia, the lecturer passed on to speak of the east pediment of the Parthenon, of the sculpture of which all that had survived was the group in each angle; the centre had disappeared, and with it the climax and key to the composition as a whole. The subject, we knew from a literary source, to have been the birth of Athena. After discussing the possible "interpretations" of this pediment, the lecturer, in conclusion, said that in archaic sculpture we had learned to admire the fine fastidious folds in which the drapery was systematically arranged, as if it had been put on a little wet and then pressed into shape. In the sculptures of the Parthenon, however, we had got rid of fashion and its fastidiousness. Beauty was found in the wider consideration of what was necessary,—no more and no less,—for a perfectly noble form. The dress, while it covered the forms, had no need to conceal them. It had, indeed, to be shown to be distinct from the forms beneath, and that was achieved by treating it as a perfectly distinct thing, movable and removable at pleasure. It thus aimed at a beauty of its own, and called upon the sculptor to reproduce the innumerable charms of light and shade which belonged to it under its aspect as an accessory with special features of its own. It was like the movement of a clear stream, which, though distinct from its rocky bed, yet owed its infinite charm to the configuration of that bed.

[We will give a report of Mr. Murray's third and concluding lecture of the series next week.]

LECTURES ON THE MYTHOLOGY AND ART OF ATHENS.

In connexion with the Chelsea centre for the extension of University teaching, Miss Harrison is giving a course of ten lectures on Athens, at the South Kensington Museum lecture-theatre. In this course the lecturer is following up and combining the subjects of her lectures on Attic mythology in the autumn of 1886, and on Attic cults in the autumn of 1888, reports of both of which appeared at the time in the *Builder*. The present lectures go with much greater detail into questions of topography, and show the result up to date of the recent excavations at Athens. One of these discoveries is especially important. The river Eridanos has been discovered by Dr. Dörpfeld, north of the Akropolis. Its course followed roughly the line of the great sewer shown on maps to pass under the northern part of Athens; the river flowed out of the city at the Dipylon. This localisation of the Eridanos dims the importance of the Kephalissos in Attic topography. In early times at least, it, and not the Kephalissos, formed the northern boundary of the city, as the Ilissos did the southern. The theory is fully confirmed by a passage in Plato (*Kritias*, 112), who says that the city in old times was bounded by the Ilissos and the Eridanos, by the hills of Pnyx and Lykabettos. The Pelasgikon (τὸ πρὸ τῆς Ἀκρόπολις. Thuc. II. 17), or old Pelasgic fortification which served as a defence to the Akropolis on its western side, is shown to have extended from the Klepsidra to the Asklepieion,—it was almost certainly used as a fortification down to the days of Herodes Atticus, when its course was slightly altered by the building of the Odeion. On the Akropolis the chief interest still attaches to the *temple of Athena*, discovered in 1835, and to the remains of Pelasgic masonry near the Erechtheion. These pre-historic foundations are doubtless those of the well-built house of Erechtheus (Homer, *Odysseus*, VII., 81). In connexion with the lecturer the lecturer gave an interesting piece of mythological analysis. Erechtheus, one of the earliest kings of Athens, is originally but a surname of Poseidon. When the worship of Athene established itself firmly at Athens, to the gradual subordination of the

Poseidon worship, it became necessary to connect the royal house intimately with the new goddess, but the ancient king, under his title of Erechtheus, was too strongly associated with Poseidon, therefore he must be, so to speak, re-born as Erichthonios. The Erichthonios of the Iliad (XX., 219), with his three thousand mares, who are loved of the north wind, is merely another form of the sea-god, but this aspect of him is less familiar to the Athenian mind, and since the end of the name *Ἐριχθωνίος* suggests a possible connexion with the earth, he is made into an earth-born King of Athens, entrusted at his birth to Athena herself. The story of his being enclosed in a chest and given in charge to the daughters of Kekrops, is one of those etiological myths which are frequently met with in Greek mythology, and which often arose to explain ritual, the original meaning of which had been either obscured or forgotten. This particular story was to account for the mysterious ceremony of the Arrhephoria (Pans. I., 27), otherwise Hersephoria, when young maidens carried on their heads chests, the contents of which were to be unknown to them. Miss Harrison contends that what they carried were effigies of young animals (*ἵππαι*). With these, the maidens were to propitiate already, at an early age, the goddesses of fertility,—but they must not understand the ceremony. Hence the injunction not to look into the chest, and threats to insure it. Hence also the story of what happened in the days of Kekrops to the maidens who opened the chest. The names of Herse and Pandrosos are themselves connected with young animals (*ἵπποι* Pandrosos). In passing from the ancient Poseidon and Erichthonios cults of the Akropolis to the Areopagos, the lecturer showed the story of the connexion of this hill with Ares to have arisen to account for the name of Areopagos, when its real meaning had been lost. The meaning may be arrived at from considering the importance of the worship of the Eumenides, who, together with the Chthonic deities (Demeter, Persephone, Triptolemos, Plouton) give the key-note to the mythology of this region. The shrine of the Eumenides was at the eastern angle of the Areopagos. From a study of (1) their early art form (note especially the series of Argos reliefs), and (2) their ritual (see Sophokl., *Ord. Col.*, 470, scholiast on the lines), we infer that Pansanias is right when he says that Aeschylus in his "Eumenides" first made them terrible. Originally they were austere and solemn, yet kindly nature-powers. It was as *Semnai*, or Venerable Ones, that they watched by the cliff on the east of the Areopagos. These Semnai themselves give a clue to the name of their hill. In Aeschylus they call themselves *Ἀοαί*, i.e. curses (Eum. 416). May not the hill mean the hill of the curses or imprecations, of the mysterious powers of the under-world? Here Pansanias also noted a tomb of Oedipus (Paus. I., 28, 7), yet in Sophokles we find the Oedipus legend and the grave of the Furies, where he disappears, localised at Kolonos. The explanation is to seek in the fact that to the early city, the Areopagos was the place *without* the gates. It was there that criminals were condemned, and outcast tyrants received. The place as such must not be within the city proper. But, as Athens spread, the hill of the *Ἀοαί* and the sacred shrine of the Semnai were no longer apart from the city,—and so a new hill of cursing was made, with its worship of the Semnai and its grave of Oedipus, safe this time beyond the walls of Themistokles. The sacred enclosure of the Eleusinion, with its two temples, one of Demeter and Persephone, and the other of Triptolemos, lay almost certainly south of the Areopagos, not far from the Pnyx. This position is confirmed by the passage of Aristophanes (*Thesmoph.*, 658), where the choros of Thesmophoriasuzai talks of searching the whole Pnyx (τὴν πύκνα πᾶσαν) for fear some man may be lurking there. During the performance of the mysteries of the Thesmophoria, which took place in the adjoining Eleusinion, the Pnyx was for three days given up to the women of Athens. For the cult and mythology of Eubouleus, another under-world deity, whom Miss Harrison shows to be originally another form of Hades and Plouton, a more general interest is now likely to be felt, owing to the beautiful head of this god recently discovered at Eleusis, and held by many to be from the hand of Praxiteles (Athens, Central Museum).

We will give a connected report of the remaining five lectures at the close of the course.

Illustrations.

SOME CHURCHES UPON THE LOWER RHINE.

ALTHOUGH the churches upon the Upper Rhine are well known to English archaeologists and architects, yet those upon the Lower Rhine, especially between the German frontier and Cologne, are far less known than they deserve to be, and some views and descriptions of some of the most important ecclesiastical buildings in this district may be of interest to our readers,—especially as the drawings are from sketches made on the spot, and the descriptions from notes taken down at the same time.

We commence our observations at Cleve, the capital of the old German Duchy of the same name. After passing through the vast plain which intervenes between Rotterdam and the German frontier, one suddenly comes upon a wooded range of hills, one of which is crowned by the old castle and Minster Church of Cleve. The pretty town winds gradually up the hill, by a steep, serpentine street. Although Cleve is a charming little place for the artist, there is not very much to detain the architect there. The castle, though an old building, has been too much modernised to be of any special value. It is true it contains two very singular-looking Romanesque kirchways; so singular, in fact, as to raise a doubt about their genuineness; and some early inscribed tablets, several of which are Roman in date. The Hauptkirche, or Catholic parish church, close at hand, is a large, fourteenth-century building,* consisting of a very long and lofty nave and aisles, terminating in apses at the east end, with two towers crowned by tall slate spires at the west, and a graceful fleche in the centre. The building is constructed of red and white bricks, used somewhat haphazard, in places arranged in stripes, and then again in other portions of the structure used indiscriminately; the window traceries, doorways, &c., are all of stone. The interior of the church, though rather bald-looking, is finely vaulted; it contains two extremely interesting fourteenth-century monuments, a well-carved tryptich altar-piece at the end of the south aisle, and an elaborate "Ambrüb." The "Kloster Kirche" (Dominican Church) in the lower town is a remarkably plain fourteenth-century building of brick, but contains a set of well-carved choir stalls. The "Evangelische Kirche" (Protestant parish church) is a most singular compromise between Gothic and Classic architecture, not unpicturesque, and dating from about the end of the seventeenth century. The neighborhood of Cleve contains a number of very interesting churches. Eight miles off, on the opposite bank of the Rhine, is Emmerich, with two fine churches,—the older of which, called the "Minster," is a most eccentric Ecclesiastical building, and we should describe it as consisting of a great north transept with a low, narrow choir and a short nave (only two bays long) attached to it. There is a picturesque brick tower and, beneath the choir, a very early Romanesque crypt. For furniture a bronze Renaissance font and very elaborately carved fourteenth-century choir stalls are worthy of notice. The principal parish church, in the centre of the town, is a vast brick structure dating from the fifteenth century, with a very lofty western tower crowned by an octagonal lantern. Unfortunately the whole of the furniture, altars, &c., are poor late Renaissance work, and are not sufficiently interesting to make up for the want of architectural detail which is lacking in this huge, plain interior.

About five miles from Cleve and three from Calcar is a village called Wisse!, which contains a very perfect twelfth-century church, consisting of a nave, aisles, transepts, and two towers, flanking the chancel, which retain their original gabled cappings. The vaulting is quadripartite, each bay enclosing two piers, but only a single triforium opening and clearstory window. There is a curious Romanesque font and part of a fifteenth-century organ-front. The whole building has been covered internally with modern decorative painting of a somewhat gaudy description.

Calcar, which is three miles further on, is an interesting little town, retaining its old walls and a plain but picturesque little fifteenth-century rath-haus; but the chief interest of the place attaches to the principal or Catholic

* Commenced in 1381.

parish church,—a most remarkable building. Externally, it is as plain as possible; it has high brick walls unadorned with either parapets, pinnacles, or string-courses,—nothing, in fact, but the window-tracery, and that very simple geometric work. The building consists of a nave and aisles of equal height, a long chancel with a chapel, the same height, on the south side, and one much lower on the north. There is a lofty brick tower, crowned with a slate spire, at the west end, and a deep porch to the south. The interior of the church is very fine, though rather plain; the piers are cylindrical, of brick plastered over, and scored in representation of alternate layers of wide and narrow courses of stone. The arrangement appears to be ancient. The capitals are foliated, and the vaulting is simple and exceedingly good. But what makes the building especially interesting is the quantity of magnificent furniture which it contains.

There are seven great triptych altars, all dating from the commencement of the sixteenth century. The high altar is a most wonderful composition. When opened, the triptych displays the whole history of the Passion of our Lord in one vast "alto-relievo" carved in oak, uncoloured. There are some 250 figures. The altar itself has an arcaded front.

Of the other six altars, that in the Lady-chapel, north of the choir, is the finest. The "Mater Dolorosa" in the centre niche, bearing the dead body of our Lord, is simply magnificent. The figures are about life-size; the finest work of the kind I know. The wings are painted. The two altars against the piers of the chancel arch are very rich, but a little confused in design. There are too many small figures introduced into them. The two other altars attached to the outer piers of the aisles are beautiful examples of very Early Renaissance carving. Each contains three large figures, standing in rich niches. Like the high altar, they are of oak, uncoloured. All these altars have painted wings or doors. That in the great chapel to the south of the choir is not so perfect as the others, but is still a beautiful work. Against the walls of this chapel are several old triptychs, pictures, monumental slabs, &c. In the chancel there is a very fine Sacraments-hauslein still in use; it is covered with the church, the stalls are excellent, and their ends remarkably richly and beautifully carved. From a boss in the centre of the nave hangs a splendid chandelier, the upper portion of which is composed of wood, and adorned by two life-sized representations of the Madonna standing in a great open bower composed of branches of a "tree of Jesse." One statue faces east and one west. Below the statue is a great pedestal adorned with carvings and statuettes, and from its six angles start the brackets which support a number of candles. The whole is a remarkably magnificent work. The old Rood and its attendant figures are now over the north doorway. There is an excellent brass chandelier near the west end of the nave, and a good, though rather plain font in the south chapel. In a kind of chapel at the west end of the south aisle is a "Pietà" composed of figures carved in wood nearly life-size, all painted. It is rather singular than a beautiful work, and dates from the commencement of the sixteenth century. Several inscribed tablets and other objects of interest are to be seen in this chapel.

The effect of this great plain church with its singularly rich furniture is very striking indeed. There is no old glass. Three modern windows, designed by Steinlie and executed by Capronier, above the high altar, though, no doubt, admired, are out of keeping, and too gaudy in effect. The grisaille in the side windows of the nave is unobjectionable.

The dimensions of the church are as follows:—Internally: Length, 180 ft.; width, 80 ft.; width of nave, centre to centre, 37 ft.; length of chancel, 60 ft.; height to vaulting of nave and aisles, about 70 ft.

The little town of Calcar has gained itself a great reputation for the school of painters who flourished there during the fifteenth and sixteenth centuries. Unfortunately, we are unacquainted with the names of most of these men, though the school had marked peculiarities which distinguish their works. John of Calcar was certainly one of the greatest German artists of the sixteenth century. The magnificent pictures upon the wings of the high altar of the church at Calcar would alone serve to establish his reputation. Other works of his

From measured drawings by Mr. J. A. Gotch.

are to be seen at Xanten, Cologne, Rees, Wesel, Dantzic. The ascertained dates of his works range from the year 1481 to 1516. The Protestant parish church of Calcar appears to be an old building, but it is very small, and so much modernised as to be of little interest.

H. W. B.

BURFORD CHURCH.

This building shows some traces of Norman work, but contains little of architectural interest beyond a fine and curious collection of tombs to the Cornwall family, especially a painted wooden altar tomb in the centre of the chancel shewn in the view, and a very curious painted oak triptych on the north side of the chancel, and the whole of this series of tombs has been carefully preserved. The greater part of the western tower was built in brick and cemented over in the last century; this has been rebuilt in Bromsgrove stone. The nave roof—an original trussed-rafter one—has been preserved and re-tiled. The chancel roof—a patchwork of recent years—has been replaced with a new one, and an oak-panelled panel ceiling with carved figures representing a complete choir of angels at the main ribs.

The church floor has been lowered to its original level and reslated in oak.

The reredos is a triptych, executed in mahogany, gilded and painted. The east window has been filled with new tracery and fine glass by Messrs. Powell & Sons.

Mr. Thomas Collins, builder, of Tewkesbury, carried out the work.

The whole expense has been borne by the Honourable Miss Rushout, of Burford House, as a memorial to her brother, the late Lord Northwich, to whom also a memorial lych-gate has been erected at the entrance to the churchyard by his friends and tenants.

ROTHWELL MARKET HOUSE.

The illustrations of this interesting old building are reproduced from measured drawings by Mr. J. A. Gotch, which formed a portion of the illustrations to his paper on "The Renaissance in Northamptonshire," read before the Institute of Architects on February 3 of this year, and which appeared in the *Builder* of February 8th. The building was fully described in the course of the paper.

CROMER TOWN HALL.

The foundation-stone of this building was laid by Mrs. B. Bond Cabbell, of Cromer Hall, on January 8, to whom a gold trowel was pre-

THE HALL, BRADLEY'S, 11, WESTMINSTER, LONDON.

sent for the occasion by Mr. Samuel Hoare, M.P., on behalf of the townspeople. The architect is Mr. George J. Skipper, of Norwich, whose plans were selected in public competition in the autumn of last year. One of the special features in the external decoration of the building is the introduction of a series of panels containing the armourial bearings of persons connected with Cromer. The panels comprise the following arms:—Sir Nicholas de Wayland, first Lord of the Manor in the reign of Edward I.; Robert Bacon, who discovered Iceland in 1405; Sir Bartholomew Read, Lord Mayor of London in 1502, and who endowed the Goldsmiths' School at Cromer; arms of the Wyndham family and of the town of Cromer; Lord Suffield, present Lord of the Manor of Cromer Gannars; E. Bond Cabbell, Esq., Lord of the Manor of Cromer; and the family arms of the following:—Samuel Hoare, Esq., M.P., Sir T. Fowell Buxton, Bart., J. H. Gurney, Esq., and S. Gurney Barclay, Esq.

As to internal arrangements, the central doorway leads through a vestibule (with side-rooms for ladies and gentlemen on either side) to a public hall capable of accommodating 900 persons. It is covered with an open timber roof, lighted by windows on one side and roof-lights. The walls are lined with match-boarding to a height of 5 ft. from the floor, and above this red brick work neatly pointed. The floor is laid in wood blocks. The heating is by hot water-pipes. Above the vestibule and cloak-rooms, and approached by a staircase, having a separate entrance from the side road, are the reading and recreation-rooms. At the rear end of the block of buildings is the fire-engine station. Special crush-doors are provided, and all the doors to the hall are arranged to open outwards. Externally the walls of the building are faced with red bricks, and the roof is covered with Dressley tiles. The ornamental brickwork, of which there is a good deal, comes from Mr. George Gunton's Costessey Works. The carving has been entrusted to Mr. Minns, of Norwich. Mr. J. Newman is clerk of the works, the builders being Messrs. Chapman & Son, of Norwich. The heating apparatus will be supplied by Messrs. Sabberton Bros., Norwich. The carving under the pediment represents Robert Bacon's ship approaching Iceland.

ARCHITECTURE IN OXFORDSHIRE.

THE ARCHITECTURAL ASSOCIATION.

AT the ordinary fortnightly meeting of this Association, held on Friday, the 23rd ult., Mr. Leonard Stokes, President, in the chair, the following members were proposed for election, viz.—Messrs. W. G. Legg, S. H. Gordon, G. H. Gill, H. B. Creswell, H. S. Morris, J. Robinson, and H. T. Bromley.

Mr. E. S. Gale (Hon. Secretary), announced the seasonal visits for March, as follows:—March 8, visit to Mr. Sedding's new church, Sloane-square, Chelsea; March 22, visit to the new Central Offices for the Metropolitan Police on the Victoria Embankment (Mr. R. Norman Shaw, R.A., architect); March 29, visit to the new Hospital for Women in Marylebone-road (Mr. J. M. Brydon, architect). Mr. Gale also moved a vote of thanks to Mr. Colcutt for his kindness in connexion with the recent visit of the Association to the Imperial Institute, South Kensington.

The Chairman said he was sorry to say that Mr. William Pite was suffering from a bad cold, and was unable to read his paper on "Architecture in Oxfordshire." Mr. Hooper, however, had kindly undertaken that duty for him. We give the latter portion of the paper:—

"When it was my happiness to start away for Oxfordshire, a tour which extended to four months, I thought I was going to do the county; but, though constantly at work, I was only able to touch four of the principal parts, so vast is the field and so much is there to see and learn, for the village church demands attention as much as her elder sister of the town or city.

Time will not permit me to do more than indicate a few churches,—a catalogue would hardly be interesting without amplification. In the northern part of the county are three important churches,—one, it is true, in three towns, separated only by a canal; but the three within sight of each other, a few miles south of Banbury, each being celebrated for spires of singular beauty. A local rhyme discriminates between their merits, which, though only doggerel, introduces the names of the

three churches, which we will review in order:—

"Bloxham for length,
Alderbury for strength,
King's Sutton for beauty."

They are a study in themselves, in their influence on one another. They were visited by the Architectural Association excursion party in 1885.*

Bloxham, now corrupted to Bloxham, in William the Conqueror's time was part of the estate of Edwin, Earl of Mercia, who, provoked by the Normans, broke into insurrection: being betrayed by three of his captains, he and his brother Morkar, and Berdon, King of Wales, were slain fighting. The estate fell into the Conqueror's hands, and remained vested in the Crown till the reign of Henry III., when Almaric de Armand obtained it of that prince. This doubtless is the key to the architectural history of Bloxham. This noble church (see plan) consists of nave, aisles, chancel, and transept; while on the south side are two very fine fifteenth-century chapels, the outer one being the Milcombe chapel. Adjoining is a fine porch, with priests' residence over, in two floors. In the church is a gigantic fresco of St. Christopher; while over the chancel arch, in a sunk recess, is a Last Judgment. A painted screen divides the chancel from nave. The former is most delightful in delicate Norman sculpture, quite equal to Romanesque as seen at Bamberg and other German places; here are pointed arches to the windows, with the Norman sculpture worked in, showing a studied economy in the Medieval builders. The church is replete with interest. The north porch has a remarkable sculptured arch. In the north aisle are some magnificent traceried windows, with slight remains of stained glass. One of the windows in the north aisle,—a similar one being at Alderbury,—has the tracery converging, and finishing in a sculptured head. When I saw this it was fortunately unrestored. On the north elevation of the church is a remarkable animal and figure corrie, as seen in other northern parts of the county. The steeple rises from an octagon in a square tower, admirably arranged. Remarkable buttresses are at the angles, with niches and canopies; these, running up, finish in pinnacles, a traceried parapet running round the octagon. The west door is a remarkable work of the fourteenth century. The label is stepped, and there are sculptures of a Last Judgment.

Alderbury, the "Edburgherig" of Domesday, which, with Bloxham, was in Earl Edwin of Mercia's estate, and with it passed to the Crown, is a short distance off, and can be seen from Bloxham: its Norman castle has gone, but the magnificent church still remains, containing many features as seen at Bloxham. The chancel is a fine specimen of the work of William of Wykeham, Bishop of Winton, and the living naturally belongs to New College, Oxford; the glass of the east window contains his arms. The detail of the chancel demands long study, with its reredos and canopy-work to sedilia and east wall, which no doubt were once richly decorated. On the north side is a remarkable priests' residence, with second altar in a fine oriel window, and good turret stair leading to the upper chambers and the leads. The church abounds in detail, braces, roof-loft, and screens, a magnificent cusped fourteenth-century roof, and open-timbered. This church has had, as also Bloxham, a western gallery, and one can trace the same hand at work on both churches. The roof in the south transept was restored by an eminent architect, and I have a note asking "Why was it varnished?" Here are also more sculptured cornices, and we get an insight into local life. A husband, presumably, is agitating a fire with the bellows under a four-legged caldron, while his spouse is licking him into shape with a basting-spoon. Animals with gorgeous tails, foliated beasts, and griffins fighting, human beings playing on instruments, wind and otherwise; a man is stroking a donkey, while a dog is licking his own ear. The tread of the roof stair, it is interesting to note, is $\frac{1}{2}$ in. by $\frac{1}{2}$ in. rise. The building presents a mass of questions relating to date and circumstance. The tower and spire are at the west end, the former opening into the nave. The spire and pinnacles do not sit very happily; they

come within a traceried parapet, and angle buttresses taper to the ground.

Of St. Peter, King's Sutton, Northamptonshire, separated from the border by the Oxford canal, suffer but a word. The same bands have been here, and the local lines, attesting the beauty of the spire go without saying. Its wondrous symmetry and simplicity are enchanting; the tapering of the spire to meet that of the tower is very beautifully arranged. It is at the west end, and comes into the church, there being a fine fifteenth-century porch beyond.

A seeming parody on the three great churches are three village ones, lying a little south, but all within view, in a valley of beauty. They are easily reached from Chipping Norton, which latter church has a wonderful fifteenth-century window, with double tracery over the chancel arch, and a most singular porch. The village churches are Wigginton, South Newington, and Barford St. Michael, all of which are studies in themselves. We must away; many delightful experiences may be had by going to by-villages, and putting up at the "waysides." My task already is too great, and to do justice to many of these churches demands an evening to themselves.

The great church of St. Mary, at Witney, however, calls for some notice, as I went there specially, with orders to make drawings of the magnificent tower and spire at the crossing. I should weary you were I to attempt to dissect the parts; I wish, however, to enter a little into the history of its times, and the memories which cluster around it, which will go far to show how our national architecture is enfolded in our national history and daily life, and to offer an interesting suggestion which may call for consideration at your hands. There are remains of a Norman church which had existence previous to the costly reconstructions, adaptations, and additions of the thirteenth, fourteenth, and fifteenth centuries in aisle and transept. The presence of many altars suggests a large establishment; while, without, the one absorbing topic is, whence came such a stately tower and spire, with its intricacy of line, and hold simplicity, and oneness of conception? Let the rolls and records of our land speak. Elfwine, or Alwinus, is reckoned as Winton's thirty-second bishop. Tradition states that there was a scandal about his relations with Queen Emma, mother of Edward the Confessor, who was born at Islip, near Oxford, and that she proved her innocence by the ordeal of red-hot ploughshares at Winchester, on which she walked unharmed. The good king made over the manor of Witney to the acquitted bishop, he likewise doing the same to his church chapter, or establishment at Winton. Dugdale gives a list of others handed over at the same time. Hence arose the episcopal palace on the east side of the church. Stigand succeeded Elfwine, and Stigand was in turn succeeded by Walkelin (Stigand being made Archbishop of Canterbury A.D. 1052, deprived by William the Conqueror in 1070, and dying the same year in prison). Walkelin was a great builder, and much of the nave of Winchester Cathedral is attributed to him. It is not improbable that he built the palace at Witney. For thirty years he is said to have divided his time between Winton and Witney; if that be the case, it is well within reason to expect that he exercised his skill upon the adjoining church. We may possibly credit him with the beautiful north porch, which is of his time; and, though not exactly relevant, it is of the highest interest to recall the fact that in his episcopacy the great Domesday Survey was made or completed. Therefore, we are led to conclude that the great Norman church owed much of its structure to Walkelin, and its inspiration to noble Winton of East Anglia; and here, housed midst shady trees, this not less learned and exalted ecclesiastic, though not so over-worked and over-worried as his more modern brethren of the bench, has added his tribute to what is to us, gentlemen, "a mine of memories." William Giffard, the next Bishop of Winton, was Lord High Chancellor to King Henry I., and in that, like Cardinal Wolsey, he was for his separated profession too much the servitor in the temporalities of his sovereign. He was succeeded by the long episcopate of Henry of Blois, who came to his throne in 1128, and spent a great deal of his time at Witney, and dying in 1174. No doubt the reconstructions were set on foot under this great prelate. But we must hurry on to the thirteenth century, when, after two bishops—to wit, Richard and Godfrey, of

* See the *Builder* for Aug. 15 and 22, 1885, pp. 237, 250; also the numbers for Sept. 12 and Sept. 19 of the same year for various sketches of Oxfordshire churches visited on that occasion.

† See sketch in the *Builder* for Sept. 12, 1885.

‡ See sketch in the *Builder* for September 19, 1885.

whom we know next to nothing—we come to Peter de Oriol (Winton's thirty-ninth bishop), who spent much leisure at the palace and park of Witney. At Cogges there still exists Park Farm, and an open ditch called Emma's Dyke, after the queen-mother of Edward the Confessor before referred to. In 1221 Bishop Peter de Oriol obtained royal warrant from Henry III. to purchase and receive of Robert de Arsic's haru at Cogges, "building timber from his woods." These woods are still at Cogges, a mile or two from Witney. The bishop's clerk, Dionysius, was Rector of Witney—a man of importance in his time. The Fifth Crusade took place under John Brievue in 1217, and the returning warriors, passing through Calvados, stand face to face with the surpassing beauty of the western façade of Bayeux Cathedral. One of the gentlemen present views the fairness of the spire and pinnacles aright for his Witney friends. Whether by a manipulated memorandum or not, we incline to the suggestion that this vision of the beautiful which was once England and bloomed again at Witney,—a French poem translated with consummate art into living English, in Witney's buttressed tower and pinnacled spire. The slopes of the tower are remarkable; also the peculiar angles and differences of the buttressing; and it should be further noted the tower is not central with the transepts. Witney has influenced Bampton and Broadwell in towers and spires, but beyond that it seems to stand alone.

Cogges lies just outside Witney, and has a small but most interesting church, with a fourteenth-century octagonal tower placed obliquely at the west end,—a singular arrangement. The place has a remarkable history in the roll of time, and has a connexion with Witney; it was the church of the Barony of Arsic, of which Manser de Arsic was lord. The family was descended from the Earls of Oxford, and as ancient as the reign of Henry I. The baron sent the Black Monks of the Black Monks of Fiscamp, in Normandy, who sent over part of their convent and founded a cell, which was dissolved by Henry V., with the other alien priories. Some of the ancient stone bars still exist adjoining the church.

Eight miles from Witney, and four from a railway station, is the enchanting town of Burford, little known, possibly through its isolated position. The importance of the place calls for notice at our hands. Delightfully situated on the Windrush, which comes from the Cotteswold, one crosses the ancient winding stone bridge, and stands at the head of the broad High-street,—ancient houses to the right and left making unnumbered mental calls to be inspected. That we cannot do now; our visit is mainly to have a hurried look at the great church, which Mr. Street, with his intimate knowledge of the county, has said that of all the churches in the diocese of Oxford, Burford is not only the grandest in sculpture but also in its architectural detail it is singularly rich and beautiful. A word on its early history gives us the origin of the dedication of the Church to St. John the Baptist. By the Saxons, Burford was known as Beorford, of which the present name is a corruption. In 685 an ecclesiastical synod was held here by the Kings Ethelred and Berthwald, at which Aldhelm, Bishop of Sherborne, was ordered to write against an error respecting Easter. In 752 a battle was fought between Ethelbald, King of Mercia, and Cathred, King of the West Saxons, who had revolted. Ethelbald was defeated, and the Royal Standard, bearing the device of a golden dragon, was captured. To the west of the town is a place called "Battle Edge"—this in all probability is the site. A custom for long was kept up of parading the streets with all "jollity" with a "Golden Dragon" on Midsummer Eve (St. John-the-Baptist's Day). After the Conquest, however, the town was bestowed on Robert, Earl of Gloucester, natural son of Henry I. in Oxfordshire, with such variety, where one sees great churches, as Bloxham, Witney, Bampton, and Dorchester, when we come to look at Burford, for concentrated interest it excels them all. We need only refer to its ground-plan, its many aisles, its great lengths, and manifest additions, to see and admit that there is historical association circling the building, without which we cannot attempt to comment upon its composition. This, again, goes to prove how in the times gone by building arose simply out of the necessities of the case; wants were felt and met, and surely such churches would not

be provided unless there was a far larger congregational demand than that which, at least at the present time, exists either at Burford or elsewhere. It is unnecessary to enumerate the dates at a church like Burford, for it affords to the chaervant student a complete dictionary of Medieval architecture in matter and detail. The church lies very low, and the mill-stream which bounds the churchyard is uncomfortably near. The interest possibly centres in the tower, which has most excellent Romanesque work, surmounted by a late fifteenth-century tower and spire. No doubt the very irregular shape of the church is the result of the linking together of two distinct buildings. Mr. Street thought that what is now called the Sylvester aisle was a chapel standing quite distinct from the church, which was founded in the thirteenth century, and was not joined to the church by the opening of the arches until the fifteenth century, when it was also lengthened eastwards. All this has resulted in detriment to the magnificent south porch, which was once entirely detached, and is now completely imbedded between this aisle and the western of the two south transepts. The altar at the east being a great distance off, and the narrowness of the tower arches being inconvenient for comfortable service, one has little doubt but that they decided to develop the church at the west end. That the porch was distinct from the Sylvester aisle is clear from the fact of there being a buttress and the plinth returning round. A chapel was accordingly erected of stone, with a wooden tester under the eastermost arch of the nave arcade. This, architecturally, is a most ingenious arrangement, which Mr. Street fully restored, and of which he remarked that he knew of no other similar example. Observation on the spot shows that most people can see better at this position than at any other; though the position is probably open to serious and divided ecclesiastical opinion. The church contains an excellent fourteenth-century sculptured font, and it is curious to observe that the sedilia to the font are only 9 in. high. Pulpit-roofs, ironwork, and many beautiful windows call for the undivided attention of the student. In the south transept is a Parbeck tomb, the inscription being on the interior soffit of the arch with a canopied niche over it; it thus runs:—"Orate pro animabus patris et matris Johannis Leggare de Borford pro quem ista fenestra decoratur." No less interesting is it to read an early specimen of English prior to the Reformation, when the people were aching to be done with the hauds of "Latinity." Here is a specimen of English as she was spoken in 1437:—

"Mary moder mayde cler, hane mercy on me. Jon Spiker."

And on me Alys his wyf, lady for thi joles fyve.

I trust my task has not been in vain in having endeavoured to show you that the characteristics of a few churches, the nave arcades of Oxford, and some other subjects, as the roofs and porches, &c., provide matter for others to take up with very great profit, and I trust that as the summer comes upon us we may have the opportunity of again seeking and studying noble work in ancient stones.

Mr. H. D. Appleton, in proposing a vote of thanks to Mr. Pite for his paper, and to Mr. Hooper for having read it, said that the paper was one of great interest to them, notwithstanding that it had been stated, during one of the annual excursions of the Association.

Mr. L. A. Shuffrey seconded the motion, which was supported by Mr. F. R. Farrow (Hon. Sec.), and Mr. C. H. Brodie, who said he was somewhat surprised to find Mr. Pite suggesting, in the first portion of his paper (which we have been obliged to abbreviate), that mouldings should be drawn one-eighth, one-quarter, or one-half full size. He thought it a good thing for Mr. Pite that his brother was not present.

The Chairman, in putting the vote of thanks to the meeting, begged to include in it the name of Mr. Bolton for his kindness in having made a large number of the many plans of churches which were exhibited on the screens.

Mr. Hooper having said a few words in reply, the meeting terminated.

The Sanitary Institute—The Council have accepted an invitation from the Town Council of Brighton to hold the Autumn Congress and Health Exhibition in that town in September next.

FREE LECTURES TO ARTISANS AT CARPENTERS' HALL:

PROFESSOR W. H. CORFIELD ON "MODERN SANITATION."

The third of the present series of free lectures to artisans and others on matters connected with building, under the auspices of the Worshipful Company of Carpenters, was delivered on Wednesday, the 19th ult., by Professor W. H. Corfield, M.A., M.D., his subject being "Modern Sanitation." Mr. Joseph Preste presided, and there was a large attendance.

Professor Corfield said the subject of "Modern Sanitation" was a very wide one indeed, and taken in its widest possible sense, it could be embraced within the limits of a single lecture. He would, therefore, limit his remarks to the question of the removal of refuse matters from our houses; and, in the first place, would consider the improvements that had been made in recent times in the materials used in the sanitation of houses; in the second place, the improvements made in the arrangement, trapping, and ventilation of drains, and other waste-pipes, and in the third place, the improvements made in appliances and apparatus. Until comparatively recent times all drains were made of stone, brick, or pervious agricultural pipes. The first and greatest improvement that was made in the construction of drain-pipes for houses was the one which consisted of making them of water-tight material. It was recognised that for the first time that pipes which had to carry away foul water should be, in themselves impervious to water, and in the first place they had pipes made of a material known as glazed stoneware. But though it was very well to have a pipe which was impervious to water, these pipes could not be made of indefinite length. Their ordinary length was 2 ft.; hence the question of jointing them, so that they might be impervious to water throughout, was of great importance. The first method adopted was that of making the other end into it, and the pipe and putting a socket at the one end, and putting in some jointing material. Pipes could be put together in that way without any jointing material at all, and so, as a matter of fact, they very frequently were. He would not at the present moment. They were, as it was technically called, "laid dry," without any material in the joints at all, so that they might as well have had the ordinary agricultural pipe drains. Sometimes they were jointed with clay, and no doubt a fairly good joint from one point of view might be made in that way; but clay was a material which easily softened when wet, and so the usual method was to joint them with cement. Several difficulties, however, arose in connexion with that method, the first being that the cement projected into the interior of the pipes, set there, formed bosses in the drain against which foul materials collected, causing obstructions, and gradually blocking up the drain. Another difficulty was that the pipes might be laid and cemented round the upper part of the joint only. Although, when inspected, the drain would look all right, yet there might be no cement in the lower part of the joint at all. That was a very serious difficulty, but it was overcome, like several others of the kind, by more accurate methods of jointing. Before these methods were devised, however, the method was sometimes resorted to of putting what was called a "cradle" underneath the joint, and filling it with liquid cement, so that then the under part of the joint must be filled with cement as well as the upper part. All these difficulties of jointing pipes with cement,—which method, however, was even now one of the very best if properly and honestly carried out,—had led to other devices. One of these was that adopted by Mr. Stamford, who first conceived the idea of making a ring round the end of each of the pipes, one in the socket and one on the spigot. These rings, made of a preparation of asphalt, were carefully made by being cast in steel moulds, and when the end of one pipe was put into the socket of the other, it made a perfectly water-tight joint. That joint of Stamford's had been very largely and successfully used, and it had been improved upon recently by Messrs. Doulton, who had made the surface of the ring curved, to fit into the ring in the socket end of the pipe, so that if the pipes shifted a little the contact still remained complete. This method avoided all the disadvantages of cement. Several other

joints had been devised for stoneware pipes, but he did not think he need do more than merely mention them. One was Messrs. Haassall's joint, and another the "Archer" joint. These, however, were somewhat more complicated. One of the great advantages of glazed stoneware pipes was that they were made of a material which was perfectly unalterable. Another kind of pipe very largely used for drain purposes was the cast-iron pipe. These had several great advantages. Of course they were impervious to water, and they were coated with a material which prevented the iron rusting. They could be jointed with perfectly water-tight joints by means of molten lead, and they were made in lengths of 6 ft., thereby lessening the number of joints. These great advantages were put forward by those who advocated these pipes of cast-iron drain-pipes, but against these had to be set the disadvantage that iron was a material which was destructible by water, moist air, acids, &c. So long as the coating was perfect it was all right; but if the pipe was chipped or knocked, or the coating became removed by abrasion or other cause, all these formed weak places, which were likely to lead to the destruction of the pipe. However, after all, that was a matter of experience. They had come to understand in recent times that it was essential that drains laid under houses should have a firm bedding, and now this was recognised as practically essential in all cases, although it was more or less of an innovation to cover them with concrete. Whatever material was used for the construction of drain-pipes, they must insist that they should be water-tight.

The lecturer next proceeded to consider the materials used for, and the improvements in, the construction of soil and other waste-pipes. Two materials had been used for a very long time,—namely, iron and lead, so that one could not say that there was much improvement in materials. Lead, generally speaking, was a better material for soil-pipes than iron; and that it was not used to the exclusion of iron was due to the fact that it was much more expensive. Not so long ago, water-closets were almost universally connected with the rain-water pipes of houses, but such a monstrosity was not allowed in "modern sanitation." Lead soil-pipes were better than iron ones, for the most obvious reason that they could be jointed with the same material, so that the joint was at least as good a part as the other portion of the pipe. Iron pipes were always jointed with a different material, and, as a general rule, when they made a joint with a different material it sooner or later leaked. Iron pipes should never be allowed to be used inside houses for soil-pipes. He had spoken of the disadvantage of iron pipes as drain-pipes owing to their liability to rust. That disadvantage became more considerable when they were used for waste and ventilation pipes, and if there was one thing he would warn his hearers against it was against ever allowing a ventilation-pipe to be made of iron, because he undertook to say that such a pipe after being in use for five years got blocked up at the bottom and did not ventilate the drain. In order to get rid of these disadvantages of iron-pipes various means of protecting the pipes had been resorted to. One was to cover the pipe with a material known as Dr. Angus Smith's solution, and another plan was to coat the pipes with an insoluble oxide. Pipes coated by this process were not universally used for sanitary work, because in the vast majority of cases the pipes protected with magnetic oxide of iron had defects in them. He had even seen pipes used for supplying houses with pure water specially prepared by this process taken out some two years afterwards because they leaked. They were simply eaten through and through by the pure water, and, therefore, they must always be on their guard against reliance upon processes for protecting a perishable material like iron. Until comparatively recent times lead pipes were made in the way in which the Romans made them, and were called "seamed" pipes. Now, they had pipes known as "drawn" lead-pipes, and these were a great improvement on the others, the soldered joint throughout the whole length of the pipe having been a source of weakness. Slip joints would not stand any test, and so the only proper joints for lead-pipes were wiped soldered joints.

Passing on to the consideration of the improvements made in the arrangement, trapping, and ventilation of drains and waste-pipes, the Professor said that not very long ago the drains

of houses used to be made to end in receptacles called cesspools, and it was found necessary to prevent in some way or other the foul air getting into the house; therefore, the contrivance known as the "dip-stone" or "mason's trap" was devised. That trap sufficed, no doubt, to prevent a rush of foul air from the cesspool or sewer into the house; but it was a most defective contrivance, because, even if it did that, it allowed an enormous accumulation of foul matter to take place in the trap itself, which became a sort of small cesspool, and very often a large one. A "dip-stone" trap, whether large or small, was really a cesspool, and Yorkshiremen, with their characteristic love of truth, always called them cesspools. Another reason why that was a most defective contrivance was that the "dip-stone" and the stone at the top were in a very large number of instances not properly fitted. In those days, too, nobody thought of ever providing ventilation for the house-drain; if any was provided, it was by accident. The most essential improvement which had been made in regard to the trapping of drains was made after the adoption of stoneware drain-pipes by the construction of the siphon-trap. That was a very unfortunate name, because if it acted as a siphon it was not a trap at all, and he preferred to call it the "U" trap, from its shape. The improvement made in traps then was by making a bent pipe, and that improvement was due to the fact that it allowed less sediment, if any, to collect. They, therefore, came to recognise that the first important function a trap should possess was that it should not allow sediment to collect in it, and they laid down now as the one important characteristic of a good water trap that it should be self-cleansing. With regard to ventilation, in the first place, it was recognised to be necessary to provide something more than outlet ventilation for drains and soil-pipes. If they had merely outlet ventilation they only provided that foul air should not accumulate under pressure; but it was now a recognised necessity to provide a means for the inlet of fresh air into the drains and soil-pipes. If the ventilation-pipe at the top of the soil-pipe was carried up above the ridge of the roof into the open air, every wind that blew across it would cause an up-draught. The air inlets might be made, and were frequently made, by an open grating in the front area or outside the house; or by a pipe with open grating, often provided with a talc flap to prevent back-draught. In all sanitary appliances and apparatus an arrangement which did the work without any moving part was always better than one that did the work with a moving part. That was a good general law, and applied, for instance, to air-inlets and cowls which had no moving parts. Another important improvement was the provision of a manhole for access to the siphon-trap. It almost went without saying that drains ought not to be laid underneath houses if such a course could possibly be avoided. That very day he had seen a large house in the country underneath which he was informed a drain 70 ft. long was going to be laid. It was quite clear, therefore, that even now it was necessary to insist that, where practicable, drains should be laid outside of houses, and that soil-pipes should be placed against the outside walls, and not inside. Another matter of recent improvement was that drains and sewers should be laid as straight as possible. Until comparatively recent times the drains used to be laid where most convenient, without any idea of inspecting or cleansing them. Now, they insisted on having them laid as far as possible in straight lines. However, that could not always be done, and so it became the more necessary to provide means for inspecting the drains at different places. There were several ways of doing this, but the best way was to have inspection-chambers in the areas. Just as the drains required to be disconnected from the cesspools and sewers, so the waste-pipes of all the sinks and baths and lavatories required to be disconnected from the drains. That was one of the greatest improvements that had been made in "modern sanitation." It was necessary to have subsidiary ventilation-pipes, or anti-siphonage pipes, in the case of water-closets as well as sinks. In large houses, a great deal of greasy water and sand was thrown down the scullery sink, which solidified in the trap and drain, and blocked them up. It was necessary to provide against this, and the method adopted up to within the last two or three years was to construct what were known

as fat or grease traps. These grease-traps were an abomination. They had to be cleaned out from time to time, and it was felt that if they could be done away with it would be a very great improvement. That had been achieved in modern times by the construction of a gully known as the grease-gully, which was large enough to hold sufficient water to chill any hot water that came into it. By means of an automatic flushing-tank, the grease and sand were washed away every day. The arrangement of water-closets against outside walls wherever possible, instead of in the middle of houses, might be regarded as a modern improvement. The improvements made in traps had been of the very greatest importance. The bell-trap had been replaced by the stoneware siphon-gully. The D-trap was at one time almost universally used for water-closets and sinks, but it had now been largely replaced by the round-made siphon or O-trap, which again had been improved by Mr. Hellyer, who had constructed what was known as the "anti-D-trap." Referring to the improvements made in water-closet apparatus, he remarked that the "short hopper" was a great modern improvement on the long hopper. The trap of a water-closet should not be regarded as part of the apparatus, but as part of the soil-pipe or drain, and they might unhesitatingly condemn all water-closets of which the trap was part of the apparatus. Other improvements which had taken place consisted in the re-substitution of the valve-closet for the pan-closet, and in the making of certain minor improvements, like the flushing-rim. Lastly, Professor Corfield exhibited an improved siphon-trap for deep disconnecting-chambers, provided with a valve by which the sewage could be easily allowed to escape in case of any blockage of the trap, which had been made by Messrs. Crapper & Co. at his suggestion.

PROFESSOR ARMSTRONG ON "THE DOMESTIC FIREPLACE."

The fourth lecture of the series was delivered on Wednesday, the 26th ult., by Professor Armstrong, Ph.D., F.R.S., his subject being "The Domestic Fireplace." Mr. Charles Barry, F.S.A., F.R.I.B.A., presided, and there was a large attendance.

Professor Armstrong said that the domestic fireplace justified that well-known adage that "Familiarity breeds contempt." They were so accustomed to it that, perhaps, they had got into the habit of considering too little whether they were constructing it properly. In these days, when they were taking stock of the efficiency of the machinery and processes which they made use of, there was a good deal that made it appear that the time had come when it was very desirable that some greater share of attention should be paid to this very simple contrivance. The domestic fireplace, in fact, was one of those time-honoured English institutions which, like most of our ancient institutions in these days of progress, had frequently of late been more or less called in question; but, like so many of our old established practices, it proved on examination to embody sound theoretical principles which, in the opinion of capable judges, entitled it to survive. But it could not be denied that it was too often wasteful, and that, while ministering to our comfort within our houses, it was in a large measure the determining cause of the great discomfort which arises from the prevalence of fog in all our large cities. If the fireplace was to continue to enjoy our confidence, the objections to its use must be met, and this could only be done by those whose business it was to construct fireplaces, and by those who had to use them, learning to understand more fully than they did the nature of the changes which occurred in an ordinary fire. They had had "smoke-objection exhibitions" all over the country, and at public meetings at the Mansion House and elsewhere the smoke-producer had been held up to universal execration; generally the comparatively guiltless manufacturer had been blamed, and the chief culprit,—at all events, in London,—the householder, had escaped notice. Only a few of the more far-seeing had pointed out the enormity of the aggregate effect of the petty misdeeds of which we were one and all guilty in this respect. It had been suggested that smoke-objection should be made compulsory by Act of Parliament, not only in the case of manufacturers, who undoubtedly, as a rule, were in a position to minimise, if not to altogether avoid, the pro-

duction of smoke, although often with very considerable difficulty and at some extra expense, but also in the case of householders. He imagined, however,—and he thought those present would agree with him after hearing his argument,—that the only effect of such legislation would be to promote the business of purveyors of reputed smokeless grates. The fact was that the production of smoke was inseparable from the use of bituminous coal in our grates, and it was idle to pretend that it could be avoided. This was but insufficiently understood, however, although it had been clearly recognised, for instance, by no less an authority on sanitary matters than Sir Douglas Galton, Sir Douglas, in the course of a lecture delivered at the Smoke Abatement Exhibition in 1882, said—

"Even if we succeeded in compelling all manufacturers to consume their own smoke, we should still have a very plentiful supply of smoke in the air of London and of every large town from the domestic fires; and we may be certain that if the smoke from domestic fires were stopped, the manufacturers would very soon follow the example, because the manufacturer is only one of the community, and smoke is allowed to exist because the community is not sufficiently educated as yet to realise the necessity of getting rid of it."

Sir Douglas Galton, both in that lecture and in a later lecture, delivered on December 1, 1887, at the Parkes Museum, had come to the conclusion,—which was the conclusion to which he (Professor Armstrong) desired to bring his hearers,—that there was no hope of solving the problem of getting rid of the nuisance unless they were content to abandon the use of bituminous coal. In order to make clear his first point,—that it was practically impossible to avoid producing smoke whatever grate they used so long as bituminous coal was burnt,—the lecturer pointed out that coal was the remains of the vegetation of ages long past, but of no ordinary vegetation. Most people knew how very differently logs or shavings of our common English woods,—beech, elm, or oak,—burnt in comparison with woods full of resin, such as pine. He illustrated the difference by burning pieces of ordinary cotton-wool and resin, and showed that the cotton-wool burnt with a perfectly smokeless flame, whereas the resin burnt with an intensely smoky flame. It might seem absurd to contrast such substances,—especially the wool,—with woods and coal; but, as a matter of fact, they were truly typical, inasmuch as vegetable structures generally largely consisted of what chemists called cellulose, which was known to them in an almost pure form in cotton-wool. In the case of most of our English woods the cellulose was not associated with resin, but most coniferous woods, such as pine, were rich in resin. The vegetation from which coal such as they usually burnt had been derived was, no doubt, highly charged with resinous matter, and when such coal was burnt it behaved very much as resin did. The consumption of coal in a fire was effected in two ways—at two distinct stages. In the first instance, the coal did not burn, if they used this expression in the sense in which it was commonly understood by chemists, but it underwent change in precisely the same way as it did when heated within a retort at the gasworks; its volatile constituents were given off: the contained resinous matters were volatilised, a complex series of changes taking place, and the volatile matters,—gases and vapours,—which were given off burnt with the bright smoky flame so familiar to and so loved by the Englishman. The coal which they usually burnt contained about 85 per cent. of combustible carbon, and 30 per cent., on the average, was volatile. The residual non-volatile matter or coke soon took fire, and, becoming red-hot, burnt away more or less rapidly provided the air had free access. Having illustrated the two stages by burning sugar and heating resin, the Professor proceeded to point out that the vapours which were given off in the first instance from coal were very much of the character of those which were produced on heating resin or bituminous shale, such as is so largely used in Scotland in the manufacture of lamp oils and paraffin. They were the vapours of hydrocarbons,—substances akin to ordinary petroleum and turpentine,—which burnt with a very smoky flame. Why did such substances burn with a bright smoky flame? The flame was bright in the first instance because it was smoky and hot. Vapours or gases which burned with smokeless flames did not give bright smoky because the hydrocarbons did not burn as wholes; the one constituent, the hydrogen,

was more combustible than the other, the carbon. Unless the vapour were intimately mixed with sufficient air to secure its complete combustion, it was impossible, therefore, to prevent the separation of some of the carbon as smoke, and the conditions which obtained at the top of a fire were such that combustion must be incomplete and must involve production of smoke. To burn turpentine completely its vapour must be mixed with fourteen times its bulk of oxygen. But the oxygen in air was mixed with four times its bulk of nitrogen, a perfectly inert gas, so $14 + (4 \times 14) = 70$ times its bulk of air at least must be mixed with the turpentine vapour. They succeeded in burning gas and petroleum without smoke production by very carefully so arranging the rate of burning, and so adjusting the supply of air, that complete combustion was secured. The gas flame had the form of a thin flat or circular sheet given to it, and a great surface was thereby presented by it to the air; and in a petroleum lamp not only was a particular shape of flame secured, but air was supplied by creating a draught round the flame by means of a chimney of proper size. Such arrangements could not very well be made, however, in the case of a fire. They could not well fix a glass chimney over it, and they had also to bear in mind that only one face of the fire was exposed to the air. In the case of a gas flame every face was exposed to the air. The combustion of vapours of hydrocarbons was rendered incomplete not only by the insufficient supply of air, but also by the cooling effect of air present in excess. When the carbon was once separated in the form of smoke it was very difficult to burn it. They were accustomed to think that carbon was a very combustible substance, but their ideas on that subject had undergone a complete change within the last few years: thus they had learned that the burning of the carbon was dependent upon water vapour being present. Hence it would be seen that many influences were at work in a fire to render combustion incomplete. In the first place, there was the shape of the flame; in the second place, the dilution of the combustible gases by the products of combustion from the fire below; and in the third place the rush of cold air, tending to produce the cooling effect to which he had alluded, rushing up the chimney. What remedies had been applied in order to meet these difficulties? How did the manufacturer prevent smoke? In the first place by never doing as they did in their domestic fireplaces—pitching on a scantful of coals. He fed in fuel gradually, and was careful to introduce air not only from below, through the bars of his furnace, but also above the fire at a point some distance beyond that at which the distillation went on. In the case of the domestic fireplace, the difficulty had been met by putting coal into a hopper at the back of the fire, or by feeding it in underneath, so that the volatile substances passed up through the fire. That was one method, and probably the most efficient method that had been contrived for getting rid of the smoke; but such an arrangement was only effective when they had got a good roaring red-hot fire. The harm was chiefly done in the morning when the fire was lit, and unless cinders were then used they could not prevent smoke being given off in the first instance. Another method was to introduce a sloping back and haffle-plate. A form of grate was described which was supposed to be a smoke-preventing one, having an air-chamber at the back of the fire, the idea being to burn the hydrocarbons at the top of the fire by bringing them into contact with fresh air. Such an arrangement might produce a certain amount of effect, but it could not produce any great result. In the official report of the Smoke Abatement Committee of the Exhibition of 1882, the results of a series of tests made with a considerable number of grates with reference to the prevention of smoke were given, and the difference between the worst and the best, after all, was very little. The worst had an average smoke shade of 3.2, and the best 2.6, so that after all the improvement was not very great. It followed, therefore, that bituminous coal must be abandoned if they wished to avoid smoke; they must be content to sacrifice the bright, cheerful flame over the top of the fire. It was one of those cases in which they could not have their cake and eat it. They did not want to raise the temperature of the air in rooms to any considerable extent, because, in the first place, hot air was unpleasant to breathe, and, in the second place, because

hot air produced an unpleasant effect on the skin. What they did want in their English system was to heat all the surrounding objects to such a temperature that heat radiated from them to persons in the room, instead of the heat radiating towards them. The lecturer proceeded to deal with the second stage, namely, the stage at which true combustion takes place in a fire. What happened? There was no production of smoke possible under these conditions, but they might be lost owing to incomplete combustion caused either by an insufficient or an excessive supply of air. Most of the grates in use in recent years were excessively wasteful, the either gave what everyone knew under the name of a black fire, and therefore did not radiate sufficient heat into the room, or excessive draught caused too rapid combustion, and great waste in consequence. The modern slow combustion stoves were an enormous improvement in this respect. Care was taken to control combustion at as slow a rate as possible in order to secure a good result, and that was done mainly by checking the draft. There was no least doubt that the mere introduction of a small baffle-plate was the secret of the success which had attended the introduction of modern stoves. The modern stoves were also very much better in the sense that all superfluous iron-work which tended to take away heat had been got rid of; any stove might be made a slow-combustion stove, in the very simple manner advocated by Mr. Prigden Teale in his book, "Economy of Coal in House Fires." He said that if they were to get rid of smoke at all, they must abandon the use of smoky coal. What, then, were they to use? They must use anthracite coal or coke. A good many people had had experience of these two forms of heating, and, I thought, were quite prepared to make selections, but there were many who had sentimental objections on the score that such fires had a bright flame playing over them. He himself during the last two years had been burning practically nothing but coke, and to him such a fire was certainly as cheerful as any ordinary fire. People generally, however, objected to the use of coke, and there was no doubt that it did require a certain amount of education. The most successful coke fire he had was one he made with a few bricks and a gridiron with very narrow bars as a front. That stove was capable of always exhibiting a perfectly brilliant red-hot face, provided the fire was not allowed to burn too low. It should be mentioned that Sir Douglas Galton, in the lecture he had previously referred to, said:—

"An open fire of smokeless coal, although it may have a glow, is not generally such a cheerful fire as a fire of bituminous coal; and, without care and a rapid draught, which is rarely attainable in the existing open fire-places, carbonic oxide is liable to be formed, and to come into the room."

He (Professor Armstrong) did not think these objections were serious. Architects as a rule had not been in the habit of providing ventilation in their own houses; the air was allowed to come in where it liked. But if the architect were to provide for the admission of air into the room at all times the objection would be dispensed. There was one other point to be called attention to in regard to the burning of smokeless coal and fuel, viz., that if they were to make some arrangement by which the air introduced at the front of the fire could be made hot they might secure a hotter fire. There were very many other points which, if time permitted, might be entered upon with advantage, but he would conclude by expressing the hope that he had succeeded in bringing home to the one point which he was anxious to make, that so long as they used coal containing volatile matter they could not hope by any practical arrangement to prevent smoke.

The fifth of this series of lectures was delivered on Wednesday evening last by Professor A. B. W. Kennedy, F.R.S., his subject being "The North Bridge," illustrated by a series of lantern views. Mr. Alfred Preston presided, and there was a crowded attendance.

The London County Council.—There was no business of special interest to our readers generally transacted at Tuesday's meeting of the London County Council, which was mainly occupied with a discussion of the provisions of the Bill promoted by the Council for the regulation and control of theatres and music-halls.

The "Hercules" Street-cleansing Machine.

THE "HERCULES" STREET-CLEANSING MACHINE.

We recently had an opportunity of being present at some trials of this machine on the roadways of Victoria-street, Westminster, and some adjacent streets in the locality. The locale was well chosen for such a purpose, for on the authority of Mr. Strachan, late Surveyor to the Chelsea Vestry, supported by our own observation, "as plentiful as mud in Victoria-street" is fast becoming not only a synonym for abundance, but a reflection on the scavenging operations of the local authority; whilst it is also somewhat of a satire on the municipal and other engineers whose offices so thickly stud this part of London.

The trials which we witnessed were very successful, and proved the capacity of the machine, which appears to be equally well suited for either asphalt, wood, or stone paving,—for any kind of road, in fact, but macadam. As will be seen by the accompanying illustration, the machine, briefly described, consists of a circular water-tank, with a revolving brush beneath it, there being a water-pipe or spreader pierced with fine holes, which travels in advance of the brush, and facilitates the operations of the latter. It seems to be quite clear to us that the continual use of this machine would not only keep our town streets clean and free from dust, but that it would confer a great boon on the horses, whose struggles and sufferings of late have been painful to witness, owing to the stiff, glutinous, pasty, greasy mud, which is very disgracefully allowed to accumulate with little or no attempt to remove it, being mostly left alone until the rain comes to wash it away. We are speaking of leading thorough-fares, such as Holborn, the Strand, Fleet-street, and Ludgate-hill. The sooner the local authorities adopt the lesson so clearly demonstrated by this machine, and use water in conjunction with the scavenger's brush for street cleansing, the better it will be for the public and their hardy-treated helpers, the horses.

Change of Address.—The United Asbestos Company, Limited, have removed from Queen Victoria-street to more commodious premises at Dock House, Billiter-street, London, E.C., lately in the occupation of the East and West India Dock Company.

ARCHITECTURAL SOCIETIES.

Birmingham Architectural Association.—At a meeting of this Association, held on the 21st ult., under the chairmanship of Mr. T. Naden, Mr. W. H. Kendrick read a paper entitled "Notes on Woodwork," which had been jointly composed by Mr. H. H. McConnell, A.R.I.B.A., and Mr. Kendrick. After a brief account of the history of the craft of the joiner, Mr. Kendrick described some local examples of his art, amongst them being the fine timber-built house of "The Oaks," at West Bromwich, which retains its artistic masses and outline and its delicately-finished details as designed by its original designer without any intervention on the part of the present day restorer. The internal fittings of Tong Church, near Shifnal, with its fine screens and beautiful stalls, which are particularly noteworthy for their harmony as a whole and for the everywhere varied detail of the parts and the screen in the south aisle of Hamstall Midway Church were given as examples of Gothic joiners' work in parish churches, and the west gallery in St. Peter's Church, Wolverhampton, as a typical example of seventeenth century work. The Bishop's throne in Lichfield Cathedral, of seventeenth century work, and probably erected by Bishop Hackett, was chosen as a final example of the noble woodwork of that period, and as being, with a few bench-ends, the sole remains of Bishop Hackett's fifty-stalls which had survived Wyatt's various efforts to beautify the cathedral. The paper was illustrated by a large number of exceptionally interesting drawings of these and other examples of woodwork in the district prepared by Messrs. Kendrick and McConnell.

Leeds and Yorkshire Architectural Society.—"The Revival of Applied Art" was the title of a lecture delivered before the members of the Leeds and Yorkshire Architectural Society, in the Law Institute, Leeds, on Monday evening, by Mr. Mervyn Macartney. Of the revival of applied art in England, said the lecturer, there was certainly no doubt so far as painting, sculpture, and architecture were concerned. Larger fortunes were made in those arts now in this country than ever before. But that did not necessarily show that the various arts were in a more flourishing condition than formerly. Painting was, or had been up to quite a recent date, very prosperous, as regarded material prosperity. That success was

to some extent owing to State patronage, and to artists producing what was eminently adapted to the wants of the present. The revival in sculpture was due largely to the same cause. Relatively sculptors had reached the highest average of excellence; and that, too, in spite of their being followers almost to a man of the Classic school, and not the popular realism of the Italians. As to architecture, he believed that there were never so many real architects as at the present day. He dwelt upon the relation of those arts to applied art, and referred to the dependence of the decorative crafts on architecture. People had found out that there was often more beauty in the thousand and one objects of every-day use than in the paintings that adorned their walls or the statues that graced the hall.

Liverpool Architectural Society.—At the meeting of this Society on Monday evening last a paper was read by Mr. James M. Hay on the "Decorative Panels of St. George's Hall." The history of the panels was given from the time when the first panel was set up in 1835, the adverse criticisms which it drew forth from all sides, its disapproval by the Council of this Society, and its forwarding the same to the City Council; the setting up of the second panel, and (for the first and only time) a description of the work and the intentions of the sculptor from the pen of Professor Conway, published in the *Liverpool Daily Post* in December, 1887. Mr. Hay strongly criticised the panels, which, he contended, ought to have been in high relief, and attached to the field of the panel, not set on a shelf or ledge. The figures are too tall for the place they occupy, and there is a paucity of oblique lines in the composition. The figure of Joy should have been merrily skipping along in front of the procession, strewn her flowers, and not standing sulking in the rear. The nude in both panels is forced and unnatural, and instead of heightening, seriously detracts from artistic expression. If the child Justice, in the first panel, had been provided with a short skirt, and the naked female figure in the second clothed in the fine Classic tunic of the Greeks, veiling without concealing the beauty of the form, the idea of "purity" would have been better symbolised, the art would have been finer, and public decency would not have been outraged. The work altogether betrays the pernicious influences of the realistic school that is doing so much in France to degrade both her literature and her art. Allusion was made to the generous and public-spirited offer of Mr. Philip Rathbone to pay the expense of completing the four remaining panels of the series. But Mr. Rathbone forgot that it was not the cost, but the unfitness of the panels that prompted the City Council to discontinue the work, and this the generous offer in no way changes. It was inconceivable that a Corporation which has spent 300,000 on a building would grudge a paltry thousand towards its completion. In conclusion, he considered that it was an injustice to one of the finest buildings in the city that those panels should remain a patch and disfigurement on the face of it; that it was an injustice to the memory and fair fame of Elmes; that it was an injustice to the citizens of Liverpool, and an outrage to public decency; and that they should respectfully ask the City Council to take immediate steps to have the offending panels removed and the stone imposts restored before any further arrangement was entered into with any sculptor.—A discussion followed, but no practical result was arrived at. [We print a *resumé* of the paper, to show what some Liverpool critics are capable of in regard to this matter. The idea that the French, who are far at the head of the whole world in imaginative sculpture, are degrading the art by realism, is truly delightful.]

Sam Deards & Co., Limited.—The report of the Directors of this Company, submitted to the shareholders at the first annual general meeting, held on Monday, the 24th ult., congratulates the shareholders on the accounts showing a profit of nearly 12½ per cent., after paying all expenses and allowing for depreciation of the patents, &c. The Directors, having regard to future operations of the Company, recommended that a dividend of 7½ per cent. be declared, and that the balance be carried forward. We are asked to add that the unallotted shares in the Company are being issued, and any one applying for same must do so at once to the London offices of the Company.

BUILDERS' CLERKS' BENEVOLENT INSTITUTION.

THE twenty-third annual general meeting of the donors and subscribers took place on Tuesday, March 4, at 21, New Bridge-street, E.C., Mr. H. E. Bartlett (President-elect) occupying the chair, supported by Mr. E. Brook (Treasurer), M.srs. E. C. Roe, H. W. Parker, C. K. Tarpin, J. Robson, T. H. Winny, E. B. Gammon, A. A. Stanger, W. D. Gilbert, and other gentlemen.

Mr. Wheatley, the Secretary, read the report, which stated that during the past year the income had been well maintained, the amounts being 288*l.* 12*s.* annual subscriptions, 317*l.* 1*s.* donations, and 98*l.* 7*s.* 5*d.* dividends; total, 704*l.* 18*s.* 5*d.* The expenditure was 472*l.* 11*s.* 7*d.*, of which amount 377*l.* 18*s.* 4*d.* was for pensions and temporary relief. Two elections had been held, the result being that Mrs. Charlotte Tucker and Mrs. Susan H. Fisher had been added to the pension-list. One pensioner, Mr. J. T. B. Miles, had died during the year, leaving a present total of nineteen pensioners now on the books, and three children at the Orphan Working Sch. of, per presentation of the Institution. The seventh annual dinner took place at the Holborn Restaurant on April 2, 1889, Mr. John Aird, M.P., presiding. The attendance was very large, more than filling the Venetian Chamber, and, as the result of the Chairman's appeal, subscriptions and donations were announced amounting to 350*l.* This sum included a large number of contributions from the builders' clerks themselves. The Committee return their best thanks to Mr. Aird for his kindness in having served the Institution as President, and for his handsome assistance in support of the funds. A further purchase of stock had been made during the year, bringing up the total of invested funds to 3,650*l.* The committee announce with great regret the death of Mr. Charles Richardson, one of the trustees, and also vice-president of the Institution. Mr. Richardson had been a regular and liberal supporter of the funds from the foundation to the period of his lamented decease. The report concluded by thanking the master builders, architects, and merchants connected with the building trade for their past help, and by expressing the hope that the same would be continued, to the end that the usefulness of the institution might be well maintained.

The Chairman, in moving the adoption of the report, expressed the pleasure it gave him to meet the subscribers and donors, and to find the Institution in such a flourishing condition. Much had been done during the past year in assisting widows and those who needed relief, additional funds had been invested, and the balance at the bank was satisfactory. He hoped to do what he could for the welfare of the Institution, and trusted that at the close of his year of office the funds would not be in a less satisfactory state than at present. He had much pleasure in proposing "That the report and balance-sheets, as read, be adopted and printed, together with the list of subscribers and rules of the Institution."

Mr. E. B. Gammon seconded the resolution, which was put from the chair and duly carried. Mr. E. C. Roe, in proposing a vote of thanks to the ex-President and other retiring officers, remarked that Mr. Aird's parliamentary and other duties had prevented his attendance at the ordinary committee meetings, but he had done the Institution good service in having acted as President. As to the future, there was one thing to consider with reference to the increasing number of pensioners, and that was the importance of adding to the invested funds, so that a steady income might arise from that source.

Mr. Stanger seconded the motion, which was carried, Mr. C. Brown replying on behalf of Mr. Aird and the other retiring officers.

Officers for the present year were then elected, and Mr. Brooks (the Treasurer) spoke in complimentary terms of Mr. Bartlett, who headed the list, and also referred to the valuable services rendered by some of the members who had already served, and whose names were included amongst those re-elected that evening.

On the motion of Mr. Gilbert, seconded by Mr. Stansfeld, a vote of thanks was presented to the Chairman, who, in replying, said that although he was a busy man, with not much time to spare, he yet hoped to come amongst them, and what he could do to the help of the Institution he would do with pleasure.

The proceedings then terminated.

BUILDERS AND THE SANITARY INSTITUTE.

SIR,—I feel sure that the remarks of "Builder and Decorator" in your last issue [p. 158] will meet with approval, and for one I wish to give more than tacit assent to the same by now to this expressing my agreement with him as to the good policy (say nothing of more sentimental reasons) of the Sanitary Institute providing such a curriculum as to meet the requirements of various trades, and at the same time satisfy the demand so rife at the present moment, which is made by both the young "go-with-the-times" tradesman and the "alive-to-

own-interests" general public, for certificates or evidences of technical knowledge.

Sanitary science is recognised as of the highest importance (richly so), and it would be well for the public, and equally well for those who give the subject their careful attention, if builders were expected to have more acquaintance with the rules and principles, which often suffer in their hands, from no bad intention, but from lack of information.

I have many times advised anxious inquirers to get the prospectus of the Sanitary Institute, and take up the subject; but have always allowed the objection to have weight,—viz., that the demands of the Institute took them over studies they could not appreciate and should never benefit by.

Whole sections of the Public Health Act could be spared the builder, and many Acts,—notably the Rivers Pollution, Canal Boats, Food and Drugs, Nuisance Removal, &c.—might be entirely passed over for something more practical in the shape of building construction. For a builder or tradesman it would be waste of time to study the Acts above-named, and would only encourage cramming, of which there is already too much.

The plumber is provided for by registration, and other branches of the building trade with similar helps by the City and Guilds and South Kensington Institutions; but it does seem to me to be eminently the work of the Sanitary Institute (if it will rise to its own position) to monopolise the particular field which is opening before it, and meet the public demand.

The Sanitary Institute has the machinery and the public confidence, and I see no reason why the builder's certificate would not be as much sought after and be as much appreciated as the ever-growing and popular one which they now give,—the Inspector of Nuisance Certificate.

AN ASSOCIATE OF THE SANITARY INSTITUTE.

VALVES TO FRESH-AIR INLETS.

SIR,—In regard to the use of valves on the fresh-air inlets to drains, I may say that for the hundreds and thousands of fresh-air inlets I have put in or caused to be put in I could not put to half-a-dozen cases where valves have been used for such. In some odd cases they are used, however, & I had a side fresh-air inlet into one of my drains, for a drain where the inlet grating was on the ground beside a lawn-tennis green. In that case it was considered advisable to put in a valve to let air in but to shut against air coming out. In cases where the fresh-air inlet is in the face of the wall of house, say, about a foot above ground, and close to a door or window, or between both and close to them, then it is a good precaution to put in a valve, but such need not be dead-tight.

W. P. BUCHAN.

Glasgow, March 1, 1890.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—X.

LAW OF THE ELECTRO-MAGNET.

THE simplest form of electro-magnet consists of a cylindrical bar of soft iron, surrounded by coils of insulated wire. When a field as intense as possible, but of limited volume, is required for practical purposes, the bar is bent into the horse-shoe form, with the ends facing each other, and the flux between these two polar faces made up of.

Many endeavours have been made to find some simple relation between the ampere-turns in the coil or coils and the strength of the magnet produced by them.* Dr. John Hopkinson published the results of a valuable investigation on this subject in 1855. It is disappointing to find that apparently before it would be possible to predict, with absolute accuracy, to what extent a given number of ampere-turns would magnetise a piece of iron, the whole previous history of the metal would have to be known. It is, however, possible, by taking mean values, to easily arrive at results which are very near the truth, and which are, moreover, sufficiently accurate for practical engineering purposes. What, therefore, is given as the law of the electro-magnet must be accepted with this reservation.

The field produced by an electro-magnet at any point can be measured in various ways, for instance the strength of the field of a dynamo-machine can be determined by finding the electro-motive force set up in its moving conductors as they cut the lines of force with a known velocity; or the field may be compared with one of known strength by means of an ordinary magnetometer. As, however, full details are to be found in all books specially devoted to practical electrical and magnetic measurements, it is unnecessary to give here any

* An interesting summary of the formulae suggested by various investigators is given in Thompson's "Dynamo-Electric Machinery."

detailed description of how the measurements may actually be made.

When two quantities vary together according to some law the mathematical equation which is not known, the results obtained are best shown by means of a curve. In the case under consideration the magneto-motive force of the coils is laid off along the horizontal line OX, and the flux produced along the vertical line OY, some convenient scale being chosen.

Fig. 24.

Suppose an M.M.F. equal to OM₁ produces a flux equal to OF₁, then a point P₁ in the curve is formed by raising a perpendicular M₁P₁ equal to OF₁, or the same point may obviously be got by drawing a F₁P₁ equal to OM₁. When a sufficient number of data have been got from actual experiment a series of these points are found and a curve drawn through them. Such a curve will enable us to find by means of a T-square and pair of dividers the flux produced by any particular M.M.F. or the M.M.F. required to produce the flux needed. As a simple example, let it be desired for some purpose to produce a flux value represented by OF. With the dividers measure off the length OF along OY, & means of the T-square draw a perpendicular through F until it cuts the curve in P, the FP is the M.M.F. required to produce the flux wanted. The equation expressing the relation between M.M.F. and flux is the equation to the curve in rectangular co-ordinates. What the equation is has yet to be found, and when found it will be too complicated to be of very much practical use, although certain approximate expressions are of service to those who do not care to use graphical methods. In the figure only three points, P₁, P₂, P₃, are drawn; it would, of course, be impossible in practice to accurately draw the curve through but three points, & great many more experiments than three must be made.

The curve of magnetisation for the electro-magnet having been found, remove the iron core and determine the points P₁, P₂, P₃ for the "soft core"; it will be found that the flux is in excess much less than when the iron was present, but that the curve for air is a straight line, since OM₁:OM₂:OM₃:M₁P₁:M₂P₂:M₃P₃.

The results shown, recorded by means of the straight line OA with air alone, and the curve OI with iron placed inside the coils, may now be considered in connexion with the magnetic circuit; the form of magnet shown in figure

Fig. 25.

is made to closely represent a portion of a circuit such as is to be found in practically all dynamo machines and will, therefore, be of use in considering the actions of these machines in later periods. Everyone who has been to an industrial exhibition of late years must be familiar with the general appearance of dynamos that are always on view. Apart from details, a dynamo-machine consists essentially of two parts, the field-magnets and the armature. As a rule, the magnets are attached to the bed of the machine, while the armature revolves; but, since relative motion alone is necessary, some makers prefer to keep the armature stationary and revolve the field-magnet or magnets, to which we

at present confine our attention, consist of a single horse-shoe, or is built up of a combination of such magnets. Fig. 25 may therefore be taken as an elementary form of this part of a dynamo; it represents an iron core of uniform cross section (S) bent so that the polar faces are opposite each other, the limbs being wound with suitable coils of insulated wire.

Returning to fig. 24. We may suppose that the points on O A were obtained from experiments on the coils alone, before they had been placed on the iron cores. Let M = M.M.F. in any one experiment, F' the flux, and R' the magnetic resistance of the air throughout the circuit, thus:—

$$R' = \frac{M}{F'}$$

but when air alone was in the circuit, $\frac{M}{F}$ was found to be a constant, no matter how the values of M and F' are varied, hence the specific magnetic resistance of air is independent of the flux passing through it. When, however, the iron cores are in use the points P, P', P'', &c. do not lie in a straight line, but along a curve O I, and the general shape of this curve shows that the magnetic resistance of iron increases as the flux passing through it increases. In other words, the value of μ for iron decreases as the metal becomes more intensely magnetised.

Since the resistance of any circuit is equal to the M.M.F. divided by the flux, the resistance in any particular case can be found; if from this be subtracted the resistance of the air, the remainder will clearly be that of the iron, and from the quantity so obtained the value of μ can be easily got by means of the formula already given. As, however, the calculation of the air-resistance presents mathematical difficulties owing to the way the lines of force spread out in curves, it is customary in making experimental determinations of the value of μ on a sample of iron for different degrees of magnetisation to make the circuit as nearly as possible entirely of iron, only a comparatively narrow slit of air-space being left for the purpose of getting at the flux to measure it. Since the lines of force will go nearly straight across the air-space, its resistance can be allowed for, and only an extremely small error introduced.

This subject is of such pre-eminent importance that it is worth while to give a numerical example by way of illustration. In fig. 25 suppose the core of the magnet to be made of a bar of annealed wrought-iron, of which the cross-section (S) is 5 square centimetres, and the average length (L) 20 centimetres. Between the two centres long (L), cut from the same bar, the air-space on each side being (d) 0.1 centimetres across. We will calculate how many ampere-turns (A) will be required to send a flux of 38,000 lines through the block. Two assumptions, neither of them perfectly true, will be made—firstly, that lines of force which go across the air-spaces are straight; secondly, that lines do not leak across the limbs of the magnet. Employing the symbols already used, the resistance of the iron portion of the circuit is $\frac{L}{\mu S}$ that of the two air-spaces $\frac{2d}{S}$ hence

$$F = \frac{4\pi A + 10}{\frac{L}{\mu S} + \frac{2d}{S}} \quad \text{that is, the flux is}$$

equal to the M.M.F. set up by the coils, $\pi A + 10$, divided by the total magnetic resistance of the circuit, or

$$A = \frac{10 F}{4\pi S} \left\{ \frac{L}{\mu} + \frac{2d}{S} \right\} \dots \dots (1)$$

Now, F is to be 38,000, that is, 9,000 lines per square centimetre, and, on referring to tables of experimental results, it will be found that under these conditions the value of μ for annealed wrought-iron is about 2,250, substituting these various values in equation (1).

$$A = \frac{10 \times 38000}{4 \times 3.142 \times 5} \left\{ \frac{20}{2250} + \frac{2 \times 0.1}{5} \right\}$$

$$\log 18000 = 4.2553$$

$$\log 472 = 2.6739$$

$$\log 3.142 = 0.4972$$

$$\log 2250 = 3.3522$$

$$\log 3.8491 = 0.5838$$

$$\log 3.0798 = \log 3.1021$$

$$\therefore A = 1201$$

RECENT PATENTS. ABSTRACTS OF SPECIFICATIONS.

4,698, Marble-pattern Papers. W. B. Blaikie and Others.

This invention 'comprises a new or improved system for producing marble-pattern or such like papers by printing them from metal plates or blocks made so as to give a finer effect than the ordinary mode of producing such blocks, and to enable the same pattern to be represented any number of times and in any variety of colour, and with lines, shadows, or relief effects. The printing-blocks are of soft metal, run so as to produce a mottled or marble effect.

4,958, Glazed Structures and Sash-bars. W. Lindsay.

The sash-bars, which are the subject of the patent, are made with ratchet-like teeth projections or corrugations upon the rib, serving to give a better hold to the putty, or with enlargements along the outer edge of the rib of the sash-bar for a similar purpose and to support strut-pieces. In glazed structures the glass is sometimes held in place by the strut-pieces so attached.

5,083, Improvements in Water-closets. W. Dunn.

The object of this invention is to construct water-closets in such a manner that they occupy but little space and can be hidden from view when not used. The pan and seat are hinged to the upper part of the syphon or water-cast trap by means of a horizontal axle and hutch-hinge placed immediately underneath the pan, and the sides of the syphon extend upwards beyond the hinge, so as to overlap and cover the sides of the pan. A flushing-basin is fixed above the pan and fits into it when the latter is turned up into its vertical or folding position. The whole apparatus is preferably enclosed in a rectangular frame fixed in a recess in the wall.

6,152, Ventilator. W. C. Williams.

According to this invention, an ornamental and efficient ventilator is made of earthenware or iron; the outer face being an ornamental plate with openings, and in the centre an ornamental solid piece with two arms which act as detectors; the inner part is of a box-like form at each end, with a passage out towards the centre. The air blowing straight against the ventilator is deflected by the wings, and passes around each of the chambers before it can pass through the central passage into the buildings.

19,611, Bench Plane. J. Crane and W. H. Winkle.

The plane-iron, which is the subject of this patent, is secured by a lever, which, being down in the front of the body of the plane, forms a forward handle, while the plane is worked by this and a wood handle at the back end of the plane. The cutting-irons are immediately released on raising the handle or lever.

20,452, Metallic Lathing. G. Hayes.

In order to better hold the plaster, the metallic sheet is, by this invention, stamped or punctured with holes, to each of which two small tongues or strips of metal are made by the process of punching out. These tongues, being bent into a hook or clip form, serve to retain the plaster, which, when applied, completely surrounds them, so that they become embedded therein. The plaster also sets into the apertures, and, protruding at the back of the lath, forms into knob-boutons, thus affording a more secure hold.

MEETINGS.

SATURDAY, MARCH 8.
 Architectural Association.—Visit to Mr. Seading's new church, Stann-street.
 Royal Institution.—The Right Hon. Lord Rayleigh, M.A., F.R.S., on "Electricity and Magnetism." IV. 3 p.m.
 Junior Engineering Society.—Visit to the London Hydraulic Power Company's Pumping Stations. No. 1 at Falcon Wharf, Blackfriars (near the bridge). No. 2 at Millbank-street, Westminster (near the Houses of Parliament).
 Edinburgh Architectural Association.—Visit to Free Library and Old University Buildings.

MONDAY, MARCH 10.
 Surveyors' Institution.—Mr. T. W. Wheeler, Q.C., on "Bettlements." 8 p.m.
 Institution of Civil Engineers.—Students' visit to the a.s. Juvana. 12 noon.

TUESDAY, MARCH 11.
 Society of Arts (Applied Art Section).—Mr. James Orrock, R.L., on "The Claims of the British School of Painting to a thorough Representation in the National Gallery." 5 p.m.
 Institution of Civil Engineers.—Discussion on the following papers (1): "The Hawkesbury Bridge, New South Wales." By Mr. C. O. Burge. (2) "The Construction of the Buffin Bridge over the Gauges at Benares." By Mr. F. T. G. Walton. (3) "The New Blackfriars Bridge on the London, Chatham, and Dover Railway." By Mr. G. E. W. Craitwell.
 Sanitary Institute (Lectures for Sanitary Inspectors).—Mr. Charles E. Cassal, F.C.S., on "Food (including Milk), Sale of Food and Drugs Act." 8 p.m.

WEDNESDAY, MARCH 12.
 Society of Arts.—Sir Douglas Galton, F.R.S., on "The Chemin De Fer Oisants, or Sliding Railway." 8 p.m.
 Architects Benevolent Society.—The Fortieth Annual General Meeting of the Subscribers and Donors. 5 p.m.
 Free Lectures in Art.—Professor Marshall Ward, M.A., on "The Tree, from the Sapling to the Bench." Carpenter's Hall, London-wall. 8 p.m.
 Sanitary Institute.—Mr. W. Kimmimond Barton on "The Sanitary Condition of Japan." 8 p.m.
 Liverpool Engineering Society.—Adjourned discussion on Mr. C. H. Yeaman's paper on "Central Station Electric Lighting." 8 p.m.

THURSDAY, MARCH 13.
 Institution of Electrical Engineers.—Adjourned discussion on (1) Mr. J. Swinburn's paper on "The Theory of Armature Reaction in Dynamos and Motors"; (2) Mr. W. B. Esson's paper on "Some Points in Dynamo and Motor Design." 8 p.m.

FRIDAY, MARCH 14.
 Architectural Association.—Mr. Henry Holiday on "Mohrism in Art." 7.30 p.m.
 Sanitary Institute (Lectures for Sanitary Inspectors). Mr. Shirley F. Murphy on "Infectious Diseases and Methods of Disinfection." 8 p.m.
 Junior Engineering Society.—Mr. A. H. Tyler on "Hydraulic Machine Tools." 7.45 p.m.

SATURDAY, MARCH 15.
 Royal Institution.—The Right Hon. Lord Rayleigh, M.A., F.R.S., on "Electricity and Magnetism." V. 3 p.m.

Miscellaneous.

"Fresco-Cement."—On Wednesday, March 5, Mr. Edwin Lucas read an interesting paper before the Civil and Mechanical Engineers' Society (Mr. H. Adams in the chair) on a new medium for fresco-painting, called "Fresco-Cement." The composition, invented by Mr. Kreymer, consists largely of tufa, together with Portland cement and lime, and the patentee claims for it that being hydraulic, absorptive, and acid-proof, it is absolutely unaffected by the severest climate. The author gave a highly interesting *resumé* of the history of the art of fresco-painting, and of the various methods employed by great Italian masters, by the modern German school, and by artists in this country, dwelling on the great difficulties with which votaries of the art had to contend, on the elaborate nature of the processes required, and the want of permanence in the completed work. In illustration of the last defect, especially in our climate, he pointed to the fact that English artists had from the twelfth century devoted great attention to works of this nature, and asked, "Where are those works now?" He then proceeded to quote a favourable report from Mr. H. Fajja, M.I.C.E., who had tested the strength of specimens which had been immersed in water for ninety-eight days. The average tensile strength of five specimens was found to be 312 lbs. per sq. in. The paper concluded with a practical demonstration of the extreme simplicity of the process by means of the portable fresco panels, which form a striking feature of the new invention.

The English Iron Trade.—The English iron market has not improved during the past week; if anything, it is rather flatter. There is also still the difficulty with the miners, the London conference having proved a failure, and this result cannot fail to disturb the iron trade. The Durham miners, on their part, have settled with the masters by accepting an advance of five per cent., and there is still a chance of wiser counsels prevailing in the southern coal-fields. The course of the warrant market continues downwards, and Scotch makers have followed by further lowering quotations. Although Cleveland pig-iron has been sold at 62s. and 51s. 9d. by merchants, makers hold on to 60s. Producers elsewhere are easier in their prices, yet not to the extent expected by would-be buyers. Makers of Bessemer iron in the north-west have gone back 5s. a ton, to 75s. Old materials have experienced a considerable drop. Manufactured iron is quieter, and lower in price in Scotland and the north of England, but steady further south. Steel can be bought at lower figures generally, rails especially. Orders for new ships are not to be secured at present, but builders have plenty to do. Engineers continue fairly busy; there is, however, a falling-off in new work.—Iron.

Drainage of Cairo.—We understand that Mr. Baldwin Latham, who left England early in November to advise the Egyptian Government as to the drainage of Cairo, has recommended a scheme for the sewerage of the city on the hydraulic system, at an estimated cost of 565,700*l.* That sanitation is receiving very great attention at the present time in the East, is evidenced by the fact that Mr. Latham, whilst at Cairo, was requested to extend his journey to Bombay, and has since been asked to advise as to the sewerage and water-supply of several other towns. Mr. Latham will have completed his investigations at Bombay shortly, and is expected in England about the middle of April.

Obituary.—The "Dombanmeister" of Strassburg, Herr A. Hartel, died last month, a few days before his forty-seventh birthday. He was known to be one of the first, if not the first, Gothic architect of the day in Germany; and his name is to be found among the winners of nearly all the great competitions of the last fifty years. He had only occupied his present post some twelve months, and it will be difficult to find so snitabile an artist to fill up the very important vacant place at Strassburg.

East Dereham Local Board.—The work of repaving the town has just been completed by the contractor, Mr. W. D. Hubbard, of East Dereham, the material used being the Imperial stone paving; in addition to this, granite channelling has been laid to the principal streets—the total cost being about 1,900*l.* The works were carried out under the directions of the Surveyor to the Board, Mr. F. W. Skipper.

Surrey Archaeological Society.—At a recent annual meeting of this Society, held at Wandsworth 26 ult., at 8, Dames'-lan, Strand, J. W. Butterworth, F.S.A., president, Mr. J. Stephenson, F.S.A., hon. secretary, read a report of the Council, which stated that the appointment of a new Hon. Secretary in the place of Mr. T. Milhourn, resigned, having been referred by the last annual meeting to the Council, they, at a special meeting, held Mar 20, 1889, elected Mr. Mill Stephenson, F.S.A., and the Rev. T. S. Cooper, M.A., as Joint Hon. Secretaries. The question of the removal of the headquarters of the society to Guildford had also been referred to the Council, and a special committee was appointed to consider it. The committee had a conference with the Mayor and Corporation of Guildford with regard to the tenancy of a house in Castle-street, and it was determined to wait until such time as the house in question should be vacant. At the afternoon meeting of the Society was held Wandsworth on June 1, under the presidency of Viscount Milderay. The Mayor, Hon. Church, and Public Library were visited, 70 papers on their read. The annual extract fixed for July 25, at Limsfield and Tithe had to be abandoned at the last moment owing to the sudden death of Mr. Romley Leveson-Gower. The Council regret that it was found impossible to arrange another such short notice, and hope to be able to hold one or more afternoon meetings during the coming summer, in addition to the annual excursion. Part 2 of Vol. 9 was issued to members in June last. The volume for the year 1890 is now in the printer's hands, and will be issued in due course. The Council hope to be able for the future to publish with regularity. During the year vacancies have occurred on the Council; the death of the Rev. J. M. Balthwate, M.A., Vicar of Croydon, and Lieut. Colonel Eustace Ansdon, Mr. John Clark Scott, F.S.A., has elected a member of the Council. The number of members now is 302. The reserve fund consists of 338*l.* 13s. 3d. The library continues to increase by exchange with societies in north and has also received several gifts from members. The Council has determined to proceed at once with a catalogue of the church plate of the county. The Rev. T. S. Cooper, M.A., of the hon. sec., and a small committee in the matter in hand, and are now engaged drawing up a circular to issue to the clergy. The Archbishop of Canterbury, the Bishops of Rochester and Winchester, and the Archdeacon of Surrey, Southwark, and Kingston-on-Thames have signified their approval of the scheme. The Council appeal to members for help, visiting the various districts, &c. Any member willing to assist are requested to communicate with the hon. sec.

Christ Church, Bristol.—The new organ gallery at Christ Church, Bristol, is to be decorated with a series of eight carved panels, four of these have just been fixed in position. One of them represents St. Cecilia seated at an organ, attended by St. Urban. This has been given to the church in memory of the late Rev. Benson. The other is a fine group, illustrating the Shepherds and the Herald Angel. This forms the centre or principal panel. The panels are the work of Mr. George Honghton of the Society of Bristol Sculptors.

"Gothic Architecture."

O much has been said and written of late years on Gothic architecture, and so much done in its illustration, that it is perhaps hardly possible for a new writer to hope to draw attention to new disquisition on the subject except by being paradoxical. We do not quite make out whether Mr. C. H. Moore's book,* which dates from the (now) æsthetic shades of Cambridge, Massachusetts, and is published on both sides of the water, is intended more especially for English or for American readers. If for the latter, and if it be adopted as a text-book by them, it is rather a dangerous one, since it takes a very one-sided view of the subject. If it is intended for English readers, it can hardly be a success, for a great deal of the reasoning about Gothic architecture, which is put forth in the book with much solemnity and importance is so familiar in England now that it is almost a commonplace: and the greater part of what is new in the book will be at once recognised by English readers as, if not paradoxical, at least involving a curiously distorted representation of the facts in order to support an adopted theory.

We may admit at once that the book is both ably written and well illustrated, and that there is evidence of great pains and study having been given to its production. The author evidently writes for the most part from direct study and observation of the buildings referred to, and many of the excellent illustrative sketches with which it abounds are reproduced from his own drawings made on the spot. It is essentially a student's book, not one for the general public, who will not be likely (in this country at least) either to understand or care for the demonstrations and diagrams of various methods of vaulting and buttressing. It is perhaps as well they should not, for if a book like this became popular at Mudie's, we know very well that the paradoxical and heretical element in it is exactly what the general reader would lay hold of at once, and parrot

about everywhere. Architectural students are not liable to be carried away in the same manner.

The author appears to have laid out his book with the special object of showing that there is, properly speaking, no Gothic architecture at all out of France. In leading up to this position he goes into a demonstration of various critical views which may possibly be new to American readers, but are certainly not new in England. That the pointed arch is not an entirely essential element in the character of Gothic architecture has been long recognised, though it must still be held that its employment in place of the round arch constitutes so important a change in the architectural expression of a building as to justify the strong line of demarcation which was drawn by Rickman and succeeding classifiers of Gothic between the round-arched and the pointed periods. That France is the central home and birthplace of Gothic architecture has been also long admitted in this country. But Mr. Moore is satisfied with nothing less than denying the term "Gothic" to either English or German architecture, on grounds which have no doubt a show of logic as the writer puts them, but which show is mainly achieved by putting undue stress on a single element in architecture, and shutting the eyes to a number of others which, if they are none of them, perhaps, as important separately as the one which the author emphasises, are collectively of the highest importance in their coordinate effect upon style.

The proposition which Mr. Moore lays down is that Gothic architecture is essentially a system of building by equipoise, of reducing all the walls to the mere skeleton framework which is necessary to construction; of treating all this structural framework, architecturally, in such a manner as to express its function, and admitting no members into the architecture which do not form an expression of constructive function. In leading up to this conclusion the author goes through the old demonstration of the gradual development of the buttress system from the Roman through the Romanesque to the fully developed Gothic, much as it has been illustrated by other writers before him; his demonstration is clearly made, but contains no new point of any kind. The special point in his deduction is that, instead of regarding Gothic architecture as a special and recognisable artistic form of architectural design, he regards it only as consisting in a particular form of building, represented by the typical French cathedral.

It is, he tells the reader, a building in which the plan consists of a nave and side aisles, terminated eastwards either by a polygon or a semicircle around which the aisles are continued. "The vaults are furnished with a complete set of ribs—namely transverse ribs, diagonal ribs, and longitudinal ribs. These ribs are independent arches, of which the transverse and longitudinal ones are pointed, while the diagonals are usually round; and upon them the vault masonry rests—the one never being incorporated with the other. The ribs spring from slender shafts, compactly grouped, and often detached, though having their bases and capitals incorporated with the great piers which rise from the pavement, through the successive stories, to the nave cornice. . . . Upon the piers are concentrated all the side pressures of the vaults, but these side pressures are so neutralised by the buttressing that the piers require only to be massive enough to bear the weight of the vaults. The clearstory buttresses, which receive the thrust of the nave vaults, are reinforced by flying buttresses springing over the aisle roofs, and rising from the vast outer buttresses, which are incorporated with the respond piers of the aisles. The walls, required for enclosure only, are reduced to a minimum of thickness, and are confined to the ground story, and to the spandrels of the arcades."

These sentences form the salient portions of a series of definitions of Gothic architecture, of which we have not space to quote the whole. The author adds, "It will thus be seen that the full development of the Gothic system is brought out only where the plan of the building includes a central nave and side aisles." No doubt the full system of building by equipoise is only fully developed in such a building; and Mr. Moore adds, as will be seen above, that a Gothic building has a polygonal or semi-circular termination eastwards. That is to say, a Gothic building is a French cathedral; and we observe in fact that in another portion of the book the author distinctly asserts that Gothic is a church style only, and was only developed in ecclesiastical buildings, and apparently only in French ecclesiastical buildings, and of these, only in three-aisled buildings! The Sainte-Chapelle, he graciously admits, is Gothic as far as it goes, or at least such a building "may be" Gothic, but only in an inferior sense. Only by the use of the flying buttress, in connexion with that of the pointed arch in the ribs of the vault, "is

* Development and Character of Gothic Architecture. By Charles Herbert Moore. London and New York: Macmillan & Co., 1890.

the Gothic attenuation of supports rendered possible."

The plain meaning of all this is that the author has carried to excess an important principle in regard to the definition of architectural style, which was no doubt comparatively neglected and passed over by English architectural critics earlier in the century, viz.: that a true style demands the consistent carrying out and expression of one predominating principle of construction. It is true that this consistency of construction and of constructive expression is the most important element in style. But to select one form only of that construction, to ignore all others, and to ignore the whole combined effect of detail, general design, and feeling, in influencing and giving distinctive character to a style, is to carry this constructive logic to an absurd and unphilosophical excess. It reduces itself, in fact, merely to a readjustment of nomenclature. We have been accustomed to apply the term "Gothic" to a certain style of architecture prevalent over great part of Northern Europe during the Middle Ages, and the main characteristics of which, some of them capable of distinct definition, some of them rather felt by the perception than definable in words, are quite familiar to all who have paid any attention to architecture and architectural style. No one who has done so has any doubt as to the kind of architectural art represented to his intellectual perception under the term "Gothic architecture." Mr. Moore proposes to restrict this nomenclature from henceforth to one class of buildings, the construction of which shows the most complete carrying out of the constructive system of equipoise of weights. All the other innumerable buildings in which this system has not been carried out fully and on the same plan are not Gothic. Then what are they? We presume King's Chapel is architecture; architecture moreover of remarkable completeness and consistency of design. If it is not Gothic, what is it? Is Mr. Moore prepared with a new nomenclature? Or what is Cologne Cathedral? or the west front of Peterborough (a somewhat important architectural production)? Mr. Moore, self-satisfied and dogmatic as he is in his style of writing, can hardly expect that the world will allow him to sweep away these buildings, and Lichfield, and Lincoln, and Canterbury, and Salisbury, &c., &c., out of the category of architecture (Westminster we observe he gives a kind of grudging allowance to, because it resembles French work to some extent). Then what style are they?

Gothic architecture is the great antithesis to Greek in the history of the art. The absurdity of Mr. Moore's manner of reasoning and classifying as to style may be best shown by applying a similar logic to Greek architecture. Let us say, then, that Greek architecture is represented by a type of building of entirely trabeated construction, consisting of an oblong chamber called a *cella*, enclosed by solid walls, sometimes divided into two apartments by a cross wall; it is surrounded externally by a colonnade of columns standing free, and supporting also cross lintels from the wall of the *cella*, which carry a coffered ceiling, the whole forming a covered aisle round the exterior of the building, which is absolutely symmetrical in regard to its two sides. The whole combined width of the *cella* and the aisles is covered by a sloping roof in one span, the end of which forms a triangular framework for decorative sculpture at each extremity of the building. This is the only true and complete form of Greek architecture, which is essentially a temple architecture. Ergo, the Erechtheion and the monument of Lysicrates are not Greek architecture. One of them contains three compartments of different sizes irregularly tacked on to each other, and both of them exhibit engaged columns or pilasters. This is not a whit more one-sided or illogical than Mr. Moore's position as to Gothic architecture.

The fallacy in both cases consists in resting

the definition of style on some elements of a building and ignoring others which are of nearly equal importance. Greek architecture is a consistently trabeated style; Gothic architecture a consistently arched style. Those are the broad facts of the constructive basis of each. To this we may add the differentiation, in the case of Gothic, that it is a style in which the thrust of the arched roof is collected on certain points of the walls, forming buttresses, instead of thrusting against the whole length of a thick wall (for this gives a character to the whole architecture radically different from that of a barrel-vaulted building with continuous walls), and this involves the pointed arch, because only with the pointed arch can we practically carry out the vaulted roof. And the pointed arch being thus thrust upon us by practical necessity in one part of the building, we must employ it throughout in order to lay claim to completeness of style. Otherwise, and but for these practical difficulties with vaulting, we might have a building in all essentials of style purely Gothic, carried out with round arches throughout. Our author's further argument is that as the arch is a form of construction supported by abutments, and not exercising vertical pressure, the complete realisation of the system is only attained when the building is reduced entirely to a system of constructional frame-work of arches and abutments, any walls between these points being only walls of enclosure unconnected with, or at least not necessary to, the construction. This is true in a certain sense, no doubt; but two important considerations seem to have been overlooked. In the first place, it does not always follow that the most complete carrying out of a system to its logical conclusion produces the most satisfactory artistic result. As a matter of fact it has been questioned by architectural critics whose judgment is worth respect at all events, whether the system of reducing the piers to the smallest possible area and propping everything with a scaffolding of flying buttresses, which has been carried out so completely in many typical French cathedrals, is really consistent with the highest aims and the highest expression of architecture; whether it is not devoid of the repose, the calm, and the dignity which should characterise the highest class of architectural monuments; and if so, then it is a questionable credit to French Gothic to have carried out a system to its utmost logical development at the expense of monumental mass and solidity of expression. The other point that seems to have been overlooked is the importance of mouldings and ornamental details in characterising style. This is, of course, not so easy to define as a matter of construction; but it is not the less important on that account. As in the case of the Erechtheion above referred to, the mouldings and the style of ornament and the general feeling of the whole design connect a building with a certain recognised style, in spite of important differences in general plan and construction. In like manner an English Gothic church or cathedral, although not cut down to the lowest limit of pier area and not dependent on a scaffolding of flying buttresses, is nevertheless, in its general character and detail, a building in the same style as the French Cathedral; and it is really a *reductio ad absurdum* to say otherwise.

It must be observed also that while Mr. Moore is never tired of picking out the logical defects of English architecture, he appears completely blind to defects of logical design in French architecture. He quotes (in his illustrations) a bay of the Cathedral of Sens and the sections of piers determined by the intended plan of the vaulting, entirely ignoring the fact of the intermediate circular pier having no suggestion on plan of the transverse groins of the sextipartite vaulting, or the fact of the vaulting shaft for this beginning over again, with a new base of its own, from the abacus of the ground story cylindrical pier. This system of placing

little hases for the vaulting shafts on the abacus of the lower piers, which is more used in Early French Gothic than anywhere else, is in fact one of the most illogical and distinctly un-Gothic features in Early Gothic architecture; it entirely breaks the connection between the vaulting and the ground story, and it materially weakens the homogeneous character of the design; yet this the author passes over without reprobation, and even in silence, because it is a French defect. I think that Gothic architecture is only church architecture it is half amusing and half vexatious to see brought up again now after the great lights of the English Gothic revival had spent so much strenuous pleading in trying to convince people of the contrary. They perhaps carried their theory a little too far in claiming that Gothic was equally suitable for any form of building, and of course we know that all the great works of Gothic architecture as a matter of fact were churches; but we find refectories and hospitals built on the same principle; a pretty clear proof that the actual workers out of the style did not look on it as an exclusive church architecture: and this appears to us in fact, to be putting the accidental before the essential.

The only really new point we have noticed in the hook, besides the general and paradoxical view of Gothic of which we have been speaking, is Mr. Moore's suggestion (pages 6 & 7 *et seq.*) as to a reason for keeping the springing of the wall rib adjoining the clearstory windows much higher than the springing of the free vaulting ribs, thus producing that curious "ploughshare" form of vaulting in the severe between the wall-rib and the diagonal rib, with which we are all familiar. This has generally been regarded merely as a device for cutting out as much of the clearstory as possible into a window; but the author points out some examples, and illustrates one from St. Len d'Esseret, in which the window does not fill up the space within the wall-rib but there is a certain degree of wall-space between the vaulting rib and the jamb of the clearstory window. Mr. Moore's view is that the object of stilted the wall arch and thus cutting back and narrowing the severity of the vault, was to confine the pressure of the vault against the wall within a narrow space, and he ingeniously points out that in his sketch from St. Len d'Esseret the flying buttresses outside is seen shutting against the wall just at the level of this stilt of the wall-rib. There is certainly reason in this, and it is a very clever suggestion worth considering; though, when the author speaks rather contemptuously of Scott for not having perceived it, and for having said that the stilt was only done to make a larger window, we should like to have heard what Scott would have to adduce in reply, and whether he in his turn could not have brought forward examples to show that the theory was untenable. However, it is worth attention and Mr. Moore is to be thanked for it; it is new and ingenious, but we are not convinced of its truth. We may observe in regard to the example given, that though the window is smaller than the space left for it, the architects might have had in view, in stilted the wall-rib, the more harmonious effect of a line concentric with the main line of the window-arch. And we may also observe that if the explanation is really what Mr. Moore suggests, it must be accepted considerably at the expense of the logical character of his beloved Gothic style, in which the builders laid out on plan quadripartite or sextipartite vaults which they could not actually carry out on the spreading and symmetrical lines of the plan, from inability to get over a constructive danger.

The criticisms which Mr. Moore makes on English Gothic are in some cases valuable and interesting; but one cannot lose sight of the fact that the chapters devoted to it are almost one continuous string of fault-finding and of picking out, in various matters of detail, undoubted weaknesses of English Gothic and representing them as typical. To say that

the Early English capital is "rarely a capital of good profile" is nonsense; and to give such an example as fig. 146, as a typical one, is "saying the thing which is not." Of such a grand portal as Peterborough he has nothing to say except a passing allusion to it in mentioning one or two German churches with triple aisles of equal height, which he strongly condemns, and says the only parallel to it is the grouping at the west front of Peterborough, which is not a parallel case; while Bristol, which he does not seem to know, is one. The condemnation of the façade of Lincoln, on account of its not representing the three-aisled section in the rear of it, is a criticism to which there is another side. Lincoln façade is unfortunately a patchwork of different dates, and therefore as it stands is in some respects hardly a fair specimen of this method of treatment; but there is something to be said for the method, in spite of its falsity in one sense. This class of façade is really a great decorative "stop" to a form of section which it is exceedingly difficult to treat in a grandiose manner if frankly shown; and we do not know that it is to be by any means regarded as an incontrovertible architectural truth that a building with a nave and lean-to side-aisles should not have this awkward form masked by a decorative screen. We are disposed to think, at all events, that Lincoln west front is more effective as it is than it would be if treated *à la Pisa*, as the author thinks it ought to have been.

There is a good deal of very clever and even brilliant writing in this book, and those portions in which the author explains and illustrates special features of Gothic architecture, such as the vault, in the generally accepted manner and without trying to twist new theories out of them, have the merit of saying what the author's predecessors have said before, in a better, clearer, and more incisive way than many of them have attained to. But in its general scope the book seems to be a curious illustration of the admiration for things French, both social and artistic, which has of late years taken possession of the American mind, coupled with a desire to "take the shine out of the Britisher." No persons in the same line of business are so jealous of each other as relations; and the feeling seems to be that if Americans have no old cathedrals of their own to boast, it is at least desirable to let "the Britisher" know what poor concerns his really are, after all. Now the discreet Britisher is quite alive to the fact that France is the centre and birthplace of Gothic architecture, and that the great Gothic monuments of France are superior to ours in scale and in monumental expression, and in some respects in completeness of method. But we consider also that a great deal of English Gothic has an artistic beauty and refinement peculiar to itself in character, and which makes it superior to French work in some points, though it is inferior perhaps in more important ones. Of the author's blindness to these English characteristics it is sufficient to note that he has not a word to say about so graceful and characteristic an invention as fan-vaulting, or such a unique and complete work as King's Chapel; and, as before observed, passes over such a façade as Peterborough with an implied sneer. He is obviously an architectural student of no small ability and industry, and might have produced what would have been a typical text-book of its class on the subject of Gothic architecture. He has unfortunately spoiled the success of his own work by weighting it with paradox and prejudice.

Moscow.—According to the *Moskauer Deutsche Zeitung*, the sewage system of the town is to undergo a thorough re-organisation. In accordance to the wishes of the authorities, a scheme has been worked out by a committee consisting of five engineers of repute and one of the civic officials, and the plans are now to be laid before the representatives of the town for adoption.

THE MAINTENANCE OF COUNTY ROADS.

BY THE REV. E. ELMHIRST, J.P.*

READ with very great interest and with general approval an article in your publication of February 1, from the pen of Major-General Luard, R.E., treating of the various proposals for the future maintenance of county roads. Very properly General Luard lays great stress upon the fact that the condition of the roads in the counties surrounding the Metropolis is a matter of no small moment to the inhabitants of the Great City. Good roads, however, are of immense benefit to the entire community. And, looking at the general condition of roads in many parts of England, it would be, as the *Times* puts it, of the greatest benefit to this country, and most of all to the more remote and more unattractive parts, if the roads were all much improved, and rendered not only passable but even pleasurable to travellers. People are so accustomed to howl along without any other sensation than that of easy motion, that they cannot bear the perpetual discomfort and occasional peril of deep ruts and big stones. In the interest of society the whole country ought to be brought within the reach of every vehicle and every horse at all fit to be used. And that does not apply to carriages and horses of a certain description only, but also to all vehicles and horses. By having good roads the draught is reduced; and a less number of horses will do a given amount of work, thereby reducing the cost of the work, and saving damage to carriage, waggon, cart, and horse of the traveller, the farmer, and the general user of the road.

The necessity of good roads everywhere being undisputed, the next question is, "Under what system can we best ensure having them?" Turnpike trustees, through the agency of competent surveyors, and with funds collected from the users of the roads, were, in not very far remote times, responsible for the repairs. But since the abolition of toll-gates, on the expiration of the Turnpike Trusts, the several turnpike roads were at once repaired by the parishes through which they passed; they became main roads, or where Highway Districts were established were repaired by the Highway District Boards, aided by contribution from the County and the Consolidated Funds; but now they are under the direction of the County Councils in each county. The ordinary highways are repaired by the parishes in those counties wherein no Highway Districts have been established, or by the Highway District Boards where they are established under the present state of the law. Speaking of the ordinary highways, our only choice is between the old parochial system, where the roads are repaired by the parish surveyor, and the highway district system. The parochial system I once heard described by a former Member of Parliament for Leicestershire who had mastered the road question, and who, when it was proposed to dissolve a Highway District Board in this county, exclaimed, "Nobody would wish to return to that old, crude, dark, unlightened system, which was a curse to the roads of this county, and is still a curse to the roads of every county that remains under it."

Since the creation of County Councils the repair of the main roads is, by sec. 11, subsec. 4, under their direction. Every road in a county which is for the time being a main road, shall be wholly maintained and repaired by the Council of the county in which the road is situated, and such Council shall have the same powers as a Highway Board. And whenever District Councils shall be established, they may contract for the undertaking by the *District Council* of the maintenance of any main road, and if the County Council so require, the District Council shall undertake the same. I observe that the County Council of Kent propose to contract with Highway Authorities for the repair of

the main roads in the East Kent district, and with private firms for the repairs in the West Kent district. It may be well to adopt the plan, as far as the East Kent district is concerned, but we cannot say; the scheme has not had time for trial; but as to that for the West Kent district, if I might presume to say so, I have no confidence in it. The question also arises, Does the Act sanction such contracts with private firms? The County Council can contract with Highway Authorities or with District Councils whenever they shall be constituted; but can County Councils contract with "private firms" so as to come within the terms of the section? I have my doubts; but I will not discuss the point further; it would be unbecoming in me to call in question the action of my brother County Councillors of another county.

To go back to what I asked,—What is the system we have to resort to for the repair of the roads, main and ordinary? The parochial system is condemned. There is the other alternative, under the present law,—the "Highway District." On my preference for that I have on many former occasions, and in many ways,—by speech, by pamphlets, by periodical reports of the working of the system in my own county, Leicester,—and by my evidence before the Select Committee of the House of Lords on the Highway Acts,—spoken with no uncertain sound, and it would be wearisome to repeat it. Let me guard myself by saying, I have spoken always with an eye to the present law, but never contended that it was beyond amendment. I am now confronted by General Luard's proposed amendment, but it is too extensive to admit of a minute examination in the space you would be able to allot to me.

Not only has General Luard thrown out suggestions for an alteration in the Highways and Locomotives law, but the County Surveyor of Hertfordshire, Mr. Urban A. Smith, contributed a very sound and practical article upon the subject in the *County Council Magazine* of January in the present year.

These two proposed amendments in the law are worthy of close examination. They differ materially from one another. The General suggests the grouping, or "uniting the highway districts, even as the parishes have been united." Each Board to be represented on the County Roads Committee, or Board, which, in such case, would be composed partly of County Councillors and partly of *ex officio* delegates, in some cases the chosen representative of the Board being the Councillor for the district. The legislative distinction between main roads and ordinary roads no longer to exist. This was pointedly recognised by the Committee of the House of Lords in their Report on the Highway Acts in 1881, p. xxi., *if the proceeds of some local tax could be contributed by the county in aid of highway rates.*

Mr. Urban Smith, amongst other objections to the present state of the law, alludes to the Act of 1878, which provided that all the expenses incurred by a Highway Board in any parish should be deemed to be incurred for the common benefit of the whole district, and should be a charge upon the general district fund. Although, says he, the soundness of this provision appears unquestionable, the effect was that, whereas, prior to 1878, the majority of waywardens on a Board had no interest in opposing proper expenditure in any individual parish after the passing of the Act of 1878, they seemed to have felt that they had a direct interest in avoiding expenditure which must be met from the common fund. Mr. Smith goes on to observe that the only remedy for this state of things is to be found in having under one competent management an area sufficiently large to admit of an intelligent and uniform system being adopted—large enough to enable a proper staff to be employed; large enough to free the governing body from petty local influences; large enough to admit of machinery being employed where desirable; and large enough to secure as chief surveyor

* And Member of the County Council of Leicestershire.

an engineer possessing technical knowledge, administrative ability, and sufficient status to enable him to carry on his duties. The whole of the roads in the county, he maintains, would be far more easily and economically maintained by such a Board than by making the fruitless effort of getting at the desired result through the medium of District Boards and their surveyors. The system has to a certain extent been tested in Ireland, Scotland, South Wales, and the Isle of Wight, as well as under the French Government, and with general success.

A scheme of a similar character, though limited to the maintenance of main roads, has been recently submitted to the Highway Committee of the Leicestershire County Council by the County Surveyor; but as the repair of the main roads has been entrusted to the Highway Districts for the coming year, the scheme of the County Surveyor stands over for the time.

In any comments upon General Luard's schemes for the maintenance of county roads, it is necessary to bear in mind the present state of the law which limits the power of dealing with the two classes of roads,—namely the main and the ordinary roads. Were our hands clear to propound and adopt any scheme whatever that we might deem most advisable, our difficulties would be vastly diminished; but, as the law now stands, we are fettered by diversities of operations which stand in our way. We have the diverse system of the old parochial Highway Surveyor, the Highway District system, and the new County Council system, which latter authority at present deals only with main roads. I need not dwell on the almost obsolete parochial system, which must very shortly give way to a more enlightened one. I know that the Highway District system has its faults and its opponents; ostensibly in the charge that is brought against it, that by the Highways and Locomotives (Amendment) Act of 1878, all expenses incurred by a Highway Board in any parish are to be deemed to be incurred for the common benefit of the whole district, and be made a charge upon the general district fund. Although the soundness of this last-mentioned provision appears unquestionable the effect was (observes Mr. Urban Smith, the County Surveyor of Hertfordshire) that prior to 1878 the majority of waywardens on a Board had no interest in opposing proper expenditure in any individual parish; after the passing of the new Act they seem to have felt that they had a direct interest in avoiding expenditure which must be met from the common fund. This alteration in the law appears, says Mr. Smith, to have been a severe blow to the Highway Board system, and many districts have since been dissolved. The maladministration of the functions of Highway Boards has never, I am glad to say, been exhibited in the Highway Board of Lutterworth, with which I am connected, though I cannot dispute the impeachment elsewhere.

The institution of County Councils now forces itself upon our serious consideration, inasmuch as the entire control of the main roads has been taken out of the hands of the other two authorities above-mentioned, and it will be necessary to deal only with this last-constituted authority in the remarks which I have to make bearing upon the maintenance of main roads. Though the repair of the main roads is thus thrown upon the County Council, the prospect of the institution of District Councils at no distant time, and the want of special organisation for undertaking this important work, have induced the County Council to shift the burden of the work from their own shoulders, in some counties at least, and to request the highway authorities, who have hitherto performed the work, to continue to repair the main roads for a certain period,—in some instances a twelvemonth,—recouping the Highway Authorities the expenses incurred. The County Council of Leicestershire has adopted that course. In Gloucestershire, however, as stated by Sir John Dorrington,

Bart., M.P., and Chairman of the County Council, the Council undertook on "the appointed day" the administration of all the main roads in the county, and so far have every reason to be satisfied that their roads are as well maintained as in the past, and with the prospect,—almost the certainty,—of spending less by 6,000*l.* in the twelve months than was paid in the previous year to effect the same result. Sir John Dorrington informs us that nine other counties have taken the same course, either from the first, or more recently, and that many others are contemplating similar action. It would occupy too large a space in your columns to give a detail of the mode in which all appointments of officers and all expenses are managed; but these are very simple, and present no difficulty, being under the charge and control of the Highway Committee of the County Council.

General Luard, not approving of the scheme of the Committee for Roads and Bridges in Kent, which they had evolved for the future management of the main roads of the county, which they had laid before the Council of that county, and which consisted, as already observed, of two plans,—one for contracting with Highway Authorities, the other for contracting with private firms,—made certain suggestions in opposition to those plans; amongst them was one that "The Highway Boards of Kent be invited to form a Roads Union under the auspices of the County Council." These suggestions were not accepted by the Council, the Council probably having in view, according to the promise of the Local Government Board, the introduction at the earliest opportunity of the District Councils Bill. Passing on from the consideration of what has been done in some of the counties, in conformity with the law as at present in existence, I should like to glance at some of the suggestions which have been made by General Luard, by Mr. Urban Smith and others, for an alteration of the law as regards all roads, both main and ordinary highways.

I will preface their suggestions by declaring that, in my opinion, there comes in now a very wide question upon the subject of the roads. Has not the time arrived for reviewing the present state of the law, and for calling upon the legislature to amend the various enactments connected with the highways? Is it not time that the recommendation of the Select Committee of the House of Lords on Highway Acts in the Session of 1881 should be adopted, and relief given in the terms of their report, which runs thus:—"In view of the great hardship complained of by ratepayers of the charge of half the cost of the main roads upon the county rate fund under the existing system, the Committee are of opinion that it is desirable to abolish the distinction between main roads, as defined by the Act of 1878, and ordinary highways." In the event of this taking place, the proceeds of some local tax, apportioned according to the mileage of roads, might be contributed by the county in aid of the highway rates. In the promised District Council Measure it is to be hoped that provision will be made for undertaking the repair, not only of main roads, but also of all ordinary roads. The distinction, as General Luard remarks, is one which has always proved exceedingly difficult to define, and the necessity for it, at all events, no longer exists.

Royal Marylebone Theatre.—This house, together with Nos. 67 and 69, Chureb-street, Paddington, will be put up for sale by auction, at the Mart, on Thursday, the 27th instant. Lately known as the "Royal Alfred," this once popular place of resort was opened as a "penny house" in 1842, but was enlarged in 1854. It is distinguished by the unusual depth of its stage, and covering an area of 9,000 sq. ft., superficial, accommodates an audience of 2,000 persons. The premises are held for a term, whereof thirty-one years are yet unexpired, and are let at a present rental of 988*l.*, which will shortly be raised to 1,040*l.* per annum.

NOTES.

THE important discussion on Mr. Slater's paper, at the last meeting of the Institute of Architects, which was kept technically "private," and of which therefore we gave no report, is now in the hands of members of the Institute, and those who were not present at the meeting will probably agree, on reading the discussion, that it was well that the unwise and rather reckless proposition to send a copy of this *mélange* of differing opinions to the County Council, as a spur to their interests in building legislation, was quashed. We can imagine nothing less likely either to promote the cause of a wise reform in building legislation, or to contribute to the dignity and status of the Institute of British Architects, than to send before the County Council a report of a meeting the general result of which would be to show that there were many differences of opinion on the subject among members, and which included no definite proposition or resolution as the expression of the meeting. If the Institute of Architects wish, as no doubt they ought to wish, to influence in what they believe to be the right direction any impending reform in building legislation, they should crystallise the result of their deliberations on the subject into definite propositions representing the opinion of the majority of a meeting formally adopted and put on record. If they wish to be heard with respect by the London County Council, let them exhibit to that body their unanimity, and not their differences. But in regard to any chance of wise and effectual Parliamentary reform in building legislation, there is one very important consideration to be borne in mind, *viz.*, that it is no use whatever to come before Parliament with a Bill for improvement and codification of the existing building law combined. Any attempt to do so would result in debates which only further complicate and entangle the whole subject,—

"And find no end, in wandering mazes lost."
What is necessary is first to get such separate improvements in detail passed as are necessary, as new subsidiary Acts. Then, and not till then, will be the time to come before Parliament and say "the existing building legislation is now good in itself, but inconveniently dispersed through a number of various enactments: these represent what we want; now codify these." That is the only way to set about a permanent and satisfactory settlement of building legislation.

THE anticipations expressed by the counsel for the railway companies, that their evidence at the Board of Trade inquiry might be made use of for other purposes, has very soon been realised,—though not exactly in the manner they apprehended, or, indeed, to their prejudice. At the recent conference between the coalowners and their employés, held for the purpose of discussing the wages question, the men, as is well known, pressed for a 10 per cent. advance on the strength of the increased charges for coal. "The price paid by the public is the barometer which indicates the prices," urged the men. "House-coal represents but a small proportion of the output," replied the masters. "The bulk of the coal is disposed of to gasworks and railway companies, and is subject to long contracts." Upon this the men appealed to the evidence given by Mr. Findlay, who had stated at the Board of Trade inquiry that the London and North-Western Railway were paying 20 to 30 per cent. increase upon their coal; while Mr. Shaw had stated that the Lancashire and Yorkshire would have to pay an advance of 4*s.* 4*d.* a ton upon their new contracts. On the other hand, the evidence of Welsh colliery proprietors might have been quoted. It was stated that in many cases the Welsh collieries were worked at an absolute loss, it being remarked that the railway companies always charged their full maximum rates unless they had a purpose of their own to serve by adopting a different policy.

This evidence, however, had not been given at the time the conference was held. Mr. Jeune, Q.C., is representing the coal-owners before the Board of Trade, and he also alluded to this part of the railway case. He considers that the companies are so protected by the contract system that they should not be given such a margin for contingencies as that to which they lay claim. He suggests that in the event of anything quite unexpected happening, the proper course would be for them to go to Parliament and make out a case. The companies doubtless consider that they are before Parliament now, and that they are, at considerable expense, making out a case now, in order to provide for "the unexpected," without having to go all over the ground again at some future time. Lord Balfour and Mr. Courtenay Boyle are getting well furnished with figures; too well, probably, for, as far as figures go, each side has made out an exceedingly strong case.

THE scheme for the amalgamation of the South-Eastern and London, Chatham, and Dover Railways, which is aired periodically, has received a severe check,—if not a death-blow. A circular was recently sent to the proprietors of the former company by Messrs. Arthur Anderson & Co., setting forth the desirability of such an amalgamation; upon which a letter was addressed by the South-Eastern Secretary to the London, Chatham, and Dover Board, the greater part of which was taken up,—to use the words of the *Times*,—with the amenities which usually appear in correspondence between these companies. It contained, however, among other matters, a definite suggestion as to arbitration upon the Continental agreements between the two companies, which have long been a source of contention. The adoption of these proposals, it was urged, "would remove the friction which must continually recur while the common fund is depleted by competition, and would at the same time smooth the way for any complete fusion of receipts which might be deemed in accordance with public policy." A reply has just been sent to the proposals, which, so far from being accepted, are spoken of by the London, Chatham, and Dover Board as being utterly impracticable and impossible of attainment. The Continental agreement alluded to, works, presumably, in their favour,—indeed, the decisions of the Law Courts point in this direction,—and they decline most emphatically to submit to its revision. The letter is anything but a "soft answer," and the relations between these two southern lines will not have been at all improved by this attempt,—if it can really be so described,—to arrive at an understanding.

VERY interesting and important report has been made by Mr. St. John Hope to the Corporation of Leeds in regard to the state of the ruins of Kirkstall Abbey, of which the Corporation are the custodians. Mr. Hope finds various parts of the building in a condition in which they require attention and repair in order to prevent further decay and downfall. The principal repairs recommended in the report are these: The walls of the presbytery, which are decayed in the upper part by percolation of water, should be carefully pointed. The gable is falling outwards and should be under-pinned. The tower has nothing to support it on the north side, and the slightest failure or a violent gale might bring it down. Mr. Hope thinks the only thing that can be done is to rebuild the fallen pier and arches, and the wall above, so far as to afford an efficient buttress to the tower. "The old stones might be used as far as they will go, and the deficiency made up with new, only roughly hewn into form, so as to mark it as a modern repair." The clearstory of the nave should be freed from ivy, and the aisle walls pointed to prevent further percolation of water. The report goes very fully into the condition of the ruins of the conventual buildings and the steps desirable to be taken to prevent them becoming further dilapidated. The whole report forms an in-

teresting and valuable record of the present state of Kirkstall. The work suggested may cost some money no doubt to carry out, but we do not suppose the Corporation of Leeds will grudge that. If they do, however, they might apply to Lord Grimthorpe, who will be willing, very likely, to remove the present ruins and build a brand new and superior abbey from his own design, or that of his builder.

A LETTER from Dr. Waldstein to the Roman correspondent of the *Times* (March 6) gives some very valuable further information as to the important discoveries made last year at Lykosura in Arcadia, by Mr. Kabbadias; discoveries, it will be remembered, we commented on last October. A considerable proportion of the sculptures have now been transported—no easy matter—from Arcadia to the Central Museum at Athens, where, though they are not yet exposed to the public view, Dr. Waldstein has inspected them. The temple excavated was dedicated to Despoina (Persephone), and we may remind our readers that Pausanias describes in detail the great cultus statue, or, rather, group of four statues, that stood within it. He says, "The images of the goddesses Despoina and Demeter, and the throne on which they are seated, and the footstool below their feet, are all of one and the same stone, and neither any portion of the drapery nor the decorations are fixed or clamped in, but the whole is one block. And this stone was not brought from a distance, but was dug up in the precinct, in accordance with a dream, and each of the images is about the size of the image of the Mother at Athens, and they are the work of Damophon. Demeter carries a torch in her right hand, and she has laid her other hand on Despoina; and Despoina holds a sceptre, and has on her knees what is called a cista, and this she holds with her right hand. And on one side of the throne near Demeter stands Artemis, wearing the skin of a deer, and a quiver on her shoulders, and in one hand she holds a torch, in the other two snakes; by Artemis is a hunting dog; and near the image of Despoina stands Anytos, represented as a man in armour." Pausanias proceeds to tell the story of Anytos. With the help of this full description, it is confidently hoped that the main composition of the whole group may be completely restored. It is scarcely possible to over-estimate the importance of the discovery. As Dr. Waldstein points out, we have here for the first time "an original *agalma*—a genuine temple statue of a good Greek period, which we can identify with a noted local artist, Damophon of Messene, who flourished about the middle of the fifth century B.C. "What most struck me," he adds, "were some large fragments of drapery belonging to the colossal figures. The folding is beautifully free, and one piece is decorated with figures of Niké and Tritons, in very flat relief, reminding one of gold *repoussé* work. There is one still larger fragment with flowers, worked in similar relief. There can be no doubt that all this class of work is a reminiscence of the gold and ivory statuary carried over to the marble work of the fourth century." Wholly in the dark as we are on the chryselephantine technique, and without hope of the recovery of a single fragment, this echo of it is simply invaluable.

THE first issue of the *Corpus* of ancient sarcophagi reliefs is promised almost immediately, and its publication will mark a distinct epoch in archaeological method. The corpus of reliefs is to be one of a series of works undertaken by the German Archaeological Institute, in which all salient examples of particular classes of antiquities are to be published collectively. Gerhard's work on Etruscan mirrors was the prototype of the series, but his example was for many years not followed. What has long been done systematically for inscriptions must be done for certain branches of sculpture, for terra-cottas, for vases, &c. Until it is done, archaeologists can not be said

to have their material in manageable form. The first series is, according to a too prevalent German custom, the second volume of the whole publication. It is to deal with such sarcophagi as represent complete mythological cycles. The volume is to be edited by Dr. Carl Robert, whose name is a sufficient guarantee for the brilliancy as well as thoroughness of the text. It is to consist of 222 pages of text, 65 whole plates, partly copper, partly heliotype according to the subject, and 293 smaller cuts in the text. This volume is to be followed at no long intervals by five others, embodying the reliefs that treat of "Daily life" of "Individual myths of the Bacchic cycle," the "Maæss, Nereids and Eroses," and "Decorative subjects." We hope there will be some arrangement by which the volumes (225 marks each) can be had separately.

TWO drawings—exterior and interior views—are now on view at St. Saviour's Church, Southwark, showing the proposed new nave, as designed by Sir Arthur Blomfield. It is to be of seven bays, with aisles and clearstory, the lines both of exterior and interior following pretty closely those of the existing choir. There is a south porch projecting but slightly beyond the aisle walls, and at the outer angles of the west end are two bold octagonal turrets carried up clear of the aisle parapets, and terminating in conical lead roofs. Lancets occur throughout the design, single lights in the clearstory and aisles, and a triplet at the west end. The two western bays of the nave are emphasised by a larger column and an arch spanning the centre aisle, and dividing them from the other five. We are informed that this feature occurred in the old nave, and it serves to break the long lines of the church, although not apparently placed for any structural purpose. The whole scheme is an attempt to bring the appearance of the church back to what it was in the thirteenth century, and if there is a lack of originality, the result will certainly be dignified, and make St. Saviour's one of the finest of the London churches. It is calculated that about 50,000*l.* is necessary for its proper completion, of which a little over 20,000*l.* has been already subscribed.

THE Society of Antiquaries issue a circular stating that they are endeavouring to found a "Research Fund" by raising a capital the interest of which should from time to time be applied towards the expense of excavations on ancient sites, "or in such other methods of advancing archaeological knowledge as the President and Council of the Society may think fit." The Society consider that a capital of 3,000*l.* would enable them to do much useful work; and towards this they are already able to announce subscriptions to the amount of 1,750*l.* We hope they will receive every support, even to a far greater extent than the 3,000*l.* spoken of, for the idea is an excellent one, and would do something towards supplying help which is often much wanted and vainly looked for towards the prosecution of researches of the highest interest in archaeology, and of course our enlightened Government is too wide-awake to "practical" considerations to assist in such schemes. As an example we may call attention to the appeal made in a letter from Mr. Penrose in another column, for assistance in illustrating the Byzantine antiquities of Greece. If the Society of Antiquaries Fund were formed and in operation this would be almost an ideal case for assistance.

AN interesting paper was read before the Geological Society on Wednesday last by Mr. W. Whitaker, F.R.S., of the Geological Survey, in which the author described certain irregularities in the occurrence of superficial deposits in the eastern counties, which have seriously interfered with the calculation of the depth of projected wells. It appears that a series of superficial clays, sands, and gravels lies in a valley

on the chalk, and a line of wells has been sunk into them, in some cases to 200 ft. or 300 ft. without reaching the chalk. This great thickness of superficial deposits is very unusual, and there is nothing at the surface to indicate the circumstance. The chalk comes to the surface only a few hundred feet off, and under ordinary conditions the well-sinkers might reasonably have expected to reach the chalk at less than 60 ft. or so. It seems that a ravine has been cut by natural agencies through the chalk, which ravine was subsequently filled up by the superficial deposits in question. It is an excellent illustration of the difficulty sometimes experienced in accurately estimating the thickness of strata to be passed through in well-boring, though fortunately the phenomenon does not often occur.

THE annual Schinkel Competition for the medallion and travelling studentship, the highest honour attainable in Germany by competition, has been won by Herr "Regierungs-Bauführer" T. Boethke, who is at present on the staff of a well-known Government Bureau at Leipsic. The subject (a Royal College for Music on the Lützow Platz, Berlin), although as interesting a one as any architect could wish for, only enticed two competitors to send in designs, and of these two, one was a mere absurdity. Herr Boethke's, on the contrary (although it shows some mistakes in the planning and little originality in the design), may be termed an excellent, as well as exceedingly laborious, piece of work for so young a member of the profession. The elevations are in a strict Palladian renaissance; the planning, which has been worked out on academical lines, shows that the author was well acquainted with the plans of the new Concert House at Leipsic, and those of the new Imperial Law Courts which are being built in the same town.

THE vacant place of "Dombaumeister" at Strasburg has already been filled up, Herr Franz Schmidt, of Cologne, having been elected to hold this very responsible post. We here find the somewhat rare occurrence of a master being chosen to take the place of his former pupil. August Hartel had worked under Herr Franz Schmidt from 1863—1868, at the time when the latter artist was occupied with his great publication of the Cologne Cathedral; and it was really during this period that the then young architect, thanks to the kind advice and directions of his "chef," formed that sound basis of knowledge of German Gothic which afterwards brought him so much fame. The new "Dombaumeister" (who has already reached his sixtieth year) is well known in German architectural circles, and is considered to be one of the leading Gothic architects of Prussia, his occupation at Cologne being the only cause of his name not having such publicity as that of his pupil.

AN interesting description is given in a foreign contemporary (*Dingler's Polytechnisches Journal*, vol. cclxvii, p. 194) of a chimney built on loose soil; thus rendering a light structure necessary. From the foundation four upright, and somewhat tapering, lattice girders were carried up, and connected together by cross-bracing. On the inner edge of the frame thus formed the chimney proper was built of tiles, about 5 in. in thickness, and having lap-joints. Angle iron bands were introduced at intervals to bind the whole firmly together. The total height of the chimney is 140 ft., and the inside diameter 8 ft. 6 in. The total weight is 543 tons; which gives a pressure of 17 lb. per square inch on the foundation. This would be about equal to half the weight and pressure per square inch of an ordinary chimney. The whole chimney was erected in thirty-nine days, the iron work occupying thirty-one days of the time. The cost is set down at 19,200 f., and it is estimated that a brick

chimney of the same height and size would have cost 14,300 f.

IN the Transactions of the Institution of Civil Engineers (Vol. xcii.) are some particulars of tests made by two American experimenters, Messrs. W. R. Nichols and J. K. Russell, to ascertain the action of water on galvanised iron pipes, such as are fitted for the Boston (Mass.) water service. It is generally possible to detect zinc in water which has passed through any considerable length of zinc-coated pipe; but it has been thought that the quantity in suspension as a hydro-carbonate, or in solution, is too small to be an objection from a sanitary point of view. Messrs. Nichols and Russell's experiments were made with a length of 39 ft. of $\frac{1}{2}$ -in. galvanised pipe, connected in such a manner that water could be introduced into the pipe to displace that which had been already standing there, but without allowing air to enter. Zinc was found, in solution and suspension, whenever the water had stood in the pipes from seven to seventy hours. Water that had remained in the pipe for several days did not contain zinc in solution in greater proportion than for shorter periods, but the quantity of zinc in suspension was augmented. The water held in solution was 0.3 to 0.6 parts of zinc per 100,000 parts of water, and in suspension from 1.5 to 2 parts per 100,000 parts of water; or 0.3 grain per gallon in solution, and 1.0 grain per gallon in suspension. In water in regular flow no zinc was discovered.

THE Duke of Newcastle's Workop Manor estate, in Nottinghamshire, will be offered for sale by auction in the course of the ensuing season. This freehold property, extending over some 6,000 acres, to be divided into lots, lies in Bassetlaw wapentake, at the northern side of Sherwood Forest. The existing manor house stands on high ground, in a finely-timbered park of about 200 acres; to the south is a range of hills, known as Manor Woods. The sale will include the Lodge (312 acres), Shireoaks Park (368 acres), twenty farms, with houses and homesteads, pasture ground, some building land adjoining the town, together with Workop and Shireoaks Manors, and the market dues and tolls of Workop itself. The manor, held in turn by the De Lovetots, the Furnivals, the Talbots, Earls of Shrewsbury, and the Howards, Dukes of Norfolk, was sold in 1843 by Henry, thirteenth Duke of Norfolk, for, it is said, 380,000 l. to the Duke of Newcastle; and the manor-house was afterwards partially dismantled. The Priory Church, strictly speaking of Radford, was founded, 3 Henry I., by William de Lovetot, for some Augustine Canons, and dedicated to St. Mary the Virgin. Its present dedication to St. Mary and St. Uthbert reminds us that De Lovetot had taken the parish church for his priory and that the parishioners, as at Crowland, Ely, Ripon, and elsewhere, subsequently enjoyed for their own use its western portion. The church is conspicuous for its two western and large central towers and long nave of ten bays, cruelly restored about thirty-five years ago. Its architectural features are described in the letterpress to a two-page illustration, published in the *Builder* on July 14, 1888, of Messrs. Carpenter & Ingelow's design for rehabilitating the fabric eastwards of the central tower.

STAINED glass will shortly be fixed in the west window of Chesterfield church. It has been executed by Messrs. Heaton, Butler, & Bayne, and consists of large figure subjects from the Life of Joshua. The window itself is of seven lights, but the glass has been treated pictorially, and the subjects extend across three of the lights on either side, the centre being occupied by a figure of Moses on Mount Sinai. There are a large number of figures, and the general effect, although fine in colour, and the figures in many cases powerfully drawn, is somewhat crowded, and it is doubtful whether a more conventional and decorative treatment would not have been more suitable.

AS will be seen in our lists of "Tenders" printed last week, Mr. Rowland Plunbe has been engaged by the Governors to make plans for some extensive alterations and additions to the London Hospital. This hospital represents the "London Infirmary," originally established in the year 1740, at a large house in Prescot-street, Whitechapel. In 1758 the hospital was incorporated, and shortly afterwards removed to its present premises in Whitechapel-road, just eastwards of "the Mount." The Mount derived its name from having been formerly the situation of one of the numerous forts upon the environment of earthworks that were thrown up around London in the winter of 1642-3, the King's headquarters being then at Oxford. This particular fort they called the Horn-work, or Mill Mount, as standing close to the mill in Whitechapel-road. It lay on the curtain between two other forts on the east side of London,—one at the Hill by the northern end of Brick-lane, another in Old Gravel-lane, Ratcliff (St. George's-in-the-East). Mount-street, Grosvenor-square, commemorates the site and name of "Oliver's Mount," upon the same line of circumvallation; hard by stood another, having four bastions, where is now Hamilton-place, Piccadilly. Some suppose that Castle,—renamed four years ago Farnival,—street, was so styled from the fort which was constructed in Holborn.

MR. CHAMBERLAIN affords us the latest example of the necessity under which those who are termed "public men" seem now to feel placed, of talking about art on some occasion or other. They are not all, however, as amusing as he is. The spectacle of Mr. Chamberlain solemnly explaining to the Birmingham Jewellers' and Silversmiths' Association that the ancient jewellers' art of Egypt and Greece was "not barbarous or savage" is as good as anything we have come across for some time back. We sincerely hope it will not escape the notice of *Punch*. No.: if Mr. Chamberlain had wanted to give an illustration of "barbarous and savage" goldsmiths' art he could have referred his hearers to some examples of their own native manufacture, which have managed on some pretext to get exposed in the cases of the Birmingham Art Gallery. We observe Mr. Chamberlain in his speech always spoke of jewellers' work as a "trade"; like the manufacture of screws, we presume. In Birmingham no doubt jewellery is a trade; in Greece it was an art; and that makes all the difference.

THE PROPOSED BLACKWALL TUNNEL.

THE question of constructing a tunnel or tunnels beneath the Thames at Blackwall, for the accommodation of vehicular and pedestrian traffic between the right and left banks of the Thames is an exceedingly difficult one, and the London County Council are acting wisely in giving careful consideration to the subject. It will be remembered that it was upon this question that, very nearly a year ago, the "appointed day" for the extinction of the Metropolitan Board of Works was accelerated by some ten days, the late Board having, in its last week of existence, accepted a tender, amounting to 318,340 l., for the construction of a footway tunnel only at this part of the river, the proposed footway tunnel being intended as the preliminary and trial portion of the complete tunnel scheme, which included, besides this footway tunnel, two larger tunnels for vehicular traffic. The then newly-elected body, the London County Council, which was about to take over the government of London from the Metropolitan Board of Works, objected, and rightly so, to be saddled by their predecessors with so heavy a responsibility as the tunnel scheme involved, just as they were entering upon office, and before they had had time to consider the project, and their objection gained additional weight from the fact that the designer of the tunnel, Sir Joseph Bazalgette, the Engineer to the Board, had resigned his appointment, and would not supervise the construction of the tunnel.

That some permanent means of crossing the river at or near this point ought to be provided,

* See *Builder*, March 8, 1890.

if possible, seems very clear. The Select Committee of the House of Commons on Thames Communications below London-bridge, appointed in 1884, reported in favour of a bridge near the Tower (now being constructed by the Corporation of London), a bridge or tunnel at Shadwell, and a tunnel at Blackwall. The Metropolitan Board of Works, in 1886, determined to obtain power to construct a tunnel at Blackwall.

It was to its determination to commit its successors to this scheme that the late Metropolitan Board of Works owed its somewhat premature decease as a body corporate, under the circumstances already referred to. Defenders of the Board's conduct in that matter were not wanting at the time. The Board, they said, had given years of consideration to the subject, and had come to their resolution on the advice of their Engineer, the practicability of whose project was testified to by other eminent engineers who were examined by the House of Commons Committee on the Thames Tunnel (Blackwall) Bill, which became an Act in 1887. Having obtained their Act, the Board considered themselves bound to proceed with the works, in fulfilment of pledges given to the local authorities of the eastern and south-eastern portions of London. There was, of course, a great deal to be said for that view of the situation, and we hope that if it should now be determined to proceed with the tunnel, the results will be such as to justify the action of the late Board, and even to realise the hope, expressed by some of its admirers, that its action in this matter would "keep its memory green."

When the London County Council entered upon office, the Bridges Committee was charged with the consideration of the late Board's Blackwall Tunnel scheme, and at the meeting of the Council on April 11 last year they presented a report stating that they had had under consideration the subject of the formation of the proposed foot-tunnel at Blackwall, for which a tender amounting to 318,840*l.* (including approaches), was accepted by the late Metropolitan Board; and had also considered as to the construction of the two tunnels for vehicular traffic, which, together with the foot-tunnel, were estimated to cost about 1,500,000*l.* The Committee had also submitted to them a scheme for a single tunnel of sufficient dimensions to accommodate two lines of vehicles and foot-passengers, and an estimate of the cost, amounting to about 1,200,000*l.* The Committee thought it desirable that the Council should have an independent opinion upon the relative merits of these two schemes. They therefore recommended:—

"That the reports, plans, specifications, and estimates of the three tunnels authorised by the Thames Tunnel (Blackwall) Act, 1887, together with the scheme for a single tunnel to accommodate two lines of vehicles and foot-passengers, be referred to an eminent engineer for examination and report."

This was agreed to, although not without an attempt to further shelve the question by the advocates of a ferry.

At the meeting of the Council on June 22 last, the Bridges Committee reported that they had proceeded upon the resolution of the Council of May 7, instructing them to take into consideration the report of the Committee appointed by the House of Commons in 1884, expressing the opinion that three means of communication were absolutely necessary east of London Bridge, viz., a bridge at or near the Tower, a tunnel at Shadwell, and a tunnel at Blackwall, and to advise the Council which of the latter should be first constructed. The Committee, in considering the matter, had had regard to the fact that an Act of Parliament had been obtained for the construction of a tunnel at Blackwall, and that contracts had been entered into and purchases completed for property required for the approaches amounting, approximately, to 150,000*l.* The Committee recommended:—

"That the Blackwall tunnel take precedence of all other schemes of trans-communication, and that the Committee be instructed to consider the other schemes proposed, with a view of reporting as to their probable cost, and as to the order in point of time in which they shall be proceeded with."

This recommendation was agreed to.

Subsequently, at a meeting of the Council held on July 2 last, it was resolved, on the recommendation of the Bridges Committee, that Mr. Wolfe Barry be retained to advise the Council upon the scheme for the construction of the proposed tunnel or tunnels.

Mr. Wolfe Barry's report to the Bridges

Committee is now before us. The reference to Mr. Barry recited the following among other particulars:—The Act of 1887 authorised the late Metropolitan Board of Works to construct a tunnel at this part of the river; it also allowed the Board to make the tunnel, if they thought fit, by either two or three separate borings, so that the tunnel might consist either of two separate and parallel tunnels for vehicular and foot traffic, or of two separate tunnels for vehicular traffic and a third for foot traffic. The size of the two tunnels for vehicular traffic was 23 ft. internal diameter, and the foot passenger tunnel was to be 15 ft. internal diameter, and to have a headway of 10 ft. The Parliamentary estimate for that portion of one footway and the two carriage tunnels, which would be constructed under compressed air, was 768,000*l.*, and the total estimate was 1,124,000*l.* for works. The estimate laid before Parliament for the whole of the scheme, including the purchase of property, was 1,568,200*l.* Towards the end of 1888 the Board invited tenders for the construction of a footway tunnel of cast-iron lined with brickwork, with approaches thereto on both sides of the river, partly in tunnel and partly in cut and cover and open cutting. Two tenders only were received,—one from Messrs. S. Pearson & Son, amounting to 354,513*l.*, and one from Mr. W. Webster, amounting to 357,601*l.* The engineer's estimate was 280,000*l.* As the lowest of these tenders was so greatly in excess of the Engineer's estimate, the Board resolved to re-advertise for tenders, and to omit the words, in clause 21 of the specification, to the effect that the contractor would not be allowed an extra charge for any modifications in the method adopted. The result was that three tenders only were sent in, viz., Messrs. Kirk & Randall, 348,212*l.* 3*s.*; Mr. W. Webster and M. Coisean, 327,745*l.*; and Messrs. S. Pearson & Son, 318,840*l.* The London County Council, upon taking over the duties of the late Board, declined to confirm the acceptance of the tender for the construction of the pedestrian tunnel, and the Bridges Committee directed the [acting] Engineer to submit to them sketch-drawings and an estimate for a tunnel which would accommodate two lines of vehicles and foot passengers. He recommended that the tunnel should be 22 ft. in diameter, and constructed within 5 ft. of the bed of the river. The method proposed for constructing this tunnel was the same as that proposed for the 15 ft. pedestrian tunnel. The total length of the subway, with its approaches, was nearly three miles, of which 10,734 ft. would be constructed upon the surface or by open excavations. The Engineer's estimate for the 22 ft. combined vehicular and pedestrian tunnel was 1,113,000*l.* The Bridges Committee asked Mr. Barry to advise them (1) as to the practicability of the schemes as set out; (2) as to the most economical way to provide for the traffic, i.e. one or more tunnels, and the dimensions he would recommend to be adopted, having regard to (a) first cost of construction, and (b) cost of maintenance, including lighting, draining, ventilating, and safeguarding by police; (3) as to drawing the specification in such a form as to provide for two prices,—one for undertaking the whole of the work and risk connected with the execution of the contract, and the other for the execution of the contract with the provision of a certain sum for pumping, such sum to be increased or lessened upon the certificate of the Engineer, as the necessity for greater or less expenditure in pumping might arise; and (4) generally.

Mr. Wolfe Barry, in his report, says, as to the practicability of the schemes set out in the terms of reference, that the nature of the soil below the bed of the river has been to some extent ascertained by borings which have been made at various points on each side of the river, and at four places in the bed of the river itself. The nature of the soil, consisting as it does of alternate bands of clay and sand, is anything but favourable to tunnelling operations, and contrasts very greatly in this respect with the impervious stratum of London clay through which tunnels have been made near London Bridge. Mr. Wolfe Barry goes on to say that there are very few examples of tunnels constructed through water-bearing strata such as exist at Blackwall. There is, of course, the well-known example of the old Thames Tunnel, which extraordinary engineering work was constructed before the days of the pneumatic system of construction. A large part of the Thames Tunnel was made through ground superior to that at Blackwall. Another well-known example

is the partially-completed double tunnel under the Hudson River. This work, constructed on the pneumatic system, but without a shield, is not nearer to the bed of the river than from 12 ft. to 15 ft. The Severn and Morsey tunnels, so far as construction is concerned, are not cases in point, as the rock through which they pass is so widely different from the soil under the Thames at Blackwall that the use of any pneumatic system was unnecessary. The Tower Subway and the City and Southwark Subway, being wholly in the impervious London clay, were made without difficulty, and without the use of any special appliances.

We quote the next two paragraphs of Mr. Wolfe Barry's report *in extenso*:—

"It is clear that at Blackwall, tunnelling by the pneumatic system is the only plan which promises success. There are numerous examples of the success of this system in the sinking of the foundations of piers, but in considering its application to a tunnel, this important difference has to be borne in mind, viz., that when working in a vertical direction, as in the case of cylinder or caissons for bridge piers, the external and internal pressures are approximately equal over the whole of the surface of ground exposed, whereas in tunnelling horizontally under water or through pervious strata, the external pressure of water will be considerably greater at the bottom of the tunnel than at the top. The pressure of air must of course be at least equal to the highest external pressure, and there is thus a great tendency for the air-pressure within the work to escape along the line of least resistance, that is, from near the top of the tunnel. The result of any such sudden escape is what is known as a 'blow,' when the air issues from the tunnel faster than the pumps can supply it; the water, as a consequence, rushes into the tunnel, and carries with it large quantities of soil. Thus any large exposure of surface in constructing a tunnel gives rise to difficulties and dangers, and these considerations point to the necessity for a shield which will not only limit the surface exposed at any one time, but which also can be so arranged that the air-pressure in its various divisions can be graduated to the external pressure opposite each division. The designs submitted to me in connexion with the footway tunnel contemplate the employment of such a shield as would render these precautions possible."

The details of the best shield require much anxious thought, and the most advantageous design will probably not be arrived at except after a certain amount of experiment; but I am of opinion that an efficient shield can be designed and constructed, under which larger tunnels than those already designed for the Metropolitan Board of Works can be carried out."

Mr. Wolfe Barry then proceeds to consider in detail the two proposals of the footway tunnel and the tunnel for combined vehicular and foot traffic. As to the smaller or footway tunnel, he considers that a tunnel of this nature is practicable, "considered as an engineering work," but he thinks that some important modifications of the proposed shield would be necessary. He is also of opinion that the top of the extrados of the arch should not be nearer to the bed of the river when dredged than 10 ft.; any less depth would, he thinks, give rise to greatly-increased difficulties of construction, and would be a source of serious danger to the tunnel when finished. Of course, depressing the tunnel will increase the gradients. Mr. Wolfe Barry also is of opinion that the larger tunnel which had been suggested by the acting Engineer of the Council is practicable as an engineering work, but he does not think that it would satisfactorily accommodate the traffic. He believes that a tunnel large enough for vehicular traffic can be made which will accommodate the footway traffic without serious addition to the size which is necessary for vehicular traffic alone.

As to the second head of the terms of reference, the most economical way of providing for the traffic, whether by the construction of one or more tunnels, Mr. Wolfe Barry says that this question is governed by the question of the design of a successful shield. If that be conceded, he thinks that one large tunnel would not be dearer in first cost than two smaller and independent tunnels, while in other respects it has great advantages. He considers that any

* It has been pointed out in the course of the discussion that the further extremity of the City and Southwark Subway has been constructed at Stockwell through water and gravel, the pneumatic shield being used.

roadway of the length of the tunnel and its approaches, which is only wide enough for two lines of heavy traffic, will not be satisfactory, and that provision should be made for one line of passing traffic in addition to two lines of slow traffic. All things considered, he recommends under the second head a tunnel circular in cross section, with an internal diameter of 31 ft. This would provide a roadway 22 ft. wide between the kerbs, with a headway of 15 ft. over the whole roadway, being a space of 2 ft. 3 in. on each side between the wheels and the kerbs for carriages and others, and to prevent the walls from being touched by loads. The foot traffic could be accommodated in an upper gallery suspended from the roof, and would have a width of 12 ft., with a height of 8 ft. in the centre, and there would be space on either side of the roadway for ventilating purposes, and for pipes, telegraph cables, &c. An alternative to this arrangement would be a tunnel also circular in cross section, but with a gallery below the roadway for foot-passengers.

On the third head of the reference to him, Mr. Wolfe Barry reports that he is inclined to think that there might be an advantage in drawing the specification in the alternative way, so as to provide for two prices, as suggested.

Lastly, under the head "generally," Mr. Wolfe Barry discusses, as alternatives to the proposed tunnel, a steam-ferry and a high-level bridge. He thinks that possibly a really good and convenient ferry, which would cost a small sum compared with a tunnel or bridge, might sufficiently accommodate the traffic for some years. A tunnel or bridge must of necessity occupy some years in construction; a ferry could, however, be set to work quickly in the meantime, and while the larger work was being matured and executed it would guide the Council as to the proper amount of accommodation to be provided, and as to the capital which could with propriety be expended on a tunnel or bridge. Any proposal for a high-level bridge would, he considers, involve raising the traffic by hydraulic lifts. There would, however, Mr. Wolfe Barry says, be no difficulty in so arranging these lifts that no delay would occur. On the whole, he sums up in favour of a high-level bridge rather than a tunnel.

The consideration of the subject is now before the Council, the greater part of two sittings having been already devoted to it. As we reported in the *Builder* for the 1st inst., the Bridges Committee, having considered Mr. Wolfe Barry's report, recommended—

"That the Council do proceed with the formation of the tunnel authorised by the Thames Tunnel (Blackwall) Act, 1837."

"That the Bridges Committee be authorised to nominate an engineer of experience in tunnelling with a pneumatic shield, to prepare the necessary plans and specifications for carrying out the works, exhibiting the whole to the Council."

To these recommendations Mr. Arthur Arnold moved an amendment as follows:—

"That the Council doth disagree with the recommendations of the Committee, and is of opinion that the report of Mr. Barry should be adopted so far as it is opposed to the construction of a tunnel at Blackwall, and that the best efforts of the Council should be directed to providing such other means of communication as may appear most desirable."

So far as the debate on the subject has yet proceeded, opinions seem to be pretty evenly divided between tunnel and ferry, while the idea of a high-level bridge seems to be generally regarded as inadmissible. But we do not quite gather from the latest report of the Bridges Committee, published by us a fortnight ago, nor from the speech of the Chairman of the Committee, in moving that report, whether the Committee are in favour of three tunnels, as proposed by Sir Joseph Bazalgette, or one tunnel to accommodate all traffic, as proposed by Mr. Wolfe Barry. It seems now to be the intention of the Bridges Committee to leave this an open question until the "engineer of experience in tunnelling with a pneumatic shield" whom they propose to appoint to prepare the working drawings and specifications advises them as to the best course to pursue. In their report as first presented to the Council on February 11 (see *Builder*, February 15, p. 119) they recommended

"That the Council do proceed with the formation of the tunnel authorised by the Thames Tunnel (Blackwall) Act, 1837,—namely, by three lines of borings, one being for foot passengers and the other two for vehicular traffic."

It will be noticed that in their recommen-

dation now before the Council the Committee have deleted the words which we have here put in italics.

Mr. Walter Hunter, J.P., who is himself an engineer and a member of the County Council, has issued a pamphlet commenting on Mr. Wolfe Barry's report. He is strongly in favour of the construction of the tunnel, and cites the opinions of Sir Frederick Bramwell, Sir Benjamin Baker, Mr. Henry Law, and other eminent engineers, as to the perfect practicability of the work. He also appends a letter from M. Coiseau, of Antwerp, who constructed the foundations of the Forth Bridge, and who has also constructed works under the Scheidt. M. Coiseau is so confident as to the practicability of executing the tunnel by the compressed air method that he last year, in conjunction with Mr. Webster, submitted a tender for the construction of one of the tunnels. Mr. Hunter and the other supporters of the tunnel project urge that if a communication is to be made across the Thames at Blackwall, it must be of a permanent and non-intermittent character, and must not interfere with the shipping. The tunnel scheme, they contend, is the only one which fulfils all these conditions. A ferry at this point, they urge, would be liable to interruption for days together by fog,* and would be at all times a serious danger and hindrance to the ships constantly passing in and out of the East India Docks.

On the other hand, the advocates of a ferry, among whom is Mr. J. G. Rhodes, point with some force to the success of the Woolwich Ferry, and lay great stress upon the uncertainty of the cost of the tunnel. They contend that, all things considered, the ferry will be amply sufficient to accommodate the traffic. The first cost of a ferry will, of course, be much less than that of a tunnel, but the yearly cost of working and maintenance will probably be as great or greater than the yearly cost of maintaining the tunnel—including, of course, interest on capital sunk.

A great many able speeches have been delivered on both sides, and the debate was to be resumed on Friday afternoon, March 14.

A FEW NOTES CONCERNING ANCIENT SEDILIA, PISCINE, AND AUMBRY'S.

ANCIENT sedilia are generally found on the south side of the chancel. These seats for the officiating clergy are most frequently recessed into the wall, and present a beautiful variety of treatment, some of them having rich canopies over them ornamented with crockets and finials. In most instances they are not more than three in number, though there are sometimes four or five of them, and occasionally only one or two. Most frequently they graduate in height eastwards; but are also to be found on the same level, especially when there are only two, as at Wolsey, in Leicestershire. Occasionally the sill of the south-eastern window forms the sedilia, as in St. Martin's Church, Brasted, in Kent. In some instances they are made to represent stone chairs, as in St. Michael's Church, Spennithorne, in Yorkshire, where the seat is wide enough for two priests, and there is a lower bench for another. These stone chairs are made with or without arms, and they are always placed in the position usually occupied by recessed seats, and we may be sure that when there are no traces of either sedilia or stone seats for the officiating clergy, there must once have been substitutes made of wood.

There is a single simple sedile in the south chancel wall of Chalk Church, in Kent. Adjoining it is the piscina. Both have trefoiled headings, whereof the two outer labels, which follow the same contour, are finished with rosettes, and the central terminal, which serves for both, takes the form of a mask. The piscina has a shelf, and the drain is in the centre of a scooped bracket which projects from the wall, and is supported on the head of a cherub. There is a single one, too, at St. Mary's, Dennington, Suffolk. In Maidstone Church the sedilia are quintupled.

In some of the ruins of ecclesiastical buildings that form such picturesque additions to many of our loveliest landscapes, we come upon sedilia open to the sky, of course, and fringed with ivy and other creeping plants; and set as they are in a background com-

* In regard to this point, we may observe that the ferry traffic between Liverpool and Birkenhead, across a much wider river, is never allowed to be interrupted by fog, though of course the transit is slower.

posed of the rest of the remains, consummate arches, pillars, traceried windows, and reticent doorways, they hold their own in the matter of interest. There is a ruined priory church standing on a knoll on the banks of the Alse, in Northumberland. Close by, on the other side of the river, is a mound, said to resemble Mount Carmel, though it is all heather, bracken, boulders, mosses, and ferns up to its breezy summit. There is a wide, strong, mellow curtain wall, with projecting battlements at the angles running round the piece of table-land on the head of this knoll, and within this enclosure lies the ruined priory. There is a strong tower in it, built by one of the ancient Percies for its protection, that is still whole and sound, even to its topmost stage, in which is a charming oriel looking over to the Carmel like mound across the river; but the monastery buildings are bare to the great canopy that covers all things. And crossing the grassy floors, in which is a dark, sunken tomb-hall here and there, we come upon the graceful sedilia, empty, silent, and windworn, but truly an exquisite and pathetic memorial.

These features are to be found in most counties. They are to be seen in the northern district that William the Conqueror gave to Robert de Uffville, on condition that he would keep it free from wolves and thieves, in Eldon Church, where, on the floor, may yet be seen the talons of Robert aforesaid. They are to be seen down in the Devonshire valleys, in several Cheshire churches, in Cambridgeshire, Buckinghamshire, Huntingdonshire, Gloucestershire, Bedfordshire, and, in short, in most counties, east and west. In Lincolnshire, especially, there are sedilia of the finest workmanship in nearly every church. Cornwall, however, appears to have disregarded them, and to have but few piscines. In different parts of the kingdom there are about half-a-dozen examples of a larger and plainer recess on the western side of the sedilia which may have been the bare bases of seats, or thrones, used only in grand ceremonials, when they may have been decorated for the occasions for which they were intended. In the church of St. Mary, Great Sampford, in Essex, besides three sedilia in the side of the chancel, there are eleven stone seats on each side of the chancel.

There are a few ancient churches in which we do not find a piscina or more than one. It was a necessary appendage to the altar in old times, and those churches that had more than one altar were furnished with more than one piscina. It has been noticed they were frequently double till the thirteenth century, when an alteration was made in an item of the service that made single piscines the rule after that date. There is an example of a triple piscina in Holy Trinity Church, Rothwell, Northamptonshire. They were nearly always placed in the south wall of the chancel, or of the aisle in which an altar was provided. The exceptions to this rule are rare. One occurs, though, in Rochester Cathedral; and another in Ditchling Church, Sussex, where they may be seen on the north side.

The most general form of a piscina is that of a small low niche, or recess, in the wall, with a shallow bowl-like base, in which is the orifice of the drain that carries off the water used in rinsing the chalice; and sometimes the drain runs down a shaft or column. Occasionally they are furnished with a shelf, which is supposed to have been used either as a credence table or as a place on which to place the cruet. The openings were finished according to the taste of the day, either plain or with columns and arches that were plain or foliated. Trefoiled piscines are, perhaps, the most common. There is one in a small Early English church at Leshury, in Northumberland, where the tall, alert, narrow, lofty arches in the nave and small window-openings are testimonies to Plantagenet masons. In the chancel, opposite to an old tombstone embedded in the north wall setting forth the memory of a vicar who lived to be more than a hundred years old in the seventh century, is the trefoil opening in question. Cinc-folled and sept-folled piscines also occur, and where there is no foliation we may sometimes find the encompassing arch of an earlier workmanship, and decorated with ball-flower and other ornament.

There is a piscina in the east wall of the south aisle of Alnwick Church. From a lingering tradition, which calls the east window of this aisle the Mary window, we may conclude there was once an altar here dedicated to the Virgin.

GRISSELL Medal Competition.
 Design for a timber octagonal spire
 By W. J. G. Pywell.

Transverse Section

forms. One of the most interesting of these archaic gems was one in the British Museum, which represented the conflict of Herakles and Nereus as it was to be seen on the frieze of Assos. The gem was no doubt rude in comparison with the frieze, and possibly was a good deal older; but the conception was the same, and we might fairly argue that both gem and frieze belonged to an artistic period or movement in which the Greek genius, with its true love of human form and heroic legend, was beginning to assert its supremacy over the influence of the East, to which it had owed its first instruction. During such a movement we could easily conceive that artists employed on public monuments or temples would not stand on their dignity as superior to the engravers of gems or the painters of vases; a common bond would unite them all. Indeed, we knew from actual tradition that the greatest of the early sculptors, Theodoros, was at the same time a gem-engraver. He also was a native of Asia Minor, and possibly was a contemporary of the sculptor of Assos. Both the frieze and the metopes of Assos were sculptured in low relief, and were, so far, true to the archaic influence of Assyria, with its vast array of sculptures in low relief. For the frieze that was necessary, but it seemed curious to us now, with our knowledge of later Greek art, to find that the height of the relief was not increased in the metopes. Probably it was thought that as the metopes were so close to the frieze, any noticeable change would have produced an inharmonious effect. But more likely it was force of artistic tradition that determined the point. In any case, it was well for the early sculptors of Greece to keep to the known methods of low relief until they felt themselves to be sufficiently masters of the technicalities of their art. The legendary subjects on the frieze referred to the exploits of the national Greek hero Herakles. The lecturer concluded his reference to the temple of Assos by saying that it was a temple in which metopes and frieze were curiously associated together, as if in one of those experiments which were inevitable in early times of art and architecture. In point of date we had not far to go to find another interesting exception to the general rule previously mentioned, though in point of distance we had to pass from the coast of Asia Minor, in the East, to the Island of Sicily, in the West. In Sicily the town of Selinus had been founded by Greek colonists. It lasted a comparatively short period, but during that period it had raised three temples, the ruins of which had survived to our times. Of these temples it was the oldest that interested us most, because of the fact that its only sculptured decorations consisted of metopes. The pediments were empty, and it had no frieze. Very probably this was no more than incompleteness. The original intention might have been to fill the pediments at least, if not also to sculpture the frieze. Pressure in other directions might have delayed the work until the destruction of the town by the Carthagenians made an end of all hopes. Of the metopes of the temple, three were found nearly complete, and they are now in the museum at Palermo. They were found by two Englishmen, and, through their good offices, casts of them were obtained for the British Museum. The subject of one of them was Perseus, backed by Athene, cutting off the head of the Gorgon Medusa. From a technical point of view these metopes of Selinus suggested a comparison with the reliefs of Assos, but while the latter were sculptured in low flat relief, the metopes of Selinus were in one sense in very high relief, and yet in another sense in very low relief; in other words, they stood out far from the background, but were not modelled with a full roundness reaching down to the background. On the contrary, they were modelled only on the surface, and it was kept flat. Wherever masses of shadow fell on the background it had merely the effect of blackness, and had little or no relation to the actual forms of the figures. In the metope of Perseus and Medusa there was very little background seen, and no doubt the desire of the sculptor throughout was to cover his space with his design, although that was not always possible. Proceeding to speak of the metopes of the Parthenon, the lecturer said there were ninety-two of them. A considerable number still remained on the building in their original places, but most of them had

suffered severely from weather and other causes,—so much so that often the very subject which they were intended to represent could not be made out. Others were destroyed in the course of the Venetian bombardment in the seventeenth century. Those that were best preserved in the early part of the present century were removed by Lord Elgin to the British Museum. There was a difference in style among these. Some of them reminded us in some measure of the metopes of Selinus, inasmuch as the relief, though it projected well from the background, was yet made to present, as far as possible, a flat surface to the front. There was an avoidance of strongly-rounded forms wherever it was possible to avoid or to minimise them. For instance, the drapery which fell between the Centaur and the Lapith, who was snub on his knees, might easily have been left out or forced back; but it was allowed to fill in the space, and thus to help out the desire of the sculptor to obtain as great as possible an extent of flat surface to the front. It was a mode of treatment which would be natural in the frieze of the Partheon, which was kept throughout in very flat relief. In the other variety of metope from the Parthenon, the sculptor had aimed at an opposite effect. He had sought the utmost degree of roundness and projection. Having referred to the presence in certain of the metopes of the Temple of Zeus at Olympia, of small drilled holes in places where the sculpture projects most, the use of which he was unable to conjecture (nor could he endorse Prof. Petersen's view that the holes had been made to contain sharp metal spikes to protect the sculptures from the birds), the lecturer described the metopes and friezes of the Thesalon at Athens, and, in his concluding remarks, said: "Pheidias and his contemporaries were able to startle the Greeks by the splendour of their conceptions and the magnificence of their ideas. Would that their works could startle us, and, making us forget the limitations of time and tradition under which they necessarily laboured, force us always to remember that the sculptures they have left us are an inheritance no less worthy of admiration than the great literature of Greek poetry and prose which has descended to our time, and in descending has had more to do in the fashioning of public spirit and character than almost any other element in our natures."

COMPETITIONS.

Asylum Buildings, near Dorchester.—The competition for additional asylum buildings at Charminster, near Dorchester, which was advertised last November by the Asylums Committee of the Dorset County Council, has resulted in sixteen sets of designs being sent in. Mr. C. H. Howell, the Consulting Architect of the Lunacy Commissioners, was appointed the assessor, and awarded the first premium to Mr. George T. Hine, of Nottingham, and the second to Messrs. Giles & Gough, of London. The Committee have confirmed the award of the assessor, and commissioned Mr. Hine to carry out the work. The present asylum accommodates 320 patients, and the new buildings will give accommodation for 400 more, together with a new administrative department, a large recreation hall, a detached church in the grounds, new laundry buildings, and various alterations to the old asylum. The total cost is estimated at from 40,000l. to 50,000l. Mr. Hine is the architect for the new asylum now being erected at Claybury, in Essex, for the London County Council, of which a view and plans were published in the *Builder* for Nov. 23 last.

Grant Monument, New York.—The result of "the international competition for a monument in honour of General Grant" has at last been published, after the designs have been in the hands of the promoters rather longer than seemed reasonable. Although the jury do not consider any of the competitors' designs suitable for erection, five prizes have been distributed. Of these the first has fallen to Messrs. Cluss & Schulz, of Washington; the second to T. P. Rinn, of Boston; the third to Messrs. Hartel & Neckelmann, of Leipzig; and the fourth and fifth to Herr Schweinfurth, of Boston, and Mr. H. A. Gribble, of London, respectively. We see that German members of the profession have taken the honours of the first, third, and fourth prizes.

Proposed Minister's House, Borough Synagogue, S.E.—A considerable number of drawings were received in this competition. The Committee called in a professional assessor to

assist them in coming to a decision. Acting on his advice the design submitted by Mr. Sidney G. Goss, A.R.I.B.A., of London, was adopted. Mr. Goss has been instructed to prepare the necessary working drawings and obtain tenders for the work as soon as possible.

Illustrations.

THE NEW LESSING THEATRE AT BERLIN.

THE new Lessing Theatre, the private property of Dr. O. Blumenthal, was completed in September, 1888, having taken barely a year to erect. Eleven hundred seats have been planned in the building, and standing-room for some sixty people has been arranged for. Of the 1,100 seats, 128 have been placed in the orchestra and side boxes of the parquet, and room has been found for 430 on the main floor of the house. The 542 seats remaining have been placed on two tiers, 214 on the first, and 328 on the second; and the standing-room has been partly allowed for in the pit, partly also in the second tier, the back places of which are priced the lowest.

The structure is almost entirely of a fireproof nature, wood having only been used for the stage flooring, the box partitions, and the lathing of the cupola. Most of the floors are vaulted in, the few exceptions being constructed in sheet iron. All the staircases are of freestone and have very easy ascents. On the proscenium side of the building four staircases have been planned, two for each tier, and each of these has not only the advantage of being in close connexion with the chief lobby, but at the same time the far greater one of leading directly into the open. The total width of the exit doors for the audience shows a figure of 14.50 metres, hence giving one metre exit width to eighty visitors. The main corridor running at the back of the boxes has a width of 4.30 metres, and, besides the very sufficient room for refreshment and cloak-room purposes, a foyer with a superficial area of nearly 150 square metres, and with its floor only 4.60 metres above street level, has been planned, thus making a crush in case of a panic nearly impossible.

The stage measures 20 metres by 18 metres, and is opening towards the audience has a width of 20 metres to a height of 7.50 metres. This opening can be closed, within seven seconds, by an iron curtain, working on a very simple system. The large fine over the stage has a superficial area of 16 square metres, or about $\frac{1}{2}$ of the stage floor. All scenic and technical apparatus is of the most modern date, and high-pressure hydrants command the whole of this part of the house.

The building, which has been designed by Messrs. v. der Hude and T. Hennicke (in conformity to the former building regulations), covers 2,300 square metres of the site, and has cost the proprietors 1,018,000 marks, or nearly 750,000l.

DESIGN FOR SPIRE.

This design, by Mr. J. A. Pywell, was awarded a Medal of Merit in the Grissell Competition of the Royal Institute of British Architects, and is for a timber octagonal spire to be covered with lead and with angle-turrets at or near the base.

ENTRANCE GATE, MANOR HOUSE, COLD ASHTON.

This gateway forms the entrance to the Manor House at Cold Ashton, or Cold Easton, so called from its exposed situation, and is of the early part of the seventeenth century. The house contains good screenwork and panelling of wood, and a rich plaster ceiling. There is no trace of the iron gables now save the hooks in the reveal of the arch, and some stonework in the reveal of the arms, which, consisting of a lion's head and paws holding a shield with three guns on it, and surmounted by wings, were formerly those of the family of Gunning. The property now belongs to Mr. Gore-Langton. The illustration is from measured drawings by Mr. M. Aston Green.

"SCATWELL," WARGRAVE.

This is merely the rebuilding of a small property adjoining Sir Mossell Mackenzie's house. It is used during the summer in connexion with the house by the owner and his family as a

erside retreat, in the village of Wargrave, or Henley-on-Thames.

The work throughout is of a very simple character. The inside joinery is stained walnut and varnished; the exterior fronts are in red brick and red-tile hangings and timber work. The gables to the garden front are in high east work of fine Thames shingle, the gable carved in cement.

The timbers are finished nearly black with pekholm tar, and the roofs are covered with slate.

Messrs. Silver & Sons, of Maidenhead, are the architects, and Mr. Arthur Ardron is the architect.

THE ARCHITECTURAL ASSOCIATION VISITS:

THE CHURCH OF THE HOLY TRINITY, CHELSEA.

The Church of the Holy Trinity, Sloane-street, which is being erected from the designs of Mr. J. D. Sedding, and will shortly be completed, was visited on Saturday afternoon by a large party of members of the Architectural Association.

The plan of this church covers a rectangle, the length of 150 ft., and comprises a nave 49 ft. 9 in. in width, with aisles 8 ft. 4 in. wide on each side. The north aisle is flanked by other and wider aisle, which will also serve as a Lady-chapel, and for this purpose is provided with a raised sanctuary adjoining the organ-chamber. A passage from the front of the building to the back is divided from the Lady-chapel by an arcade, over which light is admitted to the chapel by three windows in the aisle above. A deep gallery spans the west end, and is approached by circular stairs in the turret.

On each side of the chancel minstrel galleries overlook the altar, which are reached by spiral staircases. The altar will be set forward, and will screen a door communicating with an ambulatory behind, which extends across the chancel and is connected by doors with the side aisles and the vestries, occupying the north-east angle of the building.

Mr. Sedding, in the interesting description he gave of the building, called attention to the fact that the building was designed with a view to the decoration of a somewhat elaborate description.

A deep frieze above the nave arcade will, it is proposed, be filled with paintings from the hand of Mr. Burne Jones, whilst it is proposed to place statues of the Apostles by Mr. Thornycroft in the niches prepared for them on the vestries.

It is to be hoped that the addition of these decorations will tone down some of the baldness of the present appearance of some of the details, especially of those in the spandrels of the nave arcade.

It was stated that the east window is probably the largest in the United Kingdom, and that the main lines of the tracery of this and the other windows were drawn in with a free hand by the architect with a view to the later introduction of figures in stained glass. One of the side windows is perhaps one of the most satisfactory in its design. The clearstory windows contrast appear to be very small.

It is to be regretted that the nave has been covered with a vault of wood, springing from iron shafts, and appearing to imitate a vault of stone. A more suitable design for the material might have been conceived, if a wooden roof was unavoidable.

The front elevation has been executed in red brick and Douling stone dressings and bands, and spandrels to the entrance doors being coated in rubbed brickwork, in preparation for carving.

The turrets, which flank the west window and aisle-screens, with their gradually retreating sides, are certainly one of the most pleasing parts of the design.

The screens at first appear to terminate the side aisles, though in reality a much less projection would have been sufficient. The carrying of the battlemented parapet under the west window across the side screens, as an ornament, is open to criticism.

The building will be lighted by electricity, for the installation of which preparation is being made.

We may add that we have published the following illustrations of this church,—viz., a

double-page exterior view and an extra-large-size interior view on October 6, 1888; and a drawing of one bay of nave arcade on October 12, 1889.]

THE ASSOCIATION OF PUBLIC SANITARY INSPECTORS.

At a general meeting of this Association held on the 1st inst. at Carpenters' Hall, Mr. H. Alexander presiding, a report was presented by the Council embodying its recommendations upon the question of the status of the Sanitary Inspector, which it had been instructed to consider. The Council came to the conclusion that in the various Acts of Parliament referring to the position and work of the Sanitary Inspector, there were five defects which it was desirable to remove in future legislation, and the report therefore recommended the Association to endeavour to secure the following amendments in sanitary law:—

1. That every candidate for the position of Sanitary Inspector shall have a general knowledge of the building trades, and, in addition, shall possess a certificate in Sanitary Science.

2. That Sanitary Inspectors shall have a permanent tenure of office, and shall only be dismissible for misconduct, or proved incompetence, with right of appeal to the Local Government Board.

3. That it shall be the duty of Sanitary Inspectors to periodically inspect the dwellings in the district to which they are appointed; and to receive complaints of nuisances and serve notices forthwith, requiring all necessary works to be done for the abatement of the nuisances. Such notices to be as valid, if confirmed by the Local Authority, as if served by the Authority's order.

4. That in all appointments requiring the officer's whole time to be given to the duties of his office, an adequate minimum salary shall be prescribed.

5. That the officers now variously named "Sanitary Inspectors" and "Inspectors of Nuisances" be designated "Sanitary Inspectors."

After a brief discussion, during which the Chairman announced that his Board (Shoreditch) had formally adopted proposition 3, the report was adopted unanimously.

Mr. Richards (Battersea) read a paper on "The Removal and Disposal of House Refuse in London." The practice of storing up refuse for weeks, instead of a very few days, before removal, was strongly condemned, and the manner of collecting and conveying it through the streets of London was described as "a disgrace to this centre of civilisation." The practice, formerly common, but, as the paper stated, "happily no longer permitted," of depositing it on proposed building-sites had been followed by the wasteful disposal of it either by deposits on the marsh-lands of the estuary of the Thames, or by "barging" it out to sea, and more recently, in some districts, by the still more wasteful process of "cremation." On the basis of the cost of machinery erected in Whitechapel for the latter method of wasting refuse, it was estimated that the enormous sum of 1,031,000. would have to be got from the taxpayers of London, without counting the annual cost of working, on purpose to destroy annually 2,295,000 cubic yards of fertilising matter, a quantity sufficient to cover 1,400 acres of land with a layer of manure a foot thick.

China, and recently Scotland, offered us examples of a more sensible disposal of refuse, and in at least one London parish (Newington) these excellent examples had been followed, with good results. The larger question of the disposal of all refuse must, the lecturer declared, "ultimately receive the serious attention of the future Ministers of Health and of Agriculture. What must be more fully realised by our sanitary reformers is that the gradual diminution of the area under cultivation, and the decrease of the producing power of the land, not only means total dependence upon foreigners for our food-supply, but by withdrawing from the land those who should be employed upon it constitutes the primary cause of excessive overcrowding in our towns."

Mr. Poulson (Chelsea), in proposing the usual vote of thanks, condemned the method of storing the refuse preparatory to removal as a serious nuisance in Newington, and Mr. Grant, who seconded, said he thought cremation the only cure, opinions for and against those of the paper being expressed by other members in the course of the discussion.

THE LONDON COUNTY COUNCIL.

The ordinary weekly meeting of this Council was held on Tuesday afternoon last, in the Council Chamber, Guildhall, Lord Rosebery in the chair.

Age of Retirement of Officers.—The Standing Committee presented the following report:—

"We are giving careful and anxious consideration to the important questions referred to us by the Council, relative to an insurance scheme for the servants of the Council, and also the establishment of a benevolent fund. These questions have been referred to a sub-committee, who have been making inquiries as to the course adopted by other of their inquiry institutions. In the course of their inquiry they have remarked upon the absence of any limit of age at which officials of the Council may be required to retire. The consequence of there being no provision for compulsory retirement may be that officers will remain in the service of the Council when they no longer have the vigour necessary for the efficient discharge of their duties. The Royal Commissioners on the Civil Service establishments have recently recommended that there should be compulsory retirement at the age of sixty-five years, and we are of opinion that it would be well for the Council to follow the same principle, and to fix sixty-five years as the age at which retirement should be compulsory.

Cases may arise in which it would be advantageous to retain the services of particular officials, but this we think should only be done by a special resolution of the Council in each case. We recommend that the following be a Standing Order of the Council:—

"That every officer and servant of the Council shall retire at the age of sixty-five, unless the Council shall pass a special resolution to the effect that his retirement will cause inconvenience to the public service, in which case he shall continue for another year, and so on at the termination of each successive year of his age."

This was agreed to, after some discussion.

The Proposed Central London Railway.—The Parliamentary Committee presented the following report:—"On February 11 the Council passed a resolution that, in order to preserve the *locus standi* of the Council, to oppose, if so advised hereafter, on merits, a petition should be prepared against the preamble of the Central London Railway Bill. The report on Parliamentary schemes, prepared in the Engineer's Department, which has been circulated to the members of the Council, points out the serious interference of the proposed line with the Council's sewers, and it is evident that, in any case, proper protective clauses must be obtained. But, apart from this, as we have already pointed out in our report on the 11th instant, the question of motive power is one of very great importance. In the case of the similar scheme which was before Parliament last year, Sir John Fowler stated as follows, in evidence before the Select Committee on the Bill:—

"Those motors are liable to derangement, like anything else, and especially anything connected with electrical machinery. Electricity, so far from escaping difficulties as regards derangement, I think, according to everybody's experience at the present time, is rather liable to it; that is certainly my own personal experience."

"I quite grant you, if you like, that, that it has gone so far beyond the experimental stage that you are perfectly justified in adopting it; but we have not got so far beyond the experimental stage to know how much liability there is to derangement of these motors."

The petition of the Council, which was sealed on the 18th instant, and which was framed so as to enable the Council to oppose the preamble of the Bill, if considered advisable, contains the following allegations:—

"Your petitioners deny that any such public necessity can be shown to exist for the construction of the said subways or railway as proposed by the Bill, or that any such public advantage will result therefrom as will justify the public injury and inconvenience which the exercise of the said powers would cause, and your petitioners believe that no experience has yet been gained to show that the working of so large an undertaking, as proposed by the Bill, by means of electricity is convenient or practicable.

Your petitioners also call attention to the special provisions of the Bill as to interference with property by enabling the Company to acquire easements or rights of constructing and using their railway under certain properties, and also to the powers sought of interfering with properties by underpinning, or otherwise strengthening the same, and your petitioners submit that such powers may cause injury and inconvenience. Your petitioners refer to the settlements and cracks in their sewers, caused by similar works, as showing that the risk of such injury and inconvenience is considerable."

Owners of the freehold soil below that portion of the street which is vested in local bodies are petitioning against the Bill, and are

claiming compensation for interference with their rights; while, on the other hand, the interests of the authorities in whom the streets are vested are also affected. In the appeal case of the Wandsworth District Board of Works v. the United Telephone Company (Law Reports, Queen's Bench Division, vol. xiii., page 913), it was held by the Master of the Rolls that the property in a street passes to a certain depth, which depth is what may be called the 'area of user,' that is to say, such a depth as will enable the urban authority to do what is done in every street, to raise the street and lay down sewers. Now, we have the authority of the Engineer's report for the interference of the scheme with the Council's sewers, and we are informed that for a distance of three-quarters of a mile the line, as shown on the plans, passes within 25 ft. of the surface, and for two miles within 35 ft., there being, of course, a limit of deviation in either case, which might bring it considerably nearer. The case consequently appears to be within the limits laid down by the Master of the Rolls in the judgment above referred to. As regards the question of compensation, we desire to express the opinion that the local authorities, in whom the streets are vested, should be compensated in the same way as the freeholders of property on either side of the street. We are proceeding to obtain evidence in support of the allegations of the Council's petition, but looking to the terms of the resolution passed on the 11th inst., we are placed in a position of uncertainty, and we are anxious to have definite instructions as to the nature and extent of the proposed opposition. We, therefore, submit this report, and recommend—

"That the opposition to the Central London Railway Bill be continued on the lines laid down in the Council's petition, and that the course taken by the Parliamentary Committee with regard to obtaining evidence be approved."

Mr. Beachcroft moved the following amendment:—"That as no resolution has been come to by the Council to oppose the Central London Railway Bill on its merits, and as the object of the Bill, if successfully attained, will effect a great metropolitan improvement without charge on the rates, the opposition of the Council to such Bill be confined to the taking of needful steps to secure the special clauses required to protect the sewers and other interests of the Council." Mr. Beachcroft urged that the Council ought not to stand in the way of an improvement of this kind, provided that their interests could be safeguarded, as he believed they could be. He contended that a new central London railway from east to west, following the line of Oxford-street and Holborn, was much needed for the convenience of the public, and he cited the City and Southwark Subway (now nearly completed) as a proof that such a work could be constructed without damage to property on the line of route. Mr. Collard, however, contradicted this statement, and said that there was scarcely a building in High-street, Borough, which had not suffered from the construction of the subway.

After a good deal of further discussion, the amendment was carried, and after transacting other business, the Council adjourned.

SALT IN CEMENT MORTARS.

SOME interesting particulars regarding the use of salt in the preparation of cement mortars which are to be subject to very low temperatures are given in the Transactions of the Institution of Civil Engineers (see vol. xcii., Abstracts of Papers, &c.). The information is taken from various sources, and is of considerable interest to those engaged in building operations. It is well-known that water contained in common salt in solution freezes at a lower temperature than fresh water, and it has been proposed to take advantage of this property in preparing mortars for use when the temperature is below freezing-point. It must not, however, be concluded that sea-water would answer the same purpose, as that contains other salts also.

From some experiments made in Russia, the following results were obtained:—Hydraulic lime and Portland cement were mixed with fresh water, and also with water containing 2 per cent. and 8 per cent. of salt in solution. Bricks cemented together with these mortars were allowed to set in the open air at temperatures ranging between 17-6 deg. F. to a little above freezing-point. Two cubes made from the different cements were subject to the same con-

ditions. The cubes made with fresh water cement fell to pieces under pressure of the hand; and the bricks cemented with the same material did not adhere. The specimens prepared with water containing 2 per cent. of salt gave somewhat better results; but the samples made with water containing 8 per cent. of salt could only be destroyed by the aid of the hammer, and the bricks could not be separated. The Portland cement mortar was, in all cases, stronger than that made from hydraulic lime. Some operations carried out in America (see "Transactions of American Society of Engineers," March, 1887, p. 79), confirm the latter fact. In the construction of some canal locks, the work built with Portland cement, when examined the following year, turned out to be perfectly sound, but the hydraulic lime mortar had been destroyed to a depth of 3 to 4 in. In the course of erecting these works some concrete was laid in which a good deal of salt was mixed. The mass was completely frozen, but proved perfectly sound in the end, being impervious under a head of 15 ft. of water.

In the construction of a bridge in the United States, four piers were built, when the temperature was ranging in the case of the first between 1-4 deg. Fahr. and 21-2 deg. Fahr. During the building of the second the temperature was about 20 deg. Fahr., and the remaining two were built when the thermometer stood above the freezing-point. For the facework, Portland cement mortar, mixed with sand in the proportion of 1 to 1½, was used, and for the interior work 1 to 2½. The sand was warmed, and large quantities of salt were added to the water, yet at 1-4 deg. Fahr. the mortar froze very quickly while it was being used. In the end no difference could be discovered between the quality of the masonry of all the piers. The superiority of Portland cement over native American hydraulic lime is also testified by Mr. G. S. Morrison, an American engineer. Test specimens of the two materials were frozen in water; those of Portland cement were uninjured, but the hydraulic lime samples fell to pieces. The Superintendent of Public Works for the State of New York, Mr. Shanahan, when building walls in cold weather, adds a strong solution of salt to the mortar.

ARCHITECTURAL SOCIETIES.

Manchester Architectural Association.—At the fortnightly meeting of this Association, held on the 4th inst., a paper was read by Mr. T. Chadwick, A.R.I.B.A., the subject being a few recent notes in Holland and Belgium. The paper was illustrated by sketches made by Messrs. Chadwick, Colley, and Woodhouse during a tour in September last. The route taken was from Harwich to Rotterdam, Delft, Dordrecht, Malines, Brussels, Ghent, and Antwerp. A cordial vote of thanks was accorded to Messrs. Chadwick, Colley, and Woodhouse.

Sunderland Architectural Students' Association.—At the first general meeting, February 7, a paper, on the "Study of Mechanic in their Relation to Architecture," was read by the President (Mr. Frank Caws), and, during the discussion which followed, it was arranged to have interim meetings for the study of the subject in detail, the President undertaking to conduct these interim classes on alternate Wednesdays, and give practical demonstrations on the black-board. At the general fortnightly meeting, February 21, a paper by Mr. H. Barnes, on the "Use of Wood and Iron in Building," and on March 7th a paper by Mr. F. J. Purvis, "On Stone as a Building Material," were read, and followed by interesting and instructive discussions, in which the younger students were encouraged to take part. In addition to the classes for the study of mechanics, another class, on alternate Wednesdays, meeting under the direction of Mr. William Milburn, is engaged in the study of Grecian architecture, illustrated by lime-light photographic views and diagrams. Mr. R. Eisey Smith has most kindly lent the Association a number of photographic slides, taken by himself, of Grecian buildings. The subject of Greek architecture was divided into the following details or branches:—History, Mr. H. Barnes; Plans, Mr. John Hall; Proportions, Mr. G. T. Brown; Shafts, Mr. J. Spain; Caps and Bases, Mr. A. B. Tiffin; Entablatures and Pediments, Mr. F. E. Coates; Ornament, Mr. E. S. Welles; and the various students above-named undertook each the branch set against his name. The committee intend to further pursue this method of inchoing

all the students in share and take an interest in the work of study and preparation necessary for the successful carrying-on of this class.

ARCHÆOLOGICAL SOCIETIES.

British Archaeological Association.—At the meeting of this Association on March 5, Mr. C. H. Compton in the chair, Mr. Earle Way exhibited some remarkable Gray-beard ja found in Southwark, ornamented with coat-of-arms and having Dutch inscriptions as well as the usual head and beard of Cardinal Bellarmine. Mr. Davis described a candlestick of stone, of small size, found among some rubbish removed from a Gloucestershire church. It is circular in form and about 3 in. in height. Mr. Davis also produced a rubbing of a brass in Newlands Church, Forest of Dean, where a miner is depicted holding his candlestick in his mouth, a stick and a boss of clay in the left hand. It occurs on the brass called that of Sir H. Baynham. A rubbing of a brass in Wandsworth Church was also shown dated 1420, on which a knight is represented with a mace at his girdle. Mr. Saunders described the key of Portsmouth Town, which was thrown into the Harbour by Colonel Goring on the surrender to the Parliamentary Army. It is now in his possession, having been recovered in 1811. Mr. Oliver exhibited one of the well-known forgeries of the celebrated traders of spurious antiques known as "Billy and Charles." He did so as a warning to antiquaries, as the occasional exhibition of these will do good deal to keep a record of their fabrication. A paper, illustrated by a large collection of rubbings of the objects referred to, which occupied one side of the Hall, was then read by Mr. Romilly Allen, F.S.A. (Scot.), on the Pre-Norman Sculptured Stones of the West Riding of Yorkshire. In the comparatively limited district under review twenty-six different localities occur in which sculptured stones have been found in churchyards, or in relation to churches, mostly in the valleys. The greatest number are found within a radius of twenty miles of Leeds. After dwelling upon the historical data, especially with regard to the introduction of Christianity in the seventh century, the lecturer referred to the style of ornamentation, which agrees in peculiarities of detail with what is found in other parts of the North of England, Lindisfarne being probably the centre of the art. The stones are covered with interlaced patterns, and consist of shafts and heads of crosses. Eleven inscribed stones have already been noted, one of which appears to relate to Osbert, killed in 867. Figure subjects occur not unfrequently, and at Bingley an inscribed font, a photograph of which was exhibited.

Royal Archaeological Institute.—The Right Hon. Earl Percy presided at a meeting of the Institute held on Thursday, the 6th inst., when Mr. Oliver read a paper on a brass to the memory of Roger Thornton which was originally placed on altar tomb in the Church of St. Saints, at Newcastle-upon-Tyne. The figure of Roger Thornton was dressed in a long gown reaching to the feet. His wife's figure shows a long sleeveless gown with high collar. Mr. Oliver said that this brass was the only one of Flemish workmanship of the fifteenth century in this country. (We gave an illustration of this brass in the *Builder* for November 16 last.) Mr. J. Park Harrison read a paper on "Anglo-Norman Ornament compared with designs in Anglo-Saxon manuscripts." The paper was illustrated by many designs and copies from Early Saxon MSS. From these Mr. Harrison deduced that Saxon architecture was of a superior description than what was generally supposed. Lord Percy exhibited a silver ornament, shaped like a crescent, which was found near Newham, Northumberland. It was probably of the fifteenth century.

The Surveyors' Institution.—The Council of this Institution have decided to give a portion of the value of 100, out of the interest arising from the Crawter bequest to the candidate doing the best work in the field on Monday the 24th inst., provided he obtains not less than 75 per cent. of the marks allotted to this branch of the Surveying and Levelling Examination.

Surveyorship, Burslem.—The Burslem Corporation have appointed Mr. Fred. Bettal as their Engineer and Surveyor, in place of Mr. P. J. Sheldon, who has obtained the Burslem Council appointment.

BYZANTINE REMAINS IN GREECE.

Sir,—You were good enough about a year ago to advocate the work which was then carried on by the British Archaeological School at Athens in obtaining full-sized drawings of the profiles of the mouldings used in Greek architecture, and the response in the form of subscriptions from various donors, which, if not a large sum, yet has been of very material use in arriving at a satisfactory result, which consists of a very complete collection of mouldings taken with upolous exactness by our architect student, R. W. Schultz. These will no doubt be published in some form or other.

Since the beginning of this year the opportunity of employing so competent an artist is not been lost sight of by the school, and R. Schultz has been re-engaged by the committee in concert with another architect, Mr. Mansley, in making drawings of the Byzantine churches in Greece, of which there are an extremely valuable specimens. But your work is likely to be very seriously curtailed for want of funds, as the money which is devoted to this purpose by the British Archaeological School falls much short of what is due to the subject. Up to the present time the plans of this period in Athens itself have been examined, and one other very interesting and important specimen,—namely, the monastery of St. Luke, near Mount Helicon; but the collection will be very imperfect if it remains at Mistra and some other parts of Peloponessus are not included; which, unfortunately, cannot be done with the funds presently available. In a letter received lately from Mr. Gardner, the Director of the school, he says, "I am very sorry that Schultz and Mansley are so short of money, and I fear they will be obliged to curtail their plan, and only finish off the churches they have begun without going further afield. I think this will be a great pity, as their work makes me as more excellent than ever, especially their drawings of St. Luke."

Under these circumstances, I write to ask you would allow me, through your columns, to invite subscriptions from the lovers of archaeology in general, and early Mediaeval art in particular, for the purpose of making an undertaking more complete.

Subscriptions may be sent to Walter Lennox, Old Change, the treasurer to the British Archaeological School; or should you think, as on the former occasion, that a special subscription fund would be desirable, I should be willing (should you so desire it) to receive subscriptions, and from time to time to announce them in the *Builder*, in which case you could ask the donors to distinguish any of their subscriptions from others intended for the Greek Mouldings Fund; to signify in some way or other that Byzantine architecture is their aim.

F. C. PENROSE.
8, St. Paul's-churchyard.

"We certainly desire it.—Ed.

THE GLASGOW MILL DISASTER.

Sir,—In reference to your interesting article on the fall of the Glasgow mill, it would be instructive to your readers if a plan and drawing were given, the direction of the wind at its pressure per square foot.

It is known that at most meteorological stations the apparatus is so imperfect that the wind effects are generally blown away in a storm, and it may be hoped that this was not the case at Glasgow.

GEORGE ARCHIBOLD.

A CLAIM ON A BILL OF EXTRAS.

Sir,—Our clients, Messrs. Kirk & Randall, have drawn your attention to the paragraph in your last issue headed "A Claim on a Bill of Extras," and desire to point out to you several inaccuracies at report.

It is stated that it was shown that the amount in dispute had been paid by the Baths Commissioners to Messrs. Kirk & Randall. As a matter of fact the Baths Commissioners, who was present at the meeting, and our client, both positively stated that the amount in which the item in dispute was

included was not before the Commissioners at the time of settlement, and the Judge found, as a fact, that the item was not present to the minds either of the Commissioners or our clients at the time of settlement, and that our clients had never, personally, any knowledge of the item at all.

The plaintiffs' own evidence was that although they had been repeatedly warned by Messrs. Kirk & Randall that no amounts would be paid for unless orders were received from them, they had not in fact received any such orders, and they had not communicated the fact of the work being done to Messrs. Kirk & Randall. Furthermore, the contention of the defendants was not that the architect had exceeded his authority, but that the amount had not been included in the sum paid to them, and that it had never been received by them, as they had no knowledge whatever of the plaintiffs' claim in settling their accounts, and were, therefore, under no liability to pay the amount.

We should be obliged if you would in fairness to our clients call attention to these facts in your next issue.

We defer saying more on the subject as the case is new under appeal.

MCKERRILL, MATON, & GODLEE,
21, Cannon-street, E.C., March 8.
[This letter arrived too late for insertion last week. Our reporter informs us that our report, although brief, was substantially in accordance with the evidence; that it was proved that the item in dispute was in the accounts which were before the Baths Commissioners at the time of settlement, and that an exception was taken to it; that these accounts had been prepared jointly by the quantity-surveyors representing the builders and the building-owners respectively; that although it is true that evidence was tendered as to the plaintiffs having been cautioned by the defendants against executing orders received otherwise than through the defendants, it was proved that the architect, Mr. Vorty, had ordered the goods in question (which he had ample power to do under the terms of the contract), that they had been duly supplied, and that the architect had authorised the amount in dispute to be included in the accounts. On one point only was our reporter slightly in error, and that was in describing the nature of the action. It was not, technically speaking, an action to recover money for goods supplied to defendants, but it was an action to recover money had and received by defendants on behalf of the plaintiffs.]

"HISTORY OF CROMER."

Sir,—Will you kindly allow me space to correct an error in your last edition in reference to the above. In referring to the church, you say, "The restoration of the nave was done by Mr. Newman." This is not quite correct, as the work was carried out by the late Mr. E. Summers and myself, Mr. Newman only having the sub-contract for the bricklayers' work.

W. CHAPMAN.
Haverorth, Norfolk, March 12, 1890.

* It is not our mistake; we merely teek the statement as given in the book.

Technical Institutions in Berlin.—Mr. Brunner, M.P., during a recent visit to Berlin, took special interest in the affairs relating to the organisation of the institutions for technical education in Germany, and those at Berlin especially. Thanks to the "Rector," Prof. Jacobsthal, Mr. Brunner had the opportunity of inspecting all the interior arrangements of the Royal Technical College, and besides viewing the aula, the library, and reading-rooms, the lecture-halls, class-rooms, studies, and minor details of the main building, he also went over the Architectural Museum (of which Professor Raschdorff is the director) and some of the educational collections (building construction, building materials, geological, civil engineering, technological, and ship building). A visit was paid to the building belonging to the Chemistry division, and here the laboratories of the inorganic department (Prof. Ruedorff) were specially gone through. The Royal Testing Laboratory and workshops were visited, and here the head of the institution, Prof. Martens, explained the different apparatus used, especially those used for testing iron and steel, and those used for the testing of paper as to wear, tear, and discolour.

The Association of Municipal Engineers notify that the ninth examination of candidates for the offices of Municipal Engineer and Local Board Surveyor will be held at the Institution of Civil Engineers on Friday and Saturday, April 18 and 19 next. The Association of Municipal Engineers was instituted in 1875, and now numbers some 420 members. It has done a great deal to raise the standard of qualification for the professional officers of municipalities and Local Boards.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—XI.

DYNAMO-ELECTRIC MACHINES.

WELL-ILLUSTRATED descriptions of the details of all the important forms of dynamo-machines that are made appear from time to time in the pages of engineering papers. To these articles is referred a student who wishes to see how the general principles of dynamo-electric machinery, dealt with in this and future articles, are applied in practice. We have already explained—article VII.—how and in what direction E.M.F. is set up in a conductor which is being cut by lines of force; fig. 26 represents lines of

Fig. 26.

force between the N and S poles of the field magnet of a dynamo-machine. If the conductor A B move into the paper, the direction of the E.M.F. produced will be from A to B; some such diagram, showing the relative directions of lines of force, motion, and electro-motive force produced, should be committed to memory, though the following rule may prove useful if it is borne in mind that at the earth's surface lines of force go from south to north:—*If a man walks towards the east an E.M.F. is set up from his feet to his head.* In practice, however, the moving conductor is not a mere rod like A B, nor does the field consist of straight lines of force as in fig. 26. It is, therefore, necessary in many cases to consider parts only of the conductor at a time, and then to see in what direction acts the added electro-motive forces, set up in the different parts. It frequently happens that a conductor cuts lines of force, so that the E.M.F. set up in one part opposes that set up in another, in which case the difference between the two is all that is available for use. Before the quantity can be calculated the numerical value of the E.M.F. set up in a conductor moving in a magnetic field must be known.

Fig. 27.

In Fig. 27, A B is a conductor which slides between two fixed rods G H and K L, metallic contact being made with them at A and B, so that any E. M. F. which may be set up in A B will produce a current in the closed circuit A B D A. Let the resistance of this circuit be R and the resistance of the rods G H and K L be so small that the varying length of rod introduced into the circuit, as A B moves, does not appreciably alter the total resistance. If a uniform field of force pass through the apparatus in the direction N S and the conductor move in the direction of the arrow, an E. M. F. is set up in the direction A B and a current C flows in the direction A B D. Let l = length of A B, v = speed with which it moves, f = strength of field, E = E. M. F. set up, and t = time taken by A B to move from G to H. Then $E = CR$, and the work in Joules done in the circuit is $E C t$, that is, $10^9 E C t$ ergs, as explained in article V. Again, in the same article it was shown that if a conductor of length l , carrying a current of C amperes, was bent into the form of a circle of unit radius,

it exerted a force of $\frac{Cl}{10}$ dynes on a unit magnetic pole placed at its centre, or a force of $\frac{Clm}{10}$ dynes on a pole of strength m ; but since action and reaction are, by Newton's third law, equal and opposite, the conductor itself experiences the same force, though in the opposite direction; as, therefore, the pole of strength m produces a field of strength m at one centimetre distance, in the neighbourhood of the conductor and at right angles to the direction of the current at every point, the force produced is $\frac{Clm}{10}$ multiplied into the strength of field into which it has been introduced. Applying this to the present case, the movement of AB is resisted by the force $\frac{Clf}{10}$, and since the total distance through which it moves is $v t$ the work which is to be done to move it from G to H is $\frac{Clfv t}{10}$ or $10^{-7} Clfv t$.

By the law of the conservation of energy, the mechanical work put into the apparatus is equal to the electrical work got out of it. Hence:—

$$10^7 E C t = 10^{-7} Clfv t$$

$$E = \frac{10^7 Clfv t}{10^7 C t} = 10^{-8} lfv \quad (1)$$

But lv is the area traced out by AB per second, and $lv \times f$ is the number of lines of force cut by AB per second; so that equation (1), which is of fundamental importance, may be stated in words as follows:—The electromotive force set up in a conductor is equal to the number of lines of force through which it cuts per second multiplied by 10^{-8} .

It appears, then, that to get one single volt, a conductor must cut, in the same direction, no less than one hundred million lines of force per second.

There is now working at Deptford a dynamo-machine which gives 10,000 volts electromotive force, so that 10^{12} or 1,000,000,000,000 cuttings of lines of force by conductor per second must take place. At first sight this figure seems very extraordinary, but it must be remembered firstly, that the actual number of lines of force in the field or set of fields in a dynamo amounts to many millions; secondly, that each conductor is not a simple rod as in fig. 27, but is wound into a bobbin of many turns, so that each line in the field is cut several times by the same conductor; and, thirdly, that the armature revolves many times per second. Each of these factors multiplies the E.M.F., so that it is not so astonishing after all that the number of cuttings reaches the enormous figure it does.

Fig. 28.

We will now investigate the E.M.F. produced by the skeleton dynamo-machine in fig. 28. $ABCD$ is a rectangular conductor placed between the poles of the field magnets NS . Suppose F to be the flux through $ABCD$ when it is in the vertical position, by the time it has turned into the horizontal position AB and CD have together cut every line, i.e., F lines, setting up an E.M.F. in the direction shown. In one complete revolution $4F$ cuttings take place, and if the rectangle is revolved n times per second, the number rises to $4nF$ per second, so that an average E.M.F. of $10^{-8} \times 4nF$ volts is produced.

To give an idea of what this E.M.F. may be likely to come to, suppose the area of the rectangle to be—say, 150 square centimetres, then 10^6 would not be an out-of-the-way value for F ; if the number of revolutions per minute is 600, $n = \frac{600}{60} = 10$. Let $E = \text{E.M.F. in rectangle}$, then $E = 10^{-8} \times 4 \times 10 \times 10^6 = 4 \times 10^{-1} = 0.4$ volt.

It must be noted that average electromotive force is spoken of, as by tracing the E.M.F. set up in the conductor as it revolves it will be seen that the direction reverses at the instant when the rectangle is vertical: hence in the vertical position $e=0$, if e is the actual E.M.F. at any instant; in the horizontal position e has its maximum value, and sinks again to zero

a second time at the vertical position. We shall not trouble ourselves about this while considering machines used for giving a continuous current, because a number of conductors are connected up so that when one is contributing its maximum effect another is contributing no E.M.F. at all, the other conductors being in intermediate positions. When, therefore, all the effects are added the result is an E.M.F. equal to the average E.M.F. given by one conductor multiplied by the number of them so connected; thus by proper connections and commutation a practically constant, though slightly fluctuating, E.M.F. is obtained for external use.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

3,600, Scavenger Carts. A. H. and J. E. Hayes.

The carts made under this specification are covered to prevent spilling the liquid slop or the dust being blown about by the wind, and side and end boards are fitted to increase the carrying capacity for light dust without interfering with the action and protection of the mechanical cover. These extra boards are provided with iron pintles, which fit into sockets at the back and sides of the cart, the front being built up solid of sufficient height to close up the crown of the covering. The extra boards are fitted to the covering-flaps being, is of sufficient height to permit the flaps to conveniently rest on the top of the additional side-boards, so as still to make a joint thereon for protecting the contents as efficaciously as when the heightening boards are removed without interfering with the action of the flaps. When the contents are to be discharged, the door, on tipping, is automatically opened so as not to cause any interference with the fixed cover.

4,432, Balanced Sashes. W. S. Ingle.

The sashes, which are the subject of this invention, are hung so that one half balances the other. A grooved pulley, working in a case bracket, is employed, and is fixed to the top of each internal side of the window-frame, the centre of the pulley being midway between the two side window-sash frames. Over these pulleys is passed a cord or chain, one end of which is fixed to each top sash-frame, and the other to the bottom sash-frame. When one is lowered the other is raised correspondingly.

4,645, Door and Window-fastenings. Ellis Parr.

This invention relates to the form of fastening in which, when it is applied (for example) to a door, the latter is held sufficiently firmly in a closed or desired position; but can be opened or removed when desired by simply pressing it in either direction. A plate has a rectangular aperture stamped out, the edges of which are left standing at right angles to the side, the bolt is passed through past the aperture, and through a spiral spring in the centre of the aperture. This forms the fastening.

4,853, Centre Bits and Boring Tools. R. J. Anderson.

According to this invention, a tool for drilling or boring, whereby the diameter of the holes to be bored may be adjusted, is made by employing an arm of suitable length pivoted to the bit or tool. The extremity of this arm has a cutting edge. The end of the tool is spread out to form wings having a flat surface forming a support for the arm, and giving space for a slot, into which is fitted a tightening screw. To adjust the tool to make a hole of a proper size, the arm is rotated on its pivot till the size is attained, it is then locked and fixed by a screw.

5,205, Terra Cotta Blocks. H. Doulton and another.

According to this invention blocks are made with a number of small cells or cavities similar to the holes in perforated bricks, except that in place of running completely through the block they are open at one face, stopping short of the opposite face. The blocks may be moulded at the closed end, and owing to the smallness of the cells can be employed for building purposes without any filling, and yet since the cells on them are open at one end the clay can dry thoroughly.

5,595, Chimney Pots. R. Roberts.

At a short distance below the cover of the pot, a dish-shaped ring is, according to this invention, fixed around it to serve as a preventive in case of the rebound of the wind—as, for instance, from a roof or wall on this ring the wind impinges and down draught is prevented.

NEW APPLICATIONS FOR PATENTS.

February 24.—2,912, H. Badams, Gas-brackets and Chandeliers.—2,911, G. Appiani, Continuous-acting Kilo.

February 25.—2,965, H. Brookfield, Flush Water-closets, Drains, &c.—2,966, G. Bayl, Fastenings for Window-sashes.—2,983, J. Coll, Combined Sash-fasteners and Lits.—3,021, O'Brien and J. Carew, Stone-cutting Chisels.—3,025, G. West, Flanging Material Compositions.

February 26.—3,075, G. Light, Interceptor traps for Drains, &c.

February 27.—3,162, J. Merryweather, Pavement.

February 28.—3,184, A. Rovedino, Wood Pavement Block or Brick.—3,197, J. Bell, Circular Saw.—3,205, F. Cook, Lightning Conductors.—3,215, Meredith, Fastening Door-knobs to Spindles.—3,217, C. Spurr, Cutting Veneers.—3,221, L. Hawkins, Flushing Apparatus for Water-closets.

March 1.—3,255, E. Marples and F. Lamb, Combination Tool Cabinets.—3,266, B. Town and J. Dixon, Horizontal Sawing-machines.

PROVISIONAL SPECIFICATIONS ACCEPTED.

791, R. Crowden and R. Pulton, Paperhang Roller.—1,054, J. Connell, Sash Fasteners & Window-sashes and Doors.—1,958, W. You, Securing Sash-lines to sashes.—1,418, A. Ramman, Metal Framing for Fire-proof Floors and Walling.—1,544, G. Newman, Bolts or Fasteners.—1,619, Shilton, Electric Bolts or Gongs.—1,689, W. N. Sealing Windows.—1,730, J. Merrill, Cisterns & Water-closets, &c.—1,769, J. Jones and S. Edgar, Automatically raising Water-closet Seats.—2,008, R. Evedred and N. Colman, Flushing Drain.—2,190, E. Jobson, Open Stoves or Fire-grates.—2,445, A. Osborne, Heads and Screws.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months.

3,376, J. Becker and W. Winslow, Cleansing Whitewashing, Staining, and Painting Ceiling.—5,175, W. Wintour, Ventilating.—5,913, W. Leach, H. Lyman, Refractory or Fire-resisting Cement Ladders, &c.—6,819, J. Jacquemin and E. Sogtan, Closing Orifices in Drain-pipes.—6,874, J. I. and J. Lyon, Mosaics for Floors, &c.—6,895, S. Barwell, Draught, Rain, and Dust Excluder for Doors.—7,197, A. Goslin, Flushing Cisterns.—W. Albany, Retaining Windows at any desired Height.—8,845, N. Frowler and others, Bricks.—20,947, R. Haddon, Water-closets.

MEETINGS.

FRIDAY, MARCH 15.
 Royal Institution.—The Right Hon. Lord Rayleigh,
 F.R.S., on "Electricity and Magnetism." 7.30 p.m.

MONDAY, MARCH 17.
 Royal Institute of British Architects.—(1) Mr. Alfred
 Boswell, on "Drawings of Brick Buildings in North
 America, erected from the designs of Professor Otzen-
 berg." (2) Mr. William White on "The Gallies of
 St. Paul's Cathedral." 8 p.m.
 Society of Arts (Contar Lectures).—Professor A. H.
 Church, M.A., on "Some Considerations Concerning
 Colouring." 1. 8 p.m.
 Imperial Architectural Society.—Miscellaneous Con-
 sultations. 7 p.m.
 Leeds and Yorkshire Architectural Society.—Mr.
 Waterhouse, M.A., on "The Work and Writings
 of Alfred Rick." 7.30 p.m.

TUESDAY, MARCH 18.
 Institution of Civil Engineers.—Mr. J. Price, Jun.,
 on "Lough Erne Drainage." 8 p.m.
 Royal Institute (Lectures for Sanitary Inspectors).
 J. F. J. Sykes, B.Sc., on "General Powers and
 of Inspectors of Nuisances.—Method of Inspec-
 tion." 8 p.m.
 Society of Arts (Foreign and Colonial Section).—Mr.
 Ellis on "Brazil." 5 p.m.

WEDNESDAY, MARCH 19.
 Lectures to Artisans and others on Matters Con-
 cerning Building.—Professor W. C. Unwin, F.R.S.,
 "The Construction of Walls." Carpenters' Hall,
 11, New-wall. 8 p.m.
 Institution of Civil Engineers.—Students' visit to the
 Grand Main Drainage Works. Meet at King
 Cross Railway Station at 1.30 p.m.
 London Mechanical Engineers' Society.—Mr. H. C.
 Clarke on "Gold Mining in Merionethshire." 7 p.m.
 Society of Arts.—Mr. J. S. Kettle on "Commercial
 Geography." 8 p.m.
 Architectural Association.—Mr. W. Money,
 on "The Seal of the Dean of Newbury, 1492."

THURSDAY, MARCH 20.
 Edinburgh Architectural Association.—Principal F.
 Galvrie on "Electric Lighting of Interiors."

FRIDAY, MARCH 21.

Sanitary Institute (Lectures for Sanitary Inspectors).
 Mr. J. F. J. Sykes, B.Sc., on "The Nature of Nuisances,
 including Nuisances the Abatement of which is
 difficult." 8 p.m.
 Institution of Civil Engineers (Students' Meeting).—
 Mr. L. A. Leveque on "Economy Trials of a Compound
 Mill-engine and Lancashire Boilers." 7.50 p.m.
 Royal Institution.—Professor G. F. Fitzgerald, M.A.,
 F.R.S., on "Electromagnetic Radiation." 9 p.m.
 Sunderland Architectural Students' Association.—Mr.
 F. Purvis on "Stone as a Building Material." 7.30 p.m.

SATURDAY, MARCH 22.

Architectural Association.—Visit to the new Central
 Offices for the Metropolitan Police on the Victoria
 Embankment, Mr. R. Norman Shaw, R.A., architect.
 Royal Institution.—The Right Hon. Lord Rayleigh,
 M.A., F.R.S., on "Electricity and Magnetism." VI.
 8 p.m.

Miscellanea.

Sales of Building Property at the Mart.
 —Two well-favoured properties at Hampstead
 will be put up to auction within three or four
 weeks hence, and in all likelihood will be de-
 voted to general building purposes. These are
 the Priory Lodge and Frogmal Hall estates,
 situated between St. John's parish church and
 the top of West End-lane, and covering about
 six acres in all, with 1,000 ft. frontage to
 Frogmal and Church-row. Priory Lodge is
 close to the site of the Priory built by
 "Memory Corner" Thompson, an auctioneer
 and valuer, over the ruins, as he claimed,
 of an ancient priory, formerly occupied by
 Cardinal Wolsey, as a rural retreat. But it is
 to be remembered that the real priory,
 Godwin's hermitage, temp. Henry I, converted
 into a nunnery of St. Benedict, lay at Canehour,
 or Kilburn. At Frogmal, in the older maps, are
 marked one or two ponds, feeders of the West
 Bourne, or Ay Bourne, whereof a branch ran
 towards Kilburn. The old manor-house of
 Hampstead originally stood upon the opposite
 (or northern) side of West End-lane. It
 was rebuilt by the name of Hall Oak
 Farm. Parkin, in his "Topography and
 Natural History of Hampstead" (1818),
 conjectures that this manor's primitive name was
 Frog-mall. He also says that in Sir Samuel
 Bentham's day there stood in the garden a
 handsome old pollard, being the particular oak-
 tree which Bentham had always understood
 gave its name to the manor farm. Thompson's
 Priory, which he filled with a strange collection
 of curiosities and pseudo-rarities, is now
 demolished. Lord Alvanley, Lord Chief Justice
 of the Common Pleas, occupied, teste Walford's
 "Old and New London," Frogmal Hall; he died
 there on March 13, 1804. Isaac Ware, the
 architect, and editor of Palladio's works, lived,
 for a while, in Frogmal Hall. Hard by, in
 West End-lane, being, as Park tells us, "the
 last house in Frogmal (southward)," and stand-
 ing in his day, was the house which Dr. Johnson
 rented for his wife, and to which he himself
 occasionally resorted. There, as we read in
 Boswell, he composed (1748) the greater part,
 if not the whole, of "The Vanity of Human
 Wishes, being the Tenth Satire of Juvenal
 Imitated."

The Tansa Water Scheme.—That this is
 the greatest scheme of a gravitating water-
 supply for a city in India is well known. The
 first survey was made by Major Hector Tulloch,
 now Senior Inspector of the Local Government
 Board in England, in 1870. It was first brought
 before the Corporation as a project to be
 executed on July 27, 1883, when it was ably
 supported by Dr. Weir, and was accepted. The
 area of the water-spread, when the dam is com-
 pleted up to the height which it is now intended
 to be carried, will be about seven square miles,
 while the catchment area is fifty-two square
 miles. The water from the reservoir will be led
 into Bombay by five miles of tunnels, twenty-
 five miles of ducts, and nineteen miles of 48-in.
 mains. These will carry the water to Ghat
 Kooper. From Ghat Kooper into Bombay there
 will be twelve additional miles of mains. The
 final surveys and necessary modifications which
 were found to be required were made by Mr.
 Clarke, the talented engineer of the works,
 under whose immediate superintendence they
 are being executed.—*Indian Engineering.*

New English Art Club.—This Club has
 secured the Galleries in Humphreys' Mansions,
 Knightsbridge, for its next Exhibition. The
 private view is fixed for March 29.

The English Iron Trade.—The English
 iron market is quieter, if anything, and its ten-
 dency is still downwards. Very little is being
 done in pig-iron, makers holding on pretty
 firmly to their quotations, while buyers generally
 purchase of merchants. Scotch warrants are
 again lower on the week, the result being that
 makers in Scotland have reduced their prices
 from 6d. to 2s. a ton, according to brand.
 Middlesbrough pig has lost 1s. 3d. a ton. In
 other districts prices are easier. Although makers
 of hematite pig are putting into practice their
 agreement of blowing out furnaces, to counteract
 the effects of operations in warrants, they have
 lowered their prices 3s. a ton. Manufactured
 iron is unsettled, and very little business is put
 through. The market is easier on the whole,
 merchants offering under makers' prices, and in
 the north of England ship-plates and angles
 have fallen. The tone of the steel market is
 anything but steady, and in the north-west
 wire rods have lost 5s. a ton, while rails and
 blooms have dropped 12s. 6d. and billets and
 slabs 15s. a ton. Ship-building material is also
 generally cheaper. There are no fresh orders for
 ships, and engineers are getting quieter.—*Iron.*

A New Source of Portland Cement.—A
 new source of supply of Portland Cement has
 been opened up by the recent discovery of the
 immense deposit of carbonate of lime and
 cement clay underlying the former in the county
 of Grey, Ontario. The deposit is only two
 miles from the Grand Trunk Railway of Canada,
 and only nine miles from Owen Sound of the
 Georgian Bay. The carbonate of lime is stated
 to be purer than the European chalk, and the
 clay much the same as the well-known Medway
 clay, and contains 62 per cent. of soluble silica.
 Canada imports about 100,000 barrels of Port-
 land cement annually, and the United States
 procure from Europe over 1,000,000 barrels.
 Not a barrel of Portland cement of commerce
 has, so far, been made in America, although an
 inferior kind of cement or water lime is manu-
 factured. The reason is obvious, no carbonate
 of lime having heretofore been found on the
 American continent pure enough to make
 superior Portland cement. It is believed that
 a cement superior to any imported can be pro-
 duced as cheaply as European manufacturers
 are able to place the raw material on the
 ground.

Free Lectures at Carpenters' Hall.—
 The fifth of the present series of free lectures
 to artisans and others on matters connected
 with building, under the auspices of the
 Worshipful Company of Carpenters, was
 delivered on Wednesday, the 5th inst., by
 Professor A. B. W. Kennedy, F.R.S., his
 subject being "The Forth Bridge." Mr. Alfred
 Preston presided, and there was a crowded
 attendance. The lecture was illustrated by a
 large number of photographic slides shown by
 means of a lantern.—The sixth lecture was
 delivered on Wednesday evening last by Pro-
 fessor Marshall Ward, M.A., on "The Tree,
 from the Sapling to the Bench." This lecture
 also was illustrated by lantern views. Mr.
 Wyatt Papworth, F.R.I.B.A., Master of the
 Clothworkers' Company, presided, and there
 was again a large attendance.

Lock-out of Kentish Brickmakers.—We
 regret to see that, owing to the strike of Kentish
 bargemen, there has been a lock-out of brick-
 makers. A special meeting of the Committee of
 the Brickmakers' Association was held in Lon-
 don last week, to receive a deputation from
 the Bargemen's Society, but a letter was read
 from the latter postponing the conference. On
 Saturday the edict of the Kentish brickmasters
 to close their works and to lock-out their hands
 came into force. This had the effect of turning
 some 5,000 people out of employment in the
 Sittingbourne district alone. The men have
 been told that they are locked-out pending the
 settlement of the dispute with the bargemen.

Berlin.—The exhibition of "Stone Road-
 making Materials," which had been organised
 by the Amalgamated Association of Pavors,
 and was held here recently, cannot, although
 very interesting and fairly well managed on
 the whole, be termed a success, partly owing
 to the inexact and very incomplete cataloguing,
 and partly on account of the non-marking of
 the prices on the exhibits. The idea of having
 such an exhibition was certainly good; for,
 however much asphalt and wood-paving may
 come in use, stone-paving, especially that of a
 superior sort, will never die out. The Associa-
 tion intends repeating the exhibition on a
 larger scale and with greater care.

Mr. P. H. Rathbone and the St. George's Hall Panels.—Mr. P. H. Rathbone has addressed a letter to the Town Clerk of Liverpool acknowledging the letter accepting his offer of the remaining panels for St. George's Hall, and adding that he hopes this "may be one step in restoring to British architecture that human interest which was alike the glory of Grecian and Gothic architecture, including our own cathedrals, and which alone spoke to the heart of the people until it was crushed by Henry VIII. and the great Protector of Edward VI.'s reign, but which makes every principal street in Florence a page of Florentine history, which he who runs may read."

 B. Bowles (accepted) 128 0 0

LONDON.—For making up and paving roads in the Parish of Fulham. Mr. W. Sykes, New Streets Surveyor:—
 Gilstead-road.

Bowles, Battersea £910 0 0
 Nowell & Robson, Kensington 613 0 0
 Tomes & Wimpey, Hammersmith 603 0 0
 Mears, Kensington 506 0 0
 Serff, Holle, & Co., Chiswick 572 0 0
 Neave & Son, Paddington 527 0 0
 Coat, Hammersmith 491 0 0
 Whittinghall-road.
 Bowles, Battersea 420 0 0
 Nowell & Robson, Kensington 337 0 0
 Serff, Holle, & Co., Chiswick 315 0 0
 Tomes & Wimpey, Hammersmith 304 0 0
 Neave & Son, Paddington 293 0 0
 Coat, Hammersmith 368 0 0

LONDON.—For pulling down and rebuilding back addition and sundry repairs at 1, 2, 10, and 12, Market-place, Underhill-road, East Dulwich. Mr. Alfred Wright, architect, 61, Kennington-road:—
 Nixon £275 0 0
 Hollingsworth 230 0 0
 Ford & Son 228 0 0
 Batley 224 0 0
 G. Godson & Sons, Kilburn 208 19 0
 Greuville 175 0 0

LONDON.—For the supply of granite kerbs, pitching, channelling, macadam for roads, Yorksire stone flags, Patent Indurated stone flags, cartage of materials, and the masons' and paviors' work for one, two, or three years, from March 25, 1890, for the District Boards of Bow, Poplar, Bromley-by-Bow, and the Isle of Dogs.
 Lewis Griffiths, Millwall, E., schedule of prices (accepted).

LONDON.—For the erection of artisans' dwellings, Richard's-place, Old-street, E.C. Messrs. Elmsston & Gabriel, architects, 42, Old Broad-street. Mr. G. R. Tasker, surveyor, 38, John-street, Bedford-row:—
 J. B. G. £286 0 0
 J. B. G. 270 0 0
 Shenherd 274 0 0
 Patman & Fotheringham 239 0 0
 Taylor 209 0 0
 Scott 198 0 0
 Smith & Son 198 0 0
 Young & Lonsdale 176 0 0

LONDON.—For the construction of a new road and sewer on the Old Park-avenue Estate, Nightingale-lane, S.W. Messrs. N. S. Joseph & Smith, architects, 45, Finsbury-pavement, E.C.:—
 L. Bottoms, Wandsworth-common £72 0 0
 R. Mayo & Co., Brixton 60 0 0

LONDON.—For erecting a new proscenium to the stage of concert-hall, and for re-decorating, gilding, and other works to hall, supper, and dressing-rooms, also concert-hall, at the Queen's Gate Hall, Harrington-road, South Kensington. Messrs. Rogers, Chapman, & Thomas, surveyors, 59, Belgrave-road, South Belgravia, S.W.:—
 Adin Bros. & Davies £253 0 0
 W. K. Manders 223 0 0
 J. Douglas 213 0 0
 H. Smith & Son 212 0 0
 E. D. Hook (accepted) 250 0 0

NEWCASTLE-ON-TYNE.—For building St. Jude's Church, Newcastle-on-Tyne. Mr. A. B. Plummer, architect, Newcastle. Quantities by Mr. Geo. Connell, Grainger-street, Newcastle:—
 E. Weatherley, Newcastle £4,003 0 0
 E. B. Road, Newcastle 3,833 5 7
 J. H. Elliot, North Shields 3,618 0 0
 Tyrie & Graham, Newcastle 3,763 0 0

 W. J. Jotterill & Co. 35,937 0 0
 H. Dickson 35,966 0 0
 Nowell & Robson (accepted) 34,983 0 0
 Holme & King 33,779 15 4

RUDGWICK (Sussex).—For two pairs of cottages at Arun Bank. Mr. Benj. Tabberer, architect, 13, Basinghall-street, E.C. Quantities by Messrs. Franklin & Andrews, 25, Ludgate-hill, E.C.:—
 Waddington & Co., Spisham £1,057 0 0
 King Bros, Rudgwick 983 17 5
 Peters, Horsham 900 0 0

SALFORD.—For erecting the Ladywell Sanatorium, Salford. Messrs. Maxwell & Tuke, and E. & F. Hewitt, joint architects, 29, Princess-street, Manchester:—

Sanatorium Buildings. G. Parkinson 235,047 0 0 ... 2,307 19 0 S. & W. Pattinson 31,982 0 0 ... 802 0 0 A. Bleakley & Sons 39,548 0 0 ... 4833 0 0

Terra Cotta. Monk & Newell 2883 19 1 J. C. Edwards (accepted) 971 12 7

Concreting. Dunbar Kelly 22,905 3 2 H. H. Morton 1,932 0 0

Bell Hanging and Lightning Conductor. Rudale 171 0 0 Baker 148 0 0

SIDMOUTH.—For building new farm-house, Upper Chelson, Sidbury Manor, Sidmouth. Mr. Walter F. Cave, architect, 8, George-street, Portman-square, W.:

Turner & Skinner, Honiton 4710 0 0 Holmes & Tozer, Exeter 690 0 0

SOUTHALL (Middlesex).—For new school for 300 boys at Featherstone-road, Southall, Middlesex, for the Norwood Middlesex School Board. Mr. Thos. Newell, architect. Quantities by Messrs. Young & Brown:—

School Walls, Latrines, Building, and Play-ground. J. W. Falkner 23,732 41,647 25,370

SOUTHALL (Middlesex).—For three shops and dwelling-houses in High-street, Southall, Middlesex. Mr. Thos. Newell, architect. Quantities by Messrs. Young & Brown:—

T. Nye, Edling 23,140 0 0 H. & A. J. Jones, Edling 3,047 0 0

Reduction Estimates. Dorey 2,600 0 0 Gibson 2,476 0 0

THIRSK.—For additions, &c., to mansion, Thirskley Park, near Thirsk, for Lady Payne-Frankland, Messrs. William Lewis & Son, architects, 40, Stonegate, York. Quantities by the architects:—

James Thackeray, Ripon 22,288 0 0 John Keswick, Micklegate, York 1,936 0 0

SUDEBURY (Middlesex).—For sundry decorative works to "The Hale," for Mr. A. Hicks. Mr. Walter Graves, architect, Winchester House, E.C.:—

Oldrey & Co. 1135 0 0 Tompkins 97 5 0

WOLVERHAMPTON.—For erecting the "Vine" Inn, Stafford-street, for Messrs. Wm. Butler & Co. Mr. Arch. Paul Brevitt, architect:—

Henry Willcock, Wolverhampton 43,985 0 0 Henry Lovatt, Wolverhampton 3,960 0 0

WORCESTER.—For new tin-room, cooperage, boiler-house, and stables, for Messrs. Lewis, Clarke, & Co.'s Brewery, Worcester. Messrs. Sannell & Colyer, architects, 15, Great George-street, Westminster, S.W. Quantities by Messrs. R. L. Curtis & Sons, London-wal:—

No. 1.—Building. J. Wood & Sons, Worcester 43,729 0 0 No. 2.—Fronteroe. J. Wood & Sons, Worcester 727 0

SUBSCRIBERS IN LONDON and the SEBURES, by subscribing at the Publishing Office, 15s. per annum (or 4s. 3d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

TO CORRESPONDENTS.

H. B. B. (the subject is one to be treated from an architect's not from a lawyer's point of view).—W. B. B.—G. T. H.—H. K.—"Equator" (from what we know of the architect we should think what you suggest very improbable; and at all events we should publish your letter anonymously).—J. W. S. (too small).—M. & K. (should send specimens).

TERMS OF SUBSCRIPTION.

"THE BUILDER" is supplied direct from the Office to residents in any part of the United Kingdom at the rate of 15s. per annum in advance. To all parts of Europe, America, Australia, and New Zealand, 50s. per annum. To India, China, Ceylon, &c. 30s. per annum. Subscribers payable to DELOLAS FOUNDRIER, Publisher, No. 46, Catherine-street, W.C.

The Railways of America.

WHETHER it is a perception of an increased public interest in railway working that has called forth popular publications on the subject recently, or whether the publication of these works has itself been the means of awakening public interest on the subject, it would be difficult to decide. At all events it seems to be recognised now that railways and railway working are subjects open to treatment in popular literature. Mr. Acworth's extensive and effectively written treatise on the Railways of England has been pretty speedily followed by a similar type of book on the Railways of America;* which however is not the work of one writer, but a collection, into one volume of a series of chapters by various writers, each treating separately his own subject, but the whole being written as a series and in relation to one another.

Though it might be expected that this divided authorship, and the relegation of special subjects to special writers, should conduce to a more thorough and practical character in a book on so large and complicated a subject, we cannot say that the American book in the main compares favourably with its English forerunner in practical character, except in regard to the two first chapters, written by engineers, on "The Building of a Railway" and on "Feats of Railway Engineering." Even these are written in rather a sensational style, though they really give information supplemented by a number of illustrations; and much of the book is apparently written with the special desire to say startling and effective things rather than to give information on a practical subject in a practical manner.

It is just possible that in this desire to be effective the writers have done the railway system of their country some injustice, though their endeavours to give graphic accounts of hairbreadth escapes from dangers which ought not to have existed, and of tragic

* "The Railways of America: their construction, management, development and appliances." By various writers. With an introduction by Thomas M. Cooley, Chairman of the Interstate Commerce Commission. With more than 200 Illustrations. London: John Murray, 1890.

accidents which ought never to have happened. It is only charitable to suggest this possible allowance for the effects of literary impulsiveness. If we are to take this book *au pied de lettre*, we can only say that it gives the idea in many parts of what might be termed an organised recklessness in the making and management of railways such as would fill people with indignation in this country, and which, if it represents the plain truth, certainly serves to account for the number of bad railway accidents which we hear of from the United States.

Nothing could more decisively mark the wide distinction between the whole spirit of railway policy in England and America than the naive admission made by Mr. Curtis Clarke in the first chapter, "There is one thing more which distinguishes the American railway from its English parent, and that is the almost uniform practice of getting the road open for traffic *in the cheapest manner and in the least possible time*, and then completing it and enlarging its capacity out of its surplus earnings, and from the credit which these earnings give it." The italics are ours. The writer makes this characteristic admission without comment, and apparently without any perception of its damaging imputation. This system has been followed everywhere, it seems, except on a few branch lines, "and on one monumental example of failure," the West Shore Railway of New York, in which an attempt was made to build a railway up to the standard of one that had been forty years in reaching its standard of excellence. "Their money gave out, and they came to grief." The most elaborate essay could hardly emphasise more the distinction between the English and American spirit of responsibility in railway-making; a distinction of which we may well be proud. It has at all events been always recognised in England that the construction of a railway is a matter of grave responsibility in regard to public safety, and that it is not a kind of construction to be turned out anyhow, in a hurry, in order to realise dividends at the expense of risk to the lives of all travelling upon it. We allow jerry-building, unhappily, to far too great an extent; but we have not yet gone so far in the evil path as to sanction jerry railroad-making. That the Americans regard this as a perfectly natural and commendable system, as one which it is even a folly to depart from, is a charge which we should hardly have ventured to have made against them; but here we have it on the

authority of one of their own engineers; and the admission throws a significant light on some of the accounts of railway accidents in the States, as well as on incidents mentioned in other portions of this book. This is the bad side of a spirit in railway engineering which has also its good or at all events its interesting side. The history of the American railroad affords, it must be admitted, evidence of what may be called the adaptability of the spirit of the nation. They were not content to adopt the system as England invented it, but began early to consider railroad-making in reference to the special conditions of the country. In making railroads over immense areas of often hilly country, where there was no choice of a flatter route within the range of district to be served, it was resolved that the railway must be adapted to the country and not the country to the railway. Hence the invention of the swivelling truck or "bogies" system, by which the whole length of train was rendered as flexible as possible, so as to go round curves of short radius. Hence also the method, of which the Americans first set the example, of working railways up slopes by a series of returns and doubles, the road coiling up the hill like a snake in a long series of curves, crossing and recrossing itself at higher levels, so that one American engineer is reported to have said, "where a mule can go, I can make a locomotive go." This eccentricity of railway planning, as it appears to those who are not used to it, is in some sites, no doubt, the most practical and direct way of meeting a difficulty. But in regard to the system of a flexible train and short curves, and the boast of the American engineer that thus a costly tunnel may be avoided by doubling round a promontory for instance, on the edge of a valley, which an English train could not go round, it must be remembered that this saving is effected at the expense both of speed and safety. A comparatively straight track, with no short radius curves, means high speed with safety, besides a more direct route. It costs more to make at first, and we can easily imagine that it would not suit a country where railways seem to be regarded mainly in the light of acute financing operations, intended to bring the quickest return possible; but with a solid financial basis it means speed, safety, saving of time, and ultimate money value in proportion. So with questions of vertical irregularity of road; as Mr. Acworth very justly pointed out in his book, the adoption of a heavy

gradient by way of shortening the route, in one instance, had proved a permanent cause of delay and of cost in haulage which more than compensated for the initial saving in the adoption of the route. And our conclusion in comparing the American system of sharp curves and steep gradients, as described here, with the English system of often heavy initial expenditure in securing comparatively straight and level roads, is that the latter has in the long run the advantage in every particular.

The change in the type of locomotive engine from that first derived from England is another example of the independent line taken in America, and with better reason. The type of locomotive which originated in England has been adopted with little variation by most of the European countries, where the conditions of railway work did not differ very materially from those of this country. The swivelling truck or bogie, first used in American engines, as observed, for the sake of flexibility on short curves, has been to a great extent adopted in English locomotives since, though the sharp curves have not been introduced, and indeed hardly could be until the whole of the rolling stock should be mounted on swivelled wheels. But other conditions combined to change the form of the locomotive in America; the use of wood fuel, which appears to require a different type of chimney (a detail, by the way, not commented on or explained in the volume); the necessity of frequent progress through snow, which produced the snow-plough in front of the engine; the running of long portions of the earlier railways through desert prairies, which no doubt established the "cow-catcher" framework in front of the engine as a kind of recognised equipment; and the frequent traversing of long routes in hilly country and with very steep "grades," which has further developed in the States the coupling of wheels to gain all the frictional grip that is possible with the weight of the engine. Thus we have the "consolidation" locomotive, with its four pairs of small driving-wheels, all connected by coupling-rods, with only one pair of small leading wheels at the extreme front of the bearing; and the "Decapod," with five pairs of small connected driving-wheels, looking as if it ran on castors; and a machine contrived for climbing steep gradients. Another peculiarity of the American engine is a recent development of the body of the engine in front of the chimney and boiler, as if the boiler were extended further. This is an elongation of the smoke-box in front of the base of the chimney, to give more space for catching and detaining hands and cinders, which collect here and can be removed by taking off the front plate. We presume the fuel used has made this desirable, as no necessity for it has been found in England, as far as we are aware. All these various *differentia* combine to render the American locomotive, to European eyes, a somewhat uncanny-looking object; it is impressive in its mass and its rather uncut outline, but has a heavy and cumbersome appearance, and has not the expression of being formed for speed which the English locomotive conveys; it has other special merits of suitability to its circumstances, but we cannot help thinking that the English model is more a work of Art, of the two.

There are it appears, one hundred and fifty thousand miles of railway laid down in the United States; and various details in the chapters on Railway Construction, as well as this rather impressive statement of mileage, impress the reader with the fact that we are in a country where things are done on a very large scale, and where no obstacles are allowed to count. But although one cannot help admiring the ingenuity with which a railway is carried in all kinds of ways through all kinds of country, we do not know that a perusal of the book is exactly calculated to give one a wish to travel much on American railways. Especially considering that ominous sentence before quoted, as to the practice of making railways as speedily and as cheaply as possible in the first instance, one cannot but feel, while looking at some of the illus-

trations of sections of line carried on "trestles," that is, running on the top of a series of tripods, that while it is magnificent as long as all is right, the slightest accident must have fearful results, and that if one travelled on railways carried on these kind of viaducts one would like at all events to know that they had been built with the very best materials and with the greatest care; and such knowledge as we can get seems to point rather to a considerable lightness of heart in these matters; at all events to a feeling that economy and rapidity of construction are the main ends in view. The long "trestle" on the Colorado Midland Railway, for instance, shown in one of the plates, is described as "an expedient often of the greatest service in railway construction. These trestles are built of wood, simply but strongly framed together, and are entirely effective for the transport of traffic for a number of years." That is to say, they do wonderfully well considering their temporary nature. "They must then be renewed, or what is better, be replaced by embankment, which can be gradually made by depositing the material from cars on the trestle itself." From other remarks elsewhere, it almost seems as if piling earth on the outside of a timber structure were considered sufficient to constitute it an embankment, or what appears in America to be called a "culvert." What about the centre when the timber finally decays? It seems hardly possible that this can be the meaning, yet we do not know how else to understand the remark on page 26, in connexion with temporary wooden structures, that "a structure covered with earth is much safer than an open bridge."

In the more modern American railways the art of building lofty viaducts on very light steel piers seems to have been carried to great perfection, though from the point of view of the picturesque one is almost tempted to regret the change on comparing the view of the grand timber viaduct at Portage, on the Erie Railway, with the thin spider-like construction that has taken its place. In regard to the method of finishing the light steel viaducts for the roadway Mr. Clarke says

"Build strong iron or steel bridges and viaducts with as short spans as possible and having no trusses above the track where it can possibly be helped. Cover these and all new bridges with a solid deck of rolled steel corrugated plates, coated with asphalt to prevent rusting. Place on this broken stone ballast, and bed the ties in it as in the ordinary form of road-bed."

By this means the usual shock felt in passing from the elastic embankment to the comparatively solid bridge will be done away. Has a crack formed in a wheel or axle, this shock generally develops it into a break, the car or engine is derailed, and if it strikes the truss the bridge is wrecked. The cost of this safety floor is insignificant, compared with the security resulting from it."

Security to the bridge, no doubt, but as to security to the passengers or the train no one who looks at the drawings of the type of bridge of which this remark is made would feel much reassured. The only "security" would be that the train, unless going at a very slow speed, would go over the edge, or a great part of it at all events. The tone in which cracked and broken axles are spoken of as if they were incidents to be looked for at any day is noticeable.

The deep snows to which parts of the American railway system are subjected in winter exercise a considerable influence on the construction of roads in certain positions, most remarkably illustrated in the great covered snow-sheds built over the track on the sides of declivities, to protect the train from avalanches. The train has to be run, for a long distance in places, under covered penthouse galleries of very solid construction, the roof of which continues the slope of the ground above so that the snow slides over it. In a section given of one of these we observe that there is a double track, that outside the shed being marked "summer track" and the inside "winter track." Why people who pride themselves so much on economy in railway work should go to this expense of a double track, and

why the covered track will not serve the purpose at all times of the year, it is not very easy to see. Another special feature rendered necessary by the snow is the snow-plough, a great erection like the prow of a small vessel, which is shown as pushed by sheer force through the snow, with four engines in line behind it. A more scientific means of attaining the same end appears to be exhibited in the representation of a "rotary steam shovel" at work, pushed by three engines, and sending off the snow in thick flying showers on either hand of the front engine: the illustration, a sensational one enough in appearance, is reproduced from an instantaneous photograph. There is, however, no technical description or illustration of its method of working, which it would have been of some interest to have.

The system of signalling and managing the succession of trains is described in the chapter on "Railway Management." We observe that the block system is not referred to as if it were in general use; and in regard to the interlocking system of points it is said "sometimes, by a very expensive and complicated apparatus, it is made mechanically impossible to open a track for the movement of a train without the previously locking all openings by which another train might interfere," so that this is invaluable and, as we now consider it in England, absolutely necessary system at all complicated junctions, appears still to be regarded in America rather in the light of a costly luxury. The following passage also suggests a comparison to our advantage:—

"Any train making a stop not on its schedule must immediately send out flagmen with red flags, lights, and torpedoes to protect it. This rule is a very difficult one to enforce without rigid discipline, and its neglect is the cause of the large percentage of the accidents 'that will happen.' The flagman who must go to the rear, often half a mile, at night, across trestles and in storms, must frequently be left behind, to take his chances of getting home by being picked up by a following train. There is no one to watch him, and he will often take chances, and not go back as far or as fast as he should; and if all goes well no one is ever the wiser."

We do not think that kind of charge could be brought against even the humbler members of the staff of any good English railway. Another detail in which the Americans seem behind the age is in the exceedingly primitive provision for the brakemen of "freight trains," who appear simply to stand on the roofs of the carriages, in any weather (there is a sensational picture of one of them at work in a snowstorm), and screw down at the proper time break-wheels working on vertical axles projecting two or three feet above the carriage roof. It is possible that the idea of a glazed look-out window projecting above or at the side of the carriage, that the brakeman may see where he is, has never occurred to the American railway mind?

Another passage in regard to the difficulties of fast running (the engine-driver, by the way, in America is called the "runner") seems to argue that a good many things are as yet far from being as they should be on American railways:—

"Fast time on a railroad depends as much on having a good signal system to assure the locomotive-runners that the line is clear, as it does on the locomotives. If he is always liable to encounter, and must be on the look-out for, obstructions at frequent grade-crossings of common roads, or if he is not certain whether the train in front of him is out of his way or not, the locomotive-runner will be nervous and be almost sure to lose time. If the speed is to be increased on American railroads, the first steps should be to carry all streets and common roads either over or under the lines, have the lines well fenced, provide abundant side-tracks for trains, and adopt efficient systems of signals so that locomotive-runners can know whether the line is clear or not."

This seems unsatisfactory enough, but it is a trifle to what we read in the chapter on the railway mail service, apropos of the duty of compensating the families of employes who are injured or killed in travelling on the railway mail carriages:—

"The danger to those within the postal cars is recognised by the railway people, and . . . all that American ingenuity suggests in the way of con-

struction, both inside and outside of the cars, is provided. The body of the car is most substantially built, the platforms and couplings are of the most approved patterns, the trucks are similar to those used under the best passenger coaches" [how considerable] "and the airbrakes and other safety apparatus are all brought into requisition. Within the cars are saws, axes, hammers, and crowbars conveniently placed in case of wreck, and safety-bars extend the length of the cars over head to which the clerks may cling when the cars leave the track and roll down the embankments, as they often do." In the year ending June 1888 there were 243 accidents to trains on which postal clerks were employed. In these wrecks four clerks were killed; sixty-three were seriously, several of the number permanently, and forty-five slightly injured."

This statement is from a chapter written by Mr. Thomas L. James, Ex-Postmaster-General. We can only say that it forms a most discreditable accusation against the American railway system. English post-office clerks would laugh if they were told that in being placed on travelling mail carriages they were engaged on a service of special danger.

There is far more of interest and information in the book than we have been able to allude to; and it is perhaps not entirely unsatisfactory to the English reader to find, on the authority of the Americans themselves, that with all their energy and inventiveness, we are obviously still ahead of them in the art of rendering railway travelling at once speedy and safe, and in general principles and details of management. American engineers are behind no others of this epoch in talent and resource, but American railway working seems not yet to have surmounted the drawbacks arising from an inherently loose system of construction and working, fixed upon it at the outset by the desire for economy and by the lack of that feeling of responsibility for public safety which seems much more developed in the English character in connexion with public works of this kind. England has the credit of having invented the railway system, with all its vast consequences to the world, and we may be allowed as a nation to feel some pardonable pride in the assurance that in its working and management we are still in front of all other nations.

BERLIN "MANSIONS."

It is a well-known fact that by far the greater number of the inhabitants of Berlin live on flats, in spite of the numerous evils and the great inconveniences pertaining thereto.

As most of the building-sites in the German capital have but narrow frontages in comparison to their great depth, the typical Berlin block-plan of an ordinary house shows the letter L, or in the case of a double house the letter U, the wings containing the bedrooms, the kitchen, and the back staircase. (Fig. 1.)

Fig. 1.

Very strict police regulations are in force referring to the area of the court-yard, the height of the front and court-yard elevations, the depth of the basement floor beneath the street level, &c., &c., and hence the architect is tied hand and foot when working out his designs.

These restrictions, combined with the unfavourable lines of the block plan, account for the bad disposition of rooms mostly found in a Berlin flat; yet the greatest faults are occasioned by the average Prussian architect not considering it necessary that every room

Fig. 2.

Fig. 4.

Fig. 3.

Types of Berlin "Mansion" Plans.

Fig. 5.

should be in direct connexion with a corridor. Hence one often finds that one bedroom has to be passed to reach the second one, or discovers that the gentleman's study is only accessible by steering between the numerous small tables of the drawing-room.

The most typical feature of Berlin planning is the so-called "Berliner-Zimmer," that room which is situated near the inside corner of the block plan, and which is mostly used as dining-room,—forming at the same time, however, the only connecting link between the front and back part of the flat. (See figs. 2, 3, and 5.) Many attempts have been made to avoid this double function of dining-room and passage, but these have generally failed, on account of the difficulty of obtaining light and air for the desired connexion.

The corridor and lobby are, as a rule, badly lighted and ventilated, both as a rule only receiving their light indirectly through glass panels in the doors, or at the best from some narrow area. Even the water-closets, up till a few years ago, rarely had any ventilation (see fig. 4), but now the police have prohibited the planning of such insanitary cupboards, and have gone to what is considered the extreme measure of requiring light and air direct from the courtyard, or, under special circumstances, from an area measuring at least 9 ft. by 6 ft. at its base.

It is wonderful with what little kitchen accommodation the average German housewife is satisfied; sculleries are never to be found, even in first-class flats; a pantry is a rarity, and such a thing as a well-ventilated larder is seldom thought of; brooms, dustpans, &c., are kept in some old wardrobe, but are also often used as a decoration for the kitchen walls. Each tenement, however, receives a good area of cellarage, and also plenty of attic room—the former being used for the storage of coals, potatoes, and wine cases; and the latter taking the place of the English box and lumber room.

Bedroom accommodation is very small in comparison with the number of living and reception rooms, so that families can very rarely have a "spare bedroom" at their disposal. The servants' rooms have, till very lately, been a disgrace to a civilised country; but a short time ago the ever-vigilant police have also made some regulations which prohibit the servants' rooms in newly-built houses being placed, for instance, above the larder or bath-room, with a height of only 6 ft. (a state of affairs that has been common up till now). Bath-rooms are only to be found in flats of a higher class, or in those of very modern date; and even then they are looked upon as only a secondary consideration.

* The Italics are ours.

The most laudable features of a Berlin flat are, firstly, the good connexion of all the rooms with one another by means of folding or sliding doors; and, secondly, the fact that the height of the "étages" is not stinted, 13 ft. being the usual height for the ground-floor, 15 ft. for the first, and 14 ft. and 13 ft. for the second and third floors,—seldom less, in better-class flats often more. Air and light are abundant in the reception and living-rooms (barring the dining-room) and bedrooms, and, as a rule, in both front and back-staircases. The staircases are mostly well planned, seldom lack width, and have easy step-height. The front-staircase and the outer-hall are generally richly decorated, especially the latter, which has, however, of late assumed the form of a carriage passage; a law having been passed compelling all householders to have a free thoroughfare through which the city fire-engines can be driven without the men having to dismount.

The courtyards, which as a rule contain a pump, are well paved and drained, and always have a corner especially assigned to the dust-hins of the various tenants.

The elevations of the courtyard are kept as plain as possible, stucco with stone dressings, or brick with stucco dressings, being mostly used. The front elevations are for the greater part finished in cement with stone dressings, and always show some attempt at decoration. It will strike any stranger that a decoration of the elevations is to be found in all the Berlin streets, no matter what class of people live there; in fact, there seems to be throughout the town a leaning towards over-decoration. In the last ten years, when Prussia has not only been politically but also financially prospering, a better class of material is taking the place of plaster and cement; marble, freestone, terra-cotta, and glazed bricks are gradually finding their way into the street-fronts, so that the Berlin thoroughfares will, in course of time, not only show decorated, but solidly decorative, architecture.

NOTES.

THE second reading of the London County Council Bill was passed on Tuesday in the House of Commons, subject to Mr. Ritchie's amendment to omit clauses 55, 56, 57, 58, and 75. These are all clauses referring to questions of administration and general powers. All the clauses referring to reforms in regard to details of building regulations, such as heights of buildings, lines of streets &c., are included in the Bill and will have to be dealt with in Committee. A greater blunder in the path towards the amendment of building regulations could hardly be made. A Committee of the House of Commons is one of the most unfit bodies to deal with such questions in detail, and the result will probably be most unsatisfactory. The County Council should have avoided all details and asked for a general clause conferring power to deal with questions of the construction and laying out of buildings and streets, &c., and to make by-laws on the subject as might seem best for the public benefit. By thrusting details of this kind into an omnibus bill, they run the chance of either not getting what they want, or getting it in such a manner as to tie their own hands.

THE great strike of coal-miners is one of those events which force themselves upon the attention of a vast number of industries besides the one most directly affected. At this time last week strong hopes were entertained that it might be averted, but the determined attitude of the men failed to induce the owners to concede the advance demanded; and, consequently, work is suspended at a large proportion of the collieries. The immediate effect was that all available coal was advanced to prices which many manufacturers cannot afford to pay—preferring rather to close their works. Thus, an immense number of operatives and others are thrown

out of employment, in addition to the miners. All attempts to arrive at an understanding have hitherto proved abortive, the only alternative to the original demand for an immediate advance of ten per cent. being an offer on the part of the men to accept five per cent. now and five per cent. in July,—to which the masters have so far declined to accede. It is probable, however, that at the meeting between the representatives of the Coalowners' Federation and the Miners' Federation, which was being held as we went to press, a basis of settlement may be arrived at. The trade of the country, however, has already been considerably interfered with, and much loss inflicted upon both employers and employed in other industries. If the men resume work on Monday they will have lost a week's wages, and, while they have been standing idle, the masters will have had the satisfaction of clearing off from the pit-heads, at good prices, hundreds of tons of stuff hitherto considered almost valueless.

ON adjoining the Railway Rates Inquiry,—as far as England and Wales is concerned,—until after Easter, Lord Balfour of Burleigh drew attention to the fact that if the Court should be precluded from presenting their report to Parliament this Session, legislation could not take place until the Session of 1892. It is therefore of the greatest importance that no delay should be caused by the time of the Court being taken up with unnecessary evidence. As eighty witnesses have already been heard, it is probable that there are not very many more to follow; and Lord Balfour seemed to intimate that he should rest the responsibility upon them should the Inquiry be so delayed that insufficient time is left for the preparation of the Report this Session. In the course of the evidence at the concluding sitting last week, a large sender of "smalls,"—i.e., consignments of less than 500 lbs.,—paid a high compliment to the Parcels Post. He showed that 80 per cent. of the traffic sent by his firm was in the shape of "smalls," and mentioned that whenever they came within the Parcels Post weight and dimensions they preferred to use that mode of conveyance. He declared that the traders delighted in having this alternative, and proceeded to remark that if the railway companies had kept more in touch with the public there would have been no necessity for the institution of the Parcels Post at all. "That shows how well the Government Departments do their work," interposed Mr. Courtenay Boyle,—a remark which certainly holds good in the case in question, but which one would hesitate to make of general application.

THE "betterment" question came before the House of Commons on Tuesday, in relation to the Strand Improvement Bill, promoted by the London County Council. The question, however, was not really discussed, and if the clause remains after the Bill has gone through Committee, it will probably give rise to a debate on the third reading. The matter, therefore, still remains before Parliament, and we shall take an opportunity in the course of the session to refer to it again, and at due length.

AREACTION seems to be setting in regarding the proposed underground railway for Edinburgh. At a meeting of the Edinburgh Trades' Council, held last week, the report of the committee upon the subject was read, from which it appeared that the committee were of opinion that the proposed railway from West Princes-street to Leith would be of great benefit to the citizens, and would afford a ready means of transit between the three great shipping ports of Scotland,—Leith, Glasgow, and Greenock. It was recommended that the Trades' Council should petition the Town Council to withdraw their opposition to the preamble of the Bill and confine their action to preserve the amenity of the city. The report was adopted by 23 votes against 4. The solicitor for the Cale-

donian Railway have written to the Town Clerk a letter to be submitted to the Town Council of Edinburgh submitting a number of concessions which the directors of the railway company propose to make with a view to disarming the opposition of the Council to the underground railway scheme.

PROFESSOR RASCHDORFF'S latest design for the proposed (Renaissance) "Dom" for Berlin is now under consideration at the "Cultus Ministerium;" and, as far as rumour goes, it is believed that the present scheme has found friends there, and has been recommended to the Emperor for approval. Even if the rumour proves to be correct, it will take at least a couple of years before the foundation-stone can be laid; not only on account of the time needed for working out the design, but also on account of the time required for the pulling down of the old "Dom," the erection of a provisional church for the "Dom" community, and many other preparatory works. We are not permitted to give any description of the present design until the sheets have passed through the different stages of bureaucratic criticism; but it may be as well to mention that Professor Raschdorff has given up his former idea of connecting the old "Schloss" with the proposed "Dom" by means of a communication-gallery over the thoroughfare which runs between the two sites.

IN looking through the annual report of the municipal authorities of Berlin, we find that they have come to the conclusion that wood pavement is not advisable for the Berlin thoroughfares, and that further new work of this material has been prohibited. In the same division of the report we find figures referring to the total area of paved roadways in the town, and the ratios of the different sorts of pavement used; according to these statistics we find that 574,000 sq. metres of asphalt have so far been laid, and that this material is recommended very highly. It is of some interest to notice this experience and opinion in Berlin, just when such a cry is being raised against asphalt in London.

A FORMER English architect who is now an Australian (Sydney) architect, Mr. J. Sulman, whose name will be familiar to many of our readers, has been reading a paper to the Melbourne Architectural Association on "The Laying-out of Towns," which appears to have attracted a great deal of attention, and has been made the subject of leaders in various Australian journals, professional and non-professional. The paper dealt with the subject both from a sanitary and artistic point of view. In the latter respect Mr. Sulman's preaching was generally against the rigid system of laying-out a city in squares and right-angles like a grid-iron, and in favour of making the most of picturesque incidents in a site, and of providing for central points of architectural effect in planning a city. The kind of advice which Mr. Sulman thought it requisite to give on sanitary questions of site may be judged from the following quotation:—

"Much may no doubt be done by the skill of engineers to improve an unhealthy site, but in a new country, where the land is practically unlimited, it is little short of a crime to permit any town to be formed which, from its location, will encourage disease. The most potent evils to guard against are swampy or flooded land and an impervious sub-soil. Of the former there are by far too many examples. I will describe one. In a rich agricultural district of the parent colony, a Government township was laid out many years ago on rising ground near the banks of a river. The upset price was low, but just on the other side of the stream a large area of land was possessed by a drunken old settler. It was, however, flooded in wet seasons. So far as position was concerned, either bank would serve, as the river was bridged. Cheapness, however, won the day, and the flooded land was purchased in blocks at the price of a bottle of ruin by ignorant new chums, and on it the town was built. Every few years the river comes down a banker, covers the town several feet deep in mud and water, and leaves behind a legacy of who can say how much suffering and

death? Now the inhabitants are petitioning for extensive works of embankment, and in course of time will, no doubt, obtain a large grant of public money for the purpose. If surface unsuitability is thus ignored, what may we expect when the subsoil is in question? Its importance as bearing on the health of a town can scarcely be exaggerated, but it rarely receives a thought."

The opinions expressed by Mr. Sulman in the paper are such as would be generally accepted as wise and sound by the profession in the old country, and perhaps he may induce those in the new country to give attention to considerations which they have hitherto overlooked. Australia is a continent in which there may still be new cities to plan, and where it is not too late to learn to plan them in the best way from the commencement.

ELECTRICITY as a means of locomotion has not made much progress in the United Kingdom; Bessbrook, Blackpool, Brighton, and Portrush being our chief existing examples. We shall shortly possess a far more important installation in the City and Southwark Subway, which may now be looked upon as an assured fact. Its extreme length, however, is under four miles, even if completed, and there are some difficult problems for the engineers yet to solve. In the United States this same slow progress is not observed, if we may judge by a paper lately read by Mr. F. J. Sprague, of New York, before the National Electric Light Association of America. Two years ago, the paper tells us, the electric railway business was in an experimental stage, and it was difficult to get a dollar for investment, but to-day it demands the best energies of two great corporations and a number of smaller ones. The business done this year, it is said, will probably amount to 6,000,000 dols. There are about 130 towns in the United States with one or more electric railways in operation, construction, or under contract. These comprise 1,500 miles of track, and 1,700 motor cars requiring 3,000 motors of an aggregate capacity of 45,000 horse-power, and a daily mileage of about 100,000. Gradients of 12 per cent., and more recently 14 per cent., have been ascended with loaded cars. Gradients three miles long, varying from 4 to 8 per cent., have also been ascended, the work done being beyond that possible with horses. In crowded cities speeds have been doubled 50 per cent., and the electric car has shown that it can be run faster on both up and down gradients, and can be stopped or started faster, than can a horse-car. On the whole, it would seem that the Americans are outstripping us as much in electric traction as they have done in electric lighting. It is doubtful, however, whether we shall lose much, on the whole, by our steadier and more cautious policy.

THE British Museum has recently become possessed of a valuable and very curious vase, formerly in the collection of the Earl of Carlisle at Castle Howard. The existence of this vase has long been well known, and it is catalogued in Dr. Klein's "Meister-signaturen," p. 210. Probably, however, few archaeologists have had the opportunity of inspecting the original. It is a krater signed by the late artist Python, and represents a curious scene,—the interrupted burning of Alkmene on the pyre. Alkmene is seated on a kind of altar at the back of the pyre, which is being kindled by Amphitryon and Antenor. Death seems imminent, but the Hyades, the rain nymphs, mercifully intervene; they pour down water from the arch of the sky above Alkmene, while Zeus looks on, as a naturally interested spectator. Up to the last few weeks the only publication of this curious vase was in the French section of the Roman *Annali e Monumenti*—a section missing from many, if not most, archaeological libraries,—from all, we believe, in England. However, a few weeks back Roscher's "Mythological Lexicon" reached *Hy*; and he gives a woodcut both of the Carlisle vase and another of analogous type. His double articles on the *Hyades* should be consulted by those who wish to appreciate the new acquisition.

THE Swedish Government, through its Geological Survey, has recently issued two further instalments of the researches of one of its officers in regard to the stone industry of Great Britain. The first of these deals with the methods of working sandstones and limestones, and of shaping slates, in which the various machines now in use are brought under review; and the second,—a more important work,—is divided into three sections:—(1) Gives a general account of the building stones of England and Scotland, in which the articles that have appeared from time to time in the *Builder* on the subject are freely made use of and acknowledged; (2) contains notes on building construction with suitable illustrations, showing certain methods of placing stones in rubble walls, rustic work, ashlar, &c.; and (3) in summing up the two first sections, indicates that it is possible for Swedish architects, by constructing random-coursed and similar walls in the usual English style, to make use of many sandstones, limestones, &c., that occur in Sweden, which have hitherto been considered too expensive for building purposes in that country. In addition to the diagrams referred to, the work is illustrated by two photo-lithographs of buildings in Aberdeen, which clearly explain the author's meaning; and the practical suggestions throughout the treatise cannot fail to be of great service to the Swedish building trade.

THE progress made in framing a new charter for the Royal Scottish Academy is anything but rapid. It is supposed to be at present in the Privy Council office, and it appears that there are points of disagreement between the Academy and the Board of Manufactures in reference to the teaching of students, which may account for the delay. No arrangements have as yet been made for the hearing of parties, and it will not probably be for several months to come that the charter will be in shape. The Academy Exhibition this year is well patronised, and the sales of pictures are considerably larger than last year, although the number of works exhibited is much fewer.

THE Twyford Abbey Estate, in Middlesex, covering about 520 acres, lying between Ealing and Sudbury, and two large dairy farms adjoining, have been placed in the market. The modern nineteenth-century Gothic mansion, designed by Atkinson, and recently occupied by the late Dowager Baroness Gerard, is traditionally stated to occupy the site of an old religious house. The former residence, moated, was rebuilt by Mr. Willan, who had purchased it from the Cholmondeley family. The name of the parish is said to be derived from the two fords across the river Brent. Twyford and the adjacent Perivale, or Greenford Parva, parishes are the smallest and least-populated of any at their distances from London, and retain much of their rural aspect. In 1831 the populations were 43 and 32 respectively; they are now 75 and 34. Not many years ago the "Abbey" was the only house in Twyford parish. In the little church, standing within the grounds, was erected a monument to Henry Bold, the poet, who died 1683. Perivale Church, by the riverside, was restored about fifteen years ago; it has a curious wooden tower. To the north stands a quaint half-timbered house, one of the seven or eight in the parish.

THE Morgans automatic signalling system, shown during the past week at the Westminster Palace Hotel, is an American invention of very ingenious conception, well thought out in its details. The system consists of a central police-station and, say, one hundred street signal-posts, in each of which there is a locked box containing two discs, one for transmitting, the other for receiving, certain specified messages, and a telephone, by

which conversation, if needful, may be carried on between the officer at the street-box and the central station. As it is impossible for every police constable to be a telegraph operator, a number of short messages, such as "send officer," "send waggon and four men," "crowd threatens," &c., are printed on a dial. All the policeman has to do is to unlock the "office door," put a pointer to the message he desires to send, and close a hasp. As soon as the message has been received the pointer returns to its ordinary position automatically, while the number of the post or constable from which the message has come is duly recorded at the station. Each signal-post has also a red light fitted in its lantern. This light is ordinarily out of use, and is put on when needed to call attention by the central station or by the officer on the beat. The means by which the signals are worked are electricity, magnetism, and clockwork. The electric-wires are run out radially from the central station, one wire to each street-post, so that if any wire be broken or damaged the others are not interfered with. The electric current energizes the magnets, which then draw back the detents of the clockwork, and, as each street-wire is connected with its own representative portions of the central apparatus, each street signal acts automatically with the central station. If the officer on a beat sees a red light he reads the signal in its box. If he wants help he can ask it by his signals without leaving his place, without shouting or whistling, or messengers, without attracting attention. Keys may be furnished to residents or caretakers by which they can set up the red light of the nearest street-post, and so call the police. As this key is inscribed with the number of the residence, the policeman on coming to the box knows where his assistance is required. Special boxes can be fitted in private houses in direct communication with the nearest central station.

THE most important as well as the largest work at Mr. Wallis's Gallery, the thirty-seventh annual exhibition of which opened this week, is Professor von Uhde's life-size painting of "The Last Supper" (61). This is one of the most remarkable examples we have seen of the modern realistic spirit in the treatment of scenes from the New Testament. The apostles are frankly represented as labouring men in working garb, but with faces of great interest and variety of character. The head of Christ is very beautiful and pathetic in expression, without partaking of that too sentimental character with which it has too often been invested by artists. "Suffer Little Children to Come Unto Me" (62) by the same painter, has also great merit in the character and expression of the children, but to liken them to Dutch children of the modern period is carrying realism a little too far, or rather it is not true realism at all. Nevertheless Professor Uhde is an artist worth knowing. Another new name at the Gallery is that of Professor Liebermann, a painter of peasant life. His largest work, "Women Mending Nets, Katwyck, Holland" (60) shows in the foreground a remarkable figure of a coarsely-clad peasant girl standing and hauling at a net with that kind of unstudied energy which at times gives a kind of sublimity to the simplest personality. His picture of "Flax Spinners, Holland" (59) has a pathos in its representation of homely toil which reminds one of Millet. We are indebted to Mr. Wallis for introducing the works of these two remarkable painters to London. Among other works to be looked at are Seiler's exceedingly clever scene in a "Buffet at a Railway Station" in the Tyrol (29); the same painter's two finely-studied figures in "The Argument" (41); Walter Firlie's "First Communion" (33); Mukacsy's "The Two Families" (34) a previous edition of the brilliant painting exhibited at the Royal Academy a few years ago, but hardly equal to it; and Heilbuth's "On the Seine near Bougival" (37) a characteristic example of this painter, with a group of French ladies going boating in elaborate

costumes, as if they were on their way to an "At Home."

THE collection of sketches of London by Mr. Herbert Marshall, on view at the Fine Art Society's Gallery, includes a great many charming studies of London architecture and street scenery, but there are two queries we should propound in regard to it. First, are the effects of light and colour shown in many of these sketches really London effects, or are they not rather effects which the artist would like us to see or to think we see? "Battersea Church" (9) is a river-scene looking more like Venice than the Thames, in light and colour; other views of well-known London streets, though most effective in themselves, impress us as unfamiliar and unlike the place as we know it. Did any one ever see Westminster Abbey from Dean's-yard (58) show so white and bright as Mr. Marshall makes it? Another query is, whether the artist has done himself justice in the drawing and general treatment of the architecture. "St. Paul's from Cannon-street" (3) is badly drawn; so is St. Mary-le-Bow (32), rising from a street also which does not in the least suggest Cheapside. In the view of the Horse Guards (17) the clock turret is absolutely on the wrong side of the centre of the pediment, considering it in relation to the perspective of other portions of the building. The portico of the church in Covent-garden Market (34), which forms a foreground object, is also very inadequately treated. This would be expected at the hands of a landscape-painter merely, but Mr. Marshall professes to be a painter of scenes in which buildings play a principal part, and artists who take that position should be careful of the drawing of their buildings as well as of the effects. Among the best sketches in the collection are "St. Martin's-lane" (67), "Back of Kensington Palace" (68), "Autumn Afternoon, Chelsea" (81), "St. Mary-le-Strand" (83), and "Barges at Low Water" (89) near Lambeth Bridge. We may add one other query to our two former ones—why are the catalogues at these sort of exhibitions to be prefaced by shallow small-talk on the subject by people whose opinions on art are of no recognised value whatever, and whose names are merely used as a bait to catch the more ignorant section of society?

THE NORTH DOORWAY OF THE ERECHTHEION.

THE large doorway in the north portico of the Erechtheion—"H ὄψαία πύλη."—"The Beautiful Door" as it is called by the Greeks, has generally been accepted as contemporary with the rest of the building.

Mr. R. W. Schultz, during his investigations at Athens last session, while engaged on the work of collecting the mouldings of the buildings on the Acropolis, observed certain peculiarities in connexion with this door, which led him to doubt this general assumption, and last week he explained his views at a meeting of the British School there.

He contended that none of the door now *in situ* is part of the original work; that the present jambs belong to a period not far removed from the time of the building, although not contemporary; and that the lintel, cornice, and brackets are a still later addition. In connexion with the first point, he referred to a curious related stone on the west side of the present lintel, which he thought belonged to the original lintel which had been damaged and cut out, leaving the ends in, and he explained the various reasons which had led him to come to this conclusion. He next went on to argue that the unfixed "ὄψαία" of the British Museum inscription (the word having already been assumed to mean, in this instance, the linings and not the leaves of a door) which had generally been appropriated for the east door, could not have belonged to it on account of their dimensions not working in; and he showed how they exactly fitted this north door if they were made in two pieces in the height, which, as they were not constructional parts, but mere linings, was highly probable. He drew attention to the existing fragments of another door, one of which is now in the British Museum (Inwood, plate 20), which prob-

ably belong to the east door, and mentioned how certain indications on those had made him think the doors had originally had bronze linings inside the stone ones. He concluded that the first north door consisted of a lintel built in with the walls, and having mouldings worked on it, and of thin jamb linings having a projection of about 2½ in. from the wall face, and with bronze linings inside.

The lintel having been damaged it was cut out, leaving the ends in, and heavier jambs were inserted to take the whole weight of the new lintel. The return face of these jambs was dressed right through, and the inner bronze linings done away with. This second lintel was not, however, he thought, the one now in position; the nature of the ornament, which, although a continuation of that on the jambs, differs greatly from it in character, being much less refined and bearing on its face clear indications that it must be a late copy, faithful in general form but lacking the spirit and refinement of the original. Amongst other points in this connexion he showed how, in the rosettes of the jambs, the centres have been bored out for the insertion of a wood plug, in which was fixed a central gilt bronze disc, while in those of the lintel this has been worked solid on the stone in a convex form and was probably merely gilded over. From the general character of the work this lintel might, in his opinion, have been inserted about the second century B.C. The brackets on each side of the lintel he put down to the same time; he did not think the north door had originally any brackets at all, but merely a plain cornice. The position of these brackets appeared to him both constructively and decoratively false, set back half hid behind the projecting architrave, so that their inner face was almost lost, and in reality of no value as supports to the cornice over. He suggested that they might have been copies from the original brackets of the east door, mentioned in the inscription, which were probably of similar detail, but more suitably placed in relation to the other parts of the composition, and he showed how the one bracket which no longer existed on west side, did not fall through the wall, but had been merely doweled on to the face.

He drew attention to the nature of the ornament on the cornice of the door, which varies very much from that on the wall-band over, to which it bears a certain resemblance, and accounted for this variety of type by suggesting that it had been done by a workman who, limited by the nature of his work on the lintel and brackets to an exact reproduction of his original as he was capable of, had here given free play to his own ideas of what the ornament ought to be like.

He was influenced in his conclusion that this was of later Greek time and not Roman by observing in it several characteristics similar to the work on the later Ionic examples of Asia Minor, and by the fact that had it been the latter it would have been a close replica of that on the band over, and he instanced the work on the remains of the Temple of Rome and Augustus lying to the east of the Parthenon as an example of the Roman rendering of Greek detail. As further evidence of the later insertion of this lintel and cornice he instanced the holes cut on the underside of the stones over for the purpose of needling up the wall temporarily during the alteration, and the way in which the stones have been wedged up afterwards. He also alluded generally to the other various evidences of fixing the cramping to jambs and lintel.

The thin inner jambs and linings now round the door, he said, were put in, perhaps, in quite late Christian times, partly as a support and partly to hide the broken underside of the present lintel, which had been seriously cracked and chipped off on the under-edge.

It is, of course, impossible in a short summary to go into all the arguments adduced in support of these theories, which Mr. Schultz threw out, rather as points for consideration, than as definite fixed opinions; but we trust that it will be possible to examine them in detail when the school papers of the present session are published later on in the "Journal of Hellenic Studies."

Edinburgh.—After an expenditure of 6,000*l.* in alterations upon the Palace Hotel, Prince's-street, which was acquired by the Scottish Liberal Club, it is now in possession of the members, and it may be considered one of the finest club-houses in the country.

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE ninth ordinary general meeting of the present session of this Institute took place on Monday evening last, Mr. Arthur Cates (Vice-President) in the chair.

Proposed Extension of Premises.

The Chairman announced that a special general meeting of members only will be held on the 31st inst., at 7.30 p.m., to receive and consider a recommendation of the Council that the Royal Institute of British Architects do enter into arrangements for obtaining a lease of the shop premises now vacant at 9, Conduit-street, and to authorise the Council so to act.*

Examinations for Architects.

The Chairman also read the following requisition addressed to the Council:—

"Gentlemen,—We, the undersigned, being of opinion that it would be of advantage to the profession and the public alike, if all heretofore seeking to practice as architects were compelled by statute to pass a similar examination or examinations to those recently established by the Institute with such signal success, desire to test at as early a date as possible the opinion of the whole body of professional members of the Institute.

We therefore send this requisition, under By-law 69, for a special meeting to be held to consider the subject, and to propose the following resolutions:—

1. That at as early a date as possible statutory powers should be sought to establish, as in other professions, a system of compulsory examinations to be held by the Institute, and to be extended to all architects heretofore entering the profession, whether as members of the Institute or not.

2. That when such compulsory examination comes into force the position of all existing architects shall be completely respected."

Whether these be carried or not, we desire, under By-law 69, or if that be not applicable, then by resolution, to propose

"That a poll be taken by voting papers, in order that, under any circumstances, the opinion of the entire body of professional members may be ascertained."

He added that, in accordance with that requisition, the Council had appointed a special general meeting on the 31st inst., at 8 p.m., to consider it.

Drawings of Brick Buildings in North Germany.

Mr. Alfred Strong, Fellow, then read the following short paper:—

Towards the end of last year I had a letter from Professor Otzen, an architect in somewhat extensive practice at Berlin, in the course of which he said that, during a recent visit to England, he had noticed the very limited use made of moulded and glazed bricks in this country; and having largely used them himself, he asked whether our Institute would care to see some of his works so executed. I referred the suggestion to our Literature Committee, with the result which you see on the screens to-night. There are altogether ninety-nine drawings and eleven photographs, representing twenty buildings, of which fifteen are executed, and the rest either in contemplation or in course of execution, and I hope you will agree that the exhibition is an interesting one. The subject of moulded and glazed bricks as used in the North of Germany—I purposely exclude their use in Spain and Italy—is not a new one within these walls. Forty years ago, on February 18, 1850,* my old friend Charles Fowler—he was Charles Fowler junior then—read a paper on "Mediæval Brick Buildings in the North-east of Germany," which was reprinted by order of Council in 1874, probably *à propos* of another paper, read on November 17, 1873,† by Mr. J. Tavenor Perry, on the "Mediæval Brickwork of Pomerania." Mr. Fowler described the churches, town-halls, and gates of Stralsund, Brandenburg, Stenthal, Stargard, and Lübeck; he showed that stone was used for tracery in early examples, but that from the end of the fourteenth century brick only was employed, "and we find even such parts as crockets and finials executed in brick." Again:—

"There is one feature in particular which deserves attention—namely, the introduction of a white-glazed ground to relieve the forms of tracery." The use of dark brown and black glazed bricks was also common.

In the discussion which followed, Mr. Smirke said:—

"He had seen churches of brick at Hanover and Hamburg, with delicately moulded jambs and slender nullions of brick, and he thought we in England are scarcely aware of the great capabilities of terracotta."

* See *Builder* for March 9, 1850.

† For a report of the discussion which followed this paper see the *Builder* for November 23, 1873.

Professor Donaldson also remarked that,—
 "In this country brickwork as applied to Gothic detail had never been carried out to the same extent as in the Low Countries."

I have unearthed a few examples of such work out of my sketch-books, and enlarged copies,—about half-full-size,—are on the screen. They illustrate the mode in which effect was obtained by rendering the ground between the moulded bricks, and how patterns were obtained by the repeated use of a few simple moulds. Professor Otzen's adoption of this construction occurs frequently on these drawings. Stone is, and always was, a luxury in the North of Germany, and the architecture of the districts far away from the quarries of Saxon Switzerland and the Hartz Mountains naturally developed out of the material readiest to hand. In his paper, nearly fourteen years later, Mr. Perry says:—

"When stone was used, which was but rarely the case, it had to be shipped from Sweden, which in those days was a costly thing; but the skill with which ornamental features were moulded in clay caused less desire for carved stone than might otherwise have been felt."

Mr. Perry also mentions Stralsund, New Brandenburg, and Stargard, as also Stettin, Bergen, and Sagadahogien, and other examples. Describing the tower of St. James (1370) at Stralsund, he says:—

"The whole of the tracery and arcing is filled in with rich brick coping, which, with the ornamented bands and the mouldings of the entrance, is very highly glazed." At St. Nicholas, Stettin, he notices "a richly moulded band of vine-leaves in blocks about 12 in. square, carried along under a black string," and at Prenzlau, "a little turret, octagonal on plan, two stages high, built entirely of glazed bricks in various colours, chiefly green."

That, in the late Gothic straining after effect, the limits of sound construction were often passed cannot be denied,—as, for instance, at St. Mary's, Lübeck, where brick mullions about 12 in. wide are carried up to 60 ft. or more, apparently only kept in their place by the saddle-bars, to which the lead lights are attached. Still, in spite of these drawbacks, there are many examples of good work scattered up and down the North of Germany, and the student may with advantage examine both the ecclesiastical and the secular buildings from Hanover to well up the Baltic, and from its shores southward and westward. In connection with this subject, Mr. Street's pamphlet on Lübeck and Essenwein's examples—both in the Library—will be found interesting; the latter, perhaps, less from the point of view of English Gothic than as giving valuable hints in the use of the material under discussion. Having quoted and said this much, in the hope of starting a useful discussion on the *pros and cons* of the more extensive use of moulded, and especially, of coloured and glazed bricks, in this country, I now turn to Professor Otzen's works, which show that he has carefully and exhaustively studied the works of his ancestors, as also the manner in which he has followed in their steps. So far as I know, Mr. Otzen was the first German architect to revive the free use of ornamented bricks in church architecture, and I can remember the sensation which his first church in this style (St. John's, Altona, near Hamburg, erected in 1868-73) made at the time, and being struck with the rich effect, not dark and gloomy, but rich and warm, which the use of well-blended colours and judicious glaze here and there produced. I visited the brickyards where the materials had been prepared; some specimens are on the table.

Unfortunately, this church near Hamburg is the only one of Professor Otzen's works which I have had an opportunity of seeing, and therefore I can only refer you to the meagre information furnished by the slips in your hands. The example thus set has since found a certain amount of approval, chiefly in the old Hanse Towns, where a limited use of moulded and coloured and glazed bricks has been made in warehouses and private buildings, adding life and interest to what otherwise appear somewhat prosaic compositions. I am sure that a careful examination of the beautifully-prepared drawings which surround us will repay the lover of colour in buildings, and I cannot do better than close these few remarks as Mr. Perry closed his paper:—"I trust," he says, "you will see that there are many points of excellence to be noted in these buildings, erected as they are of materials so similar to those at our own command, and that English architects may learn something from the mediæval brickwork of the North of Germany."

Mr. Charles Fowler, in proposing a vote of

thanks to Mr. Strong, said that Professor Otzen appeared to have studied the old examples, and, though it could not always be said that he had improved upon them, he seemed to have imbued himself to a considerable extent with the characteristics of the style. From his (the speaker's) own observation, the ornamental work in the old brickwork,—he did not refer to such as was formed by moulding, but to such things as crockets and finials,—was carved out of the brick before it was burnt, by means of wire. The workmen apparently learned to use this very skillfully, and though the results were not very minute in detail, they were effective and characteristic. He happened to be engaged in studying under the late M. de Chateaufort in Hamburg when that gentleman was restoring St. Peter's Church in that city, and he visited the brickyards which had supplied the bricks for the churches built in the fourteenth century. These brickyards had never been entirely closed, and they had supplied the bricks for the restoration of the church in 1844-5-6. These bricks were large, and quite different from those made for ordinary construction in that part of the country, the dimensions being 12 in. by 6 in. by 3 in., of a fine rich purple colour, very hard and well-burnt. The mortar seemed to have been made of the best lime he ever came across. It was beautifully crystallised, and so extremely hard that after 500 years the joints had the polish of the trowel as left by the original bricklayer. The joints were thick, sometimes measuring quite an inch, showing that the work must have been carried up slowly, and that the mortar got hard before it had time to bulge out. There were a great many interesting examples of this stamp of work in that part of Germany, but his information in regard to them had all been in print for the last forty years in the paper he read.

Mr. William Woodward remarked that a fine specimen of the skillful and artistic disposition of brickwork, in cornices and mouldings, was to be seen in a church off Great College-street, Camden Town.

Mr. Hugh McLachlan said that when holding the Godwin Bursary; he had the pleasure of seeing the Church of St. Johannes at Altona, a splendid specimen of Gothic architecture. These coloured bricks, tiles, and glazed terracotta had been brought into use with great aptitude. This church contrasted with Sir Gilbert Scott's great church in Hamburg, which was built altogether of stone. It might be said that some of Herr Otzen's work was too glaring in colour, and the way in which green was introduced was a case in point. It seemed that in this country we could not produce the splendid materials Herr Otzen was able to use. These came from the east of Germany and Silesia, and they appeared to be superior to anything in this country. He was sorry that the specimens he brought home and presented to the Institute had been hidden away in some closet.

Mr. J. M. Brydon seconded the vote of thanks to Mr. Strong. When he saw some of the churches in Altona, he was not struck either with their architecture or their colour, which was somewhat crude. It was the shadow, but not the spirit, of Gothic. To use moulded bricks was to go the wrong way to work, an effect being obtained which entirely destroyed the spirit which should be introduced into such buildings. The only way to get effect was to fall back upon the old principle of cutting the bricks after they had been burnt. The green colour was certainly very crude and strong, and in the matter of mixing the colours, in glazed or unglazed bricks, makers in England were far ahead of any on the Continent. Mr. Butterfield had shown the way many years ago in the case of All Saints, Margaret-street.

Colonel Prendergast proposed a vote of thanks to Prof. Otzen for so kindly sending his splendid collection of drawings for them to see. It could not fail to be beneficial to the members of the Institute if they got those who were exercising their professional duties in other countries to assist them in their researches here.

Mr. William White seconded the vote of thanks to Prof. Otzen. He considered that the question of the use of stone or brick was very much dependent upon the matter of cost. The same amount of precision could not be got in brick by moulding as by cutting. A brick which was made 4 in. or 5 in. in thickness would not shrink in the same way as a brick made only 2½ in. or 3 in. thick. The question would always be between the cost of brickwork

and the cost of stonework, and at the present moment he was hesitating, in the midst of an essentially stone country, whether or not he should have to put up a large building in brick simply on account of the cost.

Mr. Aston Webb said he could not help feeling that this question of the treatment of brickwork which had been brought before them that evening was essentially English, and not alone German. The English Tudor brickwork was as fine as any he had seen abroad. The architecture of the Elizabethan period brought out some magnificent brickwork, and, again, in the reign of Queen Anne, there was brickwork equally fine, while a great deal of our modern brickwork would stand comparison with that of any other country. Mr. Strong had given the date of one of Prof. Otzen's churches as 1868, but many fine brick churches had been built in England before that. Mr. Street's church of St. James-the-Less must have been erected about that date, and was one of the most charming examples of modern brickwork. Mr. Butterfield, in his house for the Society for the Propagation of the Gospel, produced another example that claimed the admiration of all who saw it; and although Keble College might have been thought too bright at first, anyone who saw it now would notice that it had wonderfully toned down, and was a most picturesque and essentially English building. The brick buildings of Chester, inaugurated, he believed, by Mr. Douglas, were also essentially English, and he did not think anything in Europe could be found to beat them. Mr. Waterhouse and many others had worked in brickwork, and, he need hardly say, with the greatest possible success. The great difficulty in regard to coloured brickwork in London was that in a short time the colour disappeared. He remembered Mr. Edward Barry describing his Endell-street schools, and being quite frightened at their brightness of effect, but in a few years the pattern of the brickwork quite disappeared. With regard to glazed materials, the glaze generally given seemed to destroy all lines, and if some of the manufacturers would try to introduce a glaze which would protect the surface of the brick, and at the same time not give the great reflection which the brilliant glaze gave, a material might be found which would enable architects to carry out brick-building in towns which would be satisfactory and enduring.

Mr. Thomas Blashill remarked that nothing had been said that evening about brick bond. He had been looking at the drawings and photos exhibited to see if he could learn anything about the bond which was used in Germany, but he had not been able to do so, except in some where he found the whole face of the brickwork was in headers. What he wanted to look for was as to what was usually called "English bond," which was in principle the ordinary bond used over the greater part of the North of Europe. Flemish bond was often used here, although the construction was not so good, because of the better appearance it was supposed to give to a brick wall. But if gentlemen who travelled abroad would look at the brickwork used generally in the North of Europe, they would find there was an essential difference between the English bond used here and the bond of a somewhat similar character as used on the Continent. The difference was this: English bond was generally produced by making alternate courses of stretchers and headers. That did not make very good fine work, but in France, Belgium, Holland, and those parts of the North of Europe with which he was most familiar, they also used alternative courses of stretchers and headers, and in every course of stretchers they made the brick next the end brick, in alternate courses, the header. If gentlemen would look at the *Builder* for June 23, 1883, they would see a short paper, with illustrations which he gave, showing the difference. The effect was that the brickwork looked as well as the best Flemish work, and was very much better in construction.

Mr. Charles Fowler remarked that the old work was all Flemish bond.

Mr. E. C. Robins drew attention to the beautiful brickwork to be seen in Berlin, and to the very fine *façades* of some of the public buildings there.

The Chairman asked if the drawings could remain for some little time in the Institute rooms?

Mr. Strong said they could remain on view for a week.

The Chairman said that Prof. Otzen had sent

no fewer than 113 drawings, representing twenty-one public works, produced at a total cost of 180,000. In England great advances had been made in producing beautiful brick-work, but we had to advance still further, so that our brick architecture should be enduring under the circumstances of climate and smoke. It was to be regretted that an entire evening had not been devoted to the subject, which was one of vital interest to English architects. It would lead, however, at a later period of the session, or next session, to some one introducing a paper which would go exhaustively into the matter, and say how the carving should be done.

The votes of thanks to Mr. Strong and Prof. Otzen were then carried by acclamation.

The Galilee of Durham Cathedral.

Mr. William White then read a paper on this subject. In the introduction Mr. White stated that Durham Cathedral was celebrated for its magnificent situation, its unusual type of architecture, and also for its Galilee, which was a perfectly unique structure. The name of the Galilee was as well known as the Cathedral, but not so its true meaning, or the purposes for which it was originally erected and used. The several and diverse traditions respecting it were not only at variance with each other, but no one of them accounted for certain architectural features found in it, or for its name. In many instances it had been called the Galilee Porch, the Galilee Chapel, or the Lady Chapel. The prevailing idea was that it had been built for a chapel; but the author considered that view untenable. Having given quotations from Canon Greenwell's history of the Cathedral, and Davies's history, referring considerably to Hugo Pusey's connexion with the Cathedral, the late Joseph Gwilt's opinion was alluded to, as was also a paper by Longstaffe in the "Transactions" of the Archaeological Society of Durham. The two first mentioned and the last wrote of the Galilee as a Lady Chapel; but Gwilt differed, saying it was for the "collection of monks returning from processions, and it was used for the dead bodies previous to burial." The separation of the Galilee from the church for the first 200 years—supposing it had been separated, as some authorities considered,—certainly militated against the idea of its being recognised as a Lady Chapel. In an account of Durham Cathedral published by Ross in 1733, the Galilee was not said to have been built as a Lady Chapel; and from a MS. published by the Surtees Society one learnt that Cardinal Langley placed a font there for the baptism of children whose parents were under excommunication. After giving quotations of opinions and statements respecting the Galilee, including one that in the north side was an altar, called the Lady of Pity altar, dedicated by Cardinal Langley, reference was made to the origin and meaning of the word Galilee, which signified "circuit." It had been originally applied to the circuit of the country around Kadesh Naphtali, occupied chiefly by strangers. Mr. White considered that the Galilee at Durham took its rise from that association of ideas and circumstances, it being the court for causes extra-ecclasiastical. He believed that Pusey built the Galilee as a court external to the Cathedral, though in contiguity to it, to serve not only as his Palatine Court, but also for his regal court of justice,—both as Prince-Bishop and Chief Justiciary under Richard I. Richard I. had, however, before leaving England for the Crusades, divided the country between two Regents, still appointing Pusey Chief Justiciary for north of the Trent, and Longchamp, Bishop of Ely, for the south. Although there existed in England several so-called Galilee porches, there was but one besides Durham, that at Ely; and Ely had also been the see of a Prince-Bishop who was also a Chief Justiciary. The author then referred to Miller's, Bentham's, and Stewart's account of the Galilee at Ely, and stated that he had been told he was utterly mistaken in thinking a court would ever have been held in any part of a cathedral. But in ancient documents the Galilee at Ely was spoken of as "*Curia vocata le Galilee*," which, had it never been used as a recess between the great central portal of the Galilee at Durham was the prominent feature, architecturally, which first led the author to the opinion that the Galilee was erected as a court. The arch was of Pusey's date, and its

treatment such as was consistent, at that time, with forming a recess for a tribunal. The central division of the recesses was left with its rough plaster uncoloured, to receive a dorsal hanging or canopied seat, which was not the treatment of an altar recesses at that period. Reference to similar treatment in the old Church of St. James at Dover was made by the author, who regretted that while twelve or fourteen years ago he had seen traces of the original work, on a subsequent visit they had been covered with compo and completely obliterated. The term "Galilee" had been applied in several instances to a building attached on the west of a cathedral, as at Lincoln and Peterborough, and at the new chapel, Windsor, and St. Stephen's, Westminster. But whether in the first instance Galilees were built and used as courts or not, it was certain, he believed, that at Durham the Consistory Court had been held in the Galilee from the time of Cardinal Langley down to the end of the eighteenth century; while how early it might have been so used was unknown. In several village churches in England there was at the west end a porch or small chamber external to the church which had by some been called a Galilee. These he considered might likewise have been built for the purposes of a court,—although the actual purpose had never been definitely determined,—as the manorial courts, to which submission was made and fees paid by the tenants, must have required some recognised public place. As examples were mentioned Melton Mowbray Church; Snettisham, Norfolk; Wigginton, Bucks; and Croxland Abbey. Besides those external chambers, in many churches there was a small chamber over the north or south porch called a parvise, the origin of which was equally uncertain, but which might have been intended to serve the same purpose. Or was it a narthex reserved for the penitents? At Cluny and Vézelay the author thought it was very probable that the thirteenth-century tribune was for some such purpose as he had indicated at Durham. In conclusion, he considered that, whatever their opinion as to the origin and uses of the Galilee, all would agree that there was yet enough interest about it, both archaeologically and architecturally, to justify a record of its history.

In the discussion which followed,

Mr. Nicol said that in the Cathedral of Tann, where there was a large choir, it was used as a court.

The Chairman: As a *curia*.

Mr. Thomas Binshill said he believed that at the east end of Durham Cathedral, as was the case with similar large buildings, there was originally a small chapel dedicated to the Virgin, and used only for the members of the community; and when in the latter part of the twelfth century the services offered with special reference to the Virgin became very popular, the people, and especially the women, desired to have the same privileges in a chapel to which they could be admitted. It was impossible that they could go through the portions of the church reserved for the community to the chapel which was built for them, and probably it became a question as to where the chapel should be built. Worksp Abbey showed, on that side of Durham, and having the large size and proportions characteristic of the thirteenth and fourteenth century Lady Chapels. The Durham Galilee was probably the next in date to that of Worksp, and he had no doubt it was originally built for no other purpose than that of a Lady Chapel. Another building, he believed, built for the same purpose, was that called the Chapel of St. Joseph of Arimathea at Glastonbury. These were built so that people might get at them, because they could not get at the chapels which existed at the east end of the cathedrals. At Hereford, Worcester, and other cathedrals, arrangements were made by which the people could go along the north aisle, and so get at the great Lady Chapels made in the thirteenth century to project end of Durham. The great chapel at the east end of Durham Cathedral was the Lady Chapel, so that the building referred to by Mr. White would be no longer used as such, but might become the Consistory Court, or the Galilee, whatever that might mean. He was fairly familiar with the Church of St. James at Dover. That was made the court of the Lord Warden, but he believed it was not originally built as such, as there were all the marks of a purely ecclesiastical building upon the struc-

ture. In fact, it was only in comparatively late times that it became the Court of the Lord Warden. On the whole, then, he believed that the Galilee at Durham was built originally as a Lady Chapel, but when the eastern chapel was constructed it was no longer considered the Lady Chapel, and became the Galilee, although he confessed he could not tell the meaning of the name. He concluded by proposing a vote of thanks to Mr. White.

Mr. Wilson seconded the vote of thanks, and said that whatever the place was built for it had been all those things which had been described to them, and more; it had been a chapel, a court of justice, and a place of access for the female sex. The Consistory Courts had to move about, and they did not require more than a small amount of room. The courts, however, were held in some chapel or convenient place, where there was good access; but he had no doubt that this building was always the Chapel of Our Lady to the end.

The vote of thanks was then put and carried. Mr. White, in his reply, said he had no doubt that such buildings were used for many purposes, and that the Consistory Court was moved to various parts of the Cathedral was a point as to which they need not raise any question. A civil court, on the other hand, would not be held in the Cathedral. Bishop Pusey doubtless desired a place where he could hold his secular court, and it was not likely he would go elsewhere when he had the opportunity of making a court immediately contiguous to the Cathedral, but external to it. There was a precedent for that at the Cathedral of Aix-la-Chapelle, which contained a sort of Galilee where Charlemagne held his judicial courts, which were necessarily secular and civil. That monarch's chair was still preserved, he thought in one of the *triforia* in the centre of such a tribune as that which Viollet-le-Duc mentioned as existing at Vézelay.

The proceedings then terminated.

THE LONDON COUNTY COUNCIL.

The Blackwall Tunnel.—At the supplementary meeting of the Council held on the 14th inst., the question of the Blackwall Tunnel was further discussed, but no definite conclusion was arrived at, except that Mr. Arthur Arnold's amendment (the terms of which we have already given) was defeated by nine votes, the numbers being 56 against to 47 for. A further amendment, suggesting that the work should be postponed until the Council had obtained power to apply the principle of "betterment" to the land on Bogsby's Marshes which would be improved by the construction of the tunnel, was lost by 11 votes,—49 votes against to 38 for. The Chairman (Lord Rosebery) suggested as a compromise that a trial shaft and a small length of tunnel should be undertaken experimentally, and the further consideration of the question was adjourned until next Tuesday.

The usual weekly meeting of the London County Council was held on Tuesday afternoon last, Lord Rosebery in the chair.

Main Roads.—The Highways Committee's report contained the following important paragraphs:—

"Your Committee have considered the applications which have been made by the several Vestries and District Boards for thoroughfares in their respective districts to be declared by the Council to be 'main roads,' under the provisions of sections 11 and 41 of the Local Government Act, 1888, and the Highways and Locomotives (Amendment) Act, 1878. The last-named Act did not apply, so far as the provisions as to main roads were concerned, to London (in fact, the Metropolis was specially excluded by section 2 from the operation of the Act); but by section 41 of the Local Government Act, 1888, the provisions of the Highways Act relative to main roads were extended to London. Under section 15 of the Highways Act, 1878, the Common Council of the City, or any Vestry or District Board, if of opinion that any highway in its district ought to become a main road, by reason of such highway being a medium of communication between great towns, or a thoroughfare to a railway station, or otherwise, may apply to the London County Council for an order declaring such part of the road as lies within its district to be a main road; and if the Council be of opinion that there is probable cause for the application, it is to cause the road to be inspected, and, if satisfied that the road ought to be a main road, is to make an order accordingly.

All the local authorities in London, with the exception of the Court of Common Council and the Strand District Board, have exercised this power;

THE BUILDER, MARCH 22, 1890.

THE PHOTO. GRAPHIC & C. 32, MARTIN LANE, LONDON, E.

THE CHURCH OF THE HOLY CROSS AT BERLIN.—PROFESSOR J. OTZEN, ARCHITECT.

LIMITS OF HEIGHTS OF BUILDINGS.

WE add the following statistics as to the regulation of heights of buildings in various German cities, to those which we have already given a previous number (page 112 ante).

In Germany, the land of building regulations, we find that nearly every town of any importance has some rules referring to the height of the street front and the number of stories permissible, and these regulations are stringently enforced. It may be well to know that, for the sake of interesting comparisons, nearly every town has set up a ratio between height of street front and width of street, and we have taken note of this fact preparing the adjoining table:—

City	Width of street (= b)		Maximum height (= h) of the street front of a building. (Height measured from highest point of footpath along the facade to top of front wall.)		Ratio of height to street width.	Roofs.	Number of stories permitted.	Remarks.
	Anywhere.	In the open.	Anywhere.	In the open.				
	(Measured between the authorised lines of building frontage.)							
BRUNNEN	39 ft. 4 in.	74 ft. 2 in.	h = b	—	—	—	Five	
ESSEN	—	74 ft. 2 in.	h = b	—	—	—	Five. Only four if b is less than 82 ft.; only three if b is less than 55 ft. 9 in.	
LOGNE	37 ft. 9 in.	65 ft. 7 in.	h = b + 11 ft 6 in.	—	—	—	Four (as a rule)	Authority: — "Stadtbaumeister" T. Staebben (Cologne).—Extract from statistics of the different sanitary police regulations of continental towns, as furnished by the "Fachgruppe für Gesundheits-technik" (meeting at Vienna 12th April 1889), for publication in the "Wochenschrift des Oestr. Ing. u. Arch. Verein."

The applications received refer to thoroughfares all descriptions, and in all parts of London, the district Board, as stated by the Vestries and District Board, is a little over 412 miles. The circumstances of the main thoroughfares of London are so peculiar that your Committee have had considerable difficulty in applying the provisions of the section to the roads referred to in the applications. The thoroughfares of London are scarcely now to be considered as means of communication between great towns, in the sense which is obviously intended by the Act; for, as the greater of the goods and passenger traffic is now brought into and taken out of London by railway, there is very little of what may be deemed thoroughfare by road between great towns on either side of London; while, with so many railway stations in London, nearly every road and street may be considered to be a part of a thoroughfare to a railway station, and so would answer the description in the section. Your Committee may also point out that the extra cost of maintenance caused traffic passing through a main thoroughfare in one London district to another, or to and from a railway station, is probably more than met by the increase in the rateable value of the property consequent upon the road being used for either of these purposes.

The Local Government Act casts upon the Council the duty of maintenance of any thoroughfares declared to be main roads, but the local authorities may claim to retain the management, of such roads, and in that case the Council is obliged upon to pay the cost of such maintenance, without any power being given to the Council to exercise control in any way as to the manner in which the road shall be dealt with. Thus, in the case of a main road running through several parishes, the road may be paved with wood, or with other and granite, another with asphalt, and another part may be macadamised, at the will of the respective local authorities; but the Council, the report of its Surveyor that each part of the road has been properly maintained and repaired, and have to pay a sum, to be agreed upon from time to time, for the cost of maintenance, without any power to direct that the system of maintenance of the road shall be uniform throughout its entire length. This appears to your Committee to be an arrangement which requires some alteration, either in the direction of relieving the Council of its responsibility, or, if such responsibility be retained, of giving the Council some power of control in the manner in which the money is to be expended, and of requiring continuity in the system of paving or otherwise to be adopted with regard to the road.

The question whether a road has been maintained in a satisfactory condition, which must be decided at some time by the Council's contribution is paid, would probably give rise to constant friction. In the case of a road passing through several parishes,

the work of repair and maintenance in one district may have been done to the satisfaction of the Council's Surveyor, while in the adjoining parish the work may not have been satisfactorily performed; and should the Council require any particular standard of maintenance to be observed, as a preliminary to the payment of its contribution, great dissatisfaction might arise.

The Local Government Act provides (section 11, sub-section 7) that where the Council declares a thoroughfare to be a main road, such declaration shall not take effect until the road has been placed in proper repair and condition to the satisfaction of the Council. Some of the Vestries and District Boards have expended considerable sums in putting the thoroughfares in their districts into a state of proper repair, which sums have been borrowed on loan, and are in course of repayment; but in some districts where the roads are not in good condition, the expenditure before the declaration of the Council could take effect would probably be very large, and it might be a hardship to compel local authorities to embark at very short notice on an expenditure which they had not contemplated, and which might interfere with the carrying out of other and more pressing requirements. At the same time, it would be manifestly unfair to the other districts of London if the Council were to accept the responsibility of the cost of the future maintenance of roads which were not at the first in good and proper condition.

Under the Local Government Act, the duty of maintaining these roads in the County of London which have been disturbed since December 31, 1870, devolve upon the Council; but the local authorities have the same power of retaining the management of the portions of these roads in their respective districts, as in the case of roads to be declared by the Council to be main roads, and the Council is to make a payment towards the cost. Your Committee have found considerable difficulty in interpreting and reconciling the provisions of section 11 and the subsections thereof in the Local Government Act. Sub-section 1 casts upon the Council the duty of wholly maintaining the existing main roads; while sub-section 2 provides that in the case of a road in consideration of an annual payment by the Council for the cost of the undertaking. Your Committee have taken the opinion of counsel upon the question of the meaning of the words 'towards' and 'for,' as used in these sub-sections, but have not been able to arrive at any definite conclusion upon it.

Upon a review of all the circumstances your Committee are of opinion that the provisions in the

Local Government Act and the Highways and Locomotives Act, with reference to main roads, are totally inapplicable to the thoroughfares in the County of London, having regard to the peculiar conditions under which they are managed, and the number of authorities concerned in such management. Your Committee therefore recommend—

"That the Government be requested to take the necessary measures for the amendment of the Local Government Act by exempting the County of London from the operation of sections 11 and 41 (4) of the Act; and that the President of the Local Government Board be requested to receive a deputation from the Council on the subject."

After some discussion, in the course of which Mr. Westacott cited figures showing that the cost of maintaining main roads in the metropolis averaged 1,000l. per mile, which would mean an expenditure of 412,000l. for the 412 miles mentioned in the report, the recommendation of the Committee was agreed to.

District Councils.—On the motion of Mr. A. Hoare, it was resolved,—

"That in the opinion of the Council it is a matter of great urgency in the public interest that District Councils should be established in London."

After transacting some further business, the Council adjourned.

The English Iron Trade.—There is a partial recovery in the English iron market, at least so far as pig-iron is concerned, but the business doing is still limited. Whether the coal strike now in full operation will last long or not—and there are some who predict that it will be of brief duration—its effects have been the unsettlement of trade, and the stoppage of many works. The north of England and Scotland not being affected by the strike, it is there we observe the recovery of the market. Scotch warrants have had an upward tendency all the week, and the price of some Scotch brands has been slightly raised by makers, while Cleveland iron has advanced from 1s. to 1s. 6d. per ton on the week. In the districts subject to the cessation of work by the miners, prices of pig-iron show weakness. North-west makers of hematite have again reduced their quotation, this time by 2s. a ton. Very little is doing in finished iron and steel, and present quotations for the former are scarcely maintained. Steel rails are weak at 62. in the north-west, and this is now also the price of blooms, billets, and slabs. Shipbuilders are beginning to experience more enquiry, while engineers, where they have not been compelled by the want of fuel to restrict operations, continue fairly busy.—Iron.

Illustrations.

BUILDINGS DESIGNED BY PROFESSOR OTZEN, OF BERLIN.

WE have given in this number reproductions of some of the drawings by Professor Otzen which have been exhibited at the Institute of architects this week in connexion with a paper on the subject by Mr. A. Strong, with the double object of illustrating the paper, and of giving our provincial readers a selection from the drawings which have been exhibited to London members of the Institute.

The general subject is sufficiently discussed in Mr. Strong's paper. This section through the Einshüttel Church shows a powerful piece of work of its class, and is an example of a somewhat elaborate interior church architecture carried out in brick, with diaper surface ornament in various portions of the wall.

The style of Gothic design illustrated in the exterior of the Church of the Holy Cross, and in the reredos from a church near Wiesbaden, it is needless for us to say, is not such as is likely to meet with much favour or admiration among English architects; but it represents the class of work which is being carried out by an architect of distinction in his own country, and we presume therefore that there is a considerable population to whose tastes it appeals, which is an important fact not to be overlooked.

In the Flensburg church the spire alone is modern and the design of Herr Otzen; we selected it partly because the spire is a good example of its class, partly because the whole makes rather a pleasing and characteristic picture.

MODERNISM IN ART.*

In a paper which I had the honour of reading at the Arts and Crafts Exhibition Society, recently, on "Stained Glass," I had occasion to deplore the pedantry which still enervates and depresses so much of our decorative art; and feeling, as I do very strongly, that no art is genuine which is not modern, that no art is expressing the best of which the artist and his age are capable, I was moved to make this the subject of the paper which you kindly asked me to read to you to-night.

But there is a wide difference between the incidental reference to a question like this in its bearing on a particular technical art, and an independent examination into the question itself.

I should be shirking the responsibility I have undertaken if I contented myself with an hour's ferriand on the lack of vitality in our present day art, instead of attempting to account for it, and, if possible, to indicate a remedy.

Now what does this enquiry involve? I suppose none will deny that pedantry is an evil in art, as in everything else; that the only art worthy of the name is the work of men who speak their own minds,—not of men who pretend to be somebody else, and make a ludicrous attempt to say not what they themselves feel, but what they think somebody else would have said. But, if the thing is so manifestly absurd, how comes the evil into existence?

Here, then, is the first stage of our inquiry. What is the true cause of pedantry in art? The proximate cause is obvious. It is the lack of vitality in our artistic powers, the paucity and poverty of our ideas. No one borrows money who has a large capital of his own, and no one borrows ideas who has a wealth of them within himself clamouring for utterance.

But this answer merely leads us to the next stage. What is the cause of this low vitality? Is man going irrevocably down-hill? Is the deadly monotony and hideousness of our streets, our costume, our furniture inevitable and permanent, or is there some assignable and sufficient cause? And, if so,—finally,—is the ultimate cause one which we can reach? Can we, by getting at the root, restore health to the tree?

To me these questions appear to be the most profoundly interesting to which an artist can address himself. Till they have been answered all others seem by comparison to be academical. They concern our life, others concern the outward form which will take care of itself when life and health are restored,—if restored they can be.

* A paper by Mr. Henry Holiday, read by him to the members of the Architectural Association on the 14th inst., as elsewhere mentioned.

I have long and anxiously considered the subject myself and see no reason to depend as to an ultimate solution; no reason to suppose that the destitution, the vulgarity, and the squalor which desolate the everyday life of this age must endure and are without remedy. So long as we are aware of the evil and chafe under it, there is hope.

The unqualified satisfaction of the prosperous money-maker who comes from his office and lodgers to a home crowded with expensive articles, not one of which possesses a trace of beauty,—this is indeed a depressing subject for contemplation, but happily this state of mind is not universal. There are many who deplore the ugliness of our life and some who attempt to improve our condition.

You all know Watts's pathetic picture of "Hope." Well, this discontent, this struggle against the flaunting finery, the graceless luxury of our rich, and the crushing, brutalising misery of our poor, is the one string to our lyre, the still, small voice which must ultimately prevail.

Let us, then, with the courage of a true faith in the immortality of beauty, face the evils that beset us; let us see what they are, and whence they arise, for only so shall we be prepared to overthrow them.

First, let us contemplate this pedantry, this substitute for art which is the resource of those who have nothing to offer of their own. How came men to utter this base coin, and how came men to accept it when offered? Well, we all know how the Pugin movement began, and I take this as a very favourable instance, recognising that ecclesiastical architecture stands in many respects alone, that it embodies an ancient tradition, that it has not to meet requirements of an everyday life varying with each generation, that its conditions of existence being totally unlike those of domestic architecture, the principles which apply to one do not necessarily apply to the other.

It is not, therefore, by way of pronouncing an adverse opinion on a movement concerning which any one of you have a better right to speak than myself, that I refer to this episode to indicate how and why a course which may be necessary though regrettable in one case is followed in other cases where it is wholly objectionable.

It is long since I read Pugin's well-known comparison between Georgian and Medieval architecture, but I recall the amusing examples he gives, and his argument is a simple one: This is hideous, that is exquisite; why will you put up with this when you can have that? Whether the alternative was what Pugin thought, whether we could have "that," or only a lifeless imitation of it, I leave to architects to decide. Where we are dealing with forms only remotely, if at all, derived in any sense from nature, with mouldings and cornices, shafts and caps, arches and groings, their beauty consisting chiefly in proportion, it appears to me that an artist with a fine sense of proportion may produce and has produced works noble and impressive, though the forms in their details were borrowed from a past age. In any case there can be no doubt that the movement originated in a sincere love of beauty, and this I readily admit, though, as the lawyers say, "without prejudice"; but when we come to figure-decoration the whole question is altered.

On this the movement had a most baneful influence. The revived admiration of Medieval, and particularly thirteenth-century, architecture, having become general, it was swallowed whole with all its accompaniments with a total absence of thought and discrimination that speaks volumes for the prevalent tastelessness of the time. A thirteenth-century stained-glass window or missal exhibits commonly a power of design, a splendour of colour, and a vigour of imagination and symbolism which may well excite our wonder and envy. What effect had these windows on the commercial decorators in the early days of the Gothic revival? They saw nothing of the beauty of colour of design or of imagination. One thing alone they aimed at (to judge by their results).

Draughtsmanship in the thirteenth century was in its childhood. The figures in the best works of that period possessed a surprising vigour and spirit, but the technique was imperfect. Here was the thing to be imitated. Colour was of no consequence: the rawest and crudest that could be found would do; but a splay foot and a goggle eye would place the

work at once on a par with an Early English window. I should apologise for even referring to these babyish productions, were it not for the extraordinary fact that notwithstanding all the great advance which has since been made in the quality and colour of the material, there are still respectable decorative houses who imitate the decorative works of the thirteenth, fourteenth, and sixteenth centuries, and seem to think they are producing works of art. Not only so, but there are people who gravely accept this base coin as legal tender, and treat these travesties of genuine work as if they had anything genuine about them. Happily they are exclusively commercial productions. Art has not got so low even in this age that an artist will descend to servile, avowed imitation of other men's ideas, designs, and even manners. Nor is it expected that he should do so—outside a church. His powers may be great or small, his range of thought and conception high or low, but he is expected to give us the best he has of his own, expressed in the most perfect manner of which he is capable. A lofty soul will speak to us at our best, and will elevate that best of ours to something better. A soul of lower range may address our lighter moods, but each in its own plane may be as perfect as the other. If these that speak to us be true prophets, and have taught to say that is worth saying, they will spare no pains to see that their message is not marred by clumsiness of utterance. They will attract us by the excellence of their speech, and then move us by the worth of what they have to tell.

While writing this sentence, a paper was put into my hands, which I opened at these words: "To touch the heart of his reader, an author must coin his soul into words." Most true, and well said. Even so a painter must coin his soul into visible images, else he will certainly touch no hearts, and he must see that beautiful thoughts are coined into beautiful images worthy of that which they express.

Something like this we ask for elsewhere than in a church. We do not always get it, but we often do in greater or less measure, and we value the giver in proportion as he fulfills our desire. A Watts, a Walker, or a Leech address different natures or different moods of the same nature, but each gives us of his own, and gives something that no one else can give. Whether we weep with those that weep, or laugh with those that laugh,—soul speaks to soul, heart responds to heart. But, inside a church, what have we to do with souls and hearts? There we are only concerned with thirteenth century or fifteenth century; all we want there is a commercial firm who can coach its *employés* in the correct thirteenth-century goggle eye or the fifteenth-century wrinkle, and in all the other tricks of the trade, by which the expert may know what period is being caricatured for his benefit. In the true work of art, where the technique is but the means of expressing ideas which had insisted on utterance, we respond to the influence of a master. In the hollow substitute for art where the technique is but a mechanical imitation of something else, we find nothing but the drudgery of a slave, tied down to a dull routine, on whom we can hardly even bestow compassion, for he parades his servitude with evident satisfaction.

Surely it ought to be a truism to say that all genuine art was modern when it was produced; in no past age did men try to make their work appear to have been produced in an earlier age, and, except in decorative art, it is rarely done now. A man who would send a picture to the Royal Academy imitating all the mannerisms of Giotto would be laughed at. It would be considered idle to allege that Giotto was a great genius; that would be a reason for admiration, a reason for going to him for lessons in nobility and simplicity, but not for servile imitation of his drawing, his perspective, his light and shade, and his manner, not for the violation of every principle which he maintained. For if there is one quality which distinguishes Giotto more than other, it is his intense modernism, the daring with which he broke away from the formality of the Byzantine artists, and asserted his right to say what he himself felt, refusing to be the slave of a tradition, even though that tradition was in force, not an artificially resuscitated style, ignored by every artist of the day.

If this pedantry is absolutely indefensible on any rational artistic principle, how comes it to be permitted in any branch of art?

If modernism is the characteristic of all the

art of other ages, if we are most moved by Giottos, the Botticellis, the Signorellis, the roses of the past, by all those, in fact, who pressed and led the sentiment of their respective ages, why do any of us now regard flimsy imitations of a past age with anything but the contempt which they deserve and which they would have received at any other epoch?—if such follies can be conceived as existing in any other period.

Unhappily the cause is only too obvious: the *use*, I say, not the justification. The poverty of art of to-day is the reason why we pilfer from that of the past. Poverty does not justify art, but it is poverty which makes men slaves; and it is only in our artistic poverty that I can find any means of accounting for the prevalence of that which, to me, is the easiest of artistic crimes; for under this obvious system we are training young draughtsmen into systematic deceit, and crushing every better impulse, every genuine faculty which they may have possessed when starting. I have seen men whom I knew as students, and who were then doing hopeful work, go to one of these commercial houses, and there by degrees have seen every faculty gradually blighted till the trace of any artistic perception remained. The method which originated in poverty ends in the destruction of what little we possess. If our artistic vitality is weak, this is the laziest and the most demoralising course we can adopt. We are poor the simulation in our outward style a wealth we do not possess with absolute certainty leads us in a disgraceful bankruptcy. After by far the most modest and modest confession of our small means, and work hard like poor men to improve our condition, than make false show with other men's goods.

So much I must say in strenuous protest against the demoralising principle that pedantry justified by the feeble vitality of the artistic sense under which our age suffers; but now as that weakness itself, what is its nature and tent? Is it merely that our decorative sense is imperfect? Is it merely that we are in the lough of the artistic wave and may in another generation or so be on the crest? We all know that in painting, in poetry, in music, and in science there are waves which pass over nations, and art rising for a time to a towering height, and then sinking out of sight, or to vary the metaphor the great luminaries in any art are usually found in constellations connected with a certain epoch and a few sporadic stars. Is this all that is the matter with us? That genius is not so plentiful as in some other eras, but may become so again in the near future? I venture to say our case is much worse than this. It is not that geniuses are few—they may or may not be—but that society is corrupt, that the conditions under which we live are conditions under which art cannot possibly thrive.

What we are concerned with is not paucity of geniuses, but the almost total absence of art in our present daily life, and the question we have to answer is, "What is there in our present condition which so stunts and suppresses that love of beauty which in every other age has been one of our dominant impulses?"

I will read you a passage written some twenty-five years ago by an acute observer and profound thinker on the motives which induce modern society. John Stuart Mill is speaking of art, but his description throws a flood of light on the subject of our inquiry:—

"The acquisition of wealth was invested with a peculiar value, independent of its intrinsic utility. It became synonymous with power; and since power is the common herd of mankind gives power, wealth became the chief source of personal consideration and a measure and stamp of success in life. To get out of one rank in society into the next above it is the aim of English middle-class life, and the acquisition of wealth the means. And, inasmuch as to be rich is a measure and stamp of success in life, to get out of one rank in society into the next above it is the aim of the social scale above those who are rich by means of industry, it becomes the object of ambition to save not only as much as will afford a large income while in it, but enough to establish business and live in affluence on realised gains. These causes have in England been greatly aided by that extreme incapacity the people for personal enjoyment which is a characteristic of countries over which Puritanism has passed. If accumulation is, on one hand, rendered easier by the absence of a taste for pleasure, it is, on the other, made more difficult by the presence of a very real and intense frugality. So strong is the association between personal consequence and the signs of wealth that the desire for the appearance of a large expenditure has the force of a passion among large classes of a nation which derives less pleasure than perhaps any other in the world from what it spends."

Now I would ask you in the light of this passage to consider that depraved taste, the predominance of which we deplore. What Mill

well designates "the silly desire for the appearance of a large expenditure," on account of the consequence it gives us in society, causes us to surround ourselves with *finery for the sake of display*, instead of seeking *beauty for the sake of enjoyment*. Let us look around for a moment and note the almost total absence of art in our present daily life.

It is admitted on all hands. It is a matter of constant discussion. There are many clever and some noble works of art produced still, that is to say, there are still men, who having made art their profession from a genuine impulse, produce works which possess beauty, and sometimes noble thought, but outside these isolated cases where is the art of our daily life, the art in our houses, in our furniture, in our dress, in all our utensils, and in nineteen-twentieths of our pictures and statues and buildings? Whence arises that deadly uniformity, that depressing, all-prevailing graysness—but that is too flattering a term—that all-prevailing dinginess which fills our life, so far as its external conditions are concerned, and has filled it throughout this century? Here and there a few educated persons are cultivating taste in form and colour as an exotic, but as a spontaneous growth it is gone. Whether we look at the earlier, middle, or later years of the century, we find the same thing. If we walk down Gower-street, Westbourne-terrace, or Cromwell-road, we look in vain for a gleam of taste, for a glimpse of anything that can charm the eye or refresh the mind.

Interminable rows of identical houses all cut down to one common type—mindless, joyless. Slaves in chains must have built them; nothing else can account for the gloom which they betray and produce.

Ornament, there is, ghastly ornament, all done to order under heavy penalties, all alike, all representing—what?—the pleasure of the worker in fashioning it? Good heavens, no! It is done by machinery. It represents what is expected of the class of society to which the owners of the houses belong, or wish to be thought to belong. Let us now look at dress. Here, surely, there will be more freedom. Cannot the individual assert his personality here? Let us see. Here is a train arriving at Moorgate Station full of well-to-do citizens going to their daily avocation. We can note the charming variety of form, colour, and material which is the natural expression of that individualism we all prize so greatly. But what is it we see? All dressed exactly alike—they must then certainly have found a type of dress so beautiful, so perfect, that they have voluntarily surrendered their individualism as a tribute to that perfection which cannot be excelled. Is it so? Are these black, cut-away coats, these black boots, these cylindrical tubes of trousers, these black top-hats, are these the ideal for which all individuality is to be sacrificed? I heard a critic of Mr. Bellamy's "Looking Backward" deprecate the orderly organisation of the system he describes with the remark that under such a routine people would be like sheep. What are these like? Rather black sheep. Gloom and the total absence of individuality are the characteristics of our system. And why this deadly uniformity, this total absence of anything to show that the wearers of these clothes, the dwellers in these houses, are anything but automata, all made to order, like the hideous and barbarous things they wear and live in? Are they all alike?

Talk to them in their offices and you might almost think they are; but know them intimately, and you soon find the widest differences. Why, then, cannot they show that they are thinking, rational beings, possessing here and there a stray idea of their own? Are they slaves, or what does it all mean? Yes, they are slaves, all working in chains crushed under the tyranny of two relentless Molochs, the great god Profit and the great god Snob. These two have enshined up individuality and trampled her under foot. Beauty they have expelled from Society (with a big S). There are one or two sanctuaries where she is still allowed a refuge, and the very few who are ever allowed by the god Profit to have a spare hour occasionally visit her; but if she appears in the street, the god Snob boots her and tramples on her.

Each have their own weapons and instruments of torture. Some of the victims of Profit suffer so grievously that they dare even to make a show of resistance. But it is futile and short-

lived. He has two elubs, called Supply and Demand, and these he swings about mercilessly, and the wretched slaves are soon cowed.

Occasionally a feeble protest is made by those who groan under the rule of the god Snob; but he also has too elubs—Respectability and Social Status. At the mere sight of them down go the slaves prostrate before their relentless idol.

And meantime poor Individuality is wasting away in her prison.

Alas! what can art do without individuality? They are inseparable, each without the other must languish. Society has taken up that liveried drudge, Ostentation, and Art must keep her lonely state in a National Gallery while we are the slaves of slaves.

The jerry-builders and the fashion-books are the slaves of the gods, Profit and Snob, and we are the slaves of the jerry-builders and the fashion-books.

But still we have only got half way in our inquiry into the ultimate cause of our almost extinct love of Art. If the views I have advanced are so far sound, we have attributed the decay in our love of beauty to the growth of our love of social status, our "silly desire for the appearance of a large expenditure." But why should we substitute the base desire for the pure now any more than our ancestors of two, or three, or six centuries ago? So far we have only shifted the inquiry one step further back. If this degradation is the effect of external conditions, what are the conditions which affect us and which did not affect our ancestors?

I have hinted by references to the god Profit that they are industrial conditions, but men worked for wages and bought and sold for profit in these past centuries. Profit may not be an elevating aim in life, but it cannot be a differentiating factor between the present age and those in which Art flourished, not merely as the cult of a few, but as a daily part of the life of all.

What, then, is that differentiating factor which has destroyed all the beauty and picturesqueness of a London street in the fourteenth century, with the variety and charm of its buildings and its costumes, and given us in its place the deadly monotony of Bayswater and the pot-hat?

In my opinion this differentiating factor is the intensity of the struggle for existence in our present crowded populations. That men should live by giving as little and getting as much as they can in every transaction of life was had in former ages as now, but the pressure was so much lighter that it was, happily, quite unable to crush that buoyancy of spirit which impelled men to seek beauty in all their surroundings. Now, the pressure, instead of being just sufficient to produce a healthy emulation and to spur men on to distinguish themselves, has degenerated into a fierce competition for the highest profits,—a struggle in which each man's one object is to get to the front and thrust his neighbour aside, and none has time to think of such frivolities as grace and beauty.

In former ages the aim of men generally was to enjoy life when not oppressed by arbitrary tyranny. Evils there were,—some of them great evils,—but they were not evils which vitiated men's whole lives, which gave a sordid motive to their every act; they had leisure and energy to bestow on their work, and could indulge the desire to make it beautiful, which is natural to a free agent. Now, the struggle to live has been substituted for the enjoyment of life. That which should be only the means has become the end. In place of an inspiring emulation, we have a fierce struggle for life and death.

If it be asked how can this be avoided, I should say by substituting order for the present anarchy in our industrial systems. Our mistake has been in supposing that the haphazard system which did fairly well in thinly-populated countries can possibly succeed in the dense crowds of to-day.

Let me give a rough-and-ready illustration. Suppose one of us asks half-a-dozen friends to dine and spend a sociable evening, no special organisation is needed to enable them to do so with comfort and pleasure. They can be hospitably entertained, and they will be able readily to find their own coats, umbrellas, and hats when they leave without any elaborate pre-arrangements to enable them to do so. But increase the numbers, and the case is altered at once. At a Royal Academy *soirée*, where there is an elaborate organisation, there is nevertheless some difficulty in obtaining re-

freshment, and in recovering one's out-door garments. Without organisation it would be impossible. There would be simply a free fight, and the battle would be the strong.

Is not this what has happened in our wholly unorganised and reckless system of production and distribution?

When feudalism died out and men obtained the right to compete freely in the industrial market they believed that they possessed all that was necessary; that industry and ability would in the long run meet with its due reward, and that this principle would prove the surest incentive to the development of the best characters and the production of the best work.

With some very serious qualifications it did something like this for a time. Inequalities not arising from greater or less industry existed, but these were partly the remains of feudalism. Technically serfdom had been abolished, but wealth, rank, and privilege held its own, and though every poor man was legally free to compete with the rest, without education or means the right was a somewhat barren one.

Time gradually, however, developed unjust inequalities arising from the system itself of so-called free competition, at first gradually, but, since the great development of machine power, with frightful rapidity, with the result that we have now reached the maximum of injustice. I appeal again to Mill for an accurate description of the present distribution of the good things of the world:—

"The produce of labour is apportioned, as we now see it, almost in an inverse ratio to the labour,—the largest portions to those who have never worked at all, the next largest to those whose work is almost nominal, and so in a descending scale, the remuneration dwindling as the work grows harder and more disagreeable, until the most fatiguing and exhausting bodily labour cannot count with certainty on being able to earn even the necessaries of life."

Such a monstrous condition of things as this is manifestly intolerable to all humane and justice-loving persons, and it has long exercised the minds of thoughtful men, who not only deplore the cruel injustice of the system, but perceive that unless we can remedy it in time, it must lead to some appalling catastrophe. It is not, however, the question of justice and humanity that concerns us directly to-night, but the influence of this industrial anarchy upon art.

Well, what has been the effect of the free fight for existence on art? Why this, that people have enough to do to live, they have no time for anything else. They cannot stop to think of enjoyment of life. Their energies are exhausted in the struggle for food, clothing, and a roof over their heads. Having, some of them, got this, they then begin the struggle to have more than their neighbour; there is still no time to think of enjoying life, they have got to imitate the class above them. The labourer who is successful and gets a rise in life looks forward to the joy of wearing a shiny black chimney-pot hat. The tradesman on whom the delights of broadcloth and pot hats have begun to pall, struggles, and wears himself out in the hope of some day riding in his carriage, and so forth and so forth, through the whole degrading series. Snobbery being the guiding impulse, profit-making the efficient machine.

Sordid struggle for the necessaries of life at the bottom of the scale, far more sordid struggle to outdo one's neighbour at the upper end of the scale.

Where do Art and Beauty come in? Where is love of good work gone? There is no time for either. Will it pay? is the one question,—not "Do I love doing it?" Is it worth having when done? If I don't produce the largest number of articles in the shortest time, if I don't screw my workmen down to the lowest wages they will put up with, and make my customers pay the highest price I can get out of them, I shall fall behind in the life and death struggle for profit. Beauty! What have I to do with beauty? Will beauty pay? Fashion! That's the point! Everybody is wearing this. Everybody is asking for that. The other? Oh, I don't keep it,—I assure you, madam, it's quite gone out—no one asks for it—that is, no of consequence.

Can anyone deny that this fairly describes the present state of respectable society? And I ask, can art live in such an atmosphere? In order to picture to ourselves more vividly the contrast between our present condition and that of earlier ages, imagine for a moment the effect if we were to take any of the pictures of

Paul Veronese, a man who lived in a great business community, a mercantile state, and drew all his images from his daily experience,—take one of his works, such as "The Marriage at Cana," and put all the figures into modern respectable costume, and you will then realise the extent to which taste has been degraded, and our daily life made hideous by the intervening rapid development of the principle of competition for profit, and the growth of greed for money, to the increasing exclusion of all other interests.

Now, if it is proposed to reform these crying evils, to get rid of the iniquitous injustices of our system; and liberate art from the stifling, noxious atmosphere which is all but destroying her, one is generally met with the cynical objection that you must regenerate human nature before you can alter these things, the objection being accompanied with a sneering scepticism as to the improbability of our nature. I should like to ask these objectors how, on their theory of the unredemable baseness of human nature, they explain the past? Whence comes all the beauty bequeathed to us by our ancestors which we treasure in our museums, if it is an ineradicable part of our nature to prefer vulgar display to true beauty, the heaping-up of profit to the doing of good work?

We have before us the past history of our race, we find in all parts of the world and in every period of its existence a prevailing love of beauty so strong that it has triumphed over the defects of our nature and the imperfect conditions of society. The sense of beauty varied much with place and time, but the love of it predominated everywhere. If ravages of war trampled upon it for a time, it sprang up again spontaneously with renewed vigour, with restored freedom and peace. We have scores of centuries teaching us one great lesson, that human nature loves beauty rather than ugliness, as surely as it loves health rather than disease, joy rather than sorrow. Against this vast mass of evidence we have one century offering a partial exception to the otherwise universal rule, and yet there are people so blind to all the teaching of history, so oblivious of everything but their own limited experience, that they speak of beauty as if it were an acquired taste foreign to our nature, and that this nature must be wholly changed before we can attach any value to it. Is it not more rational to conclude that the spirit which prevailed for thousands of years is that which truly pertains to our real human nature, and that the partial exception exhibited by this century is a temporary aberration, a disease? I referred to periods when art had been for a time trampled under foot by the ravages of war. What else is it that now tramples art under foot but a great civil war, an interminable strife between neighbours forced upon us by a system so blundering, so inadequate, that the only wonder is that men have permitted it so long.

What we have to do is to change this rotten, oppressive system, to substitute order for anarchy, and then, when men are not exhausted by the mere struggle to live, they will have freedom for the expansion of their natural faculties.

How to get rid of this industrial chaos and to establish order in its place is the great problem which is engaging the earnest attention of many of our best thinkers, and which is rapidly becoming the most prominent subject of social interest. The evils have long been recognised, and crude reformers were ready in abundance to advocate the redistribution of property regardless of the consequence that if society were made equal by Act of Parliament to-morrow they would be unequal again by acts of industry or recklessness next week. A destructive principle has happily never won the approbation of the mass of the people. The confusion is bad enough already; we cannot better our condition by aiming at a confusion worse confounded. What we need is a righteously and wisely re-modelled industrial system, which shall ensure to all the fruits of their labour, and leave to each the opportunity to assert his own individuality, which shall make worthy distinction and the gratitude of one's fellows the incentive to good work instead of the debasing attraction of piling up more money and exhibiting a more vulgar display of brainless and graceless luxury than our neighbour.

As I am not here to address you on Political Economy, but on Modern Art, I will not enter upon an elaborate examination of any of the systems having the above aim, which are now

before the world, I will only say so much as is necessary for the consideration of their bearing on Art. Some of you have probably read Mr. William Morris's "Signs of Change." Some years ago Mr. Morris's views on this subject appeared to me to lead to destruction with no principle of re-construction to follow. Such a course as this is, in my opinion, worse than no solution at all. A revolution of violence without even a clear scheme of just industrial reform in view, could only end in the re-establishment of the old tyranny on a firmer basis. A red terror is usually succeeded by a white terror. I was very glad to note a totally different tone prevailing in this recent publication. It is largely constructive, and it deals chiefly with social reform in relation to industrial arts.

The admirable volume of "Fabian Essays" published in January, of which the entire first edition was sold out within a fortnight of its issue, is a collection of most thoughtful papers wholly constructive in their aim, and these also deal ably with questions of taste and art. But the most popular, and I may also say the most daring, attempt to solve the great problem is that contained in Mr. Edward Bellamy's "Looking Backward," a book which, I suppose, I may safely assume most of you have read. The main principles advocated in the book are not new, but they are exhibited and applied with extraordinary ability, and evince a most rare capacity for organisation.

It would take me too far from my main subject to touch, even lightly, on the objections urged by some to the scheme propounded in the book, but I am fortunately able to quote again from that sound authority Mill an emphatic opinion as to its practicability, as to the greater incentive to work it would provide, and its enormous superiority to our present system:—

"Whatever may be the merits or defects of these various schemes, they cannot be truly said to be impracticable. . . . The objection ordinarily made to a system of community of property and equal distribution of the produce, that each person would be necessarily occupied in evading his fair share of the work, points, undoubtedly, to a real difficulty. But those who urge this objection forget to how great an extent the same difficulty exists under the system on which nine-tenths of the business of society is now conducted. . . . A factory operative has less personal interest in his work than a member of a Communist Association, since he is not, like him, working for a partnership of which he is himself a member. . . . If Communist labour might be less vigorous than that of a peasant proprietor or a working labourer on his own account, it would probably be more energetic than that of a labourer for hire who has no personal interest in the matter at all. . . . If, therefore, the choice were to be made between Communism with all its chances, and the present state of society with all its sufferings and injustices; if the institution of private property necessarily carried with it as a consequence that the produce of labour should be apportioned as we now see it; . . . if this, or Communism, were the alternative, all the difficulties, great or small, of Communism would be but as dust in the balance."

I must ask you to accept this weighty opinion provisionally as sufficient proof that a system such as that sketched in "Looking Backward," where all contribute to the production and all receive their share in the distribution, is not a wild Utopian idea unworthy the notice of a serious political economist. If any of you have so regarded it, I will ask you to keep in mind that the greatest political economist says,—

"Whatever be its merits or defects, it cannot be truly said to be impracticable," and that "all the difficulties, great or small, attending it would be but as dust in the balance" compared with the evils of our present system.

Having given you high authority in favour of the practicability of the scheme, I am also able to quote an authority that you will all respect as to its favourable influence on art. I have discussed the book much with Mr. G. F. Watts, who is not merely a profound believer in the wisdom and justice of the social and industrial system advocated in "Looking Backward," but in the immensely favourable influence it would exert on art.

On this point, and on the reasons for holding this view, I may say we are entirely at one. We believe that the love of beauty is inborn, and inseparable from our nature; that even under most unfavourable conditions it will assert itself, and that leisure and a wholesome life are all that are needed to give it free play.

To this most vital question let me invite your attention for a few minutes. What is Love of Beauty? What is its origin? Is it inseparable from our nature? Does an enquiry into this strong impulse, that even in this dark age still actuates so many, confirm the teaching of

ry that it must predominate if not crushed one grinding tyranny? I would say we what we are by virtue of all the influences have operated on us from the remote aons, in the primitive germs from which we are descended first possessed a sentient organic tence. We have, by an unerring and bly process, been moulded into our present lition by the action of our environment.

harmony between ourselves and that en- onment is not arbitrarily determined, but itable. Between our consciousness and the or so-called accidents of nature there may occasional dissonance. Between our con- sciousness and the great enduring facts of nature, er whose influence we have come into tence, there must be consonance,—there t be harmony as between a child and the ber that gave it birth. That quick response ur sentient nature to the great mother ure is Love of Beauty, and nothing can rly destroy it, except transportation to her universe.

has been universal, and is so still, where ful monsters Profit and Snobbery have established their corrupting role.

enove these. Let men work in comfort, without sordid cares or corrupting motives, they will naturally prefer to work well than Add to this the powerful incentive of ic esteem, and they will work with zest vigour.

hat people call a routine in Mr. Bellamy's am is a simple series of inducements, which, nsuring that each worker gets the full it of his work gives him the most powerful ntive to distinguish himself, by the excel- e of his work or by the improvements he effect.

he routine proper is only applied where od, by avoiding the waste of time on worth- objects, gives us more time to devote to which is worthy. The abolition of the nderation "will it pay?" so paralysing to will enable men to do good work for the sure of doing it and for the credit and iction they will worthily gain by it. The use of snobbery, or the abolition of class ictions, of the temptation to display and t Mill calls "the silly desire for the appear- e of a large expenditure," will set men free rround themselves with that which is them pleasure, instead of that which is sed of the class of society to which they id be thought to belong. It will remove the simplest and most wholesome motive in e of the most degrading, it will create a and for that which is beautiful instead of which is ostentations and therefore ar.

roovever, the growth of brotherhood will e a great impetus to public spirit, and, e we are adding to the charm and comfort om life by substituting simplicity and ty for the senseless gewgaws of an nsively-furnished modern drawing-room, hall unite in the erection and adornment ble public buildings which all can enjoy, which, with universal education, all will y. The spirit which produced the Parthenon e middle-age cathedrals will reappear, art will have a scope hitherto unknown.

ese are the influences which such a system exert on our daily life, but not less whole- ly will be the influence of its training and its es. Every man and woman will begin life e a perfect education, and will be brought o regard work as noble, and living idle on s' work as a degradation so shocking, though it will be on record as having been dited in the Dark Ages, that it will be as unintelli- as the massacre of St. Bartholomew is to e. Every one will take their share in the e years' labour conscription, and will enter dult life with a knowledge of what it is wholly inconceivable to us, so that umption of luxuries without any regard e cost of their production must disappear. e of Mr. Bellamy's best passages is that h treats of the disappearance of the word l from the social vocabulary, and the elation of the pure rule of life that it is to ask a service of any one which we would willingly render to them; baser still to them, except because they render to us a service, while the asking it with- out of not rendering it is like borrowing y with the intention of not repaying. e have feebly indicated the benefits which d be conferred on art by the substitution just system of production and distribution e vicious one which now stifles it, but I

hope I have said enough to show that the sub- ject is one worthy of our careful study. I would go further and say that the view is one the promotion of which is worthy of our most earnest efforts if we would see art recover from the paralysis which now afflicts it.

We all deplore the inferiority of the art, especially the technical art of the day, but, as a rule, in our efforts to improve it we deal with symptoms rather than causes. It is as if we found a man earnestly poring over a book in a room where hardly any light entered, and he mourned the darkness, declaring that the sun had not shone for years, and that he was weary with straining his eyes in his efforts to learn, and we said, "You are wrong; the sun is shining brilliantly outside; but look at your window,—it is crusted with the grime of years, through which no ray can penetrate. Clean this, and your task will be easy!" So we are groping for sound principles of art and pondering how to restore our technical arts, and do not see that the windows of our mind are crusted over with the darkness of low aims, selfish desires, with all the suffocating influences of profit-mongering, greed, ostentation, and snobbery. Let us up and clean our windows and let the light in, and we shall see to do good work.

[We will give some notes of the discussion in our next.]

ENGINEERING AND BUILDING EXHIBITION AT THE AGRICULTURAL HALL.

WHAT is grandiloquently described as an "International Exhibition of Machinery, Manufactures, Appliances, and Inventions incidental to Engineers, Electricians, Builders, and Ironmongers," was opened in the Agricultural Hall, Islington, on Monday. We say was "opened" on Monday, but that is hardly correct. The hall was opened to visitors, but barely half of the exhibitors had thought it worth while to have their stands ready; and even on Wednesday afternoon there were several stands incomplete. Its scope, as will be seen from the above description of it given by its promoters, is wide enough, but the exhibition is not a very extensive one, and the building trades are very meagrely represented. The exhibition hardly covers two-thirds of the ground area of the hall, and it only serves to strengthen the opinion which we have before expressed, that these small exhibitions, recurring at frequent intervals, are almost "played out." Where the "International" element comes in it is at first difficult to see from a glance at the catalogue, for all the exhibitors are English or Welsh firms. On closer inspection, however, one sees that some of the things exhibited are of foreign origin, and shown by English agents of the manufacturers.

As we have said, the building trades are very meagrely represented, but there are some exhibits of interest to which we may briefly direct the attention of visitors.

In the arcade leading to the Hall from the Islington green entrance. Messrs. Chambers, Monney, & Co. have a very good display of stoves, grates, and ranges. Specially worthy of attention at this stand is Rogers's patent range, which is devised on scientific principles. All the air needed to support combustion is warmed on its passage to the fire, which is, of course, closed in. This arrangement is conducive to both economy of fuel and cleanliness, and as no fender is required, the cook is able to get closer to her work.

Messrs. J. H. Heathman & Co., Stand No. 2 in the Hall, have a useful display of fire-extinguishing apparatus, telescope ladders, &c. At Stand 5 Messrs. F. Edwards & Co. show the "Teale" grates and a kitchener. Some "gas-cookers" as they are somewhat curiously termed, are shown at this stand. They are made by Messrs. Galli & Co., of Leeds. Messrs. O. Berend & Co., at Stand 8, have a showy display of electroliers, gaseliers, &c.; next comes the Bristol Wagon Co., with a collection of useful carts and wagons suitable for builders, contractors, and others. Mr. F. W. Way, at Stand 16, exhibits what looks like a very good chimney-pot, calculated to prevent down-draught, and capable of being swept right through.

Mr. Robert Adams, of Newington-causeway, exhibits at Stand 18 his patent spring and pneumatic hinges in different forms to meet varying requirements. They are all admirable of their kind, and the same may be said of his reversible sash-windows. Mr. Adarus also

exhibits a very good water-bar for French casements. At Stand 25, Turpin's Parquet Floor Company have a very good show of parquet and mosaic floorings. Their inch-thick antiseptic beech-block floor is worth seeing. Messrs. Clemens, Abell, & Co., Stand 32, exhibit a street-sweeping machine and a water-van, both of good type.

At Stand 24 Mr. Dan Rylands has a very interesting exhibit in the shape of glass-lined iron piping, specially adapted for water service-pipes, chemical factories, and for channels for electric-lighting wires. This exhibit should be looked at by visitors. These pipes are stated to cost twenty per cent. less than lead pipes. At Stand 28 Messrs. R. Anderson & Co. exhibit lightning-conductors, wire-ropes, &c. The New Wire Wove Roofing Co. (Stand 52) have a light erection showing the capabilities of their roofing materials known as "Carboline" and "Duroline;" the first-named is opaque, and the second transparent. They are both very light, and well-adapted for use in portable buildings and temporary structures.

Messrs. Shand, Mason, & Co. (Stand 53) have a very good display of fire-extinguishing apparatus. Well worth notice is a new hose-holder, which is in the form of a hollow bracket pivoted so as to turn in any direction. In this hollow bracket there is space for a 50 ft. length of hose to be lightly folded up, not rolled. One end of this length of hose is attached to the hydrant or rising main, and the other end is of course fitted with a nozzle. On an alarm of fire being raised, the bracket containing the hose can be swung round to any desired angle, and on anyone catching hold of the nozzle and running away with it, the length of hose is at once extended and the water turned on, thus saving the time which is often lost in uncoiling a length of hose. In the yard, at the side of the Barford-street entrance of the Hall, Messrs. Shand & Mason give demonstrations twice a day of the efficiency of their automatic sprinklers for fire extinction. Messrs. F. Jones & Co. (Stand 60) show the various applications to building purposes of that very useful and curious fireproof material known as "silicate cotton," or "slag wool." Next door, at Stand 61, Messrs. R. W. Hitchens & Co., show their specialities in fireproof and sound-proof plastering, including their "combination slabs." At Stand 70 Messrs. Ashworth & Kneen exhibit the "Toboggan" (or sliding) springless locks and latches, which merit the notices of visitors.

In the centre of the hall the proprietors of Aspinall's enamel have a gaily-coloured stand, showing the numerous applications, to all kinds of materials, of their useful preparation. Some of the exhibitors of mantel-pieces and over-mantels, in wood and cast-iron, have decorated their exhibits with this enamel.

Messrs. Johnson, Clapham, & Morris (Stand 74) show very well the many capabilities of their patent fireproof wire-lathing for ceilings, partitions, &c. They have also a good display of wire-work generally, including wire-ropes, lightning conductors. Messrs. Yates, Heywood, & Co. (Stand 82) have a large show of stoves and ranges, together with wood and cast-iron mantels and over-mantels. There are two or three other exhibitors of this class of goods, but there is an absence of bricks, tiles, stone, and other essential elements of an exhibition which is avowedly, in part, at least, devoted to the building trades.

At Stand 101 Mr. Henry Bassant makes an excellent display of well-executed quarry work for floors, walls, or ceilings. There are numerous types of gas-engines exhibited, but one of the quietest in working is that shown by Fawcett, Preston, & Co., at Stand 112. Messrs. G. B. Kent & Sons (Stand 125) show a case of brushes. Messrs. Messer & Thorpe (Stand 140) exhibit what they call "the patent bucket fire extinguisher," which consists of a tank or cistern in the shape of a pedestal always fully containing a number of buckets. Messrs. E. H. Bayley & Co. (Stand 145) show a very good and easily-worked tip-van suitable for slopping or contractors' purposes. At Stand 147 the Patent Wood Decorating Co. exhibit a collection of Mitchell's patent ladders and steps for a variety of purposes. They are very ingenious and strong, and are well worth the attention of visitors. The Company also show their process of decorating wood, which consists merely of a thin veneer. It is shown applied to coffins, and we were informed that a common deal coffin, veneered to look like a coffin of some costlier wood, can be sold for 25s., whereas a

coffin of the real wood imitated would cost 5*l.* or 6*l.* at least. Here is another chance for the gratification of that false ostentation which Mr. Henry Holiday condemned in his paper read before the Architectural Association the other evening, even if it does not lead to fraud by unscrupulous undertakers.

Messrs. Crossley Bros. (Stand 152) exhibit a 14-horse power horizontal "Otto" gas engine, working one of Laing, Wharton, & Downs's dynamos, supplying a number of arc-lights for illuminating their stand. Messrs. E. Jacobs & Co. (Stand 163) exhibit wood-working machinery and fans in motion. The Blackman Air Propeller Ventilating Co. (Stand 173) also exhibit fans in motion. Mr. E. S. Hindley (Stand 174) shows steam-engines and saw-benches. Messrs. Lewis & Lewis, at Stand 176, have some woodworking machinery, worked by a portable steam engine and portable shafting; and Mr. H. Heim (Stand 177) shows his specialties in stoves.

We have thus enumerated some of the exhibits which are of most interest to our readers. The exhibition will remain open until the evening of Saturday, the 29th inst. We trust that before then visitors will have the advantage of a revised catalogue. The one issued on the opening day was very incomplete, and full of mistakes.

ARCHITECTURAL SOCIETIES.

The Architectural Association.—The usual fortnightly meeting of this Association was held on Friday, the 14th inst., at 9, Conduit-street, Mr. Leonard Stokes, the President, in the chair. The minutes having been read and confirmed, the following gentlemen were duly elected:—Messrs. L. C. T. Moore, E. O. Cummins, W. H. Brown, J. J. Wilson, W. A. Sugen, E. Borissov, and H. M. Brown. Mr. F. R. Farrow (Senior Hon. Sec.) announced that he had been asked to recommend to their notice an appeal for funds for the restoration of the tower of Frampton parish church, of which Mr. C. Hodgson Fowler, of Durham, was the restoring architect. Mr. E. S. Gale (Hon. Sec.) called attention to the visit on this Saturday, the 22nd inst., to the new Central Offices for the Metropolitan Police on the Victoria Embankment. The architect of the buildings, Mr. Norman Shaw, R.A., will meet the party. Mr. H. Holiday then read a paper on "Modernism in Art," which we print in another part of this week's *Builder*.

Leeds Architectural Society.—At a meeting of the Leeds and Yorkshire Architectural Society, held on Monday evening in the Law Institute, Albion-place, Leeds, a lecture on "Henry Aldrich, his Work and Writings," was delivered by Mr. Paul Waterhouse, of London. The chair was occupied by Mr. Henry Perkin, President of the Society, and there was a good attendance. Mr. Waterhouse, in the course of his lecture, pointed out how many of the greatest names in the history of architecture, especially since 1400, were those of men who had studied, and even mastered, more than one branch of apparently alien sciences before turning to architecture,—men who, having been educated to some other profession, had been led either by inclination or opportunity to the study and practice of architecture, and turning to it had found their faculties rather prepared than hindered by even half a lifetime spent in what nowadays would be classed as irrelevant studies. As examples he cited Alberti in Italy, Perrault in France, and in England Sir Christopher Wren. The Italian, besides many other occupations, was a lawyer; the Frenchman had practised as a physician; and our fellow-countryman had arrived at so great a distinction in the scientific world before he gave attention to the art of building that he did not seriously become an architect until he was a Fellow of the Royal Society and a professor of astronomy. In the same way Henry Aldrich, Dean of Christ Church, claimed attention as one who brought into his architectural studies a mind practised in many and different branches of art and science. The four designs attributed to Aldrich, who was born at Westminster in 1647, were,—the Chapel of Trinity College, the Peckwater Quadrangle of Christ Church, the garden front of Corpus Christi College, and All Saints' Church. The features of these buildings were minutely described by the lecturer. On the motion of Principal Bodington, seconded by Mr. W. H. Thorp, and supported by Mr. G. B. Bulmer, a

vote of thanks was accorded to Mr. Paul Waterhouse for his interesting paper.

Manchester Architectural Association.—At the ordinary meeting of this Association, held at the Diocesan Buildings on Tuesday, Mr. T. Chadwick in the chair, the following gentlemen were elected as officers for the next session:—President, T. Chadwick, A.R.I.B.A.; Vice-Presidents, E. Hewitt, A.R.I.B.A., and J. D. Mould, A.R.I.B.A.; Treasurer, A. H. Davies Colley, A.R.I.B.A.; Librarian, J. S. Hodgson; Registrar, J. H. Woodhouse; Secretary, J. D. Mould, A.R.I.B.A.; Committee—P. E. Barker, A.R.I.B.A.; P. Hesketh, A.R.I.B.A.; E. P. Hyde, A.R.I.B.A.; J. Horsfall, P. W. Mee, W. E. Potts, A.R.I.B.A.; F. B. Smith, E. H. Steifox, A.R.I.B.A.; and G. H. Wiloughby. Mr. W. E. Potts read a paper entitled "Creeds in Architecture." He contended that architects voluntarily fettered their achievements, and limited the possibilities of their achievements, by subscribing to certain traditions which, in course of time, crystallised into creeds, such as the belief in the cruciform plan in churches, which in many cases was now unsuitable to the present form of worship. The paper pleaded for wider sympathies, a cultivation of an open-minded ability to discover merit wherever it might exist, and a struggle against prejudices. Messrs. Mee, Colley, Ross, and Hodgson took part in the discussion which followed.

SANITARY INSTITUTE EXAMINATIONS.

Sir,—On April 17 and 18 next the Sanitary Institute Council will hold an examination to grant certificates of competency in sanitary knowledge to would-be sanitary inspectors. The time at which the examination is to take place will be between the hours of eleven and two o'clock on each day. Surely the Board of Examiners could make the time to fit in better with the arrangements of the candidates than this. The men who will offer themselves for examination are for the most part mechanics, or others whose time is not at their own disposal, and have only Saturday afternoons and evenings at their disposal, and to be absent for the most important part of two days, or one might say the whole of two days, would be at the risk of losing their present situations.

The lectures at the Institute are held in the evening, to enable the greatest number to attend; the same rule should apply to the examination. I trust that the Council will see its way to make this alteration in the forthcoming examination in April next, and thus keep in touch with the Science and Art (South Kensington), the Birmingham Polytechnic, and kindred institutions, which hold their examinations on Saturday afternoons after two o'clock.

March 13, 1890. SANITATION.

PLATINISED PLATE GLASS.

Sir,—Will any correspondent of the *Builder* kindly inform me of the name and address of any firm where I can obtain a quantity of "Platinised Plate Glass" for builder's work?

Kinsale. A. PERRY, Builder, &c.

PREPARATION OF MOULDINGS.

Sir,—We have an inquiry from abroad for an attachment to a moulding-machine for laying on the white preparation on mouldings, preparatory to gilding or painting.

We shall be much obliged for any information that any of your readers can favour us with as to the most approved method of putting on the preparation referred to, and as to whether it has ever been done in a moulding machine?

MANCHESTER ENGINEERING CO., LD.
Stalybridge, Manchester.

Patten-makers' Company.—A court dinner of the Worshipful Company of Patten-makers was held last week at the Cannon-street Hotel, by invitation of the Master, Mr. H. H. Bartlett, head of the firm of Messrs. Perry & Co., contractors, Bow. Among the guests present were Mr. Barrow Emanuel, M.A., Past Master, Major Clifford Probyn, L.C.C., Mr. Arthur J. Baker, and Mr. H. Lovegrove, members of the Company; also Sir P. Magnus, Mr. A. M. Peebles (City Architect), Mr. W. E. Stoner, Mr. Augustus Manning, Mr. T. E. Franklin, Mr. R. L. Curtis, Mr. H. A. Hunt, Mr. C. J. Shoppee, Lt.-Col. B. Fletcher, Mr. Chas. Barry, F.S.A., Capt. J. A. Thornhill, and others connected with building matters.

Munich.—According to the *Deutsche Bauwerks-Blatt*, the proposed building for the New Law Courts is to be erected on the site of the old cadet school. The rough estimate to the design of Professor Thiersch shows a cost of some 5,000,000 marks, or nearly 250,000*l.*

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—XII.

DYNAMO-ELECTRIC MACHINES—(Continued)
DRUM ARMATURE.

THE electro-motive force only, set up in the skeleton dynamo discussed in the last article, was considered, and no device for connecting the moving conductor with a circuit, so as to produce a current available for external use, was shown. In fig. 28 the ends of the rectangular conductor are connected to the two halves of a split tube, properly insulated from each other, and against these press fixed contact-springs or "brushes." B

FIG. 28.

Such an arrangement is called a commutator. If, instead of the pieces P and Q, continuous rings or "collectors" are used, so that a brush is always in connection with the same end of A B C D, the current in the external circuit will be alternating as well as intermittent. We shall in future call A B C D a coil, which may contain many turns, though for simplicity only one complete turn is shown, and a number of such coils wound radially on to a cylinder or drum form the "armature" of a large class of direct-current dynamo-machines. Armatures built up in this way are called "drum armatures," a type of armature now adopted in perhaps, the greater number of direct-current machines made, the commutator being constructed, not of a tube split into two parts, as in fig. 29, but of a tube split into as many segments as there are coils on the drum.

The way in which the E.M.F. is set up and varies in each bobbin is more easily traced in this than in any other type of machine; but the connexions between the ends of the coils and the different segments of the commutator look complicated, and should be carefully traced. There are many different methods of making the connexions, though, as the general principles underlying all of them are the same, more than one will be given.

FIG. 30.

Fig. 30 represents an end view of a drum armature with six coils. On comparing fig. 26 or 27, it will be seen that the E.M.F. set up within each coil is from big letter to little letter, and the current, if allowed to flow, will be from little letter to big letter across the external connexions. The connexions of the ends of the coils with one another are made through the segments of the commutator, and it will be seen that P is joined to two ends, while S is joined to two + ends, but that all the rest of the segments connect a — and + end together. On tracing the connexions through the armature, it will be found that two equal electro-motive forces, each produced by two coils, are developed in the two paths from segment P to segment S. The paths through coils and segments are shown diagrammatically in fig. 31, which should be used in conjunction with fig. 30.

What is happening, then, is this,—the thro

Aa, Cc, Ee, are placed in series, and this set of three is put abreast with the others of three, viz., Ff, Dd, Bb. From either it is evident that P and S are the seg-

FIG. 31

ments which are at lowest and highest potential respectively, and on these press the brushes, as shown in the drawing, so as not to confuse other connexions. It must not be supposed that a machine of this kind would have but six or forty, or even sixty, according to the size of the machine, would be nearer the truth, but the connexions for so many segments could not be shown in a small figure, six are sufficient for the present purpose.

We have now to consider how the direction of the current in each coil changes as the segments of the commutator slide beneath the brushes.

We have already stated that we do not propose, in these articles, to describe the mechanical details of any particular machines, but what we endeavour to do is to assist a student in understanding the general action of any machine, the construction of which he may be ignorant of.

FIG. 32.

Draw the segments of the commutator on a circular piece of card, with sufficient space between them to write down the letters denoting the ends of the hobbins to which they are connected. Next cut out a piece of card O, to represent the brushes and the external circuit, with an ordinary pin as axis, fasten it to the centre of the diagram of the commutator and coils. The breadth of the brushes must be sufficient to just bridge across the space between the commutator segments, otherwise a brush quitted a segment the circuit would be broken. If the commutator be now moved in the direction of the feathered arrow, the brush-piece held vertical, the current is presented as flowing in the external circuit from brush to brush in the direction shown by the arrow on O. When the brushes connect V and another, and R and S, the coils Ff and Ee are short-circuited through them; in a properly designed machine this takes place when the short-circuited coils are not cutting lines of force, or at all events so few, that they are not counting E.M.F. sufficient to drive the current through themselves, and it is therefore of advantage to have their then useless resistance cut out of the circuit. The moment the short-circuited coils are brought into action again by brushes having finally quitted P and S, currents flow in them, but in the reverse direction. The coils of an armature, instead of being permanently connected together, as in fig. 30, are sometimes connected to separate segments of the commutator, which lie side by side, and the external connexion is made by the brush as it passes over the two pieces. Such an arrangement is called an "open-coil armature." In the diagram (fig. 32) for an armature of

this description, the parallel sets of segments must be represented by two circles instead of one, or they may be drawn on a paper cylinder, and the brush piece made to touch it on the outside.

Books.

Murray's Handbook for England and Wales. Alphabetically arranged for the use of travellers. John Murray. 1890.

THE exploration of England by means of driving tours, or in humbler fashion by cyclists, is an interesting feature of modern life. Out-of-the-way-places, unvisited since mail-coaches and post-chaises passed away, are now made special objects of search, and the result is that the "Beauties of England and Wales" are obtaining a wider appreciation, and the tourists' wants have been duly recognised by Mr. Murray. Of course, it is impossible in a single volume of less than 500 pages to give detailed descriptions of every town and village in the kingdom. There are handbooks issued by the same publisher which deal more fully with the subject, and number in all some twenty volumes—a costly and rather cumbersome collection. These local books are excellent for residents and visitors who want to see everything, but as each of them necessarily treats of a limited district, their employment is similarly limited. You may have the handbook for Surrey with you, but so soon as you cross the borders of Sussex it becomes useless. To mark, therefore, the requirements of a locomotive age, this compendious volume has been issued, and merits warm commendation. The plan adopted is to describe, in alphabetical order, the principal towns and places of interest in England and Wales, to indicate the excursions that may thence be taken, and to give cross-references in those cases where a spot, unimportant in size, has claims to separate mention. We have not read every page of the book, but have examined its contents with sufficient care to be able to say that the information given is trustworthy, and, in most cases, adequate. Little errors in such a work are unavoidable. Change of ownership, in these days, occurs so frequently as to make it almost impossible for an editor to be quite up to date, though this plea, perhaps, scarcely covers the retention of Lord Medesdale's name (p. 281), for that peer was too prominent a figure to have passed unnoticed away. We are a little disappointed with the rather casual indications of the "art treasures" which form the objects of chief interest in most country seats. Thus, under Longford Castle, here mention is made of "Claude," and no hint is given that the gallery there contains two of the finest examples of that painter to be found in all England. We notice the statement that "the restoration of Ely Cathedral was set on foot by the late Dean Peacock," and that Sir G. G. Scott was the architect. Some portion of the work surely was executed under the supervision of George Basevi, whose name might have been mentioned in connexion with it, just as that of Cottingham should have been given as the restorer of Hereford Cathedral, while that of Mr. H. H. Gibbs should not have been omitted in any account of what has been done at St. Albans Abbey. These are trifles which simply show that the book is not perfect (a good index would be an improvement); but they are not the fault-findings of a captious critic, indifferent to the real excellence which distinguishes this useful volume.

Practical Iron Founding. By the Author of "Pattern Making," &c. London: Whittaker & Co.

THIS is a clearly-written and, as it claims to be, a thoroughly practical and sound little book; but yet it is difficult to see the field of usefulness it will occupy. The author announces that "it is written both for the student and for the practical man." There is, however, little, if anything, which those who have been through a good foundry are not likely to know, the greater part of the book being occupied by ordinary every-day practice. On the other hand, "the student,"—the innocent cause of so much book compiling,—is not likely to learn the practice of iron founding from book instruction. We suppose, however, such works as these fulfil some useful purpose, or they would not be produced in such numbers.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

5,846, Gas-brackets, Gaseliers, &c. J. Watkinson and T. Dodd.

According to this invention, two telescopic tubes are used, but one tube has a swelling which is packed so as to press or bear against the surface of the other tube, making a tight joint, and yet, at the same time, allowing the tubes to slide telescopically one within the other. Near the extremity of the inner tube is screwed a collar, the outer diameter of which is rather less than the inside diameter of the joint packing. This collar does not prevent free telescopic motion, but it effectually prevents the two tubes from being accidentally separated. Any number of glands or packings may be used, and gas stems or brackets applicable for attachment to walls or other supports may be similarly treated.

18,487, Brickwork. G. M. Fisk (U.S.A.).

The improvement which is the subject of this invention consists in the promiscuous use of various sizes and proportions of rectangular bricks in such a manner as to produce the effect of broken or irregular ashlar in brick work. The bricks used are of different sizes, but are all rectangular; the faces are either smooth or rough, but the manner of laying the bricks gives a better appearance to the front of a building.

18493, Bricks. G. M. Fisk (U.S.A.).

This is another specification by the same patentee, and relates to bricks for building purposes, and consists in producing a brick the face of which, while being perfectly finished and possessing the "skin" formed by pressure in moulding, has the general appearance of "split," "tumbled," or similarly rough-faced stone. The rough face is produced by a suitable die used in the process of manufacture.

87, Screwdrivers. D. R. Hart (U.S.A.).

The object of this invention is to provide a screw-driver adapted to enter and fit very closely the slots of screw-heads, with a point so formed that its tendency to slip sideways during the insertion of a screw is effectually prevented, and having the two side extremities of its point strengthened so that danger of fracture is avoided; the driver has a sunk portion at its point adapted in thickness to enter and fit the slots of screw-heads. The rear of this sunk portion has concave shoulders to fit the form of round-headed screws.

257, Saw Swages. L. P. Halladay (U.S.A.).

A complicated machine for swaging saws by striking the toothed edge with suitable dies, movable by foot or hand-power, is described in this specification.

NEW APPLICATIONS FOR PATENTS.

March 3.—3,325, W. Summerson, Chimney Top.—3,336, T. Bibby, Saws.—3,340, S. Stelfox, Hinges.—3,343, T. Fletcher and others, Brick and Pottery Kilns.—3,345, E. Ives and C. MEETINGS.

SATURDAY, MARCH 22. Architectural Association.—Visit to the new Central Offices for the Metropolitan Police on the Victoria Embankment, Mr. R. Norman Shaw, R.A., architect. 3 p.m. Royal Institution.—The Right Hon. Lord Rayleigh, M.A., F.R.S., on "Electricity and Magnetism." VI. 3 p.m.

MONDAY, MARCH 24. Surveyors' Institution.—Adjourned discussion on Mr. T. W. Wheeler's paper on "Butterments." 8 p.m. Society of Arts (Centur Lectures).—Professor A. H. Church, M.A., F.R.S., on "Some Considerations Concerning Colour and Colouring." II. 8 p.m. Estate Exchange.—Annual General Meeting of Members.—Auction Mart. 3 p.m.

TUESDAY, MARCH 25. Institution of Civil Engineers.—(1) Further discussion on Mr. J. Price's paper on "Lough Erne Drainage" (2, time permitting) Mr. J. Robinson on "Barry Dock and Railways." 8 p.m. Society of Arts (Applied Art Section).—Mr. W. J. Linton on "Engraving in Wood, Old and New." 8 p.m. Sanitary Institute (Lectures for Sanitary Inspectors).—Mr. A. Wynter Blyth on "Diseases of Animals in Relation to Meat Supply." 8 p.m. Royal Historical and Archeological Association of Ireland.—Four papers will be read. 8 p.m.

WEDNESDAY, MARCH 26. Society of Arts.—Mr. G. N. Hooper on "Carriage Building and Street Trains in England and France." 8 p.m. Liverpool Engineering Society.—Mr. T. L. Miller on "The Efficiency of Gas-engines." 8 p.m.

THURSDAY, MARCH 27. Institution of Civil Engineers.—Mr. H. N. Lawrence and Mr. A. Hartley, M.D., on "Alternate or Continuous Currents in Relation to the Human Body." 8 p.m.

FRIDAY, MARCH 28. Architectural Association.—Mr. Keith D. Young on "Hospitals." 7.30 p.m. Institution of Civil Engineers (Students' Meeting).—Mr. A. E. Young on "Detection of Spiral Springs." 7.30 p.m. Sanitary Institute (Lectures for Sanitary Inspectors).—Mr. A. Wynter Blyth on "Sanitary Law, General Enactments, Public Health Act, 1875, Model By-laws." 8 p.m.

SATURDAY, MARCH 29. Architectural Association.—Visit to the new Hospital for Women, Marylebone-rd., Mr. J. M. Brydon, architect. 3 p.m. Royal Institution.—The Right Hon. Lord Rayleigh, M.A., F.R.S., on "Electricity and Magnetism." VII. 3 p.m. Edinburgh Architectural Association.—Visit to Preston Tower, Preston Cross, and Prestonpans Church.

Miscellaneous.

Edinburgh Electrical Exhibition.—The Dean of Guild Court last week passed plans for additions to the International Electrical Exhibition buildings. These consist of a sculpture gallery extending from the west end of the main buildings and leading to the picture galleries. These galleries will be six in number, each 60 ft. long by 30 ft. wide, intersected by a gallery 40 ft. wide which will lead to the eastern annexe. This annexe will be 300 ft. long by 100 ft. wide, and will be mostly devoted to general exhibits and partly to a hall for lectures and concerts. From the west end of the annexe there will be a covered court, 40 ft. wide, carried by a bridge over the suburban railway and leading directly into the machinery department. In this way visitors who enter the main buildings by either of the principal doors may walk through the whole extent of the exhibition buildings, nearly half a mile, under cover. The construction of a Japanese village has commenced, and Swiss chalets, kiosks, &c., are to be erected in the grounds, to be appropriated as restaurants, cafes, &c.

Borough New Synagogue.—We are informed that the announcement in last week's Builder that the competition for the local minister's house had been awarded was unauthorised and premature, the award in the competition not having yet been made.

The Lock-out of Kentish Brick-makers.

According to the South-Eastern Gazette, lock-out of the Kentish brick-makers, referred in our last, appears likely to last for an indefinite period. The clergy of Sittingbourne district have sent an appeal to the brickmasters, urging them to reconsider their decision, and to re-open their works. The managers received via the effect that they are unable to do this while the barge traffic between Sittingbourne and London is at a stand-still on account of the strike of the barge-men. The Committee of the Brick-makers' Association have issued a manifesto, in which they express their regret if any dispute should have arisen with the barge-men, but they desire to record the fact that quarrel was forced upon them by the Barge-men's Protection Society. The masters of brickworks, which at the present time are being offered in the London market at a price which it is impossible to make clamp-bricks. The Kent and Essex brick trade is in a critical condition, and any further addition to the heavy burden it has already to bear would probably result in its destruction, we already several of the larger makers are preparing to reduce their prices. The managers assert that the closing of the fields is the direct and necessary result of the arbitrary action of the Barge-men's Society. The trade to the district is being paralysed by the deadlock.

New Vestry Hall and Free Library.

St. Martin's-in-the-Fields.—On Tuesday the Prince of Wales laid the foundation-stone of the new Vestry Hall and offices for the Royal parish of St. Martin's-in-the-Fields, which is part of the city of Westminster, and also a memorial-stone of the new library and reading-room. The parish has secured a site at the south-east corner of the Chancery cross-road, facing the opening to Trafalgar square, and opposite to St. Martin's Church, both municipal buildings and library for its inhabitants. The architect of the new building is Mr. Robert Walker, and the builders Messrs. John Mowlem & Co.

Free Lectures at Carpenters' Hall.

The last of this year's series of free lectures at Carpenters' Hall was delivered on Wednesday evening last by Professor W. C. Unwin, F.R.S., his subject being "The Construction of Walls." Mr. Banister Fletcher, Master of the Carpenter Company, presided, and there was, as usual, large attendance. At the close, the Chairman announced that these lectures would in all probability be continued next year, as the present course had been so much appreciated. We hope to give a report of Professor Unwin's lecture in our next.

Old Cottage Architecture.

The following letter has been received by Mr. Ralph New from Mr. R. R. Holmes, the librarian at Windmill Castle:—"Windsor Castle, March 18, 1890. Sir.—Your work on 'Old Cottage and Domestic Architecture in South-west Surrey' has been submitted to the Queen, who has been pleased to accept it. I am commanded to thank you for this interesting and useful addition to the Royal Library."

Classes in Architecture, University College, London.

The course of lectures in Modern Practice, having been completed, the usual Examination has been held, with the result that Mr. A. L. Jacob has gained a prize, and he and Mr. Dendy Watney will receive First-class Certificates, and Mr. H. Applebee and Mr. H. Halsdon will receive Second-class Certificates.

Death of Mr. J. R. Herbert, E.A.

J. R. Herbert, Hon. Retired R.A., died on Monday last, at his residence, "The Chimney Kilburn." He was in his 81st year.

PRICES CURRENT OF MATERIALS.

Table with columns: MATERIALS, UNIT, £ s. d., and £ s. d. Rows include Greenheart, Teak, Sapoia, Ash, Birch, Elm, Fir, Oak, Canada, Pine, Lath, St. Petersburg, Walscott, Deals, and various other materials.

Table with columns: Timber (continued), £. s. d., and various timber types like Pine, Spruce, Fir, etc.

Table with columns: Metals, £. s. d., and various metal types like Iron, Copper, Lead, Tin, Oils, etc.

Table with columns: Building, £. s. d., and various building materials and services like Ealing, Harrow, Hastings, etc.

CONTRACTS & PUBLIC APPOINTMENT.

Epitome of Advertisements in this Number.

CONTRACTS.

Table with columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page.

PUBLIC APPOINTMENT.

Table with columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page.

TENDERS.

Table with columns: Communications for insertion under this heading, and various tender notices for construction projects.

HASTINGS.—For formation of roads and surface-water drainage, at the site of the new workhouse, Elphinstone-road, Hastings. Mr. Philip H. Tree, architect, 59, London-road, St. Leonard-on-Sea.

LONDON.—For the erection of a house in the Leigham Court-road, Streatham, for Mr. F. Syer. Mr. T. H. Smith, architect, 17 and 18, Basinghall-street, E.C.

LONDON.—For the erection of a new police-station in the Cavendish-road, Balham, S.W., for the Receiver for the Metropolitan Police District. Mr. John Butler, architect. Quantities by Mr. W. H. Thurgood.

LONDON.—For outside painting, &c., at the North Surrey District Schools, Anerley. Mr. A. G. Hennell, architect.

LONDON.—For painting and sanitary works to Nos. 7 and 8, Talbot-villas, Leyland-road, Blackheath, under the superintendence of Messrs. Dyer, Son, & Hilton, surveyors, Wallbrook, E.C.

LONDON.—For repairs and decorations at the "Amherst Arms," Amherst-road, Beckeney, for Messrs. Watney & Co., Stag Brewery, Plumico. Mr. J. G. Ennos, architect & surveyor.

LONDON.—For pulling-down and rebuilding front of No. 22, Bishopsgate-street, E.C., for Mr. A. Wagstaff. Mr. D. R. Davis, architect, 8, Union-court, Old Broad-street, E.C.

LONDON.—For external painting and repairs to be done at the Licensed Victuallers' Asylum, Asylum-road, Old Kent-road, London, S.E. Mr. W. E. Potter, architect. Quantities prepared by Mr. C. R. Griffiths, Bank chambers, Tooley-street, London Bridge, S.E. —

W. Wythe, Dalston	250 0 0
Spencer & Co., Lambeth	800 0 0
Walker Brothers, Poplar	827 0 0
B. Cook, Stonecutter-street	690 0 0
R. J. Amos, Deptford	585 0 0
W. Wells, Paddington	525 0 0
S. Hayworth & Sons, Kingsland (accepted)	445 0 0

LONDON.—For alterations and additions to the "Surrey Canal Tavern," Trafalgar-road, Peckham, S.E., for Mr. J. M. Jones. Mr. J. Jones, jun., architect.—

Gregory	2397 0 0
Pryor	890 0 0
Bright & Co.	850 0 0
Johnson	820 0 0
Holloway	773 0 0
A. & W. Garner, Peckham	529 0 0

* Accepted subject to alterations.

LONDON.—For fitting up offices of mineral water factory at Horse Shoe-alley, Bankside, for Robert's Capsule Stopper Company, Limited.—

Money Marsland, Wandsworth	2643 0 0
----------------------------	----------

* Accepted.

LONDON.—For fitting up offices, &c., at 58, South-west-street, for Messrs. Ross, Allardye, & Co.—

Money Marsland, Wandsworth	2157 0 0
----------------------------	----------

* Accepted.

LONDON.—For repairs and alterations to eight houses in Bernersley. Mr. Richard Peters, architect, Wool Exchange, Coleman-street, E.C.—

Watson	£130 0 0
--------	----------

LONDON.—For completion of five houses, Percy-road, Shepherd's Bush. Mr. Richard Peters, architect, 72, Wool Exchange, Coleman-street.—

Sturte	£120 0 0
Bishop Bros.	95 0 0
Smith	79 0 0
Serff Horle & Co. (accepted)	75 0 0

LONDON.—For the erection of two fire-escape stairs at the infirmary wing of the St. Pancras Workhouse, for the Guardians of St. Pancras. Messrs. A. & C. Harston, architects, 15, Leadenhall-street, E.C. Quantities not supplied.—

W. Whitford & Co.	£1,295 0 0
Marshall & Hatch	350 0 0
Kirk & Randall	895 0 0
St. Pancras Iron Works Co.	815 0 0

* Accepted.

LONDON.—For pine single-nook, chimney-pieces, and panelling for hall and dining-room, at Palace-court, W., for Mr. Chas. O. Tagart. Mr. J. Armstrong Stanhouse, architect.—

C. Hindley & Sons (accepted)	£145 0 0
------------------------------	----------

LONDON.—For alterations and enlargement of drawing-room erection at No. 1, Landseer-road, Holloway, for Mrs. Sallman. Mr. James Norris, architect, 80, Vauxhall Bridge-road, Westminster.—

F. A. Aneur & Son, 1, Wood-street, Westminster	£119 0 0
--	----------

[No competition.]

NEWMARKET.—For enlarging the girls' and infants' schools for the parish of Newmarket St. Mary's. Messrs. Holland & Son, architects, Newmarket. No quantities supplied.—

H. J. Linnell	£297 0 0
J. Cowell	565 0 0
Ryth & Hunt	510 0 0
H. Plummer	509 0 0
Simpson & Son	405 0 0
Kent & Holland (accepted)	490 0 0

WEST COWES.—For scavenging the Local Board District. Mr. N. F. Dennis, C.E., Town Surveyor.—

F. Cotter	£630 0 0
John Drudge	600 0 0
R. G. Cole	587 0 0

Yorkshire Stone: Halifax District.

MALIFAX is surrounded on all sides by stone quarries; the hills bristle with cranes. Mount Tahor, Ringby, Northowram, Hipperholme, Lightcliffe, Brighouse, Southowram, Rastrick, Elland, Barkisland, form almost a complete circle around it. Sandstone of various colours and degrees of hardness, flaggy, fissile, and massive, abounds. To enumerate the quarries and quarry-owners within four miles of Halifax would prove quite a formidable task. In that part of the West Riding of Yorkshire which is known as "The Clothing District," there are more than four hundred quarry-owners and stone-merchants. In many cases the proprietor is a man of little capital, a workman himself, finding employment for perhaps half-a-score of fellow-workers. It is a large firm that holds three quarries. It would be almost impossible to describe the produce of every quarry; it would certainly be unprofitable, for many of them are worked out in a very few years, being of so limited an extent. Their small size is due in part, as before stated, to the small capital of their owners, which prevents them acquiring larger tracts of ground, and also in part to the risk that attaches to every purchase of land, inasmuch as the stone in it may prove almost worthless. Fifty yards may make all the difference between valuable and worthless in the bed of stone. The difference is not one so much of weight, or hardness, or durability, as of lamination and uniformity of colour. Each group of quarries has, however, certain characteristics more or less common to every one of that group, and, in a slight degree, differentiating it from the remaining quarries of the neighbourhood. It may, therefore, be of use to note the several groups, the mode of working them, the nature of their stones, and so forth.

It will perhaps be best, in the first place, to answer briefly the question, "What is 'Yorkshire stone'?" It is, of course, a sandstone, and, as Professor Page says, "Sandstone is simply consolidated sand, the particles having been compacted by pressure, or cemented together by lime, clay, iron-oxide, or other material." Sand consists chiefly of quartz grains, practically imperishable; it is

therefore the matrix in which these are imbedded upon which the durability of the stone depends. The matrix of "Yorkshire stone" contains little or no lime; and consequently it is, says Professor Hull, "admirably adapted for resisting smoky atmospheres." That the stone does weather well in smoky atmospheres any one can see who looks at the buildings of Bradford, Halifax, Huddersfield, and neighbouring towns; only a few days ago we visited Manchester Town-hall, built of Spinkwell stone (Bradford), and found that the mouldings and carvings and plain surfaces, though black with soot, were practically as perfect as on the day they left the mason's hands, twenty years ago. How different is the present appearance of this noble building from that of the once-beautiful church at Halsey Hill, Halifax. The latter, designed by Sir George Gilbert Scott, was built of some kind of limestone (from what quarry we do not know), and has for several years been covered with white patches, showing where the stone is rapidly crumbling away. So great was its decay that last autumn an advertisement appeared in certain Yorkshire papers asking for contributions towards a fund "for its permanent repair," and towards a bazaar "for its immediate restoration, which is sadly needed." This is somewhat of a digression, but it is a peg whereon to hang a very important maxim—it is wise to ascertain the nature of the materials which a certain locality supplies, before introducing into it from another district a material the conduct of which, under such a change of circumstances, is, to say the least, exceedingly difficult to predicate.

It is not, however, of freestone like the Spinkwell of which we wish to treat at present, but of the laminated stone which, too hard for ornamental purposes, is so extensively used for flags, landings, and wall-stones. This stone is got from the lower beds of the Upper or True Coal Measures, which rest on the Millstone Grit, and form the highest group of rocks in the Carboniferous System. This system, which is of the Palaeozoic or Primary period, lies immediately above the Old Red Sandstone or Devonian System (quarried chiefly in the far north-east of Scotland and south-west of England), and below the Permian (New Red Sandstone) System, which is quarried principally in the counties adjoining North Wales, in North-east Yorkshire, and on either side of the head of Solway Firth. The principal quarries of "Yorkshire stone" form a rough semicircle

from Leeds, by Bradford and Halifax, to Huddersfield, and if the chord of this arc be drawn, the segment will enclose the chief iron-mines of Yorkshire (Lowmoor, Bowling, Kirkstall, and Parnley), and a considerable number of valuable coal-pits. The Halifax stone-district is terminated towards the east by a great "throw" or fault, extending in a direction south-east by south from Coley to Lightcliffe to Brighouse. A shaft was sunk some time ago near Lightcliffe, and from this headings were driven east and west. From the latter valuable stone was obtained; from the former nothing but shale, rag, and thin seams of coal. The dip of the strata throughout the district is to the south of south-east, or, as the quarrymen pictorially express it, "towards the ten o'clock sun," the strata being thrown off from the anticlinal axis of the Pennine chain.

Of the quarries, or rather groups of quarries, in the vicinity of Halifax, writers have, we believe, seldom or never mentioned more than four. Comparatively little has been added to our knowledge of building stones since the Report of the Royal Commission on the Selection of Stone for Building the new Houses of Parliament was published, fifty years ago. Subsequent writers have used this as a rich mine, from which they could gather information at will. It is Gwilt's gospel. To say the least, however, this report, while still true in the main, perhaps, requires considerable additions to bring it up to date. Of Halifax quarries, Gwilt,* Professor Hull,† and Mr. John Slater, B.A.,‡ mention only Elland Edge; in the series of articles on "Stone Quarries" which appeared in the *Builder* in 1886, we named the North and South Owham Quarries; and Rivington's "Notes on Building Construction" (Part III.) includes Ringby in addition to the foregoing. But the demand for "Yorkshire stone" has increased so much during the last quarter of a century that numerous other groups of quarries have been opened or extended, notably at Hipperholme, Lightcliffe, Brighouse, and Rastrick; also at Barkisland, Greetland, Thornton, &c.

A few words may with advantage be said of the manner of quarrying the stone, which varies at different places. For whereas at Lightcliffe the whole of the quarries are opened out, at Brighouse nearly all are stone-

* Encyclopædia of Architecture

† "On Building and Ornamental Stones,"

‡ Paper on "Building Stones," read before the London Architectural Association in March, 1885.

mines. The mode of working adopted depends chiefly upon the depth at which the valuable beds are situated; to open out a quarry at Brighouse, where the stone lies about forty yards below the surface, is an undertaking seldom attempted, but at Lightcliffe a good bed of stone is found at a depth of little more than a dozen yards, and here open working is adopted. Southowram and Northowram are at elevations considerably greater than the places just mentioned, but the stone, on account of the inclination of the stratum, is not as far from the surface as at Brighouse; consequently nearly all are open quarries, the exceptions being three shafts at Park, Northowram, belonging to Messrs. J. Brooke & Sons. There is no doubt that open working is—considered apart from the first cost of clearing the ground—considerably more economical, and it has this further advantage, that blocks of stone for landings may be obtained of the largest size that the vertical seams in the rock will allow, whereas in mines the size of stone is limited by the diameter of the pit-shaft (usually 9 ft.); thus, at Roper's pit or mine at Brighouse we saw landings 12 ft. by 6 ft. 6 in., which are almost as large as can there be obtained, while at the open quarry belonging to Farrars, Limited, situate about a hundred yards from Roper's, landings have been got 16 ft. by 9 ft. 6 in., and others 10 ft. and 12 ft. square. It may be asked, "Why not enlarge the pit-shaft?" Messrs. Roper & Sons did begin to increase their shaft to 11 ft. in diameter, but desisted because it would not pay. Landings do not constitute the chief produce of their quarries, and therefore pit-owners are content to let rival traders supply stones of exceptional sizes, not considering it worth while to enter into competition with them.

It may here be stated that, as a rule, the open workings of the districts are huge pits in the earth, the stone being attacked from above,—not quarries on steep hill sides where the whole vertical face of the stone is exposed to view. There, it is true, a considerable number of the latter kind within easy distance of Halifax, situate among the precipitous hills of the Pennine range, on the borders of Lancashire and Yorkshire, but the stone from these quarries is of the Millstone Grit formation, and of a coarser texture and more massive structure than the "Yorkshire stone" of which we are speaking. It may not be out of place to say that this coarse sandstone (known in the immediate vicinity as "native sandstone" or "coarse grit," in contradistinction to the "Yorkshire stone," which is known as "fine grit") is used for heavy works, such as engine-heds, &c., and in bygone years was extensively used for building purposes; but the smaller cost of "flat-bedded" wallstones from the neighbourhood of Halifax, and the increased facilities of transporting them by boat and rail, have almost stopped its use. The stone, however, weathers excellently, as the numerous many-mullioned farm-houses, chiefly built in the peaceful years that opened the seventeenth century, testify to all who care to wander over the hills near Todmorden and Hehden Bridge.

To return to our Yorkshire quarries: we will take one special one, which is a fair type of its class. Here we find the steam-cranes are perched on the very edge of the perpendicular face of the working. Their situation is precarious; now and then one goes headlong to the bottom,—very likely to the ruin of its owner. The section of the ground shows various strata and bands of more or less worthless material, and three beds of valuable stone. The band of "hard stone" near the surface is full of small dark streaks,—fossil-twigs, or rather their impressions,—and is of no use except for road-metal and for filling-up disused workings of neighbouring stone mines; the "rag" is sold for footings in various widths and thicknesses up to 4 or 5 ft. and 8 or 9 in. respectively,* but if there are no orders in

* It is not far from truth to say that no brick foundations are used in the neighbourhood of Halifax, nor is concrete common except in large buildings; the general method of forming foundations is by one or two courses of stone footings, the upper course being narrower than the lower.

hand for footings, the rag is thrown into a worked-out portion of the quarry as so much rubbish cumbering the ground above. The band of stone in thin layers supplies the commonest kind of flags, termed "shoddy flags;" the sound rag under the last is used for steps. After a course of rough rag, a bed of ashlar, 6 ft. thick, with planes of hedding practically invisible, is reached; this is used for paving-sets, as numerous marl-balls and patches of hard glittering spar render it unfit for larger and better work. The first bed of good rock, about 10 ft. thick, now follows, and this is separated from the second by about 2 ft. of rubbish. The second bed is 4 ft. thick, and 5 ft. below it is the third or bottom bed, 11 ft. in thickness. The stone from the bottom bed is the best in the quarry, close in texture, of uniform colour, sound, hard, and durable; it will also take a good polish. The stone from the top and middle beds cleaves rather more readily than the last, and is, perhaps, not quite as close in texture, but the difference can only be perceived by a practised eye; however, there is a difference, sufficient to induce the owners to classify the two stones as of different qualities.

It will be seen from this description how various are the beds of stone which are worked in a single quarry, and the architect cannot but feel that, do what he may to select a good quarry, he is, after all, very much at the mercy of its owner. It is one thing to specify that all stone shall be from a certain bed; it is another thing to get what is specified. The carelessness of workmen, the apparent similarity of the stone from another bed,—apart from actual dishonesty—are quite enough to account for the presence of pieces of inferior stone in any large consignment. These may not be detected at the time (it is impossible for the architect to examine every single stone that comes to a job, and clerks of works, too, are only mortal), but they will proclaim themselves in a few years by discoloration or decay, or, in the case of flags, by wearing off in flakes. For the difference of quality in one consignment, stone-merchants likewise are largely responsible, as stones from several quarries, having perhaps little in common with each other, are mixed together and sold indiscriminately; the result is usually more or less unsatisfactory.

We will now look at one of the Brighouse quarries or mines, and notice the mode of working usually adopted. A circular shaft, 9 ft. in diameter, is sunk through the gravel, shale, and rag, until the bed of good stone is reached at a depth varying from 38 to 42 yards. From the bottom of the shaft a heading is driven at right angles to the dip of the strata, that is to say, nearly north-east and south-west. The width of the heading is largely regulated by the vertical "bottoming seams" which occur in the bed of stone; five or six yards may be taken as an average width, and an increase of this is not desired, as it necessitates larger timbers for supporting the roof, and consequently additional expense. The height, of course, varies with the thickness of the bed, which in some quarries is about 5 ft., in others 20 ft. The heading, however, is always 2 or 3 ft. higher than the stratum of stone which is to be quarried, just enough, in fact, to permit the insertion of the roof-timbers before the underlying stone is removed. When the roof has been securely timbered for a few yards the stone-getting begins, and the valuable stone and all rubbish which would otherwise obstruct the work are carried to the surface. As soon as this

main heading has been driven to the limits of the ground belonging to the owner, cross-

headings are commenced from one or both ends of it. In Mr. Cliffe's quarry the cross-headings are, for the sake of safety, in opposite directions. Each of these, when the stone has been exhausted to the full extent of the ground, is filled up with the waste material which had been taken to the surface, and also with large blocks of hard, rough stone from neighbouring open quarries. Some of these blocks may be had for the fetching, but for others the mine-owner must pay a shilling a load (frequently of one or two stones only), and be at the expense of carting them a distance, in some cases, of two or three miles. The roof-beams are usually removed as the filling proceeds, and when this work is completed back to the main gallery again another breadth of stone is attacked, the roof-timbers now resting at one end on the built-up gallery, and at the other on the solid rock. In this manner operations are carried on until very little stone indeed of any value is left in the pit; the shaft is filled up, and the ground left to settle. In a few years an adventurous person may perhaps utilise it as building land.

Sometimes both open-working and mining are adopted in the same quarry, as at Twait's at Southowram, where a heading is driven from the bottom of the open part under a hill which rises rapidly behind the quarry.

Let us now turn to the working of the stone after it has been brought to the surface of the ground. It is first necessary to state that the stone is divisible into two classes, which may be distinguished either as "thin lift" and "thick lift" stone, or as "self-bedded" and "ripping" stone. The terms "thin-lift" and "self-bedded" are applied to that class of stone which is separated naturally by plates of mica into layers, varying in thickness from $\frac{1}{2}$ in. to 7 in. or 8 in.; in fact the stone is that known by geologists as "flaggy." Each face of every layer is, in the language of the quarrymen, "black;" the colour when dry really varies from light grey to brown, and is powdered with glittering flakes of mica. Ripple-marks are frequently noticeable, rendering the surface of the stone uneven. The "thick-lift" or "ripping" stone is more correctly known as "fissile;" it can be split with wedges in planes parallel to the planes of bedding, but does not exhibit plates of mica, the riven faces being "white." Every group of quarries supplies some stone of the "thin-lift" or "self-bedded" class; but not by any means in equal proportions to the "ripping" stone. For instance, at Messrs. Cliffe's and other mines at Lane Head, Brighouse, the stone is obtained from a "thin-lift" bed about 3 ft. thick, and a "ripping" bed about 4 ft. thick immediately above it. At Lightcliffe and Hipperholme, and also at Northowram, the stone consists almost entirely of ripping rock. In the section of Messrs. J. Brooke & Sons' Yew Tree Quarry at Lightcliffe, the "thin-lift" band occurs about halfway down the quarry; it is little more than a foot thick, and from this and an occasional thin layer between two thick lifts of ripping rock, they obtain a very limited quantity of self-bedded material. The three groups of quarries last mentioned are on the same hill within a short distance of each other. Southowram, like Brighouse, has beds of both classes. Rastrick and Elland Lower Edge have little but ripping rock; in fact, at the latter place, the thin-lift band is only about a foot thick, whereas the remainder of the stone (which is here below the thin-lift band) is upwards of 30 ft. in thickness. At Elland and Upper Edge some of the mines and quarries are similar to the last-named, while others supply self-bedded stone almost exclusively. This general statement of the class of stone obtained at each group of quarries must be borne in mind, as the nature and marketable form of the two classes vary.

The "self-bedded" stones, on reaching the surface, are roughly squared and sorted according to their quality and thickness. Those with rough, uneven surfaces, or much thinner at one end than the other, are sold as "rough shoddy flags," at prices varying from 1s. to 2s.

s. 6d. a yard.* Architects are only just beginning to learn that such a quality of stone is obtainable, but builders have known it long enough, and, very frequently, indeed, within our own knowledge, have taken advantage of the architect's ignorance by substituting shoddy flags for the self-faced flags specified; if the architect said that the surfaces were rough and so on, the builder had the reply pat, "Ab, well, Sir, you only specified self-faced flags, and that's what these are so they are; if you want a downright good job, you should have tooled flags, Sir." The builder's conscience, as a rule, however, permits him to lay shoddy flags in cellars only, where their defects are not so easily seen.

The stones with smooth mica faces and of fairly uniform thickness are sorted according to their thickness and sold as follows: $\frac{1}{2}$ -in. thin grey slates, three-quarters to seven-eighths of an inch; "best grey slates," inch and inch-and-a-quarter; "thin shoddy flags," $1\frac{1}{2}$ in., 2 in., $2\frac{1}{2}$ in., 3 in., and (sometimes) 4 in. "self-faced flags," and "self-faced landings," up to 7 in. and even 1 ft. thick. The slates are used chiefly in the immediate vicinity of the quarries, and are sold at about 30s. per "hundred" of 120 slates of various sizes, estimated to cover about 18 square yards when laid. "River slates" with "white" faces are supplied from many quarries; these are worth 10s. per "hundred" more than the self-faced ones, and are considered more durable, but a hundred will cover only about 16 yards. The jerry builders of Lancashire buy most of the "thin shoddy flags;" they are, of course, cheaper than the thicker "self-faced flags," and being lighter cost less in carriage; when laid, no one can see the thickness, so what does it matter to the jerry-builder? Two-inch self-faced flags are sold at 2s. 2d. per square yard; $2\frac{1}{2}$ in. at 2s. 6d.; and 3 in. at 2s. 8d. The prices vary a little at the different quarries; landings, 30 ft. to 50 ft., 2d. per in. thick, 50 ft. to 90 ft., $2\frac{1}{2}$ d., above 90 ft., 3d., but seldom more than a 1d. or 2d. per yard. It is scarcely possible to give the price of landings, as it varies so much according to the size; but one rule in vogue among the quarry owners is to consider all landings containing more than about 50 square ft. to be worth per square ft. 2d. for 1 in. in thickness; thus, a large 5-in. landing would be worth 10d. a foot.

Of the sizes of landings we have already said a little in the previous article. At Roper's quarry, Lightcliffe-road, Brighouse, we saw self-faced landings measuring 12 ft. by 6 ft. 6 in., and only $2\frac{1}{2}$ in. thick. Marshall & Walker, of Elland, Upper Edge, supplied a landing 16 ft. 6 in. by 5 ft. 9 in. by 3 in. for the balcony, at the Town Hall recently built at Elland; this landing when brought to the surface measured 18 ft. by 7 ft. 9 in., and as the shaft at the quarry is only 9 ft. in diameter, the difficulty involved in raising so large a stone must have been very great. The largest landing, as far as we know, which has been sent from the Halifax district, was obtained by Farrars, Limited, at their Granny Hall Quarry, Lightcliffe-road, Brighouse; it measured 16 ft. by 9 ft. 6 in., containing therefore 152 square feet, and was 10 in. thick. Doubtless landings of this size have been and can be obtained from other quarries, but we have no accurate information on the subject.

For self-bedded material generally, we may say that Brighouse, Southwram, and Elland Upper Edge are the best in the district. Southwram stone is chiefly put into trucks at Halifax Station; the other two groups send their stone from Brighouse Station.

The "thick-lift" or "riving" rock is brought to the surface in blocks up to a yard in thickness. It is then split by wedges along the lines of lamination: these are darker streaks, sometimes barely visible, sometimes well defined. It must not be considered, however, that the stone is easily

cleft along these lines; rather, it must be understood that it *can* be split or riven in this direction, but with difficulty. The different layers, as split one after another from the block, do not present, as a rule, smooth level faces, and can therefore seldom be sold as "self-faced" material. Some of them are roughly dressed with a boasting chisel, the prominences being worked off and the flags (as it is termed) "taken out of twist." No regularity is attempted in this mode of working; the chisel-marks are at all angles with the sides of the flag, and occur merely where quite necessary. These flags are sold as "knotted" or "boasted" in various thicknesses: the $2\frac{1}{2}$ in. ones being worth nearly 3s. a yard. They are extensively used for footpaths of streets, where strict economy is practised, and are as a rule durable, although certainly not of a prepossessing appearance. Some of the flags obtained from "riving rock," if varying much in thickness or otherwise unsuitable for hoisting or tooling, are put into the class of "rough shoddy flags," previously described. By far the greatest quantity of the "thick-lift" stone, however, is carefully tooled with a chisel about 4 in. broad, and sold as "tooled flags." The usual thicknesses are $2\frac{1}{2}$ in. and 3 in., but $3\frac{1}{2}$ in. and 4 in. flags may be had to order. With the exception of those at Upper and Lower Elland Edge, all the quarries supply tooled flags. The prices vary a little, but 5s. 5d. per yard for $2\frac{1}{2}$ in. flags may be taken as the general rate. Some quarry-owners ask a penny a yard more for 3 in. flags, but others are content to sell them at the same price as $2\frac{1}{2}$ in. The reason they give for this is the extensive demand in London for $2\frac{1}{2}$ in. flags on account of the saving in carriage, and consequently an enhancement of the price of $2\frac{1}{2}$ in. and a depreciation of 3 in. Roughly speaking there are 5½ square yards of 3 in. flags to the ton, and 6½ of $2\frac{1}{2}$ in., and as the rate of carriage from the district to London is 10s. 10d. a ton, the saving effected in carriage is rather more than 3½d. a yard.

A considerable number of "polished" flags are put into the market, but none whatever are supplied from the Elland Edges, Rastrick, or Brighouse. Messrs. Joseph Brooke & Sons, at their Yew Tree Quarry, Lightcliffe, polish selected stone from their quarries at Northwram, Hipperholme, and Lightcliffe (bottom bed), and classify it as their "Silex Brand." We have specimens from all the three quarries, and notice that all of them are so close in texture that the polished surface has a considerable sheen, after the nature of granite, but, of course, inferior to it. In addition to their own stone, Messrs. Brooke & Sons polish stone for other quarry-owners at Hipperholme and Lightcliffe. The method of polishing has a primitive appearance, and consists of a strong horizontal double beam, balanced at the middle on an upright shaft, which receives a rotary motion underground from an adjoining steam-engine. The beam is 30 ft. long, and a circular table of "knotted" flags (containing about 90 square yards) is carefully laid under it; to the beam itself about 40 additional yards of flags, steps, &c., are attached by a number of chains, and these flags, as the beam turns round on its central pivot, are dragged over the table below, until they are polished. Water is continually streaming on to the stones from a supply in the centre, and a man is employed to scatter sand over the table. The upper (moving) stones are sufficiently polished in twelve or thirteen hours; the lower are finished in about double the time.

Messrs. Charnock & Sons have a polishing-machine at Charlestown in Halifax, and here stone from Southwram is brought. Messrs. John Farrar & Sons polish their stone from Southwram at Brookfoot, and also polish their stone at Thornton; but as this is nearer Bradford than Halifax, it is beyond the province of this article. We may say, however, that the stone is of a blue-grey colour, very similar to Northwram stone, but perhaps a little coarser in texture. The polishing-machines just mentioned consist of a rotary

circular table of flags, over which a rectangular table moves to-and-fro. They do not turn out as much work in a certain time as does the machine in use at Lightcliffe.

The price of $2\frac{1}{2}$ in. polished flags is about 4s. per yard.

Landings, of course, may be had either tooled, polished, or boasted. It must be borne in mind, however, that the same remarks apply to these as to flags,—namely, that all quarries except those at the Elland Edges supply tooled flags, and that there are only three firms in the district who own polishing-machines.

A considerable number of landings are supplied for the construction of chemical cisterns in Widnes and other Lancashire towns. From Farrars' quarries at Brighouse stones 12 ft. square and 1 ft. thick, weighing about ten tons each, have been sent for this purpose. Stone is severely tested by chemical manufacturers before being adopted, and it may fairly be argued that whatever will resist the continued action of powerful chemicals will be able to withstand the same chemicals in the diluted form in which they are present in the atmosphere. Stone also from Northwram and Lightcliffe is used for chemical purposes. One of the tests to which the stone from Brooke's quarries has been subjected is submersion in hydrochloric acid, both cold and heated to 120 deg. Fahrenheit; it stood both tests perfectly, did not decompose or diminish in weight, and showed no traces of lime in its composition. The presence of iron was, however, detected,—more particularly in the bluer varieties.

Besides the material already mentioned, most of the quarries supply paving-sets, steps, and curbs for footpaths. Elland Lower Edge enjoys a great reputation for paving-sets; in fact, it is not far from the mark to say that the four quarries at this place and three of those at Upper Edge supply nothing but sets, curbs, and steps. Sheffield and other Corporations, and numerous Local Boards, have used this stone. Its weight, according to the report of the Commissioners for selecting stone for the Houses of Parliament, is 153½ lbs. per cubic ft.; for purposes of comparison we may say that the Commissioners state the weight of Bath stone to be from 116 to 123 lbs. per ft., of Portland stone from 126½ (roach) to 145½ (curf), of Craigleith stone about 145 lbs., and of granite about 166 lbs.—very nearly the same weight as the Kentish rag.

Steps are frequently delivered in a rough state, and worked on the building site itself. They may, however, be obtained either tooled or polished. Street-curbs are supplied self-faced and tooled. In addition to these some of the Brighouse and Lightcliffe quarries send a large quantity of platform coping to the various railway companies. These are all brought to uniform widths of 3 or 4 ft., are 3 or 4 in. in thickness, tooled, and bull-nosed along one edge.

We may say that flags for the best work are supplied of uniform widths, or as it is termed, of a certain "gauge," so that they can be laid in equal parallel rows.

In our issue of the 14th of September last year, we printed a letter from Sir Robert Rawlinson, loudly in praise of artificial stone, and equally loudly in condemnation of Yorkshire flagstones. Sir Robert's letter elicited two excellent replies from "Town Surveyor," but we now know that certain Yorkshiresmen refrained from writing simply because they thought it was not worth while. The gist of Sir Robert's letter is in the following passage:—"I have . . . walked over the York-flagged foot-pavements in the West-end of London, and can only say that in wear they are true to the name flagstone—a stone which wears in flakes. *There is not a single square yard of foot pavement of Yorkshire flags which has been six months in wear which is not showing flakes.* The artificial Croft flags, on the contrary, will wear to the last, and be sound." Now, we do not pretend to have carefully examined every square yard of flags in the West-end of London, but we can certainly say that we entirely dissent from the

* All prices given in this article are for stone put in truck at the nearest railway station, and may be taken as the average prices current at the present time.

strong statement which we have printed in italics. It cannot be denied that a large number of the Yorkshire flags which are laid in London do in a very short time begin to wear in flakes. A cursory examination of these, before they were laid, would in most cases have shown that such would be the case,—the lines of lamination would be numerous and distinctly marked. We have seen flags which are closely striated throughout their thickness, some of the lines being dark brown,—almost black; others we have seen in which the striations only appear when the stone is wet; and others, again, there are,—we have a sample before us now,—in which even water will reveal no lines of lamination. We could point Sir Robert Rawlinson to flags, landings, and steps which are worn into hollows more than $\frac{1}{2}$ in. deep (owing to excess of traffic in particular places), and which yet do not show flakes. Just as there is good artificial stone and had, there are good and had flags. But there is another point which ought to be raised, and it is one on which Sir Robert gives no information,—are the best Yorkshire flags as durable as the best artificial ones? Of course, the instance mentioned by Sir Robert, of an artificial step lasting as long as three Portland stone steps, has nothing to do with our present subject.

NOTES.

THE coal strike terminated, as we anticipated, at the end of last week, the masters' combination not being complete enough to effectively resist the demands of the miners. The announcement that the dispute had been settled was naturally received with general satisfaction, and the incident, which created much alarm and uneasiness, will soon be forgotten. The most satisfactory feature of the affair, to our mind, consists in the statement that proposals were made at the conference for dealing with wages questions in future, and agreed upon in principle. It is time that such questions were settled in a more reasonable manner, for, as a contemporary well remarks, "the excessive cumbersomeness and costliness of the present method of haggling were never better illustrated." The prejudice which exists amongst most bodies of workmen against arbitration has long been overcome in the case of the Northumberland and Durham collieries, where the representatives of employers and employed meet periodically for the discussion of disputed points, and have been successful in settling very many such questions. Indeed, Dr. Spencer Watson, of Newcastle, in a paper read at Manchester on the 12th inst., stated that in a single year no fewer than 629 disputes were thus settled; questions upon which agreement had been found impossible being referred for decision to one or more independent persons mutually agreed upon. These conferences have from time to time established sliding scales by which wages are automatically regulated, and it seems probable that had this system been more general the recent trouble might have been averted. The question is already before the House of Commons, a Bill having been introduced this Session "for dealing with strikes among workmen and remedying some of the evils of the sweating system." We should have thought that these two great labour questions differed sufficiently in their nature to have been made the subjects of separate measures. The Bill consists of seven clauses, and the principle of dealing with strikes may be described as compulsory arbitration. It is proposed to form Courts of Arbitration, consisting of an equal number of representatives of employers and employed, Her Majesty's Inspectors of Mines, —or of Factories and Workshops, as the case may be,—being empowered to compel disputants to submit their case to such tribunal when the differences are likely to lead to a stoppage of work. Should this result in the adoption of a mutually satisfactory arrange-

ment which would obviate these vexatious and expensive disputes, it will certainly be most beneficial to the entire community.

IT is difficult to understand whence and how there first arose the idea of making a watering-place and holiday resort of Southend. Its distinction in that sense appears to date from about the last decade of the last century; at the time Jane Austen wrote it was regarded as a good seaside place to go to for a London man who could not afford the expense of a coaching journey to Cromer with a large family. Easy distance from London of course, counted for a great deal more in those days; but why choose a place where there is a shallow a mile wide in front of the beach, only just covered by the sea at high water, and not leaving at low tide even a "practicable" sandy shore, but only a wet and muddy expanse? Yet Southend seems to be by no means quiescent, but rather putting on new life. In addition to Southend proper, which is reached from Fenchurch-street, there is now a kind of new hamlet springing up half a mile inland, called for distinction Southend-on-Sea (apparently because it is exactly the part which is *not* on the sea), reached from Liverpool-street, and where the well-huilt and rather ambitious new terminal station seems to argue that the Great Eastern Railway Company, at all events, expect a considerable traffic in that direction. New traffic is partly looked for, no doubt, from future residents on the building estates along the line of railway; on the Fenchurch-street line, for instance, between Tilbury and Southend, we pass a notice-board in the midst of fields, inscribed "authorised site of the ——— station" (the name has escaped our memory). But why people should go to Southend, except because more attractive places are full, we fail to understand: still less why they should go to Southend-on-Sea. There is no sea at the one, and no pretty country at the other. Southend itself, which formerly lined the shore, has spread up into a main street inland towards the railway: the usual watering-place street. The old town, irregular and dilapidated without being picturesque, but with an interesting old house here and there, skirts the shore eastwards, with a triangular plot of ground at the eastern part, between the houses and the sea, which seems to have been meant as a "village green" originally. On the high ground westwards of the end of the main street stands the principal hotel, and extending from it westwards is "Royal terrace," dating from the time when Southend was discovered; a neat clean well-huilt row of Georgian houses with pilastered front doors and a wide gravel walk before it, the centre of the terrace emphasised architecturally by stucco pilasters after the fashion of the day. In one of these it was, no doubt, that Mr. John Knightly stayed with his family on the occasion when he incurred the criticism of the Hartfield "apothecary," Mr. Perry, for his shortsightedness as a father in taking his family there instead of to Cromer (*vide* Jane Austen's "Emma"). Westward of Royal terrace extends, at a much greater length, the row of houses forming modern Southend. They make watering-places deliberately on a set pattern now, and this part of Southend is exactly like "The Lees" at Folkestone on a smaller scale; the houses, the drive, the turf margin, and the curving walks down the cliff side, are all repeated here: but there is not the Folkestone sea, unfortunately. From the bottom of the hill beneath the hotel extends the pier, a mile and a quarter long, enabling the visitor to get out to the water at low tide. The original pier was a rather narrow timber one, but a well-built erection of its kind, constructed about forty years ago. A new and wider iron pier is being carried out alongside of it, and is now about half finished. The end of the long pier is at all events a place to breathe fresh air and see a large expanse of sea and sky, as well as plenty of craft to give life to the scene. One real beauty of Southend, we can easily imagine, will be found in the effects of sunlight seen

from the terrace, looking south across the broad estuary of the Thames, with the coastline of Kent opposite. It was a fine scene on the day we saw it, lit only by the scanty sunlight of a rather bleak early March day; under certain conditions of weather there may well be splendid effects from the terrace level: the one real attraction we could fancy in Southend.

THE Town Council of Bolton has been heaving itself, and not a moment too soon, if one may judge by the high death-rate in the borough in a recent week (43 per 1,000), and by the description which was given at its last meeting of some of the "rookeries" in the town. The present condition of the place is certainly deplorable. In many cases unoccupied cellar-dwellings are used as ashpits; back-to-back houses are common; people are living in "wretched shanties" clustered together in filthy alleys; sink-pipes are directly connected with the drains; the street-sewers are scarcely ventilated except into the houses; the public scavenging is done in a parsimonious manner; "a very large proportion of the cinder-sifting closets are now without rubbish-boxes, and, consequently, are in a highly objectionable condition;" in fact, sanitation appears to have been hitherto utterly neglected by the Council. These terrible charges are not made by any irresponsible person, but most of them by Dr. Sergeant, the Medical Officer of Health for the Borough. In his February report he further states that "the whole of Derby Ward has undergone inspection. The result shows that the sink-pipes of 1,330 houses were in direct connexion with the drains." The Sanitary Committee of the borough is now hard at work, attempting to remedy some of the existing nuisances; perhaps when the sink-pipes are all disconnected, other evils will be abated. A resolution has been passed ordering five houses in Meadow-street to be closed as unfit for habitation, and others are only waiting their turn. Ward by ward the whole town is to be purified. In Exchange Ward alone,—the first to be dealt with,—the committee found "scores of houses that required immediate attention." Houses that cannot be satisfactorily amended are to be pulled down. But the committee does not intend to build any dwellings to take the place of those demolished. This part of the sanitary reforms is to be left to "private enterprise,"—in other words, to the jerry-builder. This portion of the committee's report was subjected to considerable criticism at the last meeting of the Council. The main argument brought against those who advocated the erection of dwellings by the Corporation was the wearisome one of "economy." They would not "pay," or, as one councillor put it, they would not show "a satisfactory financial result." But it must be remembered that in providing sanitary dwellings for the poor, the larger taxpayers are not lengthening the lives of these alone, but probably their own lives too; fever bred in the slums will sometimes spread to the terrace and villa.

THE annual "Schinkel-fest" of the Berlin "Architekten-Verein" was held as usual on the anniversary of the great architect's birthday. After the annual report had been read, and the (this time very long) list of members who had died during the year had been gone through, the representative for the Minister of Public Works presented the Schinkel Medallion to Herr Jules Boethke* (Kgl. Reg.-Baufuehrer), whom the President, on behalf of the members, congratulated in hearty terms. A very interesting paper on "The Life of the deceased Archaeologist, Karl Boetticher," read by "Post-Baurath" Tuckermann, followed, the latter bringing Schinkel's and Boetticher's names in close connexion with one another,—and after a vote of thanks to the lecturer, a small pause in the proceedings of the evening followed, in which interval, however, a very fine collection of the archaeologist's drawings could be viewed. After the pause

* See *Builder*, March 15, 1890. "Schinkel Competition."

the second part,—the annual dinner, with the various performances between courses,—took place, and, even if the tone was an earnest one on the whole, as time went on mirth had its rights. An allegorical piece, written for the occasion, titled "The Competition of the Building Styles," showed some excellent ideas, "The Style of the Future" being represented by a veiled warrior, clad in resplendent mail from head to foot; whilst M. Rococo" showed a contemptuously comic figure. Ancient, Byzantine, Gothic, Italian, and German Renaissance were all typically represented; and "Culture," the controlling goddess of the piece, made an excellent impression with her strictly logical comments.

THE mausoleum for the deceased Emperor Frederick, now in course of erection at Potsdam, is progressing rapidly, but it is doubtful whether the building will be complete in time for the ceremony on the anniversary of the monarch's death, as was originally intended. The building, which has been designed by Professor Raschdorff (Hon. Cor. member of the R.I.B.A.), in accordance with the Empress Victoria's ideas, or rather special wishes, is, as far as we can now see, likely to be a success. It will, however, be advisable to leave the description till after the opening ceremony. The site has been admirably chosen, and the style is in harmony with the surroundings and with the "Friedenskirche" close by.

IN regard to the subject of technical education it may be of interest to note that Austria has at present five technical colleges. A total of 1,760 persons are being benefited by the instruction given at these institutions, and of this number 1,576 are students proper. The Vienna College, with 88 names, takes the lead; the combined Bohemian and German divisions of the one at Prague show 601 (i.e., 334 + 167) and then follow three smaller ones: Lemberg, 158; Graz, 167; and Brün, 148. Of the total of 1,760 names, only 152 have been entered for architecture. This is owing to the fact that the Austrian architectural students prefer to study at the "Kunst-Akademie" at Vienna. In comparing the above numbers with those of the German institutions,* we find that the number of students at the Royal Technical College at Berlin does not fall so very short of the number of technical students of the combined colleges in Austria.

IN a "Note" of May 4, of last year, we adverted to the establishment of a "Memorial Tablet Fund," at Newcastle-on-Tyne, for the marking of certain houses connected with the careers of its most famous townsmen. According to the *Athenæum* a similar project has been undertaken by the Clifton Antiquarian Club in respect of Bristol and Clifton. It appears, too, that the Club propose to extend their labours in a purely topographical direction, for "Roman camps and roads of the neighbourhood are likewise to receive annotations on their respective sites." Amongst the many worthies who should find special honour at Bristol, the names of the two William Canynges, who rebuilt St. Mary Redcliff Church in the fifteenth century; John Shipward, Whitson, and Edward Colston, merchant-adventurers; Thomas Blanket, wool stapler, temp. Edward III.; and the Cabots and Hugh Elliott, navigators, are pre-eminent. John Cabot, together with his three sons, Sebastian, Louis, and Saucius, by the King's charter, sailed from this port in quest of India in May, 1497, and reached the Terra Prima Vista, by the gulf of St. Lawrence. In the year following Sebastian was equipped by his fellow-burgesses for a voyage which resulted in the discovery of the Labrador coast and of what are now Nova Scotia and Newfoundland. Passing on to later times, it is to be hoped that, besides Chatterton's, the haunts or homes of the following will be indicated. Coleridge

sojourned at Clevedon and Bristol, being attracted thither by Southey, who was born in Wine, or Winch, street, where by the sign of the Hare, since the Golden Key, his father kept a draper's shop. Sir Thomas Lawrence, P.R.A., son of the landlord of the Black Bear Inn, Devizes, for a while stayed in Bristol, and set up, when sixteen years of age, in Bath. Jane Porter, novelist, with her sister, Anna Maria, natives of Durham, lived latterly in Bristol. Hannah More and her sisters kept a school here; their father was also a schoolmaster in the city. Also E. H. Baily, R.A., F.R.S., sculptor of "Eve at the Fountain," and of the "Graces" and the "Morning Star," whose father was a ship-carver at Bristol. Dr. J. C. Pritchard, the great ethnologist, born in Ross, co. Hereford, who settled at Bristol in 1810, and in 1813 gave to the world his first edition of "Researches into the Physical History of Mankind." William Herapath, analytical chemist, inventor of the blow-pipe known by his name, and the magnetic balance, and who, with Henry Clark, founded (1828) the Bristol Medical School; Thomas Edward Bowditch, whose travels on the western coast of Africa were prematurely ended by his death at the Niger's mouth in 1824; and of Miss Mary Carpenter whose philanthropic labours need no encomium. We understand that a portion of Colston's house was incorporated in the new Assize Courts buildings.

THE exhibition of the Institute of Painters in Water-colours may be characterised as

"This sown with aught of profit or delight."

The proportion of absolutely commonplace works seems greater than ever, and there are evidently a considerable number of people pursuing the craft of artist in water-colours who would have been better employed in some less ambitious calling. There are others worse than commonplace; large drawings hung on the line which are so absolutely vulgar both artistically and otherwise that to hang them in the best places in an exhibition is a kind of offence against public taste. The Hanging Committee do not seem to know what to do with some of the few really good works they have, as it is not uncommon to find a drawing that is quite above the average of the exhibition put down on the floor. Among the noticeable works Sir Jas. Linton's "Miss Ashbee" (16) is, of course, fine in colour, but very wooden and expressionless as regards the head; his other work, "Waiting" (44) is far superior—a beautiful face, picturesque costume, and very fine and rich colour. Mr. Slocombe's "Portrait of a Guarnerius Violin" (46), lovingly portrayed with its ruddy and amber tones, is an interesting and unusual work. Mr. Fulleylove's small drawing of "Greenwich Hospital" (127) shows a bit of bright breezy sky which in itself is worth a dozen of the ordinary run of works present. Mr. Anderson Hague's "Uncertain Glory of an April Day" (110) is a fine landscape effect rather spoiled by uncertain drawing of foreground figures and details. Mr. Cahianca's "Grey Weather" (137) is notable for originality of subject and composition—two white-bonnetted *religieuses* flanked by a long dull grey wall and heavy masses of trees over it. Mr. Orrock's "A Common in Essex" (184) is a fine work, apparently a little wanting in foreground colour. In "Windsor" (211) Miss Donald Smith has caught the look of moving river-water on a calm day very well. "The Last Request" (248) by Mr. H. J. Dobson, is a truly pathetic little picture which has been floored, so that it is likely to be missed unless looked for. Not so with Mr. Charles Green's brilliant little work showing "John Gilpin" (282) proud and corpulent in his "trainband" uniform, admired by his wife and daughter, in a room every detail of which is given with the greatest finish and precision. Mr. Towneley Green's "Mother and Child" (284), with less of brilliant execution of detail, is a higher work in feeling; a kind of modern Ostade in water-colour. Miss Kate Greenaway's "Boy with a Basket of Apples" (295)

is a kind of poetry-book boy walking in front of a prettily composed landscape; an original work, a little odd in colour. Mr. Fulleylove gives "Sta. Maria del Popolo from the Pincian" (296), a good little work of its class. Mr. F. Dadd's "Hawks Abroad" (303) is very cleverly painted, but wants point and incident. Mr. Gregory's little miniature, "A Step on the Stairs" (322) should be looked at. Mr. Arthur Severn sends a large study of "La Salute, Venice" (334), noticeable rather for colour than the treatment of architectural detail. Mrs. Harry Hine's "Study of a Street in Sunlight" (349) is slight but very true and bright in effect. Mr. Ammonier's large landscape (367) is hardly equal to his best. Mr. Dollman's "Hawks dinna pike out hawks' een" (427) is one of the now fashionable highwaymen subjects, clever enough, but the joke is hardly worth so much paper. Mr. Charles Green's "Pickwick Club" (435), with Mr. Pickwick standing on a chair for a benevolent speech, shows a great deal of study of character in the faces, but is not an attractive work; perhaps the subject is too near farce to admit of being seriously painted. Mr. Steer's painting of Goldsmith playing the flute to ragged children in his garret (452) is to be looked at, and Mr. Charles E. Wilson's "Blowing Bubbles" (471), a single figure of a child seated before the darkness of an open door. Mr. Carlton Smith's "Grace" (478), a family rustic scene, is not of the highest class of painting, but the expression of the child's head on the left is very sweet. In the third room Mr. Bernard Evans makes a landscape of the old school in "Byland Abbey" (545), effective in a way, but too like a revival. Mr. Hugh Carter's various figure subjects are all good, but all in too manifest and palpable imitation of Israels to give their author the credit he might otherwise gain from them. Mr. Knight's "Sheltered Vale" (639) is a fine work in his usual brown style; his smaller drawing, "A Breezy Day" (292) is better, however,—notably the bright windy sky. Mr. Chas. E. Mottram's "High Tide, Ramsgate" (634) is a very fine bit of sea-painting on a squally day. Mr. Harry Hine sends a large view of Lincoln Cathedral from the north-west (776), very correct and finished, but very deficient in tone and atmosphere.

A COLLECTION of paintings by various foreign artists, now on view at Messrs. Dowdeswell's in New Bond-street, contains a good many interesting pictures. Some of them indeed are small examples with great names, and those of Diaz do not tend to recommend him. One or two small Troyons are beautiful examples of the painter. Herr Muhrmann's more or less impressionist landscapes are unequal but include some original things. Among works by modern Italian painters Innocenti's "The Dance" is a beautiful little picture. There are some fine examples of that remarkable and versatile painter Courbet, including two very fine landscapes, "Les Saules" and "Le Ravin," and an equally fine figure study, "La Dormeuse." There are also some remarkable works in their way, by Signor Segantini, who seems to be a kind of Italian Holman Hunt, or at all events reminds one a good deal of that painter in his tendency to very strongly marked and hard painting of detail, and strong contrasts of light and shadow. But perhaps the most interesting works in the gallery are the landscapes by the late Georges Michel. None of these are large, but they are all grand, landscapes; broad and powerful in effect and composition, and full of the poetry of nature. Michel's place will eventually be higher than it has been yet.

WITHOUT going beyond our *métier* to express any opinion on the great event of the past week in European politics, we cannot withhold a word of admiration for Mr. Tenniel's pictorial comment upon it, under the title "Dropping the Pilot." Among the many cartoons, full alike of artistic and intellectual power, which have illustrated Mr. Tenniel's

* See *Builder*, February 22, 1890.

† Restored by the late George Godwin, F.R.S.

brilliant career as the chief artistic contributor to *Punch*, we do not know that he has ever done anything finer, more pathetic, and more straight to the point than this.

THE MAUSOLEUM AT CHARLOTTENBURG.

A WEEK or two since all the members of the Imperial Family of Germany in town at the time were present at the solemn ceremony held for the first time in the new extension of the Mausoleum at Charlottenburg, in honour of Emperor William I, the anniversary of whose death was the 9th of this month. The old Mausoleum building, designed by Schinkel as a tomb for the remains of Queen Louise of Prussia, was erected in 1810 (in accordance with Schinkel's design) by "Hofbaurath" Gentz, and received new façades of a more monumental material in 1826. In 1841 the Mausoleum was extended for the remains of King Frederic William III., and since that year this well-known monument has been visited by hundreds of people, not only on account of the patriotic interest of the place, but also on account of the two splendid sarcophagi it contains, the work of the sculptor Rauch. In accordance with an express wish of the late Emperor William to his dearly beloved mother, the Mausoleum has again been extended, and there is now room enough in the upper chapel, not only for the two above-named pieces of sculpture, but also for fitting tombs for the deceased founder of the new German Empire and the Empress Augusta.

Seen from the front, the Mausoleum as it now stands does not seem to have been altered, although, in fact, the alterations have been of a very extensive and also difficult kind. The back wall of the building, and hence also the apse, or rather altar-niche, in this wall, had to be pushed back some five metres, and the cupola over this niche, weighing about 800 cwt., had to make the journey as a whole, it being of great importance that the fresco on its intrados should not be damaged. These alterations and extensions have been designed by "Hofbaueinspector" Geyer, in accordance with the ideas of the late Empress Augusta, and the responsible position of architect in charge fell to Herr "Regierungs-Baumeister" Weber.

Upon entering the building we find that that part of Schinkel's design which was originally intended for Queen Louise's sarcophagus, but which now fulfils the function of a vestibule, has in its main parts been left as formerly intended. Passing between a couple of columns we find ourselves in the new, *i.e.*, extended chapel, which instead of having the long rectangular form of 1841 now shows a nearly square one, the present dimensions being 11.20 m. width to 11.60 m. depth, the altar-niche referred to above as being situated on the centre-line of the back-wall showing an opening of 4.50 m. diameter. This chapel, which is kept in light and bright colouring, makes an exceedingly good impression on the visitor, and the sites marked out for the sarcophagi receive good light through two windows on the sidewalls, each having a width of about 4 metres. The ceiling is specially worthy of note—it is a coffered one, constructed, however, in iron and stone. Its ribs, which rest on the walls at a height of about 8.50 m. above the floor, are of $\frac{1}{2}$ iron, placed 1.30 m. apart from one another. The lower and visible side of these girders shows a pattern in bronze and gold, whilst the square bays, which are of a fine grey stone, show a natural coloured margin as a frame to a deep blue ground, set out with metal rosettes in gold and white. The decoration of the walls is, of course, kept in the same strict Classic style as the remainder of the building. The flooring is of black and white marble slabs. The raised marble altar has not been altered, and has, together with the two very fine candelabra, found its old place in the apse.

Below the chapel we find the crypt in which the coffins of the deceased rest. This part of the Mausoleum can be as easily entered as before, the position of the entrances not having been altered. Passing through the old crypt, which now stands empty, and also serves as a kind of vestibule, we reach the sufficiently-well-lighted crypt proper. Here four red granite pillars serve to support the vaulted ceiling, and in the apse, which has a small window on the centre line, we see a plain altar of black marble

The floor is of this same material, and this, together with the dark-grey colour of the walls, gives the whole an extremely solemn effect.

FREE LECTURES TO ARTISANS AT CARPENTERS' HALL.

PROFESSOR KENNEDY ON THE FORTH BRIDGE.

The fifth of this series of lectures was delivered on the 5th inst. by Professor A. B. W. Kennedy, F.R.S., Professor of Engineering at University College, London.

The lecturer, at the outset, remarked that he appeared more in the capacity of a showman than in that of a lecturer. When he was asked to give the present lecture he communicated with his friend Mr. (now Sir) Benjamin Baker, to ask whether he would be good enough to lend him (the Professor), for the benefit of his audience, a series of photographs of the bridge in its construction, which he had prepared for showing in the lantern. Sir Benjamin acceded at once to his request, and really his (the Professor's) lecture would be a running description of the bridge illustrated by these photographs. When people wanted to put a bridge over a large river or ravine, there were three different fashions in which they could go to work. Supposing they were savages, the first manner in which they would go to work would be to put a tree trunk over it. If the savage grew to be an engineer, the tree trunk became a lattice girder, which was perfectly familiar to all those present. Failing the tree trunk, they might throw some kind of a rope across the river and attach a platform to it. The pre-historic rope had developed in our own time into the suspension bridge. But there was a third way in which the very oldest makers made bridges, and that was known as the cantilever principle. This very old fashion or type of bridge had had its latest development in the Forth Bridge, which was opened on the previous day. To show in what respect the cantilever bridge differed from the tree-trunk bridge or girder, and from the rope or suspension bridge, the Professor gave an illustration of the very earliest type of the cantilever bridge. The Forth Bridge had to be built across an arm of the sea over a mile in breadth, and the smallest length which could be got for one single span was a little over 1,700 ft. For certain constructive reasons it was impossible to bridge the entire span with a lattice girder. If the span had been bridged on the suspension principle the structure would not have been stiff enough to carry the enormous traffic for which it was intended, and there remained only the use of the cantilever type of bridge. The structure consisted of three piers—one on the north or Eife side of the river Forth, one on the south or Queensferry side, and the other in the middle, on an island called Inchgarvie. It was a very considerable engineering feat to build the Eiffe Tower on a firm foundation, but it was a much more difficult affair to construct the Forth Bridge, each span of which was equivalent to two Eiffe Towers built out horizontally. Views showing the progress of the undertaking from its initial to its final stage were thrown upon the screen, and the lecturer described the method of constructing the foundations of the piers, and the way in which the whole superstructure was erected. He concluded by expressing the hope that he had been able to give some kind of picture of the methods and course of construction of an undertaking which was one of the most remarkable as well as the largest of engineering structures of our time.*

PROFESSOR MARSHALL WARD ON "THE TREE, FROM THE SAPLING TO THE BENCH."

The sixth lecture of the course was delivered on the 12th inst. by Prof. H. Marshall Ward, M.A., F.R.S., F.L.S., &c., on the subject indicated in the above title. The subject was mainly treated from the arboriculturist's or forester's point of view, and was illustrated by a large number of views thrown on the screen.

The following illustrations of the Forth Bridge have been given in *The Builder*:—On January 2, 1886, we gave a general view of the bridge, two sheets of drawings showing construction of the superstructure, and a sheet showing construction of the construction and placing of the caissons for the foundations. On July 16, 1887, we gave several sketches showing the progress of the work. On February 11, 1888, and May 26 of the same year we gave other sketches and diagrams showing the further progress of the work. On July 28 following we gave two views showing the progress of the three piers and of the Inchgarvie north cantilever.

by means of a lantern. It was a mistake, said the lecturer, to imagine that trees would grow anywhere, and it was another mistake to suppose that the aid of science was not necessary for their production and selection. True, the forester and the botanist did not grow the timber,—they let it grow,—but they had a good deal to say in the matter of the thousand and one vicissitudes which affected the tree as it grew, and the forester's art was based largely on the scientific experience of the botanist. The lecturer proceeded to describe some of the vicissitudes referred to, and to sketch some of the phenomena which the tree exhibited as it passed through its long life from the seedling to the sapling and thence to the tree cut out for timber to be used in the arts. He then proceeded to enumerate the kinds of trees which yielded the timbers employed in building. All over the world, except in extreme positions towards the poles, or on high mountain tops, we met with trees, but it was not every large tree which was a timber tree in the builder's sense. For instance, the tree-ferns of Ceylon and New Zealand, although their whole column-like trunks could be used for supports, would not cut into timber in the shape of planks or beams. The same remarks applied to many other trees, including the Talipot palms of India and Ceylon. The lecturer next proceeded to describe the often unsuspected infection of timber by fungi picked up in the forests. These fungi made their way into the timber by means of cracks or wounds, and they flourished at its expense, especially when the wood was damp and warm. If the fungus got into the log as it lay on the ground before it commenced its long river journey as a portion of a raft, the damp would cause the cracks in the log to close up, and the spore would lie as snug as possible in the log as the latter pursued its watery course. Then, when the logs were stored in the collecting-yards at the other end, the warm, damp, still conditions in the timber stacks just suited the fungus, and it surely but slowly made its devastating way along the interior of the wood. There were other fungi which could penetrate into the roots of a living tree, and then ascend the stem and gradually scoop out the heart from below, and make the trunk hollow. The lecturer said he had seen miles of fine-looking tall spruce firs in Austria the stems of which were hollow for several feet up, owing to the ravages of the pest referred to. Looking at a transverse section of a piece of timber, we saw the annual rings, in addition to the medullary rays, &c. Now these "rings" were really the expression of so many cylindrical layers of the structures composing wood, and they only appeared as "rings" because they were cut across. In all ordinary timbers one of them was produced each year, and the sharp line which separated them was simply due to the greater density of the structure in that part of the annual ring which was formed at the end of the summer. In illustration of this point, the lecturer showed a highly-magnified transverse section of Rhamnus, showing how the "annual ring" was marked by the sharp contrast between the more dense and compact wood formed in the autumn, and the more open spongy wood formed in the following spring. Passing on, the lecturer insisted upon the point that it was of importance where and how a tree was grown if it were to yield good timber. In illustration, he showed the sections, side by side, of three specimens of spruce-fir grown under different conditions. They greatly differed in solidity and firmness of construction, and therefore in relative weight and hardness. Every timber had its own structural character. The lecturer, in conclusion, referred briefly to the ravages of dry-rot in the timber of floors, &c., and to the means to be taken to prevent them,—*viz.*, dry air and good ventilation.

PROFESSOR UNWIN ON THE CONSTRUCTION OF WALLS.

The seventh and concluding lecture of the course was delivered on the 19th inst., by Professor W. C. Unwin, F.R.S., who took as his subject "The Construction of Walls."

Professor Unwin, after some introductory remarks, said:—The architect and the engineer are both engaged in constructive work which in many cases is of essentially the same kind. Both alike have to build structures with pretty much the same materials and with the same object, that they shall support the loads they have to carry, and endure the destructive action

their numerical meaning and their physical meaning. The diagram shows to scale a 1-ft. cube of red Mansfield supporting a cube 21 ft. in length of side. That 21-ft. cube has a weight which is just equal to the crushing strength of the 1-ft. cube. So much for the numerical significance of the numbers.

Next, what does the crushing strength mean? As a matter of fact, stones never crush at all. They shear along diagonal planes into tolerably regular pyramids. Stone is tested usually in cubes, and great care is taken to get a uniform distribution of the load on the surface of the cube. At some value of this crushing load, reckoned on a square unit of surface of the cube, the stone gives suddenly shears along diagonal planes into a top and bottom and four side pyramids. If the crushing takes place in any other way, we may be sure the stone was badly hedged, and that the crushing resistance is less than for a well-hedged stone.

There is a special case which unavoidably occurs in building where the load, instead of being spread over the whole surface of a stone, is put on a small part of its area. Suppose a stone so strong that a cube of 1 ft. length of side would carry 500 tons uniformly distributed. If the pressure comes on the central half of its area it would crush with 350 tons; if on the central quarter of the area, with 250 tons. If the load is eccentric, or if the pressure area is diminished below as well as above, the strength is still further reduced. Now, the practical importance of that is this,—that it shows us how necessary it is that stone should be well bedded if its strength is to be depended on.

There must be unequal pressure of the stones on each other in actual structures, and hence experience has taught us never to load our structures to anything near their crushing strength. There are very few structures in which the average crushing stress in the masonry reaches 10 tons per square foot. A few great piers or pillars of churches carry more. Some of the pillars in St. Paul's are believed to be loaded to 18 tons per square foot, and, in very rare cases, double that stress seems to be safely carried. One remarkable case is the great chimney at St. Bellox, where, on the brickwork, the stress is believed to reach 30 tons in a strong wind-storm. Generally, for rubble masonry, the stress does not exceed 1 ton per square foot, or for ashlar 5 tons.

Artificial Stones.—Bricks are well known to us in London, as they were, indeed, to the Romans, from whom we have derived much of our modern constructive methods. Bricks vary much more than stone in strength, in porosity, in hardness. There are bricks made of slate refuse, blue in colour, very dense, very heavy, which carry, fairly tested, 1,000 tons to the square foot. For some engineering works they are invaluable. Staffordshire blue bricks will carry 400 tons. But most ordinary building bricks do not carry more than 100 to 150 tons. There is another thing about brickwork. So far as we know, masses of brickwork are materially weaker than single bricks. I suppose this must be due to the impossibility of getting uniform and perfect bedding, even with mortar-joints, in such compound masses.

Limes and Cements.—We shall see that in the older wall constructions no mortar or cement was used. In later times a greater use has been made of cementing material, so that some reference to this is necessary. The cementing materials now used are:—Fat limes; hydraulic limes; hydraulic cements.

The fat limes, produced by calcining nearly pure limestones, slake violently when mixed with water, and when made into mortar with sand, harden very slowly by absorbing CO₂

from the atmosphere. The mortar made with lime and sand only is even at the best of times very poor stuff from an engineer's point of view. It has little strength, little tenacity, little adherence to stone or brick. Really, the ordinary mortar used for walls can be regarded as little better than so much convenient packing material, which serves to give the stones or bricks a fair seating on each other, and to distribute their pressure evenly. In many Mediaeval structures, where mortar of this kind has been used in large quantities for filling of piers and walls, it has remained unset and unhardened to this day, and some disasters to great architectural buildings have come from this cause.

The Romans ten centuries ago had admirable and strong cements, made from volcanic material. In mediaeval work and in modern work it was common to use the poorest kind of cement, made almost entirely of lime and sand. It was known to modern builders that certain limes which slaked very slowly had the property of hardening under water, and were much stronger when set than ordinary limes. The property of these hydraulic limes was traced to their containing a proportion of alumina and silica, which in burning were brought to a condition in which, when ground and mixed with water, slow chemical combination and crystallisation went on. Then it occurred to some manufacturer to artificially produce this mixture of lime and alumina and silica, and so, about 1850, a new cement called Portland cement was introduced, which has proved of quite extraordinary value in building work. It is not too much to say that some of the great masonry walls I shall speak of presently could not have been built without it. It is immensely stronger and more trustworthy than lime of any kind. Its only fault is its cost. Lately a cheaper cement has been made from slag, almost as strong as Portland cement, with the same quick-setting property, and probably much less costly. It promises to be very valuable to the builder.

Walls.—The object of a wall is to be a fence,—a fence against enemies, like the Great Wall of China, or the early city walls, like those of Tyrins and Mycena or our own London Wall; a fence against weather, like dwelling-house walls; a fence against the slipping of embankments, like the retaining walls of railways; or a fence against water, like some of the great masonry dams. Constructurally the fortress-wall, the house-wall, the retaining-wall, and the dam are very little different except in size.

A wall rests on the soil, and if the soil is weak, its base must be spread out by footing-courses, or a concrete bed must be prepared. But I have not time now to speak of foundations, excepting just this, that a large part of the disasters to walls have arisen from the weakness of the foundation; and one object in giving a good deal of strength to a wall is just this, to enable one part to help another if the foundation under it partially fails.

The walls of Tyrins and Mycena are of large blocks (each so heavy that two oxen were required to move it), packed with smaller stones, but without mortar.

The earliest walls of importance which still exist in Southern Europe are known as Cyclopean, Pelagic, or polygonal walls. In their roughest form they consist of unworked, or nearly unworked, stones of large size, packed with smaller stones. But in the finest Cyclopean walls the stones are worked so as to bed fairly on each other. The stones are irregular prisms, with plane-worked faces on ends and beds. Such walls have no mortar.

Now, it must soon have been perceived that, on the whole, it was more convenient and practical to work the stones to a regular

f wind and rain. But there is in more respects than one a great difference in the way in which an architect and an engineer looks at a structure to be built. The architect always has to consider questions of appearance, of style of decoration as well as questions of stability or of strength. The engineer, on the other hand, pays but little attention to questions of this kind, but laying, on the whole, larger and more severely loaded structures to build, he is obliged to consider much more carefully how his structure may be made safe with the least expenditure of material. There is another difference. The architect follows a profession of great antiquity, and for the most part has to erect structures of a common type and of similar materials. He hardly needs again and again to consider how strong his structures should be. That has been settled for him by long preceding generations of builders. With the engineer it is quite otherwise. He has constantly to construct structures of new types and to work in new materials. He is far less able to rely on precedent and far more often compelled to justify his action on scientific principles.

Now it would be presumptuous in me to lecture to you from the architect's point of view; but there may be some use in looking even at architectural constructions from an engineer's point of view.

The Materials of which Walls are Built.—Walls are built of natural stones or of artificial stones. I need not say much about either, but I want to point out one or two characteristics important to the builder. Natural stones may for our purpose be classified as *crystalline stones*, such as granite and marble, the former used as a common building stone in Scotland, the latter in Italy—both hard, durable, and strong; *strata stones*, of which roofing slate is the commonest example, and used as building stone in Westmoreland and Wales. These are very strong and durable, but not easily cut to regular forms. Then come the great class of ordinary building stones, which are granular, or composed of grains, with a matrix of cementing material, and these are in two principal classes: the limestones, composed chiefly, sometimes almost entirely, of carbonate of lime; and the siliceous stones or sandstones, in which the grains are of silica. Some of the sandstones, especially when the cementing matrix is chiefly silica, are very durable. This and the facility with which they can be dressed make them very valuable for building stones. When the matrix contains alumina or lime the sandstone is less durable, sometimes quite dangerously perishable. The limestones, again, have a great range of quality. Portland stone, the merits of which Wren discovered, is one of the best and most durable of building stones. Other limestones will not stand the action of the weather, but are valuable for inside work. They admit of beautiful and delicate carving.

The durability of a stone depends partly on its chemical composition, as has been slightly indicated, but more on its hardness and resistance to absorbing water. There is no completely satisfactory test of hardness. But granite resists abrasion about three times as well as the hardest sandstones, and about ten times as well as marble, and about eighty times as well as Bath stone, the soft limestone we use for inside work. The absorption of water by stones is more easily tested. The granites in small blocks absorb less than 1 per cent. of their weight of water; the harder sandstones generally less than 7 per cent.; the limestones something like 8 to 12 per cent. Now, the importance of absorption is chiefly this, that if water absorbed by the stone freezes, its expansion disintegrates the stone; so that in selecting stone, the easy test of absorption gives really valuable information.

There remains one quality of stone which is of importance to the wall builder, and that is the strength of the stone. Almost always masonry is subject only to compression, and hence the measure of the strength of the stone for builders' purposes is its crushing strength. The following table shows some values:—

Crushing Strength of Stone.	Tons per sq. ft.
Granite.....	1,500
Siliceous block.....	800
Sandstone, York Grit.....	700
" Mansfield.....	600
Limestone, Portland.....	600
" Ketton.....	300
" Caen.....	200

I should like you to understand a little more fully what those numbers mean, both as to

prismatic form. So we get what we call ashlar. I give a diagram of a characteristic form of Greek ashlar masonry, the stones in each course being of equal height and fairly bedded with broken joints. The Greeks frequently built without mortar, and the stability of their walls depends solely on the weight of the blocks.

Now, it was not always convenient to find stone large enough to build in that way. Then came the method of building walls with faces of brick or stone and a rubble interior. Bonding stones at intervals connect the two faces. Such a wall may still be a block-work structure depending on gravity for stability.

More commonly, however, and especially in Roman building, the rubble interior is a concrete of strong cement and stone, and may be as strong or stronger than any other part of the wall. The Romans obtained from volcanic ash a splendid cement, and so originated structures in which the resistance to destruction depends not on the mere stability of the blocks, or the resistance to displacement due to their weight, but on the strength of the cemented mass. For the cement makes the wall practically a monolithic structure, and every part helps every other part. Pushing this new principle of building further, the Romans became the originators of rubble work, in which quite irregular stones are bedded in cement mortar, and the structure depends almost entirely on the cohesion of the mortar to the stones and its resistance to shearing and crushing.

You see, then, there are two absolutely different principles of building. In the Greek method, a pile of uncemented stones, each member resists displacement only by its friction due to the weight resting on it. The hedding of the stones is due entirely to masons' skill. In the Roman method the soft mortar makes the hedding without any skill at all, and, when set, forms a solid mass of a strength sometimes little inferior to stone itself.

Bond.—The bonding of stones or bricks, or placing them so as to break joint, is commonly insisted on as very important, and so, no doubt, it is, with the ordinary kinds of weak cementing material which are used. A properly-bonded wall has strength to resist shearing or tearing apart, quite irrespective of any adhesion of the mortar. But without bond it would have no strength. When we come to use really strong cementing material then the importance of bond vanishes. For instance, here is a block of cement concrete which has been crushed. The stones were without any proper bond, and yet in crushing the fracture has run almost indifferently through cement and stone.

Suppose, however, we have no cement, or a very weak cement, how must the stones or bricks be placed? I will consider brickwork as the simplest case. There are three quite distinct objects in properly placing or bonding the bricks. First, by placing the bricks properly any pressure coming on one is distributed widely to the bricks below, so that the inequalities of pressure on the lower and heavily strained courses are reduced.

Next, if the bricks break joint the wall cannot shear without cutting through the bricks themselves.

Lastly, quite apart from any tenacity due to

the mortar, the wall gets a resistance to tearing apart horizontally. In order that the wall may tear apart, the overlapping portions on one side must slide on those below; but in consequence of the weight resting on these overlapping portions there is frictional resistance to sliding.

Let us call the resistance to this horizontal sliding the longitudinal tenacity of the wall. Obviously the longitudinal tenacity of any course of brickwork is proportional to the height of brickwork above it, so that the longitudinal tenacity of the whole wall increases nearly as the square of its height; but the longitudinal tenacity also depends on the amount of overlap, and hence we shall find the longitudinal tenacity varies with different arrangements of the bricks. It is greatest if the courses are all stretchers, for then the overlap is half a brick length. In English bond and Flemish bond the overlap is a quarter-brick length, and they have the same longitudinal tenacity.

But now generally walls have more than one course of bricks in their thickness. Then these courses require bonding together, or the wall will split into two thicknesses, and, indeed, in some Mediaeval walls this has happened. The tenacity across the wall is dealt with in the same way as the longitudinal tenacity. We get the greatest transverse tenacity by putting the bricks all headers. In English bond the transverse tenacity for a 9-in. wall is double the longitudinal tenacity. In Flemish bond the transverse tenacity is less.

In the London Building Act there is a provision that the openings in a wall should not exceed half its area. Now, that strikes an engineer as a somewhat remarkable provision. I imagine there can be no reason for such a rule, except the necessity of preserving the longitudinal tenacity of the wall. Of course, the openings do diminish the tenacity, and that seriously. I have on the wall a sketch of one of the houses in Sicily shaken by the great earthquake of 1857. You see the wall has failed from end to end from imperfect tenacity, and is torn by cracks roughly normal to the direction of the earthquake wave. Further, most of these cracks have elected to pass through the wall openings. Now, a rule which merely takes note of the area of wall openings ignores the conditions which secure longitudinal tenacity altogether. Under the rule, it is possible the wall no longitudinal tenacity at all. Surely, if there is to be a rule of this kind, it should be so framed as to secure a reasonable connexion in the parts of the wall. If for a shop-front, a very large part of the wall is cut away, then the rule should provide that the tenacity destroyed should be made up for by iron, which, in fact, is commonly done.

There is a passage about the bonding of bricks in one of Smeaton's reports which is worth referring to: "There are even some workmen who suppose that nothing more is required of them than that the bricks should be properly bedded and the work level and perpendicular. But the workman who would attain perfection must acquaint himself with the different arrangements of placing (bonding) the bricks so that one part of the work shall strengthen another."

Now you know that Smeaton built the Eddy stone Lighthouse, and that structure was probably the most remarkable instance of perfect bonding ever erected in masonry work. It would have stood the impact of the waves almost as perfectly without mortar in the joints as with it. The courses in plan look more like ingenious Chinese puzzles in stone than ordinary mason work. Now, Smeaton's Lighthouse has had to be removed, not from any weakness in the tower itself, but because the rock on which it stood was being undermined, and a new and larger tower has been erected. I give a diagram which shows the bonding adopted in this case. The dovetail joints are filled with Portland cement, and the tower is probably as strong as a monolith of granite.

Resistance of Walls to Crushing and Overturning.—Looking at a wall from the engineer's point of view, the first question which has to be considered is how strong it ought to be. Curiously enough, I suppose that the thicknesses of walls required in modern building Acts are not based on any scientific examination of what a wall has to do, but purely on precedent extending back to Roman times. One great French engineer, Rondelet, did (a century ago, nearly) undertake a scientific investigation of the proper strength of walls, and he based his calculations largely on an examination of ancient Roman walls which have stood the storms of eight or ten centuries. There are standing now at Tivoli the lofty walls of Hadrian's palace. Rondelet found that these walls had a thickness of one-sixteenth of their height, and that is not widely different from the thickness which would now be required in strong and lofty buildings.

If a wall has to sustain a vertical load only it is easy to see what in an extreme case its form must be. Some thickness is required at the top for constructive reasons, and that thickness will be sufficient for a distance below the top. But at some distance below the top we shall come to a joint where the stress due to the superincumbent weight reaches the safe working limit of stress in the material. It may be one ton or five tons per square foot, according to the quality of the materials and the factor of safety we wish to allow. Below that level the wall must be splayed out, and we may so arrange the splaying that the stress on every horizontal section is the same. All the material will be at its working limit of stress, and the wall will then be of the most economical form possible.

But generally speaking the vertical load is not the most dangerous of the straining actions to which walls are subjected. If walls give way it is not often by direct vertical crushing but by some kind of overturning.

In lofty buildings in exposed positions, the wind is the most dangerous force to which a wall is exposed. In this country wind-storms giving pressures of 30 lbs. per square foot on vertical surfaces in exposed places occur every year, and in specially-exposed places a wind-pressure of 50 to 60 lbs. per square foot has been registered. Such a lateral pressure tends to overturn a wall, and is the most dangerous action to which it can be exposed.

The precise way in which a wall gives way by overturning should be understood. In some

THE BUILDER, MARCH 29, 1890.

ses the pressure on the toe of the foundation may cause the foundation to yield. It is easy to provide against that by giving adequate width to the foundation. Generally the resultant pressure on the base of the wall is kept in the middle half of the width of the foundation. In other cases the wall gives way by opening a horizontal joint and overturning.

In most books, the overturning of the wall is treated as a question of stability. The wall is regarded as perfectly rigid, and a calculation is made of the force required to make it turn over on one of its edges. The wall is taken to be stable enough if it would require from two to two and a-half times as much force to overturn it as the greatest force likely to come against it.

The wall would be just on the point of overturning if the resultant of its weight and the horizontal pressure on it just passed through one of its edges. To put it another way, the wall is just on the point of overturning if the resultant force does not deviate from the vertical by half its thickness. For safety, the actual moment to which the wall is subjected should not exceed half or two-fifths of this.

Now against this, as a practical rule, I have nothing to say. It provides, in most cases, stability enough. But it assumes a mode of overturning which, in lofty structures, could not possibly occur. The material of the wall is not strong enough to support a wall on its edge as supposed. Before any such overturning could begin the wall would crush near the edge. Hence, in lofty walls, it is much more rational to design the wall for some safe limit of crushing pressure than for some moment of overturning.

There is another accident in walls which needs to be provided against, especially in walls which have to resist a pressure of water. Supposing we cannot depend on any great adhesion of the mortar to the stones, then, in most cases, before there is any tendency to crush the one edge of the wall, the joint opens at the other edge. If the mortar is weak the joint opens at any tension occurs, and there will be tension in the resultant pressure at a joint deviates by as much as one-sixth of the thickness of the wall from the centre of the joint.

Hence, to sum up: If the resultant pressure deviates by half the thickness of the wall from its centre the wall must overturn, and the edge will crush with a less deviation than this. Further, the joints will open on the tension side unless the adhesion of the mortar prevents it, when the deviation is only one-sixth of the thickness of the wall.

Now, if these principles are applied to determine the stability of ordinary walls of buildings, I think most architects will be surprised to find how small the stability of their walls is. No doubt, in towns the wind-pressure seldom strikes against buildings with any great force. No doubt, also, most ordinary buildings have cross-walls, which add enormously to their stability. For ordinary purposes the ordinary proportions given to walls are, obviously, sufficient, for very few buildings fall down, and, when they do, some very obvious cause of bad material or weak foundation is almost always discoverable. But buildings have to be put up in exposed places, and sometimes great lengths of wall are built without support from cross-walls, and in such cases the architect should be aware of the risk he runs.

I have calculated out what may be termed a limiting case, a wall of indefinite length, standing alone, without support from cross-walls or floors.

The wall is 70 ft. high, and of at least as great thickness as any ordinary mill wall. I have supposed that besides its own weight it has to support a horizontal uniform wind pressure. I have calculated the wind pressure necessary for each of the stories to bring the walls to two conditions,—first, the wind pressure which would cause the resultant pressure on a joint to deviate one-sixth of the thickness of the wall from its centre. I think an engineer would take that condition as the limiting condition of safety. Secondly, I have calculated the wind pressure which would make the resultant pressure at a joint deviate by half the thickness of the wall. It is certain that the wall must overturn with a less pressure than that, unless (what is very improbable) a considerable adhesion of the mortar could be relied on.

Now the pressures arrived at are rather strikingly small. It seems that the wall would

become unsafe with less pressure than 5 lbs. per square foot, and must certainly overturn with 12 lbs. per square foot.

Mr. Arrol gave in evidence that every temporary work even in connexion with the Forth Bridge was braced so as to resist a wind pressure of 40 lbs. per square foot. Bearing this in mind, the stability of the wall to stand alone certainly seems inadequate.

Now, if I were really going to investigate the stability of a building, I should have to go a step further. It would be necessary to consider whether the cross walls gave any support, and whether the floors were capable of transmitting any of the pressure to the back wall.

As to the cross walls, I may be wrong, but I fail to see that when the cross walls are at distances so great as 100 ft. apart they can render any effective support to the middle part of the wall.

As to the floors, the case is somewhat more difficult. But I suppose, on the most extremely favourable assumption as to the action of the floors, they could only be assumed to transmit half the pressure to the back wall. If they did as much as that, the stability of the wall would be doubled. It would carry twice the wind pressures tabulated above. But even then the stability of the wall would seem somewhat too small to an engineer.

It can hardly be hoped that the floors will do as much as this. They are not built with any object of supporting the walls, but for a quite different purpose. If they are to fulfil that function, they should be designed with that end in view. Next, the long, elastic, and flexible joists can only transmit pressure to the back wall in proportion to the amount of the yielding of the front wall, and any yielding means a diminution of stability. Lastly, the load of the floors must itself in general be so applied to the wall as in general to diminish rather than increase the stability of the wall. If the weight of the floor comes on the inside edge of the wall, it may very seriously diminish the stability.

Most buildings in towns, no doubt, are never subjected to any appreciable wind pressure at all. They are screened by neighbouring buildings from any direct impact of the wind. All I want to draw as a moral from this discussion of wind pressure is this: architects should bear in mind that wall thicknesses which may be amply sufficient in the ordinary case of buildings in towns, may prove insufficient in more exposed places, and especially when a building has abnormally little support from cross walls. Further, I should like to see building rules take note of the fact that this cross support is important. All rules I have seen make the thickness of a wall depend only on its height. With walls as thin as those commonly built, it seems to me that the thickness should also increase when there is a great distance between the cross walls. Church architects do act as if this were their principle. They do make a much larger use of buttresses than is common in civil architecture.

Most of you must have heard of a lamentable disaster which happened at Glasgow in November last. A large mill, in course of erection, was blown down, and many lives were lost. The mill had the joists of the floors on, but not the floors, and was not roofed. It was probable, therefore, that it was exactly in the condition least favourable for resisting wind pressure. Not only was the wind directed on to the face wall by neighbouring buildings, but also, as Mr. Arrol pointed out, probably the wind found access through the window openings, and produced some, though probably a small, pressure on the back wall. It was given in evidence in the inquiry before Commissioners that the walls were of rather more than usual thickness, that they were well and strongly built, and that in all respects the owners of the mill had taken care to have a strong, well-built, carefully-designed mill. Now, notwithstanding this, the mill fell with disastrous consequences, and that in a storm of wind which, according to the evidence, was not of exceptional fury. There is no doubt, I think, that, like the Tay Bridge, the mill was blown down.

Reservoir Dams.—I now come to deal with walls of another kind and of a greater size, but strictly walls, and performing essentially the same functions as other walls.

In all countries, and for a long period, it has been necessary to husband the water-supply derived from the rainfall, by storing it in the wet period of the year, for use during the dry period; or to reserve water falling in cycles of

wet seasons, to use years after in cycles of dry seasons. Sometimes the object has been the storage of water for town's supply, in other cases the storage of water for irrigation. In either case very large quantities of water must be stored, and the mode of storing it is much the same.

In some valleys draining a sufficient catchment basin an artificial lake is formed by damming up one end of the valley by a wall of earth or masonry. The water accumulates behind the dam, and can be drawn off by suitable appliances at the times when it is needed. That is the simple idea of water storage. To carry it out under the varied condition imposed by the resources of generations of engineers.

Anyone who will look at a tolerably large-scale map of Southern India will find that the river lines look like necklaces of beads. All along every river course chains of storage reservoirs or tanks were constructed for irrigation purposes by the ancient owners of the soil; for without the irrigation water in the dry, hot season, the soil was almost uncultivable. Thousands of these tanks dot the map. In course of time many of these tanks silted up, and it has been one of the greatest tasks of the English rulers of India to restore these old tanks, and to bring abandoned land again under cultivation.

In Northern Europe, and in quite modern times, the aggregation of the population in large towns has caused also an urgent want of regular supply of large quantities of water for drinking and sanitation, and the increasing pollution of the rivers has forced us to construct large numbers of storage reservoirs precisely on the plan of irrigation tanks.

In this country it was till lately the custom to form the storage reservoir by throwing a huge earth-bank across the valley from side to side. Such earthen dams are really walls of a peculiar type. Some of them are from 100 to 120 ft. in height, and one-eighth of a mile to half a mile in length. They are not adapted for moist climates and for positions where a rock foundation is not attainable. But they are subject to two very serious kinds of danger. The water may creep through them, and if it does, it very soon enlarges its passage-way in the loose material and destroys the dam; or the water, accumulating in some violent rain-storm, may overtop the bank, and if it does, it very soon cuts down a gap which sets the waters free. Disasters of the most serious kind have happened in both these ways.

In 1864 the Dale Dyke reservoir burst at Sheffield, and 11,000,000 cubic ft. of water rushed down the valley, destroying an enormous amount of property and causing the loss of 200 lives. In that case the water crept through the dam and undermined it. Only last year the Conemaugh Dam in Pennsylvania burst, the water overtopping it and cutting a gap. In that case 3,000 lives were lost. There have been other cases.

Now, there are cases where only an earthen wall can be constructed, and for heights up to 100 ft. no doubt, with care and foresight, an earthen dam can be made safe; but it is not wonderful that engineers should have sought for some securer way of doing battle against the enormous pressure of the water. Earthen dams are built of cheap materials, it is true, but as they are loose banks, with no coherence, an enormous mass is required. On the other hand, a stone wall is much dearer per cubic foot, but if much less material is wanted it may be cheaper than an earthen dam. At any rate, it is to stone walls that engineers have looked as safer and stronger than earth banks.

The first condition of a stone wall to resist water pressure is that it should be free from fissures. But a high wall cannot be free from fissures if it is built on a yielding foundation, or a porous foundation through which the water can find a way. Hence masonry dams are only built on rock foundations. We now believe that on a sound rock foundation reservoir walls can be built which may remain uncracked and undecaying for centuries, and may be almost as permanent as the hills.

Masonry dams of quite gigantic size were built in Spain two or three centuries ago. Naturally, the Spanish engineers were the first in modern times to construct a masonry dam. A great masonry dam was built at Puentes in 1802, 150 ft. in height. Unfortunately, it was built on piles; it was undermined when the reservoir first filled, and broke, causing a loss of 800 lives. Probably the disaster at Puentes

made engineers reluctant to build stone dams for some time. However, in 1858 the French Government was directing attention to storage of water, and it became necessary to construct a dam on the Euren river, 165 ft. in height, in a narrow gorge. The engineers decided to have a masonry dam, and for the first time investigated scientifically exactly in what form such a dam should be built. The older dams were trapezoidal, and it is easy to see why such a form should be chosen.

If, as is natural, we look chiefly to the condition of things when the reservoir is full, we see we have two forces to deal with—the horizontal water pressure tending to overturn the dam, and the vertical weight of the masonry tending to prevent overturning.

Suppose the weight of the masonry is double that of the water, and the base of the dam three-fourths its height, then in a triangular dam the resultant pressure on each joint comes just within the middle third of the width—a condition we have seen to be one of the conditions of stability. Now the triangular form is not convenient, but the trapezoidal is an approximation to it.

Liverpool was one of the first towns to obtain power for the supply of water by the Municipality, and very fine reservoir storage works were constructed at Rivington between 1852 and 1857. Then Liverpool adopted constant-supply in 1864; however, in a long drought, constant-supply had to be suspended, and at one period in the next year the available water in the reservoirs only amounted to ten days' supply. Various expedients were adopted from that time to this to make the supply adequate for daily requirements till a new source of supply could be found and the necessary works carried out. The most important remedial measure was the introduction by Mr. Deacon, the Water Engineer, in 1873, of a system of measuring the flow in the mains of each district by recording meters termed waste-water meters. As soon as systematic observations were made, it was discovered that a quite enormous waste of water was going on in consequence of leaks in the mains and faulty house-fittings. By preventing this waste, without restricting any legitimate use of the water, the supply has just been made adequate up to the present time; but Liverpool has more than once been on the verge of a water famine, and a new supply was a matter of the most urgent necessity.

Now in these times there is only one way, in most cases, of obtaining a supply large enough for a town, and pure enough to be healthy. This is, to seek the water on some remote hill valley, where the rainfall is abundant and the streams unpolluted. Many sources of supply were examined. The English lakes, Ulleswater, Howeswater, Windermere, and Bala Lake in Wales were all considered. But a natural lake is not always a favourable source of supply. To get the water out of it you must tunnel beneath its bed, and more than this, you have generally the need to raise its level and increase its storage capacity by damming up its outlet. Further, round most lakes population has aggregated, the land is valuable, and the drainage is no longer unpolluted. Other districts were considered, but finally a lonely valley in mid-Wales was selected, down which flows the Yrwyd, one of the tributaries of the Severn. The valley is an old glacier-hed lying 750 ft. above the sea, and high enough to send its waters to Liverpool, seventy miles off, at a pressure then sufficient to command all parts of the town. The moorlands rise to a level of about 2,000 ft. all round the valley. The rainfall is copious and the land uncultivated. The rocks are slate, interspersed with beds of very ancient volcanic ash. Here it was that the Liverpool Corporation decided to create a new lake as large as Bala Lake itself by damming up the outlet of the valley. The dam, 1,172 ft. in length, has been built. During the past year the waters were allowed to gather. A quite beautiful lake, five miles in length, occupies the old dry valley-bottom. The small village of Llanwddyn, the only one in the valley, is submerged. The pipe-line is laid, seventy miles in length, and when, early next year, the tunnel under the Mersey is finished, Liverpool will have an abundant supply of the purest possible water. The whole cost of this great municipal work reaches nearly two millions, and as a great engineering enterprise it takes rank with the Forth Bridge and the Manchester Canal—monuments of knowledge and skill and organization and enlightened expenditure. The area of

lake is 1,121 acres; the volume of water is 12,000 million gallons; the greatest depth of water, 84 ft.

Now, of the scheme of water-supply it is not for me here to speak in detail; but the great dam which closes the valley and forms the lake is strictly a masonry wall. In some respects, it is the greatest of all these great masonry dams hitherto built. It is not quite so high as the Euren and Villar dams, nor quite so wide of base as the Vervier dam; but it is much longer than these, and has a much greater cube of masonry; and it is the first great masonry wall of this kind built in this country by English engineers.

Then, if masonry is to be used, what kind of masonry should be adopted? Should it be a great block-work structure, the ashlar blocks set in Portland cement to make the joints watertight? Well, I suppose it would have been impossible in any reasonable time, at any practicable cost, to hew the rough but hard and strong slate rock of the valley into ashlar blocks. Had it been possible it is probable it would not have been best to do so, for a blockwork mass has a regular system of thin joints, which form planes of weakness throughout the mass. It is just possible that by some settlement fissures might be formed, taking definite directions along these joints and leading the water into the core of the work. A system of rubble work, with its irregular joining, seems liable to no such danger. Hence a system of rubble masonry is adopted in all these great masonry dams, the structure being rendered almost monolithic by hedding the rubble stones in the strongest cement.

At the Yrwyd the masonry is really of a new type. It is rubble masonry of quite gigantic blocks. The limit to the size of the blocks is determined by the power of the lifting machinery at the quarry and on the work. With steam cranes it was possible to handle and set blocks of seven or eight tons' weight. Each block, selected with quite curious skill by the mason to fit its neighbours, was dropped into a soft bed of cement-mortar, and every accessible crevice packed with smaller stones and concrete. On the faces only of the dam the blocks are squared.

The slate rock on cubes carries 800 tons per square foot. The concrete in cubical blocks 180 tons. As the concrete is in comparatively thin layers between the cyclopean blocks the strength of the masonry of the dam is probably not inferior to that of slate rock itself.

Before beginning the dam an immense trench was opened across the valley, the whole of the alluvial and glacial deposits being removed and the underlying rock exposed. The greatest part of the mass of the dam is thus below ground. The form is not widely different from the theoretical form required. The height from the rock foundation in the middle of the dam is 127 ft., and the width at ground level 101 ft. Two great culverts are constructed through the dam. Through one a stream of 10,000,000 gallons a day flows to feed the Severn, while the water-supply of Liverpool, which may reach 40,000,000 gallons a day, is taken through a tunnel in a lateral hay of the lake.

A very great danger for most reservoir embankments is the discharge of surplus water if a flood occurs after the reservoir is full. For most reservoirs a by-wash or channel is constructed to lead away the surplus water down the hillside to a point below the dam. But many have been the disasters due to insufficient provision for discharging floods. The Yrwyd dam forms an immense weir over which surplus flood-water will flow, finding its way harmlessly in a comparatively thin sheet down the outer face of the dam to a water cushion below.

I have given some particulars of the strength of masonry structures. Under no conditions can the crushing stress in the Yrwyd dam exceed 9 tons to the square foot. In fact, the crushing stress is slightly greater on the inner toe when the reservoir is empty than on the outer toe when the reservoir is full.

The masonry dam alone,—apart, that is, from the pipe-line and service reservoirs and other great works which are necessary for the conveyance of the water,—has cost over half a million. In no other masonry work has the true principle of rubble building, the using of a cement so strong that the structure becomes practically a monolith, been so rigidly carried out.

A visitor with large experience of masonry work made this report about it:—That the

Liverpool people had in this dam a piece of masonry not surpassed for solidity by any masonry in the world.

Illustrations.

SHEFFIELD MUNICIPAL BUILDINGS. COMPETITION DESIGNS.

WE publish this week the elevations and principal plans of four of the designs sent in for the first competition for the Sheffield Municipal Buildings, all of which were specially mentioned in our review on January 27 last of the designs that were exhibited. We have others to publish at another time. We have considered it would add to the interest of the plans to publish several together for the purpose of comparison.

The first one is that by Mr. R. A. Briggs. We quote the following passages from the report which accompanied the drawings:—

"It will be seen from the plans and sections that, although the present building will be quite complete as designed, still the future extension can be added without any detriment to it.

The fall in Surrey-street has been made use of so that a lower ground floor is obtained towards that street and Norfolk-street, and the Health Office Department has been placed on that floor, the sill of the windows of that department being at least 2 ft. above the level of the street.

No lower has been shown on the accompanying design, as the author desires it to be distinctly understood that the building as designed can be built well within the sum mentioned, viz., 80,000l., but he desires to point out that a tower could be easily added without any detriment to the plan, but rather with a considerable enhancement to the building. It may be mentioned that a design for such a tower has been prepared, and the arrangement of the plan will allow of its being added over the grand staircase at an additional cost of 7,000l., without any alteration to the plan being necessary.

The principal entrance leading to the hall has been placed as suggested toward Pinstone-street, having three entrance floors, inside of which swing doors will also be placed to prevent draught. The height of this hall will be 17 ft., with steps up to main ground-floor, this arrangement giving a very imposing effect, and at the same time obtaining greater height for the hall.

The entrance hall gives immediate access to the vestibule where the two grand staircases are placed for the Mayor's apartments and a council-chamber.

Two general entrances have been placed, one in Norfolk-street and one in Surrey-street. There is also an entrance in Cheney-row, with a service staircase for the kitchens and workmen. It is proposed that a roadway be made to this entrance from Pinstone-street.

The council-chamber on the first-floor has been placed with windows looking into the street, being the position most favourable to the essential condition of quietness for the room. The author believes that ample light will be obtained through the windows looking into court, but a ceiling light is also provided. A gallery, reached by the general staircase towards Surrey-street, is provided, and there is also a small subsidiary iron staircase inside the room.

The ante-room, with circular glass dome, gives access to the council-chamber, and a side passage is also provided, in order that Councillors may not be obliged to enter always through the ante-room.

Two cloak-rooms are placed next the rooms above mentioned, being easy of approach to the council-chamber and the Mayor's apartments. Lavatories are provided in these cloak-rooms, and urinals might also be placed in one of them if desired. A small cloak-room, with lavatory and w.c., is also provided for the private use of the Mayor.

The reception hall, dining room, and Mayor's parlour are placed *en suite* with the Pinstone-street, so that they may be used together if desired, and patent sliding doors, 4 in. thick, and filled with slag-wool as a non-conductor of sound and heat, will divide them into three separate rooms when necessary.

The Borough Accountant's office is placed in the position which is most easy of access and central in position, corridors giving easy approach from any entrance. The staircase (towards Cheney-row) gives ready access to the wago-room on the basement.

The two large public lavatories, being well lighted, have been placed at the corners of the front towards Pinstone-street, with entrances direct from the Surrey-street and Cheney-row, these being considered the most convenient positions. This arrangement will in no way interfere with the appearance of the building.

The arrangement of the plan has been studied so that every department may be separate and complete in itself, but at the same time convenient to the other departments; as, for instance, folding doors could easily be placed to shut off the Mayor's apartments from the Council Chamber and likewise these rooms from the Town Clerk's offices.

THE BUILDER, MARCH 29, 1890.

STONE STREET.

FIRST FLOOR PLAN.

PHOTO LITND SPRAGUE & CO 22 MARKING LANE CANTON 5 LONDON E.C.

the warming and ventilation has been specially considered in this design. Fireplaces have been provided in all the offices except the large general offices, which, together with all the corridors and offices where fireplaces are not shown, will be heated by hot water, although open fireplaces may be introduced as features in dining-room and reception-hall if considered desirable. It is proposed to provide inlet ventilators to all offices and corridors heated by hot water, and there to be extract ventilating flues to all the large offices. The Mayor's apartments and the Council Chamber will have extract flues or shafts in roofs, Boyle's extractors will be fitted to same. The offices will have 9 in. by 6 in. inlet and outlet flues, and outlet ventilators will also be placed in all corridors, &c. It is proposed to light the interior of the building by the electric light, space heating apparatus being provided in the basement. The building will be built of brick and faced with the best local stone.

The design next in order is that by Mr. W. Appell Jones, who, like Mr. Briggs, makes his plan follow the lines of the site almost entirely. In his report he says:—

In order that the best possible arrangement of giving facility of access to the various departments might be obtained, it has been considered desirable to cover the whole site with buildings, leaving, however, spacious courts for light and air between the blocks.

A portion of the building at the south-eastern end of the site is shown as being raised up to the level of the first-floor ceiling only, and would be covered by a roof with a balustrade towards Cheney-row. It is, however, future extensions become desirable, this portion can be raised for one or two stories without any detriment to the appearance or comfort of the existing buildings.

The disposition of the rooms upon the various floors suggested by the Corporation, has been carried out with the following variations:—

Second Floor.—A portion of the Health Office has been placed here in preference to the first or second floor, viz., the Cleansing Inspector's room, his assistant, and four rooms for clerks, as it is considered desirable that the second floor should extend the whole length of Surrey-street for structural purposes.

First Floor.—Every room required on this floor has been provided, except the rooms mentioned above, but no rooms asked for on other floors have been put upon this floor.

Ground Floor.—Every room asked for on this floor has been provided, in addition to these, a strong room belonging to the Surveyor's department, the pay room and the wages counting room of the Borough Accountant's department, and two rooms in the Engineer's department, all suggested in your particulars to be in the basement, have found a place upon this floor.

Upper Lower Ground Floor.—Every room asked for has been provided here, except the abovementioned ones, moved to ground floor. The cubical contents of the building, calculated in the bottom of the footings, and including all eaves, projections, &c., is 1,937,400 cubic ft.

The entrance to the Council Chamber for the first time is from Surrey-street, and by the use of lifts is practically cut off from the rest of the building.

Over the Mayor's parlour on the first floor is a mezzanine gallery, which would be very useful for a band gallery or for the use of ladies, and would be an effective feature in the rooms.

The public lavatories on the lower ground floor have been carefully arranged to secure good ventilation, and a window is given to each w.c.

The warming of the offices of principal officials should be by open fireplaces; for the clerks' and other offices a system of low-pressure hot water is suggested, circulating from the boiler-room to the W. angle.

For ventilation of Council Chamber a special table is provided, 4 ft. in diameter, and in the reception-rooms the foul air would be collected into the roof and got rid of generally over the building. Fresh inlets would be provided about 5 ft. 6 in. above floor.

No principal offices would be provided with open-air stoves.

Materials: Exterior.—All walls visible from street to be faced with Ancaster stone from Messrs. Hey's quarries,—a stone well qualified to withstand a smoky atmosphere. The base or plinth of building towards the principal streets to be in Portland granite, but not polished. The interior walls to have facings of a hard white pressed brick, but dressings to be in stone. Roofs to be covered with best Westmoreland green slates. The design has been specially designed with a view to the judicious introduction of groups of sculpture in bas-reliefs, as roughly indicated upon the elevation.

The domes to be covered with copper and the figures on the summit to be in bronzes.

The next design, by Mr. John Robinson, makes some departure from the lines of the site, leaving out a corner next the church-yard in order to get a rectangular return to the

principal front—a point not without importance where dignity of effect is desired.

As the author did not forward his report we must leave the design and plans to speak for themselves. The design is the one which we characterized as looking a little too much like a theatre; but it is an effective façade nevertheless. The author adopts the central position with top-light for the Council Chamber, a very good position for that purpose, but which involves the difficulty, not we think sufficiently recognised by Mr. Waterhouse in his address to students at the Institute recently (in which he went largely into the subject of this competition), of dealing with the space under such central room on the lower floor. The author has put the accountants' office there,—a central position, certainly, but somewhat too far within the building for convenient access for an office of this kind.

Mr. R. Stark Wilkinson's design shows, as we remarked at the time of the exhibition, a bold and original treatment of the plan by taking a centre line down the site and placing the plan symmetrically on either side of it. This makes a fine plan, but it has the defect of throwing away a good deal of ground on the front of the site, and throwing the Pinstone-street front back behind the line of the church-yard wall. The following particulars are given from the report:—

"A symmetrical arrangement of the site has been adopted by the author as most suitable for what is to be the dominant building in Sheffield, especially as by this a more extensive space is obtained in front of the principal façade; and the church is better brought into the perspective grouping with the new building, instead of being somewhat blocked out if the Pinstone-street line of frontage, shown on the block plan, were built up to, and also the front is now more parallel with Pinstone-street.

A continuous corridor is carried quite round the plan on each floor, giving access to all the offices from the Grand Staircase and from secondary staircases and entrances from Surrey-street, Norfolk-street, and Cheney-row, which are sufficient for official use when the Grand Staircase is required for receptions.

Large areas give sufficient light to the corridors and to the Council-chamber and central general offices, which are thus placed away from all noises arising from street traffic.

The general water-closets and lavatories are kept in isolated blocks, with good cross-ventilation, in the centre position on each floor; and all drains will have well-ventilated inspection manholes, to enable every portion to be reached for examination and cleansing purposes.

The Reception rooms are conveniently approached from the Grand Staircase, with the Cloak-rooms adjacent to them, and to the Council Chamber, the ante-room of which could be brought into use for reception purposes if needed. Movable divisions to be provided to keep the Dining-room and Mayor's Parlour distinct from the Reception-room.

The present proposed buildings finish with a good elevation towards Norfolk-street, and the spare space next this street can be built over, in the future as shown by dotted lines, in proper continuation of the main features of the design, and for the present can be laid out as a garden or court-space, with advantage to the Norfolk-street elevation.

The public waiting-rooms and lavatories for ladies

and gentlemen are placed on the Mezzanine ground-floor level, at the corner of Pinstone and Surrey streets, as most convenient for bus and tram traffic, and have a distinct and spacious approach from the street level.

The plans now sent in competition are essentially sketches only, to be modified as to thickness of walls, spacing of windows and doors, and arrangement of pilaster columns and other ornamental features, both internally and externally, as may be necessary in the working out of further detailed plans and elevations.

All rooms not having open fireplaces to be warmed and ventilated under the general ventilation and heating scheme, the boilers being placed in a sub-basement in the centre block; but if more convenient they could be placed in a sub-basement at the Norfolk-street end.

The upcast-shafts are placed on either side of the large internal areas, and over the Council-chamber, the lobbies of the gallery stairs, and in the spaces adjoining the Reception-rooms and Grand Staircase.

The plan is generally compact, and the departments are kept together on five floors, to avoid a straggling plan, and to obtain a useful space for future extensions in Norfolk-street.

The fronts to be executed in stone of similar quality to the School Board Offices or the Yorkshire Penny Bank, with slate roofs and lead flats, gutters, and downes.

The elevations in the areas to be in stone and white glazed brick facings.

The floors generally to be of fire-proof construction, of coke breeze concrete and rolled iron joists, laid over with wood block, tile, mosaic, or cement flooring, as the case may require.

The staircases to be of stone, and the Grand Staircase of marble.

Heating and Ventilation.—Two main upcast-shafts are provided in a central position, for the extraction of the vitiated air, and to them the several offices, rooms, stairs, and corridors will be in communication by upcast-shafts provided from each of them. A special extraction-shaft is provided for the Council-chamber and also for the Mayor's Reception-rooms. The boilers are fixed in a central position, and it is proposed that the heating be by low-pressure steam, with the heating mains arranged in circuits for each department. Ventilating radiators will be used, so as to ensure in all seasons the renewal of the atmosphere of the spaces warmed and ventilated at least three or four times in the hour."

DOOR-HEAD, TAUNTON CASTLE.

THE door-head forms the entrance to a building of late date on the south side of the courtyard of Taunton Castle, and facing the great hall in which Jeffreys held the Bloody Assize. It is a fine example of its kind, the carving, although somewhat spoiled by repeated coats of paint, still retaining much of its original delicacy. The sides of the brackets are particularly good.

The Professorship of Building Construction and Architecture at King's College.—We are informed that Mr. Banister Fletcher, J.P., F.R.I.B.A., D.L., has been appointed to the Professorship of Building Construction and Architecture at King's College, London, in the place of Professor Kerr, F.R.I.B.A., who retires in July.

THE NEW "KAISER WILHELM" BRIDGE AT BERLIN.

The new bridge, which may certainly be called an exceedingly monumental one, and which, besides being in close proximity to the Imperial "Schloss," and holding the name of the founder of the new German Empire, has the practical advantage of being the chief connecting link between the old and the new town, or rather between "Unter den Linden" and the new extension of this well-known thoroughfare, was thrown open for public traffic last November, and (except some sculpture over the keystones) may now be considered complete. The erection of the bridge,—which, by the bye, looks far too monumental and solid in comparison to the small breadth of river it crosses,—has taken many a long year, far too many indeed, owing partly to the multitude of red-tape hindrances which cropped up even when the project was a mere project, and partly owing to difficulties in foundation and construction as well as in the river regulations which had to be got over.

The river police not having permitted the water to be dammed at that point where the "Kaiser Wilhelm" Bridge crosses, whilst at the same time the non-erection of piers or even pilasters would have prevented the bridge from having any claim to be an architectural feature (which latter point was required by the authorities), the architect was bound to encroach on the embankments for the necessary room for the stream to pass through, and by doing this has been able to give the bridge three spans (one of 22.20 metres, and two of 8.20 metres), and two piers (of each 5.10 metres), to a normal width of river of 38.50 metres. Owing to the bridge not crossing at right angles, and owing to the fronts showing curvilinear lines, much time was spent in projecting the stereometrical forms of the different stones, and after this theoretical work had been completed, the very laborious practical part of cutting the material as required had to be gone through. This material,—which, by the way, was often very scarce, the quarries from which it came not having an over-abundant supply of good stones,—was of two kinds: black granite from the Odenwald, and grey granite from the Bavarian Hills, the former being used for the fronts and all architectural features, the latter for such parts as were not visible. As to the measurements of the erection itself, the wood-paved thoroughfare shows a width of 26 metres, with two footways (paved with granite slabs) of 5.50 metres each, 30 centimetres being given on the outer sides for the balusters. The surface of the wood-pavement of the roadway is 1.33 metres over the intrados of the keystone of the central span, or 8.52 metres over river bottom. The architecture of the bridge is of the sternest kind, four monumental candelabra (with eight electric arc-lights) of red granite with bronze mounting, and four tripods at the corners of the bridge giving the whole a finish, whilst the somewhat superfluous sculpture over the keystones, although effective in itself, stands in too great a contrast to the other parts of the design. Whatever faults the new bridge may have from the artistic point of view, the construction of the arches and the costliness of the material used will alone make the erection a remarkable one.

THE ARCHITECTURAL ASSOCIATION VISITS:

NEW HEADQUARTERS FOR THE POLICE.

The large pile of buildings which will shortly accommodate the administrative department of the Metropolitan Police, now located at Scotland-yard, was visited on Saturday afternoon by a large party of members of the Architectural Association, who were received and conducted over the building by Mr. Norman Shaw, R.A., the architect.

The requirements of the department call for a large number of comparatively small rooms, and the convenient arrangement of these, with easy access for the public and between the different departments, formed the problem which has been successfully treated in the plan adopted by the architect.

The buildings entirely surround a square, open courtyard, and may be said to cover a square. Corridors run from end to end of each side of the square.

The interior fittings of the building will be simple and of a utilitarian character. Fire-proof construction has been adopted in all the floors, with the usual combination of concrete

and rolled iron joists. The stairs, in some cases of concrete, in others of Portland stone, will be faced with slabs of Craigleith stone, the excellent wearing qualities of which are so well known.

The treatment of the elevations calls for more attention than the simplicity of the interior. The quiet tone of the red brick facings, relieved by bands of Portland stone, is in pleasant contrast with the dulness of the lower portion executed in granite. The angle turrets, the most prominent and graceful features of the design, are in close contrast with the gables, lack of grace being singularly apparent in their treatment.

The treatment of the eaves is somewhat unusual, the deep cornice is provided with a gutter above, but it is doubtful whether the drippings from the eaves, some 4 ft. or 5 ft. above, will find their way direct, in stormy weather, into the gutter below.

The chimneys, which pierce the roof at the ridges in most cases, have been carried across frequently from the exterior walls by means of concrete flues, strengthened with iron.

The building will be illuminated by electric light.

"MODERNISM IN ART."

In the course of the discussion which followed Mr. Henry Holiday's paper* at the last meeting of the Architectural Association,

The Chairman (Mr. Leonard Stokes, President), said it had not often been his good fortune to listen to such an admirable paper as Mr. Holiday had given them.

Mr. E. C. Robins, F.S.A., said he was quite sure they all agreed with the chairman's estimate of the lecture, which was a very interesting one, although he, the speaker, had hoped that it would have dealt a little more with art, and a little less with political economy. But there was no questioning the fact that there was a close connexion between the two. Social questions were now coming to the fore, and, after all, it was nothing very unusual for men like Mr. Morris and Mr. Holiday to show broad sympathies with the well-being of the people; and as artists they of course believed in the elevating influences of art, and desired to witness its enjoyment by the people. Whether or not they thought Mr. Holiday's views were at all practicable, and whether the present generation would witness the realisation of a better state of things than now prevailed, they could not but admit that the ends aimed at, and the goal looked forward to by Mr. Holiday, were most desirable. In listening to Mr. Holiday's paper, he had been reminded of the pretty picture which Dr. Richardson had drawn some years ago of an ideal city of Hygeia. We had not yet seen that city of Hygeia constructed; indeed, in spite of much good work that had been done by sanitarians, there were parts of the country and many towns which were still in a very low sanitary condition. But he thought there was no ground for despondency as to the future of either sanitation or art, nor as to the amelioration of the lot of the poor. He had read the "Fabian Essays" which had been referred to, and he had also read in *Macmillan* a criticism upon them. It should be remembered that the wages of the working classes, according to no less an authority than Giffen, had increased by from 75 to 100 per cent. during the last fifty years. As far as money was concerned, the larger amount of it went into the pockets of the people, but they did not all make the best use of it. He quite admitted that it would be a desirable thing to give workmen a direct interest in the success of their employers, and he thought that where it had been attempted to effect that object under proper conditions the results had been satisfactory as in the case of M. Leclaire. He had been reading an account of M. Leclaire's experiment in industrial co-operation by Professor Sedley Taylor in the *Nineteenth Century*. M. Leclaire was a decorator who, although he treated his men well, found that they took no interest in preventing the waste of material. He conceived the idea of making his own interests identical with those of the men, and devised a system by which he shared his profits with his men. The scheme was very successful. When he died, not having any children he left his establishment to the chiefs of his business, which

was still being carried on and the profit divided amongst the men. Another well-known instance of individual co-operation in France was that which was carried on under the auspices of M. Godin. That scheme was a very successful, so much so that it was recognized that on one occasion when losses had been incurred the men came forward and volunteered to share the loss with their employer. On the other hand, one or two schemes of industrial co-operation which had been tried in this country had failed, notably in one case, that of a colliery. In this case, however, the experiment failed owing to breach of faith on the part of the colliery owners. Turning to the art side of the question, he admitted that it was undesirable that the people should acquire an increased love of art. But he could not admit that things were in so hopeless a condition as would be inferred from Mr. Holiday's remarks. Art, and especially the industrial art, of the present day, was not in its lowest stage. It was nothing nearly so bad as that of the time of the Georges. Ever since the 1851 Exhibition there had been a gradual rise in the level of art work. Good art could be produced now, but only, as in all ages, as a result of patient labour and long study. He had very great pleasure in moving a vote of thanks to Mr. Holiday for his interesting paper.

Mr. H. H. Stannus, in seconding the motion said that, while thanking Mr. Holiday for his able paper, he certainly must express his agreement with Mr. Robins in the view he took of it. We certainly produced finer buildings and pictures than were produced in the time of the Georges, although the Academy pictures and our buildings of the better kind were not taken as criteria of the whole mass of the art and dwellings of the people. He thought that Mr. Holiday's remarks as to the reasons for poverty in artistic ideas were very suggestive. He had very truly said that Giotto was modern in the best sense of the word, and that his was the best art of his time. With regard to architecture, he would commend to the members a passage in Garbett's book, in which speaks about richness in architecture, the author laid it down as a canon that richness was not one of the necessary elements of beauty in architecture; that there might be beauty without richness. He referred beauty rather to proportion and to the evidence of consideration for one's neighbours' buildings.

Mr. H. O. Cresswell, in supporting the vote of thanks, said that there was no doubt a great deal of force in what Mr. Holiday had said with regard to the pedantry of ecypsim, but nevertheless ecypsim had served to make us acquainted with the architecture of the past. We had certainly progressed very greatly since the time of the Georges, and he thought the outlook for the future was not altogether gloomy as some might suppose.

Mr. A. W. Earle having made a few remarks,

Mr. F. R. Farrow said he was not inclined to take so pessimistic a view of the art of the nineteenth century as Mr. Holiday had taken. He thought that there were many evidences of a real awakening of interest in art. Even in the houses built by speculative builders there was a distinct effort after some kind of artistic embellishment. True enough it was generally art of a very poor character, but the fact that it was supplied at all was evidence of the fact that speculative builders recognised that there was a demand for something more than bare walls. As to the panacea which Mr. Edward Belle had put forth in his hook, he did not think that any endeavour to exalt labour at the expense of capital would be successful.

The Chairman having made some observations, in the course of which he said that his sympathies were very largely with the view of the lecturer, the vote of thanks was put and carried, and Mr. Holiday having replied to some points raised in the course of the discussion, the meeting terminated.

Ventilation.—Alterations are being made at St. John's Church, Carlisle, including the installation of Baird, Thompson, & Co.'s exhaust ventilator being adopted for the extraction of vitiated air, and their air-inlet "panel ventilator" being used for the introduction of fresh air. The firm have opened new offices at 165, Queen Victoria-street, E.C.

Notre Dame de Fourvière, Lyons. The late M. Bossan, Architect.

NOTRE DAME DE FOURVIÈRE, LYONS.

WE give an illustration of this modern French church, from a photograph, as the architect who designed it, the late M. Bossan, a native of Lyons, was held in great esteem among the profession in France, and in the course of a eulogy pronounced upon him at the time of his death, a few months since, that church was instanced as one of his most successful works.

The view unfortunately gives only a portion of the building, but sufficient to show its peculiar style, which to English eyes will probably seem odd and unsuitable enough, regarded as church architecture.

The church stands on a hill overlooking the Faubourg de Vaise, at Lyons, on the right bank of the Saône. There is a rope railway to ascend the hill, as well as various ordinary roads. This is said to have been the site of the ancient town of Lyons.

In 839 there still remained on the summit of the hill the ruins of a Roman Forum, which served for the construction of a little chapel of "Notre Dame du Bon Conseil"; but the name of its origin, "de Foro Vetere," has clung to the site up to the present day.

"Notre Dame de Fourvière" has been the object of pilgrimages for a thousand years back. After having been abandoned for some time in this sense, the shrine regained its popularity in the seventeenth century in consequence of a pestilence under which it was regarded as a place of refuge; and at the present time there are an immense number of devotees annually visiting the church for prayer and to suspend their votive offerings there.

The ancient chapel having been found insufficient, was replaced by the present one, begun in 1872 and completed in 1881.

The principal façade does not offer much of interest; but the apse with its flanking turrets is a striking and conspicuous object above the

town. At the other end of the church is the main tower, the upper part of which is seen in the view, and which is terminated by a figure of the Virgin in bronze gilt, five and a half mètres high, modelled by a Lyonsais artist, M. Fabisch.

THE LONDON COUNTY COUNCIL.

THE usual weekly meeting of the London County Council was held in the Council Chamber of the Corporation of London, Guildhall, on Tuesday last, Lord Rosebery in the chair.

The Architect's Department.—The Standing Committee's report contained the following paragraph:—

"We have received a report from the Architect, calling attention to the need, in his department, of an official to check accounts. This need has arisen in consequence of the resolution of the Council of December 3 requiring that in future the prices of articles supplied under contract shall be doubly checked, first by the department by which the orders are given, and afterwards by the Comptroller, and that the prices of articles not included in any contract shall be checked by the department giving the order. The Architect states that he has endeavoured to have the accounts checked in the manner prescribed by the Council, but that, as the practice is quite new, and he has no assistant who could be regularly employed upon the work, he has been unable to carry out the order satisfactorily. The result is that there are several accounts for work done during last year which have not yet been examined and put forward for payment. Having carefully considered the matter, we have arrived at the conclusion that if accounts for works and for articles supplied are in future to undergo a double check, a person possessing a knowledge of this kind of work should be appointed to examine bills, to whatever department they may relate, before they are certified

by the head of the department having charge of the work, and passed on to the Comptroller. We recommend—

"That an official for the purpose above stated be appointed, that he be placed in the first class at a commencing salary of 200*l.* a year, and that it be referred back to us to take the necessary steps."

This recommendation was agreed to, after some discussion.

The Blackwall Tunnel.—The discussion of this question was then resumed, and occupied nearly the whole of the sitting.

The Vice-Chairman, Sir John Lubbock, by way of giving effect to the suggestion made by the Chairman when the subject was last under discussion by the Council, moved the following amendment to the report of the Bridges Committee:—

"That it be an instruction to the Bridges Committee to proceed provisionally with the tunnel at Blackwall under the Act of 1887, subject to the advice of an engineer of experience in subaqueous tunneling, and under such advice to sink shafts to ascertain the nature and difficulties of the soil, and then to report to the Council for further instructions."

Mr. Saunders, in seconding the amendment, spoke in favour of a tunnel extending only under the bed of the river, and with lifts in lieu of inclined approaches.

The amendment was opposed by Sir Thomas Farrer, Mr. Charles Harrison, and other prominent members, but was carried on a division by 57 votes to 48,—a majority of 9.

Sir John Lubbock's amendment having thus become the substantive motion, Mr. Corbett moved, and Mr. Beachcroft seconded, the following rider to it:—

"But that beyond the question of these provisional works the Council does not at present commit itself."

This was accepted by Sir John Lubbock and carried, after which, by 41 votes against 39, the Council approved the following further rider, moved by Lord Langton:—

"And that the engineer conducting the experiments do report monthly to the Bridges Committee the nature

of the information obtained, and the progress of the expenditure.

Mr. Costelloe then moved, as a further amendment—

"And that it be referred to the Bridges Committee and the Parliamentary Committee, acting jointly, to consider and report upon the expediency of obtaining an amending Bill, containing such modifications of the existing powers as to works as may be found desirable, and such provisions as to the method of providing for the future expense of the undertaking as may seem to be just."

Other amendments, seeking to make the execution of the work contingent upon the Council's obtaining powers to apply the principle of "betterment" to the property benefited by the construction of the tunnel, having been lost, it was resolved, by 47 votes against 42, that the following words should be added to the motion:—

"Provided the expenditure thereon shall not exceed 10,000."

The resolution as amended was then formally approved.

Tramway Legislation.—The Highways Committee reported as follows:—"Your Committee have had before them a letter from Mr. T. H. Bolton, M.P., stating that he has given notice of a motion for the appointment of a Select Committee 'to inquire into the operation of the Tramways Act, 1870, and to consider as to the desirability of further legislation in the interest of the public with reference to tramways.' Mr. Bolton asks to be informed whether the Council is in favour of such an inquiry. Your Committee are of opinion that, having regard to the anomalous state of the existing legislation with regard to London tramways, an inquiry by a Select Committee of the House of Commons might be of advantage; and they therefore recommend—

"That Mr. Bolton be informed that the Council approves of the proposal for a Select Committee on tramway legislation, and will be prepared to give any assistance in its power to further the object of the inquiry."

This was agreed to.

Subways.—On this subject the Highways Committee reported as follows:—"The Council on the 19th of November last made by-laws under the Metropolitan Subways Act, 1868, and other Acts, for the regulation of the use of the subways in Garrick-street, Southwark-street, Victoria-embankment, Queen Victoria-street, and Commercial-road East. These by-laws have now been allowed by the Board of Trade, and the Home Secretary has signified his approval of the penalties specified therein. Section 202 of the Metropolitan Management Act, 1855, provides that no by-law shall be of any force or effect until the same shall have been submitted to and confirmed at a subsequent meeting. Your committee therefore recommend—

"That the Council do confirm the by-laws made on November 19, 1889, for regulating the use of the subways in Garrick-street, Southwark-street, Victoria-embankment, Queen Victoria-street, and Commercial-road East."

This was also agreed to.

Disturbed Main Roads in the Metropolis.—On this subject the Highways Committee presented the following report:—

"The Council, on February 11 last, decided to offer to the respective Vestries and District Boards, in respect of the maintenance, during the year 1889-90, of the roads in their districts disturbed since December 31, 1870, and which by the Local Government Act became vested in the Council, equivalent sums to those paid by the Local Government Board in respect of such roads during each of the two preceding years. The sum thus offered in respect of Finsley and Edgware roads, which are in the parish of Hampstead, was £377, 17s. 4d. With respect to this the Vestry has, by resolution, expressed the opinion that the proportion hitherto paid by the Local Government Board is inapplicable to present circumstances, especially as a large proportion of the wear and tear is due to through traffic, and has suggested that as the roads have during the year ended June 30, 1889, cost 4,736l., the Council should allow the Vestry at least half that amount. This expenditure was incurred during a year with only the last quarter of which the Council is concerned. Your Committee, having fully considered the matter, recommend—

"That the Council do adhere to the offer already made to pay the sum of £377, 17s. 4d. towards the cost of maintenance of the Edgware and Finsley roads during the year 1889-90, and that the Vestry of Hampstead be so informed."

With respect to the Commercial-road East, East and West India Dock-roads, and Horseferry-road, which were also vested in the Council by the Local Government Act, the offer made by the Council was to pay £877, in respect of maintenance during the year 1889-90. The Limehouse District Board, in whose district these roads are situated, has decided not to accept this sum, which, in the opinion of the District Board, is quite inadequate; and the District Board has, moreover, determined not to undertake the maintenance of the roads after March 31 next. It appears to your Committee that the Council should in this case also adhere to the offer already made; and with respect to the future maintenance, should exercise the power given by the Local Government Act of requiring the District Board to retain the management of the roads. They therefore recommend—

"(a) That the Council do adhere to the offer already made to pay the sum of £877 towards the cost of maintenance of Commercial-road East, East and West India Dock-roads and Horseferry-road, during the year 1889-90, and that the Limehouse District Board be so informed."

"(b) That the Council, in the case of Commercial-road East, East and West India Dock-roads, and Horseferry-road (which roads have been disturbed since December 31, 1870) do exercise the rights conferred upon it by the Local Government Act, 1888, section 11 (sub-section 4), by requiring the Limehouse District Board to undertake the maintenance, &c., of the said roads, in consideration of such annual payment by the Council for the cost of the undertaking as may be determined in the manner provided by the said sub-section."

After some discussion these recommendations were agreed to.

After transacting other business the Council adjourned until Tuesday next.

THE ARCHITECTS' BENEVOLENT SOCIETY:

ANNUAL GENERAL MEETING.

The fortieth annual general meeting of the Architects' Benevolent Society was held on Wednesday, the 12th inst., at 9, Conduit-street, Mr. J. Macvicar Anderson, Vice-President of the Royal Institute of British Architects, in the Chair. The minutes of the thirty-ninth annual general meeting having been read and signed as correct, the Hon. Secretary (Mr. W. H. White) read the Report of the Council, of which the following is an extract:—

"Gentlemen,—The *Red Book* published last year contained a brief summary of the reports for the years 1884—85 to 1887—88, in addition to a report of the past year's work, in order to preserve a continuity of the history of the society; and, consequently, the present report will deal only with the work of the society during the year 1889—90.

While being again able to congratulate the Society upon a considerable increase to its invested capital, your Council regret having to state that the subscriptions have decreased in amount; and they would urge upon each and every contributor the desirability of obtaining new subscribers. At the same time, your Council have pleasure in stating that the result of a special letter in place of the usual circular, to several subscribers who were in arrears in January of this year, has been satisfactory; and as a similar appeal is being made to all subscribers whose subscriptions for 1889 have not yet been received, there is great probability that the increased amount of subscriptions obtained in 1890 will more than balance the decrease of the past year. The Income Account and Balance Sheet for the year ended December 31, 1889, are herewith submitted.

During the past twelve months six meetings have been held by your Council; 2415 has been distributed among thirty persons out of forty-four applicants; and three pensions of £25 each have been paid. The amount received by subscriptions shows a decrease of about £28, being £308, 12s. as against £335, 18s. received in 1888. The Capital Account receipts amount to £567, 6s. 4d., including a donation of £500 from Mr. Robert P. Page, joint heir of the late Mr. Palgrave, who, it may be remembered, by some, expressed his intention to leave £1,000 to this society, but who died without signing the codicil to that effect. Upon coming of age Mr. Samuel P. Page made a donation of £500, and his brother, Mr. Robert Page, has now done the same—both acts of generosity worthy of emulation. Among others, donations were received from the British Architectural Book Society, Mr. Cole Adams of the Northern Architectural Association; the Nottingham Architectural Society; Mr. John Cotton; Mr. A. S. Gover; Mr. C. H. Howell; Mr. George Inskipp, and Mr. R. St. A. Rounie. The capital of the Society, which in 1883 consisted of investments of £6,174, 17s. 8d., and Cash 100l. 2s. 6d., or a total of £6,274, 17s. 8d., at the present time amounts to almost 8,000l., viz., investments 7,871, 2s. 4d., and Cash 53l. 18s. 8d., or a total of 7,925l. 18s. 8d.

Your Council regret to have to announce the

decease of Mr. John Turner, who held the office of Hon. Secretary to the Society for a period of more than a quarter of a century, resigning in 1871, when the Council tendered their cordial thanks and acknowledgment for the able and zealous manner in which he had performed the various duties entrusted to him, and also for 'the care and untiring energy evinced by him in carrying out the principles laid down for the guidance and distribution of the benefits afforded by the Society.' Mr. John Turner was one of the founders of the Society, and had remained a subscriber to the present year.

Your Council have also to record with sincere regret the decease of Mr. George J. J. Mair, for twelve years the Hon. Treasurer, who was one of the first Life Members, and a Member of the Council for eighteen years. Mr. Mair resigned the office of Hon. Treasurer in 1885, in which year your Council referred with gratitude to the long services rendered by the genial Honorary Treasurer, then giving up that office.

In consequence of the retirement of Professor J. Hayer Lewis, who succeeded the late Mr. Mair as Hon. Treasurer in 1885, the duty of electing a new Treasurer devolves upon the contributors."

The Chairman having moved the adoption of the report, Mr. E. A. Gruning seconded the motion; after which Mr. T. M. Rickman, F.S.A., and Mr. John Hebb made some remarks, and the adoption of the report was agreed to.

A vote of thanks was then passed to the outgoing Members of Council, viz.,—Messrs. Arthur Cates, Edward A. Gruning, Herbert D. Appleton, C. Forster Hayward, F.S.A., and W. Hilted Nash; and the Council for the year of office 1890-91 was elected as follows:—Mr. Alfred Waterhouse, R.A., President; Messrs. G. R. Raggett, George Inskipp, R. H. Carpenter, F.S.A., E. Blakey l'Anson, M.A., J. Alfred Gotch, Samuel Hill, R. St. A. Rounie, George Scamell, F.G.S., Lewis Solomon, Thomas Verity, William Emerson, H. L. Florence, Professor J. Hayer Lewis, F.S.A., Thomas M. Rickman, F.S.A., and Aston Webb. A vote of thanks having been passed to the auditors for the past year, namely, Mr. Charles Fowler and Mr. T. M. Rickman, F.S.A.—Mr. W. Hilton Nash and Mr. John Hebb were elected auditors for the ensuing year of office. Mr. Arthur Cates was elected Hon. Treasurer, and the Hon. Secretary was re-elected.

ARCHITECTURAL SOCIETIES.

Sheffield Society of Architects and Surveyors.—The usual monthly meeting of this Society was held in the School of Art on the 21st inst. Mr. F. Fowler, President, in the chair, and a large number of members were present, including Messrs. C. J. Innocent, Vice-President, C. Haedfield, E. M. Gibbs, W. F. Hemsoll, J. B. Mitchell, Withers, Frank Massie, W. C. Fenton, J. I. Simpson, H. W. Lockwood, and many others. Mr. C. F. Wike, C.E., the Borough Surveyor, read an interesting paper entitled "Municipal and Sanitary Engineering." He presented statistics showing the relative sizes of Sheffield and other towns, and pointed out that Sheffield and Leeds had the largest areas of any English boroughs, each having an area of 20,000 acres. The next town in size was Bradford, with 10,776 acres. He also stated that Sheffield had an area equal to the areas of Manchester, Liverpool, Bristol, and Salford combined. He next dealt with the construction of roads, described the different kinds of granite, gritstone, and other materials used, gave particulars as to the manufacture of tar and concrete pavement, and as to the cost of maintenance. He also gave statistics as to the comparative cost of granite and gritstone paving, showing that at the end of twenty-five years the latter would have cost 50 per cent more than the former. He then referred to the sections and gradients of roads, giving the formulae of the most experienced engineers for cross sections. The second part of the paper dealt with sewerage and house drainage. The most modern methods of sewer construction were described, and particulars given as to the different forms of sewers, and the volume of sewage and amount of rainfall to be provided for. The question of sewer ventilation was also discussed, and various systems in work in other towns were described. Drawings were exhibited showing how engine chimney shafts could be utilised for ventilating purposes, and the results of numerous experiments made with different sewer ventilators were given. The question of house drainage was then thoroughly gone into, and different methods of drain disconnection and ventilation were ex-

lained. The use of rain-water pipes as sewer ventilators, and the use of soil-pipes as rain-water pipes, were condemned. The paper was illustrated with a large number of models, diagrams, &c., and excited considerable interest amongst the members of the Society, and an exhaustive discussion took place. A hearty vote of thanks to Mr. Wilke was accorded on the motion of Mr. J. B. Mitchell-Withers, supported by Messrs. Frank Massie, C. Hadfield, V. C. Fenton, and H. W. Lockwood. The hon. secretary announced that next month Mr. T. M. Dickman, of London, would read a paper on "The Present State of Questions relating to Sanities."

Edinburgh Architectural Association.—At a meeting of this Association held in the Heriot-Watt College, on the 21st inst., Professor Baldwin Brown, residing, Principal Grant Ogilvie delivered a lecture on "Electric Lighting of interiors." He began by explaining the terms used in describing electric currents, and showed the effect of the current on the conductor through which it passed, pointing out the application of the heating effect in the use of visible "cut-outs," where a thin wire is used as part of the circuit, so as to cut off the current from a section where it might be becoming too strong for safety. He further explained the construction of incandescent lamps, and showed the high lighting efficiency now attained by some of these of 200-candle power and upwards. The arrangements for distributing the current to the various lamps in a house, the use of storage cells, and the distribution of electricity from central stations by high-tension alternating currents and transformers, were also discussed in the lecture. At the close Principal Ogilvie received a cordial vote of thanks.

PARTY-WALL CASES.

FOOT v. HODGSON.

In the City of London Court on Saturday last, Mr. Commissioner Kerr gave judgment in the case of Foot v. Hodgson, which had been before him on two previous occasions and which involved a question of considerable importance to architects, builders, and building-owners. The action was brought by Mr. George E. Foot, of 15, Little Trinity-lane, E.C., against Mr. James Hodgson, of 1, Queenbith, E.C., by way of an appeal against an award made by two out of three arbitrators, which directed that the party-wall between Nos. 16 and 17, Little Trinity-lane, E.C., should be pulled down and rebuilt in accordance with the provisions of the Metropolitan Building Act.

Mr. Fullerton was counsel for the appellant and Mr. A. H. Spokes for the respondent. It seemed that in April last a fire occurred on the premises of the respondent, and now that the premises were cleared, it was urged on his behalf that the party-wall was so far defective and out of repair to render it both necessary and desirable to pull down and rebuild the wall. The respondent, on the other hand, the arbitrators being Mr. T. M. Deacon, the respondent, and Mr. Stenning for the appellant, Professor Roger Smith being appointed third surveyor. In their award they ordered that the wall should be pulled down, but this decision is appealed against.

Mr. Stenning, Mr. H. H. Bridgman, Mr. Collins, Mr. Fullerton, and Mr. Spokes were in sufficient good pair as not to render it necessary to pull it down. On the other hand, Professor Roger Smith, Mr. Deacon, and others said the wall was not strong enough. They said that as there was a sloping roof they were justified in measuring the party-wall in the way as to show that its breadth of two bricks was insufficient, and that it should consist of one and a half bricks. Mr. Spokes said the mode of measurement was very important, as some District Surveyors in London were measuring one way, and others the other. Mr. Commissioner Kerr now gave judgment, and he said the question had received the very careful attention not only of himself but of the assessors who had sat with him. He said it was represented to the Court that the building intended to be built was of the same height and in every respect similar to that which had been burned down; but it came out in the evidence at the end of the case at the building under consideration, if he could obtain the assent of the persons interested in preventing his raising the building, really to make his building a story higher by having what he called a rafter instead of a sloping side to the upper story; or other words, instead of laying his rafters on a wall of the same height as that which had been burned down, he intended, if possible, to raise that wall a story in height. It further appeared that an alteration was made in the building five years ago which had made the sloping roof to consist of two stories instead of one, and the result, it was contended, was to add a flat, if not a story, to the height of the building. Much contradictory evidence was

adduced on the question of measurement, and there was great controversy as to what constituted a "story" within the meaning of the Act, the appellant contending that a story must mean a flat enclosed by four walls, the respondents urging that a story might be, and was, a story, although it might be what was ordinarily termed an attic or a flat in the roof. He (the learned Judge) agreed with the appellant, and considered that the roof began from the stonework on which the rafters of the roof rested; that all above the story enclosed by four walls was roof, and must, therefore, uphold the appeal.

Appeal allowed with costs.

MESSENGER v. LOADER.—GROOM v. LOADER.

THESE actions have been tried together in the Court of Chancery, before Mr. Justice Ford North. The plaintiffs are respectively lessor and lessee of the "Highlander" beehouse, High-road, Loe, and the defendant is a builder, who, after serving the usual party-wall notice, proceeded to build a separate external wall to his premises adjoining the party-wall.

The plaintiffs, for whom Mr. Cozens Hardy and Mr. Moyses appeared, claimed damages for trespass and for damage to the wall, calling the managers of the house, and Messrs. Pountney and Roberts, surveyors.

The defendant called Mr. Chas. Bell, F.R.I.B.A., and Mr. H. Lovgrove, F.S.I., to prove that the old wall was a party-wall, and that the alleged damage could be made good for a few pounds.

The Judge decided to dismiss the action by the freeholder (Messenger), each party to pay his own costs; and in the other action he awarded 25*l.* damages for the trespass, with costs on that part of the action only, as he dismissed that part relating to ancient lights.

CASE UNDER THE EMPLOYERS' LIABILITY ACT.

PUGH v. THE HORSLEY ENGINEERING CO., LIMITED.

In the Westminster County Court, on Monday, the case of Pugh v. The Horsley Engineering Company, Limited, was before his Honour Judge Bayley and a jury. The action was brought by the plaintiff to recover damages by way of compensation for personal injuries sustained owing to an alleged defect in the defendants' plant.

Mr. Moyses was counsel for the plaintiff, and Mr. Tatlock for the defendant company.

The plaintiff, Thomas Pugh, was called, and said he entered into the service of the defendants in November last year, at which time they had a large contract in hand for the construction of a railway at Liverpool-street. On the day of the accident, November 6, he was ordered by the foreman to assist a number of other workmen in moving a massive iron girder, weighing some 8 or 9 tons. The method adopted to move the girder was to get a bar of old railway line and lay under either end, and having well greased it, to slide the girder along. That operation proved very successful until the girder reached the end of the rails, when, owing to the upward projection of a head, or what is technically known as a "burr," the girder refused to go any further, and it then became necessary to prise it up with crowbars in order to get it over the "burr." He (the plaintiff) was ordered by the foreman to assist with others in bearing upon the crowbar, and the result was that when the girder got over the obstacle it came down with very great force, and buried the crowbar round in such a manner that it struck him violently in the chest, with the result that he was first thrown up into the air, and then precipitated into a cutting beneath, a distance of something like 15 or 20 ft. He remembered no more until he found himself in the hospital. There was no proper staging erected for the men to work upon, but only a few feet of platform composed of old sleepers laid side by side.

Cross-examined: He was compelled to obey the orders of the foreman, or he would have been discharged. He was acting under the instructions of the foreman when the accident happened.

A house-surgeon from the London Hospital was called, and gave evidence as to the nature of the injuries which the plaintiff had sustained. In his opinion the plaintiff would never again be fit to do laborious work.

That being the case for the plaintiff, Mr. Tatlock submitted that there was no case to go to the jury, as he contended that neither negligence nor defect had been proved against his clients, and therefore he was entitled to a non-suit. He did not propose to call any evidence.

His Honour said he did not think that the plaintiff had made out a case, but he (the Judge) thought he had better take the opinion of the jury on the matter.

Mr. Tatlock then addressed the jury at some length, and contended that the plaintiff was not entitled to recover any damages.

His Honour then summed up the evidence, and told the jury that if they were of opinion that there was negligence or defect, then they ought to give the plaintiff damages, but otherwise he was not entitled to anything.

The jury, after a brief consultation, gave a ver-

dict for the plaintiff, and assessed the damages at £50.

Mr. Tatlock said that in spite of the finding of the jury, he should ask his Honour to enter judgment for the defendants.

His Honour said he should not adopt that course, but the defendants could have leave to appeal.

THE BRITISH COMMISSION AT THE PARIS EXHIBITION.

SIR.—As there is no wrong without a remedy, there must be a remedy for being slandered in *Truth*, but it is hard to find.

May I try and discover one by appealing to the fairness of the press in general to correct some mis-statements by one of their number, but which he has not had the generosity to withdraw?

It was stated in a paragraph in *Truth* that exhibitors at the Paris Exhibition were being dunned for a testimonial to the British Commission, and various comments were made on the fact.

May I ask you to state: 1. That no testimonial has ever been proposed to the Commission, Committee, or Council. 2. That I myself some months ago declined to accept any testimonial whatever, when on two several occasions the flattering suggestion was made. 3. That some of the exhibitors, acting entirely on their own initiative, are subscribing to make a gift to the members of the staff, who did the work and got none of the credit.

The question is one entirely without public interest, but it is hard, after trying to do one's best honestly, that one should be accused of petty meanness. I would not have troubled you had the editor of *Truth* published even the substance of the disclaimer I sent him, instead of absolutely distorting it. A copy of my letter to him is enclosed.

H. TRUEMAN WOOD,

Secretary, British Committee,

Paris Exhibition.

Society of Arts, John-street, Adelphi.

March 26.

PROVINCIAL NEWS.

Newcastle-on-Tyne.—A special meeting of the Newcastle Town-hall and Municipal Offices Committee was held on the 18th inst., under the presidency of Mr. W. Temple. Plans were presented by the City Engineer (Mr. Laws), showing the five sites retained, namely, No. 1, Singleton House; No. 2, Eldon-square; No. 3, ground between Clayton-street and *Journal* Office, including the Assembly-rooms; Nos. 4 and 5, two sites in Pilgrim-street, from Worswick-street to Manor Chare. Considerable discussion followed, and the two latter sites were struck out of the list as impracticable and unfavourable. It was then agreed that the City Engineer should prepare an estimate of the cost of the ground of each of the remaining sites, to be ready for presentation at the next meeting of the committee. Fresh plans were also presented by the City Engineer showing amended arrangements for dealing with the present Town-hall, and the conversion of the same into municipal offices, a concert-room, and an art gallery to be provided elsewhere in the city. This plan shows the whole ground-floor in the front portion of the building, to be adequate for the purpose of the treasury department; the first-floor for the Town Clerk's department, and the upper floor for the City Engineer. An elaborate plan for converting the present concert room into a Council Chamber with a public gallery. Mayor's chamber, and other offices were also put in.—The Chairman stated that these alterations, if agreed to by the Council, would supply the wants and requirements of the city for the next fifty or hundred years.—A further scheme, combining the sale of a portion of the present Town Hall buildings, and leaving the concert room and Corn Market as at present, was also presented.—It was agreed that the entire schemes, when completed and put into order, should be submitted to the Council before any final decision was arrived at.

Sunderland.—On the 19th inst. a special meeting of the Sunderland Town Council, called by Alderman Fairless, Vice-Chairman of the Municipal Buildings Committee, was held in the Council Chamber of the new Town Hall, Fawcett-street, under the presidency of the Mayor (Councillor Shadforth). The Mayor congratulated the Council on meeting for the first time in the new Council Chamber.—Mr.

Brightwen Binyon, the architect, spoke in reply to the criticisms of Councillor Ranken at the last Council meeting. He had gone carefully into the figures, and he could not see how it was possible to make such a large reduction in the estimate as was proposed. £3,000 was inadequate to furnish the buildings.—The Mayor then suggested that the buildings should be furnished in such a manner as would not lead them to reflect afterwards on having furnished them inadequately.—Mr. Kirtley asked if Mr. Binyon was aware that £3,000 had first been put down for the furnishing of the building, and if he was also aware that such a sum would be totally inadequate, and that it was simply put down with a view of keeping the estimate within a sum which would pass the Council? Was Mr. Binyon aware of this, or a party to it?—Mr. Binyon replied that the estimate was made a long time before he was thought of.—Mr. Rickaby said that the general opinion of the Council at the last meeting was that the price put down for furnishing and decorating was too much. They desired to know if Mr. Binyon could see his way clear to having the building furnished for less, still maintaining the respectable character of the place.—In reply to Mr. Annison, Mr. Binyon said that the specification he had drawn up did not provide for the furnishing of the Town Hall in anything like the handsome manner some Town Halls in small Yorkshire towns were furnished. If the Council desired him to make another plan for furnishing he would do so.—The Council adjourned without coming to any decision beyond the general expression of a hope that economy would be effected wherever possible in the estimates.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—XIII.

DYNAMO-ELECTRIC MACHINES.—(Continued). RING ARMATURE.

THE greater the flux through the armature of a machine, by so much the greater will be its possible output. For this reason iron is used in the construction of armatures, which, by reducing the magnetic resistance, enables the magneto-motive force of the field magnets to send a larger number of lines of force through the coils than they would through air. Another function of the iron is to direct the lines where they are most needed, as well as to increase their number.

In the armature described in the last article the drum should be built up of thin discs, insulated from one another, as, were a solid iron drum used, current would be set up in it, for the same reason that current is set up in the parts of the coils which lie along its periphery. The iron should be continuous along lines of force and divided at right angles to them, as it is in this direction that the E.M.F. is set up; unless this is carefully done, currents are produced in the iron core, which not only absorb power uselessly, but produce heat to a dangerous degree. Even when laminated to the utmost extent practicable, the iron has still certain disadvantages; little local eddy currents, sometimes called Foucault currents, are formed in the solid portions, however thin, which require a small amount of power for their unavoidable production, and which cause a corresponding amount of mischievous heating. Again, as the iron revolves the magnetisation changes its direction, involving a constant movement of its molecules (see article II.) and since there is a certain amount of friction between the molecules, heat is also generated from this cause. Hysteresis is a word lately introduced to explain this and other phenomena observable in the magnetisation of iron.

Although it is difficult to separate the effects of Foucault currents and hysteresis, yet there is every reason to believe that, even if Foucault currents could be entirely eliminated, hysteresis would remain. In certain forms of armature, then, it becomes a question as to whether the advantages of reduced magnetic resistance are not more than counterbalanced by the introduction of the disadvantages just named, for although such substances as air or wood have a relatively high specific magnetic resistance, Foucault currents and hysteresis are absent from them.

A form of armature in which the iron is designed to direct the field as well as lower the

magnetic resistance is the "ring armature," or "Gramme ring," shown in fig. 32. The iron core is entirely covered with bobbins connected in series. In the figure six skeleton bobbins are shown with their ends connected through the segments of the commutator.

In order to understand clearly the exact functions of the iron in the Gramme ring, suppose, in the first instance, that the ring itself in fig. 32 is made of wood or some non-magnetic substance, and that lines of force pass straight across the armature between the faces N and S of the field magnets. Remembering the diagram or rule for the direction of the E.M.F. set up in a conductor when it cuts a line of force, it will be seen that the directions of the electro-motive forces set up in the turns of the bobbins inside and outside the ring are such as to oppose each other. But all the lines between N₁S₁ and N₂S₂ are cut as many times in a complete revolution in passing through the interior of the ring as they are cut at the sides of the ring facing the field magnets; so that the whole field between N₁S₁ and N₂S₂ is absolutely useless, and the only parts of the field in which unbalanced E.M.F. is produced are those which lie, in the figure, above and below these lines. Assuming the field to be uniform, it is easy to measure, with a pair of dividers, what proportion of the total amount of the wire on the armature is of any use at one time.

In the case of the drum armature, no such opposing E.M.F. would be set up, as there are no interior parts to the turns of the bobbins; absence of iron in this case, therefore, would merely result in a lessening of the flux across the armature, not in making one part of a hobbin oppose the E.M.F. set up in it to that set up in another part.

Now, however, suppose the wooden core exchanged for a soft iron one. A line of force starting at N₁ will, on entering the iron, pass through the core, owing to its low magnetic resistance as compared to the air-path through the interior of the ring, and emerge opposite the point S₂, where it enters the other field face. It will be seen from this that the iron core diverts the lines, and screens the wire on the interior surface of the ring from them, so that the opposing E.M.F., which is set up without the iron, is not produced at all in this latter case. The connections shown in fig. 33

Fig 33.

are so extremely simple that it does not seem necessary to draw a supplementary diagram in order to show the action of the commutator, but a diagram to show its action may be drawn for fig. 33, just in the same way that fig. 32 was drawn to help the explanation of fig. 30. Figures 30 and 33 should, however, be compared. In fig. 33 electro-motive force is set up in the portions of the conductors on the outer surface of the ring, in precisely the same way that electro-motive force is set up at the surface of the drum. As the inner portions of the bobbins on the ring are screened from lines of force, they need not be considered from this point of view. In both figures P and S are the segments of the commutator between which there is the greatest difference of potential, and on them should press the brushes.

In both armatures the bobbins are always divided into two groups, those in each group being connected in series, and the two groups thus formed put abreast. As the brushes of a machine are fixed, and the segments of the commutator on which they press are in connexion with two points in the armature, they may be regarded as being fixed in space when the armature revolves, although they do in reality oscillate backwards and forwards through a small angle when the segments slip under the brushes. The brushes have the potentials of these points, and if there is an external circuit, current is always being drawn between these

points. A line joining them is called the "diameter of commutation." With the brushes placed on P and S the diameter of commutation would be a vertical line passing through the axis of the armature. It does not follow that a line joining the points of contact of the brushes will be the diameter of commutation, for the commutator may be bodily shifted round the spindle of the machine, provided that the connexions are kept intact.

We have hitherto supposed the armatures to revolve, open-circuited, in a field produced either by permanent steel magnets or by separately-excited electro-magnets, and the diameter of commutation, chosen so as to get the greatest difference of potential between the brushes, has been a line at right angles to the direction of the field. It will be shown in the next article that, when the armature is producing the current for which it has been designed, this is not the best diameter of commutation, but that it has to be slightly shifted forward. The angle which a diameter of commutation makes with the direction of the field produced by the field magnets is called the "angle of lead" of the brushes.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

2,388, Chimney-pots. R. Fox.

To prevent smoky chimneys, according to this invention a pot is made with the body cylindrical and the lower portion square or oblong on plan, with a flange at bottom. Near the top of the body and to the outside of it there are soldered two pieces of metal, one in the form of a hollow truncated cone, and the other of a similar shape, but inverted. The two pieces of metal at the edge of their larger diameters are soldered together, and at their smaller ones they are soldered into the body of the pot. In the lower of these two cones holes are formed for the entry of air. Three cones are placed one above the other on the pot, the whole surmounted by a dwarf cylinder, in which also are holes protected by wind guards. The wind entering the holes in the lower cone, passes through the small spaces, and issues in a cylindrical stream into the body of the pot from the space left between the inner and outer cones.

5,748, Fixing Letters to Fascias. J. Willmott. This invention consists in applying holding devices to support the letters in such a way that the device is not visible in front of the letter.

5,790, Drain-pipe Joints. W. S. Emden. The socket of the pipe which is the subject of this patent is made with an inwardly projecting lip at its mouth, the lip nearly fitting the outer periphery of the inserted pipe, or a collar is fitted for a similar purpose. To make the joint, a lateral hole is made through the wall of the socket on its upper side, and after the pipe is inserted and luted round the narrow mouth of the socket, liquid cement is poured through this hole to fill the annular space within the socket.

5,806, Casement Windows. G. Prince and G. Clough.

A pinion wheel is fixed on a stud plate fixed to the casement window. Two brackets are fixed on the window frame, and the worm on a rod. This rod works in the brackets by means of a wheel or bands, which, when it is turned, opens or shuts the window at any required distance.

915, Paint Cans. E. Norton.

In order to provide a paint can of cheap and simple construction, which may be securely closed without the use of solder after the can is filled, a seam is by this invention folded or formed upon the top of the can, so that an ordinary slip cover may fit snugly over the same.

19,288, Blower for Grates. G. Lake.

The blower is a sheet of metal fitting close about the open front of the grate above the bars, and adapted to make a practically air-tight contact to prevent access of air above the fire. It is simply fixed by resting on the top bar of the grate, the difference in atmospheric pressure keeping it in position.

NEW APPLICATIONS FOR PATENTS.

March 10.—3,763, H. Horesey, Glazing, Withaws, &c.—3,774, S. Ingram, Sash Fastener.

March 11.—3,793, S. Flavel, Cooking-ranges and Fire-grates.—3,798, E. Cammish, Brick Moulds and Dies.

March 12.—3,882, T. Birtwistle and S. Bardsley, Safety Hinge for Folding Ladders.—3,883, C. Whitfield, Open Fire-places.—3,887, W. Thompson, Ventilators.

March 13.—3,942, G. Smith and B. Cooper, Joining Head-pipes.—3,974, J. Hart, Nails.—3,985, G. Moller, Kilns for bricks, tiles, &c.

March 14.—3,994, J. Anderson, Mortar-cutting Machines.

March 15.—4,066, J. Tracy, Heating Buildings, &c.—4,069, H. Conway, Brick for building pu

Lead and Lead-workers.—A lecture on "Lead and Lead-workers" was delivered in the Lecture Hall of the Philosophical Institution, Edinburgh, a few days ago, under the auspices of the National Registration of Plumbers District Council for East Scotland. There was a large attendance of members of the plumbing trade and the public. The lecturer, Mr. James Macdonald, R.P.C., said it was during the Middle Ages that lead first began to assume that important character with regard to architecture which it still maintained. There could be no doubt that leaden roofs were known as far back as the gardens of Nebuchadnezzar and the porches of the Latin basilica, but it was to the magnificent roofs of the French and English cathedrals that they must look for the best possible type of its architectural value and importance. After referring to the frequent mention of lead in Scripture, the lecturer stated that the first gravitation supply of water to the city of Edinburgh was by means of a leaden pipe which in 1681 was laid from the Couiston Springs to a reservoir on Castle Hill. He inveighed against the modern plumber for consigning everything in the shape of lead to the melting-pot, and expressed his opinion that it was not creditable to the Edinburgh National Museum that it contained so few and meagre specimens of old lead-work. He particularly urged that a scientific knowledge of the properties of lead was essential to plumbers to enable them to so manipulate it as to secure the greatest durability and the most satisfactory results generally. Scottish plumbers were to be found in all parts of the globe, and, generally speaking, they took a distinguished position; but they, and all other plumbers, must improve themselves by earnest study in order to keep themselves abreast of the exacting demands and varying conditions of modern house sanitation. In conclusion, he strongly advised his hearers to take advantage of the facilities offered by the Plumbers' Laboratory in connexion with the Heriot Watt College.

The English Iron Trade.—The English iron market continues quiet, and reports as to its tendency vary greatly. The process of buying pig-iron is still a slow one, consumers only purchasing for immediate requirements, and this of merchants, as makers are out of the market at present, owing to the great difference of prices quoted by second-hand holders and producers. Although the Glasgow warrant-market has been firmer, not much business has been done during the week. Scotch makers' iron is also quiet, and prices quoted are irregular. Middlesbrough iron has gone up from 1s. to 1s. 6d. per ton. Bessemer iron in the north-west is unchanged with makers, while hematite warrants are advancing. In other districts prices are still weak. The trade done in finished iron is small, and values have not recovered strength. The demand for steel is dull, and as orders are not coming forward very readily, prices are going down. There is no further decline in rails in the north-west, but no orders can be obtained for blooms, billets, and slabs at 5s. 5s. to 5s. 10s., which is quite 10s. a ton lower than last week. Plates are likewise falling away in price. Shipbuilders are not booking any new orders, and engineers also report themselves quieter.—*Iron.*

Selby New Town-hall.—The Leeds Mercury reports that in a limited competition, plans submitted by Mr. H. Thorp, of Leeds, have been accepted by the Selby Local Board for a new Town-hall, to be erected on a corner site at the junction of Gowthorpe-street and New-lane. The building is intended to take the place of the existing inconvenient Local Board offices, which will be pulled down to make way for the new structure. The accommodation to be provided will comprise a large Board-room, committee-room, Clerk's and Surveyor's offices, and a fire-engine station. The building is designed in the Tudor-Gothic style. It will have gables to each street, mullioned windows, and an angle oriel, with a steep pitched roof. Externally it will be faced with brickwork of a deep red colour, contrast being obtained by the use of cream-coloured Ancaster stone for the door and window dressings, and other architectural features.

Assistant Surveyorships, Staffordshire County Council.—We are informed that the successful applicants for the five assistant surveyorships under this Council are Mr. J. Percy Gates, Worthing; Mr. J. Howarth, Liverpool; Mr. Alex. Kinnison, Eassie, Forfarshire; Mr. Chas. S. Morris, Bury St. Edmunds; and Mr. James Wylie, Linlithgow.

Madagascar Timber.—Strenuous efforts are being made to introduce timber from Madagascar into the English market. Hitherto the "Great African island" has exported but little in this direction, and most of what has arrived, chiefly smuggled ebony, seems to command good prices. Until quite recently the Malagasy Government prohibited the export of timber from the island, but at length a concession was granted to an Englishman, and a company has been formed to work it. This, the "Madagascar Forests Company, Limited," entertained a large number of timber merchants and others at luncheon at the Cannon-street Hotel, on Thursday, the 20th inst., Mr. J. W. Shepherd (of Messrs. Seccion & Shepherd) in the chair, to inspect samples of the wood. Amongst those present who referred to the timber resources of the country were Mr. S. Procter (Consul for Madagascar) and Mr. T. Roe, M.P. The principal varieties exhibited were a kind of rosewood, yellow teak, mahogany, and a remarkable species of the last-mentioned called "matte." All were peculiar in being very heavy, and, at the same time, not difficult to work. Subsequently the party went to the docks and viewed the materials in bulk. Judging from inquiries already made by merchants, it seems tolerably certain that Madagascar wood will soon become a conspicuous feature in the timber trade.

ROMFORD.—For enlarging the Albert-road Schools, for the Romford School Board. Mr. John Hudson, architect, 80, Leman-street, E. Quantities supplied:—
 D. Argent, Barking £1,175 0 0
 T. Bray, Hornchurch 1,150 0 0
 W. Watson, Ilford 1,137 0 0
 W. Gladding, Mile End 1,038 0 0
 Consell Bros., Rednal Green 1,033 0 0
 C. Barnes, Ilford 996 0 0
 Hammond & Son, Romford* 917 0 0
 * Accepted.

STRATFORD.—For the erection of shop and warehouse in Burford-road, Stratford, E., for Mr. Samuel Clapp. Mr. John Hudson, architect, 80, Leman-street, E.:—
 W. R. Boney, Forest Gate £785 0 0
 A. Reed, Stratford 711 0 0
 Norton & Son, Stratford (accepted) 706 0 0

WOBURN SANDS.—For building "Wavendon Towers," at Wavendon. Mr. Charles Granville Baker, architect, 5, Bloomsbury-square, London, W.C.:—
 S. Foster £4,805 0 0
 [No competition.]

Lists of Tenders for works at Southwark, Mitcham, and Loughton, received without senders' names, are ineligible for insertion.

* * Next week, communications for insertion under this heading must reach us not later than 12 noon on Wednesday, as we go to press a day earlier than usual.

SUBSCRIBERS IN LONDON and the SUBURBS, by prepaying at the Publishing Office, 19s. per annum (or 4s. 6d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

TO CORRESPONDENTS.
 J. F. L. (the statement is practically an advertisement).—P. D.—A. H. (too late).—W. A. H. (we will inquire).—G. V. (we do not care for such local).—A. S. (for space).—All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, and necessarily for publication. We are compelled to decline pointing out books and giving addresses. Note.—The responsibility of signed articles, and papers read at public meetings, rests, of course, with the authors. We cannot undertake to return rejected communications. Letters or communications (beyond newsworthy) which have been duplicated for other journals, are NOT DESIRED. All communications regarding editorial and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

PUBLISHER'S NOTICES.
 Registered Telegraphic Address, "THE BUILDER, LONDON."

GOOD FRIDAY.—THE BUILDER for the Week ending THURSDAY, APRIL 5th, will be issued on THURSDAY, the 3rd. Advertisements for insertion in that issue must therefore reach the Office before THREE p.m. on WEDNESDAY, the 2nd. Alterations in Standing Advertisements, or ORDERS to DISCONTINUE the same, must be at the Office by TEN o'clock on TUESDAY Morning.

CHARGES FOR ADVERTISEMENTS.
 SITUATIONS VACANT, PARTNERSHIPS, APPRENTICESHIPS, TRADE, AND GENERAL ADVERTISEMENTS.
 Six lines (about fifty words) or under 4s. 6d.
 Each additional line (about ten words) 6s. 6d.
 Terms for Series of Trade Advertisements, also for Special Advertisements on front page, Competitions, Contracts, Sales by Auction &c. may be obtained on application to the Publisher.

SITUATIONS WANTED.
 Four Lines (about thirty words) or under 2s. 6d.
 Each additional line (about ten words) 6s. 6d.
 PREPAYMENT IS ABSOLUTELY NECESSARY.
 * * Stamps must not be sent, but all small sums should be remitted by Cash in Registered Letter or by Money Order, payable at the Post-office, Covent-garden, W.C. to DOUGLAS FOUNDRINER, Publisher.

Advertisements for the current week's issue must reach the Office before THREE o'clock p.m. on THURSDAY, but those intended for the front Page should be in by the same hour WEDNESDAY.

SPECIAL.—ALTERATIONS IN STANDING ADVERTISEMENTS or ORDERS to DISCONTINUE the same must reach the Office before TEN o'clock on WEDNESDAY morning.

The Publisher cannot be responsible for DRAWINGS, TESTIMONIALS, &c. left at the Office in reply to Advertisements, and strongly recommends that of the latter COPIES ONLY should be sent.

PERSONS Advertising in "The Builder" may have Replies addressed to the Office, 46, Colindale-street, Covent-garden, W.C. free of charge. Letters will be forwarded if addressed envelopes are sent, together with sufficient stamps to cover the postage.

AN EDITION Printed on TRIN PAPER, for FOREIGN and COLONIAL CIRCULATION, is issued every week.

BEADING CASES, New ready, NINEPENCE EACH. [By post (carefully packed), 1s.]

Safety in Theatres and Places of Public Amusement.

MUCH has been done of late by the lessees and owners of London places of amusement to secure the safety and comfort of the public. New theatres and halls have risen to take

the place of dangerous structures; old theatres have been rebuilt and remodelled; thousands of pounds have been spent by our managers to meet the requisitions of the late Board of Works and the London County Council; houses and lands adjoining their premises, mostly in our busiest thoroughfares, have been purchased at great outlay; staircases have been widened, and additional exits provided to benefit a public knowing little or nothing of all that has been done for their security.

Not only have structural alterations been executed under the Metropolis Management and Building Act Amendment Act, but other important changes have been carried on voluntarily by the lessees. The advance of science has brought a valuable aid to them in the form of the electric light, which has been installed in many theatres and halls at considerable outlay. In some cases "power" has had to be specially provided, and the scenery repainted to adapt it to the varied quality of the new light. The installation of the new fittings, both to auditorium and stage, and the extra nightly cost over and above that of gas, have all been additional expenses borne by lessees for the good of the public.

Where electric light is used, we can now go to a theatre without experiencing a feeling of suffocation; the risk of getting overheated, and catching cold after hy going into the night air, is avoided. Even a much more important object than this is attained—the reduction of fire risk. The old gas system was and is a bad one in every way. The proximity of gas, too often unprotected, to inflammable material, and the escape from the joints of the temporary pipes which connect up the border and ground rows, are dangers that occur in the best supervised theatres. Where the electric light is used all this danger is avoided.

In dealing with places of public amusement,

one must ever bear in mind that one great object is to prevent panic; in order to do this avoid fire risk, narrow passages, winding staircases, insufficient exits, crowded seating, and an unsuitable site. Theatres, and all public buildings of this class, should be entirely fire-resisting, having nothing in their construction that will readily ignite; hy this means the ordinary methods of fire extinction, along with strict supervision and adequate appliances, will be found sufficient for the protection of the building. By giving careful consideration to the planning and disposition of the various parts, and judicious choice of the materials for construction, a theatre can, in spite of its being such a heavy fire risk, be made as safe as any other building, and the business of the house can be carried on with perfect security to both life and property.

The first thing, however, for the architect to learn is, what is wanted in a theatre, and how a house should be arranged in every detail; until this is ascertained it is useless to try and plan a "safe" theatre. It is a *sine qua non* that there must be a place for everything, and everything in its place; it is necessary to know what this everything is before the place for it can be provided, and it is only by becoming thoroughly acquainted with the *modus operandi* of "show" business that provision can be made to minimise and avoid the risks that follow.

The first point is to provide, in planning a house, that the audience and staff should be able to get out of the building in the shortest possible time, at the slightest warning. Avoid all risks of panic. Panic has more victims than fire. Many deaths occur where there is not a spark of fire in the building, and literally no danger whatever, this being in most cases due entirely to an ill-constructed and badly-planned house, unfit for the reception of numbers of people. Create confidence in the audience, and half the battle is won; show to them their safety is in their own hands, and that everything possible has been done to secure it for them by erecting a building from which they can find their way out with ease, by using materials of fire-resisting qualities, by dividing the house into many risks, and by providing separate departments for all the trades and businesses of the house.

If the public were better acquainted with the means of getting out of places of amusement, there is no doubt they would feel safer when visiting them. A great number enter

with the idea that they could never find their way out if they wanted. This is not to be wondered at considering what some of the entrances are, that the entrances are not always the exits, and the exits not always in nightly use. What are commonly labelled "emergency" doors are too often found locked and bolted—they are therefore worse than useless.

Such notices as "In case of need," "Exit in case of fire," "In case of panic," "Emergency," "Alarm exit," should never be seen; they only suggest the presence of danger, which should never be brought to the minds of the audience. Above all, the architect should study to obtain simplicity and uniformity of design in the plan. Let both sides of the house be as similar as possible.

Where there is a pit entrance on one side, let there be a corresponding one on the other; where there is a gallery staircase on the right let there be a similar staircase on the left. Place all entrances and exits where they can easily be found, and have them all used nightly every time the house is open to the public. All seats should be numbered, and the house licensed to hold that number, and no more admitted under penalty of heavy fines,—then the gangways would be left unobstructed. Until the manager is fined passages will continue to be blocked up, and the weak-minded man will be found who is willing to part with a sixpence to the obliging attendant for a camp-stool or loose chair for his own personal convenience but to the danger of his fellow-visitors.*

Judgment in the choice of materials with which to construct the building requires such great care and study that too much importance cannot be placed upon this branch of the subject. The materials employed for the erection of places for the assembly of the public, whether for amusement, instruction, or devotion, must be in every sense of the words "the best of their several kinds." The scantlings, or thicknesses, must be far in excess of what would appear to be necessary for the actual and present work which they have to perform, so that they may resist any shock or pressure that may from any cause be brought to bear upon them. In short, a

* The public themselves are greatly to blame for the way in which they enter places of amusement. They are, however, easily led, and it is a pity other managers do not follow the example of the managers of the Shaftesbury and Savoy, and compel the adoption of the queue system; then many, who cannot afford the dearer seats of the house, would be able to visit the cheaper parts in comfort and safety.

theatre, or any building of public resort, must of necessity, in comparison with other buildings, be exceedingly costly. In this we refer only to the structural part, leaving out of consideration the decoration and fittings.

As long as there are cheap buildings, danger will be rife. Sometimes, where a place of amusement is in a leading thoroughfare, the ground-floor is set aside for shops. This cannot be too strongly protested against; the reason that it is done is, of course, to get the rent of the shops, and thereby lessen the cost of the premises: but it robs the house of the very means of providing good entrances and exits, which it would otherwise glory in. We may say "glory in" advisedly, for every manager glories in his exits, and will tell you his house has better and more numerous exits than any other building in the town. Business or trade premises within the same block of buildings should never be allowed: it is only adding the risks of such trade to that of the theatre or hall. The dangers accruing from the surrounding property are often as great as from a theatre itself. In no case should persons be allowed to live or sleep, as is often done, in or about this class of building: it only increases the danger, through the carelessness of the class of people who are likely to occupy the position of caretakers. The house should be left at night to a proper fire-watch, not to persons who have been occupied in other callings all day, and who therefore are in want of sleep at night.

In enlarging theatres and halls, adjacent premises are often taken in by knocking openings in party-walls, perhaps for an extra scene-dock or additional dressing-rooms. The house next door is taken, and though never designed or built for the purposes of a public building, it is brought into the same "risk." A building, or part of a building, not specially erected for "show" business, should never be used for such purposes, as it is nearly sure to be unfit for them.

In regard to choosing a site for a theatre, it may be said that no house should be permitted to exist that is hemmed in on all sides, with only a narrow entrance as a frontage in a public thoroughfare. We too often thrust our places of amusement into cramped and crowded spaces, not caring as long as they are in the right quarter of the town for a paying concern. This, more frequently than not, is the first thought, and it is not considered if the site adapts itself to the requirements of a public building. True, it is difficult to obtain a building isolated on all four sides, and it is of course no use building a house where it will not pay; but never ought a place of public resort to be permitted where there are not wide streets running past three sides of the building, with the fourth side cut off from adjacent premises by a high party-wall, many feet higher than the buildings on either side of it.

One of the most important points to be borne in mind in planning may be called the "party-wall system;" have as many party-walls in the building as possible, making thereby every division of the house a separate fire risk. Do not be content by merely dividing the stage from the auditorium, but isolate the workshops from the main building, the dressing-rooms from the stage, the stage from the auditorium, the auditorium from the offices, cloak-rooms, saloons, corridors, passages, &c., &c. Divide each and every one of these and other sections of the house from all others vertically by strong brick walls, filling the openings with fire-resisting doors, and horizontally by fire-resisting floors. Should a fire occur in any section it would be localised, and if not extinguished, left to burn itself out where it originated, without danger to other parts of the building. The position of the workshops should be such as to ensure an entirely separate building, connected with the rest of the house by one opening only, which should be closed by a double fire-resisting door, a door which should on no account be allowed to be opened during the time of a performance. Should space permit, an open area should be left between the workshop and the theatre

proper, but where no area can be obtained, a thick brick party-wall, passing through and above the roof, should divide the workshops from all other parts of the house. Provision should be made in the workshop section for paint room, carpenter's shop, property-making room, and docks for scenery and property not in nightly use.

The painting gallery should be placed where a top studio light could be obtained, which lights should be protected from falling materials, timbers and sparks by strong wire guards. There is no special danger from scene painting, as is sometimes supposed; oil is not the medium employed except when scenes are wanted for out-door use, to resist the weather; as in the cases of open-air plays and scenic decorations such as are used in exhibition grounds.

The stage is too often used as a carpenter's shop—a custom which should never be allowed; the many dangers thus incurred need no pointing out, yet it is strange, that seldom is a special room provided for the carpenter: this work in some houses used to be carried on over the auditorium ceiling, but at any rate in London this has been stopped. A special workshop for each trade should always be provided. The gasman, the electricians, the bill-poster, the needle-women, the cleaners, should all have their respective rooms.

Many theatres still have dressing-rooms which are little better than dark holes under the stage, over-heated boxes, made of match-boarded partitions, on flies or stage floor, devoid of ventilation and light. It should be remembered that too often dressing-rooms are overcrowded, and that the heat from the glaring gas-lights over each looking-glass, where the actor "makes up," renders the room unfit for occupation. The remedy is in the hands of the architect, and is, complete ventilation; not only should as much window-space as possible be provided, but also inlets and outlets for fresh air at the floor and ceiling levels, since, unfortunately, one cannot depend upon the occupants of the room to open the windows. Every dressing-room should have a separate washing-basin for each performer, with water laid on and waste-pipes properly trapped; this would avoid the slopping about of water, and also encourage cleanliness among the poorer classes, who are engaged as supers and extras in such large numbers at many places of entertainment. Gas or electric light should be placed over each looking-glass, otherwise the artists will provide candles for their own convenience, and add greatly to the risk of fire.

Dressing-rooms might be with convenience placed to the right and left of the stage, on one side for men, and the other for women, each block separated horizontally and vertically from the stage and the rest of the building by brick-walls and fire-resisting floors. There should be separate staircases, and direct exit into the street from each section; the construction throughout should be fire-resisting, no more wood being used than is actually necessary for the provision of drawers and hanging cupboards for the disposal of the costumes in constant use. For the stock of costumes a special wardrobe should be provided. There should be no fireplaces in dressing-rooms; hot water or hot air should be used for heating purposes. The stage floor and sliders must of necessity be of wood, on which to set the scenes with ease, but much of the machinery might be well made in iron, and answer the purpose much better than the present clumsy bridges and traps, in which no alteration or advance has been made for many a long day.

On a level with the stage there should be scene-docks and property-docks, for the stowage of the scenes and properties in constant use; all other scenes and properties should be placed in the workshop section above described. The mezzanine and cellars below the stage should be used for the purpose of the machinery only, and on no account should rubbish and scenes be allowed to accumulate under the stage. Here too often the band-room is situated, and other

the building has left the hands of the architect. There should be a separate passage to the orchestra, so that the band need never approach the precincts of the stage or pass through the auditorium. Proper accommodation must be supplied for band, band-master, stage-manager, firemen, property-master, and all other sections of the staff employed behind the scenes.

The gridiron above the stage must be made sufficiently strong to carry the weight of the cloths, &c. Cases have been known where it has given way under the weight of the scenery, and let everything down in dangerous confusion on to the stage. The construction of the gridiron, flies, and fly-rails, should be of iron. Proper staircases should be provided, to enable the flymen to escape in case of danger; and direct exit into the street should not be forgotten for the stagemen and any who may be employed on the stage.

The stage should be divided from the auditorium, as is now generally recognised, by a thick, solid brick proscenium wall; this should be arched over the opening, passing through and for some height,—not less than 3ft. 6in.—above the highest part of the roofs of stage and auditorium. There need only be one opening in this wall in addition to the large or proscenium opening: namely, one pass door, from the stage to the front, for the acting manager. This opening should be protected on both sides of the walls by fire-resisting, self-closing doors. The stage should undoubtedly be cut off from the auditorium by some sort of fire-resisting or smoke-proof curtain. The failure of some of the iron curtains used on the Continent and in America has shown that they are not always to be relied on, and it is not so long ago that one stuck in a London house, and the audience had to depart without seeing the play. Thin iron curtains are really useless to retard fire, although for a time they would keep back the smoke, and allow the auditorium to be cleared. Asbestos curtains have been advocated, and seem far more fire-resisting in character than the iron curtains generally adopted. Water curtains have been proposed, but as these could not be periodically tested, on account of the destruction of property that would ensue, they cannot be recommended. Whatever is adopted must be in constant use, for anything designed to act only in case of need or in the outbreak of fire, is liable to be found wanting at the very moment it is needed. The fire curtain must be used nightly and between every act, to ensure its being in working order, and to let the audience know that it exists, helping thereby to strengthen that confidence of safety which is the cure of all fear and panic: for an "emergency" curtain coming down unexpectedly would be but the signal for a stampede.

Everything in and about a theatre, to be of any good, must be in constant use. Automatic water-sprays, and appliances that depend upon the solder melting when a certain heat is attained, and all such-like arrangements, are of very doubtful value. The system is altogether wrong. You depend upon the existence of the very danger you are trying to overcome; and where automatic appliances are provided people are apt to put such reliance in them that they ignore the ordinary precautions and become careless in their false security.

In regard to lighting, no precaution should be left untried to mitigate the dangers arising on the stage, for it is here we have to contend with the great risk. The use of the electric light has reduced the danger more than any other step that has yet been taken, but there are still hundreds of houses where an immense amount of gas is used nightly, too often in a careless manner. As the pipes are being constantly connected and disconnected during the performance, small escapes occur near naked lights, which makes one wonder that accidents happen as seldom as they do. All gas lights should be protected by wire-guards throughout the whole house.

The gas or electric light should be under the control of an expert, with a sufficient staff

of assistants. This man, during the whole time the house is open, should be stationed at the indicating plate fixed on one side of the stage near the curtain, on which plate every cock should be distinctly labelled, naming the section of the lighting system it governs, so that no error can possibly be made, and the lights lowered or put out in the wrong part of the house. A mistake like this, slight in itself, might lead to dire consequences. It takes little to start a panic—once started it is hard to stop, and prevention is better than cure.

Gas-meters should be placed in a specially-prepared and ventilated vault; the supply-pipes should be of hard metal, left visible, and coated to prevent corrosion. There should be a stop-cock on the main in the street, near the stage door, at which entrance the key should be kept, to cut off the gas from the house in case of fire. Separate meters should be fixed for each section of the house, and the gas supply made distinct, and where frequented by the public a dual system of supply should exist.

Sun-burners are preferable to gaseliers, as they greatly assist the ventilation of the house by the up draught they create; but they should be periodically cleansed, and accumulated carbon removed. This also applies to all other gas-fittings; a foul gas-burner may at any time drop a spark on inflammable materials in dressing-rooms or elsewhere.

Although the electric light is so much better than gas for lighting public buildings, it is not without its attending dangers. Recently it was reported at the Royal Opera House, Madrid, that an unusual stir was noticed on the stage, and the stage-manager requested the audience to disperse, as an accident had occurred in the electric-lighting machinery, which made it impossible to go on with the performance. Much excitement and alarm is said to have been created behind the scenes among the employes, for two of their number had been injured by the electric wires. With electricity, as with gas, safety depends on having everything in proper order. The principal danger from fire arises from over-charged wires.

It is advisable not to depend entirely upon the gas or the electric system of lighting. The electric light is sometimes apt to fail, perhaps only for a moment, from such accidents as an over-heated hearing, a broken belt, or other unforeseen cause. Although it may leave the house in darkness but for a few minutes, panic will prevail. To avoid all this, oil lamps should be placed about the building, in all sections, "in front" and "behind." These lamps should, like the notices on the walls, indicate the direction of the exits, with white lettering on red glass ground. They should be fed with oil, not spirit, and be lit before the admission of the audience.

Provision for plenty of window space should be made in all parts. This would admit of the use of artificial light being discontinued during the day, avoiding one of the great risks in such building as the careless handling of lamps, candles, and matches. Many people are in the habit after striking a match of throwing down the semi-burnt incandescent end. Firemen say that this is the origin of a large number of fires. For other reasons it is a mistake. It is a great blunder to make a place of public resort dark. In a house flooded by day with as much light as our varying climate will allow the women whose duty it is to clean the "front" of the house would not have the opportunities of scamping their work as they now do. Darkness means the accumulation of dirt and rubbish in all odd corners, ready to flare up on coming in contact with the slightest spark. A theatre or hall, for everybody's comfort and safety, should be kept clean, but as long as it is a dark hole it will not be.

There should be access from any one part of the roof to any other, with escape-ladders leading to the ground. This is of the greatest value to the firemen. The construction of the roofs throughout should be of iron embedded in concrete, finished on the outside with asphalt or other weather-resisting material. It has been found with wooden roofs over the stage

that the excessive heat and constant changes of temperature to which the roof is subject desiccates the trusses and rafters, and converts them into something little better than touchwood. For this reason the gridiron floor should be of iron. Parapet walls should divide each "risk" in a similar manner to all party-wall structures.

The several divisions of the auditorium should each have their separate entrances, exits, passages, corridors, staircases, saloons, lavatories, &c. Each section of the audience should have two exits, used also as entrances, in corresponding and relative positions on the plan, on either side of the house, placed so as each to take half of the people accommodated in such section. All exits and their approaches should lead directly into the street, and should be used only by that division of the audience for which they are designated. There should be no pass-doors, or emergency exits, leading from one part of the house to another. A door known as an "emergency door" is often only a trap, for when opened it too frequently leads into a passage, or staircase, already crowded to its utmost.

The number of tiers depends upon the class of entertainment for which the house is built. An opera-house must of necessity differ from a theatre for the drama, and a music-hall from a theatre for grand spectacle. It is a good thing, however, to reduce the number of tiers where the business will allow. A high building is a mistake for seeing, if not for hearing, as well as for safety. The arrangement of seats should be such as to allow a 3 ft. 6 in. gangway at either end of every ten to twelve seats. This would avoid that disagreeable pushing-by of the late-comer, who has a seat in the centre of a row, and who enters with no feeling of regret for the disturbance and discomfort he produces. The widths of the seats depend upon the parts of the house in which they are placed; but by the By-laws of the late Metropolitan Board of Works each person should be allowed 1 ft. 6 in. by 2 ft. 3 in. This would, however, scarcely do for the occupant of a half-guinea stall, although the 6d. gallery might be contented with it. Every seat should be divided and numbered, and the house licensed to contain that number only. Seats should be made to tip up automatically on the occupant rising, so as to widen the distance between the rows for the convenience of people getting in and out. All seats should be securely screwed to the floor, and be constructed of iron frames to reduce the inflammable contents of the house. There need not be anything combustible in the auditorium beyond the seat-stuffing, the curtains to the boxes, and the carpets, and even these latter might be done away with, and wood block or parquet floors substituted.

Staircases and passage-ways should be from 4 ft. 6 in. to 5 ft. wide, such width being only sufficient for 500 people. Where the division of the audience is in excess of this, additional staircases and passage-ways should be provided, rather than the width of the original staircase increased. By this means every 500 people would have a separate and distinct way to the street. Staircases should consist of flights of not more than eight or ten steps, intersected by wide landings to break the possibility of stumbling and falling over one another, that long flights entail. There should, of course, be no winders or steps at half-landings. The steps and landings should be of concrete with bearings on solid brick walls at both ends; brick arches should be turned at intervals to support long passage-ways or landings; these are better than iron joists, as brickwork will stand changes of temperature where iron will not. A square staircase is perhaps the best form, having six to eight steps to every one of the four flights, with a square landing at the bottom of every flight; the inner, or newel wall, should be built of solid brickwork, with the steps and landings securely bedded on it. This wall should be carried to the same height as the outer wall, and the whole staircase roofed in with a solid fire-resisting ceiling.

Strong handrails, on brackets built into the

walls, should be fixed to both sides of all flights of steps and landings, leaving a space of 3 in. clear between the wall and the handrail, to allow room for a firm grip. So as not to lessen the width of the staircase by the projection of the handrail, a chase could be cut in the wall parallel with the handrail, thus allowing room for hand between the rail and the wall. This, however, tends to weaken the wall.

Slopes should always be adopted where only a slight difference in the levels exist; never should single steps or flights of three or four steps be allowed.

The corridors behind each tier of seating should be of such superficial area that the whole of the occupants of each tier could easily be accommodated therein without crushing. The corridors should be divided, on the party-wall system, from the auditorium by brick walls and self-closing fire-resisting doors, so that immediately the audience left their seats and reached the corridor, they would be in perfect security from any fire or smoke that might be filling the auditorium.

Fire-resisting doors in the "party-walls" should be hung to close automatically, in duplicate, one on each side of the wall, and fixed into iron frames built into the walls. The material of which to construct fire-resisting doors is difficult to decide upon; if of iron, to be of any real service to retard the progress of the fire, the metal would have to be used in such thickness that the weight of the door would be very great. Thinner metal doors are serviceable to keep back the flames for a time, but are useless to stop the fire. Concrete doors in iron frames on wire netting have been tried, but they are heavy and liable to fracture. Perhaps there is nothing better than a good solid thick oak door, and these, at any rate, could be used in the minor divisions of the auditorium. Thick wooden doors lined with iron would be better than thin iron doors.

A fire-resisting door, as nearly perfect as possible, could be made upon the same model as safe doors, having an inner case of iron packed with sawdust and alum, surrounded by a strong well-hound and well-hung outer case; these would be heavy and expensive, and as all fire-resisting doors should be self-closing, in some degree dangerous, but they should be used to divide the larger risks of the house, such as workshops from stage, stage from auditorium, where the doors are not in frequent use.

The question of what fastenings should be used seems a small one, till one remembers the terrible disaster which occurred some years back in Sunderland, only because the wrong kind of bolt was used on a door. In this case, if we remember right, a common barrel-bolt caught in a hole in the floor, and the door remained only partly opened, while hundreds of poor children were crushing each other to death in their struggle to get out. One cannot lay too much stress on the fact that it is from these insignificant and minor details, which are not thought of sufficient consequence to receive the attention that experience afterwards teaches they require, that the death-list is swelled. Bolts, when used, should be of such a nature that, if lifted, they will not be in danger of falling and catching in the floor.

Locks are bad, padlocks worse; keys are seldom to be found when required in a hurry; for instance, in the recent disaster at Forest Gate, we hear of a key that was not forthcoming when wanted; a door barred and padlocked is hard to burst open, and never should such fastening be allowed in a public building. What is required is a fastening which will enable those who are inside to let themselves out at will, and with ease, while it acts as an effectual barrier to those outside. This we know can now be had, and it is a question whether its use should not be made compulsory.

The hooking of all parts of the house would do away with the necessity for barriers at the pay-boxes. Where these are used they should be hung to open outwards, and not made so as to depend upon the memory and intelli-

gence of some attendant to remove or unship them.

The pay-boxes and box-office should be made a permanent part of the building, so arranged as to be in proximity to the treasurer's office, and under his supervision. Pay-boxes may be so placed that they may serve for more than one division of the house, by having pay-windows from the same box in two different passages, thereby saving the expense of one money-taker nightly, and helping to provide a house cheap to work. Some theatres are much more profitable to work than others, on account of such details as these having been observed, whereby the working staff can be reduced. The treasurer's office should be planned with regard to the fact that therefrom the whole of the staff, actors and actresses, are paid weekly, and assemble there in large numbers. There should, therefore, be a waiting-room, pay-office, and private-room, with the safes built into the walls. The offices for the acting-manager, and his staff of clerks, should be on a similar scale in the same suite.

Every means should be taken to keep places of public resort at an even temperature, thus adding to the health, comfort, and safety of all. The stage must be well ventilated, and, at the same time, there must be no draught to cause the scenery to flap about. Shafts immediately over the "gridiron," with gas-jets burning in them to cause an up draught,—on the same principle as the sun burner in the auditorium,—would carry off all that foul, heated air which hangs about a theatre for hours and hours after the performance is over. The up-draught caused by the shafts would serve another valuable purpose. Should a fire break out on the stage, the smoke would immediately find an escape, instead of rushing, as it would otherwise do, into the auditorium, and up towards the sun-burner. The gas jets in the shafts could be regulated by the gasman at his indicator-plate on the stage, when the up-draught should be cut off. Fresh air should be admitted to the auditorium as near the floor-level as possible; in winter it should be previously warmed; and the number of inlets should be regulated by the number of people that the house will seat. Gas-burners in corridors or passages are bad, and should be replaced by electric light; however, where they do exist they should have over them a funnel-shaped flue, by which the products of combustion could escape.

The number of deaths indirectly caused through breathing bad air in crowded buildings is probably far in excess of those caused by fire in such buildings. How frequently do we hear of colds caught through going to this play or that concert, to say nothing of the minor inconveniences of headache and lassitude next day? With regard to ventilation, buildings of this sort have been left too long to take care of themselves; it is true our new theatres and halls show great advance in the right direction, but old houses are left untouched, are still poisonous pits and little better than slow death-traps. Large sums of money have been expended in providing against contingencies which may not arise, while the fact that thousands upon thousands are nightly sowing the seed of disease and untimely death by breathing poisonous air is totally ignored, and neglect is shown in many sanitary matters in public buildings.

In regard to materials it is now almost a truism that the accepted significance of the term "fire-proof" is an erroneous one. Materials that are incombustible are not, therefore, fire-proof. Take, for instance, iron and stone, both recognised as fireproof substances, yet they are among the first materials to suffer under excessive heat or sudden changes of temperature. Wherever possible brickwork is to be preferred in preference to any other material. Every opening should be arched over, and the use of lintels of wood or stone discarded.

The floors of the various tiers should either be constructed of iron embedded in concrete, or of timber in very large balks, of the hardest description, such as elm or oak, or a

wood with qualities such as the Australian iron bark. Where wood is used it should be thoroughly protected from the action of fire by being thickly coated with gypsum or plaster of Paris. The pit and stall floors should be of concrete covered with wood blocks for warmth and comfort; all the rooms behind the scenes should be similarly treated. The floors of corridors, passages, and landings, should be constructed of concrete supported upon brick arches, abutting against the brick walls. Never use an iron joist where a brick arch can be turned.

Where iron is used to form the back-bone of the constructions it must be completely embedded in cement concrete, with no face to be exposed to a fire. The concrete should be composed of the very best Portland cement, with the aggregate of calcined material, such as broken bricks or pottery, and where it is used for light partitions of coke breeze. The staircase, as before observed, should be constructed of the same material or of some approved hard artificial stone or fire-clay, with solid steps, having a bearing both ends on brick walls. By its contraction and expansion iron adds to the danger of fire, as frequently brickwork is pulled over by the ironwork, and walls which would have stood the fire unhurt are torn down. Where iron is used it must be well bedded in cement or fire-clay, but even then avoid its use as much as possible.

Wood, when used in large balks, and of the harder sort, especially when protected with plaster, is preferable to naked ironwork. Wood is dangerous chiefly when used in thin slices.

Plaster is a valuable fire-resisting agent, it is light and resists fire for an indefinite period, it adapts itself to the entire enrichment and decoration of the auditorium, from ceiling and proscenium frame to circle fronts and private boxes.

In choosing materials for the construction of public buildings always give the preference to those that are already calcined, and have undergone the action of great heat; these will not add fuel to the fire.

NOTES.

 THE meeting of members only at the Institute on Monday, specially convened by a requisition in order to pass a vote in favour of a resolution to obtain legal powers to render it compulsory on all practising architects to pass the examination by the Institute, was largely attended, and was at all events instructive in one sense, as showing who are the people within the ranks of the Institute who are calling out for "registration" as a means of raising the profession. To have to listen to exhortations in this direction from members who "appen to know" this and that in favour of it, and who define architecture as practical work with "perhaps a little art added on to it, more or less" (a good deal less, we should imagine), is a kind of degradation which certainly gives some excuse for the position taken by several of the real artists of the profession who refuse to have any connexion with the Institute. They are at all events safe from this kind of thing. The meeting was of course called as a "move" in favour of the scheme before Parliament, at the instance of some of those interested in it. The full report will we believe be in the hands of all members of the Institute in a few days, as by another "requisition" (for which, in accordance with the By-law, six signatories were with some difficulty obtained) the sense of all the members is to be taken on the question by a general vote. We need only now observe that an amendment against the proposed resolution, put by Professor Roger Smith, was carried by a large majority, and we hope that members who vote upon it from a distance will not fail to read the arguments in favour of the amendment (now the substantive motion), and will also note the relative status and position in the profession of the speakers on both sides, bearing in mind

that those who actually spoke in favour of Professor Roger Smith's amendment represented only a very small proportion of the well-known and eminent architects who attended to give it their support.

THE proposed new Employers' Liability Bill still includes the doctrine of "common employment," so obnoxious to many working men and their Unions, but which we believe it would be found impossible to get rid of without serious risk of employers being victimised. Other modifications of existing law are in favour of the artisan, especially that which gives him a right of claim for compensation for injuries sustained in obeying the orders of any foreman or other person whom he was bound to obey, whether the latter is or is not "ordinarily engaged in manual labour." This is a step in the right direction, though it may perhaps somewhat increase the difficulty, often considerable as it is, of defining clearly wherein "superintendence," and therefore the right to give orders, consists.

IF such terrible tornadoes as that which has produced such disaster in the United States should appear to be on the increase in that part of the world, it seems almost as if those in danger of them would have to give their minds to the production of some new method of constructing buildings which would give, if not security, at least greater chance of safety and less of destruction under such a tempest. The construction of buildings which should be comparatively earthquake-proof is a question that has been seriously and practically considered; is it possible that the next step must be to endeavour to make them tornado-proof? If there is any possibility of doing so, the Americans, who are at present principally subject to this scourge, are perhaps also the most likely of all people to have the spirit and ingenuity to make some serious attempt to secure themselves against its worst consequences.

THE last number of *L'Architecture Moderne*. M. Lenoir makes an exceedingly interesting communication in the shape of a copy of an original document in his possession, consisting of an order by Louis XIV. dated October 31, 1660, for the completion of the Louvre and Tuileries and of the gallery to unite the two palaces. M. Lenoir communicated the document a week previously to the Académie des Beaux-Arts, prefacing it by a short résumé of the main points in the history of the Louvre. The order itself is of so much interest that it is worth while to reprint it for our readers:—

"31 octobre 1660.—Ordre du Roy pour faire achever son Chateau du Louvre et estre joint avec celuy des Tuileries.

Extrait des registres du greffe de la prausosté de l'hostel de sa Majesté et grande prausosté de France.

Le Roy ayant resolu, par l'aduis de Monsieur le Cardinal Mazarin, son premier ministre, de faire achever jussamment tant le bastiment de son chateau du Louvre que celuy du palais des Tuileries, pour estre joint ensemble, suivant l'ancien et magnifique dessein qui en a esté fait par les Roys ses predecesseurs, et par cet effet donné ses ordres au Surintendant ordonnateur général de ses bastimens et à l'Intendant en exercice, de faire abattre dès à present tant l'hostel de Bourbon que les autres hostels, maisons et bastimens qui se trouveront dans l'enceinte du dit bastiment suivant le dessein. A commencer par ceux dont les places doivent servir pour en faire la fondation, et de faire faire le plus grand préparatif qui sera possible tant de pierre dure, qualités des carrieres de Saint-Cloud, Mondon, Vaugirard, Arcueil, Gentilly, fauxbourg Saint-Germain, et pierre tendre de Saint-Leu, Trossy, Tinoray et autres lieux et carrieres généralement par ceux dont les places excepter, chaux, sable, bois en charpenterie et menuiserie de toutes qualités, et autres choses et matieres nécessaires pour la construction des dits ouvrages, les quels matériaux seront pris et enleués dans tous les dits lieux ou ils se trouveront, en les payant raisonnablement, et d'autant que pour la prompte perfection des dits bastimens, l'Intendant de Sa dite Majesté est d'establir et dresser quatre grands ateliers royaux pour commencer à trailler, commençant au premier jour du mois de mars de l'année prochaine mil six cent soixante un,

ou plutôt sy le temps le pouvait permettre, et qu'il serait impossible de fournir suffisamment d'ouvriers ny de matériaux, en dits ateliers, s'il était permis aux particuliers d'entreprendre aucuns nouveaux bastimens, outre que cela retardoit entièrement le service et le plaisir de sa Majesté, et quelle desire que tous les ouvriers en quelque vacation qu'ils soient, qui se trouveront à Paris et aux Environs, mesmes ceux qui viendront des provinces, soient seulement employez et reçus es dits ateliers du Louvre en ceux de Vincennes, Val de grace, et autres bastimens et maisons de sa Majesté, et payés punctuellement de leurs journées au prix courant et au taux qui sera estimé juste et raisonnable, selon le cours du temps; et pour ses considerations, Sa dite Majesté defendit très expressément à tous particuliers, en quelque qualité et considerations qu'ils soient, sans unil excepter, d'entreprendre aucun nouveaux bastimens, ny faire aucuns reparatifs de matts-reaux; tant dans sa bonne ville et faubourgs de Paris que dix lieues à la ronde, sans permission expressé de sa Majesté signée de l'un de ses secretaires d'estat et scellée de son grand sceau avec attache du dit sieur surintendant des bastimens, à peine de dix mille livres d'amande payable sans desport à l'hospital general; et aux ouvriers de prison pour la premiere fois et de galères pour la seconde; mande sa dite majesté au dit surintendant et ordonnateur d'y veuë en exercice, de tenir expressément la main à l'exécution des présentes. Enjoignons au Sieur marquis d'Aligre, premier des finances et grand prestre de France, et Lieutenant civil de Paris et tous autres ses officiers et juges qu'il appartiendra, d'y tenir la main et donner l'assistance comme en chose qui regarde son service et son plaisir particulier, et afin que nul n'en présume cause d'ignorance, elle veut et ordonne que la présente ordonnance soit mise en public par affiches et affichés en public dans tous les lieux de la ville et es faubourgs accoustumés; Fait à Paris ce dernier jour d'octobre mil six cent soixante. Signé Louis et plus bas de Gueneaud.

Collations au huitième Registres des enregistrements du greffe de la préfecture de l'Hotel de sa Majesté et grande procureur au Palais, Nos 108 V et N° et V° 109 par nous procureur chef soussigné.

DEVOIGNE."

THE District Surveyors' Association have addressed to the London County Council a short summary of their opinion, expressed in five resolutions, in regard to certain clauses of the County Council General Powers Bill which have reference to the working of the Building Acts. The following are the terms of the resolutions in question:—

"Section 63.—APPEAL AGAINST CERTIFICATE OF ARCHITECT AS TO GENERAL LINE OF BUILDINGS.—It was resolved that approval should be expressed of the tribunal provided by this section, consisting of one member appointed by the Council, one by the R.I.B.A., and one by the Institution of Surveyors, and that the members thereof should only be appointed for a limited time, and reappointed from time to time, say every session, also that the Councils of the R.I.B.A. and of the Institution of Surveyors should be empowered to make the appointments.

"Section 64.—POWER TO AUTHORISE LARGER BUILDINGS WITHOUT PERMITS.—Resolved that this power should be limited to very special cases, and where such are approved by the London County Council, the reasons for the approval should be specified in writing with the approval, but in every case where such building or division thereof exceeds 210,000 cubic feet the construction shall be specially approved by the D. S., or in the event of disagreement, by the London County Council, who shall also appoint a special fee to the D. S. for the special labour and responsibility involved. Also that it is assumed that under this section a properly constructed fireproof floor or similar party structure should be deemed to form a sufficient separation between the divisions of the building, as in section 27, clause 2, of the Building Act, 1855. Further, that in view of the difficulties which have arisen by reason of there not being any definition in the Building Act, 1855, of the meaning of the words, 'Warehouse, or other building used for the purposes of trade or manufacture,' it is very desirable that the Bill should give such definition.

"Section 65.—BY-LAWS AS TO PRESERVING, &c.—Resolved with regard to Clause 1: That the supervision of the work referred to is not such as falls within the general duties of a D. S., but if the Clause became law provision should be made in the By-laws that proper notice should be given to him of such work. Resolved also that any By-laws would be subject to the same approval by the Secretary of State as under the Act of 1875.

"Section 69.—BUILDINGS ABUTTING ON MORE THAN ONE STREET.—It was resolved that the provisions of the Section would involve, in many cases, a sacrifice of property, and great injustice where the corner plot was owned by one person and the adjoining land in the side street by another, which has objects to be obtained do not appear to justify, and that they would induce owners to bring forward

their frontages in side streets more than they otherwise would, thus tending to lessen the total width of the space between the houses by shortening the forecourts or gardens.

"Section 72.—HEIGHT OF BUILDINGS.—It was resolved that the regulations should be confined to buildings abutting on a street, and that the height should be governed by the width of the street, as in Paris and other cities; that for any other building the limit should be extended by the distance they may be set back from the street up to a total height of 100 ft., as rules for buildings of that height are given in the Building Act, 1855, that the height should be measured from the crown of the roadway opposite the centre of the building, that the regulations should not restrict existing rights in rebuilding, that the limitation of height proposed would exclude important architectural features, such as towers, gables, dormers, &c., and that the section should be modified so as to allow them."

IN regard to the subject of accommodation for our troops, especially on the hut-system, it may be of interest to know that the German Government intends quartering one of the line battalions in a camp of twelve "pasteboard" huts. These huts, each of which measures 32 metres by 7 metres, have a skeleton, or rather framework of wood, the walls and roofs being of pasteboard, double, with an insulation of compressed peat and similar materials, which will tend to keep the cold out in winter and the heat off in summer. In spite of their somewhat fragile appearance, these huts are strong and well-made, and promise to be a success.

THE new "Asyl" which is about to be erected by the Italian Alpine Club, in memory of Prince Amadeus, on one of the points of the Southern Alps, will be by far the highest inhabited abode in Europe, its altitude above the level of the sea being some 4,000 metres, whilst the St. Bernhard Hospice has only 2,472 metres, and the meteorological station on the Pic Mezzogiorno only 2,870 metres. Asia and America, however, have settlements, and even cities, at the same and even greater heights,—for instance, Potoli, in Columbia, a town with 30,000 inhabitants, lies 4,900 metres above sea-level; and the gold-searchers of Thok-Jakoune in Thibet, numbering some 6,000, have their settlement at an altitude of 5,000 metres.

THE competition for designs for a new "Arts and Science Museum," at Dusseldorf, has been decided, the first prize falling to Herr Karl Hecker, of Dusseldorf, and the second to Messrs. Lieblein & Wiegand, of Offenbach. It had been generally expected that this competition would show some interesting designs, but, on the contrary, the jury had but a very poor collection to choose from, the majority of the forty-nine designs sent in being far below the usual standard.

THE cutting of the new canal in Sweden between the Categat and Lake Wener, or rather between the towns Uddevalla and Wenersborg, will be taken in hand as soon as possible, the Government having approved of the scheme. The new connexion, some twenty-five kilometres in length, is to have a depth of seven metres, and will hence permit ships of pretty large tonnage to pass,—a great advantage to the commercial intercourse between inner Sweden and the outer world. The export of timber will be greatly facilitated, and the large iron foundries in the interior will be specially benefited by this new water-way.

THE honour of being chairman of the jury to this year's International Art Exhibition at Munich has fallen to an architect, Professor Albert Schmidt. This is the first time that a member of the profession has held this responsible post, and this fact is all the more worthy of note since the Munich artists, among whose ranks painters are in a great majority, have up till now nearly always selected a painter for this function.

AMONG the list of proposed new monumental buildings for Berlin, one, a new home for the Prussian "Landtag," has lately

again come to the foreground; but owing to practical reasons it will scarcely be possible to think of erecting this building till the members of the Reichstag have taken quarters in their new house on the Koenigsplatz. A second scheme much talked about of late, the new building for the Academy, or rather the proposed buildings for the Academy proper at Berlin and for the Academy-Schools at Charlottenburg, is as yet but in its initial stage, neither sites nor programmes having been definitely fixed. A well-known Berlin architectural firm is, however, working out a series of sketch designs for the Berlin building, which are to be laid before the Emperor for approval; and a second firm of repute is working out a design for the Schools at Charlottenburg on a site in close proximity to the buildings of the Royal Technical College.

IT is proposed, as we read in the *Daily News*, to set up a stained-glass window in the parish church of St. John the Baptist, Mersham, near to Ashford, in Kent, to commemorate the rectorship there of one who may be legitimately designated as father of the medical profession in this country. Thomas Linaere, physician, scholar, and priest, the friend of Lily and Melancthon, was born circa 1460, and it is supposed, in Canterbury. Having studied at Cambridge, Oxford, Padua, and elsewhere in Italy, he was appointed tutor to Arthur, Prince of Wales, and is said to have instructed Erasmus and More in the then "new learning," viz. Greek. Two years after he had founded at his own house, since known as "The Stone House," No. 5, over against Bell-yard, in Knightrider-street, the College of Physicians, Linaere took orders, and for awhile held preferments in Wigan, Aldington, and at York Minster. Dying on October 20, 1524, at his house in Knightrider-street, which he devised to the College, Linaere was buried in Old St. Paul's, where, near to the north middle door, Dr. John Caius erected a monument to his memory. The inscription ended thus, "Thomas Linaere, clarissimo Medico, Johannes Caius, posuit anno 1557." Mersham Church was restored in 1877, *e curis* Sir Wyndham Knatchbull, bart., and the Reverend R. Knatchbull-Hugessen, rector. It contains several memorials to the Knatchbull family, who were seised of the manor of Le Hasted, in this parish, temp. Henry VII., *vide* Hasted's "Kent," Vol. III. (1790). In Dr. William MacMichael's little work, entitled "The Gold-headed Cane" (1827) will be found a notice of Linaere's portrait, therein ascribed to Holbein, as being then at Kensington Palace*; and a wood-cut, since reproduced in Vol. I. of Walter Thornbury's "Old and New London," of the house we mention. Dr. William Monk's edition (1884) of "The Gold-headed Cane" contains an account of the silver caduceus which Caius presented to the College for its President's use.

ON Saturday last the congregation of the Great Synagogue in St. James's, formerly Duke's, place, Aldgate, celebrated the hundredth anniversary of the building of their place of worship. That community of German and Polish Jews known, we believe, as the Ashkenazim, settled here in 1692. The present building, which, by the United Synagogue Act of 1870, was thenceforth to rank as the Great Synagogue, had supplanted the building that, in 1722, was built in place of one which Moses Hart had erected for their use in Broad-court, Duke's-place. It should not be confounded with the neighbouring synagogue for Spanish and Portuguese Jews, or Sephardim, in Devis Marks, as re-built in 1701, and which is associated with the memories of the late Sir Moses Montefiore and the Disraelis. We gave an account of this letter in our columns of January 30, 1886, upon the

* It is that the portrait which, seventy years ago, used to hang in Queen Caroline's Dining-room, and has been ascribed to Q. Matsys!

occasion of the migration of a portion of the congregation to a new synagogue in Bryanstone-street, Bryanstone-square.

PERHAPS it is with a consciousness that their works are best seen and appreciated in a half light that the members of the New English Art Club have chosen to have their exhibition this year in the rooms at Humphreys' Mansions, which are almost entirely destitute of such a light as pictures are generally supposed to need, and in which half the works are seen in shadow. Thus Mr. McLachlan's evening landscape, "When the Dew Falls" (133) is in a twilight corner which perhaps materially assists the effect the painter desired, and has not been unsuccessful in producing. Other works are less assisted by these conditions, and are so lighted that it is difficult to form any judgment of what their effect might be in a proper light. In regard to some of the best works there it may be said that if the New English Art Club is supposed to consist of artists who are "in search of truth" (so we read somewhere), they seem to have stopped half way in the search. Miss Mackay's "Quiet Chat" (10) shows at a little distance a very expressive character in the attitude of the two figures: is it really any better for the fact that on a nearer view neither features nor hands can be made out? It is an unfinished sketch for a picture, that is all. Mr. Roussel's portrait of a little girl (13) is fine in colour and the expression of the head, but the hands are two lumps of dough. Mr. Sickert's portraits of Miss Fancourt and Mr. Bradlaugh (9 and 27) are powerful sketches on a large scale: nearly all the larger works are sketches on a large scale. "Is this 'terewth'?" we may ask. Or is it truth to paint a portrait of a girl with a wooden head—*vide* number 148; poor "Lily"! Truth seems to us to be realised mostly in some of the small landscapes; Mr. Paterson's "Seascale" (132); Mr. Laidlay's "French Village at Evening" (19); Mr. T. M. Dow's "A Northern Shore" (2); this latter is a study of breakers and foam on the shore on a bright and breezy summer day, which is remarkably true in the movement and lines of the water, though the foreground shallows seem rather destitute of the reflected lights which should be seen from the film of water. However, this is a very clever work. There are other landscapes or landscape and cattle-pieces which have an idyllic sentiment, towards which it seems to be thought that the omission of detail contributes. Hence the members of the club seem to lean much towards twilight scenes, which can be treated conformably with their aims. There is a cleverness in all this, combined, to our thinking, with a very pronounced affectation.

WE would commend to the attention of builders' clerks a statement made by Mr. H. H. Bartlett when presiding at the annual dinner of the Builders' Clerks' Benevolent Institution on Monday, to the effect that last year the Institution's income from invested funds and annual subscriptions did not suffice by about 120*l.* to meet the working expenses of the year, in consequence of which the Committee had to trench upon the donations given at the annual dinner last year, which they would have preferred to add to the invested fund. The Institution is doing, and has done, admirable work since its establishment, and is very economically managed. The Committee would be very glad to see a large increase in the number of members and annual subscribers. The annual subscription is but half a guinea, and there must be hundreds, if not thousands, of builders' clerks who are not members of the Institution. The offices of the Institution are at 21, New Bridge-street, Blackfriars, E.C., and Mr. H. J. Wheatley, the Secretary, would be very glad to answer inquiries. Master builders could do much to help the Institution by bringing its claims to the notice of their clerks.

THE April number of the *Art Journal* contains, under the title "An Old English Homestead," an illustrated article on that peculiarly English house, Moreton Old Hall. The illustrations are reproduced from photographs by Mr. R. Keene, the author of the article. The *Portfolio* continues Mr. Clark Russell's articles on "The British Seas," with various sketches by Mr. J. R. Wells, and a reproduction of a sea-study by Mr. Henry Moore. Mr. Armstrong contributes an article on the work of Mr. Onslow Ford (one of a series on English sculptors of the day), with illustrations, including a fine separate plate of Mr. Ford's figure "The Dance," a commission from an Indian Maharajah, along with a companion figure of "Music," of which a smaller illustration is given, and which is a very original work. At the close of the article Mr. Armstrong speaks strongly, and with reason, of the neglect of English sculptors by the Government:—

"In our English public buildings, we have niches and pedestals by the hundred, preparations made by the sanction of Government for statues which never come. The Houses of Parliament, the offices in Whitehall, the bridges, the Victoria Embankment, the Royal Courts of Justice, all these are besprinkled with empty perches, which at present are simple disfigurements. Some, of course, are waiting for statesmen or soldiers. But the vast majority belong so intimately to the architectural scheme that they could not be rightly abandoned to iconic figures. Why should not a certain number of these be filled each year?"

Why, indeed? The French Government or the Paris Municipality would have set themselves to such a work as a matter of course; but in England it would be scouted, probably, as idle extravagance.

LETTER FROM PARIS.

THE Parliamentary Committee for examination of the scheme for the maintenance of the Champ de Mars buildings did not report in a very favourable sense, and found that the maintenance of the Galerie des Machines, the central dome and its gallery, would alone involve an annual expenditure of about 160,000 francs. The Committee reported also, not without reason, against the idea of making buildings of this kind serve for another exhibition, as the novelty of decorative effect is one of the principal attractions of this kind of entertainment. This was the opinion of M. Antonin Proust and M. Georges Berger. In spite of these and other good reasons the Municipal Council, carried away by the eloquence of M. Alphand, has voted the maintenance of these structures and the transformation of the Champ de Mars into a public garden traversed by a new road connecting the Avenue Suffren with the Avenue Bourdonnais. We shall probably this summer, therefore, see the terraces and fountains illuminated by electric light as before.

The exhibition of the "Salon Meissonnier" to be held in the Palais des Beaux Arts of course gives some additional public interest to this scheme, and in order to prove to the artists that in spite of the distance they are much better off here than they would be in the Palais d'Industrie, M. Alphand is prodigal of his favours to the new society, and is disposing of the municipal conservatories in order to transform the Avenue Rapp into a great winter garden.

The Jury of Painting of the new Salon has elected M. Carolus Duran as its President and M. Galland as Vice-president. The reception of works of art, which was originally fixed for March 1 to March 8, has been postponed to April 12 for painters and the 22nd for sculptors. The old Salon does not seem to have suffered so far, at all events numerically, by the rivalry of the new one. The Jury of Painting, presided over by M. Gerôme, assisted by M.M. Dusson and Jean Paul Laurens as the Presidents, has terminated its laborious operations. It has been unusually severe, it is said, in its judgments this year, and has refused many painters who have been received in former Salons. 2,250 pictures have been admitted. The numbers offered have been nearly the same as last year, amounting to the respectable total of about 7,000.

In the meantime the Musée des Arts Décoratifs has just opened an exhibition in the Champs d'Élysées building, comprising about 400 works purchased from the universal exhibi-

tion of last year. At the same time, the exhibition of the "Artists Independents" has succeeded to that of the "Femmes Peintres et Sculpteurs" in the Pavillon of the Ville de Paris. As usual, this exhibition is an odd affair, and one finds really interesting work mixed with the oldest fancies both in pictures and frames: though on the whole, among the 800 paintings exhibited, there is less extravagance than in last year's exhibition.

While the second exhibition of "Peintres-Graveurs" is being held at M. Durand Ruel's gallery, the "Cercle Volney" is holding also its annual exhibition of about 200 works. M. Munkacsy on his part is exhibiting to the public the design for the ceiling which the Austrian Government has commissioned from him for the Museum of History and Arts at Vienna. The painting is of colossal proportions, and represents the apotheosis of the Italian Renaissance. In spite of its popular success with "tout Paris élégant," we are obliged to confess that, while exhibiting some fine decorative qualities, the artist has not altered or improved either the hardness of execution or the crudity of colour which characterise his ordinary work.

The pictures and studies of the lamented painter Protais have been dispersed at a general sale, after having been exhibited publicly for many days. We found among them the finest sketches for more of his well-known pictures among them the "Halte d'Infanterie," the "Manœuvres d'Artillerie," the "Chasseurs à pied à Saint Trivoux," the "Regiment en Marche," and other pictures well known from engravings, and which reflect the ardent patriotism of their author, who was not only a fine artist but a brave and loyal citizen.

The Committee of National Museums has now come to any definite conclusion in regard to Manet's "Olympia" picture, to which we have before referred. It has confined itself to expressing an opinion against admitting this sensational painting to the Louvre, and in favour of admitting it to the Luxembourg, but without any promise one way or the other. This undefined position will perhaps leave some room for the operation of public opinion in the matter. The attitude of the authorities is quite otherwise in regard to Courbet, once such a subject of dispute, but who now enters vigorously into the Louvre before even the regulation ten years have expired since his death. It is melancholy to add that Art has nothing to do with this decision, and that it arises from political feeling and a desire to reward Courbet for his hostility to the Empire. This is why the Louvre already possesses the famous "Enterrement d'Ornan," a picture disagreeable in colour and careless in execution, and will soon have another picture by the same artist, the "Remise des Cleverouils," which a group of admirers has combined to purchase. This work however is infinitely superior to the latter.

The Louvre has just been enriched with a fine picture by Bonington, a portrait of an old woman. There are up to this time only nineteen oil paintings of the English school, among which are four Boningtons, "Francis I. and the Duchesse d'Étampes," "Mazarin and Anne of Austria," a view of Venice, and a sketch of the Park of Versailles.

We are happy to add that, thanks to M. Guillaume, the Louvre galleries have been much improved recently in regard to comfort and that the ground-floor especially is now given up to the cold which made it in winter almost impossible for artists and students to draw. The Museum of the Renaissance was also shortly to be enlarged by two new saloons; in a few days the Tunisian collection will be open to the public, and the square built last year on the site of the Tuileries will be the object of numerous embellishments. The fine group by M. Mercié, entitled "Quand Même," will be placed a few steps from the triumphal arch of the Carrousel; numerous statues will decorate the grounds, among which will be the "Exiles" of M. Mathurin-Moreau, published in the *Beillevue* last year.

The work at Versailles is being continued under the superintendence of M. Marcel Lauxbert. The restoration of the "hassin du dragon" has just been terminated, by M. Tony Noël, in accordance with old documents which have furnished evidence as to the original intention.

The bronze casting of the monument to General Lafayette, just completed, has been on view at the foundry. It is about ten mètres high, with a granite plinth, on which is a white marble pedestal supporting the statue. On the

principal face of the monument is a bas-relief of a female figure presenting a sword to the General; on the reverse face a cartouche supported by two figures of children. Bronze statues representing Lafayette's four companions in arms are grouped, two on each side, on the lateral faces; Rochambeau, Du Portal, de Grasse and Estaing. The statues are the work of M. Falguère and M. Mercié, the pedestal is designed by the architect M. Pujol. Another memorial statue, that to Paul Bert, is exhibited temporarily on the Place de la Sorbonne, and is to be transported to Tonkin to be erected at Hanoi. This is the design of M. Paul Lenoir, author of the Berlioz statue on the Place Vintimille.

Various public works of some importance are under discussion. The rebuilding of the Mairie of the Eighth Arrondissement has been put up to competition, though it is thought by some that it would have been wiser to have adopted the design made some time since for this purpose by M. Hermant, an architect whose ability is unquestioned. Another competition has been opened for the construction in the Faubourg St. Antoine of a school of furniture design, very usefully placed in this quarter, which is almost entirely inhabited by cabinetmakers and upholsters. The works of the new hospital in the Faubourg St. Germain are also to be shortly commenced, thanks to the liberality of M^{me}. Boucaut.

The Church of the Sacré Cœur has been relieved of its great scaffoldings, and now presents an entirely new appearance. As soon as the fine weather comes the work of vaulting the nave will be commenced, a piece of work which will hardly be completed within the year.

Another question of the moment is as to the proposed removal of the École Polytechnique to St. Cloud, to the site of the Palace burned in the Franco-German war. This is not the first time the removal of the École has been mooted; and in 1871, just after the war, there was a talk of rebuilding it where the Trocadéro now stands. Probably the same reasons then given against the change will operate now. No doubt the present building is too small, too old, and in the midst of a crowded and not too sanitary neighbourhood. But these drawbacks may be corrected, while the removal will involve so much inconvenience and interruption of the work that it is probable the Government will confine itself to improving the present building, isolating it by large streets bordered by new buildings, where the amphitheatre, laboratories &c. can be commodiously arranged. Something of this kind must be done soon, for the present building, erected in 1794, and which occupies the sites of the old colleges of Navarre and Boncourt, is no doubt too restricted for present requirements.

The Académie des Beaux-Arts a few days ago proceeded to the election of a member to replace the late M. Diet in the Architecture Section. After six "tours de scrutin" M. Normand was elected by 16 votes out of 31. M. Ancelet had 8 votes, M. Pascal 5, and M. Dubet 2. The new Academician obtained the Prix de Rome in 1846, a first medal in the Exhibition of 1855, the Cross of the Legion of Honour in 1890, and a second medal in the Exhibition of 1878. It was he who designed for Prince Napoleon the pretty Pompeian house in the Avenue Montaigne.

At the Écoles des Beaux-Arts the prize founded by the American architects in favour of French architects has been awarded to M. Bauchain, pupil of M. André.

In consequence of frequent abuses, the Académie des Beaux-Arts have come to a serious decision in regard to the former pensionnaires of the Villa Medici having the enjoyment for three years after their return to Paris of the pension founded by the Comtesse de Caen. Henceforth this bounty, which amounts to 3,000 francs for architects and 4,000 for painters and sculptors, will not be accorded except to those who have executed a work worthy of a place in the museum to be founded for that purpose by the generous benefactors.

This last month has witnessed the death of two sculptors. One of them, Adolphe Leofanti, who exhibited in the last Salon a bust of M. Jules Simon, has committed suicide for reasons unknown, but supposed to be connected with family troubles. He was a conscientious and hardworking artist who unfortunately met with very little success.

The other sculptor, M. Oliva, who has died

at the age of 66, had a certain reputation under the Second Empire. He obtained medals of the third class in 1852 and 1855, and a medal of the second class in 1861, and the Cross of the Legion in 1867. Among his most remarkable works are the statues of Napoleon III. and the Empress, those of Alphonse XII. Cardinal Guibert, Marshal Macmahon, and "The Message," a work which figures in the Louvre. M. Oliva had great talent and facility in his art, and excelled especially in portrait-statues and busts. It is to him we owe the bronze statue of François Arago, exhibited in last year's Salon, and which is to be erected in Paris.

THE MEDIEVAL HOUSE.*

THE first impression which this subject makes upon any one who tries to grapple with it is its unmanageable extent. To try to indicate with anything like definite precision how our forefathers and their contemporaries lived in Europe during several centuries of constant change, would be a task impossible within the limits of an hour's lecture, even were it within my powers at all; and the first step must be to set bounds to the range of our enquiries. First, then, I propose to omit all mention of religious houses. As far as is possible, I shall also omit the castle. It is true that the castle was the home,—and the only home,—of many noble and gentle persons in the Middle Ages, and of vast numbers of retainers, and that it was at last turned into a very commodious dwelling; but still it was so much influenced in its arrangement and build by military considerations that we need hardly scruple to do this. Lastly, I propose not to travel far from home. English examples fail, I must admit, in several particulars to give a complete series of domestic Medieval buildings, or groups of buildings; and we can hardly avoid going to France to fill up gaps; but it will not be necessary to go any further afield, and, as far as possible, the subject will be treated with reference to our own country only.

In one respect,—that of time,—however, the lecturer must be allowed to overstep the limits that the title seems to prescribe. Houses of Medieval character continued to be built here for long after the real close of the Middle Ages, and these, being the most recent, are the most numerous and the best preserved, so that we shall be unable altogether to exclude sixteenth-century, and in some cases seventeenth-century, work.

Dwelling-houses have seldom been built with anything like the solidity of churches and cathedrals; consequently, they have not withstood the tooth of time so well. They are, far more than churches, exposed to damage from fire, and also to plunder and devastation in time of war or civil strife, and to so-called improvement in time of peace. Fortunately for the students of Medieval architecture, church alteration and church building practically came to a standstill in this country after the secularization of the vast revenues of the Church by Henry VIII., but it was far otherwise with houses. Every owner of a historical house has felt at liberty, and in too many instances has been rich enough, to alter, pull down, rebuild,—in short, modernize after his lights,—the dwelling of his ancestors; and this has occurred more thoroughly still with the smaller, less substantial, and often less convenient houses in towns, so that we have nothing now left but what accident or chance has preserved in the shape of scattered and often incomplete specimens of the more early Medieval house.

I propose to speak to you first about houses in towns, and then about houses in the country,—the simplest division of the theme it seems possible to introduce.

First, then, as to houses in towns.

The Middle Ages, it must not be forgotten, was a period of great and constant strife, and life and property were insecure to an extent that we cannot easily realize. Accordingly, the shelter of fortified towns was sought by persons who had anything to lose. Towns were content to dwell in small and crowded houses for the sake partly of protection and partly of the opportunities for trade which a town afforded. Of Saxon houses we have no remaining specimens, and next to no traces; but some

information can be gleaned from ancient writers and the illuminations of old manuscripts. Ordinary dwelling-houses in towns are believed to have been small, built of wood, thatched, in most cases of one story, and often consisting of only one room,—in short, huts,—and with the fire on a hearth in the middle of the floor, and the windows closed only by shutters. Representations of palaces give, however, some reason to suppose that the kings and influential thanes had, even then, houses built of masonry, and with some attempt at decoration.

In the Norman period houses seem to have been built in London and Winchester, and presumably elsewhere, of much the same material, though probably mostly of two stories. A very curious piece of documentary evidence upon this head remains in the Assize of 1189. This name is given to a formal document, the result of an inquiry by a jury of twelve citizens of London, elected in what, I suppose, would correspond to the common hall of the present day,—"*in pleno hustingo*,"—to regulate building disputes. This document arranges that two adjoining neighbours who desire to build shall erect a party-wall of some 3 ft. thick and 16 ft. high between them, each man giving up 18 in. of his ground for it to stand on, and that either party may carry bis half of the wall to a greater height if he wishes. It will be noticed that the height of such a wall would suffice for two low stories, and that the provision for heightening seems to point to the occasional habit of using three or more floors. Almost the only English examples of masonry houses of this early date occur at Lincoln, where one very well preserved small house, known as the Jews' House,* still exists. The doorway and two upper windows, of good and somewhat rich Norman architectural character, remain. There were, apparently, only two rooms in this house, and the fireplace of the upper room is curiously corbelled out over the entrance door. A peculiarity worth noting is that this house does not present a gable to the street, but has gables at the sides, so that the eaves of the roof overhang the street pavement. Remains of a larger but less perfect Norman house, also of masonry, often known as John of Gaunt's Stables, also exist at Lincoln.

Of town-houses of Medieval architecture we find far more examples remaining in France than in England, probably because the greater activity in English towns has caused more rebuilding; indeed, in our own day in some of the French towns (such, for example, as Rouen), where manufactures have gained ground, the remaining old houses have been swept away by the score. There was very frequently, especially in the wine-growing parts of France, a vaulted cellar, usually reached by steps from the road. The ground-story was often, even if it were a shop, raised a little above the level of the pavement. The house was usually narrow and deep, and very often had a gable end towards the street. Partition-walls, such as those referred to in the Assize of Stephen's reign already cited, often existed, but sometimes each house was distinct, and a very narrow space separated it from its neighbour. The front wall next the street was mostly of masonry in the ground story, and if the house were for business purposes there would be a wide window and a door besides. Above this the front was generally of what is termed half-timbered construction; and there was usually a first floor and a story of attics, though sometimes the house was carried to a greater height. Where there was not a gable end to the street there would be dormer windows to light the attics. The general disposition or plan of a small house of this sort was simple enough. There would be on the ground-floor the shop (or a room, if no shop) and a staircase, a yard behind, and a low building in that yard used as a kitchen. The best room in the house was the first-floor room, occupying all the space between the walls; it was used as a living-room, and partly a sleeping-room also, and with a fireplace—a luxury not always introduced below. The upper floor, or floors, would be divided by internal partitions into smaller rooms. Sometimes, where more space was occupied, a more ambitious programme was attempted; but the one principal living-room on the first floor was almost always a prominent feature in the arrangement of the house.†

The point in structure to which attention should be first drawn is the half-timbered con-

* A lecture delivered by Professor Roger Smith at University College, London, as part of the Course of Archaeology now being given there.

• Illustrated in Parker's "Domestic Architecture," vol. i. p. 40.
† Illustrated in Viollet-le-Duc, "Dictionnaire," art. Maison.

struction already referred to, and which was largely employed both in France and England, and in town and country alike. A very few specimens of it linger in London, the best being the upper parts of some houses on the south side of Holborn, nearly opposite Gray's Inn-road, which have recently been carefully cleaned and repaired.

What may be described as timber walls were in use through several centuries. They were thus built: on the top of the stone-walling, which served as a base, and was sometimes a mere foundation, or at other times a wall the height of a story, a strong horizontal timber was securely laid. This was what a carpenter would call a wall-plate. The ends of a series of sturdy upright timbers standing side by side are let into this plate (tenoned into it), and at the top of them a second horizontal timber is secured in the same way. The lengths of the upright timbers and thickness of the horizontal pieces are so adjusted that, including the two plates, the whole equals the height of a story. The floor-joists, which were heavy timbers, rest on this framework, and generally are made to overhang. A second series of upright timbers forms the main structure of the next story, which rests on the ends of the joists, and so on to the top. There are sundry minor variations in procedure, as, for example, in early times—say, the twelfth century—the timbers were close together, forming a wall wholly of timber, like that of a Swiss chalet. Later on, they were placed some distance apart, and the spaces filled in with plastering. At a late period panels so formed were sometimes occupied by tiles, and sometimes with wood-work. There are several modes of managing the overhanging of the upper floors, and diagonal or horizontal pieces are sometimes introduced for the sake of architectural effect. The gables are generally finished with a richly ornamented deep rafter called a barge-board or verge-board, and sometimes with carved timbers; and the dormer windows, when they occur, are often charmingly treated. Altogether, no manner of building can well be more picturesque or more thoroughly domestic in its appearance.*

Much building of this sort remains in country places in England, though most of it belongs to that group of buildings already alluded to as in quality Medieval, though built after the Middle Ages had closed. There is a group of half-timbered halls and manor houses in Lancashire and Cheshire especially worthy notice, including some answering to this description, and others genuinely Medieval. In towns a few specimens only of timber construction now survive. Tewkesbury, Coventry, Salisbury, Shrewsbury, Exeter, are among the places where examples of this work still linger. In constructing corner houses with these timber-framed walls it became usual to employ a very strong corner-post of bent timber, and to carve it richly; and in some cases (as, for example, at one or two street-corners at Colchester), where the timber-framed wall has been replaced by a modern one of brick, the post has been still retained as an ornament.

Occasionally, especially late on in the Medieval period, a dweller in a city secured a large plot of ground and erected a stately town-house. In London, Crosby Hall, in Bishopsgate-street, alone remains to show a few traces of what such houses were. It was a splendid pile erected by Sir Thomas Crosby, who died in 1475, and it was at one period the residence of the famous Sir Thomas More. This building, fortunately, escaped the fire of London, and its exterior is an interesting specimen of rich fifteenth-century domestic architecture, largely carried out in timber. Crosby Hall has fallen on evil days, and is now, alas! occupied as a great City dining-rooms, and has been varnished, painted, and done up in various ways with Modern Gothic, but still it is the best, almost the only, example of a Medieval town-house of the first-class remaining in London. Some remains of Medieval work also linger in the Deanery at Westminster and at Lambeth Palace, and some favour of Medieval character hangs about the Charterhouse.

For better, however, as a specimen of such a building is the Hôtel Cluny, at Paris, a place which every traveller goes to see, as it is the French South Kensington Museum. This is a town mansion of great beauty, kept up in a perfect state of repair, and filled with the

finest examples of Medieval furniture and curiosities.

The Hôtel Cluny* was built at the very end of the fifteenth century, and is in the French style of that period, a style often neither so dignified nor so regular as our own Perpendicular, but well and soberly treated in this example. The site is a large irregular plot, and the palace was set down so as to leave an entrance courtyard next the street, and a formal walled garden in the rear. The court is jealously shut in by a high wall, and when you pass the doorway you find facing you the principal building—three stories high, and with a rich octagonal turret staircase projecting from the front. A kind of ante-loggia on the left gives access, through an open room, to a range of four noble and very spacious rooms, opening out of each other. These, with two other adjoining ones, not *en suite* with them, form the state part of the house, and the same arrangement is repeated on the two upper floors. Detached from this block there are also a porter's lodge and a kitchen, and opening on to the garden there is a kind of vaulted open hall, over which, on the next floor, comes the chapel. Dignity, grace, and elegance combine well in this building, and the richly-carved chimney-pieces, with their fire-dogs, the panelled walls, and timber ceilings, the windows with their mullions and transoms and rich glass, and the fine floors laid in patterns, combine to give a great air of luxury to the interior. Famous as a more extensive and ambitious Medieval house is one at Bourges, known as the House of Jacques Cœur,* of which illustrations are to be found in most books on the subject.

Of Medieval towns some, in England, and a few in France, follow the lines both of the roads and walls of an earlier Roman town. The Romans always planned a fortified town (as they did their camps) four square, with a gate in the centre of each side and two main cross-roads cutting up the enclosed space into four equal squares. This description applies to Chester, to Dorchester, and to Colchester. In the first-named city the walls were rebuilt in Medieval times, and remain perfect. In the other two the Roman walls were retained, and portions of them still exist. At Colchester there is even one of the Roman gates still standing. A Medieval town was, however, usually irregular, with narrow, winding streets and many small houses crowded into the fortified enclosure whose outline had been dictated by the shape and levels of the ground rather than by convenience. The finest existing example of such a town is Carcassonne, in the South of France, where the fortifications still remain as perfect as in the fourteenth century. Not so far off from England, and but little more modernised, is Mont St. Michel, on the coast of Normandy, probably the most picturesque spot in Europe, and like Carcassonne retaining its fortifications. I do not think I can point to any English city quite parallel to these, though the older streets of several of our cathedral towns are not unlike bits of them.

Perhaps the best idea of what a Medieval town looked like which we can get in England is obtained by visiting Chester. Here the fortifications remain; most of the houses have gables to the street, and many of them have ornamental woodwork, while a most picturesque and unusual arrangement of footpaths two storeys in height gives a great air of quaintness to the streets. It is true that almost all these buildings date from a period later than the Medieval time, but they have been rebuilt one by one as necessity arose, but they retain their gables, with barge boards and overhanging upper stories, and even the most recent have been built with care and taste, so that the antique flavour has not been entirely lost.

In the Middle Ages there were also a few brand-new towns established, just as Alexander the Great set up Alexandria on an absolutely new site, and laid out with formal exactness. During the English occupation of a large part of France, Edward I. founded several such towns, as, for example, Libourne on the Gironde, not very far from Bordeaux, and Montpazier, Winchester was a new-built town, founded also by Edward I., and was extremely regular in its plan, though not quite so formal as Libourne,

Houses in the Country.

When we pass from town to country we find ourselves on more familiar ground, the examples—especially the English examples—are more numerous, in better preservation, and more in-

teresting. They chiefly, however, date from the fifteenth century or later, and as it is not possible to go very far into dates and differences, I will ask you to bear in mind generally that the later in date the example, the more complete, but also the more complicated will its arrangements be; that the earliest houses, so far as they can be found, are those that exhibit the essential features of an English country house in their bare simplicity, and that each century witnessed a large increase in domestic comfort and even luxury in the extent of the buildings erected.

The distinctive feature,—the one apartment essential to an English country house,—was the hall. In that delightful poem in prose and verse, "The Wolfings," Mr. Morris has drawn a picture of some primitive clan apparently akin to our Saxon ancestors, whose great hall was at once their pride and their place of meeting, feasting, and living, and so it was in our own land.

Probably in this country there once were houses which were literally a hall and nothing else. In very remote days, cooking took place at a fire on the hearth in the middle of the floor, and the hall was sometimes the place where it was done, while it then, and long afterwards, served as the living-room and sleeping-chamber of most of the folk. Two other rooms at least were, however, generally met with, even in remote times, and always in days of comfort. One was the kitchen, the other the solar or parlour, a room which afforded some retreat for the lord, or his family, from the noise and drunken revelry which, I fear, was only too prevalent in the hall.

The hall was always spacious and lofty in proportion to the general run of the house. It usually had an open roof, and the framework of the roof was often richly moulded and ornamented. A portion of the floor at the upper end of the room was slightly raised and was called the dais. On this was a mighty oak table with benches, at which sat the lord and his family and guests; the retainers, servants, and others dined below the dais. There was often a grand bay-window in the hall, which usually was at the end where the dais occurred. There was always a fire, either on a hearth on the floor or in a fireplace at the side of the hall. There was very often a gallery, in which at festivities musicians could be stationed. This generally crossed the lower end of the hall, and at that end there was (usually under this gallery) a passage carried from side to side, often behind a screen. Before the music gallery became common the division between the passage and the hall was usually carried up to the roof of the hall, and there was often a wide arched opening in the centre of it, the whole stoutly formed of timber. To the sides of this opening the name of "the speers" is given.

This national feature extended from private to corporate and public buildings. The halls of the principal colleges at Oxford and Cambridge, those of Hampton Court, Windsor, and Ethelham palaces, are and were fine and large structures; so are those of the Inns of Court, among which the notable Middle Temple hall is pre-eminent. All these lead us up to Westminster Hall, with its great hammer-beam roof, unrivalled in Europe.

Next the dais, and usually immediately behind the hall and up a few steps, was the solar or parlour. This apartment had more comfort than the hall must often have afforded. A very fine example of the solar is the Jerusalem Chamber of the Deanery at Westminster, which is the solar—as the boys' dining hall is the hall, of the house of the Abbot of Westminster. Below the floor of the solar was usually the cellar. Near the lower end of the hall but separated from it by the passage already alluded to, was the kitchen, with, in a large house, sundry pantries, larders, and store-places, and a battery hatch, from which provisions were given out. A Medieval kitchen is often vaulted, and almost always a noble room with a vast fireplace.

In addition to these three rooms most houses contained some other rooms for service and for sleeping, but the amount of accommodation varied, and, in most cases, such extra rooms were added on at a later date as required.

In many cases the house was protected by a moat, that is to say, an artificial deep ditch, some 10 ft. or 12 ft. wide, and full of water, and was approached by a drawbridge. It was usual (I think invariably) to arrange a moated house as a square block, with a quadrangle in the centre, and other houses were not infrequently

ST. VICTOR.
VIEW FROM THE EAST.

PHOTO LITHO. SIMMAGE & CO. 52 MARTIN LANE, LONDON E.C.

so planned, or were made to take the shape of three sides of a square, but in this respect practice varied.

Wardley Hall, near Worsley, in Lancashire,* is a good example of a moated manor house. It is a quadrangle, singularly irregular in shape, owing, apparently, to the irregular shape of the land enclosed by the moat. Wardley Hall is believed to have been built in the time of Henry VI., 1422-1460, that is to say, the middle of the fifteenth century, and to have been originally wholly of half-timbered construction, though it has been altered and, to some extent, defaced in later times. There is a gate-house at the north side of the quadrangle, in front of which used to be a drawbridge. Part of the gate-house was used as the chapel. The south side is occupied by a hall, about 40 ft. by 21 ft., with bay and great fireplace and passage. The east wing is the servants' wing, and contained the kitchen and dependencies; the west wing is the family wing, with solar or dining-room and withdrawing-room. The wings and gate-house were of two stories. The present staircase is of the seventeenth century,—it probably replaces an earlier one of smaller size. The chimneys are of brick.

Many country houses were, to some extent, fortified, and, even if they had not the protection of a moat, were made strong enough to resist the attack of a party of freebooters, at a time when gunpowder was not yet known. It was requisite to get a licence from the Crown before you added battlements and such-like military features to your house, and the licences to crenellate, as they are called, still exist among the public records, and are often of great value in fixing the date of the erection of a house.†

THE ARCHITECTURAL ASSOCIATION VISITS:

THE NEW HOSPITAL FOR WOMEN.

This latest addition to the hospitals of the metropolis, which is now being completed from the designs of Mr. J. M. Brydon, in the Easton-road, was visited on Saturday afternoon by a party of members of the Architectural Association, under the guidance of the architect.

The staff of this institution for the treatment of diseases of women and children will be composed entirely of women, and attached to the hospital a small number of lady students will receive a medical training, which many of them will put into practice in the zenana of India, from which medical men are so rigidly excluded.

The building, in comparison with other metropolitan hospitals, may be termed a small one, but efforts have been made to make the arrangements as complete and perfect as possible.

The site of the building is extensive, and will, probably, in due course, be bounded on the west by a new street. Part of the site will be laid out as gardens for the use of the patients.

The group of buildings consists of three blocks, a rectangular ward block, another rectangular administrative block with a circular ward block behind it.

The ground-floor of the front block is occupied by a library for students, and a large entrance-hall. Rectangular wards occupy the two floors above, and nurses' bedrooms the uppermost floor.

The administrative block has the drug, convalescent, and consulting rooms, with out-patients' waiting-rooms conveniently arranged, whilst the nurses' rooms and the kitchen are on the upper floors.

The arrangements for heating and ventilating the wards and the rest of the building have been carefully planned. Fresh, warm air is introduced through the stoves, which occupy a central position in both circular and rectangular wards, and through the hot-water coils placed under the windows, whilst extract ventilators, with Bunsen burners, are provided to carry off the vitiated air.

The floors of the wards are of fireproof construction, and covered with carefully-laid wood-block flooring.

The arrangement of the light which pervades all parts of this building cannot be too highly praised. The building seems well suited to meet the requirements, for which it has been carefully designed from a utilitarian standpoint.

* Illustrated in Henry Taylor's "Old Halls of Lancashire and Cheshire."
 † The conclusion in our next.

Sketch-Design for a Sundial: by M. Armbruster.

SKETCH DESIGN FOR A SUNDIAL.

It was mentioned in our "Letter from Paris" of February 1 that the subject of a "cadran solaire" had been set for the students' competition in decorative design at the Ecole des Beaux-Arts, and M. Armbruster's design had been awarded the prize. The accompanying illustration is reproduced from a photograph taken from the clay model of this design submitted in the competition. The design is for a wall-dial, surmounted by a figure of Time, and flanked by figures of Day and Night.

The Lock-out of Kentish Brickmakers.

Saturday last completed the fourth week of the strike of the Kentish bargemen, while on the same day the brickmakers, locked-out in consequence of the bargemen's strike, completed their third week of enforced idleness. According to the *South Eastern Gazette*, the trade of Sittingbourne and district is slowly but surely drifting away, and probably will never be regained. The brickmakers take a very gloomy view of the situation, and argue, with some truth, that the brick industry will never be what it has been. The action of the Kentish bargemen has been suicidal, so far as the interests of the brickmaking districts are concerned, for not only will many fields which found employment for a large number of hands be closed, but employers in some instances are seriously contemplating retiring from business altogether. This will compel many men to remove from the district, and the prosperity of the place must consequently decline. Subscriptions for relief of distress amongst the brickmakers are being received at Sittingbourne by the Central Relief Committee, of which the Rev. Henry Venn, vicar of Sittingbourne, is chairman, and Mr. G. F. Evans treasurer.

Illustrations.

SOME CHURCHES ON THE LOWER RHINE.—II.*

SEVERAL old churches are passed on the road from Calcar to Xanten, but they are not of any great importance. The approach to Xanten is remarkably picturesque, and we give a sketch of it. By the roadside is a pretty little shrine, containing an altar dating from the end of the seventeenth century; a fine old windmill; some singular clipped trees are seen to the left; whereas a fourteenth-century brick gateway, with its barbican, is seen to the right; and above all rise the spires and lofty roof of the Minster. Passing through the old gateway, which upon nearer approach is seen to be adorned by a number of carved shields, one is admitted into the principal street of the town, which enters the market-place by a sudden turn. The whole of one side of this great square is occupied by ecclesiastical buildings. The first object which attracts attention is the Protestant church, a small seventeenth-century building with a rather picturesque octagonal bell tower. Close to it is another small church or chapel, dedicated to St. Michael, the nave of which is above a gateway. It is a very pretty little building, with an elegant octagonal turret, the nave Romanesque, and the apse fourteenth century work; it is now used as a school. Rising over these two small churches are seen the great Romanesque towers of the Minster church of Saint Victor, crowned by two lofty slate spires, the long roof-line of the nave, and the grand range of pinnacles and flying buttresses.

* See *Builder* for March 8 last, p. 173.

St. Alban's Cath. etc.
E. End of Lady Chapel.

Outside Xanten Gateway.

Passing under the archway beneath the little church of St. Michael, one is admitted into the churchyard of the Minster. Immediately facing us is the very rich south doorway and the extended flank of that beautiful building, with its rich pierced flying buttresses, elaborate groups of pinnacles, and elegant traceried windows. To our right is a fine representation of the Crucifixion, composed of a group of statues, larger than life, carved in stone, dated 1330. Immediately to the left is the picturesque porch and stairway leading up to St. Michael's Chapel, and scattered about are various vaulted shrines, containing representations of Our

Lord's Passion. Passing on to the left one comes in front of the west-end of the church, flanked by Romanesque towers, and adorned with arcade work. It is, however, rather a flat and bald composition.

On the north side of the Minster is a very beautiful set of cloisters, surrounded by the old buildings formerly inhabited by the canons and other members of the Chapter before the ecclesiastical establishment was suppressed; in the centre of the earth is a most exquisite cross. The walls of the cloisters are covered with tablets, memorials, and inscriptions of every date, some of them undoubtedly Roman. I

should mention the fact that Xanten was one of the most important Roman stations in Germany. The remains of an amphitheatre and other works are still to be seen close to the town. Altars, cinerary urns, coins, &c., are discovered in every direction. There is an interesting collection of such antiquities in the Town-hall. From the cloisters, the noble flying buttresses of the north side of the church are well seen. The chapter-house is a fine apartment with a row of slender octagonal columns supporting the vaulting; it is full of ancient vestments dating from the eleventh to the seventeenth centuries, hangings, altar frontals, &c.,—

THE BUILDER, APRIL 5, 1890.

WINDOW IN APSE, RANMOOR CHURCH, SHEFFIELD.

By MESSRS SHRIGLEY & HUNT

VIEW OF CHOIR FROM NORTH TRANSEPT.

PHOTO LITHO. BARRAGUE & CO., 22, MARTIN LANE, CANNON ST., LONDON, E.C.

INTERIOR OF THE NORTH TRANSEPT, BEFORE "RESTORATION."

most remarkable collection of ancient embroidery. As will be noticed at once, the western portion of the church, including the two great towers, is Romanesque, but the nave and choir are very rich, thoroughly-developed Gothic work. It is said that the choir was commenced in 1153, and that the nave is at least a century earlier. The building has very little in common with the general run of North German churches, but bears a greater resemblance to the much richer ones of South Germany. In fact, the resemblance to Ratisbon Cathedral is remarkable that it is not improbable that the same architect. It would occupy too much space here to discuss this question. We reserve more detailed description of the building, its noble interior, and its most interesting contents, for a future article.

H. W. B.

ST. ALBAN'S CATHEDRAL.

THE interior views of St. Alban's Cathedral, which are given to-day, show the original work of the north transept and choir before Lord Grimthorpe's recent restoration (?), and also the present condition of the Lady-chapel, which is far untouched, but which will doubtless be dealt with shortly under the faculty granted to Lord Grimthorpe not many weeks ago. The choir of the north transept gives Abbot Bentham-Atstead's window of seven lights, of the same pattern as those formerly at the west end of the nave and in the south transept. All have now been swept away, the one shown having given place to an enormous rose window

which even unscals the solid Norman work near it. The old flat painted ceiling, which had a curious representation of the martyrdom of St. Alban in the centre, has also disappeared, and a plain ceiling has been substituted. In the arched recesses of the transept, on its eastern side, are an interesting series of encaustic and embossed tiles.

The only alteration, so far, made in the choir—a portion of which is shown in the view from the north transept—is the substitution of three-light Geometrical windows for the original three lancets under an enclosing arch. The beautiful window over the east end of the presbytery, which shows in the view of the exterior, has also been taken down, and a new one put in its place.

The Lady-chapel, which remains in an un-restored state, is illustrated by two views—one a general view taken from the ante-chapel, and a portion of the south-east angle with the Sedilia.

As will be seen by the general view, the chapel is of two dates. Up to the cill level it is Early English work, with arcading trefoiled on the north side, and cinquefoiled on the south. Over this, all is of Decorated date, the work of Abbot Everseden, 1308-1326, who also built the ante-chapel between this and the presbytery. The Lady-chapel fared badly during the period of its use as a school, the old arcading and the canopied niches having been cut down to accommodate the panelling, and a good many of the statues being destroyed. The chapel proper is of three bays, each with a four-light Decorated window. At the east end is a five-light window curiously designed, the principal lights being

surmounted both inside and out by crocketed gables with finials. On the south side are the remains of some gorgeous sedilia, with a row of canopied niches, and a triangular window over. Projecting south at this point is a vestry, formerly the Chapel of Saint Saviour, and of Late Perpendicular date.

The vaulting of the chapel is of wood with stone springers. On the splay and central mullions of the side windows are little canopied niches with figures of bishops, and rows of half-flower ornaments occur both at the inside angle of the splay and against the window tracery. Church has been largely used in the interior and Tottenhoe stone outside, together with flint and brickwork. The buttresses and mouldings of the exterior generally have become much worn, and much of the detail has entirely disappeared.

The heltry-tower or "clock house," a sketch of which is subjoined, is in the market-place, immediately north of the Abbey; and, according to Clutterbuck, there are deeds showing that it was built 1402-27. Near it was formerly one of the Eleanor crosses, destroyed in 1702.

WINDOW, RANMOOR CHURCH, SHEFFIELD.

THE subject of this window, which is placed in the apse of Ranmoor Church, near Sheffield, is the Resurrection. The principal figures are in toned white draperies relieved against the dark background formed by the rich colour of the foliage and rocks. The angels have ruby wings, and this colour is repeated in the dexter light in the cross upon the banner and in the nimbus around the head of Our Lord. The sleeping soldiers at the base are clad in brazen armour, which is subdued and in pleasant harmony of colour with the pearly tones of the tomb.

The window is by Messrs. Shrigley & Hunt, and the drawing from which the illustration is taken was exhibited at last year's Royal Academy.

THE ARCHITECTURAL ASSOCIATION:

NOTES BY THE A.A. TRAVELLING STUDENT.

AT the ordinary fortnightly meeting of this Association, held on Friday, the 28th ult., Mr. Leonard Stokes, President, in the chair,

Mr. E. S. Gale (hon. sec.) moved a vote of thanks to Mr. Norman Shaw, R.A., for receiving the members on the occasion of their visit to the new headquarters for the Metropolitan Police on the Victoria Embankment, on the 21st ult.

Messrs. F. E. Bristowe and F. W. Bryan were then elected members of the Association.

The Chairman then submitted to the meeting the committee's "house-list" of members proposed for officers and committee for next session, but it was open to any member to make other nominations for any of the offices up to that day four weeks. We may mention that the "house-list" nominates Mr. Stokes for re-election as President, and Messrs. F. R. Farrow and E. S. Gale for re-election as honorary secretaries.

Mr. A. E. Bartlett, holder of the Architectural Association Travelling Studentship for 1889, then read a paper, entitled, "An Account of a Tour in France, chiefly in the Loire Valley." The tour extended over a period of seven weeks, and the author left London on July 1, carrying with him an ample supply of sketching-paper, lining-paper for full-size details, and scale-paper for measured drawings. After a short stay of four days at Rouen (to which city he returned and spent a fortnight there at the end of his tour), he went to Chartres, and there he wandered about the cathedral some time before he could make up his mind what to set to work upon. The place was so colossal, and its details were so much in keeping with its grandeur, that it seemed useless, in the short time at his disposal, to attempt to measure any of the actual cathedral work, so he contented himself with making sketches about the place, and with measuring one or two details. The first thing that struck him on seeing the Cathedral of Chartres under a blazing July sun was the glorious effect of colour given by the bright green copper roof which topped the rich brownish-grey walls. The roof was skillfully constructed of iron, and was a comparatively new addition, to replace the old lead-covered wooden roof which was destroyed by fire

in 1836, and which, by reason of the multitude of its timbers, was known by the name of "the forest." The inside of the present roof was worth a visit, if only to see how little the vaulting had to do with the construction of the roof, the tie-rods of which came several feet above the cement finishing of the vaulting. It seemed rather a wasteful piece of construction, though it was undoubtedly effective. It showed us that constructive sbeams, for the sake of artistic effect, were not confined to one age or one style. Chartres seemed fated to suffer from fire. Five successive times before the present church was built was the cathedral burned to the ground, and on one occasion the greater part of the town was involved in the catastrophe. The graceful tower which stood at the north-west angle was designed by Jean Texier in 1506 to replace another which had been burned down. Though of so late a date, it showed little Renaissance feeling, except in some of the panels near the top. M. Durand, in his excellent monograph of Chartres, gave an interesting account of the building of the cathedral which stood here before the present one, and which was burnt down in 1174, and he quoted a letter from Hugh, Archbishop of Rouen at that time, who narrated that the clergy, holding High Mass in their ruined church, kindled in the neighbouring countryfolk a keen interest in its rebuilding; and he told how, by reason of certain miracles, performed on the sick, who were brought to the church, the interest afterwards grew till the whole countryside was in a fever of religious enthusiasm, and men, forming themselves into brotherhoods, loaded their carts with stone, wood, lime, and victuals for the workmen, and yoking themselves to them, set out on a pilgrimage to Chartres, to help forward the building of the church. So great were their loads, he told us, that sometimes it took a thousand men to drag one cart! Such was the account given by Archbishop Hugh of the building of the Cathedral of Chartres in 1037. The existing cathedral as we now saw it was begun in the year 1194, in the reign of Philip Augustus and the episcopate of Regnault de Monçon, and was consecrated on the 17th of October, 1260, as some said in the presence of St. Louis himself. He (Mr. Bartlett) could do no more than mention the rose windows, the stained glass, the excellent sculptures, the marvellous Renaissance screen running round the choir (which Fergusson compared to point-lace in stone), the intricate labyrinth marked out in black marble on the floor of the nave (over which in days gone by penitents used to crawl on their knees, saying a prayer at each turn), or the Black Virgin, the most precious treasure of the Cathedral, and which the mob of the Revolution crowned with a red cap of liberty, but did not dare to destroy. Except one small house in the Rue du Grand Cerf, there was not much good domestic work in the town. There was, however, a curious little Renaissance clock tower on the north side of the Cathedral, the cornice of which was almost exactly the same as the cornice on the main entrance front at the Château of Chenonceaux. Another detail worth noticing was the little cast-iron fountain in the market-place, which was a very excellent little design.

At Le Mans, one thing to be specially noted was the extreme care with which the Medieval builders chose their sites, taking that part for their church which seemed left by nature as the site best fitted for the noblest building, and letting the other buildings of the town group round it as they would. The great choir towered high above the surrounding town, with a broad flight of steps leading up to the level of the floor of the church. If the builders of the choir had pulled down and rebuilt the nave in accord with it, the Cathedral of Le Mans would probably be about the largest in France. As it stood, the nave was an interesting archaeological study, the caps of some of the columns in the nave showing their Classic origin in a very marked manner. There was a very good piece of colour decoration in the apse, and a very nice piece of domestic work at the west end of the cathedral.

The author's next stopping-place was Tours, in the very centre of all the great works of the François Premier period, and whence he visited Azay-le-Rideau, Loches, Beaulieu, Chenonceaux, Amboise, and Blois, and got his first impressions of the works of the French Renaissance. The early builders of the French Renaissance seemed to have used their own brains in devising their houses, and to have employed the skilful

hands of the Italian workmen to complete them, even as their predecessors the Romans, whom they professedly copied, used the cunning handiwork of the Grecian craftsmen to draw their own designs, and so they produced a series of works which seemed to belong to a distinct class; for in spite of their Gothic feeling and Classic detail, there was no appearance of the two styles clashing, and the François Premier style itself was as distinct from the Flamboyant which preceded it, and from the heavy Classicity of the Henri Quatre, which came after, as two adjacent styles could well be. As the requirements and occupations of the people who lived in these châteaux could not have been very different from those of the ordinary country gentleman of our own day, the author thought we might learn a good deal, not only by bagging detail, but by studying the planning and general arrangement of those châteaux. Their roofs were steep-pitched to throw off the snow, and so high sometimes as to savour of an affectation. Nearly every one had each its little chapel or oratory (often too small, one would have thought, for the needs of the household), where, if anywhere in the building, the Gothic feeling predominated. Their reception-rooms were stately and well-proportioned, and often decorated with carved panels into which the craftsman must have put months of labour. The windows of these apartments were of course so arranged as to gain some fair view over the neighbouring country, and the main staircase was treated as an important feature, worthy of the highest consideration. Thus at Azay-le-Rideau the beautiful little staircase was more lavishly decorated than any other part of the house. The great external staircase at Blois, again, allowed the chateau to be divided up into a series of flats. Then there was the great double staircase at Chambord, a curious device, by means of which two persons might pass one another on their way from floor to floor and neither be aware of the other's existence. The treatment of the balconies of the châteaux, and the way in which they were generally screened from the rain and sun, were worth attention. Every detail, in fact, pointed to an age almost as civilised, and, perhaps, quite as luxurious as our own. There was one detail, viz., the lead finial, which seemed at this period to have reached its highest excellence. The author exhibited the measured drawing of a finial at Blois, a very good one of a comparatively simple kind. He was fortunate enough to find it blown down, otherwise it would have been inaccessible. The upper part, which resembled the flower of the fuchsia, was made of wrought and hammered iron, and the base was of wood, covered with lead. It was at Tours that he saw some Renaissance detail which left a stronger impression on his mind than anything else he saw during his trip. In a chapel at the south transept of the cathedral, stood the beautiful monument of the two children of Charles VIII. and Anne of Brittany. The two children, watched over by four angels, all carved in white marble, lie on a black marble slab, underneath which was a white marble sarcophagus decorated with the arms of France and somewhat weak cherubs; the angles of the tomb were marked by dolphins and conventional eagle's wings. Along the upper portion of the sarcophagus were carved scenes from Bible history, most of which seemed to be illustrations of the exploits of Samson, conventionalised for decorative purposes. The monument was hacked to pieces by some of the furies of the Revolution, but it was restored as far as possible in 1815. It was the work of two brothers, natives of Tours, named Juste, who were contemporaries of Jean Goujon, and, in spite of a few faults of detail, it was an extremely beautiful and appropriate monument. Another monument which the author saw during his tour was the beautiful tomb of Agnes Sorel, the favourite of Charles VII., which stood in a tiny chapel in the stem castle of Loches. The general idea of the tomb was much the same as that of the one just described. The beautiful figure of the "Belle of Belles" lay, carved in white limestone, on a slab of black marble, with two angels at her head and two lambs at her feet. The effigy was a splendid piece of work, and the tomb was a lesson both to the sculptor and architect. Unlike the one at Tours, the body of the tomb was simple and devoid of ornament, which was, perhaps, an advantage, as it concentrated the attention on the beautiful figure at the top. It was a monument to be seen and remembered. Tombs such as these served a distinct purpose, recalling, as

they did, the figure, and often telling the history of the person whose death they commemorated. In an ordinary English graveyard the tomb of the present day savoured too much of the monumental marble-mason's catalogue to show any individuality, or interest any one except those who were immediately concerned in a person to whose memory they were raised. That would always be so until people understood that a work of art, such as any permanent memorial ought to be, could only be produced by the individual artist, and not by the wholesale manufacturer.

While in Tours the author's time was mainly occupied in measuring the tomb of which he had spoken, but he had time to make a few notes of various interesting buildings, among them a charming old fifteenth-century houses the Rue de Briçonnet which was known as a house of Tristan L'Hermite, the Prime Minister of Louis XI. The stories of the house were divided by string courses formed of the knots of an ordinary English greyware; the tomb of the house has also an excellent doorway, with twisted columns. The remains of the old castle of Plessis-les-Tours, about a mile and a half out, were well worth a visit. The chateau, in the house in the Rue de Briçonnet, was in a fifteenth century style, of red brick and stone dressings, and had a good new staircase.

At Azay-le-Rideau, the chateau contained good collection of pictures; the staircase, though small, was lavishly decorated and ceiling with sort of barrel vault. The lead work at the top of the turrets was very noticeable. Each turret had a different moulding at the base. The church was worth a visit; it had a curious detail of a bay covered with a three-centred arch. Most of the cottages in the neighbourhood were built in the solid sandstone.

There was a great deal to be seen in the neighbourhood of Loches. The chateau was more famous for its terrible dungeons than for the modern group of buildings standing a little way off which formed the chateau proper. The Church of St. Urs was built in the latter part of the twelfth century. Its four cone-shaped roofs formed an effective and interesting skyline, and the circular western doorway, opening from the porch into the nave, was a splendid piece of Romanesque detail. The town contained a picturesque little François Premier Hôtel de Ville, and an interesting Gothic gateway to the town known as the Porte des Cordeliers. At Beaulieu, a little village close to Loches, there was a good deal to be seen and learnt. Between the town and the village of the pretty little Château de Sausac, of the François 1^{er} period. The Church of St. Laurent at Beaulieu, was a Romanesque structure, with the vaulting of the aisles of the same height as that of the choir, giving the church, in its present state of dilapidation and neglect, the appearance of a large ball than that of a church. In this village also were the remains of the Eglise des Moines, which was formed attached to a Benedictine convent; all that now left of it was the tall, graceful west-work and the lofty choir, which had been carefully restored, and was now used for services. The rest of the church was destroyed by the English in 1412.

The author's next stopping-place was Chenonceaux, with its famous little chateau built on a bridge spanning the river. At that time it belonged to Diana of Poitiers. On the death of Henry II. it was enlarged by Catherine de Medicis, who took up her abode there. The year the chateau was bought by a French financial company, the Crédit de Paris, and its future was somewhat uncertain. In the gallery were a couple of fireplaces, said to be by Philibert de l'Orme, but they were not particularly striking.

From Chenonceaux the author went to Amboise, passing through Tours again on the way. At Amboise he found the most charming little Gothic chapels standing in the Castle gardens, and built on a solid rock tower high above the town. It was dedicated to St. Hubert of Liège, and over the two chief western doorways under one arch is carved large representation of his miraculous death while hunting one day in Holy Week in a Forest of Ardennes, with a pure white cross bearing a crucifix between its horns. He afterwards lived for some years as a hermit in a Forest of Ardennes, but was at length ordained priest and finally made Bishop of Liège, and his death was canonised as the patron saint of the chase and dogs. This little chapel dedicated to him was worth a good deal of study.

GENERAL VIEW LOOKING N.E.

St. Alban's Cathedral: Interior of the Lady Chapel

PHOTO-LITHO SPRAGUE & CO. 22 MARTINS LANE, LONDON S. W.

THE S. E. ANGLE.

t was a cruciform structure, measuring 40 ft. by 30 ft. inside. A plain stone slab on the floor of the chapel, with his name inscribed, marks the grave of Leonardo da Vinci.

The Château of Chenonceaux was an interesting building of red brick and stone dressings, built about the end of the fifteenth century, and containing a good deal of useful detail. Two great towers sprang from the base of the rock on which the castle stood; they were 42 ft. in diameter and 92 ft. in height, and each contained, instead of a staircase, a great inclined plane broad enough almost to allow a coach-and-four to drive up. The Romanesque church of St. Denis was well worth a visit; it contained some good twelfth-century detail and a handsome north door.

The author's next stopping-place was Blois. He supposed that the best known feature about the Château of Blois was the great open staircase standing in the courtyard of the castle, there was also a very excellent fifteenth-century staircase of red brick and stone dressings, of which there was a good illustration in Mr. Norman Shaw's sketches of mediæval architecture. The greater part of the château has been restored by the Government, and although it had been undoubtedly well done, it struck the author that it had been somewhat overpainted, as, inside at least, it was impossible to tell what was old and what was new work, and he often found himself wondering whether some paint-laden detail was of stone or wood. The work at the château was of various dates, from the thirteenth century Salle des États down to the western side of the quadrangle, erected by one of the Mansards, who, it was said, hoped to be able at some future time to remodel the three remaining sides of the quadrangle to suit the one he had already put up; happily that idea was never accomplished. The Salle des États was a big hall, 97 ft. long by 59 ft. broad, with a row of cylindrical columns running down the middle, supporting pointed thirteenth-century ribs with a broad, flat soffit. It had been so much restored that it savoured now rather much of modern thirteenth-century Gothic. At first light it seemed a somewhat undesirable arrangement in a salle des États to have a row of columns running right down the middle of the hall, but, of course, it depended entirely upon the arrangement of the seats.

There were several good churches in Blois. The principal one was St. Nicholas, a large cruciform twelfth-century church, with the ceiling covered by a Gothic dome, which was owned outside by a wooden fish. The tower was the cathedral and the Renaissance church of St. Vincent de Paul, close to the château. There were a few good domestic details about the place, mostly in unexpected places, but most of the streets were comparatively modern and uninteresting. From Blois the author went by train to Menars, whence he walked to Chambord. Of all the famous châteaux he saw during his tour, the most striking, the largest, and certainly the one which left the most vivid impression on his mind, was the Château de Chambord. But here, although the great house was empty, and stripped of its furniture, and although it was skillfully planned, ably executed, and carefully finished—a lesson to architectural students of all ages and countries—by the order of the owner's agent no less, unless he were a student of the Ecole des Beaux-Arts, was allowed to make any drawing inside the house, or on the terrace, or in the open galleries. Perhaps, on behalf of English architectural students, the Institute or the Association might be persuaded to take some action in regard to this matter before the summer holidays were with us again, so as to get for the English student the same privileges that were granted to, but he believed little appreciated by, the French students.

At Orleans the author visited the cathedral, a Gothic erection of the seventeenth century and singularly uninteresting. There was, however, some good domestic work in Orleans.

Leaving Orleans he travelled on to a place at which was little known to English architects, though a great deal visited by Americans, viz., the town of Chateaudun. It contained a most interesting chateau of late Gothic or early Renaissance, which was absolutely untouched by the hand of the restorer, and over which one is allowed to roam at will unaccompanied by any chattering guide or romancing cicerone, and in which the sketcher could work undisturbed by visitors from morning to night. The chief feature about this chateau was a

staircase which was illustrated in Viollet-le-Duc's "Dictionnaire." There were two or three good bits of domestic work in Chateaudun, one of the best of which was the Maison des Petits Bonhommes, a house with a stone ground-floor and a half-timbered first-floor, supported on sixteen wooden brackets, each of which was carved (so it was said) unto the likeness of some local celebrity of the sixteenth century.

The author spent the last fortnight of his tour at Rouen, chiefly in measuring up the sacristy of St. Ouen, where the old sacristan gave him a very animated and interesting description of a visit made by Mr. Ruskin to the church. Mr. Ruskin's most salient criticisms, done into English, seemed to have been that the church was too light for a religious building. The Church of St. Ouen at Rouen and the Cathedral of Chartres were, probably the two most famous churches which the author visited during his tour, and he was struck by the contrast between them, although they were built by the same nation and for people of the same creed. Chartres gave one an idea of grandeur and simplicity of detail, of massiveness and everlasting strength. In the great nave, which was low for a French church, even on the brightest days the light which came through the stained glass windows was subdued, and the church was in a perpetual twilight. St. Ouen, on the other hand, was lightness written in stone. Inside, the church was as light as a conservatory, and every line seemed soaring upwards. Besides St. Ouen, there was the Cathedral of Rouen, which was worth some weeks of study. The third great church of Rouen was St. Maclou; and the Church of St. Patrick had a very good, simple plan. The aisles ran the whole length of the church, but by the choir there were double aisles on each side, which arrangement gave a very good effect. There were many other churches and buildings in Rouen which were worth attention, and these were described by the author in concluding his paper.

The Chairman, in inviting discussion, said that Mr. Bartlett had given them a very interesting paper, although he was afraid that there was not a very great deal to discuss in it, from the nature of the subject.

Mr. F. R. Farrow proposed a vote of thanks to Mr. Bartlett for his interesting paper, and for exhibiting his drawings, the large number of which showed that he had made good use of his time during his seven weeks' tour. He thought that Mr. Bartlett had maintained the honour of the A. A. Travelling Studentship in a very worthy fashion. He thought he was to be congratulated, too, upon the manner in which he had dealt with the architecture of the district he had traversed, upon the catholicity of taste which he had shown, and upon the variety of methods of study which he had adopted. He was also to be congratulated upon having brought back a great many details which would be useful to him. With regard to the use of the steep-pitched roofs of the François Premier period of architecture in France, he thought the practice was due to something more than a mere desire to build such roofs as would throw off the snow, because those roofs were abnormally steep. One of the great aims of the noblesse of the François Premier period was to make a great show and appearance of luxury. He believed that one reason why these steep-pitched roofs were built was that they were expensive to build. He was very much interested in the description which Mr. Bartlett gave of the little church near Lèches. It was very interesting to hear of a church planned on what the Germans called the "hall" principle, which was very seldom seen outside Germany; he meant churches in which the aisles were of the same height as the nave. He thought that Mr. Bartlett had very mildly criticised the spire at Rouen, which was a most ghastly thing, spoiling the effect not only of the cathedral, but of the entire city. When visiting Rouen, members would do well to go a couple of miles out, to a little village named Boos, where they would find a very fine *colombier*, one of the finest examples of the kind to be found in that characteristic period, the French Renaissance. That period, and the Late Flamboyant period, were remarkable for these *colombiers*.

Mr. Bernard Dicksee, in seconding the vote of thanks to Mr. Bartlett, said he could not agree with Mr. Farrow that the high roofs of the François Premier period were due to any wish on the part of the owners to spend money for the mere sake of spending money. These steep-pitched roofs, he took it, were naturally

descended from the high roofs of the Gothic period.

The Chairman, in putting the vote of thanks, said they had all listened with very great pleasure to the paper, and he thought that Mr. Bartlett had been very wise in choosing the district which he had traversed during his tour, for the particular style which there abounded was coming into vogue. He thought Mr. Bartlett had acted very wisely, and as all students on tour should act, in taking with him a supply of lining-paper for full-sized details. Apart from their thanks to Mr. Bartlett for the paper itself, and for the drawings which he had shown, he was additionally entitled to their thanks for having come forward in an emergency to read his paper a month before the time for which it was promised. He was sorry to say that Mr. Keith D. Young, who was to have read a paper that evening on "Hospitals," had been obliged to postpone it through an accident. Mr. Bartlett had said rather regretfully that he had not always been able to tell modern work from the old, owing to the painted decoration which he found in many of the buildings. No doubt it was sometimes aggravating to be unable to decide readily what was new and what was old, but he thought it would perhaps be more useful if students generally would ask themselves whether work was good or bad, not whether it was old or new. As to the question of the high-pitched roofs of the François Premier period, he did not know that it was a very vital one for them to consider; there was perhaps something in what Mr. Farrow had said, but he (the Chairman) took it that these large roofs were, after all, less expensive constructions than stone façades would have been if carried up to an equivalent height. There was only one other point upon which he should like to ask for information, and that was as to the question of the cost of such a tour as Mr. Bartlett had described to them in his interesting and well-written paper.

The vote of thanks having been carried by acclamation,

Mr. Bartlett, in reply, said that in regard to cost, the tour had only cost him a pound or two more than he received as Travelling Student. He reckoned six or seven francs a day to cover all his outlay, exclusive of travelling expenses,—and these did not come to so very much. He hoped that the Association would try and get for its members the same privileges for visiting the Château de Chambord as were possessed by the students of the Ecole des Beaux-Arts. With regard to the question of the steep-pitched roofs, he was not prepared to say anything as to their origin.

The meeting then terminated.

THE LONDON COUNTY COUNCIL.

THE London County Council held its last meeting before the Easter recess, and probably its last meeting in the Council Chamber at Guildhall, on Tuesday evening last, Lord Rosebery in the chair.

Thanks to the Corporation of London.—The Chairman said that after the recess they would probably meet in their own enlarged Council Chamber at Spring Gardens. He suggested that the Council should agree to a hearty vote of thanks to the Corporation of London for their generous hospitality in lending the Guildhall Council Chamber. This was agreed to by acclamation.

Finance.—The Finance Committee brought up the estimates for the year 1890-91. Lord Lingen, in a long and explanatory speech, moved their adoption, and said that for most of the purposes of the Council they raised a rate both upon the new Administrative County of London and upon the City, but for certain purposes the City was exempt, and they had to levy a further rate upon that part of the County outside the City. That which they levied in common constituted really the rate which was imposed on the City. The proposed increased rate for the County and City together was estimated at 12-5d. in the pound, in place of 10-63d. raised in 1889-90; the rate upon the County, exclusive of the City, 7-5d., as compared with 1-90d. in 1889-90; and the total rate for the County outside the City would be 13-25d., instead of 12-53d., the rate of last year.

Mr. Campbell, in moving an amendment having reference to the form of the estimates, which was substantially adopted, pointed out that the increase of rates was only apparent,

not real. Out of 13d. in the pound referred to as the amount of the County-rate for London outside the City, 2d. was for Poor-law purposes, levied by the County Council instead of by the Poor-law Guardians; so that the rate for municipal purposes apart from Poor-law purposes would be about the same as that levied by the Metropolitan Board of Works, 10d. in the pound. The Poor-rates would be, or should be, reduced in a corresponding ratio to the increase of the County Council rate. The apparent increase of 2d. in the pound would, in fact, be only transferred from our pocket to another by the ratepayer.

After a good deal of discussion, the estimates were adopted.

The Money Bill of 1890.—The Finance Committee also recommended

"That the estimate, now before the Council, of the borrowing power to be provided in the Money Bill of 1890, be approved, and that the Council do hereby estimate the amount of new borrowing power (as detailed in the estimate), as follows:—

The new borrowing power recommended is	£2,180,306
Deducting the amount required to lend to other bodies	913,216
The amount required for the Council's own purposes is	£1,276,090"

Water Companies and their Charges.—The Special Committee on Water Supply and Markets reported as follows:—"We have to report that in pursuance of the following resolution of the Council of February 11, 1890—'That in view of the quinquennial re-assessment of property in London, which will come into force next year (1891), and the resulting effect, which will give the water companies power to exact an increased charge for their supply, this Council instructs its Special Water Committee to immediately take the question into consideration, and report thereon,' we have given careful consideration to the subject of the reference, and we submit the following recommendation—

"That the Council do introduce into Parliament during the present session a Bill for the purpose of suspending the powers of the water companies to increase their charges for water consequent upon any increase that may be made in the assessment of property in the County of London by the quinquennial valuation, and that it be referred to the Parliamentary Committee to take the necessary steps for the purpose."

Mr. James Beal, moved the adoption of this report, and it was unanimously agreed to.

Subways and Overhead Wires.—The Parliamentary Committee reported as follows:—"In concert with the Highways Committee, we have considered the thirty-seven petitions presented against the London Subways and Overhead Wires Bill by the gas, water, electric light, telephone, and other companies, and we instructed Mr. Wolfe Barry, C.E., and Mr. Cripps, the Parliamentary agent, to enter into negotiations with the various opponents in order to ascertain how far the objections expressed in these petitions might be met by modifications of the Bill. But, at a meeting with the solicitor, agent, and engineers acting for the associated water companies, these gentlemen declined even to enter into discussion on any of the details of the Bill, on the ground that the Bill is wholly objectionable, and that to discuss its details might have the appearance of accepting its principle. We understood that the object of the Council in promoting this Bill was to effect some scheme by which subways could be made under streets, not solely to relieve the inhabitants and ratepayers from the inconvenience and cost due to frequent obstruction and breaking-up of the streets, but also to promote the convenience of the gas, water, and other companies, in the conduct of their business. But, having regard to the attitude of uncompromising opposition to the project taken up by so many of the companies, and to the prolonged and expensive contest which the prosecution of the Bill in its present form would apparently involve, we recommend—

"That the application to Parliament for the powers sought by the Bill as to new subways be not proceeded with this session."

The introduction of the Bill has led to much valuable information being elicited upon the whole subject, which may enable the Council to deal with it more satisfactorily in a future session, after more mature consideration. As regards that part of the Bill which relates to overhead wires, we have been met in a more friendly spirit by the Telephone Company. Modifications have been suggested which we are not prepared to accept in their entirety, but which seem to afford a basis for further discus-

sion, and we hope the objections to this part of the Bill may be adjusted satisfactorily, or at least narrowed to a comparatively small issue. We recommend,—

"That this part of the Bill be proceeded with, and that we be empowered to make such modifications as we may think advisable to remove or lessen opposition."

If these recommendations are adopted by the Council, and the Bill in its amended form is passed by the House of Commons, we will report the Bill as amended to the Council for further consideration. We have consulted the Highways Committee on the points referred to in this report, and they concur with us in the above recommendations."

The recommendations were agreed to.

Building Act Business during the Easter Recess.—The Building Act Committee reported as follows:—"Your Committee believe that considerable inconvenience to the public would result from their adjournment over the Easter vacation, and they recommend—

"That the Council do, under the provisions of the Local Government Act, 1888, sec. 23 (2), delegate to the Building Act Committee power to hold one meeting during the recess, for the purpose of considering applications made to the Council under the Metropolitan Building and Management Acts, and at such meeting to act on behalf of the Council, and to grant or refuse such applications; provided, however, that the Committee shall only act upon such decisions as shall be unanimously arrived at by the members present, and that all such decisions shall be reported to the Council at its first meeting after the recess."

After transacting other business, the Council adjourned until Tuesday, April 22.

BUILDERS' CLERKS' BENEVOLENT INSTITUTION: ANNUAL DINNER.

The twelfth annual dinner in aid of the funds of this excellent Institution was held on Monday evening last, in the Venetian Room of the Holborn Restaurant.

Mr. H. H. Bartlett (Perry & Co.) presided, and was supported by about 240 members and friends of the Institution, including Mr. Thos. F. Rider, Mr. W. A. Colls, Mr. Colin Patrick, Mr. W. Eckstein, Mr. W. R. Freeman (Mowlem & Co.), Mr. H. H. Leonard (Leonard & Clarke), Mr. Joseph Wilkinson, Mr. C. K. Turpin, Mr. E. C. Roe, Mr. Edwin Brooks, and many other gentlemen.

The usual loyal and patriotic toasts having been duly honoured, Captain Roe replying on behalf of "The Army, Navy, and Auxiliary Forces."

The Chairman proposed the toast of the evening, "The Builders' Clerks' Benevolent Institution," and said that it had been established about a quarter of a century, and during its existence it had paid away in temporary relief and in pensions the sum of 4,173*l.*, in addition to 787*l.* spent in purchasing three orphan presentations (each one tenable for twenty-one years), making a total of 4,960*l.* During the twenty-three years of the Institution's existence thirty-two pensioners had been elected on the Relief Fund. The number on the books at the present time was nineteen. The male pensioners received 25*l.* per annum, and the widows 20*l.* That meant a very considerable annual expenditure, and it was very desirable that the regular income should be materially increased by a large addition to the number of annual subscribers, as during the past year the income resulting from the invested funds and annual subscriptions had not sufficed to meet the expenditure, and the Committee had to trench to the extent of 120*l.* upon the amount received in donations at the last annual dinner, instead of investing the whole of it, as they would have liked to do. The Institution was one eminently deserving of the support of all builders' clerks and of the building trade generally. The calling of a builder's clerk was one of some precariousness, and involved considerable strain upon the mind and nervous system. The Institution had the hearty good will and support of leading master builders, many of whom, however, were unable to be present that evening. Letters had been received expressing the inability of the writers to attend from, amongst others, Mr. Taprell Holland, Mr. Thos. Stirling, Mr. Geo. Burt, Mr. Stanley G. Bird, Mr. Howard Colls, Mr. G. H. Trollope, Professor Banister Fletcher, and Messrs. Fowler & Hugman. Speaking for the master builders generally, he was warranted in saying that they were very admirably served by their clerks, who were a body second to no body of clerks in their

attainments and in their loyalty to their employers. They were engaged in a very good work in carrying on with so much energy and with so little expenditure in management an Institution so useful to the more unfortunate of their craft, and he therefore had much pleasure in proposing the toast of "The Builders' Clerks' Benevolent Institution."

The toast was very heartily received. Mr. Joseph Wilkinson proposed "The Architects and Surveyors," coupled with the name of Mr. H. H. Leonard, who briefly replied, speaking highly of builders' clerks as a body.

Mr. W. Eckstein, in proposing "The Builders," said he regarded that toast as only second to the toast of the evening, "The Institution," for without the builders where would their clerks be? With the toast he coupled the name of Mr. W. A. Colls (Colls & Sons).

Mr. W. A. Colls, in replying, said he was quite in agreement with what had been said by previous speakers as to the excellent manner in which builders were served by their clerks.

Mr. E. Brooks (Treasurer of the Institution) proposed the past-Presidents, who were, he said, all gentlemen occupying the most prominent and respected positions in the building trade. Their first President was Alderman Sir William Lawrence, who held office in 1867. Since that date they had had a succession of able and energetic Presidents, including Mr. Thos. F. Rider, who occupied the chair for two years and Mr. W. R. Freeman, who was also a most assiduous President. Last year they were fortunate in having as President Mr. John Aird, M.P., who was unable to be present that evening. With the toast were coupled the names of Mr. W. R. Freeman and Mr. T. F. Rider, who both briefly replied, Mr. Freeman speaking very highly of the energy and zeal of the Committee and their Secretary, Mr. H. J. Wheatley.

The remaining toasts were "The President" (proposed by Mr. T. F. Rider), and "The Visitors."

During the evening subscriptions and donations to the amount of nearly 300*l.* were announced, including 21*l.* from the Chairman.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—XIV.

ARMATURE REACTION.

If the armatures shown in figs. 30 and 31 be removed from the influence of the field magnets, and a current from some external source sent through the coils from P to S, the cores will become magnetised, fig. 34, so that lines of force traverse the iron

Fig. 34.

from the lowest to the highest point. The drum armature becomes a cylindrical electro-magnet, magnetised in the direction of a vertical diameter, while the ring armature is practically converted into two semi-circular magnets with their north ends in contact at the top and their south ends at the bottom. The lines of force within the cores are, of course, curved, but the coils may be regarded as producing in both cases magneto-motive force in the direction S-N. Whether the currents in the coils arise from an electro-motive force altogether outside the armatures, or from the electro-motive force set up within the coils themselves, when they cut lines of force as they revolve between the poles of their field magnets, can make no difference to their magnetising effects on the core. Hence, when current flows from an armature through the brushes, the coils tend to magnetise the core in the direction of the diameter of commutation.

To better understand this so-called "reaction of armature upon field," we may regard the core as a magnetised mass traversed by lines of force which are cut by the coils where they, the lines, pass into the core from the air and again as they emerge into the air from the core. The core revolves, but the lines do

MEETINGS.

SATURDAY, APRIL 5.
Association of Public Sanitary Inspectors.—Mr. F. T. Poulson on "Social Environments." 6 p.m.

MONDAY, APRIL 7.
Royal Institution.—General monthly meeting. 5 p.m.
Liverpool Architectural Society.—Mr. W. E. Hill on "Ormskirk Parish Church."

THURSDAY, APRIL 10.
Guild and School of Handicraft.—Mr. T. Cobden Sanderson on "Book-binding (34, Commercial-street, E.)." 8 p.m.
Institution of Electrical Engineers.—8 p.m.
Edinburgh Architectural Association.—Mr. John Keppie on "Accessories of Architecture." 8 p.m.

Miscellaneous.

Proposed Bas-relief in Rome in Honour of Sir Joseph Lister.—In Rome the magnificent Policlinico Umberto I., or great medical and surgical hospital and school, now slowly rising to completion, is to have its two principal facades ornamented with bas-reliefs in honour of the two men who, in the judgment of our Italian brethren, have conferred the most signal benefits on the sister branches of the healing art. Medicine is to be represented by the pioneer of pathology as it is now studied and taught, Giovanni Battista Morgagni, of Padua; surgery, by the author of the antiseptic system, Sir Joseph Lister. Already a competition for the best designs for the bas-reliefs in question has been announced, and a Commissione Aggudicatrice, consisting of two architects, two sculptors, and two painters, has been formed, under the presidency of the guiding spirit of the Policlinico, Professor Guido Baccelli. The best artists in Italy are expected to compete, the prize for the successful design of each bas-relief being great enough to induce the leaders of the statuary art throughout the peninsula to suspend all other engagements for the honourable rivalry. The stone employed for the bas-reliefs will be the "pietra di Monte Aflano," well chosen to combine the requisites of fineness of grain, richness of colour, and durability for the material in which Rome seeks to embody a worthy accession to her artistic masterpieces.—*Lancet.*

Edinburgh Architectural Association.—On Saturday afternoon last the Edinburgh Architectural Association visited Prestonpans and, notwithstanding the somewhat unsettled condition of the weather, a large number of members were present. The party was under the leadership of Mr. Hippolyte J. Blanc, who first introduced to them the interesting feudal tower of Preston, which was described as a work of early fifteenth century, comprising, in an area of about 34 ft. by 28 ft., a tall keep about 50 ft. to the parapet, with a seventeenth century addition, increasing the height by 17 ft. more. The original structure had been divided into four floors, with the usual appropriation of lord's hall, private apartments, and accommodation for retainers and stores. In a wing projected from the west side of the keep an interesting and unique construction of dungeons was examined, as also the special features of construction for the defence of the main entrance exhibited on the outside elevations. Originally a possession of the Hamiltons, the tower has remained, with but short intervals, from the period of its erection with the family; and although much of the property originally attached to it has been disposed of, the tower itself, with the enclosure in which it stands, is now owned by General Sir William Hamilton, through whose kindness the party was allowed to view it. The tower seems to have been occupied up to 1663, when a fire, the third from which it had suffered, rendered it no longer habitable. It possesses a good deal of interesting detail, sufficient to have elicited the interest of antiquaries, by whom, a few years ago, a considerable sum was expended, under the direction of Mr. Blanc, in replacing a great deal of the carved stonework found among the ruins, and generally receding to Preston Cross, which was explained to be one of a type of market crosses erected in various towns in Scotland at the beginning of the seventeenth century. Its details were separately pointed out and examined, and after visiting the ruins of Preston House,—the mansion of the Hamiltons after their occupancy of the Tower,—and the old parish church of Preston, the party returned by Northfield House, the apartments of which the party, by the permission of the agents, Messrs. Davidson & Syme, had an opportunity of examining. Points of interest were also brought under notice by the Rev. Mr. Mackay, of Prestonpans, who, in the absence through illness of Mr. Hislop, accompanied the party through their two hours' very enjoyable visit.—*Scotman.*

Gay's Hospital.—The students' new Residential College, which has been built after the designs of Messrs. Wood & Ainslie, architects, was opened on the 26th ult. by the Rt. Hon. W. E. Gladstone. The building is four-sided, but not rectangular, and is adapted for purposes of chambers and a medical students' club. The club premises comprise a gymnasium in the inner court, a dining-hall, with open timber roof, and a reading and smoking-room. The residential portion consists of a Warden's house, with apartments for the house staff, and thirty-nine sets of rooms, varying from one to three rooms apiece, to be let at rents ranging from 9s. to 20s. per week each. Thirty-four of these contain two rooms. This provision for medical students within the hospital precincts is a considerable improvement when contrasted with what it used to be in the times illustrated and described by Cruikshank, Albert Smith, and Dickens,—such as, for instance, Bob Sawyer's "first-floor front" in Lant-street, Borough. We shall publish an illustration of the new building next week.

Trade Dinner.—The foremen and workmen now employed by Messrs. Foster & Dicksee (of Rugby, and Mansera-road, Chelsea) on their London contracts, held their annual dinner at Clout's Restaurant, Victoria-street, S.W., on Tuesday evening, March 25. Upwards of 100 were present, and a very pleasant evening was spent. Mr. Dicksee presided, and was supported by Mr. Goddard, the head of the London staff.

Royal Victoria Hall, Waterloo-bridge-road.—The following "Penny Science Lectures" are arranged for April:—April 15, "The Colours of a Soap-bubble," illustrated by slides and experiments, by Mr. John Cox, late Fellow of Trinity College, Cambridge. April 22, Rev. Blomfield Jackson, on "Old London," with dissolving views. April 29, Sir Vincent Barrington on "Personal Experiences of Ambulance-work During War."

Liverpool Engineering Society.—The twelfth ordinary meeting of the sixteenth session of this Society was held on Wednesday evening, March 26. Mr. Henry H. Warren, M. Inst. C.E., President, in the chair. A paper on the usual business, a paper was read by Mr. Thomas L. Miller, Assoc. M. Inst. C.E., M.I.M.E., on the "Efficiency of Gas Engines." In his opening remarks the author referred to the practical statement of the efficiency of gas engines in terms of the gas consumption per horse-power per hour without any reference to the thermal value of the gas used, and showed, from a comparison of the calorific value of the gas in different countries, how unfair such a practice was when the efficiency of engines tested in different localities were so compared. An explanation of the different senses in which the term "efficiency" was used in the paper was then given, after which the author proceeded to explain a system of classification of gas engines adopted by Mr. D. Clerk, the theoretical efficiency of various types being given. The causes of loss in the gas engine were then referred to in detail, and the means by which such losses might be reduced explained. The experiments of Messrs. D. Clerk and G. C. Douglas on the explosion of gaseous mixtures were then touched upon, and the various theories advanced to account for the suppression of heat at the moment of ignition were dealt with. A discussion of the more important tests of gas engines then followed, the absolute amount of heat supplied to the engines per horse-power together with their efficiency, being given. The Hargreaves Motor was then referred to, and its method of working explained, and comparison was made between the results of tests with this engine and those of the more economical gas-engines mentioned. The author then concluded the paper with a comparison of the efficiency of the gas-engine with that of the steam-engine, in the course of which he pointed out that, while the gas-engine had the advantage from a thermo-dynamic point of view, its high price of its fuel soon placed it at a disadvantage, as, with coal-gas at 3s. per 1,000 cubic feet and coal at 15s. per ton, the gas engine, with a consumption of 20 cubic feet of gas per indicated horse-power per hour was just equal in cost of fuel to that of a steam-engine indicating 1 horse-power per hour for a consumption of 9 lbs. of coal. The discussion was adjourned to Wednesday, April 16th.

Guild and School of Handicraft.—The following course of lectures will be given in the Workshop of the School of Handicraft, 3, Commercial-street, E. (admission free), viz.:—Thursday, April 3, 8 p.m., Mr. Henry Holland on "Looking Backward," in its Relation to Life, Taste, and Art." Thursday, April 10, 8 p.m., Mr. T. Cobden Sanderson, on "Book-binding." Thursday, April 17, 8 p.m., Mr. W. L. Richmond, A.R.A., on "Gesso." Thursday, April 24, 8 p.m., Mr. Stirling Lee, on "A Talk on Sculpture," with practical illustration. Thursday, May 1, 8 p.m., Mr. E. Prioleau Warren, on "Parlour Architecture." On Monday, May 5, C. R. Ashbee (Architect and Hon. Director of the Guild of Schools) will give a lecture on "The Architectural Story of England." The chair will be taken at 8 p.m. by the Most Hon. the Marquis of Ripon, K.C. Admission to this lecture will also be free. It will be the first of a course of six on "Architecture, as the Language of the English People."

Partnerships.—Mr. Wm. Kidner, F.R.I.B.A. of 23, Old Broad-street, has taken into partnership Mr. W. H. Atkin Berry, A.R.I.B.A. formerly of 35, Bedford-row, who has been associated with Mr. Kidner in business five periods extending over the last seven years. The new firm's practice as architects and surveyors will be carried on at Old Broad-street under the style of "Kidner & Berry." We understand that Mr. Edward G. Williams, who some years manager to Messrs. Goodman & Company, brick and cement merchants, of Bishopsgate-street, has been taken into partnership by Messrs. Pilkington & Co., of King William-street, who have made arrangements to extend the scope of their trading operations to slating and tiling (encaustic and roofing).

The "Archer" Drain-pipe Joint.—We are asked to mention that a company has been formed (of which Colonel A. C. Hamilton, late Royal Engineers, is Chairman) to make and sell sanitary tubes with "Archer joints," and that offices and show-rooms have been opened in Shaftesbury-avenue.

"The Air We Breathe"—Mr. W. J. Lidcock, Assoc. San. Inst., gave a lecture on the 25th ult. in the George-street Lecture Hall, Plymouth, on "The Air We Breathe." Dr. Dance occupied the chair. The lecturer dealt with the normal condition, weight, and temperature of the atmospheric envelope which surrounds the earth, and to what depth we would plunge into this aerial ocean without sing our lives; and passed on to treat the object from a physiological and hygienic standpoint, explaining the actions of respiration, showing how inspired air and expired air differed one from another, pointing out the dangers of breathing in air that had been breathed over and over again through the want of adequate ventilation. References were made to a number of systems which could be adopted for ventilating our rooms and public buildings, and of the newest being the Crose ventilator, in which the freshest air is allowed to be indicated or disinfected air being thrown into the room, the disinfecting fluid being held in a metal trough out of sight, the advantage of this mode being that no space was taken up by unsightly tubes, shafts, &c., the whole contrivance being built into the wall, and mingling flush with its surface. The Bamber, Kyle, and other ventilators were shown and explained, and the lecturer concluded by an experiment showing that as well as providing outlets for foul air, provision must be made for supplying fresh air, or the extractors would not do could not be expected to work.

Drainage and Paving of New Orleans.—According to a recent report of the British Consul at New Orleans, the project for draining and paving that city by means of a tax on public property, to be passed judgment upon by the vote, has been defeated. The measure was opposed by all the objections attached to public works in American municipalities; but it had already been defeated before its adversaries reported of their work,—the deliberate refusal of 250,000 inhabitants to protect dirt and disease having subjected it not only to favourable comment, but to actual loss. The step, which helped to destroy the germs of disease, and the rain-storms, which supplemented scavengers' incomplete labours, have been shielded, and the canals, gutters, and streets in a condition which threatens disaster in summer sets in.

Soothill Nether Sewerage.—Mr. Arnold Taylor a few days since held an inquiry at the board-room, Soothill Nether, near Dewsbury, with respect to taking four acres of land otherwise than by agreement, for the purpose of dealing with the sewage of the district. Mr. Malcolm Johnson, M. Inst. C.E., of Bradford, explained a scheme. The estimated cost is £1,500, exclusive of the main drainage of the district, sewage-tanks for lime-treatment, and land for intermittent filtration. A special feature of the scheme is the provision for taking trade refuse to the sewers, in accordance with the Rivers Pollution Act, 1875, thus striking at the root of sewer pollution in the manufacturing districts. Soothill Nether is one of the districts proposed to be incorporated by Dewsbury, whose extension scheme, however, was rejected in its entirety by the Local Government Board.

The Recent Discussion at the Institute.

THE proceedings of the special meeting of members only, held at the rooms of the Institute of Architects on March 31, are now in the hands of all members, and may, therefore, be considered so far public property as to be the subject of public comment. The minor business, but first in order, of the meeting was to consider a recommendation from the Council that the Institute should enter into a lease with the Architectural Union Company for a further portion of the premises of 9, Conduit-street, hitherto in use as a shop; in other words that the permanent enlargement of the Institute premises has become a necessity, and that the opportunity should be taken of effecting this object. This was soon disposed of by a unanimous vote, and the real business of the evening then followed.

The meeting resolved itself into a special general meeting called by the Council under the provisions of by-law 60, whereby the Council shall be bound to call a special meeting to consider any proposed resolution on the receipt of a written requisition to that effect signed by twelve subscribing members, of whom the majority shall be Fellows. The subject proposed for discussion was summed up in the following resolution:—

1. That, at as early a date as possible, statutory powers should be sought to establish, as in other professions, a system of compulsory examination to be held by the Institute, and to be extended to all architects hereafter entering the profession, whether as members of the Institute or not.
2. That when such compulsory examination comes into force, the position of all existing architects shall be completely respected.
3. That, whether these (Nos. 1 and 2) be carried or not, a poll be taken by voting-papers, in order that under any circumstances the opinion of the entire body of professional members may be ascertained."

As we recorded in general terms in a former issue, a counter resolution to these was moved by Professor Roger Smith, and carried at first by a majority of about three to one, and subsequently adopted, in the usual form, in a substantive motion, by a practically

unanimous vote. The following are the terms of this amendment:—

"That, while not opposed to the principle of compulsory examination as applied to those about to practise architecture, this Institute is of opinion that the difficulty of restricting by statutory powers the practice of architecture to those who have passed an examination is at present so insuperable that it is undesirable to make an immediate application for such powers."

The first comment we have to make on these main facts of the procedure is to endeavour to clear up the minds of some people who seem to be under a very mistaken impression as to the real meaning of the two opposing resolutions, and of the act of calling the meeting at all. From one or two letters we have received it seems that some of the provincial members are under an impression that the Institute having made up its mind in favour of compulsory registration, and called a meeting to put the matter in train, had at the last moment allowed a red herring to be drawn across the track in the shape of a counter-resolution, and had stultified itself by carrying this instead of the originally proposed resolution. That anyone should think so only shows how carelessly members read the printed documents circulated by the Institute to give them information. The Council were summoned by a requisition, in the prescribed form of the by-law, to call the meeting, and had no power to refuse. The requisition was promoted and signed by the people who were concerned in getting up the Architects' Registration Bill which is again being attempted to be thrust on Parliament, and it was simply an attempt to drag the Institute at the heels of that Bill and its promoters. The list of signatories to the requisition does not include the name of a single member who is in the front rank of the profession, and a majority of them are those of persons almost unknown. Among the speakers in favour of the resolutions the only one whose opinion on a matter affecting the welfare and honour of the profession could be considered worth any serious consideration was Mr. Common, of Leeds, who moved the resolution, and who perhaps may be in earnest in his ill-regulated zeal; but Mr. Common seems to be quite *l'été monté* in opposition to the Institute, and has shown on various occasions, in his attacks upon it, an absolute want of moderation, of logic, or of tact, which have really taken away all serious value from his utterances. Of his speech at this meeting we are glad to be able to say

that it was considerably less unreasonable than others which he has made in the same room, though he did descend to the foolish claptrap of accusing the Council of being opposed to registration because they had all made their reputations and position and required nothing further: a kind of insinuation which is made simply for effect, and which those who make it do not really believe. Of the other speakers on the same side it is not worth while to take any notice here, further than to observe that if the profession of architecture is to be reduced by compulsory registration to their standard, it would probably be the desire of most of the high-minded artists in the profession to escape from any nominal adherence to its ranks, and to find some other denomination under which to range themselves than the one of "architect," which would by that time have become a badge of inferiority rather than a title of honour.

Apart from this, the main question is no doubt one that is worth serious discussion, if only to remove some of the fallacies which are rife in connexion with it. We print in another column a letter from Professor Aitchison, than whom no one has a better right to speak in regard to whatever concerns the higher interests of the profession. It is by the leaders of the profession that such a matter must be deliberated, and by their opinion that it must be settled, not by the clamour of a few obscure persons who are desirous to pose as reformers, and who are not particular as to the means they employ to recommend their tactics. *Non tali auxilio* is no doubt the feeling which is tacitly present to the minds of many who are supporting the action of the Institute against this noisy minority. If so important a step is to be taken, let it be taken at the instance and under the guidance of people whom we honour and in whose *bona fides* we can have confidence. And this is a point in regard to which the Colonial and American journals which have commented on the subject seem to be very much in the dark. We have observed in such quarters references to the "unhappy dissensions" among the English architects on the subject of registration. They are misled into this idea, probably, by those who have an interest in misleading them. Colonial critics may rest assured that nothing of the kind is the case. There are no "unhappy dissensions" among those English architects who are worthy of the name and whose talents and reputation are an honour to this

country. There may be decided differences of opinion among them, but there is no acrimony, and there is a perfect willingness to discuss the subject dispassionately in all its bearings. But this is a very different thing from putting up tamely with an attempt to force registration upon them by unworthy tactics, and by an appeal to a Parliament the members of which are mostly quite destitute of the special knowledge and culture which alone could enable them to understand and to weigh the possible effect upon architects and architecture of such a piece of legislation.

There are two distinct points to be considered in regard to the question of placing barriers by legislation to the entrance of the architectural profession: first, is it desirable at all? and secondly, is this the time for it? Professor Roger Smith's motion dealt really only with the second question. It is easy to reply that the objections existing now will exist at any time, and that to bow to them is only to postpone the encountering of them to a future day. Professor Smith gave sufficient reasons against this view; but nothing in the debate was so well put or so conclusive as what was urged by Mr. Phené Spiers in his very practical speech. He adduced the case first of the chemists, who applied for a recognition from Government in order to prevent the danger of anyone calling himself a chemist being allowed to sell poisonous drugs. The Government replied that it was impossible to make the restriction, but that if they instituted an examination they might obtain a title in course of time: which was the course adopted. Again, the Plumbers' Guild has started examinations, and has registered many plumbers, but they were not registered without passing an examination, "and it never seems to have occurred to the Plumbers' Guild," adds Mr. Spiers, "to ask that 'the position of all the jehing plumbers in the country should be respected.' If you were to go to Parliament and ask them now to admit all architects who have been in practice (however incompetent they might be), you would be met at once with the reply that it would be impossible to register as competent architects who have never been submitted to any test or examination." We hope so. At all events that is the plain common sense of the matter. If the Institute Examination is continued for some years, and meets with proper numerical support, there would come a time when there would be a sufficient body of men in the profession who had passed an examination, to render it worth while to ask for legal recognition for them. The outsiders would then in all probability find themselves compelled to pass the Examination also.

But whether that would necessarily be to the highest interests of architecture and of the profession is still doubtful; or if we conclude that it could do no harm, it does not follow necessarily that it would do any good. That the institution of an examination for entrance to the Institute has been a good thing for the credit of the Institute, under existing circumstances, we certainly think; but we must take into account what those circumstances are. We have before our eyes the example of the Institution of Civil Engineers, who have never held, nor we believe talked of holding, any test examination for entrance to their body. Yet the fact remains that membership of the Institution is so valued and is so generally recognised as an indication, if not a guarantee, of professional ability and competency, that every engineer, we believe, becomes a member of that body as soon as he can. And this fact is the more striking because one of the great difficulties in regard to an examination for the architectural profession does not exist in regard to engineering. An architect can be tested by examination in regard to his knowledge of the practical side of his profession; but the great and highest value of architects and architecture to the nation consists (though the majority of the nation have not yet recognised the fact) in artistic genius and consequent power of artistic design; and in regard to that it is utterly impossible to set

any standard of examination. Nor can you, perhaps, test by examination the possession of those qualities of readiness and resource under unforeseen difficulties, of enterprise, of boldness and inventiveness of constructive conception, which go to make up engineering genius: for it is unquestionable that genius, and not merely acquired knowledge, is an element in the character of a really great engineer: and it is perhaps the perception of this which has kept back the Institution of Civil Engineers from adopting a system of examination. But at all events the principal studies in which an engineer is engaged in preparing for his profession are practical studies, his proficiency in which could be tested by examination, whereas the highest elements of an architect's studies are artistic, and cannot be tested by examination. Yet in spite of this the Institution of Civil Engineers finds an examination test unnecessary; the profession is kept up to an adequate standard, and membership of the Institution is desired by the profession, and is accepted by the public as an indication of competency in the profession. If there is not the same feeling on the part of the architects that it is essential to be members of the Institute, nor the same feeling on the part of the public that such membership is a guarantee of competency, it is obvious, by comparison with the conditions of the engineering profession, that this difference has nothing to do with the existence or non-existence of an examination test. Then what is the reason of it?

The cause of the difference rests to some extent with the public. They know what they want in engineering works, and ask for it; and, as Sir F. Leighton said about art, what the public ask for they will get. They do not know what they want in architecture, and the highest part of architecture, architecture as an art, they mostly do not want at all. They therefore ask for nothing definite and consequently get nothing definite. But the reason lies far more with the architectural profession themselves; in their want of unity and *esprit de corps*. That a great many of them do not belong to the Institute is not the fault of the Institute; it is their own fault. Mr. Canon mentioned, in the discussion in question, that only a very small proportion of the Leeds architects were members of the Institute, and that their acknowledged leading man in that town was not; and he seemed to think this fact was a slur on the Institute. He is quite mistaken; it is a slur on his own townsmen: not because the Institute is a perfect or a perfectly-mangled body, though we do consider that at the present moment it is a very well-manged representative body, and is doing its best, in a very energetic manner and amid much discouragement, to benefit the profession and the art of architecture. But it is a slur upon those who do not join it, that they should be so shortsighted and indifferent as not to see the advantages to the whole profession of united action and a united front. A well-known architect who is not a member of the Institute, said, in reply to a question why he was not, "What advantage should I get by it?" That is a narrow-minded, shortsighted, and selfish view to take. Probably he would get no direct personal advantage, but the profession at large would benefit by greater unity of action, and each individual member can contribute to that. The engineering profession has proved practically that, without any examination test or legislative recognition, the profession can hold its position uncompromisingly before the public, and that membership of its representative society is regarded as an indication of a certain standard of professional acquirement. That the case is not similar with the architectural profession and its representative society is to some extent due to the ignorance and indifference of the public about architecture, but to a far greater extent it is due to the want of unity and loyalty to a common cause among the members of the profession themselves. Their representative body is not a power-

ful one like that of the engineers, simply because they will not take the only way to make it so. Until that spirit of loyalty is got rid of, test examinations will not, we fear, do very much to put the profession in a better position; and if it were got rid of, examination tests would be unnecessary, for the profession would be strong enough to hold its own in public estimation and to keep up the standard of efficiency within its own ranks, without the necessity of legislative interference, as the experience and example of the sister profession and the Institution irrefragably proves.

NOTES FROM ATHENS.

AFTER an unusually severe winter for Athens, the warmer spring weather and the bright sunshine has at last set in, and the near approach of Easter has brought the annual influx of University men who come full of energy and enthusiasm to visit the familiar Classic sites. This year Professor Middleton has brought a party of his students from Cambridge, and he is taking them round in that delightfully instructive way which is so pleasantly remembered by those who have had the advantage of participating in his former visits to Rome. They will probably stay for about a fortnight in Athens, visiting all the principal sites in the neighbourhood, such as Sunium, Egina, Eleusis, &c., and afterwards go to Mycenae and Epidaurus, allowing a few days for a short stay in Rome on their way back in time for the commencement of Term.

The work of the English and American Schools in Athens has been going on continuously during the winter, and many public meetings have been held in both schools; where papers have been read by directors and students on various subjects of archaeological interest. In addition, the directors have lectured to the students on special branches of archaeology, such as sculpture, vases, inscriptions, &c., in the museums, and on the topography of the various sites. Complete harmony exists between the two schools, and they have worked together amicably and pleasantly through the winter.

The American School resumed their excavations on the site of Plataea in February and carried on work there for about a month. They were greatly hampered by bad weather, especially during the early part of the time, when the ground was covered with snow for several days. Advantage was taken of the presence of an architect, as a student of the school, to make a complete survey both of the walls of the city, which date mostly from the time of Alexander, and of the whole region where the battle was fought, and important historical data have been verified and doubtful positions more definitely fixed.

A large number of remains of ruined Byzantine churches have been unearthed, and also a considerable quantity of Roman and Byzantine pottery and lamps. This points to the existence of a large Byzantine town on the site of the older city, and, we should think, makes the chances of discovering much work of good Greek times less probable. But until more extensive investigations than opportunity has hitherto allowed have been made, it would be a pity to abandon the site.

In one of these churches which lies at the south-east corner of the city, near the wall, was found, forming part of a grave beneath the floor, a slab containing another portion of the Edict of Diocletian, the preamble of which was discovered last year on a slab in the floor of another church. This inscription, which is in three columns, supplies about a column and a quarter of hitherto unknown matter, consisting principally of a list fixing the maximum prices of different textile materials. In the same church was also found another inscription of over seventy lines, dating from probably the end of the third century or the beginning of the second century B.C.; it contains a dedication by a number of women to a goddess, whose name

is not given, of votive torches, lamps, &c. It is especially interesting as giving us a large number of female names, some of which are new to us.

A number of small inscriptions were also discovered, some belonging to funeral stelæ, and one dedicated by a victor in the games of the festival of the Eleutheria. Part of a water conduit was also unearthed running into the city, under the walls, from the direction of the hills. It is formed of U-shaped terra-cotta tiles resting on the solid rock, and covered over with stone.

Several trenches were sunk in the part of the city where Leake places the temple of Hera, but without result. However, in a small church near this, where some architectural remains were also discovered, was found, among the debris, a foot of a large archaic seated statue in poros stone. Trenches were also sunk in what seemed a promising site for a temple, in the north-west part of the town, but owing to the depth of soil, had weather, and limited time, operations had to be suspended in the meantime. It is hoped that further excavations will be made by the American school on this interesting and extensive site, where much must still remain hidden which may throw valuable light on the history of Platea in Greek times.

The British School have commenced operations on the site of Megalopolis, in Arcadia. This is their first excavation on Greek soil, and the results of the first few days seem to promise well for the future. Almost immediately under the present level of the ground on the north side of the river Helisson, where the Agora was situated, the foundations of a large stoa have been discovered running for a considerable distance in a straight line east and west, and it seems to have had two rows of columns, the outer Doric and the inner Ionic. The remains already found point to a Roman restoration. Foundations have also been unearthed of what promises to be the plan of a temple, but operations at these two places cannot be proceeded with further at present owing to the standing crops of corn, interference with which would necessitate heavy compensation. Attention has consequently been directed to the site of the theatre on the south side of the river. This was the largest theatre in Greece, and there seems every chance of finding the complete arrangement of the stage walls as they stood in the fourth century B.C. These stage buildings, as far as can be at present seen, seem to differ entirely in arrangement from those of already excavated theatres. Behind the line of the stage wall an isolated unfluted column was found, with three deep holes on the top. This may possibly have had something to do with the machinery of the stage. The digging here is much deeper than on the north side of the river, the pits going down in some cases 15 ft. It will consequently take a little time before everything can be laid bare. Wherever trial-pits were dug, foundations of some sort were come across, and these were not confined to places where walls showed above the surface, but were done generally over the whole area. We hope to say something further about these promising excavations in the course of a few weeks. Two students are at present looking after the works, which were set going by the Director in person about the middle of March. The school now numbers ten students, including two who are in Cyprus, where the excavations on the site of Salamis, which are being carried on under the auspices of the Cyprus Exploration Fund, are, according to latest accounts received here, likely to show important results.

The French School have commenced excavations on the site of Troezen in Argolis, opposite the island of Poros.

The usual winter course of architectural and topographical lectures given by Dr. Dörpfeld, the Director of the German School, in Athens and neighbourhood, has been somewhat interrupted this year through his absence for some time in Cyprus, where he went to look into questions connected with German excavation in the island. While there he

took advantage of the opportunity to visit various places of archaeological interest,—amongst others, the site of the former British diggings at Papho, and the works now in progress at Salamis. He has since gone to Troy with Dr. Schliemann, who is making further explorations there this spring.

A number of the fragments of the large temple statues found by the Greek Archaeological Society last season during the course of their exploration of the site of the temple of Despoena at Lykosoura, in Arcadia, have been brought to Athens and stored in the Central Museum till arrangements can be made for bringing on the remainder, the present rough tracks being insufficient to transport some of the larger torsos. When these arrive the remains will be pieced together, and great hopes are entertained that almost the entire group, consisting of figures of Demeter and Kora with Artemis and Anytos, which, according to Pausanias, stood in this temple, will be recovered, and the Museum of Athens will then be enriched by the addition of a genuine temple-statue group of the fourth century B.C.

The very fine Byzantine mosaics in the church at Daphne, which suffered so much from an earthquake about the beginning of last year, have been temporarily secured till the arrival of a competent craftsman from Italy, who is shortly expected, and who, it is hoped, will be able to leave them in such a state as will ensure their stability for some time to come; but, while it is very important and necessary to thoroughly fix these, we trust that no attempt will be made to do anything in the way of restoration, which would utterly ruin their value as records of the finest period which have remained as they left the hands of their creator, and which, but for the injury they received from enraged and fanatic Turks during the time of the Greek Revolution, might have been preserved to us till to-day in an almost perfect state.

In three small rooms on the first floor of the offices of the Ecclesiastical Synod in Athens has been got together the nucleus of what promises to be a most interesting and valuable collection of Greek Christian antiquities. This small museum, which, we understand, is indebted for substantial help to Lord Bute, whose interest in Greek Christian remains is well known, was opened two or three weeks ago by the King and Queen of Greece. The collection embraces a general series of objects connected with the architecture and ritual of the Greek Church, and also includes a number of plans, drawings, and photographs of churches and of mosaics and frescoes, several old church service books, and some reproductions of illuminated manuscripts.

The architectural fragments consist principally of sculptured slabs, ceramic ornaments, fragments of mosaics and frescoes, portions of details of internal fittings such as the Iconostasis, &c., pieces of pavements and points of interesting constructional detail.

In connexion with ritual, we find a large number of vestments of various kinds, some being beautifully and richly embroidered, several croziers, specimens of flagons, chalices and patters, many of them of pewter, rich altar-crosses of delicate silver filigree work, often inlaid or picked out with gold, and usually enclosing intricate and minute figure-subjects cut out of olive wood. We also find several bottles for holding the sacred oil, made of cast lead with ornamental borders and quaint figure panels, ceramic plaques for stamping the sacred bread, Christian hand and other lamps, and large flagons for storing the oil for these.

There are also many very carefully-taken stamped impressions of Christian inscriptions and of the flat, slightly-cut ornament which was so commonly used round the doors and in other parts of the churches; a number of old and interesting typical sacred pictures of Christ and the Virgin, and of saints and prophets, and a collection of about 800 Byzantine coins.

We hope shortly to give a more detailed

account of this interesting series of objects, with perhaps a few sketches of the various types.

NOTES.

are still in the midst of an epidemic of strikes, and the subject engrosses the attention of a large section of the commercial and industrial community, having been discussed during the last few weeks at numerous meetings both of employers and employed. It appears highly probable that the Strikes Bill alluded to in our "Notes" of the 29th ult., will be quietly dropped. There could be no hope for such a measure unless the principle underlying it was acceptable to the majority of those concerned; and, so far from this being the case, it does not commend itself to either party. The element of compulsion in the Bill is condemned by all,—not excepting those responsible for it. Among the names appearing on the back of the Bill is that of Mr. Cremer, M.P.; and he has actually stated that he shall ask the hon. member who introduced it to withdraw it, and apologise to the House! The Trades Council term it "an unwise and astounding proposal," and earnestly entreat Parliament to reject it: while the Associated Chambers of Commerce simply ignore it as impracticable, and not worth consideration. They suggested the formation by the various Chambers of Boards of Conciliation, which would command the confidence of both parties, to arbitrate upon labour disputes; and invited the Trades Council to elect delegates to serve upon the Board. The latter, however, virtually decline to comply, although expressing themselves willing to assist to prevent conflicts. The result of most of the recent strikes has rendered workmen even more disinclined than before to submit to arbitration, under any name, and the proposals of the Chambers of Commerce were regarded with suspicion and designated "capitalist humbug." At the same time, they cannot go to the length of condemning the principle of conciliation, but they would only allow it to take the form of conferences between the parties to a dispute. This promises no improvement upon the existing unsatisfactory state of things, for the tone of recent Conferences of this nature has frequently been far from conciliatory. Indeed, it is impossible for the parties to a dispute to approach it with impartiality, though such conferences would serve to clear the way and narrow the issues. A practical but unprejudiced arbitrator, or Board of Arbitration, would then constitute the best and fairest mediator, and be far more likely to effect a speedy settlement of the dispute. In the absence, however, of permanent recognised "Courts of Appeal," there is always the danger of a dispute passing into the acute phase of a strike or lock-out before such a tribunal could be formed, or a suitable arbitrator selected.

THE academic labours of the Berlin congress came to a conclusion on March 29 with mutual congratulations to each other by the delegates and many expressions of gratitude to the Emperor of Germany for initiating the congress. We have called them "academic" labours because the very report of the delegates shows that the only force which can bring forth practical results is the national opinion of each separate European community. It is recommended that the States which may follow out the suggestions of the congress should "exchange the text of all legal measures adopted by them" with reference to the subjects before the congress. To pass legal measures it is necessary to have some popular force behind,—any changes, however small, will have to be discussed before popular audiences in this country,—whereas in Spain, where public opinion on such subjects as the labour of children in factories is not in so forward a condition as in this country, it is not likely that the recommendation of the congress will receive much

attention. A good deal of the proposed legislation has also been anticipated in this country, as, for instance, the prohibition of underground work for females. On the whole, the congress has been interesting rather as throwing light on the apparently benevolent autocracy of the young Emperor of Germany than for its practical usefulness.

THE whole archaeological world will have heard with regret the death of Mr. J. T. Wood, whose name will be connected for all time with the recovery of the remains of one of the most famous buildings of the world's history, and who it is to be feared impaired a naturally strong constitution and physique by his ardent labours at his chosen work under very great disadvantages from climate and circumstances. The melancholy part of it is that several years of these labours were, as we mentioned at the time of the appearance of his book on the Temple of Diana, unnecessarily wasted in hopeless search on the wrong side of the city; and that had he made due use of the information open to every one as to the probabilities of the site of the Temple, he might have achieved his object with far less waste of vital energy and in a much shorter space of time, and might have thus reserved health and time to publish the results of his labours in a form worthy of their importance. As it is, his best friends can only regret that he produced nothing but a popular book on the subject, an admirably-written and most interesting narrative, but not a monumental monograph of the type which archaeologists had hoped to see from him, and which any German savant who had made such a discovery would certainly not have failed to give to the world, and which remains to be done, if at all, by other hands. However, the fact remains that he did discover what it had long been said could be discovered by any one who would seriously make the attempt, and that in the carrying out of his determination he exhibited a degree of energy and perseverance which is worth as much in its way as the highest archaeological sagacity; leaving an example to others not to be discouraged by long delay and difficulties in prosecuting such a work, besides building himself an enduring name and place in the records of archaeological enterprise.

ALTHOUGH apparently Captain Bötticher has not responded to Dr. Schliemann's invitation to meet him at Hissarlik and there discuss the question whether the remains are only, as Captain Bötticher asserted, those of a cemetery where the dead had been burned, Dr. Schliemann has produced a counterblast to the assertions of his critic by summoning a jury of experts and others to sit on the question and sign their names to a statement in French which was communicated to the *Times* of Tuesday. The list of signatories to the declaration, eight in number, includes the names of Professor Virchow and Dr. Waldstein, the former being probably included as being one of the best-known scientific men of the day, and one who was not likely to be easily taken in with respect to the weighing of evidence and the logical deductions to be made from it. Otherwise, Herr Virchow is not exactly an archaeological expert, nor we presume is Mr. Calvert, the United States Consular Agent at the Hellespont. The others are M. Babin, Ingénieur des Ponts et Chaussées, and delegate of the Academy of Inscriptions and Belles Lettres of Paris; Dr. von Duhn, Professor of Archaeological Literature at Heidelberg; Dr. Grempler, President of the Society of Antiquaries of Breslau; M. Hamdy, Director of the Imperial Museum at Constantinople; and Dr. Humann, Director of the Royal Prussian Museum. These gentlemen, the opinion of the majority of whom at all events should carry some weight on such a subject, have entirely dismissed Captain Bötticher's criticism, and certify that the remains are obviously those of a fortified town; that there is no sign anywhere of provision for the

burning of human remains; that the ruins afford evidence of being composed of strata of débris belonging to successive periods, and that they found the foundations of Greco-Roman houses "dans la dernière couche," by which they mean, we presume, the upper stratum. They do not commit themselves to maintaining that Hissarlik is Troy, which could hardly be expected of them; but their evidence is, short of that, entirely in favour of the correctness of Dr. Schliemann's views as to the nature of his find; nor should we have expected otherwise. Whether the trouble which has been taken to secure this formal support is not impolitic in the sense of attaching too much importance to what was obviously a captious and sensational criticism, may be another question.

A PAMPHLET has been circulated by Mr. W. Saunders, member of the London County Council, consisting of "a statement of facts compiled from official sources" in regard to the question of Thames communication and the Blackwall Tunnel, and intended as putting a case in favour of a short tunnel and hydraulic lifts rather than a long tunnel and inclined approaches. He formulates the case briefly on the title-page as thus:—

Three tunnels with inclines,	= £2,500,000
Time in crossing 40 minutes.	
Two tunnels with lifts,	= £400,000
Time in crossing, 8 minutes.	

We do not believe there will be such a difference in the times of crossing as is suggested here. We presume the figures refer in the first instance to the whole time occupied on the inclined roads at each approach as well as in the tunnel: but that is hardly a fair way to put it; and the eight minutes must be calculated on the assumption that the descent and crossing is commenced as soon as the vehicle arrives at the lift, which is certainly not likely to be the case always or even in the majority of instances: where one lift serves all crossers one way, it is inevitable that many must be kept waiting till the lift is fairly filled, and that even when there were a sufficient number of vehicles waiting to fill it at once, there must be time occupied in getting them into position. At the Mersey Tunnel the delay at the lift is very considerable, with foot passengers only. Apart from this, there is a great deal in Mr. Saunders's pamphlet that deserves serious consideration. The expenditure of horse-power in dragging up long inclines would mean a serious annual waste, besides the first cost both in actual operations and in purchase and compensation that would be entailed in making the sloping road approaches. Mr. Saunders states that Messrs. Armstrong estimated the annual cost of working lifts at the Tower-subway, for a traffic of 4,412 vehicles daily, at 4,000*l.* a year. Taking the traffic at Blackwall to amount to 2,500 vehicles daily, the cost of the lifts would not much exceed 2,500*l.* a year; a very small percentage certainly on the probable saving in first outlay, even if we regard Mr. Saunders's figures as somewhat too favourable (as they probably will prove to be) to his short tunnel theory.

WE have received the third annual report for 1889 of the Herkomer School of Art, Bushey. It appears to have attained a thoroughly sound and self-supporting position; the maximum number of students is seventy, formed into two main divisions, "preliminary students" and those attending the life class. Appended to the report is a reprint of Professor Herkomer's paper in a recent number of the *Universal Review*, "How we Teach at Bushey," in which he points out that the aim of his teaching is "the suppression of the art student" and "to coax out individuality," and to make successful work the aim of the student, and not praise or prizes. In these days of bustle and commonplace monotony of work, no objects could be more admirable. At the end of the report is a list of the present and past students who have during the

past year exhibited works at the principal public galleries. We naturally turn to it to see the results of the six years' existence of the Herkomer School. The Royal Academy Exhibition comes first, and we receive a mild shock when we observe that the first picture which heads the list is entitled "Three to One on the Field" (oil)! Can this be the result of these high views, of this pure artistic life, of these pastoral plays on sunlit lawns; has the national sport even swallowed up this community too? A further perusal of the list does not raise our spirits. There is not one work which deals with the higher subjects of art; there are portraits, "Shiplake Backwater," "A Poacher's Bag," "On the Thames near Wargrave," and so on through the regular stereotyped subjects. What is the last? "Purple Clematis" (oil). "Far too many people dabble in art nowadays," says Professor Herkomer, in the above-mentioned paper: the works exhibited by the past and present students would, on the first appearance, seem to fortify this assertion.

THE Workmen's Exhibition which was opened on Saturday last at the Central Hall, under the auspices of the Working Men's Club and Institute Union, and which closed on Thursday last, was not very large or varied in extent, but in some respects it afforded a better display than is generally witnessed in such exhibitions. That this was so was mainly due to the fact that the amateur element, although quite sufficiently obtrusive, was more than counterbalanced by the exhibits which were the productions of workmen and workwomen in their own special trades and handicrafts. The majority of the exhibits showed good workmanship,—workmanship so good, in fact, that it was regrettable to see that the design of many of them was so poor. The trade which was most fully represented in the exhibition was cabinet-making; the building trades were very poorly represented. Among building trade exhibits we noticed some good specimens of plumbers' work by H. Goldman, a member of the Jewish Working Men's Club; and there were many good specimens of decorative work, as well as some bad examples. Among the curiosities of the exhibition we may mention what was apparently a very carefully-executed model of the South Hackney Club, made by Mr. C. Hamilton, a law clerk. The model was stated to consist of no fewer than 11,000 separate pieces of wood, each individual brick, seemingly, being represented by a separate piece of wood. The model is very cleverly executed, but, while commending Mr. Hamilton's industry and skill, we cannot but regret that so much time and ingenuity have been expended on making a model of what is a very commonplace brick house. Another thing that struck us, more, we must confess, on account of the exhibitor's name than on its own account, was "an imitation chess-table-top," as it is described in the catalogue: an "imitation-marble chess-table top" was what was meant to be described. It was apparently made of scagliola, in bright colours, and its exhibitor was "J. Ruskin," described as an "artist," and as a member of the United Radical Club. There are, it seems, two Ruskins in the field. We understand that this is the first exhibition of the kind held under the same auspices. The results have been so far encouraging, on the whole, but we shall look for improvement in future displays of the prowess of the "pick of the working classes" understood to be included in the membership of the workmen's clubs.

WE presume that the new hydraulic railway, at a gradient of 1 in 1 $\frac{1}{2}$, which is to facilitate intercourse between Lynton and Lynmouth, is a practical convenience to people who are not strong enough to climb a hilly road, and it will probably also provide a merciful relief for many unfortunate horses from a weary pull up the hill; but it would be of some interest to know exactly what are the "devices" for stopping the cars and

verting danger in case of any accident to them or the machinery. A railway with such a gradient might be the scene of a very serious casualty, unless the provisions made against any chance of coming down with an air are thoroughly trustworthy.

A CORRESPONDENT draws our attention to the following interesting bit of "æsthetic" from *The Queen* of March 29. It is in reference to the works of an American idyl sculptor, Miss Freehorn:—

"Sarcophagi monuments have claimed her attention, in the first instance in memory of her own parents. It would be difficult to find anything more original or beautifully adapted to its purpose than this public memorial that represents two large columns, the one straight, the other spiral, intended to embody separately the idea of female grace and virginal strength, blended by a spiral arch at the summit. While purely original, the spirit is Byzantine."

Which is the manly strength and which the female grace, the spiral or the straight, does not appear, nor does it appear to have occurred to the writer that columns are constructive features designed with reference to a superincumbent load, and therefore hardly suitable for separate and symbolic use. However, spiral arch "is good."

A QUERY of Lord Bury's as to the need of a verb which should be applicable to the movements of an electrically-driven launch, as steam ("to steam so many knots") is applied, very irregularly and inelegantly, to the movement of a steamer, has drawn a number of letters in *Thursday's Times* making suggestions which are amusing at all events, but very practical. The first correspondent suggests "to motor,"—"an electric-launch kicks half an hour to motor from Morlake to Putney,"—which would be the same as if we said that a boat driven by a steam-engine took half-an-hour to engine "from the one place to the other. That is not happy. R. W. S." is better with his suggestion to "mote," a verb properly formed from the same root as "motor," and already received into the language under the intensive form "promote." This is ingenious and logical. Two other correspondents suggest "electrize" and one "electrate." So long, and not convenient words. Mr. Andrew W. Tuer distinguishes himself by the invention of a new cockneyism, and suggests that as Lord Bury calls a monovalent, "to tric" will do to describe going in an electric launch: about as vulgar as "bas," and for the same reason most likely to be taken up. To "volt" will not do, if only because it is the same sound as "vault," and its formation into a verb of description is as absurd as it would be to apply to a steam-engine the word "to horse-power" from one place to another, because steam-power is roughly measured by horse-power. To "ohm" is worse, since, as another correspondent remarks, ohm is a measure of resistance, and therefore suggests the contrary idea to speed. We have no doubt that electric word must give rise to some new word-coinage, and we hope it will be made on better principles and in a less awkward manner than has been done so far, the barbarous jargon of "ohm," "ampère," "volt," "watt," &c., which have no innate suitability of meaning, and which give to treatises on electricity the effect of being written in a foreign language. Meantime, in regard to the present query, we are in accordance with the Rector of St. Mary's, Colchester, (another contributor to the correspondence in question) in thinking that no new word is required at all, and that it is perfectly intelligible, as well as good English, to say that an electric launch "runs" from one place to another in a given time, and that her work may be described as "a fair day's run." We may observe that the use of "to steam" as a verb applied to the progress of a steamship is not only irregular but unnecessary, and is not in universal use; it is in fact a piece of newspaper reporter's phraseology, and not classical English.

THE MEDIEVAL HOUSE.*

A GOOD example of an early house is Stokesay, near Shrewsbury.† It appears that the Hall was built some time in the thirteenth century, and that in 1291 the lord obtained a licence to crenellate, and built a tower. The buildings and courtyard are surrounded by a moat, 22 ft. wide, and are mostly of stone and in good preservation, but in some respects they depart from the customary arrangement. There is a gate-house. Opposite stands the house. It consists of a hall 51 ft. by 30 ft., with an open roof, and tiered windows which had glass in the tracery but shutters below. The hall has no fireplace. North of this is a room apparently intended for the cellar, with two rooms over, the upper one being of timber construction, and with a fireplace and good windows. The cellar and intermediate rooms have narrow windows (loops) intended for defence. At the other end of the hall is the solar—up steps, and with small rooms below it. Detached, but connected by a passage, is a tower of singular but picturesque shape. It was of three stories, and it seems probable, as there is a large fireplace in the ground-floor room, that that may have been the kitchen. The window openings in the tower all had shutters, and most of them had seats formed in the eills.

This may be taken as a good specimen of an English manor house as they were built about the time when the choir of Westminster was completed, and to which little has been since added. Much picturesque beauty it is true there is, the design of the windows, gables, buttresses, and open roof of the hall, most artistic and careful precautions against attack, but of comfort, convenience, privacy, warmth, and even shelter, very little indeed.

Stabling and other offices were in this instance, as in others, appended so as often to make three sides of a quadrangle.

The fifteenth century saw a great advance in the social condition of our ancestors, an advance which had begun in the century previous, and the Medieval house was in that century accordingly much improved. A large number of noblemen and gentlemen had for country houses some sort of castle, and they had begun, in the fourteenth century, in those cases where a stout tower or keep was standing by itself, to surround it with enclosed and fortified courtyards, within the shelter of whose walls rooms of various dimensions had been erected. This process was, in the fifteenth century, extended. The hall, whether in the castle or the manor house, ceased to be the common sleeping-place of retainers, and, by degrees, as manners and customs grew more refined, it ceased to be the dining-room of the lord and his family. Consequently more rooms, some of them for servants, others of larger size and higher finish for their masters, were added, and there were also not a few places which were required as stabling for horses, and occasionally for cattle and sheep. To the solar was often added a second large room. Of these two, one served as dining-room, while the other began to do duty as a ladies' withdrawing-room; and here we meet the drawing of our own invariable dining-room and drawing-room. A long room, called a gallery, begins to make its appearance in large houses. It was often hung with the family pictures, and hence probably our modern use of the word gallery to signify a place where pictures are collected. Sometimes, as at Hever, and, I think, at Penshurst, it is in the roofs; sometimes it seems to have been arranged at a lower level, in order that it might be used on state occasions *en suite* with the other principal living-rooms, as in the case of the magnificent gallery usually known as the ball-room at Haddon Hall.

Not infrequently a private chapel forms part of the construction of a large manor house, as it usually did of a castle. This is not usually large, but is often a graceful and well-contrived specimen of the architecture of the time.

At every period the architectural treatment of tracery, mouldings and carving with which we are familiar in churches, is paralleled by the treatment of the same parts in the domestic work. Vaulting, which is the finest, or almost the finest feature of church architecture, is, however, not largely employed in manor houses, though often in the more stoutly-built castles.

* A lecture delivered by Professor Roger Smith at University College, London, as part of the Course of Archaeology now being given there. (Concluded from p. 249, ante).
† Illustrations in Parker's "Dom. Arch.," Vol. I., p. 158.

On the other hand, the specially domestic features of fireplaces and chimneys, and the arrangement and treatment of the windows, so as to correspond to the many rooms of a mansion instead of the one space of a church, give a very different aspect to the Medieval house from that of a church, and this difference is very much intensified by the constant presence of chimneys, and by the retention down to a late period of some of the features which the manor house borrowed from the fortifications of the castle,—as, for example, the tower, the turret-staircase, the battlemented parapet, the moat, and the protected entrance, with its drawbridge or portcullis.

To the interior of houses the art of the fifteenth century contributed a great deal that was eminently domestic in character; but, at the same time, rich and even sumptuous in quality. Carved and moulded woodwork in panelled dados and wall-linings, doors, staircases, and so forth; ornamental ironwork in fire-dogs, the latches of doors and windows, and other minor fittings. Ornamental lead-lights in windows, filled often with armorial bearings. Tapestry, and, as time wore on, stamped leather for lining the walls, and well-wrought plasterers' work for ceilings. These resources, together with painting, gilding, and colouring, were now all at the disposal of the architect of a country house, and what he was able to do with them now invites our attention a little in detail.

All that went to make up the Medieval house is fortunately not of equal interest to us here, and there are many portions and features that we may well pass over, but upon one or two of them we should bestow a little attention.

First, the *fire*, and what it involved. The domestic hearth, much as the ancients made of it, cannot have been half so precious to them as to us and our forefathers in this chilly climate, probably worse in the Middle Ages than now. When there was only one room, whether it was a small house or a goodly hall, the fire in early days was, as has been remarked, at a hearth in the midst, and there was, of course, no chimney. In the hall-roof it was then common for there to be what is called a louvre,—that is to say, a kind of raised roof at the ridge of the general roof, and just over the hearth, with openings screened by what we still call louvre-boarding,—that is to say, boards some little distance apart placed on the slope like the laths of a venetian blind, so as partly to keep out rain, and yet to let smoke escape through the gaps between them. This feature is seldom left in halls that are in any way in use, as, if smoke is not going out of it, cold wind is apt to come in; but in the hall attached to the deanery at Westminster Abbey, already referred to, used as a refectory by the Westminster School, there is a louvre in the roof, very much in its original state, though the hearth has been replaced by a modern stove.

In smaller rooms, and before we have the fire-halls, it began to be customary to have the fire at the side, and to carry the smoke up a chimney. It was very early an established custom, when a fire was to be provided for, to build a regular projection, often 10 ft. or so wide, and several feet deep, from the side of the room, to form a hearth in the middle of the space so gained, to throw a great beam across the opening between this hearth-place and the room, and gradually to contract the great space above and behind this beam into a chimney. Thus, there were two very warm, if perchance, smoky snuggeries, created on each side of the hearth. These were the chimney-corners, or ingle-nooks. The fire was of wood, and there were iron bars at each side the hearth, called dogs, on which the logs could lie a few inches above the glowing ashes on the hearth. The front supports of these dogs were often richly ornamented with iron or brass work.

When the room was smaller, and especially in upper floors, the fire opening was smaller, and was constructed very much as we make them now, only that where we put a grate there was a hearth,—usually a little raised, with iron dogs.

The lintel over the openings of such fireplaces is generally not a timber beam, but a beautifully-constructed stone lintel, worked in many interlocking pieces. Sometimes it is an arch. These lintels and arches also frequently occur over fire openings of very wide space in Medieval kitchens and halls.

When coal came into use, the iron grate to hold it followed as a matter of course, and the fireplaces became smaller, but substantially

though coal may have been used early in the North of England, the fires of the Middle Ages were wood fires, with their cheerful flame, ruddy glow, great heat, and pleasant smell; and the collecting, storing, and cutting of wood for fuel must have been one of the constant occupations of the household servants.

Next to the fireplace, perhaps the window is the part of a house that has most home-like character. No windows of any Mediæval house were like the sash-window of our day. It is a modern invention.

In early times, though glass was known and used for churches, the window-openings in houses were closed only by shutters. In the thirteenth century and down into the fourteenth we find domestic windows with tracery in the heads, the beads having been glazed, but the lower parts fitted with shutters, and the hinges and holes for the bolts and stone ledges for the shutters to close against show this clearly. If I am not mistaken, this was the case in some monastic buildings down to a later period.

When glass began to be obtainable, it was at first so scarce and costly that we are told that gentlemen in the Middle Ages used to carry their casement-windows with them from one house to another—and also, by the by, their tapestry hangings.

When glass became fairly plentiful,—which, we may assume, was in the fifteenth century,—the windows were made up of small pieces set in leadwork, often in the familiar diamond-shaped quarry, but not infrequently in more complex ornamental patterns, and these were secured usually to iron frames and bars let into the stonework of the window-opening. Such portions of the windows as opened (and they were not many) were hung as casements, and often fitted badly, and did not open far, but the latches and stays were usually charming specimens of ornamental ironwork. Of course, in timber-built houses the casements were of wood.

A feature which is of such frequent occurrence that its absence,—when it is absent from stone-built houses,—is a surprise, is the window-seat. The walls being mostly thick, there was plenty of room inside the window-sill to form a seat, which is frequently so fashioned that two persons could sit and face each other. At other times it is arranged,—as we mostly do it now when we employ it, bench-wise,—so that those who occupy it sit with their backs to the window. In all the Mediæval period it must be remembered that domestic windows were divided into comparatively narrow lights by upright bars of stone or timber, called mullions, and in the latter part of the time they were also frequently provided with one or more horizontal bars known as transoms. By this means, though the individual light was kept down to such dimensions that a leaded window was strong enough to fill it, it became possible to have wide and lofty windows, made up of many lights, when they were wanted.

The bay-window and oriel-window are features of the Mediæval house which added much to its beauty and also to its brightness. A bay window is a wide projecting window, sometimes square, sometimes half-octagon, and occasionally of other forms in plan, rising from the ground floor of the house.

It became usual, as has been already said, to introduce a bay-window into the hall. It was generally at the distal end of the apartment, and usually reached from floor to ceiling, often being of great size. In the Elizabethan mansions this feature was introduced into many other parts of the house (fifteenth century).

The oriel-window was a bay-window on an upper floor, only corbelled out, and consequently rarely so large as the bay. When the bay is introduced elsewhere than in the hall, it is very useful for it to be carried up through all the storeys of the house, and as the desire to make upper rooms pleasant increased bay-windows of this sort and oriel-windows came more and more into vogue.

You will probably turn next to the walls, and inquire in what manner they were finished. In early times,—and in less important rooms at all times,—they were plastered; but the Mediæval plastering was a very thin coating, not like the inch or inch-and-a-half which we at the present day heap on to our rough walls and then smooth down. When the inner face of the walls was not smooth the plastering did little to hide the roughness, and other methods were employed. I ought to add that this plastering seems to have been usually decorated by the painter, often being lined out in red, in imitation of

masonry, or else painted upon with histories or fables.

As early as the thirteenth century, wainscoting, *i. e.*, lining walls with woodwork, began to come into use. It appears that Norway planks, *i. e.*, planks of fir, were imported into this country for this purpose, though most of our joinery was in oak. In later times the custom of so lining the walls of rooms to which it was desired to impart an air of comfort and finish became common. In the fifteenth century the curious ornament known as the linen-fold came into general use in the panelling, and towards the close of the century stamped leather began to be employed as a sumptuous wall-lining. The finest wall-covering, however, was the tapestry which was one of the glories of the Middle Ages, and may be said in Domestic work to have held a place something akin to that of stained glass in the churches and cathedrals.

As early as the twelfth century tapestry was occasionally in use, but it appears to have not been till far on in the thirteenth that it was often employed. The town of Arras became so celebrated for the production of tapestry that the Arras became the familiar name for it. In Shakespeare's *Henry V.*, at the inconvenient moment when the search for the Gad's Hill robbers had become warm, you may remember the Prince says to Falstaff, "Go hide thee behind the Arras." Much good tapestry was produced in London, while Norwich became famous for worsted stuffs, while were used as a substitute for tapestry as a wall covering.

Tapestry was first employed to ornament the upper end of the hall, and gradually introduced into other parts of the house. It seems to have been usually so arranged as to take down and hang up from pegs or books so that it might be put away when not wanted or (as is stated to have been done) carried from the town house to the country one and back. I need not dwell on the capacity of this kind of material for serving as coloured decorations of the noblest sort.

It would he, I think, treason against the highest attributions of the study of archaeology if in this lecture no word should be said on the group of buildings of which it takes cognizance viewed as works of art. When we endeavor to discern the special merits of their architecture, we, I think, must at once admit that they are singularly full of character. No buildings of any age or country are more happily successful in conveying to the spectator the impression that they are built for the purpose they were meant to serve. This is probably the first quality of good architecture; it is the one most commonly missed in imperfect modern work, and the complete attainment of it is the quality above all others which gives to the best ancient work its high value. Of such places as Ightham, Penshurst, Knole, or Haddon, your first impression is that they are dwellings: English, feudal, dignified, if you will, but, before anything else, domestic.

The next most prominent quality, especially of their exteriors, is picturesqueness. The accidents of situation, of varying requirements, and of subsequent alteration have provoked the most charming irregularities, and the most telling contrasts; and, so far as the interiors remain untouched, the same thing is there also true, though unfortunately nearly every Mediæval house that has been kept up has been dreadfully modernized, like Windsor or Alnwick; while almost every one that has not been kept up has been allowed to fall into ruinous decay. Few and far between are the Mediæval houses of which the hall and rooms have escaped one or other of these fates!

Ludor, Elizabethan, and Jacobean houses have been, in this respect, much more fortunate, and I am inclined to believe that a better general impression of what Mediæval interiors were at their best,—how artistic, how rich, and how varied,—would be derived from a visit to such a house as, for example, Audley End than from anything else. Time will not permit my saying anything about the furniture which went to create the artistic effect of those interiors, but it would be a subject worth your study, and in case you care to see a splendid series of copies of old decorations and furniture, I ought to add that the late Emperor of the French, with all the resources of the most artistic nation of modern Europe at his command, strove to restore the magnificent county Chateau of Pierrefonds, near Compiègne, to a condition of completeness, inside and out, including its furniture. He had the advantage of the learning of Viollet-

le-Duc. The old walls were almost, if quite, perfect when the work was begun, but all else is the creation of the great architect. I believe it has probably been overlooked by those who are interested in Mediæval domestic art to recommend a visit to Pierrefonds as an archaeological lesson worth taking.

I propose now to invite you to accompany me on an imaginary visit to one Mediæval house, in many respects the best for our purpose which England affords, and of which fortunately, excellent photographic illustrations have been provided by Mr. Brooks. I allude to Haddon Hall, in Derbyshire.

Haddon Hall* is the property of the Duke of Rutland. How it came to them, and why have been its fortunes since Domesday, which survey the place is named, is very pleasantly told in the article in the current number of the "Quarterly Review" from *T. P.*, as it is said, of the present Duchess of Rutland. The hall has not been occupied since the year 1700, and no alterations and modernizations have been introduced since that date, and though it has been robbed of much of its furniture, whatever remains is appropriate. There is much good tapestry, and the fabric has been constantly looked after, and is not allowed to fall into decay.

It is erected entirely with stone-walling, strongly built, but very picturesque, and is a house of very considerable extent, quite fit for a nobleman's seat.

Haddon has no mote. It stands on a projecting crag or spur of no great height, throwing forward from the rising ground that forms the west boundary of the valley of the Wye, and the stream washes part of the foot of the rock, but can never have formed a substitute for a mote, and though walled it never was a castle, only a strongly-built manor house. Haddon was built and altered at several times during the Mediæval period, and part of the place was built or rebuilt in Elizabeth's time, and a little internal fitting was done to a few rooms at a rather later date still. I propose, however, that for our present purpose we accept it entire as an example of the Mediæval house. The block of buildings is a parallelogram of slightly broken outline, and there are two internal, somewhat irregular, quadrangles. The entrance front faces due north; the garden front is south; and the quadrangles are east and west. The hall, with its butteries and kitchen at its north end, and its solar and upper withdrawing room, at its south end, forms the middle block, and extends across the whole building from north to south, and so has a quadrangle on either side. Each quadrangle is separately entered, and each entrance is under a tower, the two towers forming the ends of the north front. The Eagle Tower, the north-east one, is the earliest, and appears to have been built in the thirteenth century. The Entrance Tower, chiefly made use of, is at the north-west angle, and forms a commanding feature. It is of much later date, being, as we see it, probably part of the work of Sir George Vernon, known as the King of the Peak, who held Haddon from 1515 to 1565.

The chapel, one of the oldest parts of the building, is at the south-west corner. It adds to the hall, the solar, and the kitchen are the only important parts of the building on the ground floor; the other rooms, for family occupation or state, are on the first floor; and under them, on the ground level, are offices or very inferior rooms, and in some cases no rooms at all. The general disposition of the first-floor rooms may be described as follows:—There is a range of rooms, formerly used as family living rooms and bedrooms, in the north range of buildings and part of the west. There are three such rooms also on the south range at its west end. Over the solar (or dining-room) there is a drawing-room. The whole of the remainder of the south wing is occupied by the gallery, often called the ball-room, 109 ft. 6 in. long and 18 ft. wide, exclusive of the bays. The east range of buildings is mainly occupied by the great state bedrooms, and the two ante-rooms belonging to it.

Thus we have the normal arrangement of the hall, with all its usual appendages, forming the heart of the house, and added on to it the various ranges of buildings which were necessary to make Haddon a lordly mansion.

* The plan of Haddon Hall occurs in Parker's "Domestic Architecture," vol. III., p. 97, also in the *Quarterly Review* for January, 1890, and is given with many other illustrations in Mr. Jewitt's guide to Haddon Hall. For a careful account of the architecture of the Hall see a paper by Prof. Roper Smith in the *Builder* for May 15, 1880, with illustrations.

Sarcophagi recently discovered at Rome.

A COMPULSORY EXAMINATION FOR ARCHITECTS.

SIR.—The members of the Royal Institute of British Architects are now being asked to vote on this momentous question: "Whether it be expedient or not to at once close, if they can, the hitherto open profession of architecture."

It seems to me an opportune moment for the whole profession to give this question a full and impartial consideration.

I think such a devotion towards architecture animates the whole body of the profession, from the humblest to the highest, that the body would not hesitate for a moment to sacrifice the present good of the architects for the good of the art, did such an antagonism exist. At the same time, I think it is possible that some important considerations may be overlooked when an immediate answer is called for.

As I take it, the question to be solved is this: Will a compulsory examination of all, who shall hereafter be allowed to practise the profession, really promote greater excellence in the art?

If a compulsory examination becomes law, the efforts of the students must be directed to fitting themselves to pass it. Can any examination be devised that will really aid men of genius in becoming better architects? For I hold it to be of infinitely greater importance that the few great men should not be hampered in the attainment of the requisite knowledge and skill, than that the bulk of architects should be a little better, and that absolutely ignorant impostors should be excluded.

If the examination he slight it is illusory, and if severe it comes under Mark Pattison's description that, by another turn of the examination screw, not only is more useless torture inflicted, but all independent thought is crushed out.

If we knew how the great architects of the great fine art epochs had been trained we should have some safe ground-work to build on, but on this subject we are in the profoundest ignorance. Some believe the Greek architects were sculptors, but if so, what was their subsequent training? We do not even know how the Roman architects were trained, though we believe that most of them were Greeks. We know nothing of how the Byzantine architects were trained, though Procopius states that Anthemius of Tralles was a great mathematician.

We read in the "Arabian Nights" that when great buildings were to be erected the "geomet-

ters and mathematicians" were called in. In the dark ages and in the early Middle ages the architects are called "stone-cutters." We learn from Viollet-le-Duc that there were schools of architecture in some monasteries, and that in the thirteenth century architecture fell into the hands of laymen, but the "Bons" who built the Ducal Palace, the Porta della Carta, and refronted the Ca' d'Oro at Venice were called "stone-cutters." Lombardo contracted for a certain sum to build and carve Santa Maria dei Miracoli, according to a model he had made. Baldassare Longhena kept a mason's shop to the end of his life.

Brunelleschi was a goldsmith and sculptor before he domed the Cathedral of Florence, and he learned how to do it by studying Roman vaulting and making models. Most, if not all, the Italian architects of the Early Renaissance were brought up as goldsmiths, and became painters or sculptors before they became architects, and their main architectural study was measuring Roman ruins. We know that Bramante, Baldassare Peruzzi, and Vignola were painters, that Fra Giocondo was a monk and a scholar, and that Sansovino was a sculptor. Bernini was first a sculptor, then a painter, and then an architect. Inigo Jones was a landscape painter, and became a pupil of Palladio; Wren was a universal philosopher—he was a demonstrator of anatomy and a lecturer on astronomy as well as an architect. Perrault was originally a doctor, Allievi a harrister. What was Sir John Vanbrugh besides a playwright? how did he acquire his architectural skill? though we know he was for some time clerk-of-the-works to Wren. Were Gibbs, R. Adam, Sir W. Chambers, and Wilkins brought up as architects, in our sense of the word?

We might possibly learn how the Persian architects are trained, and the native architects of India, for no matter how skillful our architects may be who go there, most of them soon adopt Persian or Indian styles.

Let us suppose that a love for architecture should arise, and the public begin to have a taste in some definite direction, can we now say from what class the architects would arise who would put that taste into shape? Would they arise from the carpenters, bricklayers, masons, or plasterers, from the engineers or ornamentalists, from the architects, or from a class that has nothing to do with the constructive professions or trades?

Some years ago the Royal Institute of

The hall is entered by a porch which gives access to a passage cut off by an oak screen with two arched door-openings. At the higher end of the hall there is a dais or platform raised one step, on which still stands the massive oak table and bench. In the middle of one side is a wide fireplace, and there are windows with pointed heads and fourteenth-century tracery, but there is no bay. Unfortunately the original roof has perished. It, of course, was an open one, but as there is a regular chimney it probably had to leave. Over the passage already alluded to as cut off by the screen is a minstrel's gallery.

At the south end of this room up some steps is a fine parlour with woodwork of the time of Henry VIII. This is the solar, and over it is a drawing-room—part of the Elizabethan additions.

The finest Elizabethan feature is, however, the noble hall-room with three vast bays, its walls lined with wainscoting, its ceiling a beautiful specimen of ornamental plastering, and its extensive floor of oak furnished, it is said, by a single tree.

SARCOPHAGI RECENTLY DISCOVERED AT ROME.

OUTSIDE the Porta S. Lorenzo, the engineer Cantoni, making some excavations for the foundation of a new house, discovered, a few weeks since, two interesting Roman sarcophagi, of marble, of which we give illustrations, reproduced from photographs. The first, of rectangular form, is covered in the front with sculpture in high relief, representing the story of Medea. The style of art is that of the second century after Christ.

The second sarcophagus, very interesting for its ornamental motive, exhibits, in the centre, a group of the Graces, and above this is a bust (probably a portrait of the deceased person) in a medallion. The remainder of the surface is treated with an undulated fluting. On the ends were sculptured decorative lions' heads, of which only one remains in position.

This sarcophagus, according to the character and coiffure of the bust, may probably be referred to the time of Alexander Severus (222-235 A.D.).

L. B.

British Architects settled that in future no person should become a professional member of its body who could not show by examination that he had an acquaintance with the main elements of the profession, or could prove it by the works he had erected; but beyond this the candidate has to show that he has passed some sort of apprenticeship to the profession. It cannot be denied that this examination has given an impetus to the students to study the subjects included in it. No one knows, however, how it will eventually succeed, as it has not been tried long enough, and the system, too, has just been changed; nor can any one say that the success achieved is wholly due to this examination, and not to other concurrent circumstances.

The professional sense of the word "architect" is a person who, besides planning conveniently, building soundly and healthfully, can add a certain amount of heauty to the structure.

The bulk of the public probably take it to mean anyone from whose drawings any building has been erected or altered.

Suppose the votes in favour of closing the profession preponderate, and that every future architect must pass a legal examination to be allowed to practise; can it for a moment be supposed that the Legislature will insist on a fine-art test? The material good of the public is certainly all that will be legislated for,—unless, indeed, a change has come over its views, and it will require an examination to be passed before a man can practise as a painter, sculptor, musician, actor, or author. Will the Legislature break at once with Adam Smith and the philosophers of the last century, and insist on apprenticeship or any other test but the examination in construction and sanitation? Every person of legal age who can pass this will be allowed the title of architect, and permission to practise. Every tradesman, too, who has had "Architect" painted on his shop before the passing of the Act, or who has furnished drawings for a building erected or altered, will be an architect by Act of Parliament.

As to the effect of the examination, if it be slight, as at present, it will not present grave obstacles to those whose strength lies in esthetic design, provided they have had a good education, but make it severe, and it will exclude a vast proportion of esthetic talent.

I am told that in Austria, where the constructive examination is severe, it excludes many of the artistic architects, so that the certificated engineering architect has to keep as a partner an uncertificated architectural designer.

It was from this point of view that Professors Cockerell and Street deprecated a compulsory examination, both of whom put this question to the Institute, "Are we so overwhelmed with artistic talent that we can afford to exclude any of it?"

I may add that Professor Huxley published a paper deprecating the compulsory examination for doctors.

G. AITCHISON.

ATHENS: ITS MYTHOLOGY AND ART.

BEFORE proceeding with her examination of the Athenian cults, Miss Harrison devoted the whole of her sixth lecture to a sketch of the topography of Athens, following in her exposition the views of Dr. Dörpfeld. The chief points to be noted are:—The ancient district of the *Limnai* (Marshes), so long thought of as south of the Akropolis, is now placed just by the Dipylon Gate. Here Pausanias (l. 2, 5), soon after he enters the city, sees a precinct sacred to Dionysos,—here would naturally be the god's older worship, first established on his entrance into Athens. Later, this cult in the *Limnai* was thrown into the shade by the more important theatre and temples south-east of the Akropolis. This *Limnai* district was watered by the newly rediscovered Eridanos (*Builder*, March 1). About here lay the Kerameikos, or potter's quarter, and the commercial *agora* or market-place, commanded by the Kolonos Agoraios (market-hill) on which was a temple of Hephaistos (long misnamed "Theseion"), patron of potters and all artisans. Slightly to the north of this temple may be placed the shrine of Aphrodite Ourania. (A beautiful type of this, the heavenly Aphrodite, may be seen on the matchless plate from Kameiros, in the British Museum,—it shows Aphrodite passing through the air on a swan.) Below the eastern slope of the Kolonos Agoraios were the various famous *Stoa* (Basileos, Eleutherios, &c.), and the temple of Apollo Patroos, noted

by Pausanias on his progress south towards the Areopagos. Under the north slope of the latter hill was the *Metroom*, or shrine of the mother of gods, within whose sacred precinct were enclosed the *Bouleuterion* or Council Chamber, and the *Tholos*, or dining-place of the Prytanes (Paus. l. 3, 5). Above the Metroom under the north-western brow of the Areopagos were the statues of the Eponymous heroes of the Attic tribes. Opposite these, on the other side of a road leading to the Akropolis, were the famous statues of the tyrant-slayers, Harmodios and Aristogiton, by Kritias and Nesiotos. The *agora* proper,—the ancient political *agora*, not to be confounded with the commercial market-place mentioned above,—occupied, Miss Harrison maintains, the ground between the Areopagos, Phyx, and Akropolis. Here, about the south-west angle of the Areopagos, was the celebrated *Enneakroonios* fountain, of which Dr. Dörpfeld believes he has discovered the channels. Next was the sacred enclosure of the Eleusinian deities (*Builder*, March 1). South of the *agora*, near the *Pelagion* was the temple of Aphrodite *Pandemos* (of the people). This new explanation of the topography of Athens makes the long-discussed route of the Panathenaic procession quite clear. Starting from the *Dipylon*, it passed through the *Limnai*, then east of the *Kolonos Agoraios*, down the road between the *Areopagos* and *Phyx*, passed through the *agora*, skirting the *Eleusinion*, and so went up to the Akropolis. The district south of the Akropolis, stretching to the *Liissos*, where the Athenians of the fifth century had their dwelling-houses, was shown to have been built on at a much later date than the whole western region. In resuming her exposition of cults with that of Dionysos, the lecturer showed his intimate connexion with the Eleusinian deities. The theatre of Dionysos, the old *orchestra*, or round dancing-place, the *choros*, and the mimetic character of Greek choros dancing, had all been discussed in the autumn of 1888, and Miss Harrison seems to abide by the views then expressed. In returning to the Akropolis, an interesting analysis was given of the old and rather dim cult of *Zeus Polieus*, guardian of the city, who guarded it in the days of Kekrops, before ever Athene came, and contested for the lordship of the land with Poseidon. *Zeus*, too, was the original lord of the olive-tree, afterwards the special token of Athene. Sophokles keeps up this tradition for us in the fifth century, when in the chorus of the *Oedipus at Kolonos* he says of the olive: "Youth shall not mar it, . . . for the sleepless eye of the Morian Zeus beholds it." The lectures ended with an examination of the sculptures of the Parthenon. It is interesting to note that Miss Harrison holds the view which seems, slowly but surely, to be gaining ground among archaeologists, to the effect that in the Eastern pediment of the Parthenon the birth of Athene was represented realistically, i.e., the goddess was springing, fully-armed from the head of her father, in the old Athene Polias type, in striding motion, with shield and spear. This supposed scheme is echoed for us in many vase-paintings. It would have the double advantage of giving us the actual moment of the birth, so important in a temple of the goddess, whereas all other schemes have given vague and undefined moments, and the small figure of the goddess would admirably fill up the angle at the apex of the pediment towards which drive all the lines of the composition, architectural and sculptural. For the Western pediment, the lecturer, in accordance with a theory of Mr. Cecil Smith, of the British Museum, thinks the exact moment represented was that in which the two deities, Athene and Poseidon, move aside to show their tokens—the great olive-tree and the well of salt-water. These tokens would occupy the centre of the pediment, and from the top branches of the olive-tree would perhaps float down a little Nike to crown Athene,—such a figure would well correspond to the new-born Athene of the Eastern pediment. This new conception, instead of the old one of strife, when Poseidon with his trident was looked upon as attacking the olive-tree, gives great dignity to the composition—the gods, after striking the earth with their respective weapons, are moving aside in corresponding attitude to the left and right, to show their great gifts to the land.

Within the temple, the great ivory and gold statue of Athene Parthenos, by Phidias, was the embodiment of the best thought of Athens, religious and political, and was, moreover, the

highest artistic expression of the most sacred type of Athene; for the Parthenos is merely the old fighting Polias softened down to suit a time of triumph and of peace; with the religious myths most dear to the Attic race serving as rich designs for her pedestal, her sandals, or her shield,—with all the great attributes of the city grouped about her, the snake, the Victory, and, doubtless, the olive, she might well let spear and shield sink to the ground in rest; she needs them no longer in the strife, but only as emblems of power, for the Athens of the age of Perikles is a victorious Athens; and Athene, conqueror herself in her great ritual, to the exclusion or absorption of all other gods, stands there in the famous temple as the sole protector and guardian of the city.

"Pallas, our lady of Athens."

The lectures have been admirably organised by Mr. R. G. Tatton, secretary of the Chelsea centre for the Extension of University Teaching. The audience has been very large, and regular in attendance. At the close of the last lecture a vote of thanks to Miss Harrison was moved by Mr. Ernest Myers, in the name of the Council for the University Extension.

THE EXAMINATION IN ARCHITECTURE, MARCH, 1890.

AT the Examination to qualify for candidature as Associate, held in London during the week commencing the 24th ult., fifty-three gentlemen out of fifty-six admitted by the Board of Examiners presented themselves. Of these, twenty-one have been relegated to their studies for one year, and six have not passed. The names of the twenty-six gentlemen who have passed are:—

Ancombe, A. E.	Hill, H. L.
Beckett, R. T.	Howard, E. P.
Bedford, F. W.	Hughes, H. H.
Carter, E.	Metnam, W. J.
Eaton, W.	Nunn, B. W.
Eccles, T. E.	Russell, S. Bridgman.
Frere, E. C.	Scott, J. D.
Gibson, J. S.	Spackman, A. E.
Goodwin, W. B.	Wehh, W. A.
Habershon, A. E.	Wood, H. S.
Hart, A. H.	Woodington, H. A.
Harvey, G.	Worthington, P. S.
Heron, A. H.	Young, E. A.

The oral examination of the fifty-three gentlemen who presented themselves, which was conducted by the Board of Examiners in Architecture, commenced at 10 a.m. on Friday, 28th ult., and terminated at 7.30 p.m. on the following day. No Qualifying Examination was held this March by the Allied Societies.

THE PRELIMINARY EXAMINATION,* MARCH 1890.

Seventy candidates were admitted to the Second Preliminary Examination, of whom eighteen have been declared exempt. Of the remaining fifty-two candidates, eighteen have been relegated to their studies until next November, and thirty-four have passed. Of the latter, twenty-two were examined in London, five in Bristol, and seven in Manchester. The names and addresses of the fifty-two passed candidates, which have been entered on the Register of Probationers, are here given, that is to say:—

Austin, C. A.	King, A. S.
Bailey, H.	Lawrence, G. C.
Beckett, J. H.	Leslie, H. G.
Bishop, T. H.	Ligertwood, G.
Booth, H.	Longworth, W. H.
Brown, W. G.	Lucas, T. G.
Bulman, H. G.	Lynan, T. R.
Carré, H. B.	Marchant, R.
Cox, H. J.	Middleton, O.
Delves, S. W. W.	Morton, R. H.
Finch, W. H.	Nicholson, E.
Fraser, G. W.	Pearce, R. L.
Galt, W.	Pearson, H. L. D.
Goldie, C. R.	Price, F. J.
Goodwin, W. D.	Rochester, C. D.
Gullan, H. F.	Savage, R.
Harris, S. S.	Scrivener, H. M.
Harrison, J. E.	Simpson, G. M.
Haywood, G. W.	Simpson, W. H.
Hennell, A. R.	Sterry, H. E.
Hicks, F. G.	Stratton, A. J.
Honfrey, H.	Streetfield, G. E. S.
Hunt, J.	Watkins, W. G.
Hunter, R. H.	Ware, E. F.
Johnson, H. W.	Wells, W. W.
Jones, W. S.	Whitmore, S. W.

* To qualify for registration as Probationer.

OBITUARY.

Mr. J. T. Wood, F.S.A.—We announce with much regret the death of Mr. John Tuttle Wood, F.S.A., Hon. Fellow of the Royal Institute of British Architects, Mr. Wyatt Papworth contributes to the *R.I.B.A. Journal* for April 3 the following appreciative notice:—"In the Annual Report of the Institute, read May 3, 1875, reference was made to the election in 1874 of Mr. J. T. Wood as a Fellow, 'whose antiquarian researches at Ephesus have won for him an European reputation, and whose valuable services in rescuing from oblivion the site and remains of the famous Temple of Diana, have been deservedly recognised by Her Majesty's Government.' To-day it has to be announced that Mr. Wood died on the 25th ult. at Worthing, of heart disease, in his 70th year. He had been advised in January to reside for a time at the seaside to escape the London fogs, and had hoped to return to town this month. Having been away from England for so many years, there are few probably who know much of Wood; my acquaintance, however, dates from about 1849, in connection with his making a plan of part of St. Martin's parish, at which time his office was near Somerset House. He was born February 13, 1821, in London, and studied at Cambridge under a tutor. His master's name is unknown to me, but I think he was in the office of Mr. H. E. Kendall. In 1850 he was at Venice. In 1853 he married, and practised in Victoria-square, Grosvenor-place, as an architect. In the early part of 1858 he accepted the appointment of architect to the Smyrna and Aidin Railway, and went out there in April to design the stations on that line. He commenced the first excavations at Ephesus in May, 1863, exploring the Odeum and the great Theatre. Whilst so engaged in April, 1865, the place was visited by the Duke of Connaught, and Mr. Wood accompanied him to Mitylene, Pergamos, and Assos. After spending his own money on the work for two years, he commenced his search for the Temple in 1867, under the auspices of the Trustees of the British Museum, who forwarded to him a small sum. With a larger grant, and after six years of toil, just at a moment of despair, he fortunately hit upon a corner of a thick wall of large stones, which proved to be the Periholus wall built by Augustus. A sufficient sum was then granted to complete the discovery of the Temple itself, which was effected in May, 1869. He then returned to England, and, in July, 1871, read a Paper at the Society for the Encouragement of the Fine Arts,* when he gave an account of the discovery, and stated that the first clue which led to the finding of the Temple was an inscription, unearthed by him at the great Theatre, particularising the circuit of the city to be made by the priests of the temple in their sacred processions, and specifying a certain Gate. This Gate he found about May, 1868, and choosing the most worn of two roads, he opened it up; then, following a road branching towards the open country, he at last came upon this Periholus wall. Trial holes showed a white marble pavement and remains of large columns with their capitals and bases. Wood afterwards resumed the excavations. Then came the discovery of buildings connected with the Temple from 12 to 20 ft. deep; mosaic pavements and inscriptions; the pavement and other remains of the Temple itself; the discovery of columns *in situ*, and many fragments. The site of about eight acres was then purchased. Some coins, portions of a large sculptured frieze, and of a sculptured drum of the *columna velata* of Pliny, were obtained. These occupied the time up to April, 1872. Probably Wood was again in London pressing for money, for I find that in July the Institute, with other societies, had considered the question of the continuance of the excavations, as shown by the President's Address of November 4, 1872. The public press now began to take an interest in the discoveries. In the *Builder* of February 10, 1872, vol. xxx. p. 106, appears the first illustration, a plan and part of a column, and, p. 726, a drum of one of the sculptured columns. In 1873 Mr. Wood forwarded a plan of the Temple, with a letter dated January 18,† describing his researches and conclusions; for explorations on the site were continued from season to season to 30 ft. beyond the lowest step of the platform on which the last step had

been raised.* More of the great sculptured frieze, of the sculptured columns, and of architectural detail, were discovered. The plan of the Temple was gradually developed; discovery was made of the distinct remains of three temples of Diana on the same site, and of the evident use of gold and colour in the building. The excavations were finally abandoned in the spring of 1874. The pit dug out was 500 ft. long, 300 ft. wide, and 22 ft. deep. All this cost about 12,000l.; the total amount expended from first to last was 16,000l.† Wood then returned to London, and in January and February of 1875 he gave a course of four lectures at the Royal Institution of Great Britain, 'On the Results of the Temple of Diana, and other remains of the Government Excavations at Ephesus.' In 1875, February 15, Mr. Wood read a Paper at the Institute, 'On the Temple of Diana at Ephesus.' After its perusal, a resolution was passed 'to consider the propriety of memorialising her Majesty's Government with a view of soliciting its substantial aid towards continuing the researches at Ephesus, &c.,‡' and on March 1, 1875, it was announced that her Majesty's Government had recommended Mr. John T. Wood for a pension of 2000l. a year, in recognition of the valuable services which he had rendered by his exploration and discoveries at Ephesus. He had been employed on this work for thirty-six months out of five years. When out of these five years are taken the periods devoted to fever and other circumstances trenching upon a considerable part of the thirty-six months, and that he had to work below the surface some 20 ft. down to the ancient water-bed, and to contend, not only with miasma and fever, but with many obstacles and privations, it is fortunate he has discovered as much, and so much of a remarkable character. In 1877 Wood published his well-known work, 'Discoveries at Ephesus, including the Site and Remains of the Great Temple,' in octavo, with numerous illustrations.§ As was said of it at the time, 'No one will read this book without a lively interest in its graphic descriptions, and a feeling of respect and admiration for the indomitable perseverance of the author, and for the healthy, manly, unaffected tone which pervades his narrative.' Moreover, in it he refers to the valuable assistance he and his labourers experienced from the care and attention bestowed upon them by Mrs. Wood. At the Society of Biblical Archaeology, on February 6, 1878, he read a Paper 'On the Antiquities of Ephesus having relation to Christianity, the Sejour of St. Paul in that City, the Tomb of St. Luke, &c. In this year he resigned his membership of the Institute, and thereupon was elected an Honorary Fellow. In July, 1882, finding that Government would not aid in further excavations, his friends obtained permission to hold a meeting at the Mansion House to promote the resumption of the work. It was expressed that 12,000l. spent on the previous labours was nothing to the amount expended by the Germans at Olympia. A public subscription was proposed. Another meeting was held at the South Kensington Museum.¶ A sum, moderate in amount, was raised, and with it he worked at Ephesus. In June, 1883, Mr. Ferguson, having read a Paper at the Institute, 'The Temple of Diana at Ephesus, with especial reference to Mr. Wood's discoveries of its remains,' he replied to it by one on June 9, 1884. Both papers are in our 'Transactions.' Towards the end of 1884 he wrote for the *Builder*¶ an 'Account of the early works, and of the excavations carried on by the private subscriptions,' which had been raised under a committee, from March, 1883, to February, 1884, by which he was enabled to explore the portico surrounding the Temple area; and giving his modifications of his plan. A fund was proposed for further works, Sir John Lubbock being the hon. treasurer.** Last year Wood lost his son, his only child, by fever, while practising as a civil engineer in Spain, which appeared to his friends to tell

upon his health, and may have hastened his decease.†

Mr. Ernest C. Ayton - Lee.—We also regret to have to record the death, on the 29th ult., of Mr. Ernest Claude Ayton-Lee, better known by his old name of Ernest C. Lee, at the early age of forty-four. Mr. Lacy W. Ridge, writing of him in the *R.I.B.A. Journal*, says:—"Among the students of a generation who have now passed well into middle life, he was conspicuous for his ability and originality as designer and draughtsman. He gained both the Pugin Travelling Studentship and the Soane Medallion in 1870. When the Gothic revival was at the top of its tide, he came under the influence of William Burges; and, like him, brought great care, genuine enthusiasm, and a quaint power of design to bear on the study and development of architectural detail and ornament. The studies which he earnestly pursued himself he endeavoured to commend to others, and he was among the first promoters of the 'Architectural Association Sketch-book,' and almost the founder of the Colour-decoration Class. He became in turn President of the Class of Design, and ultimately of the Association itself. The influence given by this position he used to promote the welfare of the Architects' Benevolent Society. He built, and rebuilt after fire, the parish Church of Whitechapel. He erected churches at Brentwood and elsewhere; also Berechurch Hall, near Colchester, for his uncle, Mr. O. E. Coope, the late member for Middlesex, as well as many other works. A professional career so well begun was not destined to be long. He was elected an Associate of the Institute in 1869 and a Fellow in 1881. Ill-health necessitated retirement to the bracing air of Ramsgate, and to-day 'Goths' and 'Picts' mourn the loss of a talented professional brother and a genial friend." From another source we learn that Mr. Lee was born on April 17, 1845. In 1864 he was articled to Mr. R. W. Edis. In 1869 he gained the Soane Medallion for a design for a railway station. In 1870 he was elected Pugin Travelling Student. In 1880-81 he was President of the Architectural Association. It was mainly due to his exertions that the A. A. Travelling Studentship was established. Later on he was instrumental in securing the gift of a silver medal by the R.I.B.A. to all Pugin Students. He was one of the five successful competitors in the first (open) competition for the new Dublin Museum buildings. The following buildings were erected from his designs and under his superintendence, viz.:—Church of St. Thomas, Brentwood, Essex; Church of St. Paul, Bentley, Essex; Church of St. Mary, Whitechapel (two churches, the first of which was destroyed by fire in 1880); Church at Collier Row, Romford, Essex; and a church at West Greenwich. He restored the Church of St. Andrew, Hornchurch, Essex; and the Churches at Dagenham, Essex, and St. Mary, Iford, in the same county. Among his miscellaneous works are the following:—St. Matthew's Mission House, Westminster; schools at Barrow-Furness (in conjunction with Mr. H. Curzon); schools at Brentwood, Essex; bank at Colchester, for Messrs. Round & Green; Berechurch Hall, for the late Mr. O. E. Coope, M.P.; Gower's-walk Free Schools, Whitechapel; The Grange and cottages at South Weald, Essex; houses at Kedbrook-park and Maida-vale; vicarage at Bentley, Essex; vicarage at Horsell, near Woking; house at Bentley, for Mr. E. W. Matthews; houses at Brentwood, for Captain Cole; and houses at Shere, Surrey. In 1887 he added his original family name of "Ayton" to that of "Lee." His remains are interred in Teddington Cemetery.

The Rev. Prebendary Searth, F.S.A.—The death is announced of the Rev. Prebendary Searth, F.S.A. He died at Tangier on the 5th inst., whither he had gone for the benefit of his health. He was in his seventy-sixth year. Mr. Searth was one of the oldest beneficed clergymen in his diocese, having entered it so far back as 1841, when he was presented by the Duke of Cleveland to the important living of Bathwick. Here he laboured for thirty years. In 1871 he retired to Wroughton, hoping in the greater ease and tranquillity of a rural parish to devote more time to those antiquarian studies and researches in which he took such delight, and which had brought him not simply national, but European fame. His genial manner and his great knowledge of Roman antiquities rendered him a welcome visitor at archaeological congresses. His death will be deeply regretted by all who knew him.

Illustrations.

THE NEW PALACE OF JUSTICE, ROME.

IN 1887 the Italian Government opened a competition for the erection of a Palace of Justice, which was won by Prof. William Calderini. The area on which this edifice will be built is in the prati di Castello, to the east of Castle S. Angelo, opposite the new bridge Umberto I.

The works, which were commenced last year, are being continued rapidly, and besides the excavations which have been executed on the vast area, in order to lay the foundations, the extensive platform of concrete, on which the edifice is to be raised, has already been completed.

The building will contain the following departments:—1. A basement floor, inwardly communicating with the ground-floor, which is accessible on all sides to carriages for prisoners and witnesses, and for the general business or trade traffic of the building. 2. The ground-floor, containing the Corti d'Assize, the Pretura Urbana, and the Sezione del Tribunale Correzionale, and the Ufficio del Registro. 3. The first floor, in which will be the Corti di Cassazione and di Appello, the principal hall for general meetings, and the library of the Corti and of the Publico Ministero. 4. A special staircase will be constructed to communicate with the two courts independently from the other entrances. 5. The second floor will contain the Tribunale Civile, the Tribunale di Commercio, the Consiglio dell'Ordine degli Avvocati, and the Tribunal of discipline for the Procuratori, and the Biblioteca delle Autorità Giudiziarie. 6. The entresols will be used as Chancery offices, archives, &c. 7. Eight large courtyards will be provided for air and light; of these, the four central ones will be 50 metres in length and 23 metres in breadth.

The whole edifice will be mainly built of bricks, but it will be faced with travertine marble up to the windows of the ground-floor, and the rest of the decorations will be in cement. The ceilings of the portico and of the principal halls, as well as the architectural and ornamental decorations in the Palace, will be of brick, covered with fine plaster. The pavement of the basement will be of asphalt and peperino stone, where carts or wagons will have to pass; the other floors will be paved in the so-called Venetian manner. The steps on the outside will be of Travertine marble; those in the palace itself of Tuscan pietra serena, while the principal staircase will be entirely of Carrara marble.

The architect has evidently aimed at giving to the design the stern and severe character which is best suited for the architectural treatment of a Palace of Justice, and the scale of the building is so large that it will assert its importance even by the side of the great neighbouring mass of the Castle of St. Angelo; and on the whole it may be said to be, in its severe dignity of style, a modern building not unworthy of its site and surroundings.

PRESBYTERIAN CHURCH, NORTH DULWICH.

ABOUT four years ago an effort was made to organise a congregation for service according to the Presbyterian ritual, and there being a large number of Presbyterians in and near Dulwich, the matter was warmly taken up, and by the exertions of the energetic minister, the Rev. Rupert Patterson, a regular service was organised in a temporary building, and funds collected for a permanent structure.

An excellent site has been secured on the Dulwich College Estate, at the corner of Townley-road and East Dulwich-grove. Plans have been prepared by Mr. Charles Barry, architect, as here illustrated, to accommodate about 500 worshippers, at an estimated cost of 5,200*l.*, including not only a church, but large lecture-hall, class-rooms, vestry, &c. Funds have been collected or promised sufficient to proceed with the erection of the church, and this will be immediately commenced.

HOLY TRINITY SPIRE, COVENTRY.

THE view of this spire, one of the famous three, is from a sketch made by Mr. C. E. Mallows on his tour as Pugin Student.

The sketch was made from the roof of the north aisle of St. Michael's Church, some portions of which form an effective foreground.

LODGE, GUARDS' CORNER, DITCHAM PARK.

THIS lodge has a plinth of red bricks, the upper part being entirely composed of timber and concrete panels, with a roof of Broseley tiles. The architect was Mr. Walter F. Cave, and the builders were Messrs. J. Simpson & Son.

GUY'S HOSPITAL COLLEGE.

THIS building has been erected from plans prepared by Messrs. Wood & Ainslie upon a site in the immediate neighbourhood of Guy's Hospital, with the view of providing suitable residential accommodation for about forty students and fourteen officers of the medical school connected with the hospital.

The scheme is based upon the life in vogue at our old universities. A set of two rooms, or a bed and sitting-room combined, is provided for each resident, and also a smoking-room, read-

ing-room, and dining-hall with lavatories, kitchens, and offices for the use in common of the members of Guy's Hospital Students' Club and the residents in the College. A gymnasium (not shown on the plans) has, through the generosity of a member of the medical staff, been constructed under the courtyard.

A subway connects the college with the hospital for the convenience of those engaged on night duty in the wards. The basement contains bath-rooms, and accommodation for the house-keeper and servants in charge of the institution.

The building, satisfactorily completed under the superintendence of Mr. Powell as foreman and Mr. Abbott as clerk of works, was formally opened on March 26 by the Right Hon. W. E. Gladstone.

Messrs. Shillitoe & Son, of Bury St. Edmunds, were the general contractors. Messrs. Berry & Sons, of Westminster, executed the oth cooking apparatus and hot-water work, and Messrs. Clark, Bunnett, & Co., the hydraulic lifts throughout the building.

WAYSIDE NOTES IN EAST ANGLIA:

LAVENHAM STREETS.

IN previous notes on Lavenham I have coated somewhat fully on the circumstances and causes of its rise and prosperity, so shall content myself with a few brief remarks upon the subjects I have depicted. One can but imperfectly realize, unless a visit be paid to the town itself, how rapidly it must have sprung into importance, the construction and design of its buildings exhibiting such a marked similarity. Only here and there we see the out-of-line of jetty-houses broken by the insertion of a red or white brick front, erected in later times by some ambitious owner over the old timber framing, causing a certain disagreeing break in the restful freedom of the old outlines. The houses remain little altered, whilst the undulating nature of the situation (for there are no level streets), combined with the quaintness of the architecture, constitute at every turn views full of picturesque completeness. The ugly sash window has supplanted the original casement, the ledged door has gone down before the four-panel trade mould invention, and the chimneys are crippled and mutilated beyond recognition. All the outlines of the post-and-pan walls and high-pitched roofs remain, whilst the interiors are rich with carved and moulded beams and joists, to the beauties of which the present humble occupants are strangely insensible, unthelssly covering them over with plaster.

The sketch in the centre of the sheet shows a mediæval house almost complete in all its details, excepting that the chimney and the portion to the left have been taken down.

There is a large entrance door, with a smaller one opening in the centre of it, leading into a hall, about 5 ft. wide, running the whole length of the building, with a small door at the end communicating with the garden. From this hall all two Tudor-headed doors, separated by an upright stud, lead into two reception-rooms, and the staircase was placed at the garden end of the hall, and gave access to two rooms overhead, partly in the roof. The kitchen and room over, which would be to the left of the building, have been taken down, and the building is now used as a stable and coach-house.

The overhang is only carried out to the street, and the bay windows, the lower one of which is perfect, finished under the overhanging on each floor. On the ground-floor the small lights above the transom of the bay were continued along the front on each side, after the manner of the Old Guildhall. This house is an excellent example of timber-framed construction, and is worthy of a careful study. The stud-work inside and out, for at this period raftering was unknown. The fireplaces were large open ones, with just a chambered and moulded oak beam over the opening. Doors were simple in construction, being formed of moulded upright boarding nailed to ledges, and hung on wrought-iron band hinges. The floor boards were laid in rebates in the joists, and in the same way as the joists themselves, the back of each joist forming part of the floor.

The value of passages as a means of communication was little appreciated, as we fail to find them in houses of this date, all the rooms communicating one with another. Stairs either went up straight between walls, or were constructed round a centre newel. Balusters had not come into use, the stairs themselves were solid balks cut through diagonally and resting on strong bearers.

Another feature introduced at a subsequent date was the plastering over of the external face, which was largely practised in Elizabethan and Jacobean times, the shrinkage of the clay filling from the oak studs giving an unbecoming access to the weather. The Tudor rose, the fleur-de-lis, and the bishop's mitre, supposed to be in honour of St. Blaize, patron of the wool trade, are frequently to be met with on the Lavenham houses, and on several the rose has six petals, instead of five, as is most usual.

Pentice-street gives a good idea of the hilly nature of the streets. It is the steepest gradient in the town, and the stepping of the houses with the prospect of the open country beyond is a fine subject for an artist's pencil. In conclusion, I would advise those who are interested in old timber construction to visit

this place; they will find much to attract their attention in rambling through the streets, whilst an inspection of the interior of some of the more perfect structures will reveal unsuspected beauties in the shape of carving and moulding which will excite at once their wonder and admiration.

JOHN SHEWELL CORDER.

SHEFFIELD SOCIETY OF ARCHITECTS AND SURVEYORS.

THE monthly meeting of this Society was held at the Montgomery Hall on Tuesday evening last. Mr. F. Fowler, the President, occupied the chair, and there was a good attendance of members, including Messrs. C. J. Innocent, Vice-President; C. Hadfield, Hon. Secretary; J. B. Mitchell-Withers, J. D. Webster, W. F. Hemsoll, J. Smith, J. Fawcett, W. C. Fenton, H. W. Lockwood, J. T. When, J. McInery, &c. Mr. W. Farrington was proposed by Mr. C. Hadfield and seconded by Mr. J. B. Mitchell-Withers for the Associateship.

Mr. Thomas M. Rickman, architect and surveyor of London, read an exhaustive paper on "The Present state of Questions Relating to Quantities." The object of the paper, he remarked, was to enable the Society to discuss the position which the quantities now take in estimates and contracts. Precise definition was desirable to avoid misunderstandings as to materials, designs, and mode of measurement. The variety of terms in use throughout the country, and their derivations, and the changes in design and style of architecture, and in the present purposes of buildings, have all complicated the subject. The custom for architects to prepare quantities for their own works, implied that the preparation of quantities was part of an architect's education. The position of the Royal Institute of British Architects, as regards this practice, had somewhat changed of late. The lecturer described the different duties required of an architect, and enlarged on the value of a surveyor's services as regards the more important class of work. The appointment of the measuring surveyor, once usually made by the builder, was now commonly made by the architect for his client. The appointment of a surveyor, who from his position could insist on justice for both parties, which, in some instances, the architect was unable to obtain, was of great importance. The growing practice of making the quantities part of the contract was considered, and the arguments on both sides of the question. The present position of the Builders' Institutions, and of those of architects and surveyors with reference to the appointment of quantity takers, were explained, and the extent of responsibility resting with the supplier of quantities considered. The report of the committee appointed by the Conference of Architects held in London in 1871 was given in detail. The position of architects supplying quantities for their own works was gone into by the lecturer, who pointed out the special difficulties which they must encounter in the settlement of accounts, which had led the committee before mentioned to recommend that quantities so supplied should form part of the contract. The complications arising from a course occasionally taken of throwing on the builder the onus of testing the quantities so furnished, and the consequences to the employer from the insertion of such a clause, were obvious. In conclusion, Mr. Rickman recommended a uniform system of measurement, and the diffusion amongst employers and their solicitors of a larger amount of knowledge as to the bearings of all these questions upon their own interests. An interesting discussion took place, and on the motion of Mr. Innocent, seconded by Mr. McInery, and supported by Messrs. C. Hadfield, J. B. Mitchell-Withers, W. C. Fenton, H. W. Lockwood, and the President, a hearty vote of thanks was awarded to Mr. Rickman for his paper.

Window, Ranmoor Church, Sheffield.—We find that the design for the window by Messrs. Shrigley & Hunt, published in our last, is not, as we supposed, the one executed, but was a design submitted in competition. The actual window placed in the apse of the church was executed by Messrs. Heaton Butler & Bayne from a design by Mr. G. Moore McDowell.

THE INSTITUTION OF CIVIL ENGINEERS:

LOUGH ERNE DRAINAGE.

AT the sixteenth Ordinary Meeting of the Session, on Tuesday, March 18, Sir John Coode, K.C.M.G., President, in the chair, the Paper read was on the "Lough Erne Drainage," by Mr. James Price, jun., M.Inst.C.E.

The physical characteristics of the Lough Erne district, comprising 1,056,160 acres, were first described, and the various schemes proposed at different times for effecting the drainage of the district, without lowering the navigation level, were referred to. The works which had been carried out were designed by Mr. James Price, sen., M.Inst.C.E., in 1878, and consisted in cutting a channel through a rocky barrier at Belleek, on the River Erne, below the Lower Lough Erne; controlling the discharge through this channel by large sluice-gates; and improving the channels above Belleek and between the two lakes. The sluice-gates, when closed, retained the water at its normal summer level; whilst the raising of the gates, on the first intimation of heavy rain commencing in the upper districts, enabled the large water-surface, of 27,643 acres on the lower lake, and 9,453 acres on the upper lake, to be drawn down 6 inches, so as to make provision for a flood in anticipation of its arrival, and thus prevent the flooding of the adjacent lands. The works were commenced in 1882, at the lower end, and the sluices were completed in September, 1883, the upper works being subsequently carried out. The channel at Belleek was excavated under the protection of clay dams; and the upper channels were mainly improved by dredging. The four sluice-gates* designed by Mr. F. G. M. Stoney, M.Inst.C.E., sliding against a train of 8-inch live rollers, were 29 ft. 2 in. wide and 14 ft. 6 in. high, and capable of being raised 9 ft., and had been working most satisfactorily for the last six years. Each gate weighed 13 tons, and could be easily raised by one man to its full height in forty-five minutes; or the four gates could be lifted simultaneously by a turbine in half-an-hour. Their total cost, exclusive of masonry, was 4,000*l.* Large compensation had to be paid for anticipated injury to the fishery-rights, though the works had actually improved the salmon fishery. The total cost of the works was 180,000*l.*, of which 30,000*l.* was for navigation and 150,000*l.* for drainage. The author was the Resident Engineer for the whole of the works, and the lower works were carried out under his supervision; whilst the works between the lakes, and in the upper lake, were executed by contract. Observations of the rain-fall, lake-levels, and sluice-discharges, for the years 1885-88, had been put in the form of a diagram. Allowance had been made for a discharge of 600,000 cubic feet per minute, of which 400,000 cubic feet had been provided for by enlargements of the channels; but it appeared from the diagrams that, owing to the power of anticipating a flood by means of the sluices, a discharge of 500,000 cubic feet per minute would have sufficed to prevent flooding, without unduly lowering the navigation level of the lakes. The Erne diagrams showed how little the storage in the lakes affected the summer flow, and indicated that the great store for the summer yield of a river was the ground-water. The general effect of the Erne drainage had been to render the water-level of the lakes more uniform—higher in summer and lower in winter. The bad effects of the flooding, during a wet summer, of the extensive flat lands bordering Lough Erne, which extended in an unbroken sheet of water for fifty miles, were not confined to the loss of the year's crop of grass, for the decayed grass affected the next year's hay crop; whilst large tracts of undrained land, by exposing large surfaces of spongy grass to evaporation, chilled the air, preventing or delaying the ripening of corn; and the damp chilled air, mixed with the products of decaying vegetation, fostered disease. In some cases, occasional flooding might be beneficial to land, owing to the manurial qualities of the flooded deposits; and sluices enabled such flooding of flat lands to be effected for short periods, at suitable seasons.

The author advocated the following general principles in designing drainage works:—(1) That the cross section of the enlarged channels should be hyperbolic instead of trapezoidal, increasing the discharge in proportion to the

* *Engineering*, September 19, 1884, Vol. xxxviii, pp. 268-270 and 272. *The Engineer*, September 19 and October 10, 1884, vol. lviii, pp. 218 and 222-224.

section, obviating slips by flattened slopes next the land, facilitating dredging, and confining the low-water-channel so that the sides could be cleaned; (2) that the channels should be given a fall of only 1 ft. or 2 ft. per mile, with embankments and back drains where necessary, and accumulating any excess of fall at certain points where the discharge might be effected along paved channels. Embankments were generally avoided in Ireland; but it was clearly a mistake to lower a large river in order to preserve a small area of land from flooding. Though not applicable to the Erne, embankments should be used for the Barrow drainage. The extension of arterial drainage in Ireland would render large areas of land available, and would raise the mean summer temperature, which at present was only 53 deg. Fahr. Amended laws, however, would be required for carrying out any large drainage works in the future, and the initiation of the schemes could no longer be left to the landowners who, under their altered conditions of tenure, had lost their former interest in the improvement of their estates.

THE BARRY DOCK-WORKS.

At the eighteenth ordinary meeting of the session, on Tuesday, April 1, Sir John Coope, K.C.M.G., President, in the chair, the paper read was "On the Barry Dock-works, including the Hydraulic Machinery and the Mode of Tipping Coal," by Mr. John Robinson, M.Inst.C.E.

Barry Dock was situated on the north shore of the Bristol Channel, between Barry Island and the mainland of Glamorganshire, seven miles in a direct line south-west of Cardiff. The site chosen for the dock occupied the eastern portion of the channel which formerly ran between the island and the mainland. An Act of Parliament to authorise the construction of the dock, and the railways connected therewith, obtained the Royal Assent on August 14, 1884. The undertaking comprised a tidal basin of 7 acres, a dock of 73 acres, and a timber-pond of 24 acres. The entrance to the dock was at the eastern end of the island, under the shelter of the high land of Nell's Point. This excellent natural shelter was supplemented by two outlying converging breakwaters. The tidal range was 36 ft. at ordinary spring-tides, increasing to 40 ft. at extraordinary springs; and 19 ft. 6 in. at ordinary neaps, diminishing to 16 ft. at extraordinary neaps. The dock was not fed with water from any river. The width of the entrance between the masonry walls was 80 ft., and gave access to the basin. In the entrance was placed a single pair of wrought-iron gates, and the dock not being exposed to heavy seas, there were no gates pointing outwards. The passage between the basin and the dock also had a width of 80 ft.

The dock was 3,400 ft. in length, the maximum width being 1,100 ft., divided at the western end by a mole into two arms, the full width being left at the eastern end for a length of 1,600 ft., where vessels of the largest class could swing. The bottom of the dock, which was not puddled, was 20 ft. below mean sea-level. The mole was 1,300 ft. in length and 200 ft. in width, with pitched slopes of $1\frac{1}{2}$ to 1 on the north side, and of 2 to 1 on the south side. Along the northern side of the dock were eleven high-level tips, and on the northern side of the mole were three low-level fixed tips, and masonry towers for two others had been built. Two more low-level tips were stationed on the south side of the dock, and one at the western end. To prevent the basin and docks being flooded whilst the temporary stone dam was removed, a caisson was erected, which could be used for future requirements.

The breakwaters were formed of rubble excavated from the basin and railway cuttings, and the sea slope was protected by blocks of mountain limestone, weighing from four to seven tons each. At the head of the west breakwater there was erected a cast-iron tower, 30 ft. in height, the diameter at the base being 7 ft. 9 in., and at the top 6 ft. 6 in. with a spiral staircase inside. In the tower was placed a fourth-order dioptric occulting white light, visible in clear weather at a distance of ten miles.

The hydraulic power was obtained by means of two pairs of compound horizontal condensing pumping-engines of the tandem type. The boiler pressure was 80 lb. per square inch, and condensing water was obtained from, and returned to, the dock through pipes 15 in. in diameter, by the circulating-pumps. Another

hydraulic engine-house was in course of construction at the north-west end of the dock.

The entrance from the sea into the basin, and the passage between the basin and the dock, were each provided with a pair of wrought-iron gates, having a span of 80 ft. and a rise of 20 ft. There were six sluices in each leaf, having a combined area of 100 square ft. These were worked from the top by direct-acting hydraulic cylinders and pistons. The gates at the entrance were opened and closed by hydraulic power, chains being dispensed with. The water was admitted to a direct-acting hydraulic cylinder, having a piston 2 ft. 5 $\frac{1}{2}$ in. in diameter, and a ram 1 ft. 9 in. in diameter, with a stroke of 25 ft. 9 in., attached direct to the gate, the cylinder being in three parts of cast steel. Trunnions were cast on the cylinders, projecting above and below, and pivoted in saddle bearings, which also had trunnions on their sides, and these pivoted in bearings fixed to the walls of the ram-chamber, thus permitting the cylinder to oscillate both horizontally and vertically. The hydraulic rams were of sufficient strength to resist shocks of waves, and to hold the gates rigidly during movement. The passage gates were worked in the same manner as those at the entrance; but in this case the ram was attached to a radius arm near the top, with a slide against the back of the gate, the other end of the arm working on a pin in the holding-down bracket over the top of the heel-post. As the power required was less, the diameter of the piston was only 2 ft. 1 $\frac{1}{2}$ in., and that of the ram 1 ft. 6 in., with a stroke of 16 ft. 7 in. The cylinder for the passage-gate machine was of iron, cast in one length, and tested to a pressure of 2,400 lbs. per square inch. The ram was also of cast-iron, and the whole machine was arranged in a similar manner to that for the entrance gates. For the protection of the gates stout chain-cables and wrought-iron box-hoofs were placed in front of the masonry. To prevent the gates rising and floating away, a cast-steel holding-down bracket was provided at the top of each heel-post. The ordinary time occupied in opening the gates was one minute and a-half, and the same in closing; but those at the passage occupied less than a minute in opening, and the same in closing.

The following modes were adopted at Barry for the shipment of coal, where it was shipped both from high and from low levels. On the high level the trains were hauled into curved sidings intended for full wagons, where the engine left them. These sidings were on gradients of 1 in 233. No stop-checks were employed, neither had they been found necessary. The loaded wagons were sent from the collieries with the doors up-hill, to prevent their opening on some of the steep inclines in the valleys, and did not therefore require to be turned for tipping when shunted into the sidings, thereby saving both time and labour. The wagons were drawn forward, and run one by one on to the weigh-bridge, and afterwards drawn on to the coal-tip by means of another hydraulic cylinder. The coal-tips consisted of masonry towers, 30 ft. square, on which were erected wrought-iron framings, braced together by angle, tee, and har irons. This framing served to support the wrought-iron guides for the cradle. The latter was provided with the necessary tip-up table, hinged in front, and worked by hydraulic power, by means of a cylinder hung on trunnions to girders underneath the cradle, which travelled with it, and capable of tipping loads up to 19 tons. The tips were provided with coal-shoots, anti-breakage cranes, boxes, &c. The shoot was tapered towards the point, to check the sliding of the coal, and had a single door across near the end for regulating the same. In the bottom plate of each shoot were two iron bar screens for separating the small coal when required. On the underside of the shoots, immediately below the screens, were hinged doors to allow of single-screening, double-screening, or the passage of the coal unscreened. At one of the high-level tips 400 tons had been shipped in one hour in the ordinary course of working.

The tips on the low level differed from those on the high level, inasmuch that wagons were received into the hoists at quay level, and the empty wagons were returned from the tip at the same level. The wagon had thus to be lifted the required height for tipping. A movable tip was in course of construction for the high level, which would run on rails along

the quay for a distance of about 50 ft. each side of the centre of approach, and could be used in connexion with a fixed tip. The tip was moved by a hydraulic engine geared to the travelling wheels. There was also a movable tip in course of construction for the low level. The passage was crossed by a rolling bridge, worked by hydraulic power, carrying a single line of railway and forming part of a roadway. There were eleven movable cranes, capable of lifting from 30 cwt. to 4 tons, for loading and discharging cargoes of vessels lying along the quay wall and against the timber jetties at the east end of the dock. The cranes were of the elevated type, and constructed on a pedestal of wrought-iron plate, with an arch underneath for the wagons to pass while the cranes were at work. The dock and sidings were lighted by electric light. The engineers of the dock works were Mr. John Wolfe Barry, Mr. T. Forster Brown, and Mr. H. M. Brunel. The author was the resident engineer.

The discussion upon the foregoing paper was commenced, but not concluded when the time for adjournment arrived. It will be resumed after Sir Frederick Bramwell's paper, to be read on Tuesday next, has been disposed of.

THE ASSOCIATION OF PUBLIC SANITARY INSPECTORS OF GREAT BRITAIN.

At the monthly meeting of this Association, held at Carpenters' Hall, London-wall, on Saturday evening last, Mr. Hugh Alexander presiding, a paper on "Social Environment" was read by Mr. F. T. Poulson (Chief Inspector, Chelsea). In regarding man as a gregarious animal, the lecturer found his leading characteristic to be voracity. He had an insatiable and omnivorous appetite, both as regarded what he ate and what he drank. Another characteristic of man as animal was his indifference to the quality of what he consumed, and the urgency he displayed in vitating even the breath of life itself. In many dwellings every inlet and outlet for air was carefully hoked, the occupants being in consequence pale, weakly, and anemic. The method of introducing currents of warmed fresh air, by admitting them through flues behind the fireplace, as advocated by Sir Douglas Galton, was commended in this connexion. Some good had followed such revelations as those in "How the Poor Live;" but immense was the ignorance that still prevailed on the subject of sanitation and the use of such sanitary appliances as were now commonly applied to dwelling-houses. Wherever the surroundings, whether dampness of sites, or walls, or other defects, were the cause of fungoid growths on the walls, similar growths in the animal membrane were to be feared in the fearful form of diphtheria, the worst zymotic of whose existence the lecturer was aware. On the question of water-supply, "a compulsory constant service" was advocated, and the withdrawal of the power of cutting off a service for any cause. An intermittent service was liable to constant pollution from the sucking in of noxious matter from water-closet, soil-pipe, house-drain, or other sanitary arrangements of the dwelling to which the fittings might be connected. As an illustration of this danger, he exhibited a small sketch, showing how a kitchen-boiler was supplied with sewage in his district, owing to the overflow-pipe of the feed-cistern being connected directly to the house-drain. The drain becoming obstructed, and the water-closet being at a higher level than the top of the overflow-pipe of the cistern, when the closet was used the sewage was forced up the overflow-pipe into the cistern, and thus sent into the kitchen-boiler. This showed how easily a family might be poisoned by a plumber's defective work. With regard to the removal of refuse, the lecturer preferred to see it carried away in closed vehicles to be applied to the soil as manure, in place of burning it in "destructors." The paper next touched upon the disposal of the dead, and, without absolutely declaring it, the principle of cremation was upheld, with a recommendation that the residuum should be ground to powder for agricultural uses. The environments of childhood would never be what they should until mothers had more knowledge of the physical necessities of their children. The lecturer concluded by applying the Darwinian phrase, "the survival of the fittest," to the environments of man, and showed that a completer knowledge of physiology and sanitation meant for the work-

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—XV.

SEPARATELY-EXCITED DYNAMO-MACHINE.

If there were no reaction between the armature of a dynamo-machine and the field, the current which a separately-excited machine would send through any external resistance, when the armature was revolving at a known speed, could be calculated as easily as for an ordinary voltaic battery.

A set of working drawings of the machine, together with a knowledge of the materials from which it was constructed, would enable us to estimate the flux that would be sent through the armature, when the exciting current flowed in the field magnet coils (article X.), and the flux being known, the electro-motive force set up in the armature, if it revolved once in a second, could be immediately calculated (article XI.).

Let e = E.M.F. set up in armature when revolving once in a second; n = number of revolutions per second; r = resistance of armature from brush to brush; R = resistance of external circuit; C = current. Then:—

$$C = \frac{ne}{r + R}$$

Since, however, owing to armature reaction, the value of e depends upon that of C , the above equation gives results very far from the truth when C approaches its ordinary working value. In the very simple case under consideration it would not be difficult to find an equation that would give, with considerable accuracy, the current produced by the machine under varying conditions of speed and external resistance. Graphical methods, however, afford means of dealing with machines in which the winding is complicated as easily as with the simpler forms; we shall, therefore, at once have recourse to curves.

A curve which shows the connexion between the electromotive force produced in the armature of a machine, the speed being constant, and the current flowing, is called a "characteristic curve." This curve is to the dynamo-machine what the indicator diagram is to the steam-engine. The characteristic curve, or briefly the characteristic, of a machine can be got experimentally by connecting it to a circuit consisting of an ammeter and a variable resistance, while a voltmeter is in connexion with its terminals. The readings on the ammeter are laid off as abscissæ to the curve; the current indicated by the ammeter is multiplied into the resistance of the armature, and the quantity so obtained added to the corresponding voltmeter reading, thus giving the actual number of volts set up in the armature, and these results are then laid off as ordinates. If a sufficient number of points have been determined in this way, the characteristic curve for the machine, when running at the speed at which the experiments were carried out, can be drawn through them. As the method of constructing a curve for a similar purpose has already been described in article X., no further description need be given here. The brushes are naturally shifted into the proper position before each reading is taken.

The main reasons why the characteristic curves of different kinds of dynamo-machines consist of the shapes they do, may be easily seen by constructing their general forms theoretically, having regard merely to the components of the field due to the field magnets and to the currents circulating in the coils of the armature.

Fig. 38.

A construction was given in fig. 36 for finding the actual field, in magnitude and direction, for different positions of the brushes; in fig. 38 the same construction is used, but the diameter of commutation is always at right-angles to the resultant field. Draw NS_0 equal, on a suitable scale, to the field produced by the field magnets. As the machine is separately excited,

this quantity has always the same value; with NS_0 as diameter, describe the dotted semi-circle and draw the chords S_0S_1, S_0S_2, \dots to represent the fields produced by the armature when the currents c_1, c_2, \dots flow from it, then NS_1, NS_2, \dots will be the resultant fields in each case.

Fig. 39.

To construct the characteristic curve, fig. 39, on OX lay off lengths OC_1, OC_2, \dots equal to the currents c_1, c_2, \dots they will be proportional to S_0S_1, S_0S_2, \dots . On OY lay off OE_0, OE_1, \dots equal to the electromotive forces produced at the particular speed at which the armature is running; these lines will be proportional to NS_0, NS_1, \dots . Taking these two sets of values as abscissæ and ordinates, the points P_1, P_2, \dots, P_6 are obtained, through which the characteristic curve can be drawn.

The characteristic curve, while primarily showing the relations between electromotive force and current under all conditions, can be used for determining many other quantities connected with the complete circuit. Let P be the point on the characteristic of a machine showing the electromotive force and current being produced. Join OP. If R is the total resistance in circuit:— $R = \frac{E}{C} = \frac{OP}{OC} = \tan POC$.

When, therefore, it is necessary to know what the machine will do when a certain resistance is placed in the circuit, from O draw a line so that the tangent of the angle it makes with OX is equal to the given resistance, and where this line cuts the characteristic at P, will be the point showing the behaviour of the machine under the given conditions.

In the figure, OA is the line of the armature resistance, so that the characteristic stops short at A, the machine being then short-circuited. This line is of great use in showing the electromotive force absorbed by the armature itself, and hence the balance left for use in the external circuit. In the case just considered, PC is the total E.M.F. developed, OC is the amount absorbed in the armature, and hence PP_0 the difference of potential between the terminals of the machine. Many other uses of characteristics might be catalogued here, but such uses as we shall require to make of them will be described when considering other kinds of dynamo-machines.

It may, however, be pointed out that if the characteristic (fig. 39) be that for which the armature is running at n revolutions per second, the characteristic at n_1 revolutions per second can be at once drawn by multiplying the ordinates by the constant $\frac{n_1}{n}$.

Civil and Mechanical Engineers' Society.—On the 2nd inst., Mr. Ernest Spon, Assoc. M.Inst. C.E., read a paper before the Civil and Mechanical Engineers' Society, the President (Mr. Henry Adams) in the chair. After describing bygone blasting-powders and the early forms of gun-cotton and nitro-glycerine, the author came to modern explosives, which he described in detail. These included dynamite, blasting gelatine, Rohrbitt, Securite, smokeless blasting-powder (S. B.), and others. While speaking of the manufacture of gun-cotton, the author said that in one manufactory there is an annual output of 3,500 tons. The picrate compositions were touched upon, with the various forms of detonators, and their practical effect was discussed.

man and workwoman the retention of the earning and enjoying faculties for a longer period, and for the nation and the commercial world more profit, thrift, and industry, and therefore more peace and contentment both for capitalist and labourer.

A discussion followed, in which Messrs. Tidman, Dee, Fairchild, Wootton, West, Young, and the Chairman and other members took part. Some criticism was offered on minor points, but a general agreement with the views of the paper was expressed. Among other suggestions made in the course of the discussion was a recommendation to make the teaching of hygiene and physiology compulsory in all schools, and the abolition of cisterns, on account of their liability to get foul and to pollute the water available for drinking purposes.

A cordial vote of thanks was given to Mr. Poulson, who briefly replied, and the proceedings closed.

We understand that by invitation of the Mayor and Corporation of Leamington, the fifth annual provincial meeting of the Association will be held in that town on Saturday, May 24. The President and Sir Douglas Galton, K.C.B., have promised addresses on that occasion.

ST. SAVIOUR'S CHURCH, SOUTHWARK.

SIR,—You expressed a hope some weeks ago that something more would be done with the nave than to make an imitation, as nearly as possible, of what was done in the thirteenth century. Seeing that was done in the nave of the present congregation, would it not be better, when the ugly nave is pulled down, not to rebuild at all, but to utilise the space as a garden? With the money thus saved a good church could be built elsewhere. But if a new nave is built, I hope, as you do, that something more will be the result than a mere copy of what has been done in the past. When the late Chaplain (Mr. Benson) wrote the Guide to St. Saviour's, everyone was quite satisfied with a copy of the old masters, as the following words from the guide will tend to show:—"A very appropriate window has been introduced in the north wall (of the north transept), the original of which may be found in Westminster Abbey; and speaking of the south transept:—"The principal window having been destroyed, a new design, formed on the model of an exquisite circular window remaining in the ruins of the adjacent episcopal palace, was introduced." And it was not only in Gothic architecture that this want of originality was shown. The front of the Reform Club in Pall Mall resembles the Farnese Palace in Rome; and the Travellers' Club is supposed to be an improved version of the Padofini Palace, Florence; and in the Carlton Club, Sidney Smirke copied the east front of St. Mark's Library, Venice.

I was hoping that the day for this kind of thing had passed, but it does not appear to have died out in church work yet. CHARLES F. MOXON.

STAINED GLASS.

Brecon.—The stained-glass window, from the studio of Mr. Taylor, of Borneo-street, given by the South Wales Borderers (24th Regiment) in memory of their comrades who fell in the Burmah Campaign, has been erected in the Priory Church, Brecon, the territorial district of the Regiment. The memorial brass beneath it records the name of every man (fifty-one in all) who fell in action or died of disease during the campaign—1886-7-8.

Whitechurch.—On Sunday afternoon last the stained-glass window in the south aisle of Whitechurch parish church, in memory of the Rev. John Carter, who was vicar of Whitechurch or over ten years, was dedicated. The window is painted in two lights, with tracery, and the subject is "The Incredulity of St. Thomas." The central figure is that of the Saviour showing the prints of the nails in his hands and feet to Thomas and two other disciples. Under the two groups, which are surmounted by canopies, are the following inscriptions:—"Peace be unto you," and "My Lord and my God." At the base of the window is written the following:—"In memory of John Carter, M.A., LL.B., 10 years vicar of this parish, who died 13th of April, 1888, aged 51 years." The work has been carried out by Messrs. Bell & Sons, of Bristol.

Aachen.—The restoration of the Municipal buildings is to be carried out according to the designs of Professor Frengen, the latter having in his latest scheme paid special regard to the suggestions made by the Academy of Public Works when discussing the matter, September, 1888.

Books.

Roofs and Bridges. Part II. Graphic Statics.
By MANSFIELD MERRIMAN and HENRY S. JACOBY. New York: John Wiley & Sons.

THIS work forms one of the text-books of the course of instruction given in Lehigh University, where one of the authors, Mr. Merriman, is engaged as Professor of Civil Engineering, and the other, Mr. Jacoby, acts as Instructor. In dealing with roofs and bridges, students at this University divide the subject into four parts:— 1. The computation of stresses in various styles of trusses. 2. The analysis of these stresses by graphic methods, as explained in the volume before us. 3. The design of a bridge, including the arrangement of details and preparation of working drawings. 4. The consideration of cantilever, suspension, continuous and arched forms. The "force polygon" (as the authors term it) is shown to be the foundation of the science of graphic statics, and the triangle of forces is treated as a particular case of a force polygon. For equilibrium to exist, not only must the algebraic sum of the components of the forces, measured in both a horizontal and a vertical direction, amount to zero, but the algebraic sum of the moments of these forces must also be zero, so that there may be no tendency to motion, either of translation or of rotation. To prove this the authors show the use of what they term an "equilibrium polygon," by means of which the exact line of action of the resultant of a number of forces acting upon a body is determined, the magnitude of the resultant being graphically found by the closing line of a force polygon. Equilibrium results when both the "force polygon" and the "equilibrium polygon" close. In all instances of non-equilibrium, where the force polygon closes, "a couple" is necessary to maintain equilibrium.

For any given number of forces it is clearly demonstrated that an infinite number of equilibrium polygons, or curves of equilibrium, can be constructed, varying according to the position of "the pole" of the force polygon from which point the rays, or the resolved components, of the given resultant forces are drawn. The pole may be taken either within or without the force polygon, as may be found most convenient for the solution of the problem under consideration. In dealing with parallel forces the pole must necessarily lie outside the force polygon. The resultant of any number of forces is a single force which would produce the same effect as the forces themselves, and may therefore replace them, whether the direction of these forces meet in a single point or not. The equilibrium polygon may be explained as consisting of an imaginary jointed frame, which holds the exterior forces in balance; and, viewed in this light, the authors show that when the equilibrium polygon does not close, the given forces cannot without the aid of additional force be held in equilibrium, but that if the force polygon closes, equilibrium may be effected by moving one or more of the given forces parallel to its direction, so as to bring its line of action through the angle of the equilibrium polygon, upon which it is necessary for the force in question to pass. The practical application of such graphic diagrams is shown in relation to various types of roof trusses and bridge girders, and the character of the stress in the individual members (tension or compression) of the equilibrium polygon is seen to be indicated by the component members of the force polygon. The book is well printed, and contains excellent diagrams. It is interleaved with blank pages for additional notes to be made by the student. Problems to be worked out are added at the end of each article, and answers to these problems are given in an appendix at the end of the volume.

Stone: How to Get it, and How to Use it. By Major-General C. E. LUARD (Retired), Royal Engineers. London: E. & F. Spon. 1890.

THIS little work is an introductory treatise on stone, adapted for the special use of students in architecture, engineering, surveying, and estate agency, it having been originally written for the Surveyors' Institution. It commences by briefly referring to the bibliography of the subject, and this portion is supplemented by a useful list of works in the first appendix. Alluding to geological works, the author says, "There is no more practically useful work in

the whole list than Professor Ansted's Lectures on the Application of Geology to the Arts and Manufactures." This is quite true, but at the same time that work is rather antiquated, whilst it does not profess to be more than an outline. As a matter of fact, no really good work entering exhaustively into the different kinds of stone from both scientific and practical points of view, has yet been published in England: we have special treatises, but not general, and we heartily endorse the author's belief that the different kinds of stone have not yet been studied in a manner commensurate with the practical and pecuniary importance of the subject. A general account of the localities is then given, in which a few new openings are mentioned, whilst the next section deals with the renting and leasing of the same. This is by far the most important and original part of the work. The author explains the various methods of leasing quarries, of fixing minimum and "further" rents, and sums up the main causes of dispute, which he says "chiefly arise on whether the lessee was or was not making the most of the land entrusted to him." It is mentioned that people are too apt to treat the receipts from stone quarries as income in place of capital, and that in the case of entailed estates, a portion of this should be invested for the heirs to the estate, who are otherwise deprived for ever of this part of its value. Some of the principal steam-saws, tooling, and moulding machines are shortly discussed, after which the author devotes a few pages to the consideration of the comparative wear of stone, pointing out the great pecuniary advantages attaching to a proper understanding of the matter in respect of the maintenance of roads. The preservation and seasoning of stone, and a brief mention of some of the principal artificial stones in the market, appropriately form the conclusion. The appendices include also a list of granite quarries, the comparative prices of some igneous road-metals, a note on Bath stone, a table showing valuation of some Yorkshire quarries, and a list of persons who furnished the author with information during the preparation of the work. We observe that in giving the principal quarries of Bath stone the well-known Monk's-park stone is not mentioned. Altogether the author is to be congratulated on giving a very fair introductory treatise on stone to the students of the profession, and the arrangement of the work and the suppression of unimportant details are manifest indications of the selective care with which it has been prepared. We might point out, however, that the title is not well chosen, for we do not find much in the book as to the methods of getting stone, and there are no particular instructions as to "How to use it."

Practical Plane and Solid Geometry, including Graphic Arithmetic. By H. J. SPOONER, Assoc. Mem. Inst. C.E. Third edition. London: Cassell & Co. (Limited).

An elementary treatise, forming one of the Polytechnic Series, written to meet the requirements of the Science and Art Department, South Kensington. Each chapter concludes with a series of examples to be worked out. Lines, angles, proportion, triangles, polygons, circles, and their combinations are dealt with, in addition to the construction of various conic sections, and a table of definitions with the derivation of the terms employed is introduced. The author very properly recommends that a student should first learn to draw accurately and neatly with his instruments, and he gives valuable suggestions as to drawing scales on a sheet of paper. He also adds useful hints to guide an inexperienced draughtsman in his work, with the object of obviating common errors. Graphic arithmetic, or the art of working by geometry various arithmetical processes, is dealt with. As a test of the students' reasoning powers in geometrical work the process is as ingenious as it is profitable, and it is useful in its application to graphic stresses in mechanics, but so far as ordinary arithmetic is concerned the numerical process is, in our opinion, preferable. In solid geometry the author deals at length with the question of simple projection, and argues that beginners frequently fail to make much progress owing to their want of this information. He asserts that the realisation of the projection of simple solids upon paper, according to special conditions, should precede that of the representation of

points and lines in various positions in relation to the planes of projection, notwithstanding the fact that points and lines constitute the simplest element of a solid, because solids, being more tangible, can be taught *objectively*, and afterwards the relation of traces of lines and points may be more comprehensively grasped, when the solid with which they are connected is realised in projection. The idea is novel and worthy the attention of teachers. The type of the book is good, and the volume contains sufficient practical geometry for the work of any ordinary drawing-office.

Forty Lessons in Carpentry Workshop Practice.
By CHALRS F. MITCHELL. London: Cassell & Co. (Limited).

THE author of this book is the lecturer on carpentry and joinery at the Polytechnic Institute, London; and the work, which is illustrated by eighty-nine well-drawn diagrams, has been revised by Mr. G. C. Pope, the teacher of practical carpentry at the same Institute. The contents include a list of tools necessary for use in a workshop, a description of means employed for grinding and sharpening, sawing, planing, preparing a straight-edge, preparing winding-strips, taking timber out of winding, making a square or plain joint, grooved and tongued joint, plough-grooving and cross-tongues, &c. The descriptions form a useful account of what every well-trained carpenter and joiner is fully conversant with, but which students who spend no time in actual workshop practice desire to know.

Forty Lessons in Engineering Workshop Practice.
By C. F. MITCHELL and A. G. DAVEY. London: Cassell & Co. (Limited).

THIS useful little manual, which forms one of the Polytechnic Series, has been prepared to assist students in the acquisition of such necessary technical knowledge as shall enable them to construct useful workshop tools. The lessons are arranged in a progressive manner, and the contents, which are clear and concise, have received the benefit of careful revision by Mr. J. Rogers, instructor in engineering workshop practice at the Polytechnic Institute. The book truly states that in these matters "experience is the best guide," but for all its statements the authors furnish reasons. The illustrations are clear and fully dimensioned. A perusal of the work by those whose duties are chiefly limited to the drawing-office, would prevent foolish questions being asked by inexperienced draughtsmen in the workshop. The book exhibits several details which require special attention in making "workshop drawings," and show a draughtsman what to observe as he walks through a manufacturer's yard and shops.

School Hygiene. By W. J. ABEL. London: Longmans, Green, & Co.

THIS little book contains clear, concise rules for the ventilating and warming of schools, the disinfecting of rooms, clothing, &c., and the periods of infectivity and length of quarantine necessary for all infectious diseases.

There is an excellent chapter on "Eyesight, and the Use of Test-types." Were this book in the hands of all school-masters and mistresses many a little scholar's sight might be saved the terrible strain to which it is often subjected by being given work to do and types to read which are too small.

There are also short rules for administering first aid in injuries; indeed the book is full of useful information, written so clearly that a child might understand. It is merely one of the army of hygienic hooks, but each one helps on the good cause. We do not hold to the doctrine that a little knowledge is a dangerous thing; provided the individual is aware that he knows but little, that little may prove a great boon to many. We hope that hooks on school ventilation may be unnecessary some day. There may be a happy time coming when a hill for "compulsory ventilation" will be passed, and every room in every house will have its fresh-air inlet, and its ventilated gas-ring as a foul air exit. Until that golden age shall come, and whilst children are growing up stunted and sickly in ill-ventilated rooms, let as many hooks be written on the subject as possible, and diffused throughout the country, so that "our sons may grow up as the young plants, and our daughters may be as the polished corners of the temple."

Blackie's Modern Cyclopaedia. Edited by CHARLES ANNANDALE, M.A., LL.D. Vol. V. London, Glasgow, Edinburgh, and Dublin: Blackie & Son.

The fifth volume brings this encyclopaedia down to the latter part of M., and it appears to keep up the good quality shown in the former volumes. Among the architectural subjects which come into this volume is "Impost" which is shortly and correctly treated and illustrated (time was when such a word, in its architectural signification, would never have found a place in a general dictionary); "Indian Architecture" has a short article with three or four rather inadequate illustrations, better than nothing; however, "Ionic order," &c. The subject of "Iron-rod Vessels" receives very good illustration for a popular general dictionary, and is accompanied by plans and sections to a small scale of two of the latest English iron-clads. Under the heading "Kaulhaeb" is a short but very just review of that painter's position in art, his merits and defects. We may add that good small-scale maps are given of the principal countries described in the dictionary.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

5,175. Ventilating Apparatus. T. F. G. Wintour.

According to this invention, in the spaces of the water cones of metal, gauze-wire, india-rubber, &c., are inserted. These are fixed with a free air-space between the cones, and, if required, a mica valve to prevent the ingress or egress of air, if wished. The ventilation is controlled by means of the valve.

6,838. Stoves. G. A. Jones.

The stove which is the subject of this patent has a chamber, into which the products of combustion have to pass before they can get away through one or more flues connected to the lower portion of the said chamber for that purpose. In order to absorb and utilise the greatest amount of heat from this chamber, it is surrounded with a jacket open at bottom and top, which induces an upward current of pure air, which becomes heated in its passage. If a damp air is desired, an open vessel is placed on the top of the chamber, and kept supplied with water, which is carried to the top of the chamber by a water-supply of a similar level, so maintained by an inverted vessel on the principle of a "fowl fountain." As the water evaporates, the vapour mixes with the pure hot air current, which is led in any direction by means of flues.

7,289. Improvements in Water-closets. B. R. Phillipson.

The form of water-closet which is the subject of this invention, and which may also be used as a slop-sink, is provided with two water-sealed traps in succession to each other. These have an air-space between them which is provided with a ventilation carried to the open air. An air-valve is fixed and so operated that when the water supply is open the air-valve is closed. When water is thrown into the basin from a pail or vessel it passes through the two seals without unsynphoning either of them, because the open ventilation between the two seals prevents syphonage. When water is sent into the basin from the cistern or supply, however, the air-valve is closed by a lever, and when a certain quantity of water has entered the basin, syphonage takes place, and the basin is discharged.

8,201. Window-sashes. W. Allenby.

According to this invention, in drop-windows, such as railway-carriage, tramcar, and other windows, the sash is held by the action of an inclined rubber covered roller pressing against it. A little force will, however, raise or lower it, the elasticity of the roller then allowing the frame or window to move up and down.

20,957. Improvements in Water-closets. S. Mayo (U.S.A.).

In the form of water-closet which is the subject of this invention, and which is a modification of the "wash-out" closet, mechanism is described which connects the cover of the seat with the valve and flushing apparatus by which two washes or heads of water are allowed to enter the basin and effectually flush and cleanse it.

NEW APPLICATIONS FOR PATENTS.

March 24.—4,572, J. Watson, Stoves.—4,579, A. Harris, Drain-pipes, &c.—4,580, W. Baker, Fire-grates.

March 25.—4,603, C. Mackoy, Roses of Door and other Knobs.—4,608, C. Longley, Wood-block Flooring.—4,692, J. B. Bewling Square.—4,678, H. Hinkley, Indicators for Doors.

March 25.—4,702, J. Mayoh, Steel or Iron Plate or Joist for Supporting Floors, Walls, &c.—4,705, G. Tweedy and B. Lawrence, Wood Blocks for

MEETINGS.

SATURDAY, APRIL 12. Edinburgh Architectural Association.—Special Visit to the Buildings of the Edinburgh International Exhibition.

MONDAY, APRIL 14. Royal Institute of British Architects.—(1) Special General Meeting for Members only, to receive and consider a recommendation of the Council that Mr. Alfred Waterhouse, R.A., President, be requested to allow himself to be nominated as President for the ensuing year of office. (2) Tenth Ordinary General Meeting of the Session. Paper by Mr. John F. Seddon on "Church Fittings." 8 p.m. Surveyors' Institution.—Adjourned discussion on Mr. T. W. Wheeler's paper on "Retirements." 8 p.m. Society of Engineers.—Mr. W. H. Brothers on "Weighing Machinery and Automatic Apparatus in connection therewith." 7.30 p.m. Clerks of Works Association (Carpenters' Hall).—Eighty Annual Meeting. 8 p.m. Liverpool Architectural Society.—Mr. W. E. Hill on "Ormskirk Parish Church." 7 p.m.

TUESDAY, APRIL 15. Society of Arts (Applied Art Section).—Mr. C. Purdon Clarke on "Modern Indian Art." 8 p.m. Institution of Civil Engineers.—Sir Frederick Bramwell, Bart., F.R.S., on "The Application of Electricity to Welding, Stamping, and other Cognate Purposes." 8 p.m.

WEDNESDAY, APRIL 16. British Archaeological Association.—(1) The Rev. Dr. Hoopwell on "Excavation of the site of Vinovium, Durham." (2) Mr. Jas. H. Macmahon on "Baynard's Castle, and antiquities found on its site, 1880-90." 8 p.m. Cleveland Mechanical Engineers' Society.—Mr. Ambrose A. Myall on "Recent Improvements in Dredging Machinery." 7 p.m.

Thursday, April 17. Guild and School of Handicraft.—Mr. W. B. Richmond, A.R.A., on "Oesso." 8 p.m. Royal Archaeological Institute.—(1) Mr. R. H. Bask on the "Sixth Centenary of Dante's Beatrice." (2) Mr. J. J. Doherty on "Bells: their history, uses, and inscriptions." (3) Mr. F. Haverfield on "Roman inscriptions found in Britain." 4 p.m.

Society for the Encouragement of the Fine Arts.—The Second Conversazione at the Galleries of the Royal Institute of Painters in Water Colours, Piccadilly. 8 p.m.

FRIDAY, APRIL 18. Architectural Association.—Members' Soiree. 8 p.m. Royal Institution.—Sir Frederick Bramwell, Bart., F.R.S., on "Welding by Electricity." 9 p.m.

SATURDAY, APRIL 19. Royal Institution.—Captain W. de W. Abney, F.R.S., on "Colour and its Chemical Action." 8 p.m. Edinburgh Architectural Association.—Visit to Tantallon Castle.

Miscellanea.

Docks and Harbour at Mobile.—From a recent report of the British Vice-Consul at Mobile we learn that the long-talked-of scheme—the Mobile and Dauphin Island Railway and Harbour Company—is about to be carried out by an English Company, which is convinced that Mobile Bay, on account of its geographical position, depth of water, and ample ship room, should be the great port of the gulf. Ample docks will be built at deep water at the terminus of the railway, with all modern facilities for handling ocean freights. Mobile is the nearest gulf port to St. Louis, Cincinnati, Memphis, Chicago, and Kansas City, and a large part of imports and exports to and from these places will pass through Mobile when such terminal facilities are made.

Appointments.—Mr. J. D. Lewis, from the offices of Messrs. John Wballey & Son, surveyors, Chester and Birkenhead, has been appointed Assistant Road Surveyor of the Borough of Birkenhead, at a salary of 150*l.* per annum. The applications were very numerous.—Mr. W. H. Radford, C.E., Nottingham, has been appointed representative and consulting engineer in England for the Corporation of Durban in South Africa. He will, we understand, act conjointly with the London agents in ordering and testing the materials required for the waterworks extension. The cost of the new works when finally completed will be about 120,000*l.*

Strikes in the Building Trade Abroad.—Telegrams from Toronto state that a general strike for higher wages among the men employed in the building trade is in progress in that city. The stonemasons struck last week, and the bricklayers went out on Monday. About 2,000 men altogether will be affected. The men's demands are endorsed by the International Union, and some masters have conceded an advance to their men to induce them to continue at work. The carpenters and joiners are expected to strike in a few days. The strike of masons continues in Vienna, and building has been brought to a standstill.

The Lock-out of Kentish Brickmakers.—The dispute between the Kentish hargemen and the brickmakers assumed a new phase on Saturday, one which aroused hopes in many quarters that at last a way to a settlement was opened. Following a demonstration held on Good Friday, a meeting of bargemen and mates in the Sittingbourne district was held, at which representatives from Faversham, Rainham, Halstow, Conyer, and other places were present. A suggestion was put before the hargemen to withdraw their lists, one of the conditions which the brickmasters have insisted upon from the first. The matter was discussed at some length, and ultimately the following resolution was passed unanimously:—"That we withdraw the list issued by our society provided that the whole question be submitted by the Brickmasters' Association to the conciliation committee of the London Chamber of Commerce, such question to be settled by May 1, and that the prices laid down by the Chamber of Commerce shall be paid from the time of resuming work, and that every member of the Bargemen's Union shall be reinstated in the position previously held by him." A copy of the resolution was at once forwarded to the Kent and Essex Brickmasters' Association, who held a meeting at Cannon-street Hotel on Monday, when it was resolved—"That the Association insists upon the absolute and unreserved withdrawal of the lists issued by the bargemen, and upon the hargemen returning to work at the old prices." And it was also resolved—"That moulding shall cease not later than August 31, and that the make of bricks be reduced by 20 per cent.; that is, that one stool out of every five now worked be stopped." In consequence of the dead-lock, brickmasters have had to refuse large orders for bricks, and they are consequently losing custom that may perhaps never be recovered.

Portsea Synagogue.—The Hebrew Synagogue at Portsea was re-opened on Sunday, the 23rd ult., by the Delegate Chief Rabbi (the Rev. Dr. H. Adler), after restoration. The architect for the work was Mr. Harry A. Smith, of Gosport, and the contractor Mr. J. Dugan, of Portsea; the total cost has been 1,100. A new porch has been erected, to avoid the panic which might otherwise ensue in the event of a hurried exit from the ladies' galleries. The reading-desk has been rebuilt, and the whole of the interior resetated. The ark, which was opened in the synagogue 175 years ago, has been carefully restored and preserved. The floor is laid in mosaic, by Mr. Ebner, of Old-street, London. The ark is surmounted by the first two letters in the Decalogue, in Hebrew, symbolical of the two tables of stone delivered to Moses on Mount Sinai, and stands on new circular polished marble steps, in lieu of the original wooden steps, a brass pulpit rising from same.

Technical Scales.—Messrs. Cassell & Co. issue a series of scales printed on slips of glazed cardboard and with a case to keep them in, under the name of the "Polytechnic Series Technical Scales." These give a number of scales, two on each strip on the opposite edges, each defined as the proportion of an inch to a foot and as the proportion to full size, thus: "Scale of one-fifth of an inch to a foot, or $\frac{1}{5}$." A scale of chords is added on each slip. They make a useful set, comprising a greater variety of scales than can be shown on any single scale of the ordinary make.

Association of Municipal and Sanitary Engineers and Surveyors.—The Council of the Association of Municipal Engineers have transferred the following Graduates to the class of Members, they having obtained chief appointments, viz., Messrs. M. Aspinall, Town Surveyor, Stroud; C. H. Cooper, Surveyor to the Local Board, Wimbledon; J. Cook, Borough Surveyor, Lancaster; and H. W. Jamieson, Surveyor to the South Hornsey Local Board.

British Archaeological Association.—At the meeting of this Association on Wednesday, April 2, Mr. J. W. Grover, F.S.A., in the chair, the arrangements for holding the congress at Oxford, to commence on July 7, were detailed. Mr. Loftus Brock, F.S.A., to illustrate Mr. Cust's lecture, exhibited a copy of "Le Bruin's Travels in the East," which contains curious seventeenth century panoramas of Smyrna and other places which were referred to. The chairman described two gold British coins, the obverses being imitations of the statue of Philip of Macedon, and the reverse of one of the coins a plain convex surface. Mr. Ronilly Allen, F.S.A. (Scot.), described a remarkable base of a stone cross which exists in the churchyard at Hasrick, Yorks. It is covered with Late Saxon interlaced work and scroll of the same period, but very like some decorations of the thirteenth century. While there are many remains of the shafts of Saxon crosses, the bases do not frequently occur. The Rev. R. G. Irving, vicar of Hasrick, exhibited full-sized rubbings of the ornamentation. Mr. R. Peters rendered a description of further discoveries on the site of Launceston Priory, where, to erect a new gasholder, the site of the chancel of the Priory church was excavated. The plans exhibited show this to have been 66 ft. long from east to west within the walls, and 19 ft. wide. There are transept chapels to the west of the chancel. A paper was then read on "Gokewell Nunnery, Lincolnshire," prepared by Mr. E. Peacock, F.S.A., and read by Mr. W. de Gray Birch, F.S.A., in the author's absence. The buildings stood to the west of the village of Broughton, on a site where a farmhouse now exists, but the remains which were noted in the seventeenth century have been entirely swept away, and the site has been a matter of conjecture. The Rev. Henry Cust then proceeded to describe his journey to Smyrna and Ephesus, where he visited the principal remains, and found that Mr. Wood's excavations of the Temple of Ephesus were getting covered up, and will soon be difficult to trace. A fine series of photographs were exhibited, and also of the supposed columns from the Temple of Diana, now in Sta Sophia, Constantinople. Mr. G. Patrick exhibited an Ionic volute which he found at Ephesus several years ago.

The Wenham System of Lighting and Ventilating.—Early in the current year the *Journal of Gaslighting* noticed the adoption of the Wenham system of regenerative ventilating lighting at the Nottingham Free Library, under the direction of Mr. W. R. Chester, the Gas Engineer to the Corporation. The Library forms one wing of the Natural History Museum, which has for some time been undergoing repair. The work, however, the *Journal* reports, is now finished; and arrangements were made for the opening ceremony to take place on the 31st ult. As the museum will be open in the evening, the question of lighting had to be considered; and the experience of the Wenham system in the reading-room, where it had worked very satisfactorily, led to its extension to the museum. As in the installation in the other part of the building, any danger of heat from the lamps carrying the beams of the ceiling has been avoided by the construction of four shafts running the whole length of the room. The heat of the lamps will be carried into the open air by tubes which also form ducts for the removal of vitiated, or partly vitiated, air from the room. This new lighting arrangement has been entirely carried out by the workmen of the Corporation, under Mr. Chester's supervision. The Wenham Company, we are asked to mention, have now added to their business in gaslighting and ventilation an electrical department, with especial reference to electric lighting.

Gift to Reading.—Mr. George Palmer head of the Reading biscuit firm, and formerly M.P. for the borough, has just announced to the Town Council that he will give a park of 49 acres at the east end of the town for the public benefit of the inhabitants. He has promised to fence in the land, plant trees, and lay it out for cricket, tennis, football, and other games, and for public gardens. He asks that no intoxicating liquors should be sold upon the ground. Mr. Palmer has already given over 20 acres in another part of the town for a public recreation-ground near the Thames. The Town Council passed a vote of thanks to Mr. Palmer for his gift. Previous to his last generous offer a movement was initiated to erect a memorial to Mr. Palmer's munificence.—*Times*.

A Bristol Newspaper Office.—The *Printers' Register* describes the new office of the *Western Daily Press* at Bristol, now nearly completed. Part of the building has been occupied since 1886. The facade is of fine red brick, with freestone courses and window-frames. The building stands at the corner of Baldwin-street,—the widest central thoroughfare in Bristol—and St. Stephen-street. For about a quarter of a century the *Daily Press* offices were situated in Broad-street, adjoining the chief municipal building, the Council House, but after several additions had been made to the original premises Mr. Maciver, the proprietor, decided to build new offices which would be fitted up to meet the modern requirements of newspaper work. A site was purchased from the Corporation at a cost of about 8,000, and on this the new building has been erected. On the ground-floor (there are no cellars) are the advertisement office—a splendid apartment—a publishing office from which the trade is supplied with papers, a machine-room, engine-room, and paper-store. The machine-room contains three Victoria machines, and on these are printed the *Western Daily Press*, the *Bristol Evening News*, and the *Bristol Observer*. On the first floor are a suite of offices, including artists' room and store-rooms; the second floor accommodates the editors, sub-editors, and reporters; and on the third floor are the composing-room—which is lighted from two streets and from the roof—and the stereotyping-room, which contains, besides the usual appliances for stereotyping, a gas engine and a Shanks' engraving machine. The whole of the building is heated by one fire and hot-water pipes. As a precaution against fire, all gas-pipes are of iron and the brackets are not movable. On each floor there is a hydrant and hose, by Merryweather & Sons, London, with a very copious supply of water always under pressure. Pneumatic tubes, by Cooke, of York, communicate between the publishing and advertisement offices and the composing room and sub-editors' room. All telegrams are delivered by these tubes to the sub-editors without using a messenger, and by the same means advertisements are despatched from the advertisement office to the desk of the foreman in the composing room. The whole arrangements are planned to ensure despatch and the convenient working of the various departments, which are nine in number—namely, editors and sub-editors, reporters, readers, compositors, stereotypers, machinists, publishers, and commercial staff. No doubt the arrangements are very complete, but the *Printers' Register* omits to give the name of the architect.

Industrial Exhibitions.—In addition to the workmen's exhibition to which we have referred in one of our "Notes" two other exhibitions of the kind have been opened this week. On Tuesday the Duchess of Teck opened the fourth annual exhibition of the Hammersmith Industrial Exhibition Society, at Flora-gardens Board School, Hammersmith. The object of the society is to encourage the young to employ their spare time in the pursuit of industrial art. There are six hundred exhibits of work done by children, and for the best results one hundred prizes are awarded. On the previous day an industrial and art exhibition was opened at Bournemouth. It is described as the first venture of the sort in that fashionable watering-place.

Society of Arts.—The papers for the Wednesday evening meetings after Easter to the end of the session have been fixed as follows:—On April 16, "Old and New Fashions in Typography," by Talbot B. Reed; April 23, "Coal in the South-East of England," by William Whitaker, F.R.S.; April 30, "Photographic Lenses," by T. B. Dalmeier; May 7, "The Aim and Scope of Higher Technical Teaching," by Dr. Percy F. Frankland; May 14, "Professor Blunt Thomson's Electro-Magnetic Induction Experiments," by Dr. J. A. Fleming; May 21, "The Mannesmann Process for making Seamless Tubes," by J. G. Gordon.

Reported Collapse of a Parish Church.—The newspapers report that the parish church of Helpringham, Lincolnshire, has been partially destroyed. Two large beams, each weighing more than a ton, supporting the east end of the nave, fell into the body of the church, smashing the pews and injuring the vault beneath. The roof, on losing the support of the beams, became displaced. No one was in the church at the time. In 1854 the spire was half destroyed by lightning.

COMPETITIONS, CONTRACTS, & PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

COMPETITIONS.

Table with 5 columns: Nature of Work, By whom Required, Premium, Designs to be delivered, Page. Includes entries for North Wales University and Public Library.

CONTRACTS.

Table with 5 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page. Includes entries for Great Western Ry. Co., London County Council, and various engineering works.

PUBLIC APPOINTMENTS.

Table with 5 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page. Includes entries for Assistant Surveyors and Waterworks Clerk.

The English Iron Trade.—The English on market shows in somewhat better form this week, but the business doing is small. The prices of pig-iron are stronger, and this is partly due to the improved nature of the Cleveland ironmasters' returns for March, but partly so to a recovery in warrants. Middlesbrough pig-iron has gone up 3s. a ton. Scotch-makers on has also improved slightly for some brands, assemer iron is steady at former rates. There is less firmness in Lancashire pig-iron, but her districts report fair strength. Business ill continues moderate in finished iron, and steel is also quiet. Rails are 5s. a ton lower, and steel plates are easier. Shipbuilders are not booking fresh work, while engineers are not receiving many new enquiries; still, both branches of trade keep fairly busy.—Iron.

PRICES CURRENT OF MATERIALS.

Table listing prices for various materials including timber, iron, and other goods. Columns include item name, quantity, and price.

METALS.

Table listing prices for various metals and alloys.

OLDS.

Table listing prices for various oils.

TENDERS.

Communications for insertion under this heading to reach us not later than 12 noon on Thursdays.
HANSTEAD (Surrey).—For extension of tailors' shop the cottage home, for the Managers of the Kenzen and Chelsea School District, Messrs. A. & C. Crston, architects, 15, Leadenhall-street, E.C. Quantities not supplied:—

Further Notes on Yorkshire Stone (Halifax District).

In our issue of March 29 we gave a general account of the groups of quarries, and of the kinds of stone which they supplied. In addition to the information conveyed in our last article respecting flags, &c., it may be well to distinguish the meaning of the two terms so frequently used, "self-faced" and "self-bedded." These ought not to be confounded; the latter is applied to "thin-lift" stone with micaceous faces; the former refers primarily to material which happens to come away from a mass of riving rock with a moderately even surface. The term "self-faced" is, however, frequently used to include "self-bedded," but "self-bedded" ought never to be employed to mean "self-faced." The two kinds of material are usually classed together, and are often sold under the name of "common" flags or landings; they do not, however, wear equally well, nor do they present the same appearance. The self-bedded flags, with their micaceous faces, are sometimes almost as smooth as if polished, and when laid form floors of commendable evenness; their appearance is certainly in their favour, but an examination of the edge of the flag will show that the lines of lamination are very marked, being sometimes almost black. Sometimes the edge of the stone has been "stunned" by the blows received during the operation of squaring, and the flag will be seen to gape at several of the more pronounced mica-streaks. A flag of this kind 2 or 3 in. thick can often be split into three or four slates with surfaces partly "white" and partly "black." In any case, the tendency of self-bedded flags is to wear in flakes. On the contrary, self-faced flags have a rougher surface, and require, as a rule, a certain amount of labour to be expended in taking them out of twist before they can be laid to form a floor of tolerable evenness; but their less flaky nature more than counterbalances these disadvantages, if durability be any object. Frost is a very powerful agent in the destruction of flags, especially self-

bedded ones; if the stone is of a flaky nature, frost will find it out. The only thing to do under the circumstances is to keep the joints of the flagging well pointed with cement, renewing it as often as necessary; but this will only mitigate the effects of the frost,—it will not render the flags proof against it. Architects and surveyors are largely to blame for not insisting on having flags squared "full" throughout their thickness. We know of one or two Vestries in London whose Surveyors insist on this with good results; it is the best plan for public bodies to buy flags, &c., directly of the quarry-owners, and to have them squared and laid by their own workmen.

We have heard it stated that polished flags are obtained from stone of worse quality than that used for tooling; in fact, that "anything is good enough to polish." This is not true of the polished material now sent from the district of which we are writing; it is true, however, of some of the Lancashire quarries. In these, the "rag" is polished and wears very unevenly, while frost will burst fragments off the face of the stone; in addition to this, polished flags of this ragstone (which cannot easily be split) are sent with scarcely an approximation to the thickness ordered; a "three-inch" flag means anything from 3 in. to 6 in. or 7 in., and this excess entails not only a considerable increase in cost of carriage, but also more labour in laying. Only the best beds in the Halifax quarries supply the stone for polishing; never, we believe, are self-bedded flags placed in the polishing machines.

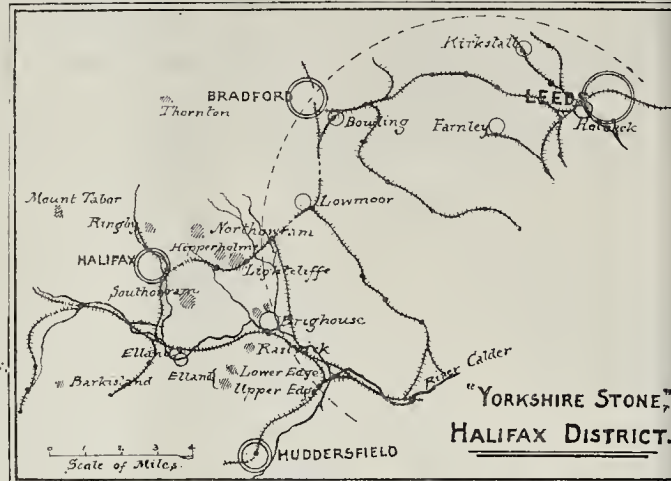

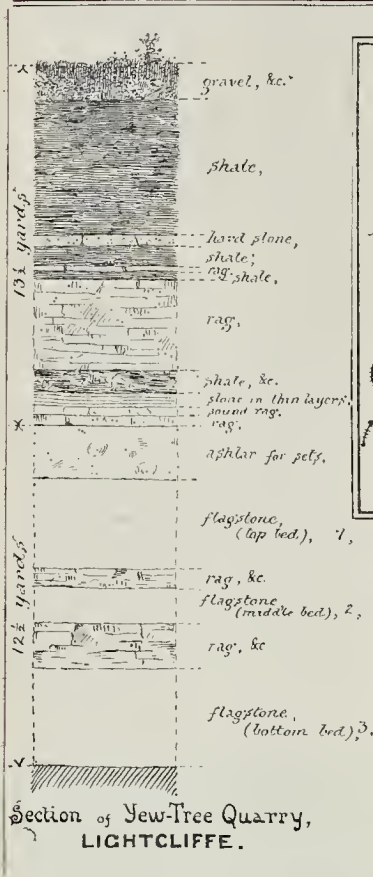

A new departure, which we watch with interest, has recently been taken by one of the principal firms of the district; we refer to the practice of branding with a certain name every polished flag, landing, and step which is found to be of the best quality.

We give a small map of part of Yorkshire, showing the position of the several groups of quarries in the neighbourhood of Halifax. The dotted semi-circle roughly indicates the boundary of the stone district, and encloses the ironworks of Lowmoor, Bowling, Kirkstall, Holbeck, and Farnley, and also a number of coal-pits. It will be noticed that the quarries at Hipperholme, Lightcliffe, Brighouse, and Rastrick are situated near the railways, whereas the older quarries at Northowram, Southowram, and Elland Edge are further removed. The three last-named have also the disadvantage of

being near the summits of lofty hills. The mere difference in cost of carriage from quarry to station is considerable; from the Lightcliffe quarries a cart will carry ten or twelve loads a day to the station, whereas from Northowram only three or four journeys a day can be made. This saving in carriage has a tendency to withdraw the quarry-owners from the older and better-known (in books, we mean) groups to the newer and more convenient. Lightcliffe now heads the list with sixteen quarries, but Southowram is a close second, having fourteen.

We supplement our remarks on the different beds of stone worked in the same quarry (see issue for March 29, p. 222) by giving a section of the quarry there described (see next page). It will convey a better idea of the strata than a verbal description. From 6-in. cubes of stone from the three principal beds we have ascertained the weights to be as follows:—Top bed, 15½ lbs. per cubic foot; middle bed, 15½ lbs.; and bottom bed, 15½ lbs. It is difficult to distinguish the stones when dry; but if the stones are wetted and then examined, it will be found that the stone from the top bed is very closely striated throughout its entire thickness (not, however, with streaks of mica); that in the middle bed the lines of lamination are less distinct; and that in the bottom bed the natural bed of the stone is not discernible, but there are a number of minute reddish-brown specks scattered throughout the stone. It is considered that this absence of beddiness in the last more than counterbalances its slightly less weight. It should be stated that some of the Lightcliffe quarries contain only two beds of stone, and some only one, even though they are within fifty yards of the one illustrated.

We have preferred to treat of the quarries in groups, and have endeavoured to show in some sort the features which the several members of each group have in common, but an intimate acquaintance with the subject shows us that almost every quarry, however near it may be to others, has some distinctive feature of its own. In the mere quantity of marketable stone the difference is very great; for instance, at Lane Head, Brighouse, in the two contiguous pits belonging to Messrs. S. & L. Cliffe respectively, the stratum is about 7 ft. thick, the lowest 3 ft. of this being "thin-lift" or "self-bedded" stone and the remaining 4 ft. being "thick-lift" or "riving" stone; at Swallow's quarry on the opposite side of the

Halifax-road (perhaps 50 yards away) the bed of stone is about 9 ft. thick, but the "thin-lift" has dwindled to 2 ft. Again, in the field adjoining his present quarry Mr. S. Cliffe sank several shafts, and in addition to the bottom bed 40 yards from the surface, he found and quarried at half that depth an upper stratum about 5 ft. thick; on trying this top bed in his present shaft he found that it had thinned out to about 18 in. and was not worth working.

Immediately beyond this most fortunate field he purchased a triangular plot of ground, but the shaft he sank in it proved quite unremunerative, for the stone, on account of oblique lamination or some primeval catastrophe, was found to be broken up into almost worthless fragments. About 200 yards distant (in Lightcliffe-road) J. Roper & Sons mine a bed of stone 19 ft. in thickness, and Farrars, Limited, at their vast open quarries utilise 33 ft. of stone.

Midway between the quarries at Rastrick and Lower Elland Edge, a shaft was lately sunk to the depth of 48 yards, but the stone was nearly all worthless; not only was it unevenly bedded, but it was also broken into small pieces, and cracked perpendicularly to the planes of bedding.

Besides the difference in quantity and lamination, there is also a considerable variety in colour, even in the same quarry and the same block of stone. At Lane Head, Brighouse, all the stone is light brown or yellow; at Lightcliffe-road there is a considerable quantity of "blue" stone, the colour showing the presence of iron. A block of stone is frequently "blue" in the middle, with an outer portion grey or white.

From these remarks it will be seen that there may be exceptions to the general con-

clusions which are here stated respecting the several groups of quarries. For all large works the architect or engineer ought to see for himself the state of the quarry proposed to be selected, besides obtaining and testing proper specimens of the stone.

In addition to the materials already mentioned, an extensive trade is carried on in what are termed "flat-bedded wallstones." A considerable quantity of "inside wallstones" are used in the immediate neighbourhood of the quarries, but not many of these are sent away by train. There is, however, a great and increasing demand for "outside wallstones," chiefly in the West Riding of Yorkshire, in Lancashire, and in the adjoining counties; several consignments have been delivered in London and suburbs for churches and halls.

The wallstones are obtained (by splitting with wedges and cutting with chisel and hammer) from the larger fragments which are cut off for the purpose of squaring the blocks of flagstones and landings, and also from those pieces of rock which are not of suitable shape and size for splitting into flags. They are usually 6 in. on the bed, but larger sizes are cut to order. Their thickness varies from 2½ in. to 6 in., and their length approximately from 9 in. to 2 ft. 6 in. It would be better, however, if wallstones of less than 3 in. thick were rejected, as they are frequently obtained from self-bedded material. Usually these wallstones are specified to be squared back from the face 3 in., and to be walled in courses of diminishing thickness from bottom to top of the building. This last is a point of considerable importance, and ought to be strictly observed, for the sake of appearance. The two kinds always in the market are known as "pitched-face" (sometimes

termed "rock-face"), and "straight-face" (also variously known as "common outside," "hammer-dressed," and "delf-dressed," but the last is certainly a misnomer, as the "pitched-face" wallstones are quite as much delf-dressed,—that is to say, quarry-dressed,—as are the "straight-face"). The epithet "pitched-face" quite sufficiently describes the rough surface of the first-class stones; the term "straight-face" is also explicit enough with this addition,—wallstones of this class always have upon their faces a number of hammer-marks vertical but irregularly spaced, varying in part according to the evenness or unevenness of the face-fracture. Those wallstones which present a perfectly even face after cleavage are sometimes left free from hammer-marks and sold at a slightly higher price as "clean-cut." Sometimes these clean-cut wallstones have a small chamfer taken off the edges, and are then sold as "slight-pitched;" they have a good appearance, and do not harbour dirt and moisture to the same extent as ordinary pitched-face wallstones. For the best work tooled wallstones are often used, but the tooling is usually done upon the building site itself, selected "straight face" wallstones being the kind obtained from the quarries for the purpose; on account of the hardness of the stone, the cost of tooling is very great. In some parts of Lancashire, it may be stated, the generic name "Yorkshire parpoints" is used to designate this kind of building-stone. By far the greatest number of buildings, erected in and around Halifax at the present time, are faced with flat-bedded wallstones of one or other of these classes. Sometimes the front or front and sides of a building will be faced with "pitched-face" wall-

Table of information respecting the principal groups of "Yorkshire Stone" Quarries in the neighbourhood of Halifax.

Situation of Quarries.	Miles from.	Nearest Railway Station.	Approximate number of Quarries.	Method of Working, &c.	Some of the Owners.	Colour.	Output.	Weight per cubic foot.	Remarks.
1. Northowram ...	1½	Hipperholme.	9	Open and mined, the latter 23 yards from surface.	Joseph Brooke & Sons, Appleyard & Booth, Haicy, Brearley, Briggs & Holmes, Wharton.	"Blue" and white, and also light yellow.	All kinds of flags and landings, hutchieffy-knotted and tooled (J. B. & S. supplying the only polished ones), sets, curbs, steps, slates (chiefly riven), wallstones, footings, &c.	lbs. 135·5 "Blue" Parkstone.	The quarries are situate on the top of the steep and lofty hill, on the lower portion of which Hipperholme and Lightcliffe stand. The wallstones are sorted into two classes, and sold as "hest white" and "blue and white," the latter presenting both colours in the same stone. The flags enjoy a good reputation for durability, the "blue" variety, from Park Quarries, being especially hard and heavy. The stone is nearly all "riving," or "thick-lift" stone. The "blue" stone has been tested and used for chemical cisterns, and can be obtained any size up to 14 ft. by 9 ft. by 2 ft.
2. Hipperholme ... (Pearson Brow)	½	Hipperholme.	5	Open, about 22 yards from surface.	J. Brooke & Sons, Shepherd & Bentley, Smith, Aspinall, Mackrill.	"White," really very very light grey, or greyish-white.	Ditto.	152	The quarries (especially the ones at Stubbins, belonging to the two first-named owners) supply the hest <i>selite</i> wallstones in the district. Sometimes the stone is sold mixed with Northowram stone, and further confusion arises because the two groups despatch their stone from the same station. The "blue" stone put into trucks at Hipperholme is almost invariably from Northowram. The stone is nearly all riving stone.
3. Lightcliffe (Hill Top) ...	¾	Lightcliffe.	13	Open, about 15 yards from surface.	J. Brooke & Sons, Shepherd & Bentley, Turner, Bentley, Crowther & Lodge, Walker & Co., Naylor, Cliffe, Blackburn & Co.	Light warm grey, (sold frequently as "white," but the colour is not as pure and uniform as Hipperholme stone).	Ditto, and also platform copings, and landings for chemical cisterns up to 12 ft. square.	150·76*	The bottom bed, found in some of these quarries, does not when wet show the lines of lamination. Selected stone from this and the preceding groups is polished by J. B. & S., at their Yew Tree Quarry, and stamped "Sillex brand." The stone is nearly all riving stone.
4. Lightcliffe (Harley Head) ...	¾	Hipperholme, Lightcliffe.	3	Mined about 20 yds. from surface.	Butterfield, Naylor, Goodyear.	Ditto.	Chiefly knotted and tooled flags, sets, curbs, wallstones, &c.	—	The stone is very similar to that at Hill Top, Lightcliffe.
5. Southowram ...	2	Halifax or Elland.	14	Ditto.	John Farrar & Sons, J. Charnock & Sons, S. Greenwood, Smith & Greenwood, Marshall & Greenwood, J. Thompson, A. Twait, Thornton, Clegg & Bartle, Maude & Deuham.	Light grey ...	All kinds of flags landings, a considerable quantity of <i>self-bedded</i> slates, flags, and landings; sets, curbs, steps, wallstones, footings.	—	Self-hedded material, with very smooth micaceous surfaces, and riving stone, are obtained at these quarries. J. Charnock & Sons have a polishing machine at Halifax, and J. Farrar & Sons one at Brookfoot, near Brighouse, and another at Thornton.
6. Brighouse (Lane Head).	¾	Brighouse.	4	Mined, about 40 yards from surface.	Samuel Cliffe, Isaac Cliffe, Thornton Cookson & Ellis, Swallow.	Light brown or light yellow.	All kinds of flags and landings (except polished), a large quantity of <i>self-bedded</i> slates, flags, and landings, a few sets curbs and steps, wallstones.	—	The wallstones are of good and uniform colour (especially the Cliffe's). The riving (very hard) and self-hedded (smooth) stones are in nearly equal quantities.
7. Brighouse (Lightcliffe-road).	¾	Brighouse.	6	Open and mined, 30 to 40 yards from surface.	Farrars Limited, Marshall, John Roper & Sons, Longhottom & Barker, Robinson.	Light grey or "white," and "blue."	Ditto, footings, and landings for chemical cisterns, tooled platform copings, tooled street-curbs, &c.	154	Some of the wallstones are variegated "blue" and "white." Self-hedded and riving stone are nearly equal in quantity — landings have been sent off containing 152 square feet.
8. Rastrick ...	¾	Brighouse.	8	Mined, about 35 yards from surface.	Bentley & Kaye, Bentley & Smith, Sunderland, Clayton, Sheffield, Jagger.	Light, warm grey, (a little blue).	All kinds of flags and landings (except polished), not many self-hedded; a few sets, curbs, steps; wallstones.	—	Nearly all riving stone.

* Mean of four weights, namely, Yew Tree Quarry, top bed, 151·5; middle bed, 150·8; bottom bed, 150·6; and Ganbert Hall Quarry, 150·14.

Table of information, &c.—continued.

Situation of Quarries.	Miles from	Nearest Railway Station.	Approximate number of Quarries.	Method of Working, &c.	Some of the Owners.	Colour.	Output.	Weight per cubic foot.	Remarks.
9. Elland Lower Edge	2	Brighouse.	4	Open, about 20 yards from surface.	Marshall & Walker, Normanton & Gledhill, John Wood & Co.	Light brown.	Sets almost exclusively; a few self-faced flags and slates; curbs, steps, footings.	lbs. 153½	Practically all riving stone. Sometimes the sets are used as wallstones or bearing retaining walls.
10. Elland Upper Edge	2½	Brighouse.	10	Open and mined, one of the latter 43 yards from surface.	F. Normanton, Walker & Brook, Rawnsley & Spencer. Marshall & Walker, Paul Normanton & Co., Richard Marsden, James Marsden.	Ditto. Ditto.	Ditto. Shoddy and self-bedded flags and landings (none tooled or polished); a few sets, steps, curbs, footings, and wallstones.	153½	Ditto. Almost exclusively self-bedded stone with smooth faces; landings up to 130 square feet.
11. Barkisland	1½	Ripponden	3	Open	Crowther & Lumb...	Ditto, but slightly darker.	Sets, flags, curbs, wallstones.		This is not as important a group as the ones previously mentioned; Mr. S. Cliffe, of Brighouse, has just stopped working a quarry here. The wallstones are not very uniform in colour.

stones, and the remainder, for the sake of economy, with straight-face. But there is not now as great a difference in the price of the two kinds as there was about ten years ago; then the pitched-face stones were ten shillings a rood more than the other, whereas one or two years ago, on account of the increased demand for straight-face ones, the prices were equalised, and now the straight-face have again fallen below the other. The difference in price between the two may be taken as 6s. per rood, that being the difference in the cost of dressing at the quarries. A rood of wallstones is 14 square yards, the stones being set up at the quarries in eight rows, 5 ft. 3 in. long and 3 ft. high. In each rood of wallstones a number of "throughs" are included, not exceeding one per yard; these, of course, vary on the bed according to the thickness of the wall for which they are required. Except near the quarries, where inside wallstones are easily attainable, the external stone-faced walls of buildings are lined with brick, and the general mode of tying the two parts of the wall together is by these throughstones. Where the internal brickwork is to remain unplastered, iron ties are frequently used, or the inner faces of the throughstones are dressed. If the brick lining is 9 in. thick, sometimes, instead of throughs, *bondstones* are used, reaching over one-half of the brick lining, this being bonded with the other half by ordinary brick headers.

The chief causes of the so general use of these wallstones in the locality are their durability and substantial appearance when compared with brickwork, and their economy in comparison with wrought ashlar. Like bricks, they are delivered upon the building site ready for use, the only working required being for the formation of the necessary headers for the angles of the building and the reveals of doors and windows. The external angles of pitched-face headers are almost invariably draughted about an inch wide on the front and return faces, and straight-face angles are also sometimes treated in the same way. It may be interesting for a moment to compare the prices current in the district for various kinds of walls. A solid brick-and-a-half wall costs 7s. a yard; a wall of the same thickness built with straight-face wallstones, 6 in. on the bed and 4½ in. brick, is worth from 7s. 6d. to 8s. 6d. a yard; and a similar wall built of tooled ashlar (from Ringhy or Hunter Hill), 6 in. on the bed and 4½ in. brick, cannot be built for less than

15s. or 16s. a yard. It will be seen, therefore, that these flat-bedded wallstones, although more expensive than brickwork, are considerably more economical than ashlar; the saving is effected not only in first cost of material but also in labour in dressing. The prices of wallstones vary according to the season, the summer prices being sometimes nearly 10 per cent. more than winter; but the following may be taken as average prices for material put on truck at the nearest railway station: straight-face wallstones, 43s. a rood, or about 3s. 1d. a yard; and pitched-face wallstones, 49s. a rood, or 3s. 6d. a yard; ashlar is worth about 1s. 6d. a cubic foot. The weight of a rood of wallstones is not more than 3½ tons, and, as the rate of carriage from the Halifax district to different parts of London varies from 10s. 10d. to 12s. 10d. a ton, the cost of wallstones delivered in the metropolis would be, say, 6s. a yard for straight-face and 6s. 5d. for pitched-face. We do not think that these prices are so high as to prohibit the use of Yorkshire wallstones in London, but we are of opinion that they might often be employed with advantage, as most of the stone weathers very well and has a pleasing appearance.

This question of durability is, perhaps, the most important of all, and the answer to it is "yes" and "no." In a house dated 1724, now standing opposite the east end of the Parish Church at Halifax, the tool-marks are still visible; in another house, which stands facing the east, within a few yards of the south gateway of the same church, and which is dated sixteen-hundred and something undecipherable, many of the wallstones are eaten into deep furrows along the joints and the most marked lines of lamination, and the surface will crumble away at a touch of the hand. To take another instance—certain houses at Northowram, dated 1651, still retain tool-marks on many of the stones; whereas a school in the same village, erected only sixteen years ago, exhibits wallstones in an incipient state of decay, some showing shallow furrows and others presenting a chalky appearance, which augurs ill for their durability. It is impossible, of course, to ascertain from what particular quarry or bed of stone the material of the older buildings just mentioned was obtained, and we are informed that the stone used in the erection of the school was supplied from several quarries at Northowram, some of which have since been worked out; other quarries, as the Park, &c., have since been opened.

It is imperative that these flat-bedded wallstones be laid on their natural bed. In a tooled or rubbed cube of the stone, it would in some cases be impossible to find the natural bed without trying to split the stone, but in most instances the lines of lamination are plainly visible, and in others they are revealed by wetting the stone. The shape of the wallstone, however, leaves no doubt as to the way in which it must be laid. Gwilt says, quoting the Commissioners, "Sandstones, from the mode of their formations, are very frequently laminated, more especially when micaceous, the planes of mica being generally deposited in planes parallel to their beds. Hence, if such stone be placed in buildings with the planes of lamination in a vertical position, it will decompose in flakes according to the thickness of the lamina; whereas, if it be placed so that the planes of lamination be horizontal,—that is, most commonly upon its natural bed,—the amount of decomposition will be comparatively immaterial." We have, however, seen very thin flakes, more than half an inch square, peeling off the vertical faces of stones laid on their natural beds, the flakes themselves being striated horizontally. Some of the striations we have seen are dark brown. This surface-flaking results, we think, from the "stunning" of the stone during squaring, and the subsequent action of the atmosphere and of rain; it serves to prove that not all striations are sources of weakness. In fact, there are many dark streaks in blocks of riving stone, along which the quarryman strives in vain to cleave the stone. But streaks of mica must be shunned; these are the edges of planes along which rain will penetrate further and further year by year, wearing them out into furrows, and sometimes freezing and lifting the stone. Generally it may be said that self-bedded stone, as it contains a considerable quantity of mica, ought to be rejected, and only riving stone employed. Care should also be taken that the joints in flat-bedded walling are well flushed up and pointed, for if not, the edges forming the joints will be the first to decay. Straight-face wallstones are to be preferred before pitched-face, as the latter harbour dirt, soot, and moisture.

It should also be stipulated that no wallstones be cut from the "rag" or "shoddy" beds of the quarries, but that they be obtained solely from the best flag-beds. If these points are observed, Yorkshire wallstones will withstand the smoky and acidulated atmospheres of our towns for centuries.

To compare the weight and strength of the stone of which we are speaking, we have prepared the following table:—

Material.	Average weight in lbs. crushing weight per square foot in ton, and	Remarks on same.
Aberdeen and Peterhead Granite.	166 534	Mean of four experiments on 1-in. and 1½-in. cubes.
Craigleith Sandstone	146 505	Stronger of two 2-in. cubes tested by the Commissioners, &c.
Portland Stone	137 276	Mean of two experiments on 6-in. cubes by Committee of R.I.B.A. in 1864.
Bath Stone (Box)	123 216	Experiments on 6-in. cubes.
Patent Victoria Stone	415	Company's own Circular.
"YORKSHIRE STONE"		
Park Quarry, North-owram.	155·5 715	Mean of three 6-in. cubes recently tested by David Kirkcaldy & Son.
Yew Tree Quarry, Lightcliffe (bottom bed).	150·6 629	Ditto.

These six experiments show that Yorkshire stone will not, on the average, yield under a pressure less than 11,000 lbs. per square inch. The "Park" stone, we may add, cracked slightly at 629 tons, and the "Yew Tree" at 532.

We append a succinct account in tabular form of the quarries of "Yorkshire Stone" in the Halifax district.

Flags, &c., from many of the quarries named in the table accompanying this article are sold to stone-merchants, and the quarry-owners do not know where they have been used, but in nearly all cases they are aware that some, at any rate, have gone to London. Great quantities are used throughout the provinces, and also in Germany and America. The principal owners, however, can point to many executed works, and some of them have agents of their own in London. Before specifying flags or other material for large works, architects and surveyors will do well to obtain from the best firms minute particulars of the places where their stone has been used, and then to inspect these places for the purpose of ascertaining the stone's durability and appearance. In no other way can a really satisfactory result be always obtained. If a firm can only state generally that its flags have been used, say, in London, and cannot point out the particular street, or rather portion of street, in which they have been laid, the information is of no value, and the architect must apply elsewhere; for it may be safely assumed that the quarry-owner who does not take the trouble to ascertain where his largest consignments of stone have been used has no pride in his work, and takes very little thought of the quality of his stone and of its future behaviour. It has not been considered advisable to state in this article where material from each group of quarries has been used, on account of the extreme difficulty of ascertaining and then of describing the exact locale, and also because in nearly all large buildings and streets stone from several quarries has been used by contractors.

To take one instance,—it is stated in Rivington's "Notes on Building Construction" (Part III.), that flags from Elland Edge were used in the Victoria Station, Manchester; but this information is really either too much or too little, for flags were supplied for this building from at least two other groups of quarries in the Halifax District, and also from certain Lancashire quarries. It may be added that "special tooled" flags have been largely used in Lambeth and by the London County Council. These are of selected stone, tooled down to a perfectly level face, and are worth nearly a shilling a yard more than ordinary tooled flags on account of the extra labour in facing.

NOTES.

HE verdict on the deaths from the Carlisle railway accident amounts to a censure on the London and North-Western Railway for the use of a brake whose action could not be depended on. It is not often that any censure as to their manner of working their line could be sustained against this company, but we fear it will be the general consensus of opinion in this case that they have been trusting the safety of their passengers to a brake which is at all events not the best known, and against which a good many failures are recorded. One or two points the jury seem to have missed in their verdict. It was certainly an omission on the part of the conductor, Downie, not to have informed the driver who joined the train at Crewe that there had been trouble with the brake in the early part of the journey. Had he been informed of this, he would at all events have been put on his guard. On the published evidence we considered from the first that no blame attached to the driver, who acted according to rules and on the supposition that the brake in his hands would do what it professed to do. But one admission by Mr. Whale, the assistant locomotive superintendent of the company, is very remarkable, and seems also to have been overlooked. He admitted that the driver tested the vacuum brake a mile further from Carlisle than he need have done, according to rules, but went on to say that he would have done better to have left the vacuum brake alone and trusted to the hand and steam brakes. This would of course mean shutting off steam a great deal sooner and taking more time to pull up. That is a precise confirmation, out of the lips of an official of the company, of the criticism we first made on the accident—that it was one of the results of running it fine in pulling up a train, trusting to the power of the modern brakes to pull up within a short distance; a system which almost ensures an accident at a large junction station if the brake does fail. We have noticed this increasing tendency to trust to the brakes for pulling up short over and over again on the leading English lines of late years; we have been in a railway accident caused by that practice; and we now have another instance of it, and we have the admission of an important practical official on a great line to the effect that it is a recognised source of danger. Then the practice ought to be abandoned. Drivers should be instructed to allow more space for pulling up, at large stations, and proportionate time should be allowed them for doing so; and the power of pulling up quickly by the continuous brake should be regarded as a power for avoiding unexpected danger, not for habitual use so as to create an unnecessary chance of danger. Journeys by fast trains would be a trifle less fast in this case, but they would be both safer and more agreeable. The habit of pulling up quickly when at high speeds is calculated to add very much to the detrimental effect which frequent railway travelling already exercises on most constitutions.

IN regard to the question of a diploma for architects in France, the *Semaine des Constructeurs* quotes with approval a letter by M. de Baudot on this subject, of which the following is the first paragraph:—

"J'ai la conviction que l'institution d'un diplôme est dangereuse pour l'art, d'une application difficile dans la pratique, et qu'elle ne peut donner sérieusement satisfaction à aucun des intérêts mis en jeu; en tout cas, si cette opinion est erronée en principe, je ne pense pas que, dans l'état actuel des choses, qui est le résultat d'un système d'enseignement vague et d'un manque absolument de véritable éducation professionnelle, il soit opportun d'armer aujourd'hui l'architecte d'un droit exclusif à l'exercice d'une profession dont les limites ne sont pas nettes."

This, it will be seen, is a repetition almost in so many words of the argument in support of Professor Roger Smith's resolution at the Institute the other evening. M. A. Lefeuille, in *L'Architecture* of April 12, has the following

remarks on the same subject, which forms nearly a repetition of the argument we used in our last in regard to the real cause of the want of power of the architectural profession, in comparison with that of the engineers, to act effectually in protecting their own highest interests:—

"Donc alors, un diplôme, un titre quelconque, ne serait autre qu'une satisfaction personnelle, et cela d'autant plus qu'aucun client n'oserait jamais demander la production d'une pareille valeur, d'un pareil titre.

Somme toute, aujourd'hui que le diplôme n'existe pas, est-ce que les choses marchent mal, et mal à ce point de voir chacun se plaindre? Est-ce qu'on manque d'hommes intelligents, capables? On manquerait plutôt d'hommes vraiment sérieux, foncièrement honnêtes (les capacités ne donnent pas toujours ces dernières qualités). Aussi aujourd'hui, et pour le moment, au lieu de diplôme, d'exigences, soyons tous égaux (en apparence du moins). Tendons-nous franchement la main! aidons-nous; unissons-nous! L'union fait la force! C'est ce nous voyant plus souvent, et d'un œil vraiment confraternel, que nous apprendons à nous mieux connaître, à nous apprécier plus sûrement, à nous respecter enfin. Là est le meilleur moyen de diminuer les faux frères qui peuvent exister encore et de ramener les récalcitrants."

WE report in another column the decision come to at the Institute special meeting on Monday last, to elect Mr. Waterhouse as a president for a third year. There could be no better opportunity for departing from the usual rule of two years than in the case of Mr. Waterhouse, who has attained a position in the profession which is in some respects unique, and who as President has exhibited a rare combination of courtesy and tact with business capacity.

THE Railway Rates Inquiry has now entered upon what we regard as one of the most practical stages. Indeed, it seems a pity that the time of the Court should have been occupied for sixty days before reaching this important stage, and that a large proportion of the evidence already offered might have been profitably reserved until now. The position of the articles in the proposed classification is at last being considered, commencing with the lowest,—the railway companies defending their proposals and the traders explaining their objections. Thus, bricks are placed in Class B, and makers urge they should be in Class A. The companies take the broad ground that the latter class should consist exclusively of unmanufactured raw material; while the traders urge that bricks are carried in heavy, compact loads, and are dealt with in the matter of loading, &c., in precisely the same manner as raw material. The brick and tile makers' interests were well looked after by Mr. Impey, of the South Staffordshire Brickmakers' Association, and others, and the position of various descriptions of iron, &c., were subsequently argued in a similar manner. The rate of progression is very slow, and when the higher classes are reached it will probably be still more tedious, as they include many more articles than the lower. Of course, the Court reserve their decision upon the disputed points, but they give expression to their opinion occasionally in a manner which shows that the position is clearly grasped, and that the arguments of both sides are well weighed.

THE case of Barlow v. Ross, reported in the current number of the *Law Reports* (24 Queen's Bench Division, p. 381), is of interest and importance. Fortunately, also, it is as simple as it is important. The Artisans and Labourers' Dwellings' Improvement Act, 1875, section 20, provides that upon the purchase of any lands for the purpose of the Act, "all rights of way . . . and all other rights or easements in or relating to such land or any part thereof shall be extinguished," subject to persons who are proved to have sustained loss under this section obtaining compensation. In 1877 the Corporation of Birmingham purchased some land for artisans' dwellings; opposite to it was the plaintiff's house, which for ten years had en-

joyed an easement of light over this land. In 1886 the defendant obtained under lease from the Corporation a part of this land for the purposes of the Act, and in 1888 obstructed the plaintiff's light. The question then arose whether the operation of the Act obstructed inchoate and accruing rights to light. For when the Corporation purchased the land, only ten years of the prescriptive period had run. The Court of Appeal decided that the Act by its terms did extinguish such right, and therefore that after the Corporation had bought the land in 1877, the growth of the plaintiff's rights ceased. But they were also of opinion that such growing rights were the subject of compensation, and that the plaintiff had had "a legitimate ground of applying to the Corporation for compensation." That this decision is in the main correct cannot be doubted; were such inchoate rights to light to be allowed to go on growing the whole use of the purchase of a piece of ground might be put an end to. Of course when the land was purchased there could not be said to be a right or easement of light in existence, and we have some doubt whether legally or morally a man with an inchoate right to light should have compensation. It is clear that if an ordinary purchaser bought the land and erected an obstruction to the light, the man with a growing right would have no right of action. Consequently it is difficult to see why a public body should be in a worse position than a private individual. On the other hand, if the private individual did not obstruct the light before the prescriptive period of twenty years had elapsed, he never could do so. Hence the compensation for an inchoate right is a kind of golden mean to enable a Corporation to be safe in the future.

WE hear from Athens that some gold ornaments have been discovered by the British School at Megalopolis. Owing to recent heavy rains, operations had to be stopped at the theatre, and attention was directed to the tumulus mentioned by Pausanias as the tomb of Aristomenes. A trench was started outside of this, and almost at once a quite plain marble sarcophagus was come across, containing bones and fragments of gold ornament. These are described as being of beaten gold, somewhat similar to the Mycenaean ones, but no definite conclusion can be come to as to their date till they have been more carefully examined. Work was stopped next day for the Easter holidays, and immediately these are over further investigations will be proceeded with at this spot.

IT seems that Manchester is hestiring itself in earnest to get rid of its canopy of smoke. Mr. Alfred E. Fletcher, in a letter to the *Times* of Monday, gives an account of the constitution of a committee to examine and report on the subject with the special view of improving the present condition of the atmosphere overhanging the manufacturing towns of Lancashire, and Manchester in particular. The two special causes of inaction hitherto, he says, have been first, a habit of acceptance of the present condition of things, as an unavoidable evil:—

"In Lancashire the workers are so accustomed to their darkened sky, the very blackness of which is sometimes taken as a sign of prosperity, that a passing grumble is all that escapes them; they accept the dirt as being inseparable from work:—

and secondly a fear that smoke-prevention appliances are likely to be too expensive for use with due regard to economy of production. "When summoned before the magistrates on the charge of emitting black smoke, the smokers say, 'show us an economical and effective arrangement, and we are quite willing, even anxious, to adopt it.' To this a fair answer would be 'the emission of smoke is illegal; choose your own course for abating it.' The average coal consumer is, however, not a scientific man; he is bewildered by the conflicting reports as to methods of burning coal without producing smoke." The newly-formed committee, of which Mr. Fletcher is chairman, proposes in a paternal

spirit to make things easier in this way for the manufacturer by collecting and arranging all the available information on the subject. The following are the main objects proposed by the committee:—

I. Collation of the results of past experience.
II. Examinations or tests to be conducted by experts, appointed by the committee, at places where the appliances for, or methods of, consuming coal smokelessly are already at work, with the object of ascertaining whether, under ordinary working conditions,—*i.e.*, with ordinary workmen, ordinary coal, and under varying demands for work,—these methods or appliances do produce or are accompanied by,—

(a) Practical freedom from smoke.
(b) Reasonable amount of duty.
(c) Economy of fuel.
(d) Moderate cost in wear and tear and simplicity of construction.

(e) Moderate cost of application.
III. Examinations or tests to be conducted on premises temporarily occupied and furnished with boilers, chimneys, and apparatus of such appliances or methods as cannot be adequately tested where they are in use, and which are of sufficiently promising and distinct a character.

IV. Issue a report embodying the results of the committee's operations."

We wish every success to this truly philanthropic effort.

FROM a passage in the *Building and Engineering Journal* of Australia and New Zealand, for March 1, it appears that the subject of the publication of tenders is being discussed in that part of the world, and that the publication of such tenders, and the occasional objections made to it, are alike on a footing exactly the reverse of what practically obtains in this country. The persons who seem specially to desire the publication of tenders here are the builders, and the only persons who occasionally make an objection thereto are the architects. The Australian journal above-named strongly urges the publication of lists of tenders, but states that "our representatives except in a few instances have been told by the architects of Sydney that builders objected" and therefore they could not adopt such a practice." On what ground the builders should or do object our Australian contemporary does not suggest, but gives some reasons why it is their own interest not to object, as indeed would seem almost self-evident. It appears from the same paper, however, that the "New South Wales Builders' and Contractors' Association" has formally and officially expressed itself in favour of the fullest publication, and it is expected that in consequence of this expression of opinion the difficulty formerly felt about the publication of tenders will soon cease to exist.

IN the autumn of this year will be opened at Turin what is we believe the first Italian exhibition of architecture and architectural design. The exhibition will comprise three sections: (1) Architecture, including studies and restorations of ancient architecture and designs in modern architecture; (2) Decorative work and art manufacture, including marble and stone work, terra-cotta, stained glass, mosaic, decorative painting, wrought and cast iron work, wood carving and inlay. The third main section will consist of architectural publications, historical and illustrative.

WHEN the scheme of St. Martin's-in-the-Fields Vestry for acquiring the property north of Green-street and improving the street is carried out, old Green-street will practically disappear. The name by which the street is now known (for it appears to have been once known by the euphonious appellation of "Dirty-lane") commemorates the site of the Green Mews of the Earl of Leicester, which stood where are now St. George's Barracks, behind the National Gallery. A chapter of the biographical sketches added by J. T. Smith to his life of Nollekens, contains some account of Woollett's early struggles as a line-engraver and etcher in Green-court, where he executed a copper-

plate of Wilson's landscape, the "Niobe," for Alderman Boydell, receiving one hundred guineas for the work. Woollett was born in 1735, in King-street, Maidstone, where his father was a flax-dresser. He learned his art at the hands of John Tinney, in London. He removed from Green-court, circa 1769, to No. 11, Green-street, and was buried, 1785, in old St. Pancras Churchyard, where his grave-stone, and that of his widow, were restored by the Graphic Society in 1846. In the cloisters at Westminster was set up a monument, with a bust by Banks, in honour of him who engraved the "Death of General Wolfe" and the "Battle of La Hogue," and other well-known works of his day.

WHEN the present General Post Office in Edinburgh was completed, about forty years ago, the accommodation provided for the department was considered excessive, but it was thought prudent to make provision for future expansion of work. A suite of rooms, over and above the requirements, were occupied by the General Board of Lunacy, but, in the course of time, that Board had to find quarters elsewhere. The increase of business has of late years been such as to cause great inconvenience to the officials, and it has become absolutely necessary to provide additional accommodation. Mr. W. W. Robertson, of Her Majesty's Board of Works, has accordingly been directed to prepare plans for an addition to the building, which was designed by his predecessor, the late Mr. Robert Matheson. Over the present sorting office an additional storey is to be erected, and the southern façade will be extended to about double its present width, which will then be about 180 ft. long, and rising from the level of the North British Railway Station to a height of about 100 ft. The benefit of these extensions will chiefly be felt by the telegraph department, sorters, letter-carriers, and parcels post. These additions will, of necessity, have to be carried on by degrees, so as not to interfere with the current post-office work. The estimated cost of the additions is placed at 30,000.

ONE of the objections advanced against the proposed underground railway in Princes-street, Edinburgh, was that the formation of a station at the west-end of Waterloo-place would necessitate the destruction of one of the finest architectural features in the neighbourhood. Sir James Gowans, the Lord Dean of Guild, has suggested, in the pages of the *Scottsman*, an alternative, which would be in every respect more suitable; it is that the Caledonian Railway Company, the promoters of the scheme, should secure the vegetable market, which is on about the same level as the proposed railway, and convert it into their East Princes-street Station. One evident advantage of such an arrangement would be that the market is in contact with the North British Railway Station, and greater facility of transit from the one station to the other would be had than if the Waterloo-place site was adopted. Sir James Gowans expresses a hope that if the projected railway is carried out, the bridge across London-road shall be made an architectural feature and not an eyesore, as such erections generally are when left entirely in the hands of engineers.

ON Wednesday, 30th inst., will be put up for sale, at the Mart, the ground leases, for fifteen years unexpired, of Nos. 166-173, Piccadilly, comprising the Dudley Gallery and the Egyptian Hall (No. 170). The three leases, with ground-rents, amounting to 3882. 3s. 6d. per annum, are held directly from the Crown; the property is at present under-leased at a total rent of 3,144l. a year. The Egyptian Hall was built in 1812, at a cost of 16,000l., after the designs of G. F. Robinson, architect—(the figures of Osiris and Isis are by L. Gahagan)—for W. Bullock's museum of natural history specimens gathered in Africa, the Pacific, and the Americas, together with many objects from the Leverian collection,

all of which were sold seven years later. The hall was then used from time to time for the exhibition of numerous pictures, models, "marvels," and other shows. These included Seurat, the "Living Skeleton," of whom a full account is given in Hone's "Every Day Book," vol. 1., columns 1017-31: Haydon's painting of the mock-election at the King's Bench Prison (1828), which George IV. purchased for 500 guineas; and, in 1844, his "Ostracism of Aristides," which, as that unfortunate man has himself told us, proved so sorry an attraction as compared with the dwarf "Tom Thumb" in the same building at the same time; and the "Siamese Twins," in 1829. Also a model of the tomb of Psammuthis, discovered by Belzoni (1821); Captain Siborne's model, with figures, of Waterloo, shown twice, in 1838 and 1845, and since deposited at the United Service Museum, Whitehall; Sir George Hayter's picture of the first reformed House of Commons (1843); Brunetti's two models of Jerusalem (1847); Banvard's diorama of the rivers Missouri and Mississippi (1848); and Bonomi's panorama of the Nile (1850). In 1852 Albert Smith first gave here his illustrated lecture upon his ascent of Mont Blanc.

THE latest of the series of paintings which Mr. Ford Madox Brown is executing as decorations for the Town Hall of Manchester (the tenth in number) is at present on view at Messrs. Dowdeswell's in New Bond-street. It represents John Kay, the inventor of the Fly-Shuttle, saved by his wife from the rioters, who proposed to take vengeance on him for the same reason that the Luddites in later times attempted to wreck machinery and lynch the owners of it, viz: for the crime of inventing labour-saving appliances. Kay's wife had him carried out, according to the story, by two of his workmen, concealed in a woollen sack or wrapper, and conveyed away in a cart from the scene. The painting shows the moment when Kay is being unwrapped and two of his men are about to carry him off. The whole scene has been cleverly got into a form for decorative painting, the long side of the room occupying the length of the panel, with the rioters seen through a window on the left and the cart through an open door on the right, the main group of figures being towards the right. This group is rather a confused tangle, and at first sight the head and shoulders of Kay appear to belong to the legs and feet of the man who is stooping to lift him; an unfortunate effect which the eye does not quite lose sight of even after the various personalities have been disentangled. The figures of the wife and children, all of whom seem very young in comparison with Kay's bald head and grey hair, are curiously short and stumpy in their proportions. The boy half lying on the table to get a look through the window is very cleverly drawn. On the whole we fear the general effect of the scene, in spite of the fine character and individuality of the heads, is a little ludicrous, though it tells its story with energy enough no doubt. It is a painting decorative in method and execution, but realistic in conception; and the two things hardly go together.

An excellent piece of arras tapestry has recently been executed by Messrs. Morris & Co., from the cartoons of Mr. E. Burne-Jones, and is intended to occupy the wall over the rector's stall in the chapel at Exeter College, Oxford. The subject, the visit of the Three Wise Men, has been treated in much the same manner as is usually done, but some of the details, such as the "Star of Bethlehem," being held in the hands of an angel in white and gold, and the Virgin being seated in an arbour surrounded by flowers, is a departure from the conventional treatment. The scheme of colour generally is low in tone, blues and reds forming the chief colours in the draperies, and the background a dark blue forest; but much light has been intro-

duced in the central figure of the angel, and on the steel armour of one of the figures. The execution of this steel work, and of the watered-silk worn by another of the Wise Men, is especially noticeable. The foreground is composed of grass thickly carpeted with flowers,—chiefly white lilies and blue iris.

AMONG the principal works at the Dudley Gallery Art Society's Exhibition are various large drawings by Mr. Walter Severn, two from Mentone, "The East Cliff" (163) and "The Old Town" (234), both of them rather hard in effect, especially as to the treatment of the sea; in the last-named the irregular piles of red-roofed houses are effectively treated. His "Crinan Canal" is a fine work (221), though here again the water is the least satisfactory portion. Among the most artistic works exhibited are various drawings by Mr. Fullwood, especially "By the River, Old Windsor" (122), a fine landscape with very rich colour and with a style of its own. His "Harvest" (120) is really a study of an old churchyard with its company of moss-grown head-stones in the foreground; a powerful work. Miss O'Hara's "Night's Shadows Falling" (212) is a study of sea in twilight of more than ordinary merit. A large drawing by Mr. R. Jones "Early Spring" (224) shows some fine painting of trees. Mr. F. G. Coleridge's various scenes on the Thames are good, and resemble the places they are meant for, which is not always the case. Signor Giampietri sends one of his admirable studies of Roman architectural remains, "Clivus Capitolinus" (58). Along with a good deal that is commonplace there are various other works of interest which we have not space to mention more particularly.

THE Ruskin Museum at Sheffield has at last been brought into a more accessible situation, experience having proved that the working man, when he has a holiday, will not take the trouble to walk two or three miles up hills to study a collection of art-treasures, as anyone but Mr. Ruskin might have known from the first. The new Museum, in Meersbrook Park, was opened on Tuesday last by the Earl of Carlisle, whose speech was followed by one from Mr. Arthur Severn which afforded a characteristic example of the logic of the disciples of the Ruskinian cultus. Mr. Severn is grieved that it should be necessary to show in the British Museum and other museums so many things that are not beautiful; "he would have no South-Sea gods, no skeletons, and no ugliness of that kind." So that history and anthropology go for nothing, we presume. But there is another question besides this: is Mr. Severn quite certain that we should fully realise beauty if we had no conception of its reverse? Does he forget Goethe's answer to the man who objected to the presence of evil in the world—"So you want to jump off your own shadow?" The same thing applies in the artistic as in the moral world: we cannot jump off our own shadow.

Land at Knightsbridge.—A correspondent writes:—"The unique building site forming the 'island' at the junction of the Brompton and Knightsbridge roads, which has for so long been occupied by small buildings entirely out of character with the present requirements of the neighbourhood and surroundings, has, we understand, been recently disposed of by Messrs. Chadwick, of Parliament-street, Whitehall, Messrs. Pinder, Simpson, & Newman, acting for the lessee. The site, which occupies an area of about 36,000 ft., with the extensive frontage of between 700 ft. and 800 ft., is believed to be one of the most valuable and important pieces of land which have come under development in the West-end of London for several years past. It is to be hoped that the buildings about to be erected on it will be of a higher architectural character than those with which some other important London sites have of recent years been covered." We believe the architect is to be Mr. Spencer Chadwick, but do not know for what purpose the buildings are intended.

THE NEW MUSEUM AT BERLIN.*

IN 1883 a new building, destined to hold the geological, paleontological, mineralogical, petrographical, and zoological collections of the Berlin University was commenced, and in December last its inauguration took place, the German Emperor personally declaring it "open."

Although situated at some distance from the homes of those people most likely to visit it, the new Museum has wisely been placed in close proximity to the Royal Agricultural and Royal Mining Colleges (both of which contain valuable collections), and it now takes up the central position in this imposing group of buildings.

As to the exterior of this new home of Natural Science, not much can be said, excepting that the architect-in-chief, Professor Tiede, has done as much as he could to ensure a monumental appearance of the building, considering what very meagre means were granted for the benefit of the façades. The central feature of the front elevation, which stands in advance of the main flight, is emphasised by a columnar order, and this part has been adorned with the statues of Johannes Mueller and Leopold von Buch and the sculptured heads of Ehrenberg, Alexander von Humboldt, and Weiss. All the other parts of the exterior are of a very monotonous and rather badly-proportioned design.

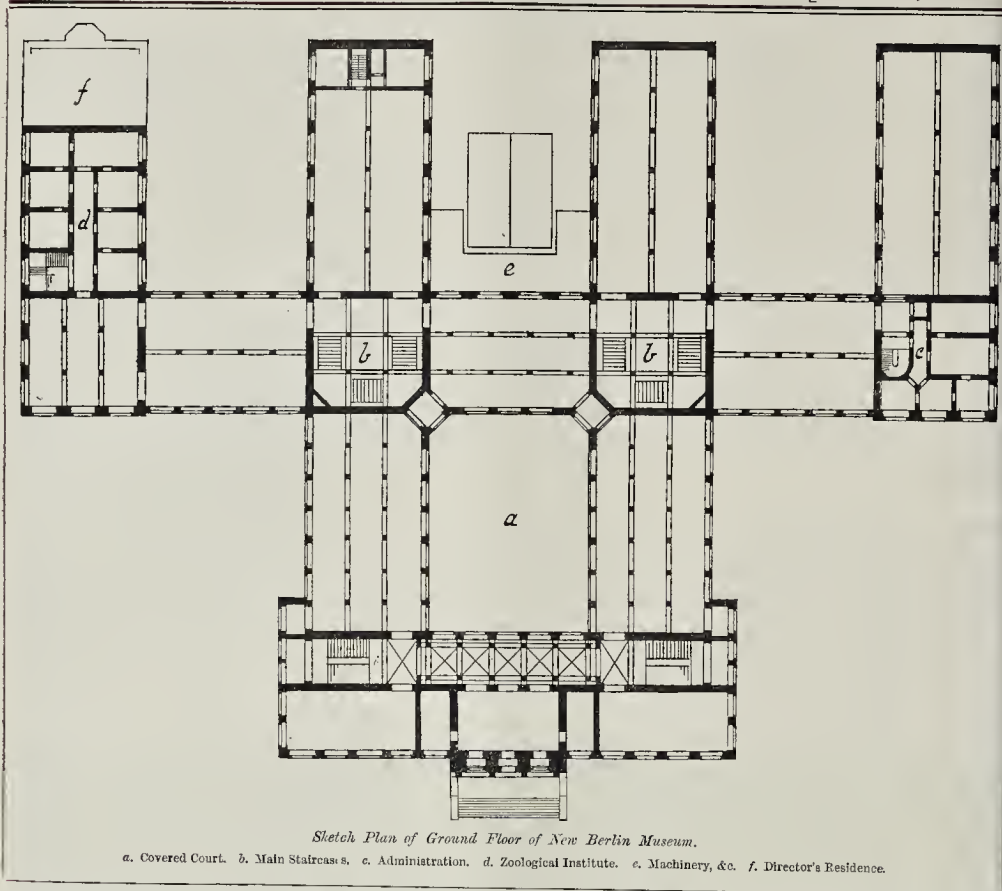

The new building covers 8,145 square metres of the site, and faces due south. The central court is covered in the boilers, machinery, &c., have been placed outside the main building between the two central wings on the basement level, with a top light; and in the north-west corner the plan shows the official residence of the director. In the extensive garden at the back of the building, huts for mammals, an aviary, and a reptile house have been erected, it being the intention of the present chief to keep such species of live-stock as might be required for scientific investigation close at hand.

Owing to the death of the former keeper of the Zoological collections, the interior arrangements are in many ways different to the original intentions of the promoters, and hence the grouping, &c., of the collections does not quite accord with what might be expected when looking at the plans. Whilst the original idea was to have all the collections (and hence also the different stories) accessible to the public, the Museum as it now stands is divided into two separate departments,—(1) scientific collections for the professional student; (2) popular collections for the general public; and as the latter are all situated on the ground and basement floors the enormous staircases leading to the upper stories become quite unnecessary. Another point not at first intended is the organisation of a so-called Zoological Institute, which takes up the greater part of the west wing; here some of the large show-rooms have had to be divided up and he changed into a set of lecture-rooms, work-rooms, and studies, together with all such offices as are required for the scientific investigation of zoological questions. Besides these two considerable alterations, which are solely due to the new director, Professor K. Moebius, various smaller but, perhaps, not less important new dispositions have been made.

For instance, Professor Moebius has taken special interest in the planning (*i.e.*, positions, measurements, colour, &c.) of his show-cases, and the internal arrangements of every room under his control have been worked out under his direct superintendence. Numerous trials have been made, and the Professor's great aim has been that the new museum should even excel in detail the model museum he had organised at Kiel some years ago. He has reached his ideal, his show-cases have been planned in a most practical way, all receiving excellent light, and their positions not only leave the visitor plenty of free passage, but naturally compel him to make a systematic tour through each room.

It has been Professor Moebius' great desire to prevent the eye being distracted more than needs be, and therefore he has placed the exhibits so that the visitor can never see too much at a time. All his show-cases, excepting now and then a corner one (which then contains exhibits of larger size than the rest), are divided lengthways by movable

* Das Neue Museum für Naturkunde zu Berlin. We are indebted to the Director, Prof. Moebius, and the superintending architect, Baunsp. Kleinwachter, for the particulars.

canvas partitions, as shown in the diagram, thereby causing the show-room to consist of a set of separate compartments in which can be seen only those things that are contained therein. Of course, the visitor does not, according to this arrangement, find such an agreeable view, or perhaps one may say such a picturesque confusion, as he has been wont to find in most museums; he does not find a room full of transparent cases filled with many-coloured objects on which the light plays on from different directions; but it is argued that this is not the object in visiting a museum.

Arrangement of Screens to Cases.

All the halls and rooms of this new Museum have, by the Professor's directions, been kept as plain as possible, and the show-cases (which are of iron) have no unnecessary mouldings or ornamentation. The fittings, partitions (*i.e.*, backgrounds), &c., of these cases are all uniformly painted in a yellowish-grey tone, somewhat like the tint of a lithographic stone, and all such apparatus (both of wood and iron) as

are used for mounting the objects exhibited are of the same colour. This prevailing tint forms an excellent background for showing up the various objects exhibited, and marking the outline of the object as distinctly as possible, and at the same time does not attract or distract the eye in the least.

Such objects as are entirely transparent, or nearly so, and which hence require a good light at the back of them if their fibres, &c., are to be seen at all, have been placed in small show-cases in front of the north windows, and can be examined with ease without incommoding the free passage.

All the details of the plan have been devised with a view to giving every facility for the examination of the contents of the building.

The Zoological Institute, under the direction of Professor Schultze, has, in spite of its quite recent organisation, according to the requirements of the new administration, been excellently arranged. It has been so planned that the visitor ascends from the garden in which the live animals are kept, or from the cellars, where an aquarium has been placed, to the rooms in the basement, where the coarser work of the preparator is done by his servants, and from this floor to the one above, which is destined for more careful work and scientific investigation, and then finally ascends to the second floor, which is taken up by lecture and demonstration-rooms. A large lecture-hall on this floor has 300 seats, and another on the first floor 80; and room has been found for the tables, instruments, &c., for the 50 students who will take the practical courses in "observation and examination" of zoological matter. At the top of this wing, hot and cold rooms and also an open terrace have been planned for the reception of living animals coming from other climates, and in close proximity to these novel habitations a set of photographic ateliers and observation rooms are to be found.

On the first and second floors of the east wing

the committee-room and library, the studies of the Director, several keepers and assistants and the offices of the administration have been placed, and if there is any mistake in the planning it is certainly to be found in the steep and very badly lighted staircase which leads to this very important part of the building. In fact, the whole of this little bit has been wrongly placed; its natural position would have been in the west wing in close proximity to the Zoological Institute and the official residence of the Director. As to the latter, it shows no point of interest; it is, if anything, too roomy, lacks comfort, and according to its position in the building receives the north and east winds,—a great disadvantage in a German climate.

As a whole, however, the building may be well called a success; it is well adapted to its purpose, has plenty of air and light, and has the advantage of not being over-decorated. As mentioned above, the working out of the designs was placed in Professor Hilde's hands, who, together with Ban-Inspector Kleinwachter, has superintended the erection, the latter gentleman being especially appointed for the technical and business superintendence. As to construction, the whole of the building, except the roof, is of fireproof materials. Steam and hot-water coils have been used for heating purposes. The Museum building, not counting fittings, has cost 3,200,000 marks, the fittings alone 970,000 marks, making a total of 4,170,000 marks, or nearly 208,500*l.*

French Exhibition in London.—It is announced that the French Exhibition at Earl's Court and West Brompton will be opened at 3 p.m. on Saturday, May 10, by the Lord Mayor of London. The French Committee, we are informed, are of opinion that this will be the most representative display of arts and industries yet made by France abroad.

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS:

RE-ELECTION OF THE PRESIDENT.

A special general meeting of the members of this Institute was held on Monday evening last, Mr. Arthur Cates, Vice-President, in the chair. On the motion of the Chairman, seconded by Mr. J. Macvicar Anderson, and supported by Mr. Henry Dawson, it was unanimously resolved to suspend By-law 26, which limits the term of office of the President to two years, in order that Mr. Waterhouse might be elected to that office for a third year.

Mr. Waterhouse shortly afterwards entered the room, and on taking the chair expressed his thanks for this mark of the members' goodwill and confidence.

The tenth ordinary general meeting of the session was then held, Mr. Alfred Waterhouse, R.A. (President), in the chair.

Church Fittings.

Mr. J. P. Seddon read a paper on "Church Fittings." The following is an abstract of it:—It is a question depending on the special circumstances of each particular case how far the fittings of a church should correspond in character with the architecture of the fabric. It is doubtful, as this age possesses no special style of architecture of its own to bespeak its historical succession, whether artistic harmony or archaeological consistency be the more important. A good rule where an old church is concerned is to leave it alone; but when one has to be refitted, it would seem that its furniture should not be of an earlier, but might be of a later style than that which is the prominent one of the structure; while with regard to wholly new buildings, they and their contents should certainly correspond. In all cases, however, the introduction of novel materials or modes of workmanship, and of the highest class of the subsidiary arts employed, may well serve to distinguish church fittings as being of the nineteenth century, and not merely slavish copies of old examples. As to church planning, the native Gothic style, than which (as laid down in the paper on "Requirements and Suggestions," issued by the Incorporated Church Building Society) none is more generally suitable for a church in the United Kingdom, is elastic enough to admit of any change needed to accommodate modern use and ritual; whereas that now fashionable for secular architecture, which ignores the scientific invention and beauty of the pointed arch, does not seem, even in its *chef-d'œuvre* of St. Paul's Cathedral, to have been able to assimilate a frank expression of constructional and ecclesiastical needs with its empirical rules of design. Simplicity of plan and amplitude of scale are more preferable for modern use than elaborate but diminutive detail, and in this respect it would be well that our architectural works should emulate the engineering ones of the day. The author has endeavoured in this new Church of St. James at Great Yarmouth to apply his own ideas of the manner in which he would deal with modern problems, in the architectural language inherited from our Medieval ancestors.

Church fittings, without reckless abandonment of precedent, should as a first requisite subserv utility, but may at the same time be made objects of beauty, and admit of ornamentation of high class and varied nature; among them

Fonts have in past time been specially distinguished by the lavish thought and art bestowed upon them and their accessories, and nowhere more so than in this country. Those of the Norman period, though the earliest, are generally the richest and most vigorous; those of the thirteenth and fourteenth centuries are more refined in their ornamental detail, but display less fancy in design; the Perpendicular fonts of the fifteenth century are no longer grotesque, but graceful in proportion and more appropriately enriched. The exquisite canopied spire of the font cover of Ufford Church, Suffolk, and the noble baldachin-like enclosures of the fonts of St. Peter Mancroft Church, Norwich,* and of Trunch Church, Norfolk, are examples of the magnificence often indulged in as regards this particular feature of church fittings by our ancestors. Modern munificence is often displayed upon the same objects, and we have at disposal for the purpose still richer marbles, with cloisonné and other kinds of mosaic, and the zealous services of able

* Illustrated, as restored by Mr. F. T. Buggallay, in the *Builder* for January 4 last.

sculptors if we would only employ them. In the fonts of Llandaff Cathedral, Rotherham Church, St. Margaret's Church, Westminster, and others, executed from the designs of the author, some of these means have been made use of as far as funds have permitted.

Pulpits, as Mr. Ruskin has said, may be over-ornamented, and if the preacher is to be thereby made to appear insignificant in comparison, as in some of the extravagant examples in Continental cathedrals, this has obviously been the case, yet the moderate richness of design seen in the specimens collected and published by Mr. Dollman from old churches in England cannot fairly be so censured. In the pulpit in course of erection for the choir of Norwich Cathedral, in honour of Dean Goulburn, from the designs of the author, the material employed is oak; that for Llandaff Cathedral is in stone, with marble columns; while others are entirely of marble, as at St. James's Church, Paddington, and Betchworth Church, Surrey (executed by Messrs. Blacklee, of St. Marychurch, Torquay, in their marbles from that locality); in the latter, mosaic has also been extensively employed. Drawings of other designs of a simpler character both in stone and wood suitable for small and cheaper churches are also exhibited.

Lessons may be considered in connection with pulpits as being the appliances in most churches where the Lessons are read; yet for this particular purpose their usage dates only from the seventeenth century. Many old examples of lecterns are, however, to be found, and those which take the form of eagle-desks were no doubt intended for the reading of the Gospels from the north side of the sanctuary, and other simpler ones were provided for the Epistles to be read from, and for other purposes for which uses were formerly and might again be found. As, however, one lectern only is now usually employed in moderate-sized churches, there seems no reason to object to this being of the eagle-desk variety. This is generally made in brass, and may be a costly object. That at Llanbadern Church, near Aberystwith, has an eagle made in majolica ware, with stone support; and that at Ingham Church, Norfolk, has a similar eagle on a wooden base, and designs for several of a simple and inexpensive character are also shown.

The Altar, with its surroundings, is, of course, the principal object in a church, on which the highest efforts of the architect to dignify it should be employed. The altar-table should be of sufficient width and height—not less than 8 ft. long as a rule, nor more than one-third the width of the chancel; 3 ft. 5 in. is the minimum height, 2 ft. 3 in. is sufficient for the width, as such will permit of the retable being then conveniently reached. The table itself does not require elaborate ornamentation, as its purpose is to be vested with rich altar-cloths; at the same time it should not be mean. Wood is the material most in use, but the altar-shelf behind it, to support the cross, candlesticks, and flower-vases, should be a part of the structure of the east end, and may be of stone or marble built into it. The drawings shown comprise the table in Lambeth Palace Chapel, St. James's Church, Great Yarmouth, and Christ College Chapel, Brecknock. The example given of an altar-shelf is from the new church at Gorse Hill, near Swindon Station; and that for the altar-rail for Norwich Cathedral, recently executed from the author's designs by Messrs. Starkie, Gardner, & Co., in brass and enamel on groups of marble columns; together with others in wood for smaller churches, are also shown.

The Reredos is the background to the altar-table, and therefore it is enriched in order to concentrate attention to that. Consequently it should not appear as if its object were to draw all eyes to itself. Even though the whole east end of the chancel be combined into one magnificent scheme of decoration, prominence should be given to what is the reredos proper—the immediate background of the altar-table, extending but little on either side of it, and rising to no great height above it, and not encumbered with sensational sculpture. This is the position generally chosen for a carved panel representing the Last Supper, a subject essentially picturesque in contradistinction to sculpturesque, and in white marble ineffective at a distance. Such a panel was placed in the reredos designed by the author for St. James's Church, Paddington, to his great regret. In St. Saviour's Church at Bath the reredos is of stone, executed by Mr. Hems, with a white marble cross in the central panel surrounded by foliage, with seven doves; and in the side

ones are the four Evangelists' emblems, and all are in high relief carved in alabaster. At St. Peter Mancroft Church in Norwich the reredos is in oak, and in the Perpendicular style, of which that noble church is a fine example; other examples of a simpler character shown are from Llanbadern Church, Aberystwith, and elsewhere.

The Seats for the congregation are the principal fittings for a church, and it is essential that they should be comfortable, and yet not conducive to lounging, and that they should afford proper facilities for kneeling. The variation of practice in so simple a matter is astonishing, and therefore the subject is now under the consideration of the Committee of Architecture of the Incorporated Church Building Society, as the paper entitled "Requirements and Suggestions," already referred to, is now under revision, and it is proposed to submit it to the criticism of this Institute before it is finally settled upon. Mr. William Butterfield has given his views, founded on great experience, in a pamphlet entitled "Church Seats and Kneeling-Boards," which deserves careful consideration. Several examples are shown in which the author has from time to time striven to arrive at the best result with regard to economy, and he also submits an attempt to provide suitable kneeling accommodation in cases where churches are furnished with chairs instead of fixed seats, which has been worked out by Mr. Carter, joint architect with himself for Grange Town Church, near Cardiff.

The Choir-stalls and Desks which were given to Rochester Cathedral nave as a memorial to the memory of his father by Canon Cazanove, and the stallwork in the chancel of St. Nicholas's Church, Great Yarmouth, are shown as examples designed to suit special conditions in the former case, and as suitable for a large church in the latter, and others for smaller churches in addition.

Church Screens are objects of extreme importance with regard to the effect of church interiors, against which, unfortunately, there is a modern prejudice, and in one diocese, at any rate, they were all but prohibited. They have, however, a useful purpose as marking the separation of the sanctuary from the congregation, and, aesthetically, a church seems unfinished without one. At Ingham Church, in Norfolk, the lower part of a magnificent old stone screen exists, and a design for a conjectural restoration of the upper portion to accord with what remains is exhibited. Wood, however, is the more ordinary material employed, and admits of great variety of treatment, whether simple or rich, and some examples are shown.

These and other church fittings, with monuments to the memory of the departed, are, perhaps, the best opportunities afforded to architects at the present day upon which they can devote their efforts to realise their own ideas of beauty; but it is earnestly to be desired that they would, whenever able, call to their assistance sculptors and painters as well; and this, by re-establishing the unity of the arts, which is an essential to their success, strive to enlist the sympathy and interest of the public, and render our churches once more museums for the people of this highest order of sacred and ecclesiastical art.

Mr. Wm. White, F.S.A., opened the discussion. Upon the general principles which the paper had brought forward he believed they would be all pretty well agreed. There could be no doubt that the Medieval Gothic of England was sufficiently elastic for all present purposes, in spite of some objections to it as representing disused and abolished practices and ritual. The present Prayer-book, including the at present much-discussed Ornaments Rubric, really represented the views which the Reformers had in eradicating from the Church what were regarded as superstitions. Mr. White continued that he was glad to hear that was considered an offensive term. It was not the term he would use, but what was much used at present to bring into discredit the treatment of churches generally, which he maintained ought to be followed. For such subordinate fittings as seats they ought to beware of great elaboration; nevertheless in churches which were elaborately finished it would not be right to leave the seats uncared for in their general treatment. At the same time strict convenience in treatment ought to be followed, and the question of the sloping seat was a matter, which had created a great deal of difficulty

Lecterns, again, ought to be designed with a sufficient slope to enable the reader to see readily without turning his face downwards towards the book. The height of many old altars was 3 ft. 3 in., and that, he believed, was better than a higher one. The centre should be treated as one with the altar itself, and not as a separate panel. He did not like the plain Latin cross in the centre. It was a distinctly modern invention, and not introduced in Mediaeval or earlier times in this way, being then considered as worthy of the highest decoration. The treatment of sculpture and painting for the centre of the reredos ought not to be suggestive, or what was termed conventional. In this connection he was sorry to have to express an opinion on one of the most magnificent frescoes of the present day, viz., that on the reredos at Lyndhurst Church, which, to his mind, set at defiance those principles. In that case, there was a realistic figure standing apparently in the middle of the altar in a way which was not agreeable. A church for a very large congregation was not the best for sound, unless divided up into aisles as well as nave, when it would in reality cost less than if it were not so constructed. The position recommended in the paper for the pulpit was the north side, but he considered the other side the right position; and in old churches where pulpits occupied their original place, they were found to be on the south side. Mr. White concluded by proposing a vote of thanks to Mr. Seddon.

Mr. S. J. Nicholl seconded the motion, and complimented Mr. Seddon on the fine collection of drawings he had exhibited. The old tradition of the font was that it should be approached down some steps, the original idea being that as they were born again in baptism, so they should descend into the tomb. The "wine-glass" pulpits were apparently reached by a portion of the staircase to the rood-screen. There were two ideas connected with the altar: the one that it was a table, and the other as to its being the tomb of the Martyr. The old idea of the communion-rail was that of a kneeling-bench. One could not help observing the great convenience of the loose seats common on the Continent. Something had been said as to the pulpit not being made magnificent, and Mr. Seddon had remarked that they were frequently too large. But any one who had seen an archbishop preaching from one of those Continental pulpits, especially with his mitre and crozier, would not consider the pulpits were too large.

Mr. R. Herbert Carpenter supported the vote of thanks, and spoke of the magnificent bronze fonts he had seen in the churches of Bremen. At St. Margaret's, Westminster, the font was so situated that it would suffer when the church was crowded. In the foreign churches he had referred to, however, the fonts were surrounded by splendid screens. He also mentioned the splendid font with stone spire and screen, at Lubeck, standing in the centre of the nave. This was parallel to those he had referred to, only on a much grander scale. He was glad Mr. Seddon had objected to the introduction into the reredos of sculptured representations of the Last Supper, it being a subject which never told in sculpture unless it was falsified, the great expense of white tahlecloth, in fact, spoiling any picture.

Mr. E. J. Tarver said that on the first occasion when he had to design church seats he cut out a facsimile of the human figure in cardboard, and having arranged it in what looked like a comfortable posture, he fitted the seats to it.

Mr. William Woodward remarked that he had been very much struck with the beauty of a font in the Baptistery at Pisa. The finest benches for seats that he knew were in the parish church of Hamstead, designed by Mr. Cockerell. These were classic in feeling, and, to his mind, were very beautiful. With regard to chairs, those who had visited Continental cathedrals would be sorry to see the chair principle adopted in this country. The noise created through the dragging of the chairs during the service was very detrimental to the attention which ought to be paid in church; and for the same reason he objected to a tile paving. As to the organ, it was not necessary that an architect should be a musician; but in designing a church he should make provision for the organ, giving it sufficient space, and not providing a small chamber in which the organ was buried, and its music lost. With regard to the church at Lyndhurst, he considered the fresco there by Sir Frederic Leighton the most

beautiful and harmonious treatment possible of the eastern end of a church.

The President said it was refreshing to have this old subject brought before their notice again. No one in the discussion had alluded to Mr. Seddon's remarks as to grandeur of scale and simplicity being a desirable object in building churches. This had been very much brought to his mind lately during his sojourn in Spain, where the churches were so very noble in their proportions. One felt on coming back to English churches that there was something very mean and despicable in a seat. It should be borne in mind, too, that if the seats were made too comfortable it rather tended to long services, which, perhaps, were not desirable.

The vote of thanks was then put, and carried by acclamation.

Mr. Seddon, in his reply, agreed with what Mr. White had said as to the use of the Latin cross. In regard to another question, in one of his drawings he had shown a board specially put for hats, and at the end was a place for umbrellas.

The proceedings then terminated.

Illustrations.

THE DRAWING-ROOM, GREYFRIARS, DUNWICH.

THIS room forms part of an extensive addition to Greyfriars, Dunwich, the seat of Colonel St. John and Lady Constance Barne.

The mansion stands in a well-wooded park close to the sea, and the site is altogether a beautiful spot. A seaside treatment has been adopted for the additions, with a wide verandah on the ground-floor and balcony above, whilst the style of the exterior is a free treatment of Tudor to harmonise with the old part of the house. Adjoining the drawing-room, and opening into it, is the boudoir, fitted up in similar style to the drawing-room.

The woodwork of the drawing-room is in light-coloured wainscot with inlaid parquetry floor and plaster ceiling. The dimensions of the room are 60 ft., by 25 ft., by 13 ft. high.

Music is the chief subject illustrated by the carvings, full-size details of every portion of which have been supplied to the carvers, Messrs. John Groom & Son, of Ipswich.

Mr. Alfred Brown, of Baintree, is the contractor, and Mr. E. F. Bisshopp, the diocesan surveyor, is the architect.

ASHLEY HOUSE, SHAPTESBURY AVENUE.

THIS building occupies a prominent corner site at the junction of Dyott-street and Shaftesbury Avenue—the Oxford-street end—and adjoins the French Protestant Church.

The site was originally acquired by Sir H. W. Peek, Bart., for the erection of a Huguenot Institute, but in consequence of the refusal of the London County Council to sell the freehold, the project was abandoned.

The site has now been taken by Mr. Henry Bailey, of Highbury, and the present building is in course of erection. It will contain shops and basements, with four floors of residential flats, which will be entered by a separate entrance near the French Protestant Church.

Each suite will be lighted from the surrounding streets, and not by areas. By careful planning the site has enabled this to be done.

The building will be of red brick, with stone dressings and slated roofs, the pilasters to the ground floor being of polished Aberdeen granite. Mr. Charles Bell is the architect.

MUSEUM, BORDIGHERA.

THIS Museum has been built for the Rev. Clarence Bicknell, of Villa Rosa, Bordighera, in a cleared olive-garden, off the Via Romano.

Although primarily a Museum for the storing of botanical drawings, and specimens,—of which Mr. Bicknell has made and collected a large number,—of Roman remains from the excavations at Ventimiglia, and other things of interest, it is also intended it should be a miniature "Palace of Delight," wherein the townsfolk may enjoy spectacles and gatherings of one sort and another. There is a library in the gallery, and there is to be a kiosk for a band in the garden.

The building, with the exception of the dressings, entrance arcade, and coursed work, is of rubble, stuccoed and coloured. The stone is of

the neighbourhood, and the brickwork lines that alternate with it are of the small red bricks of the country, with not too fine a joint. Below this work there is a broken frieze of pictures, with birds, beasts, and fowls of the air done in *aggraffito*. The roof is covered with plain Italian tiles. Inside, the walls are divided by colour into dado, filling, and frieze, and designs are being painted, thereon by Mr. Bicknell. The ceiling is flat, displaying the beams, and coffered by pieces filled in. The fireplaces are bold, with stone lintels and high brick hoods, crossed by shelves with coloured pottery, and brick jambs, lined with large green tiles.

The architect, Mr. C. J. Tait, of Exeter, is indebted to Signors Gastaldi, engineers, and Giovannelli, builders, for their assistance in the carrying out of the work.

HOUSE FOR THE BELLAGGIO ESTATE.

THIS house is now nearly finished, being faced with red local bricks, and the roofs covered with Broseley tiles. The woodwork is painted white.

The architect is Mr. R. A. Briggs.

WROUGHT-IRON LAMP BRACKETS.

THE smiths of the last century have produced some very fine specimens of wrought-iron work, and the lamp brackets illustrated are interesting proofs that their inventive faculty was equal to the necessities of the age. No. 1 is one of a pair to the town house of the Gurfurths, in Micklegate, York, an old Yorkshire family, now, I believe, extinct. Nos. 2, 4, and 5 are to houses of more or less importance in the same street. No. 3, now at the Manor House, or School for the Blind, until recently formed part of the railing to the Mansion House, York, when it was sold as old iron in exchange for a modern "improvement," dependent on paint and gilding for its attractions. Nos. 6 and 7 are from Newark, and, though exceedingly simple, are none the less graceful and effective. The remainder are from Carlisle. No. 8 has recently disappeared. No. 9 occupies its old position to St. Cuthbert's Churchyard, embodied in a new scheme of wrought-iron railing. No. 11 was over the gateway to Mushroom Hall, in Fisher-street, a house of some historical importance, now swept away by the tide of modern improvements; fortunately the ironwork has been saved from the marine-store dealer, and is now over the gate to the residence of Chancellor Ferguson, in Lowther-street. No. 13 occupies a new position in the Green Market. It is rather difficult to account for the Y-shaped arrangement in Nos. 8, 10, and 12; a rest for a ladder is out of the question. Both York and Carlisle, until the close of last century, had their town residences for the county gentry, and there are numerous examples of leadwork bearing their crests, panelled rooms and ceilings, and picturesque gables, reminding us of a past when individual work was recognised and flourished accordingly.

J. W. BESWELL.

BROMLEY COLLEGE, BROMLEY, KENT.

THE two illustrations of this interesting though exceedingly simple bit of old school architecture are from sketches by Mr. A. C. Breden.

THE ENLARGED COUNCIL CHAMBER AT SPRING-GARDENS.

THE London County Council will re-assemble next Tuesday, after the Easter recess. The members will then sit for the first time in the enlarged Council Chamber at Spring-gardens.

When the Council succeeded, in March, 1889, to the Metropolitan Board of Works, it found the premises in Spring-gardens, which had been barely sufficient for the work of the Board, manifestly inadequate to its own larger requirements. In particular, the Board Room, which was part of the design of the late Mr. Fredk. Marshall, the first Architect to the Board, and which in the first instance was intended for forty-five members,—a number that was afterwards increased to sixty,—could only just contain, but by no means accommodate, the 137 members of the Council. The Council, by the courtesy of the Corporation of London, obtained the use for a limited period of the Council Chamber at Guildhall, and directed the preparation of designs for alterations, the chief object of which was the provision of an

adequate Council Chamber, with such additional Committee-rooms as would admit of the whole of the business of itself and its committees being carried on at Spring-gardens.

The new Chamber has been formed by removing the north wall of the old Board Room, slightly lengthening the end walls, and adding a semicircular space beyond the line of the former north wall. The Chairman's seat is now placed in the centre of the old south wall, which remains undisturbed. The size of the chamber is about 50 ft. across the straight side, and 52 ft. from the latter to the centre of the semicircular wall, thus making it about twice the size of the old Board Room. The dais or chairman's platform extends along the south side, and the Press gallery (which is much more commodious than its predecessor in the old Board Room) is constructed at a higher level over the rear part of the dais; it is approached by the main staircase and members' lobby, and hence by a new short flight of stairs.

The floor of the body of the Chamber has been sunk to the extent of 1 ft., making the height of the seats for the members rise in four steps, following the course of the semicircular wall. They are massed together in seven separate blocks, and so arranged that from every seat a very large proportion of the members (from one-half to two-thirds) can be directly addressed by speaker. The six radial gangways and the semicircular ambulatory or corridor at the rear, under the public gallery, are so planned that no member need pass more than two other members in order to reach his seat, or to pass on one side of the Chamber to the other. The ambulatory or corridor referred to has its two ends in the division lobbies right and left of the dais, and is entered from the rear of the Council Chamber by two doors.

The seats are of American walnut, covered with maroon morocco leather. They are provided with elbows, and in front of each is a ledge for paper, pens, and ink. The floor generally is covered with dull green "Napier" matting, that under the seats being covered with green druggel laid upon felt. The walls are hung as a temporary measure with maroon hangings. On the floor of the Chamber in front of the platform is a table for the Clerk, the Solicitor, and the other officers of the Council who require to be in attendance at the sittings.

Behind the seats of the members, and on a higher level, is a public gallery for about 150 persons, accessible by a separate entrance reached from the gateway adjoining Messrs. Stanford's premises in Cockspur-street, and not on Spring-gardens, as formerly.

Two new committee-rooms have been provided, one of which will be used as a tea-room for the meetings of the Council. There is also available the provision of lobbies and lavatories accessible from the corridor that adjoins the chamber. The ground-floor of the new building is entirely devoted to the accommodation of the official staff, replacing some small and ill-lighted rooms that before existed. The Council Chamber is well lighted by day by skylights and windows, and the artificial lighting will be by electricity, supplied by the London Electric Supply Corporation, Adelphi-race, and fitted up by Messrs. Strode, of Osnaburgh-street, in addition to the provision of gas by means of three sunlights. The electric fittings include one eleven-light and eleven eight-light electrolights suspended from the ceiling, and a few two-light brackets over the dais.

The whole of the works are being carried out on the designs and under the superintendence of Mr. Basbill, the Architect to the Council, who is to be congratulated on having produced, at a small cost, a very convenient, well-lighted, and effective Chamber. He has been somewhat fettered by the necessity of preserving the existing plaster on the opposite (flat) side of the Chamber over the new Press Gallery. The enlarged Chamber in Spring-gardens will part from the convenience of its situation in the midst of the Council's offices) be found a much more satisfactory place of meeting for the Council than the costly Council Chamber of the Corporation of London. It will be lighted by day, ample provision has been made for warming and ventilation,

and it will surprise us if its acoustic properties do not prove to be much more satisfactory than those of the Guildhall Chamber. But at best it is only regarded as a temporary expedient. The time will no doubt come when the Council will find it to be advisable and necessary to build new and adequate premises for itself and its large staff. Already the central premises at Spring-gardens cannot accommodate all the departments of the Council's work, and separate houses in Spring-gardens and Craven-street have been taken on short leases to receive the overflow. But with its enlarged Chamber the Council will be able to "rub along" at Spring-gardens for a few years to come, and in the interval it will be able to form a mature estimate of the permanent accommodation which it will require, and will sooner or later have to obtain.

The contractors for the general works are Messrs. Allen & Sons, of Palmerston-road, Kiburn. The furniture is by Messrs. Hampton, of Pall Mall East. The ventilating, heating, and gas-lighting of the Chamber are by Messrs. Verity, of Regent-street. The electric-lighting fittings, as before mentioned, are by Messrs. Strode, of Osnaburgh-street; and the structural ironwork is by Mr. A. D. Dawday.

A sum of about 10,000*l.* in all has been allocated by the Council for the different branches of expenditure in connexion with the enlargement of the Chamber, and that amount will cover the cost.

REGISTRATION OF ARCHITECTS.

SIR,—The measure for the registration of architects is stated by its promoters to be intended at once for the protection of the public and the good of the profession. It would be unfair to say that these laudable objects are merely the stalking-horse, behind which lurks an unconcerned spirit of exclusiveness, and I am far from doing so; but, in admitting the sincerity of those who are moving in the matter, it is impossible to view without regret the inherent selfishness of their demand, or to refrain from asking, in the simple spirit of inquiry, in what way the public need, or will find, protection?

Can it be seriously suggested that the man who wants a house built goes, as he would go to the nearest chemist, to the first door on which he sees an architect's brass plate, and puts himself confidently and unreservedly into the hands of the *genius loci*? Does he not go to a connection, a neighbour, to some one whose work he has seen and liked, or failing all these, to a man of established reputation. It would be a poor compliment to the world of "clients" to hold the former supposition.

But for the people at large, for the poor and the ignorant, what can ensure them immunity from insanitary surroundings short of an Act of Parliament making illegal the erection of any building not supervised by a registered architect, even if that would? Will the leopard change his spots, the jerry-builder his skin, because he sees the architects being drilled and put through their paces? He is hardly likely to beg to be reformed in consequence of it. People go to their relations, it is said, when they want work done. Why not? and will they do so less because the relation happens to be unregistered? It may be doubted.

Materially speaking, registration might benefit the profession; commissions would be more readily recoverable in a court of law, and appointments go to a rather larger percentage of those in practice; but, in any other than a material sense, would the result be satisfactory?

A qualifying examination is undeniably a test of education up to a certain point, and it is not open to some of the objections which are taken to competition, pure and simple, but too much reliance may easily be placed in what it is taken to prove.

There is such a thing as cramming—"an exchange of knowledge for a diploma"—when the revulsion from forced labour opens the tap and lets most of the information trickle out again. There is again a faculty for passing examinations—mimetic rather than reasoning—the possessor of which is not necessarily competent to carry out what he can write about, nor, in any case, is the candidate's practical power of judging between good and bad work, and varieties of material, properly tested.

Still, *ceteris paribus*, the man whose know-

ledge has been tested by examination is in a better position than he who has not submitted himself to the test, and may reasonably reap some benefit from it. The point where examination fails is, of course, that at which architecture ceases to be a profession and becomes an art. To be unpractical is not to be artistic, but there are some men who, without the gift of acquiring accurate knowledge, may possess genius for beauty of form and disposition. Such men are usually quite alive to their want of thoroughness where it exists, and might be trusted to supply it from other sources, but the purely practical man asks to have them tabooed, and does so without any apparent consciousness that, practical as he is, he is asserting the half to be more than the whole, and himself to be that half. The closely-trimmed hedge is very well in its place, but there are some who prefer the natural growth of graceful tendrils and flowering shoot, and view with proportionate dislike the mechanical lopping of the hedge-cutter.

If Parliament sanctioned registration at this moment, which it is hardly likely to do, we should be in the position of men who, acting under a momentary impulse, have riveted their own chains, turned the key in the padlock, and thrown it into the sea. There it would rust into nothingness, and no hand would ever be stretched out to loose our self-imposed fetters.

A. E. STREET.

SIR,—Considerable anxiety prevails amongst the loyal members of the Institute as to the future of the profession, though I fancy there is no need for alarm. The idea that "Registration" will advance architecture cannot for a moment be seriously entertained. As Professor Aitchison pertinently reminds us, most of the best work in the past has been done by men educated for something else.—How devoutly we may wish that many educated for the profession would betake themselves to some other!—An architect is born, and cannot be made by Act of Parliament. The many subtle refinements which go to make good architecture, relate to plan, design, and constructive skill; to each there is added something which lifts it beyond mere convenience in arrangement, beauty in design, or strength in construction. No amount of examination will insure this product.

In many a man these powers may be latent or lie dormant until opportunity calls them forth, and the direction of the examination should be to arouse enthusiasm. But a large proportion of young men who enter themselves can never rise to any proper standard, and here compulsory examination may step in to hinder the waste of time and life in the pursuit of an art which is beyond their reach. The man of genius may be rare, but men of talent are numerous, and there is room for those capable at least of doing work which may fairly be entitled architecture; but from the genius downwards all require education, and though you cannot make an artist, by examination you can stimulate and test his study with advantage to himself as well as the public.

Admitting the principle of examination, the quantity and quality of it is a problem worth considering. Professor Aitchison draws attention to one evil of the method adopted in Austria; and both in Germany and Denmark, where the tests are severe and the course arduous, the results are alike disastrous. While much of the modern work is strictly academic and proper, all "life" seems to have been smothered, and, as a consequence, any development or advance has been prevented.

The object of the examinations should be to help artists, and not to turn out good builders or clerks of works, but to give too great a predominance to mere scientific branches would be sure to have this effect.

It is a mistake to look upon examination and registration as a means of protecting the public, and the advocacy of registration on that score is delusive. The only way to protect the public by legislation is to make jerry-building criminal. If bad drainage or shoddy materials, or faulty construction which endangered life, were punishable, the public would be sure to employ only those duly qualified; and the architect would take care that he knew his business, and be thankful to the Institute examinations, which direct his studies and secure him a recognised position.

JOHN BELCHER.

20, Hanover-square, W., April 14, 1890.

THE OLD QUESTION: "WHAT IS AN ARCHITECT?"

STR.—Before the question of registration goes any farther it is as well to understand what an architect is and what he is not.

In the opinion of some of the speakers at the Institute meeting an architect is a "member of a learned profession," "the servant of the public," "nothing if he is not practical," and architecture is a business about which "there is a certain amount of fine art more or less." We all know that a certain section of the public hold this view of architects and architecture; but surely even the most humble "servant of the public" has at any rate a vague idea that architecture is an art and not a matter of "light and air," drains, diameters of cast-iron columns, and the like, and that an architect is an artist and not a sort of compound animal, partly huilder, partly lawyer, and the rest policeman, to see that the huilder does not cheat.

Of course, if architecture is a learned profession, and architects learned professors, let them be examined, found correct, and registered without loss of time.

It is an old remark that building is not necessarily architecture, but apparently this truth is not generally accepted, and many seem to think that building, at any rate when it is ornamented, is architecture.

An architect must possess a very considerable amount of technical knowledge, but this is a means to an end, not the end itself. By all means let the Institute examine, and give certificates of proficiency in technical knowledge; but let us, once for all, face the fact that it is the one quality which makes an architect which cannot be tested by examination.

Let people once realise what an architect is (and in order to do this architects must make haste to realise what they are meant to be themselves), and there will be no necessity for registration; only those who are fit to do the work will get the work to do; the "business architect" must call himself by another name, and the "undertaker architect" can bury himself.

Finally, let our endeavour be to get altogether out of our minds the "learned profession" idea, and remember that the only reason for our existence is that we may, in the words of the Architectural Association motto, "Design with beauty, and build in truth."

ERNEST NEWTON,
MERYVN MACARTNEY,
JOHN BELCHER.

DAMAGE TO GAS-PIPES BY STEAM ROLLERS.

SIR,—I shall be obliged to any of your readers if they inform me of a case which will strengthen me in resisting a claim by a Gas Corporation against a Borough Corporation for damage done to their gas main by a steam-roller engaged in rolling a coating of metal upon a macadamised street. I understand that a case occurred in London about two years ago, when it was held that the Gas Company was bound to prove that their main was laid sufficiently deep to resist legitimate pressure from the surface. Definite information will oblige.

A BOROUGH ENGINEER.

CONDENSATION WATER IN STRONG ROOMS.

SIR,—I shall feel obliged if you, or any of your readers, can inform me through the columns of the *Builder* what is the best method for keeping a strong-room free from condensation water.

In the autumn of 1888 I built a strong room for a firm of solicitors, attached to the main building, but three sides being exposed. Walls 17 in. thick with an air-space between kept ventilated by air bricks; roof arched over in three spans with white bricks, the centre span being glazed bricks; the covering to roof 1 in. asphalt.

The walls are thoroughly dry, but water caused by condensation collects on the underside of the roof in such quantities as to render the strong-room practically useless for storing deeds and valuable papers.

A gas-jet is kept burning all day and night, and the iron door is left open during the day.

E. A. EMORR.

[Was the damp noticed before the use of the gas-light?—Ed.]

CHARLES SMITH & SONS (LIMITED), v. KIRK AND RANDALL.

SIR,—In your issue of March 15, you published a letter from Messrs. Kirk & Randall's solicitors, in which they stated their intention to appeal

against the decision in our favour given by the Breconshire County Court Judge.

We have received a letter from our solicitors, Messrs. Ingle, Cooper, & Holmes, stating that Messrs. Kirk & Randall have withdrawn the appeal, and paid costs.

This case being a matter of interest to the architectural profession and the trade generally, we thought you would like to know the final result.

At the same time, we have to thank you for the interest you have taken in the matter, and your able explanation of the facts given on March 15.

CHAS. G. SMITH, Managing Director.

OBITUARY.

Mr. J. A. P. M'Bride, Sculptor.—We hear with regret of the death of Mr. John Alexander Paterson M'Bride. According to the *Liverpool Mercury* he was born in February, 1819, and was the son of the late Archibald M'Bride, of Campbeltown, Argyllshire. His mother was a M'Kenzie, and his grandmother a M'Kinnon; so that, as he was fond of saying, every drop of blood in his veins was Celtic. At an early age Mr. M'Bride entered the studio of the late William Spence, of Liverpool, the friend and fellow pupil of John Gibson, R.A. At the Liverpool Art School, then held in Duke-street, he studied drawing along with Richard Ansdell, R.A., Samuel Haggins, and others of note, carrying all before him in the way of medals and prizes. After completing his time with Mr. Spence, Mr. M'Bride removed to London, where he became a student at the British Museum. It was at this time that he modelled his life-size group of "Margaret of Anjou and her Son" which was exhibited at the first sculptural contest in Westminster Hall, and highly commended by the judges, one of whom, the late Samuel Joseph, R.S.A., the sculptor of the Wilherforce statue in Westminster Abbey, and of the Wilkie in the National Gallery, was so struck by the work that he took Mr. M'Bride into his studio as premier pupil and manager, foregoing, on account of the excellence of the group, his customary fee of 500 guineas. After leaving Mr. Joseph, Mr. M'Bride returned to Liverpool, where he took an active part in the art movement then going forward, headed by the members of the Liverpool Academy. He became their honorary secretary in 1852. Among his chief works are the marble bust of the late Field-Marshal Lord Combermere, ordered by the Freemasons of Cheshire; his competitive model for the Wellington Memorial in St. Paul's Cathedral; a colossal statue of the famous Biblical commentator, Dr. Adam Clarke, ordered by the Wesleyan body; full-size statues of the Four Seasons, in front of Garswood Hall, the seat of Lord Gerard; group of "A Mother and Child"; half-size statues of Sir William Wallace and of the Duke of Wellington; bas-relief in Rock Ferry Church from the words, "Come ye blessed of My Father"; bas-relief in Birkenhead Church from the words, "Visit the sick and the afflicted"; a heroic-size bust of the late Mr. John Laird, M.P., in the Borough Hospital, Birkenhead; and many others. Mr. M'Bride's last work is the statuette of Mr. H. M. Stanley, which is now being published by Messrs. Minton. The first copy of this work reached Mr. M'Bride only a few days before his death, and was shown to him on his death-bed. Mr. M'Bride was a lecturer of much ability, and of late years, his health not permitting him to undergo much of the fatigue of his profession, he devoted a good deal of his time to lecturing on sculpture, and delivered courses to large audiences at the British Museum and Crystal Palace and for the Corporations of Liverpool, Bradford, and Greenock. He removed to London some seven years ago, and his health failing, early last year he left London for Southend-on-Sea, where, after a painful illness, he succumbed to a malady from which he had suffered for many years.

Mr. T. C. Noble, F.S.A.—Mr. T. C. Noble, F.S.A., a well-known antiquary, died recently. He was an old contributor to the columns of the *Builder*, and was of late very closely identified with the Ironmongers' Company, of which Guild he was compiling a history at the time of his death. He will be remembered also, for his efforts to secure reasonable facilities of light for those engaged in searches at the Public Record Office, where a few years ago searches were much hampered by regulations of the "red-tape" species.

* See report in *Builder* for March 1, p. 158.—J. A. Claim on a Bill of Extras.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—XVI.

SERIES-WOUND DYNAMO-MACHINE.

IT was not until some twenty years after the construction of the first dynamo-machine that the idea was conceived, obvious enough as it appears now, of making the current produced in the armature excite the field magnets. The whole, or a part only, of the current may be used for this purpose.

Fig. 40.

Fig. 40 shows the connections between the armature and field-magnet coils in a "Series-wound Dynamo-Machine." That is a machine in which the armature coils are placed in series with those on the field-magnet cores, so that the whole of the current given by the armature flows through them.

The characteristic of a series machine is very different in shape from that of a separately excited dynamo, fig. 39, as the strength of the field produced by the magnets rises continuously with increase of current from the armature, and consequently the line N₀, fig. 38, varies with the currents e_1, e_2, e_3, \dots , though not directly with them, but according to the law of the electro-magnet, article X, otherwise the characteristic would simply be a straight line passing through the origin of the curve. Different as are the two curves, yet with supplementary curves, fig. 41, to determine the length of the diameter N₀, fig. 38, in each case, precisely the same construction as that explained in the last article will enable us to determine the general form of the characteristic for the series machine. In fig. 24 a curve was given showing the connexion between the M.M.F. and flux produced through an electro-magnet. Fig. 41

Fig. 41.

represents a very similar curve for the field magnets of the series machine, fig. 40. The lengths O K₁, O K₂, &c., set off on O X, are proportional to the ampere-turns or to the currents e_1, e_2, e_3, \dots , which flow from the machine running at a constant speed, when R is varied, while O F₁, O F₂, . . . O F₆, measured along O Y are the corresponding strengths of field produced in the direction N S, fig. 40, thus determining a series of points Q₁, Q₂, . . . Q₆, through which a curve can be traced, giving the relationship between the current through the coils of the field-magnets and the strength of field in the direction N S, fig. 40.

In fig. 42 these strengths of field are set off as N₁S, N₂S, . . . N₆S, and semicircles are drawn with these latter lines as diameters. From S mark off a series of chords S S₁, S S₂, . . . S S₆ proportional to the fields produced by the armature currents, in the direction of the diameter of commutation, that is, lines propor-

ional to the currents c_1, c_2, \dots, c_6 ; then $N_1 S_1, N_2 S_2, \dots, N_6 S_6$ will give the resultant field in each case. Figures 38 and 42 are really the same constructions, except that in fig. 38 the strength of field produced by the magnets was constant, so that $N_8 S_8$ was the same for all

this is the case, and the winding in both machines occupies the same volume, the same amount of power is absorbed by both fields. In the series machine the whole of the current and a small

islands, and the too little known island of Corsica. Detailed descriptions of places of interest and of monuments of antiquity are out of place in any handbook, especially in a work which is mostly an epitome of matter extracted from other handbooks or works of recognised value. For instance, a traveller making an excursion to Delphi would not expect to find a minute account of the remains of the first temple of which this was the fifth erected there in honour of Apollo; that the names of the architect and the contractors are still on record; that the building was constructed with local limestone; and that, according to Herodotus, the white marble columns of the portico were the gift of the contractors. Nor, in the excursion to Eleusis, would the average traveller care to know that the plan of the vast temple of Ceres was more like that of the hypostyle halls of Egypt, and that the form of the edifice itself remains as much a mystery as the Eleusinian mysteries, for the celebration of which it was designed. Nor would he look for more than passing allusion to the remains at Olympia, of which the best description may be found in Adolf Bötticher's little octavo volume. A few footnotes referring to this and some other recent works would have added to the value of many of the pages in this handbook. The chapter on Dalmatia has been mostly re-written, but it would have been as well if more notice had been taken of Mr. T. G. Jackson's scholarly work on the architecture of that country. The sculptured west doorway of the Duomo at Trù, which will hold its own for beauty and richness of detail with any portal of Romanesque design, deserved more than passing mention. Respecting the great campanile at Spalato, the most important specimen of Dalmatian architecture of the fourteenth century, the handbook informs us that it was commenced in 1416 by Marie, Queen of Naples; and only finished during the last century. This latter statement is true in respect of the octagonal lantern, but there is little doubt that the tower itself was begun at the commencement of the fourteenth century, and completed in 1416. In the foot-notes referring to standard works on this part of the Mediterranean, no notice has been taken of Le Cassas' magnificent volume, entitled, "Voyage Pittoresque de l'Istrie et Dalmatie," fol. 1802. Whether this was intended to supplement Adams' great work, published some twenty years previously, is doubtful. Many of the illustrations, some fifty in number, are very beautiful, and those relating to the architecture of Diocletian's palace are worthy of reproduction, as examples of the transitional phase of Roman art. The original water-colour drawings, of high artistic value, may still be seen on the walls of a library in Bedford-square. The chapter on Sicily is an outline of the matter contained in Murray's handbook for South Italy. Why the remarkable monumental remains of the Greek city of Acragas should be styled as appertaining to the insignificant Roman town of Agrigentu requires explanation. This is an error that has crept into most handbooks. The city of Acragas, although the latest of the Greek cities of Sicily, was for more than three centuries one of the strongholds of the Mediterranean. The six centuries of occupation by the Romans have left so few traces of their presence that it is fair to presume this old Greek colony was neglected till the invasion by the Normans in the eleventh century.

Fig. 44.

part of the electro-motive force is used. In the shunt machine the whole of the external electro-motive force and a small part of the current is used. But the product EC is the same in both cases; the number of turns of wire employed varies directly as the electro-motive force used, and inversely as the current flowing through them.

currents in fig. 38, while the corresponding line arises when the current changes in fig. 42. The construction of the characteristic can now be proceeded with in precisely the same manner as before.

Along OX (fig. 43) the currents OC_1, OC_2, \dots, OC_6 are set off, and along OY , lengths OE_1, OE_2, \dots, OE_6 proportional respectively to $N_1 S_1, N_2 S_2, N_3 S_3, \dots, N_6 S_6$, fig. 42, since electro-motive force, at constant speed, is proportional to strength of resultant field.

Fig. 43.

The points P_1, P_2, \dots, P_6 being determined, the characteristic can now be drawn. The E letters in figs. 39 and 43 have corresponding meanings, and the two should be carefully compared, OA in the present case being the distance line for the field-magnets, in addition to that of the armature.

A very curious property of the series machine can be seen from fig. 43. Suppose that R is increased until the resistance-line turns into the position OK , that is to say, a position in which is the tangent to the curve at O . Then, though the resistance in circuit is only OK , the machine gives no current. This distance is called the "critical resistance," and varies with the speed of the armature. It has also been seen that if speed is sufficiently reduced, the curve sinks below OA , so that OA is the tangent to the new curve at O . In such a case the machine gives no current, even when short-circuited; there is, therefore, a speed below which a series machine is unable to give any current at all. For every speed, then, there is a "critical resistance," and for every resistance there is a "critical speed."

It must be noted that in the constructions given above no account has been taken of the fact that the core of the armature, being of iron, the value of μ for it also varies, tending to become 1, the effect of which is to flatten the characteristic. A glance at fig. 42 will, however, show that unless there is very little iron in the armature, it will never really reach saturation-point, and that it would be needless for our purpose to complicate the constructions to correct an error, on this score, which is practically non-existent.

SHUNT-WOUND DYNAMO-MACHINE.

When the field-magnets are excited by a part of the armature-currents, the field-magnets are placed as a "shunt" across the brushes, and share the current with the external circuit R . When this method of excitation is employed the name "Shunt-wound Dynamo-machine" is given. If the two machines, figs. 40 and 41, are to deliver the same amount of power into the external circuit, the field-magnets must be equally excited in both—in other words, the same number of amperes-turns to envelope the limbs of both magnets. If

Books.

Handbook to the Mediterranean; its Cities, Coasts, and Islands. For the Use of General Travellers and Yachtsmen. By Lieut.-Col. Sir R. LAMBERT PLAYFAIR, K.C.M.G. Third edition, revised. London: John Murray, Albemarle-street. 1890.

Handbook for Travellers in Algeria and Tunis. By Sir R. LAMBERT PLAYFAIR, K.C.M.G. Fourth edition, thoroughly revised. London: John Murray, Albemarle-street. 1890.

No branch of general literature has been marked by greater progress during the last twenty years than that relating to handbooks or guides for travellers. The old road-book that did duty for so many decades, indicating the position and distance of turnpike and tavern, church and forge, was superseded, in the earlier days of railway locomotion, by a class of works in which hotel tariffs and cab fares were freely intermixed with scraps of descriptive poetry, and padded with information that was rarely accepted as trustworthy. Higher education and constantly-increasing facilities for visiting every part of the habitable world have created a demand for a class of literature that had no existence in a previous generation. More than this. The eagerness to acquire knowledge with a minimum of trouble, and the impatience that rebels against staid investigation, have called into existence a class of books in which a mass of useful and trustworthy matter is placed before us in a handy and concise form. It was a new departure to issue ten years ago a handbook to the Mediterranean for the use of general travellers and yachtsmen. The wisdom of the step and the success of the undertaking are marked by the issue of a third edition, thoroughly revised up to date. To condense within the limits of two handy little volumes a reasonable and reliable amount of information regarding all the countries in the vast basin of the Mediterranean, including such inland excursions as the average traveller would naturally make from its ports, is a creditable undertaking, and fairly merits the success it has already achieved. It might be expected that so keen an observer of the monuments of antiquity, and so diligent a student of antiquarian literature as the accomplished author of this handbook, could not fail to satisfy the expectations of the architect and the archaeologist. A glance at the pages of these volumes is sufficient to show that their expectations are realised, and that every endeavour has been made on the part of the editor and his fellow-workers to secure accuracy without losing sight of the great desideratum of a handbook—practical utility.

Respective of the revision to which previous editions of this work have been subject, parts having been re-written, the attention of travellers is specially directed to the chapters relating to localities insufficiently described before, such as the coast of Africa, Greece, Dalmatia, Cyprus, Malta, Sicily, Sardinia, the Balearic

The success of the last edition of the "Handbook to Algeria and Tunis" has induced the publishers to issue another revise under the same experienced editorship. The knowledge and enthusiasm which prompted Ford many years ago to write for the benefit of travellers in Spain the best handbook of his time, or indeed of any time, are equally conspicuous in the volume before us, and it would be difficult to name any other work of the kind where more care has been taken to ensure accuracy of description throughout all its pages. Railway communication has now placed the chief points of interest within easy access of London, and excellent roads to the military stations in the interior, as far as the Desert line, offer as many facilities to the pleasure-seeker and the student as are to be found in most parts of Europe. There is no country that possesses such abundant traces of every stage of civilization as the region described in this handbook. In the Museum at Carthage the traveller will find a varied collection of early Punic sculptured remains:—The disc of Baal, "the abomination of the Sidonians," the upright hand, the crescent of Astarte, palm trees, rams, and other

symbols of long-forgotten creeds. On the coast below Mahadia he may explore the tombs of still earlier settlers, far back into pre-historic times. Inland, almost wherever he turns, he may study the monuments of the long and prosperous period of Roman dominion, and the short rule of the Byzantine Emperors. From the borders of Tripoli to the holy city of Kairouan, and westward up to the pillars of Hercules, he may trace the march of the victorious Arabs. In Tunis and Susa, and Sfax and other towns, he may note that the arts and crafts of this once conquering race, notwithstanding long centuries of decay and misuse, are not yet wholly extinct. And at Tlemcen, hitherto neglected by the architect and the archaeologist, he will find admirable specimens of Moorish art not surpassed, except in grandeur of scale, by any of the better known work at Granada or Seville.

Electrical Influence Machines. A full account of their Historical Development and Modern Forms, with Instructions for making them. By JOHN GRAY, B.Sc. London: Whittaker & Co., 1890.

In his preface the author states that "In the present work an attempt has been made to bring together in one volume all that is useful and interesting about Influence Machines. In the first part is given a sketch of the elements of static electricity sufficient, it is hoped, to make the reader independent of a text-book on the subject, and at the same time, in such a form as will enable those with little mathematical knowledge to understand the nature of electrical quantities. . . . In the second part, the history of the Influence Machine, from its earliest known form up to its modern forms, has been given. . . . The construction and working of all the important machines, have also been described in this part of the book." Those who are familiar with electrical theory and measurement may omit reading Part I. without missing anything necessary for the proper understanding of the subsequent portions of the book, though the author is happy in his treatment of this well-worn branch of the subject, and, in places, original. After giving "The Experimental Data of Static Electricity," Mr. Gray devotes a chapter to "A Working Hypothesis of the Electric Field." A dielectric is represented by a collection of cells, with elastic walls, filled with incompressible fluid, and the walls of these cells are bulged out in the direction of a line of force. "The potential at any point in an electric field or strained dielectric is the pressure in the cell in which the point lies." How far such a hypothesis will assist the average reader is an open question, but the definition or explanation of E. M. F., which the author deduces from it, is altogether unwarrantable and calculated to lead a beginner into hopeless confusion. E. M. F. is defined as "the rate at which the potential decreases," that is, E. M. F. is defined as though it meant "electric force" and not "electromotive force." Electric force and electro-motive force being totally different things, we are at a loss to understand how Mr. Gray can have committed such a blunder. In the next paragraph it is stated that E. M. F. at "points" on a conductor would be infinite, and "this explains the discharging effects of points." Considering that the letters E. M. F. are now universally used to mean something quite different from the above, Mr. Gray ought at least to warn his readers that he is attaching a new signification to them.

The final chapter of Part I. is taken up with very full descriptions of Sir William Thomson's well-known electrometers and a brief description of one of his volt-meters. As the most important step in the progress of every science is the measurement of quantities, the reader may reasonably expect, after reading through some twenty-five pages of detailed descriptions of instruments for measuring potential and current, that the actual performances of the influence machines about to be described will be given. Such, however, is not the case; qualitative results, not quantitative, alone are recorded except in one or two cases.

Part II. begins with the description of an electrophorus, given by Wilke in 1762, and in due course details are given of the influence machines of Belli, Bertsch, Dieckrode, Rohmberger, Cavallo, Carré, Clarke, Clerk Maxwell, Goodman, Haebette and Desormes, Holtz, Kaiser, Kundt, Leyser, Musaeus, Nicholson, Pogendorff, Riess, Rigbi, Ronald, Rohmkorff, Thomson, Töpler, Varley, Voss, Wilson,

Wimbhurst, Wimbhurst-Holtz. This list will indicate the amount of information about this type of electrical machine that Mr. Gray's little book affords; and it is extremely interesting to note how, and at what rate, influence machines have been gradually developed from that of Wilke in 1762 to that of Wimbhurst in 1890.

The rate of development has, however, been by no means uniform, for, as the author points out, "subsequent to the invention of Belli's machine [1831], no real progress was made till Varley's machine appeared in 1860, with the exception of Goodman's machine [1840], which showed no advance except in the use of uncoated glass as a carrier of electricity. . . . This sudden loss of interest in the subject appears to have been due to the fact that the attention of scientific men became absorbed in the magnificent discoveries of Faraday in electro-magnetism and other kindred branches of electricity, which covered a period extending from 1831 to 1857."

It is needless to say that in some of the older forms of machines curious devices appear. In one of Töpler's machines a sort of electrical safety-valve, consisting of two points opposed to each other, the distance between which can be adjusted, is introduced "to prevent the difference of potential becoming so great as to cause internal sparking in the machine." Some instructive figures are given in connexion with the great Töpler machine. "A machine with 20 discs, each 26 cm. diameter, the axis of which made 22 revolutions per second, with an expenditure of 4 kilogrammetres of work, supplied a current of electricity of 0.0081 absolute units, when measured by passing the current through a U-formed glass tube filled with water and a tangent galvanometer."

The author has himself made some interesting experiments on the Holtz machine by substituting tin-foil for the usual paper armatures. "Tin-foil sectors subtending an angle of 20 deg. were found to answer, while it was found that the machine would work with paper sectors of about one-half that length." The Bleekrode Machine appears to be a very remarkable one, and we wish the author had allowed more space to it. It is a modified Holtz, with vulcanite instead of glass discs. "Contrary to the usual practice, the electrodes of the machine must not be in contact when the machine is started. But the most interesting points are in connexion with the neutralising rod. It has been found that a machine such as this, having vulcanite discs, will not work at all without the neutralising rod. . . . the machine will cease to act, and all electricity will apparently disappear from it. . . . when the neutralising rod is again brought into position, the machine will commence to act as before." A final extract is made for the purpose of showing how little is really known as to the behaviour of influence-machines, owing to the apathy displayed towards them by modern electricians. "It has been observed that these Holtz machines of the 'second kind' are liable to die out when the electrodes are separated beyond the striking distance, though, according to other authorities, a reversal of the current takes place." It is indeed curious that so interesting a point as to the behaviour of a well-known machine has never been definitely settled. A chapter is devoted to the tiny machines of "the celebrated physicist, Sir W. Thomson," and Part III. gives pretty complete instructions for the practical construction of that most successful of modern machines, the Wimbhurst, as well as of the Holtz and Voss machines.

The descriptions given throughout the book are excellently illustrated with eighty-eight figures and three plates. The matter it contains, collected, as far as we are aware, for the first time in a single volume, proves how much this branch of electrical science has been neglected and the immense field for original research offered by it.

SOME TRADE CATALOGUES.

Messrs. DOULTON & Co., of Lambeth, have lately issued a very complete illustrated catalogue and price list of sanitary appliances. There are figured in it several novelties in the way of pedestal "combination" and other closets, as well as baths, lavatories, water-fittings, and urinals of an improved type, such as were provided by this firm for the chalets of the Paris Exhibition, where, we learn, they planned and fitted up 300 water-closets, 100 urinals, and sixty lavatories. Their new cata-

logue will be found very useful to architects and the building trade. Messrs. Doulton, we may add, have lately erected an additional manufactory for sanitary appliances at Paisley.

Messrs. Adams & Co., of York, London, and elsewhere, have sent us their new illustrated list of patent sanitary specialties. Amongst the novelties it contains we would call special attention to a new form of lavatory basin, which is devoid of the old-fashioned plug and chain outlet. The water is admitted from the rear, towards the bottom of the basin; a continuous current strikes the front of the basin, is directed upwards, and then flows back at the top of the basin towards the back, where there is an outlet weir. By this means the water can be continually renewed while it is being used, all dirt and foul matter being carried away at once. We may also mention Messrs. Adams's special disconnecting chamber, made of stoneware; their improved automatic flushing syphon; their patent revolving disc panstick, which is ingenious and secures a tight fit, as well as a quick and easy lift; and their patent "automatic" flushing-door, useful for large cisterns, &c. These and other appliances in the list are well worth the attention of Borough Engineers and Surveyors.

Messrs. D. Hulet & Co., Limited, of Holborn, send us a copy of their illustrated catalogue of electric-lighting plant and material, which appears to be very complete, and cannot but be found useful by architects and builders. It is very well got up, and every article illustrated or described is priced, so that some approximate idea of the cost of an installation may be arrived at.

From Messrs. H. Binko & Co., of Leadenhall-street, we have received another useful catalogue of electric fittings and appliances, including bells, telephones, telegraphs, lighting, and motors.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

7,415, Window Sockets. C. J. Harcourt. The "sockets" which are the subject of this patent are chiefly designed for shop-fittings, and are so made as to be easily fastened around any pillar or projection, and removable without being passed over the top, or permanently fixed.

20,914, Fireproof Ceilings and Walls. A. Klapperstuck and A. H. Meyer.

According to this invention, mortar and gypsum, with colophony and diluted acid, are mixed and applied as a plaster, which is thrown against a suitable fireproof backing, preferably a coarse-wired wire netting. It is applied to both sides, and is smoothed off the usual way. The colophony remains in a neutral condition within the wall until subject to heat. When, however, a fire breaks out, the colophony will cause the wall to assume a glazed structure, which renders it incombustible. This structure the wall will always after maintain. The walls may be made very light and thin, waterproof, and poor transmitters of sound, and, moreover, the walls may be made in small portable sections.

1,525, Brick Kilns. I. Button and others.

In continuous kilns improvements are made according to this invention, by the combination and arrangement of a series of separate arched compartments in connexion with a smoke-chamber and in the novel arrangement of a temporary and permanent part of the kiln. The temporary parts are made of green bricks, and each compartment as it is filled is closed by a wall of green bricks, a sand filling, and an iron gate.

1,762, Railway Sleepers. R. Hirschberg.

This invention consists in a means for retaining metal sleepers in a proper position with relation to each other, and in locking devices for the same. The clamping devices are peculiarly arranged.

1,839, Windows or Casements. F. Schmidt.

This invention refers to means for preventing the said inner and outer casements from clashing together, or being thrown apart by influences such as the weather or the sudden opening or closing of doors. The frames for the two panes are fixed that they are rigid, and always maintain a parallel position to each other. The socket is made by piercing a hole in the centre of the frame carrying the two panes.

1,868, Forming Holes and Screw-threads in Clay and Earthenware. G. Schönau.

According to this invention, mandrels used are forced into the holes in which the threads are to be cut, or sectional mandrels having removable dies, are pressed around the projectors on which the threads are to be made.

"Structure" is the word used in the specification but "surface" seems to be the word intended.

1,890, Drive Chains. T. Moxon and others.

The object of this invention is to produce a chain of pivoted links which shall be extra strong and simple in construction, and which may be easily shortened by the removal of links or lengthened by the insertion of new links without the employment of pins, screws, or rivets; the links being held together by simply keeping the chain taut. The links are formed in one piece, each link having one end and a hook at the other, and being a link apart from the others. When it is desired thus to separate them, it is first loosened a little, and then the upper part is slid far enough to disengage its hook from the lower section, the eyes formed by the hooks being sufficiently elongated to permit this to be done.

2,200, Closing and Sealing Device for Discharge Openings. J. L. Bradley.

This device is for closing and sealing the discharge apertures of vessels containing liquids or gases, free or under pressure, to prevent leakage and setting fast by corrosion, such as occurs with ordinary cocks or taps, to ensure a certain and immediate discharge of the vessel when required, and to render impossible any tampering with the device without detection. It consists of a peculiarly shaped cover piece or plate, soldered or otherwise fastened over the discharge aperture.

2,326, Blind Furniture. J. Robertsshaw.

According to this invention, a pivot, ratchet-wheel, spiral spring, and a screw nut are employed in combination to effect a tension of blind board and even rotation of the blind roller.

* * Owing to the failure of the Patent Office to issue the official Journal of Patents last week, we are compelled to hold over the "New Applications," &c., until next week.

RECENT SALES OF PROPERTY:

ESTATE EXCHANGE REPORT.

Table listing real estate transactions with columns for date, location, and price. Includes entries for Messrs. Cobb, Rogers, Chapman, & Thomas, Henry & Larchford, Westacott, Moore, Newbon & Harding, Reynolds & Eason, and Slade & Butler.

MEETINGS.

- SATURDAY, APRIL 19. Royal Institution.—Captain W. de W. Abney, F.R.S., "Colour and its Chemical Aspects." 3 p.m. Edinburgh Architectural Association.—Visit to Carlton Castle. St. Paul's Ecclesiological Society.—Visit to the Battersea Churches of St. Mark, St. Peter, and St. Mary by St. Paul's Park, under the direction of Mr. William White, S.A. MONDAY, APRIL 21. Royal Institute of British Architects.—Special General Meeting for Members only. 8 p.m. TUESDAY, APRIL 22. Institution of Civil Engineers.—Discussion on Sir Richard Branson's paper on "The Application of Electricity to Welding, Stamping, and other Cognate Processes." 8 p.m. Society of Arts (Foreign and Colonial Section).—Sir Stokes, on "The Danube and its Trade." 5 p.m.

WEDNESDAY, APRIL 23. Society of Arts.—Mr. W. Whitaker, F.R.S., on "Coal in the South-east of England." 8 p.m. Sanitary Institute.—Address by Sir Robert Rawlinson, who will present the Metals and Certificates awarded to the successful Exhibitors at the Exhibition held at Worcester in 1889. 8 p.m.

Liverpool Engineering Society.—(1) Nomination of Council and Officers for ensuing Session. (2) Adjourned Discussion on Mr. T. J. Miller's paper on "The Efficiency of Gas Engines." 8 p.m. THURSDAY, APRIL 24. Guild and School of Handicraft.—Mr. Stirling Lee on "A Talk on Sculpture." 8 p.m. Institution of Electrical Engineers.—Dr. Oliver Lodge, F.R.S., on "A Lightning Guard for Telegraph Purposes and the Protection of Cables from Lightning." 8 p.m.

Institution of Civil Engineers (Students' Meeting).—Mr. C. F. Jenkin on "Some Applications of Electricity in Engineering Workshops." 7.30 p.m. SATURDAY, APRIL 26. Association of Municipal and Sanitary Engineers and Surveyors.—Home District Meeting at Acron, Ealing, and Hampton. Royal Institution.—Captain W. de W. Abney, F.R.S., on "Colour and its Chemical Action." 11. 3 p.m.

Miscellaneous.

Robert Boyle & Son (Limited).—The directors of Robert Boyle & Son, Limited, ventilating engineers, London and Glasgow, have resolved to pay an instalment on account of dividend at the rate of 12 per cent. per annum for the half-year ending March 31 last, which is stated to have been the most prosperous since the formation of the Company. The directors attribute this success to the great and ever-increasing demand for the latest improved form of their self-acting "Air-Pump" ventilator, upon which further improvements have recently been effected by Mr. Robert Boyle, adding considerably (so we are informed) to its power as an exhaust ventilator, weatherproof and free from down-draught. It is now made of a more ornamental character, of the best rolled steel plates, galvanised, and painted with enamel paint, and, though superior to those Messrs. Boyle have hitherto made, is sold at 50 per cent. less in price, and it is claimed that it is not only the most efficient but also the most substantially-made and cheapest ventilator in the market. The Company have just applied their system of ventilation to the Lord Mayor's Court, Guildhall, H.M.S. Conquest, the new "White Star" line steamers Pentonic and Mejestic, and the new steamer of the Compagnie Générale Transatlantique, La Touraine. The Company have at present some very important ventilating contracts in hand and in prospect. Mr. Robert Boyle, the managing director, is now in India, arranging contracts for Government buildings and establishing "agencies," after which he proceeds to China and Japan.

University College, London.—A series of Saturday morning lectures on "Architecture; Classic and Christian," intended for art students and others, and open to ladies, will be commenced by Professor T. Roger Smith, F.R.I.B.A., on Saturday, April 19, at 11 a.m. The following is the syllabus:—Classic Architecture (three lectures and one visit); The nature of architecture; the origins of Greek architecture; Greek archaic buildings and temples; public buildings; parallel between Greek and Roman art; Roman temples; public and domestic buildings; monuments; Basilicas; visit to the British Museum. Christian Architecture (three lectures and one visit); Byzantine and Romanesque architecture; Gothic architecture in England; the usual division into periods; cathedrals, churches, and monastic buildings in England; domestic and military buildings; Gothic architecture in France, Germany, and Italy; visit to Westminster Abbey. The lectures will be fully illustrated by diagrams and photographs. The fee for the course is one guinea, admission to the first lecture being free.

The "Marlborough" Patent Pamphlet Cases.—We have previously noticed these admirable cases for preserving loose pamphlets, periodicals, &c. We have now received a specimen of the case which has been prepared specially for containing numbers of the Builder. Messrs. Marlborough, Gould, & Co., of Old Bailey, are the manufacturers, but the cases may be had to order from all stationers and booksellers. The cases are very convenient. They facilitate order and tidiness, and help greatly in the classification of loose pamphlets and periodicals, dust and "blacks" being effectually excluded. They are made in sizes to suit all magazines and periodicals.

The English Iron Trade.—The English iron market is very quiet, with a general downward movement in prices. Business in pig-iron is of a very restricted nature. Consumers are holding back in the expectation of still lower prices, while producers are unable to sell at the reduced rates, owing to the dearth of raw material, the business done passing almost exclusively through the hands of merchants and holders of warrants. The Glasgow and Middlesbrough warrant markets have been on the downward course all the week. Scotch warrants are about 2s. a ton lower, and Cleveland warrants as much as 6s. The drop in Scotch makers' iron ranges from 6d. to 5s. per ton, and in Cleveland makers' iron it is 5s. a ton. Lancashire pig-iron has lost 2s. a ton, Lincolnshire 1s., and Derbyshire 5s. Other descriptions of pig-iron have experienced a corresponding fall, while West Coast hematites are obtainable at prices 5s. below those ruling a week ago. The demand for manufactured iron and steel continues very limited, and prices have further declined. The decline in finished iron is from 2s. 6d. to 5s. a ton, and in steel from 2s. 6d. to 15s. Shipbuilders, although pretty well engaged on work in hand, are not looking any fresh orders. Engineers are taking some new work, but they are quieter on the whole.—Iron.

Proposed Artisans' Dwellings.—On Tuesday next, at the Mart, the London County Council will offer for sale some lands lying east and west of Rosebery-avenue. The two lots, being about 41,150 feet superficial together, abut against that portion of the new street from Gray's Inn-road to St. John-street-road which is now nearly completed. They will be utilised for artisans' dwellings, to be constructed in accordance with plans to be approved by the Council. It is required that the dwellings shall accommodate 660 persons of the "labouring class" as defined by statute, and shall be built for a least total of 20,500. Their erection here is stipulated for by the Metropolitan Board of Works (Various Powers) Act of 1855, in terms whereof the late Board made a scheme in this behalf. At the part in question, Rosebery-avenue passes between Mount Pleasant and Clerkenwell-road, and is carried upon a viaduct of brick arches, crossing Warner-street by a girder-bridge. The height of the footway above the lowest point of the hollow is 27 ft. The two lots are traversed, at a depth of about 18 ft., by the Old Fleet sewer, which here forms a boundary between the parishes of St. Andrew, Holborn, and St. James' and St. John, Clerkenwell. The stream ran along the northern sides of the present Poole's-buildings, on Mount Pleasant, and the Field-lane Refuges in Vine-street.

Copping's Automatic Sash-lock.—This sash fastener, of which a working model has been submitted to us, is one of the best recent patents of this kind that has come under our notice. A small barrel bolt, fixed in a strong sheath on the rail of the inner sash, shoots with a spring into a brass socket fixed on the rail of the outer sash; the socket is combined with a striking-plate which automatically pushes back the bolt on closing the window, until it is opposite the socket. The bolt works at right-angles to the sash-rails. Combined with the bolt are a couple of clips on the inner sash sliding on a brass hed on the outer sash which slopes obliquely, so that, on meeting, the sash-rails are drawn together and held tight. The bolt is withdrawn by a dropping-rod on the inner side. As we have observed in former instances, a spring is always a certain element of weakness; but in every other respect this is an excellent and workmanlike fastener, good in principle and very strongly made, and we commend it to the attention of architects.

The Zolus Waterspray System of Ventilation.—It will be seen from our advertising columns that Messrs. Baird, Thompson & Co., ventilating and sanitary engineers, of Queen Victoria-street and Glasgow, have purchased the patent rights and plant of the Zolus Waterspray General Ventilating and Electrical Engineering Company, together with the goodwill of the business carried on by that company. The Zolus Waterspray System of Ventilation has been largely applied on the Continent of Europe, where many important Government and other buildings have been ventilated by it. In Canada and Queensland it has been applied to the Government Offices; while in this country many important buildings have been heated and ventilated by the company.

Registration of Plumbers at Plymouth.

The Mayor of Plymouth presided, on the 10th inst., over a public meeting held in the Municipal Buildings, Plymouth, in furtherance of the national system for training and registration of plumbers. There was a large and influential attendance. The Mayor opened the proceedings by introducing the Master of the Worshipful Company of Plumbers, Mr. W. H. Bishop, who said that Plymouth was very rapidly growing, and in the race between seaside places for public favour as health resorts there was no reason why it should not take the front rank. The subject of sanitation was an eminently practical one, and was pressing itself on the public attention more and more every day.

He said that the Company's object was not confined to the registration of competent men; they were doing their utmost to provide the younger members of the craft with facilities for rendering themselves competent, and he referred to the rapid spread of technical classes in various parts of the kingdom. The men who attended those classes showed by their study and application to the work during three hours of voluntary schooling a determination to improve themselves and their trade which could not fail to ultimately succeed. Referring to the way in which the movement was being carried out, he said they were met there in public to elect a Council composed equally of each section of the plumbing trade, and representatives of the public. With a body so constituted, surely it would be hard to find fault. They would draw up their by-laws, fix the time and place of their meetings, and prepare for examinations; for the feeling throughout the country was growing stronger every day that applicants for registration should be admitted on examination only. The Earl of Morley moved that a Council be formed at Plymouth to carry out the registration system in South Devon and Cornwall. Several other speakers having warmly supported the resolution, it was carried unanimously, and a District Council elected, including, besides the representatives of the master and operative plumbers, the following public representatives:—The Mayor of Plymouth, the Mayor of Devonport, Dr. Greenway (Medical Officer, Plymouth), Dr. Lear (Medical Officer, Stonehouse), Dr. W. May (Medical Officer, Devonport), Dr. Kerswill (Medical Officer, St. German's Union), Dr. France, Dr. of Hingston, Dr. J. H. S. May, Messrs. C. King, F. Hine, W. Snell, and Luff (architects), J. Bellamy (Borough Surveyor, Plymouth), W. Burns (Borough Surveyor, Devonport), and A. E. Lyons (Chairman, Stonehouse Local Board). The Mayor of Plymouth presented Certificates of Registration granted by the Plumbers' Company to a number of local plumbers who had passed the examinations, and the proceedings ended with the usual votes of thanks.

Association of Municipal and Sanitary Engineers and Surveyors.—A Home District meeting of this Association will be held on Saturday, April 26, 1890, at Acton, Ealing, and Hampton. The members will proceed to the sewage works of the Acton Local Board, on the morning of the 26th inst., by railway to either Turnham Green Station (Metropolitan Railway), or Acton Station (North London Railway), from each of which stations the works are about three-quarters of a mile distant. The programme of the meeting will be as follows, viz.:—11 a.m. Assemble at sewage works of Acton Local Board, where a short paper descriptive of the process of the International Rivers Purification Co. will be read by Mr. Ehhets, Surveyor of Acton, and the works afterwards inspected. 12 p.m.: Proceed by breaks to Ealing. 12.20 p.m.: Arrive at Ealing, where a paper descriptive of the new Public Offices and other recent works at Ealing will be read by Mr. Jones, and an inspection made of the Baths, Offices, Free Library, Fire Brigade Station, stabling, &c. 1.30 p.m.: Light refreshments will be provided by Messrs. Jones and Robson at the Public Offices, Ealing. 2.30 p.m.: Proceed by breaks to Haupp'n, where by the kind permission of Mr. Frase, the large Extension Works of the Grand Junction Waterworks Co. will be viewed, including special pumping machinery now in course of erection.

Surveyorship, Luton.—We understand that the Town Council of Luton have appointed Mr. E. J. Lovegrove, A.M.I.C.E. (Assistant Borough Engineer and Surveyor of Croydon), as Borough Engineer and Surveyor. Mr. Lovegrove is the son of Mr. Jas. Lovegrove, C.E., Surveyor to the Hackney District Board of Works.

Edinburgh Architectural Association.

The usual fortnightly meeting of this Association was held on the 9th inst. in the Architectural Hall, 42, George-street, Professor G. Baldwin Brown, President, in the chair. After the usual preliminary business, a paper on "The Accessories of Architecture" was read by Mr. John Keppie, President of the Glasgow Architectural Association. The subject of the paper, which is one of the most important with which the architect has to deal, and which in a great number of instances does not receive the attention it deserves, was the first accessory to which attention was drawn. Comparison was made between the setting-out of cities in Britain and on the Continent, considerably to the advantage of the latter. Paris particularly was alluded to as a city in which most of the fine buildings were beautifully situated, and the lecturer said that consequently they received a much greater degree of public appreciative attention. Sculpture and metal-work were next alluded to as valuable aids to the architect, not only on account of fine form, but of the texture and coloration of which they were capable, and which was as valuable in architecture as in painting. Some remarks were made on the correct method of designing in different materials, such as cast-iron, plaster, &c. The lecturer said, in conclusion, that, owing to the increase of interest in the various accessories, these arts were now in a more flourishing condition than they were fifty years ago, and consequently architecture ought now to be, if it was not, more interesting and thorough than it was then. At the close, a hearty vote of thanks was accorded to the lecturer.

Lifts.—Messrs. Archibald Smith & Stevens have received instructions to erect one of their "Rialance" hydraulic lifts at the Badminton Club-chambers. They are also erecting similar lifts at Ashley-mansions, Victoria-street, Westminster; and in several other buildings.

Building Land at Northwood.—We may call the attention of our readers to the sale of freehold building land to be held at Northwood, on the borders of Middlesex and Herts, on the 30th inst., by Messrs. Humbert, Son, & Flint, as advertised.

PRICES CURRENT OF MATERIALS.

Table with columns for material names (e.g., Greenheart, B.G., Teak, E.I., Sequoia, U.S., Ash, Canada, Birch, Elm, Fir, Dantico, &c., Oak, Canada, Pine, Canada red, yellow, Lath, Bantale, St. Petersburg, Watuscot, Riga, &c., Deals, Finland, 2nd and 1st, std., 100, 4th and 3rd, Riga, St. Petersburg, 1st, yellow, 2nd, white, Swedish, White Sea, Canada, Pine, 1st, 2nd, 3rd, &c., Spruce, 1st, 2nd and 3rd, New Brunswick, &c., Batters, all kinds, Flooring Boards, sq., 1 in, prepared, First, Second, Other qualities, Cedar, Cuba, Honduras, &c., Mahogany, Cuba, St. Domingo, cargo average, Mexican, cargo average, Ohio, Honduras, Box, Turkey, Rose, Rio, Bahia, &c., Satin, St. Domingo, Porto Rico, Walnut, Italian) and columns for prices in £, s., d., and c.

METALS.

Table listing metal prices for Iron-Bar, Welsh, in London (at works in Wales, at works in London), Best selected, COPPER—British, cake and ingot, 53, 0, 0, Best, Sheets, strong, CHINA BARS, Yellow Metal, LEAD—Pig, Spanish, English, com. brands, sheet, English, Pipe.

METALS (continued). Table with columns for material names (Tin—Strait, Australian, English Ingots) and columns for prices in £, s., d., and c.

OILS.

Table listing oil prices for Lincseed, Coconut, Ceylon, Palm, Lagos, Rapeseed, brown, Cottonseed, refined, Tallow and Oleine, Lubricating, U.S., refined, TAR—Stockholm, Archangel.

TENDERS.

[Communications for insertion under this heading must reach us not later than 12 noon on Thursdays.]

ABINGDON.—For the erection and completion of Salvation Army Fortress, Abingdon, for General Booth. Mr. J. Williams Danford, architect and surveyor, 101, Queen Victoria-street, E.C. 4:— E. Williams, Abingdon, 2546 0 0; Ellwood & Sons, Sandy, 497 0 0; S. Drew, Abingdon, 490 0 0; T. Barrett, Abingdon, 455 0 0; J. Buckle, Abingdon, 445 0 0; G. H. Wheeler, Abingdon, 437 0 0; Martin & Barclay, Battersea, 430 0 0.

ANSTEY (near Dorchester).—For the erection of a pair of semi-detached villas, for Messrs. Hall & Woodhouse. Mr. A. L. T. Tilley, architect, Dorchester:— W. House, Hurlfoot Lane (accepted), £786 0 0.

BROADSTAIRS (Kent).—For erecting a Convalescent Home, for the Board of Managers of the North Surrey District Schools, Anerley. Mr. A. G. Hennell, architect, Forest Hill. Quantities supplied by Mr. J. B. Vinney, 89, Chancery-lane, W.C. 1:— H. L. Holloway, 24,290 0 0; A. G. Lockwood & Co., 3,750 0 0; W. Johnson, 3,800 0 0; J. T. May, 3,800 0 0; Foster & Dicksee, 3,681 0 0; W. & T. Denne, 3,680 0 0; Holloway Bros., 3,600 0 0; Charles Home, 3,695 0 0; R. G. Battley, 3,574 0 0; W. Akers & Co., 3,670 0 0; J. Shillbee & Son, 3,400 0 0; F. J. Coxhead, 3,439 0 0; W. H. Port, 3,490 0 0; W. J. Adcock, 3,397 0 0; C. J. Adcock, 3,365 0 0; T. Pearce, 3,353 10 0; F. J. Doughty, 3,288 0 0; J. Longley & Co., 3,293 0 0; W. W. Martin, 3,149 0 0; Robeson & Rickett, 3,138 0 0; J. Pocock, 3,133 0 0; Andrew Black & Sill, 3,128 0 0; L. Shrubsole, 3,095 0 0; G. H. Denne & Son, 3,083 0 0; J. Brown & Son (accepted), 2,933 0 0.

BROADWELL (Gloucestershire).—For new wing and alterations, at Broadwell, Gloucestershire, for Mr. R. G. Francis. Mr. E. Guy Dawber, architect:— H. Kotham, Stow-on-the-Wold, 2,999 0 0; Groves, Milton-under-Wychwood, 587 0 0; Howman Bros., Stow-on-the-Wold, 510 0 0.

BUTION-ON-TRENT.—For the erection of new malt-house, avenue, hop and barley stores, and other works, at Clarence-street Brewery, Burton, for the trustees of the late Mr. P. Walker. Mr. Robey E. Carpenter, architect. Quantities by the architect:— Wood, Derby, 46,465 0 0; Hunter, Burton, 6,440 0 0; Walker & Slater, Derby, 6,345 0 0; Hojages, Burton, 6,290 0 0; Chamberlain, Burton, 6,195 0 0; Lowe & Sons, Burton, 6,100 0 0; Varlow, Burton (accepted), 5,997 0 0. [Architect's estimate, £6,250.]

COLCHESTER.—For erecting new schools, Kendall-road. Mr. Frank Whitmore, architect, Chelmsford:— E. S. Ward, 21,490 0 0; F. Dupont, 1,393 0 0; Everett & Son (accepted), 1,389 0 0. [All of Colchester.]

EASTBOURNE.—For the erection and completion of Salvation Army Chadel buildings in Eastbourne, Sussex, for General Booth. Mr. J. Williams Danford, architect and surveyor, 101, Queen Victoria-street, E.C. 4:— J. Peerless, Eastbourne, 42,625 0 0; I. Huggett, Eastbourne, 2,488 17 8; J. Coster, Eastbourne, 2,250 0 0; J. Pinn, jun., Eastbourne, 1,979 10 0; E. Cornwall & Son, Eastbourne, 1,860 0 0; Rowland Bros., Horsham, 1,749 0 0; Coxhead, Leytonstone, 1,679 0 0; J. Beckhurst, Eastbourne, 1,569 0 0; F. Mitchell, Bexhill-on-Sea, 1,557 0 0; Martin & Barclay, Battersea, 1,385 0 0.

EAST BRENT (Somersetshire).—For the first portion of the work to be done at the parish church, for the Ven. Archdeacon Denison. Mr. E. H. Lingen Barker, architect:— Jones & Willis, 2,600 0 0; Midland Joinery Co., 517 12 0; Goss, 400 0 0; Hems, 380 0 0; Kibbey, 365 0 0; Cowlin, 349 0 0; Pollard, 345 0 0; Hawkins & Co., 293 19 0; Nerrick, 263 0 0; Dart (accepted), 240 0 0.

PUBLIC APPOINTMENTS.

Table with 5 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page. Includes 'Assistant Surveyors' and 'Civil Service Commission'.

INCHLEY.—For erecting coach-house and stables, Torrington Park, North Finchley. Mr. F. D. Dixon, architect. The Oaks, Woodside Park, N. S. Wheeler & Co. (accepted) £203 0 0

INCHLEY.—For repairs, &c., to two houses in Torrington Park, North Finchley. Mr. F. D. Dixon, architect. The Oaks, Woodside Park, N. S. Wheeler & Co. (accepted) £203 0 0

INCHLEY.—For repairs, &c., to Congregational Church, North Finchley. Mr. F. D. Dixon, architect. The Oaks, Woodside Park, N. S. Wheeler & Co. (accepted) £203 0 0

BREAST GATE.—For new banking premises and 4, Forest Gate, for the London and South-Western Ry. Co., Limited. Mr. Edward Gabriel, architect, Old Broad-street. Quantities by Mr. G. R. Tasker, John-street, Bedford-row, W.C. :-

BRNSEY.—For new road, sewer, surface water, &c., for the British Land Company, and, on their estate at Harringay Park. Mr. Henry Nichell, surveyor :-

NEGSTON.—For alterations and additions to 'Millist' Mr. T. Searancke Archer, architect :-

LONDON.—For rebuilding the "Plough" Inn, Mile-end-road, E. Mr. W. D. Church, architect, 12, South-place, Finsbury, E.C. Quantities by Messrs. C. Stanger & Son, surveyors, 21, Finsbury-pavement, E.C. :-

LONDON.—For alterations at St. James's Schools, Wandsworth Common, S.W., for the Guardians of the Westminster Union, Mr. Jno. Waldram, C.E., surveyor, 10, Craven-street, Charing-cross, W.C. :-

LONDON.—For painting and other work at the Lambeth Infirmary, for the Guardians of the Poor of the parish of Lambeth. Quantities supplied :-

LONDON.—For decorating and painting, &c., at 12, Carlton House-terrace, for Sir Savile Crossley, Bart., M.P. :-

LONDON.—For the erection of one pair of semi-detached houses on the Frogmole Mansion Estate, Hampstead (exclusive of mosaic floors, tile hearths, stoves, mantelpieces, painted glass, door furniture, painting, and papering). No quantities supplied. Mr. James Neale, F.S.A., architect and surveyor, 10, Bloomsbury-square, W.C. :-

Langdale, Hallett, & Co., London £5,500
Holloway Bros. 5,420
Garlick & Horton 5,305
Foster & Dicksee, Rugby 5,252
McCormick & Sons, London 4,387

LONDON.—For the erection of Clarendon Chapel and Schools, Clarendon-street, Camberwell, New-road, S.E. Mr. George Baines, architect, 4, Great Winchester-street, E.C. Quantities by Messrs. G. E. Goodchild & Son, St. Finsbury-pavement, E.C. :-

Holiday & Greenwood £6,139
R. E. Nightingale 6,132
F. & H. F. Higgs 6,120
F. Tarrant 5,983
R. G. Battley 5,957
R. J. Coxhead 5,598
W. Johnson 5,500
S. J. Jerrard 5,433
H. L. Holloway 5,470

LONDON.—For constructing swimming-bath at the Licensed Victuallers' School, Mr. G. Trescher, architect :-

Allen & Son £3,400 0 0
Holiday & Greenwood 3,120 0 0
Beaf 3,120 0 0
Gould & Brand 3,079 0 0
Burnham & Son 3,050 0 0
Mower & Son 3,915 0 0

LONDON.—For alterations at the "Good Intent" public-house, Cambridge-heath. Mr. Batts, architect :-

J. & H. Cox £1,297 0 0
Blow 1,282 0 0
Mower & Son 1,275 0 0
Edwards 1,237 0 0

LONDON.—For alterations at the "Crooked Billet" Upper Clapton, for Mrs. Fairhead. Mr. Brown, architect, 21, Liverpool-street. No quantities :-

Godfrey & Son £793 0 0
Mower & Son 777 0 0
Walker Bros. 694 0 0
J. Anley 690 0 0
S. Goodall 677 0 0

LONDON.—For additional workshops, 120, East-road, N., for Messrs. Dotteridge Bros. Mr. A. G. Collins, architect, 32, Finsbury-pavement. No quantities :-

J. Chesnam & Sons £194 0 0
J. Godfrey & Son 194 0 0

LONDON.—For pulling down and rebuilding warehouse, No. 6, Henegage-lane, Evers Mark, E.C. Mr. H. Percy Monckton, architect, 32, Walbrook, E.C. :-

J. Greenwood £1,153 0 0
Harrison & Spooner 1,087 0 0
Turtle & Appleton 1,013 0 0
E. A. Roome (accepted) 846 0 0

LONDON.—For fittings and decorations to Oliphant's Restaurant, No. 5, St. Erle's-street, E.C., for Mr. W. Oliphant. Mr. Walter Graves, architect, Winchester House, Old Broad-street, E.C. :-

J. & S. Bowyer £436 0 0
A. Siegmund 478 0 0
B. E. Nightingale 388 0 0
P. Sage & Co. 340 0 0
Pitman & Son (accepted) 238 0 0

LONDON.—For drainage and sanitary works at "Claremont," Allyn Park, Dulwich, for Mr. O. A. King. Mr. Walter Graves, architect, Winchester House, Old Broad-street, E.C. :-

J. & S. Bowyer £195 0 0
B. E. Nightingale 188 0 0

LONDON.—For additions to laundry at Charlotte-place, Walworth, for Mr. T. B. King. Quantities by Messrs. Young & Brown, 5, Henrietta-street, Covent Garden :-

Downs £469 0 0
Colls 435 0 0
Castle 397 0 0
Marland, Wandsworth 377 0 0

MAIDENHEAD.—For house and stables at Maidenhead Court. Mr. T. Scrancke Archer, architect.—
Gibson..... £2,545 8 6
Joseph Higgs..... 3,418 0 0
For Billiard-room.
Joseph Higgs..... £450 0 0

PETERBOROUGH.—For the erection and completion of three shops in Cowgate, Peterborough, for the Salvation Army. Mr. J. Williams Dunford, architect and surveyor, 101, Queen Victoria street, E.C. 1.—
Martin & Barclay, Battersea..... £2,850 0 0
W. Jennings, Peterborough..... 2,465 11 9
F. J. Coxhead, Leytonstone..... 2,247 0 0
J. Wenlock, Peterborough..... 2,150 0 0
D. Gray, Peterborough..... 2,040 0 0
Ellwood & Sons, Sandy..... 1,975 0 0
Solden Hipwell, Wisbech..... 1,948 0 0

REDHILL.—For the erection of Salvation Army Messrs at Redhill, Surrey, for General Booth. Mr. J. Williams Dunford, architect and surveyor, 101, Queen Victoria street, E.C. 1.—
Bushy, Reigate..... £640 0 0
Coxhead, Leytonstone..... 555 0 0
Amos & Foad, Whistable..... 555 0 0
Wright, Broadwater..... 500 0 0
Martin & Barclay, Battersea..... 470 0 0

REDHILL.—For alterations and decorations at Furze Hill Lodge, Redhill, for Sir Francis Truscott.—
Messrs. Charlwood Bros., East Grinstead (accepted)..... £750 0 0

SANDIACRE (near Nottingham).—For the erection of a hotel, stabling, &c. Mr. T. W. Latham, architect, Sandiacre. Quantities by the architect.—
George Bantable..... £1195 0 0
C. Youngman..... 1180 0 0
F. Perks & Son (accepted)..... 1119 5 5

SOUTHAMPTON.—For taking down New Place House, Southampton, and erecting new house and offices on the site. Mr. W. H. Mitchell, architect, Southampton.—
Udall, Southampton..... £10,331 12 0
Dyer & Sons, Southampton..... 10,152 0 0
H. Stevens & Co., Southampton..... 9,576 0 0
Sanders, Southampton..... 9,770 0 0
W. R. & C. Light, Portsmouth..... 8,909 0 0
Bull, Sons, & Co., Limited, Southampton (accepted)..... 8,908 0 0

STOCKPORT.—For alterations and additions to premises situate in Short-street, Stockport, to form same into a Salvation Army Barracks for General Booth. Mr. J. Williams Dunford, architect and surveyor, 101, Queen Victoria street, E.C. 1.—
Coxhead, Leytonstone..... £829 0 0
Martin & Barclay, Battersea..... 826 0 0
Batsion, Heston Norris (accepted)..... 793 0 0

TEDDINGTON.—For finishing, draining, and decorating two houses in Teddington Park-road, for Messrs. J. & H. Pullman.—
Stanway, Acton..... £222 0 0
Slade, Twickenham..... 157 2 0
Eydman, Chiswick..... 142 0 0
Collinson, Teddington..... 124 0 0
* Accepted.
† Without the drainage.

WANSTEAD (Essex).—For alterations and additions to Cam Hall and Downsall-road Schools. Messrs. Bressay & Liddon-Walters, architects.—
Norths Bros..... £3,170 0 0
Flaxman..... 2,696 0 0
Mundy..... 2,800 0 0
Allen & Sons..... 2,775 0 0
Coxhead..... 2,728 0 0
Reed..... 2,696 0 0
Barrett & Power..... 2,604 0 0
Holland..... 2,652 0 0
Dahls..... 2,624 0 0
Cutley, Leytonstone (accepted)..... 2,626 0 0

WHETSTONE.—For the erection of a house at Oakleigh Park, Whetstone, N., for Mr. W. B. Passmore. Mr. Herbert Passmore, architect, 6, Cumberland terrace, Regent's Park, N.W. Quantities by Mr. W. Ralph Low.—
John Grover & Son..... £1,048 0 0
E. Laurence & Sons..... 1,923 0 0
James Smith & Son..... 1,857 0 0
R. Battley..... 1,839 0 0
Mattock Bros. (accepted)..... 1,511 0 0

WIVENHOE.—For the erection of new schools for 400 children, and alterations and additions to the present schools for boys, boundary walls, drainage, &c., for Wivenhoe School Board. Mr. J. W. Start, F.S.I., architect and surveyor, Cups Chambers, High-street, Colchester. Quantities by the architect.—
W. Bell & Sons, Saffron Walden..... £5,527 0 0
John Saint & Sons, St. Ives..... 5,515 0 0
Harcourt Runnacles, Halstead..... 5,446 0 0
D. Mackenzie, Claxton..... 4,998 0 0
T. J. Ward, Colchester..... 5,260 0 0
Geo. Dobson, Colchester..... 5,080 0 0
D. Ellwood & Son, Sandy, Beds..... 5,045 0 0
C. E. Orfeur, Colchester..... 4,980 0 0
H. Plummer, Ratcliffen, Suffolk..... 4,909 0 0
W. A. Chambers, Colchester..... 4,893 0 0
F. Dupont, Colchester (accepted)..... 4,790 0 0

WRACKLEFORD (Dorset).—For alterations and additions to Wrackleford dairy-house, for Mr. Alfred Pope, J.P. Mr. A. L. T. Tilley, architect, Dorchester.—
Davis & Son, Dorchester (accepted)..... £519 0 0

Burry-road Congregational Church, East Dulwich.—Referring to the list of tenders for this job in our issue of the 12th inst. Messrs. Henry Everett & Son, of Colchester, write to say that the amount of their tender was £11,298, not £12,298, as printed.

SUBSCRIBERS IN LONDON AND THE SUBURBS, by preparing at the Publishing Office, 10s. per annum (or 4s. 6d. per quarter), can ensure receiving "The Builder" by Friday Morning's post.

TO CORRESPONDENTS.
V. N.—H. & H. generally speaking an done's this is an undesirable kind of condition to make; but we do not know what special circumstances may have led to it in this case.—J. K. (hardly within our province).—C. B. B. (thanks).—A. C. H. (we are glad to hear it, but the case is of no public interest).—S. T. (too late, and also illegible).—F. R. (too late).
All statements of facts, lists of tenders, &c. must be accompanied by the name and address of the sender, and not merely for publication. We are compelled to decline pointing out books and giving addresses.
Note.—The responsibility of signed articles, and papers read at public meetings, rests of course, with the authors.
We cannot undertake to return rejected communications.
Letters or communications (beyond advertisements) which have been duplicated for other journals, are NOT DESIRED.
All communications regarding literary and artistic matters should be addressed to THE EDITOR; all communications relating to advertisements and other exclusively business matters should be addressed to THE PUBLISHER, and not to the Editor.

TERMS OF SUBSCRIPTION.
"THE BUILDER" is supplied *ex-omino* from the Office to residents in any part of the United Kingdom at the rate of 10s. per annum *post-paid*. To all parts of Europe, America, Australia, and New Zealand, 20s. per annum. To India, China, Ceylon, &c. 30s. per annum. Remittances payable to DOUGLASS FOUNDING, Publisher, No. 46, Catherine-street, W.C.

Sanitary Blue-Books from Melbourne.

THE sanitary condition of Melbourne has been the subject of an elaborate inquiry by a Royal Commission appointed two years ago, and which appears since to have been prosecuting its inquiries with most commendable zeal and

thoroughness. The result of its procedure is now before us in the shape of four reports and a formidable mass of evidence. Three "Progress Reports" were issued, and a final report has now followed, which, we presume, closes the labours of the Commission. The evidence taken includes a good deal in regard to the capitals of others of the Australian colonies, Sydney and Adelaide, as well as in regard to lesser towns, into the state of which inquiry was made, especially as to the success or non-success of various sanitary schemes, in order to throw light on the general question of what could or ought to be done in Melbourne. The evidence thus taken gives an interesting view of the state of sanitary matters, and of the special difficulties to be contended with in this comparatively new country.

The present population of Melbourne City is only 76,000, with a density of 23 per acre, though the city proper is surrounded by various suburban municipalities, some of them more thickly populated, but with an average density over the whole area of only 6·3 per acre, and numbering altogether over 420,000 inhabitants; but we gather that the inquiry concerns all these suburban districts also, that any public works undertaken would be for the benefit of the whole of the collective districts as well as of the city, and that hence some of the difficulties attending sanitary action and improvement are such as arise from the extent of the area to be dealt with and the rather scattered nature of the population.

The heads of inquiry under which the First Progress Report is issued are those of "General Sanitary Condition of Melbourne," "Meat Supply," "Abattoirs," "Noxious Trades," and "Water Supply." The first and the last two headings include such considerations as would be common to large towns in any other part of the world, but the question of method of

ment supply and the position and construction of abattoirs assumes a special importance in Melbourne and other Australian cities, in consequence of the immense and quite exceptional export trade in meat which is carried on from them.

The preamble of the First Report states that the Commission, besides examining into the sanitary state of Melbourne, had visited Adelaide and Sydney in order to inquire into the state of drainage and of the regulations in regard to noxious trades in those cities. The report then commences with a description of the existing sanitary condition of Melbourne, which is rather surprising reading, and quite contradicts the idea which many English people, we believe, entertain as to the spirit of progress abroad in the Australian cities. Sanitary matters in Melbourne, at all events, seem to be in a sadly inchoate condition. The pan or pail system for solid refuse is in full operation, with accompanying results which are detailed with painful minuteness in some of the evidence. All liquid refuse flows down open channels in the streets. This drainage goes into the river Yarra, a stream which, as we see from the map of Melbourne and suburbs appended to the report, winds through a considerable portion of the suburbs and through a part of the city. This river is further polluted by the direct drainage into it of waste liquids from noxious trades situated on its banks, such as abattoirs, wool-scouring establishments, and tanneries. The Yarra flows from the North-east portion of the suburbs, and meets what is called the salt-water river flowing from the North-western suburb, the two forming roughly the forks of a Y of which the stem runs southwards into the sea. The salt-water river is described as even more polluted by drainage from noxious trades on its banks. "Into it pass large quantities of blood-stained fluid from the city abattoirs, and blood from the slaughter-yards at Footscray and Braybrook, of the contents of intestines from gut factories, of waste liquids from bone mills, manure works and boiling-down establishments, and the washings of pelts and wool from fellmongeries." As these streams mostly "wash" (?) the region of the suburbs, it is not surprising to read further on in the report that the death-rate in the suburbs is higher than in the city itself. It appears that even the somewhat primitive method of drainage by open channels in the streets is in anything but a complete or satisfactory state

in itself, as the following extract from the report sufficiently indicates:—

"In many of the suburbs a large proportion of the channels are still unmade; the liquid sewage from the houses passes sluggishly along natural channels in the ground, here and there accumulating and stagnating, and everywhere soaking into and polluting the soil. In sandy districts the liquid house-refuse is largely allowed to lose itself in the sand around the houses. The channels which have been made are not in all cases accurately levelled, with a sufficient fall, and not infrequently the flow is checked by solid refuges which collect in them. Under such circumstances, the sewage lingers in the channels, and undergoes decomposition. The permeable joints of the pitchers allow great contamination of the soil beneath. This evil is greatest where blocks of houses are intersected by branching lanes and passages, in which channels, having often only a slight fall, may be traced for long distances, uniting together and bending at various angles before they reach the main channel in the street. In some instances, those complicated channels in the blocks cannot reach the streets directly; a length of underground piping is necessary, which commences as a catch-pit, covered by a grating. During heavy rains, solid refuse of all kinds is swept down the channels and accumulates over the gratings, and the drainage then overflows the lanes and yards. Thus the soil is constantly being polluted in greater or less degree; and in the crowded portions of the metropolis, where the evil is greatest, the floors of the houses are often close to the ground, so that the mischief is intensified. In certain places crude forms of underground drainage have been introduced to remedy the ill conditions of groups or terraces of houses; but it is questionable whether the remedy so applied does not involve greater dangers to health than the open nuisance originally existing."

This is bad enough reading, but what follows is worse:—

"The underground sewers are not sufficiently ventilated, offensive gases escape through the various openings, and accumulations of a black and very offensive silt frequently occur, which is removed through manholes. During this process of removal the smell from the sewers is very offensive, and the air is necessarily polluted. The greatest pollution of the air, however, is produced by emanations from the pans for night-soil. The closets are frequently placed very close to dwelling-houses, and are not ventilated. No earth nor deodorant is used in these pan-closets, except in a few cases; the pans are not cleansed in any way, and in many instances are not emptied with sufficient frequency. Hence, most intolerable odours arise during the process of emptying these receptacles into the night-carts. The moist residue left in every pan after emptying produces offensive effluvia, which persist till the residue has dried and crusted. Less perceptible but constantly present are the emanations from the thousands of pans all through the metropolis."

This evidence on the effect of the pan

system in Melbourne ought to be of interest to those English local authorities who still partially retain and even defend it for special districts.

Adelaide and Sydney, it would appear, have both taken the lead of Melbourne in regard to drainage, though the movement has only been very recent in Adelaide, which was described by one witness as having been, prior to the commencement of its new drainage system in 1885, "a city of stinks." Now all this is altered. "The city is now free from offensive ordours, the subsoil is recovering, the street channels are used only for surface water, and the Torrens has been changed from a filthy sewer to a beautiful lake." The sewage is carried out of the city by gravitation to a sewage farm four and a half miles from the centre of the city (rather close quarters); the following particulars as to the working of the farm may be of interest in this country:—

"The farm is 450 acres in extent, and receives in round numbers the sewage of 70,000 inhabitants. About one-third of the soil is of a gravelly, porous character; the remainder is loamy, with a thin layer of clay underneath. The farm is worked on the broad irrigation principle, combined in the winter months with intermittent downward filtration. Before passing on to the land the sewage is strained—the solid matter is collected and trenched in, and the liquid portion is distributed over the farm by wooden troughs.

The cost of the system, up to June 30, 1888, was £21,500*l.*, and the sewage rate on the citizens is 8*d.* in the £. The cost of converting the old closets to water-closets was about 10*l.* per closet. Concerning the financial working of the farm, it may be briefly stated that the balance-sheet, at the end of June, 1886, showed a profit on the working expenses during the previous six months of 720*l.* In the following six months there was a profit of 200*l.* But when the balance-sheet for the year ending June 30, 1887, was prepared, there was a loss of 740*l.*, the profit made in the first six months of that financial year being swept away. The loss was due to the excessive wetness of the season, the farm being unable to absorb all the sewage. The operations for the year ending June 30, 1888, resulted in a profit of 391*l.*"

At Sydney underground sewers were laid down as early as 1854, which, however, discharged directly into the harbour. In 1860 a complete deep-drainage system was carried out, with an intercepting sewer to the northern portion of the system, which carried away the sewage to the ocean at Bondi, where there is a strong current which carries it away. The southern portion of the city drains into a shallow estuary, and the sewage is conducted by a main sewer to a sewage-farm at Botany, where there are a thousand acres of sandy soil suitable for filtration purposes. So runs the description in the report, though we do not quite see, if this part of the sewage is taken on to land in the end, what is the use of the episode of the "estuary." It is stated, however, that the Sydney drainage works, which are still in progress, have proved eminently satisfactory in their results so far. We do not gather anywhere from the evidence what is the distance of the sea outfall of the Bondi sewer from the town, but we observe in the minutes of evidence that the commissioners very properly questioned their expert witness closely in regard to the construction of the sea outfall and in regard to the evidence as to the behaviour of the sewage after delivery into the sea. This witness was Mr. W. C. Bennett, Commissioner and Engineer-in-Chief of Roads for the Government of New South Wales, who in his evidence expressed himself strongly in favour of running sewage away into the sea where possible to do this at reasonable cost. "There is no money," he said, "to be made of it, however elaborate all the statements in England may be." On the south side of Sydney, Mr. Bennett said, there was no opportunity of doing this; "the sewage drained into a large shallow estuary, and we thought it better there to provide the sewage farm." This is the estuary referred to in the Report, apparently, though the evidence still does not explain the relation of the sewage farm to the estuary. In regard to sea outfall, the witness stated that there was an iron shield or ferrule used to protect the openings,

and after this was rather vaguely described the following evidence was given as to the getting away of the sewage from the outfall:

"2,287. Opposite the outlet I noticed at our visit, there was discolouration of the water; and that the discoloured part bore away towards the south—is there any constant current in that direction?—The current outside is very constant to the south, but the long-shore current varies with the tides; there are eddies, but we have never had any complaint of anything being carried inland, because it is a very salient point of the coast.

2,288. No complaints from Coogee?—No.

2,289. Have you made experiments to see what course the sewage takes when it gets into the sea? We examined with corks before we bored it.

2,290. There is no eddying round in the Coogee?—No, it goes away well to seaward.

2,291. What became of the corks?—They floated away to seaward with the south current."

This seems satisfactory so far; and no doubt when you can get a sea outfall far enough off, and a sea current which will carry the sewage well away from the coast, there is much truth in Mr. Bennett's theory of the desirability of getting rid of it and seeing no more of it. But the sewage of London (to which one's mind naturally reverts) is of too exceptional proportions to be regarded in the same light as that of cities of ordinary or secondary size, nor have we such an advantageous place of outfall as appears to be available for Sydney: so we can only look on with a certain amount of envy at this comparatively easy solution of the problem.

To return to the main business of the report, before us, the sanitary improvement of Melbourne, the Commissioners in their first report came to what appears the inevitable conclusion from the evidence, that no half measures in the way of attempting to better regulate the present system of refuse disposal would be of the slightest ultimate advantage:—

"No thorough reform would be secured by improved pan services for solid sewage, or by the use of destructors for general refuse, without such a system of drainage. The liquid sewage of the city, which constitutes the great bulk of the refuse to be disposed of, would still remain untreated; the street-channels, whether on the surface or beneath it, would still remain offensive; the subsoil would still be damp and foul; and the river would continue to be progressively polluted. Intercepting sewers would not diminish the offensiveness of the drains, nor sensibly improve the condition of the subsoil; and the pollution of the river would simply be replaced by pollution of the harbour. Being thus definitely of opinion that a system of underground drainage must be instituted, we propose to take such skilled evidence as may be available concerning the best method or methods to be adopted, but we are satisfied that the evidence which may be so obtained cannot be more than ancillary. . . .

We therefore recommend that, as soon as possible, a civil engineer of the highest attainments, and of practical experience in sanitary and hydraulic works, be selected to prepare such a scheme after a thorough study of the local conditions, which are admittedly full of difficulties. The question arises by whom shall such an engineer be appointed, and from what fund shall he and his assistants be remunerated?

In our opinion such engineer should be appointed as soon as possible by the Government, and should be provided with such assistance as he may require; and the remuneration of such engineer and his assistants, also the expenses incidental to the formulation of the scheme, should be a first charge upon the funds at the disposal of a Metropolitan Board of Works, which Board should be created without delay, and should be charged with the control of the water supply and sewage.

In the meantime, it is our intention to gather as much local information as possible from the best sources, to obtain sections and other geodetic measurements across country likely to be traversed by main lines of sewers beyond the metropolitan districts, also the levels and particulars of soils and subsoils of lands whereon might perhaps be ultimately selected sites for sewage farms and filtering beds. The information might be placed at the disposal of the engineer when appointed."

The Commissioners then go into the question of the constitution of the proposed Board of Works, adding a number of recommendations as to the special powers to be given to it; and following the example of Sydney, they recommend (and wisely) that the numbers of the Board should not be large, as the object is to work and not to talk. They then subjoin some "interim recommendations" for the sanitary benefit of Melbourne until such period as the proposed Board may

be formed and the proposed drainage works carried out. The main suggestions in this part of the report are that all "tips" of rubbish should be abolished, that ordinary refuse should be burned in destructors, and that an effort should be made to render the administration of the pan-system at all events as innocuous as possible for the present:—

"That the ordinary system of pans for night-soil be abolished; that instead thereof, every closet be furnished with a double-pan service; that at least once a week, or so much more frequently as the local board of health may from time to time direct, the pan in use be closed with a tight-fitting lid, and removed in the day time in a suitable cart; that a pan cleaned by superheated steam, or some equally efficient means approved by the local board of health, be left in its place; that the use of a suitable deodorant be made compulsory; that the night-soil removed be either treated in a destructor or be trenched or ploughed into land; that failing the use of a destructor the contractor be compelled to obtain a receipt from the occupier of the land whereon deposit is made, or from the manager of some approved depot for night-soil, for the number of pans there emptied or delivered; that stringent supervision be exercised by the boards of health over all such depots or places of deposit."

They also add the very pertinent suggestion that the inspectors of nuisances in all districts "be as far as possible freed from all other duties;" and it would certainly seem that in a city in the present condition of Melbourne an inspector of nuisances who was disposed to do his duty would be likely to find his hands full.

Then follows the consideration of the important question of abattoirs, and of the whole system of meat supply, which, as observed, assumes such large proportions in the Australian cities. The result of the Commissioners' inquiries is that the suburban abattoirs should be immediately abolished, and they are not disposed to listen to any half-measures, but advocate a general adoption of the system of country abattoirs and chilled meat trains; the process of chilling being, it is to be gathered from the evidence, not deleterious to the meat in the same manner that freezing is held to be. This is a question beyond our province; but as to the main question of the health and comfort of the town there can be no doubt that the Commissioners are entirely in the right, and it seems indeed quite monstrous that immense establishments for the continual slaughter of cattle on a large scale, not for the provision of the town but for export, should be kept up within the precincts of the town. As to other inconveniences to the town from this state of things the evidence of Mr. Dickinson, a medical man residing in one of the suburban districts, is rather striking. The cattle, he says, are not allowed to be driven through the streets, except after ten at night, but after that hour, on what is called "cattle night," the roads are unsafe for pedestrians; there is one street, Epsom-road, that is useless after ten on "cattle night," the inhabitants dare not go into Melbourne to the theatre for fear of encountering these half-wild cattle on their return, and the witness had himself, even when driving, had to go a long way round to avoid the cattle; to try to drive through them, he said, was unsafe. With all this, and the mass of evidence as to the nuisance from the abattoirs, it is not surprising that the Commissioners should have made a very decided stand as to the removal of the abattoirs from the precincts of the town, except with the allowance of one in the neighbourhood of the town under very stringent regulations. Yet in their final report, issued since the commencement of the present year, the Commissioners note that no improvement of importance has been made, and that things are still as unsatisfactory and insanitary as before. It does not appear, however, that Melbourne stands alone in respect of the bad administration of its abattoirs: the evidence of one witness who had made the subject a special study gave a most unfavourable impression as to the great Chicago pig-killing establishments, in which he said it was literally true that the pigs were driven in at one end and came out in the

shape of tinned meat at the other end; the arrangements for the production of this metropolis were, the witness testified, most ingenious and elaborate; but the approaches to the works were in so filthy a state that no one could walk up to the entrance, and the general impression produced by the whole place, in regard to cleanliness and sanitary condition, was summed up in the remark of one of his party—"I will never eat tinned meat again!"

The second Progress Report deals with the water supply of Melbourne, the oldest and principal portion of which is from the Yan Yean reservoir, a supply which dates from the year 1853, and consists of water impounded from a large catchment area. The great drawback to this supply seems to have been the existence of farms on the slopes draining towards it, a point several times touched upon in the report, with regard to various localities. The Commissioners take a very strong view of the matter; they recommend, for instance, that no dogs should be kept on catchment areas, a prohibition no doubt desirable, but which we should fear it would be exceedingly difficult to carry out. The strong representations made in the Progress Report do not seem to have borne much fruit, for we find the subject again returned to in the Final Report of this year:—

"Professor Masson's analyses showed that the water underwent decided improvement while stored in the Yan Yean Reservoir. They gave no positive evidence of constant pollution. Some of the passages of the water through the mains in Melbourne, but it has been noted that at certain times, apart from rainfall, the water is dirty. A yield of such discoloured water, when analyzed, yielded unfavourable results. In our Second Report we made detailed recommendations for the protection of the water-supply from pollution. Some of these recommendations have been partly carried out; others, so we understand, under consideration. We regret that, although we drew attention to the unfinished siphon when inspecting the aqueduct on April 19, 1889, and subsequently recommended in our Report, dated July 30, that the siphon should be completed at once, it still remains in its old condition, capable of delivering roadway and other drainage into the clear-water channel, and this, too, notwithstanding that the then Minister of Public Works in our presence gave instructions that it should be completed immediately. We trust that no further delay will occur in removing the two embouchures from within the direct catchment area of the Yan Yean Reservoir. We regret that we are compelled to draw attention to the fact that many street-hydrants remain in dangerous positions, notwithstanding our urgent recommendation and the special report of the officer appointed by us. We would also suggest, again, that the water supplied to the metropolis should be analyzed at least once each month, and that the question of the filtration of the Yan Yean water on a large scale should receive careful consideration."

This last sentence touches on one of the most serious and radical deficiencies of this portion of the Melbourne water supply. It appears that this water, thus collected from a large surface area, undergoes no systematic filtering whatever! No wonder the Commissioners are anxious to keep the area uncontaminated; but they speak strongly also of the necessity for filtration works on a large scale being instituted. A large portion of the immediate catchment basin, however, is, it appears, permanently reserved and unoccupied, and the Commissioners add that the manner in which the portion of the reserved land immediately about the reservoirs is cleared, grassed, and planted, reflects great credit on the resident inspector. We come to the unsatisfactory side of the case again when the Commissioners have to speak of the state of the water supply mechanism in Melbourne itself. We are told that "all the mains, which have been laid for any time, tend to become choked to a greater or less extent by incrustations of rust and silt. Pipes of all sizes are affected. The silt is decidedly offensive. It consists largely of decomposing vegetable matter. But the analyses made by Professor Masson do not afford evidence that there is any constant contamination between the Yan Yean Reservoir and Melbourne, though they show that occasional disturbances occur, which render the tap water turbid."

Then does it not appear that the contamination, which consists of decomposing vegetable

matter, has its origin in the reservoir itself? Another defect more than once referred to is the placing of street hydrants at too low a level, so that surface storm-water, carrying of course various impurities, runs over and may trickle into them. This is bad, and the removal of the hydrants (several times insisted on by the Commissioners) to more suitable and higher points should undoubtedly be carried out; but on the basis of the evidence we should not be inclined to attribute the unsatisfactory state of the water in the mains to this cause, unless to a very slight extent. The filtration is what is wanted, and the sooner Melbourne sets about it the better.

The third Progress Report deals with the subject of drainage and sewerage of Melbourne in a more special manner than in the First Report, and with some additional evidence, chiefly from experts. On this subject Mr. Mansergh has been consulted, and paid a few weeks' visit of inspection and inquiry, and we gather from the Final Report that a special report by him is in preparation, though the Commissioners express their regret that he did not or was not prepared to remain long enough in Melbourne to obtain the data for drawing out a detailed scheme of drainage, and the Commissioners express a fear that any mere sketch of a scheme, without details, "if prepared during a short visit and without full knowledge of local conditions, may cause embarrassment and delay. The Commissioners include in their report three schemes submitted to them by Mr. W. Thwaites, Mr. G. Gordon, and Mr. W. F. Bell. These schemes are embodied in the "Blue-book," with explanatory plans accompanying two of them. All three engineers recommended the separate system, with the admission of a small proportion of the earlier part of a rainfall into the sewers; one-tenth of an inch, it was suggested by one witness, was ample, though not too ample for getting all the cleansing effect of the rain in carrying off surface impurities. With a climate subject to violent rainfall of course any other but the separate system would be out of the question. It seems to be thought that the existing surface channels may be left to carry off the bulk, the clean portion, of the storm-water. But all the three engineers who submitted schemes concurred in this point at least, in emphatically advising the entire relinquishment of all relic of the pan system, and the adoption of water carriage alone, and we are glad to see that the Commissioners adopt this view in their report, though with some cautious expressions as to the possible insanitary effects of a water-carriage scheme unless carried out in the very best manner. This is perhaps a truism; in fact, any sort of sewage scheme must be carried out in the best possible manner to be satisfactory; but we doubt if the worst evils incident to an imperfect water-carriage scheme could be as bad as those which are almost inseparable from a pan system when applied to a large city as its only method of removal of excreta.

The final report leaves things in this position. The Commissioners recapitulate briefly their former recommendations about noxious trades—that these should be classified, and the more offensive ones distinguished from those which are not offensive unless negligently conducted, and that the former should be removed from their present proximity to population; and they thus state the result so far:—

"The Public Health Act 1883, section 32, enacts that no noxious trade shall be carried on without the consent of the local authority, and provides heavy penalties against offenders; it also empowers persons, whether resident in the district or not, to object to the continuance or extension of any such trade, and constitutes the Board of Public Health a board of final appeal whenever objection is taken to any consent given by the local council to the continuance and extension of such trade. Section 33 enacts that whenever there shall have been three convictions for nuisance after the passing of the Act, the local council may refuse to renew registration, and again provides for a final appeal to the Board. Section 41 enacts not only that every local council may prevent discharge of noxious matter into rivers, lagoons, &c., but empowers the Board when necessary to issue orders according to the local authorities. The powers so conferred

on both the local councils and the Board of Public Health are very large, and, in our opinion, if fearlessly exercised, will suffice to secure the necessary reforms. At present, however, the evil conditions described in our First Progress Report remain practically unchanged."

This is not very satisfactory, but it must be something for the Commissioners to congratulate themselves on that they have at any rate procured the formation of the legal machinery necessary for action, and it is to be hoped that this will not long be allowed to remain inert. In regard to abattoirs, which are classified separately from other "noxious trades," we learn that the Port Melbourne abattoirs were to be closed at the end of January in consequence of action taken by the Melbourne Harbour Trust, which resolved to pay £1,250 in compensation to get rid of this nuisance. But, adds the Report, "the South Melbourne abattoirs remain in the offensive condition described in our First Progress Report. The continuance of this establishment on Crown lands, under a so-called 'permissive occupancy' is, in our opinion, highly unsatisfactory, and likely to increase the difficulty of dealing with such establishments. Councils and private individuals can hardly be expected to conform promptly with the law, when such a place as this abattoir is permitted to remain, without any legal authority, on Crown land." In reference to the question of water supply, the Commissioners repeat and emphasise their cautions expressed in a previous report against too great confidence being placed in intercepting drains for the protection of the aqueduct; their recommendations as to a filtration scheme we have already referred to. The final report is largely occupied with a summary of the results of chemical and biological investigations as to the presence or absence of the germs of various diseases in the water. The conclusion of the report is that freedom from any water bacteria or water-borne germs may be ensured, in regard to the Yan Yean water, by the use of a pressure-filter on the pipe, and they add a brief expression of the very wholesome doctrine that "it is the duty of purveyors, and not of consumers of water, to see that a proper standard of quality is maintained." In conclusion, the Commissioners refer to the two legislative factors which must be looked to for effecting the sanitary improvement of Melbourne; one of them the Public Health Act, already passed, and just now referred to; the other the establishment of a Board of Works, which is still *in futuro*. If such a Board were to be a large body of which the members might be elected on political and partisan grounds, like another Board we have heard of, we should very much doubt its benign influence; but if the wise recommendations of the Commissioners are carried out, and a small Board of practical and working members appointed, they will probably be able to give a better account before long of the sanitary condition of Melbourne.

NOTES.

SPECIAL meeting of the Institute (not largely attended) was held on Monday to announce the result of the general vote of members, by letter, on Professor Roger Smith's resolution passed at the meeting of March 31, the terms of which were given in our leading article of the 12th, but which it may be convenient to reprint here: it was as follows:—

"That while not opposed to the principle of compulsory examination as applied to those about to practise architecture, this Institute is of opinion that the difficulty of restricting by statutory powers the practice of architecture to those who have passed an examination is at present so insuperable that it is undesirable to make an immediate application for such powers."

The result of the voting was that 708 replies were sent to the circular, of which six were too late, and eighteen were put aside as informal. Of the remaining 684, 520 were "for" and "164" against. The majority "for" would probably have been much larger, proportionally, if a larger number of the members had voted, and also if the point

for consideration had been more clearly conveyed; for we surmise that it was probably not by any means clear to many, at all events to those who had not followed out the whole proceedings of the meeting of March 31, precisely to what effect they were voting; and we doubt if the Institute would not have done better for itself in "going to the country" with the original motion, in which it would at all events have been quite clear what was voted on and whence the proposition came, viz.: from people who under pretence of benefitting the profession have been doing all they can to injure the Institute and bring it into contempt to serve their own purposes, though it now suits their tactics to proclaim the contrary. The resolution as sent out, it must also be observed, embodied an adherence in principle to the theory of compulsory examination, to which some who might otherwise have voted may have felt unable at the moment to commit themselves.

PERHAPS no feature of Mr. Goschen's Budget proposals will give more general satisfaction than the announcement that the Government intend to deal with the question of postage to India and the Colonies; and Mr. Henniker Heaton may be congratulated upon the measure of success with which his persistent efforts in the cause of postal reform have at last been attended. The existing rates to India, Australia, and the Cape range from 4d. to 6d., and it has long been urged that a uniform rate of 2½d. to all our colonies and dependencies should be established. Mr. Goschen stated that the Postmaster-General would endeavour to induce the respective Colonial authorities to agree to this being effected in future, by any route. It appears to be inevitable that the step will involve a certain amount of loss, but as it is highly probable that such loss will be greater during the first year than afterwards, it could not be introduced at a more fitting time. The country can best afford it now, and the Chancellor of the Exchequer has done well to make use of the opportunity now presented for dealing with this question. He could not, of course, definitely promise the reduction, but the announcement of his approval of the principle, and of his readiness to adopt it, will doubtless be responded to by our Colonies, who will, however, be called upon to bear some loss at first in connexion with the scheme. At home the proposal would not meet with much opposition in less prosperous times, and we should think that the concession would be equally appreciated in our dependencies. On Monday the postage of circulars was again mentioned in the House of Commons, and the Postmaster-General stated that it is being considered whether the Book-post rules can be modified in this and some other respects. It is notorious that circulars for home distribution are frequently sent abroad wholesale for re-posting to England, a saving being thereby effected by the senders, although the country must be the loser. It is high time that the existing rules were altered in some way. Altogether, the cause of postal reform appears to be in the ascendant just now.

WE learn that the Committee of the British School at Athens, in continuation of the scheme for collecting and publishing a series of drawings of the remains of Byzantine architecture in Greece, have decided to take up, but as a separate and distinct work, examples of the most typical churches in the Monasteries at Mount Athos. Mr. R. W. Schultz and Mr. Sidney H. Barnsley have already made a beginning with drawings of the Monastery of St. Luke, near Livadia, in North Greece, and are at present busy with the churches in Athens and the neighbourhood. They intend continuing their work in the interior of Greece for the present, but hope to be in a position to go to Salonica and Mount Athos towards the end of June, and to spend the summer there. They purpose making careful measured drawings of the architecture of the most important of the churches, and special studies of the most interesting portions of their detail, and they

also hope to include a few of the finest mosaics and frescoes. A representative series of photographs will also be got together, and some time will be devoted to a general description of the various schemes of iconography. The architects also hope to measure several of the smaller brick churches in Salonica which have been insufficiently noticed in Texier and Pullan's work on Byzantine architecture. Mr. Penrose referred to this subject in a letter in our columns a few weeks since, and then mentioned that funds were much wanted to assist in this very valuable work of architectural illustration, and that subscriptions in aid of it would be received either by Mr. Walter Leaf, the Treasurer to the British School, at Old Changi, E.C., or by Mr. E. A. Gardner, the Director, at Athens. We hope some assistance will be forthcoming towards this work, which is being undertaken by very competent persons, and the results of which may form a very important and interesting addition to existing illustrations of ancient architecture.

THE following letter from Professor Aitchison appears in the issue of the *R.L.B.A. Journal* for the 17th:—

"In the interesting account of the late Mr. J. T. Wood, of Ephesian fame, given by Mr. W. Papworth, nothing is said of Wood's architectural works in this country. He built an office at the north-east corner of Kings-street, Cheapside (with one front in Gresham-street), and was the architect of the stations to some English railway. Possibly the requisite information about his works may yet be obtained. It would be superfluous to make any remark on the action of our Government in reference to the archaeological researches made wholly or partly with public money. When a few of the marbles have been brought over and exhibited in the British Museum the Government considers it has done its duty, and all that is mainly valuable for improving our knowledge of antiquity is left to be done by the public spirit of the discoverers. Nothing has been published as yet but Wood's popular book, and now, alas! no further aid or information can be got from the discoverer. Are all his invaluable drawings, sketches, and memoranda to be left to the chances of destruction? Is nothing to be done to have these digested and published, and to obtain the services of a learned architect to make a restoration of the temple? Are no classical scholars and classical archaeologists to be employed in writing an elucidatory text?"

Professor Aitchison, we see, has a letter in Thursday's *Times*, ably setting the matter before the public.

THE Royal Veterinary College, Camden Town, for which a new Museum is about to be erected, stands along the eastern side of Great College-street, and was established in 1791, with the Duke of Northumberland as president, under the not very successful management of a Frenchman, M. St. Bel. After his death, two years later, a committee was formed of some leading medical men of the day, including Abernethy and Sir Astley Cooper. We gather that the Veterinary School attached to the College has, at times, received aid from the State; yet it is only in this country, perhaps, that so useful and indeed so national an institution would be allowed to exist as a virtually private enterprise.

THE *Pall Mall Gazette* is often sadly at fault in its information about London matters, but it has never been more ludicrously wrong than it is in one of its "Occasional Notes" in its issue of Wednesday last, in which it says, writing of the London County Council, that "duty calls the Councillor now to Spring-gardens, now to Guildhall; one moment to the Mansion House, and the next to a sort of annexe in Craven-street." Further on, our oracular contemporary speaks, in the present tense, of "London's Parliament" as alternating "between sitting as a pensioner in the City and working in a two-pair back at home." From the context the writer of the "Occasional Note" is evidently quite unaware of the fact that the Council no longer sits at Guildhall; and we believe that it has never had the least occasion to appear for any purpose at the Mansion House,—which is primarily the official

* See also the *Builder* for April 12, p. 297.

residence of the Lord Mayor, though a small portion of it is used as a police-court. Curiously enough, another column of the same issue of the *Pall Mall* gives an account of the London County Council "at home," in which it is stated that the Council assembled for the first time on Tuesday in its "enlarged and transfigured hall." Here again another blunder is made, for the members' seats are described as "radiating from a base formed by the dais." The arrangement of the seats is really that of four concentric arcs of which the dais may be said to form the chord. The intersecting gangways radiate, not the seats.

MR. THOMAS NELSON, publisher, writes to the *Scotsman* as follows, on the subject of the extension of Princes'-street:—

"The citizens of Edinburgh are rightly jealous of anything that would interfere with the amenity of a place which has, by every one, to be one of the noblest streets in Europe. From Waverley Bridge westward there is little to find fault with—the Gardens and the Castle Rock making it the admiration of visitors from all parts of the world.

But there is one blot at the East End, and that is the North British Railway-station, an unsightly jumble of a place quite unworthy of the city of Edinburgh. It has occurred to me that the matter is not yet past remedy, and that one of the greatest improvements that could be made to Princes'-street could still be carried out, and in a way to benefit the railway itself.

My suggestion is that the entire area of the railway station be converted into a public place, on the level of Princes'-street, with the railway station, as at present, below, but greatly improved. I reckon that the area thus acquired would give to Princes'-street an extension greatly more than the entire area of St. Andrew-square. It could be made suitable for carriages, cabs, foot-passengers to the railway, and promenades. With a little architectural skill this new place might be made one of the finest features in the city. The cost, no doubt, would be considerable, but not more than I think might warrantably be spent between the city and the Railway Company. It would add greatly to the value of the railway property, and immensely to the beauty of Princes'-street."

The "grand place" over the railway-station would, we presume, be constructed after the manner of the Waverley garden over the vegetable market, the lights being placed in the centre of flower-beds. To make the place suitable for carriages would necessitate greater strength in construction. The thing could be done, but, as Mr. Nelson hints, the cost would be considerable.

IN connexion with the London University Extension Society, Mr. Arnold Mitchell intends giving six lectures, or rather three lectures alternating with three demonstrations on architecture, at 3 p.m. on successive Saturdays, commencing on May 3. The lectures will be given at Gresham College, and the demonstrations will be given successively at the Church of St. Bartholomew, Smithfield; Stone Church, Greenhith; and at Westminster Abbey.

A NEW laboratory for electrical engineering has been instituted at King's College, London, by the aid of a gift from Lady Siemens; it is to be called the "William Siemens Laboratory," and is to be constructed and fitted, we are told, with every modern electrical appliance. Dr. Hopkinson, the President of the Institution of Electrical Engineers, has been appointed the first professor in connexion with the Siemens Laboratory.

IT is stated in *Notes and Queries* that Sir Arthur Blomfield is commissioned by the Duke of Buccleuch, who is lord of the manor, to superintend the repairs of the Eleanor cross at Geddington, in Northamptonshire, and that the restoration will be carried out in a strictly conservative spirit. The cross, being triangular on plan, and about 40 ft. high, stands in the centre of the village. It bears the customary coat of arms of Leon, Ponthoise in Ponthieu, and Castile, and at top the figures of three queens lamenting. Nearly two years ago we published an account of its then condition, in an article entitled "A Tour in the Weldon Stone District," with some particulars of other similar crosses,

and of the royal progress from Herdrey to London.* The hexagonal cross at Waltham, which was at first constructed of Caen stone, having been set free from the Falcon Tavern which abutted against it, was a year or two ago restored by Mr. C. E. Ponting, architect; and in 1888 Mr. Hams, of Exeter, completed the sculpture.

OF the six invited designs for a Mausoleum for the Grand Duke of Baden, for which a site has been found in the Fassen Garden of Karlsruhe, not one has been found suitable; and hence another design,—one in Early (German) Gothic, with an open timber roof, proposed by Herr Hemberger,—will most likely be carried out.

AN Exhibition of Architecture will be opened at Amsterdam on May 11. Designs (in drawing or model) of buildings erected within the last ten years, and also drawings or models for ideal projects or competitions made within the last six years, will be on view. A small collection of sketches and measured drawings will also be hung.

THE biennial general meeting of the combined Architectural Societies of the German Empire will be held in Hamburg this August. We will give some particulars as to the arrangements for this meeting at a later date; but it may be well to note that the "Hamburger Architekten-und Ingenieur-Verein" are already hard at work preparing for the event, and that as some eight hundred guests from all parts of Germany are expected, the meeting promises to be a success.

THE *Building and Engineering Journal* of Australia (March 8) contains a report of a deputation of Sydney architects to the Mayor of that town, asking that in future municipal works should be thrown open to the profession generally, instead of being carried out by the City Architect. The deputation, through their spokesman Mr. Mansfield, said they believed New South Wales was the only part of the world in which Government buildings were wholly and entirely carried out by a Government architect. They were not considering a question of persons or of individuals, but one of principle; and he thought if the Mayor would take the matter into consideration he would be doing a duty to the public and conserve the great interests confided to his care. He also mentioned that, under the auspices of the Institute of Architects, certain rules were framed for the conduct of competitions, and which he thought were accepted by the profession generally as most desirable to avoid those evils frequently arising out of competitions; and he suggested, in the event of the views of the deputation being adopted, the advisability of adopting those rules. The Mayor said he had complete sympathy with the views thus put before him, and thought it more in accord with the spirit of the times to get the best results from the widest selection. He considered the City Architect's duty was really more that of an adviser, and it might be that different works in the municipality required different skill. We certainly think it is more for the architectural interest of a city that its principal works should be designed by various independent architects than that they should all be the work of one official mind, however able.

IN a recent report to the Local Government Board on the causes of the prevalence of diphtheria in the Tredegar Urban Sanitary District, Mr. Spenn draws attention to the extraordinarily primitive condition in regard to sanitary matters in parts of this district:—

"The much-infected localities are alike in this, that the air about the dwellings is contaminated with sewage effluvia from defective drains and sewers. George Town South is provided with sewers, chiefly of stone and of the 'box' type, possessing two main outfalls and four minor ones into

the river. The sewers in their outfall portion are laid with a steep descent towards the river, but the street branches have sometimes only a poor gradient. Privies are built right over them without the intervention of any pan or trap, so that sewer air comes freely through the closet seat. Slop-water gullies are likewise untrapped. Moreover, as the houses are built in terraces along the bank side, these direct openings into the sewers, affording the only means by which the latter, he it observed, are ventilated, are often in very confined situations; the slop-water gullies being generally, in fact, in a sort of well yard or area, close by the back doors. A certain number of the houses, again, have no through ventilation, so that sewage effluvia often in such cases pollute the sole source of air supply.

In Vale terrace, diphtheria, as I before said, concentrated itself upon one portion of the row; the further and smaller division, consisting of thirty-houses, entirely escaping. In the division affected a brick culvert, 3 ft. 6 in. in diameter, passes the whole length at the rear, some 24 ft. from the houses. The gradient is so flat that this sewer has habitually to be cleansed by the digging and scraping out of the contents; and yet the privies of every house empty over it, as in the case of the George Town privies, without any pan or trap; it is, in fact, one long cesspool, and the slop-water drains empty likewise into it."

THE exhibition of the Society of Painters in Winter Colours is hardly one of the strongest; as usual, where it is strongest is in landscape. Mr. Alfred Hunt, however, is represented by only one drawing, a small view of "Windsor Castle" (212) from the opposite side of the river, seen under a peculiar effect of rich misty atmosphere. It is refreshing to meet the name of Mr. G. P. Boyce again, too often absent of late years; his one drawing, "Richard's Castle Church, Herefordshire" (197) is in his best style of delicate detail of buildings and foliage, and that peculiarly soft and aerial effect of sky in which he excels. Mr. R. W. Allan is working his recipe of brown buildings and bright blue spots of colour in his figures far too much; all his works are powerful in effect, but it is all one effect, unless we except "Machrie Bay, Arran" (182), which is a variation on the usual theme. Mr. Wilmot Pilsbury is more and more brilliant in his highly-worked realistic scenes, but the sentiment of nature is not there. Mrs. Allingham's finest contribution is perhaps "Bilshere House, Hamstead Heath" (11), a perfect work of art, in which a true picture is made out of the simplest materials; the "Cottage under the Copse" is another beautiful little work (113), remarkable, as usual, for the perfect execution and expression of the small figures that give human interest to the scene. Mr. Thorne Waite's chief contribution is a large field scene, entitled "The Blue Waggon" (59), with a waggon and horses going away from the foreground and forming with the figures in the waggon an admirably-drawn group as the centre of the foreground; the picture has more of open-air freshness about it than some of the artist's recent works, which have occasionally been over refined in sentiment, the landscapes of a dream rather than of real life. Perhaps the same charge might be made against Mr. Tom Lloyd's nevertheless beautiful work, "Rush-Cutters" (29), in which a long barge with some figures in it moves across below the parallel line of a level bank, with a harmonious decorative effect which makes one of the charms of the idyll. Mr. Napier Homy has never done anything more fresh and more full of movement in the boat and the sea than "Bowling Along" (62). Mr. C. B. Philip, one of the more recent members, is one of the most powerful landscape painters in the Society now, and perhaps there is nothing finer and broader in style in the exhibition than his large desolate landscape, "Glen Feshie, Inverness-shire" (163), notable too for the truth of effect and texture conveyed along with this broad handling, as shown especially in the straggling river-bed with its broad pebble shoals. This truth of texture is what is wanting in Miss Montalba's otherwise effective drawings, as in "The Old Mill, Zaandam" (52), where the water is merely a pearly grey surface with no look of water about it; but her little

sketch of the "Ponte della Pnglia, Venice" (5), with its gaily-coloured groups, is a masterpiece of colour-poetry. Among other noticeable works are Mr. Goodwin's picture from "Sindbad the Sailor" (94), though this is not a scene of this earth, and on the whole we prefer his exquisite little paintings of what may be called city scenery; Mr. Herbert Marshall's "Arnheim" (92); Mr. Beavis's "Hrvesting in Pearly" (87); Mr. Alfred Fripp's "Durdle Door" (90), with a wonderfully real effect of sunlight on the sea through a natural arch in the cliff; Mr. Robertson's "Serpent Charming" (188), and "Le Roi S'Amuse" (154); but these brilliantly painted oriental scenes have little interest beyond that of brilliant execution; Mr. Jessop Hardwick's "In the Woods" (172), an exquisite painting of primroses; and Mr. Walter Field's "Hamstead Heath—a Hail-storm coming on" (186), a very fine piece of storm effect. Mr. Bulleid's classical marble and drapery pictures, "In Cynthia's Garden" (162), and "After the Bath" (181), are delightfully decorative in effect, but this is a kind of thing that is too mannered and conventional to retain its interest, in spite of much cleverness of execution.

THE collection of Anton Mauve's works at the Goupil Gallery consists mostly of studies and sketches, with but few finished paintings, as much even as he ever did finish. Mauve was a true painter in his feeling for the composition and sentiment of a scene, and in his perception of colour within certain limits; but a room full of his work has rather a depressing and monotonous effect, owing to the prevalent dinginess of colour and a certain smeariness of execution which goes very well with some of his subjects, but not with all. His "Cavaliers on the Shore" (21) is an admirable rendering of the appearance of a wide expanse of seashore seen from a sloping lane leading down to it, and the dark and pronounced effect of the figures and horses against the bright sand; and "The Flock" (22) is an admirable treatment of sheep in his peculiar way. "A Shower on the Heath" (41), and "Morning near the Canal" (68), are very good pieces of effect; in the latter the delicate way in which the faint morning light on the ground beyond the shadow of the dyke is just indicated is remarkable. His artistic feeling for composition and effect is nowhere better shown than in the little picture called "The Paling" (49), a mere corner of a field with a tree and some palings showing dark against the sky; but Mauve has made a real picture out of it. The painting called "The Brown Cow" (20) is rather exceptional in the collection, being much richer in colour than is usual with the artist; the animal stands in front of and half-shadowed by a dense dark mass of foliage, the feeling of the picture rather recalling the art of Troyon.

THE Executive Council of the British Section at the Paris Exhibition have published their Report, from which we learn that while throughout the Exhibition the average of awards was 50 per cent. of the number of exhibitors, in the British Section it was 90 per cent., and in the Industrial Section taken alone it was 120 per cent., double awards having been given in not a few cases. The Council complain of the manner in which the foreign exhibits were split up into sections in various portions of the building, so as very much to detract from their impression; the British and Colonial Section would they urge, have made a remarkable show if concentrated, whereas it was scattered about over no less than twenty different localities. The Executive Council give their thanks to the jurors, "who accepted without fee or reward a laborious and thankless duty." This, we believe, is painfully true in regard to most of those who actually did the work, though we believe some official honours were bestowed on honorary jurors who never went near the exhibits, while professional men who had left their work in England and were living for a long time at their own cost in

* See *Builder*, July 14 and October 27, 1888.

Paris, and giving unremitting attention to the labours of jurying, had the satisfaction of seeing the honours and the credit given to those who were only ornamental names.

FROM NEW YORK.

THE average American, it has always appeared to us, is never happy until he is a member of a society or organisation of some sort. The New Yorker is especially favoured in that, whatever may be his social position, his creed, his avocation, or his social position, he can find in his own city a society of some sort to which he may become affiliated. There is a Holland Society for the descendants of the old Dutch Settlers; a New England Society for the progeny of the Puritans; a St. Patrick's Society for those of Irish descent; a Southern Society; an Ohio Society for the energetic and thrifty natives of that State, which is to the rest of the Union what Scotland is to England; each College has its Society, as has each profession; and so on down each rung of the social ladder.

We are led to dwell upon this national tendency in view of the fact that American architects have had, so far, no association or society which may worthily represent an important profession in the eyes of the public. There is, it is true, an American Institute of Architects, which has been in existence some thirty years or so, with the expressed object of "uniting in fellowship the architects of this continent, and combining their efforts so as to properly promote the artistic, scientific, and practical efficiency of the profession." The headquarters were originally, and have always remained, in New York; but local associations were formed under its auspices throughout the Union. The Institute has for years suffered from a species of dry-rot, which has impaired its usefulness either to the profession or the public, and the most that could be said for it was that a majority of its members were estimable individuals of a high degree of respectability. Other societies sprang up here and there in different cities, and finally, Chicago, jealous, as is its nature, of all that bears the stamp of New York, evolved a new association of its own. This was only a few years ago, but it is termed, quickly outstripping the sedate Eastern Institute, as far as numbers, and probably influence went. This was, no doubt, due to the fact that all were fish who came to the Western body's net, and as long as the applicant for membership knew a 1-square from a 2-square, he was architect enough for the Association. That there is a sufficiency of smaller and more purely local bodies can readily be imagined, each one of which is, in a measure, diverting some element of strength from the two important societies above referred to. This being the state of affairs, it is with a lively sense of satisfaction that the profession in general has hailed the scheme for the coalition of these various opposing bodies and the consequent disappearance of annoying friction and clash of interests. This happy state of affairs is due to the labours of a Committee appointed some two years ago, and representing both the Institute and the Association. Each has given membership has at length been arrived at. The name of the American Institute of Architects has been preserved, and the new association will admit as members all practising architects, no matter what their professional ability. Local chapters will retain their individuality, and will be represented in the Institute by delegates, and it is hoped that thus constituted the body will elevate the profession, and the individual architect, and raise the standard of architecture throughout the country. At a joint convention of the two organisations, held in Cincinnati, a couple of months ago, the President outlined the purpose of the new Institute as follows:—

"We have much before us in the line of improving the present system of designing our Government buildings, and in this we cannot hope to accomplish the needed reform until we are able to impress upon the public mind some of the principles which should govern the carrying out of such undertakings, and bring those in authority to see the manifest advantages which should be the result of placing the designing of buildings intended for different portions of the country and covering the widest range of materials and uses in the hands of professional men who were constantly dealing with the same factors and conditions in their every-day work.

A great deal might also be said in favour of a bureau of legal intelligence, which should include the best attainable talent, to be retained as a sort of district attorney for the whole association, to assist in defining and establishing the rights of the members who most stood in need of such service, and should also include the collecting and compiling of all matters of legal record pertaining to building interests.

We also need a better plan of education for our draughtsmen than that which is within the reach of the average student in an architect's office. It is of infinitely more importance that they should be able to detail a window-frame or other portion of a building in such a manner as to admit of its proper construction and service, or correctly compute the quantities and dimensions of a building, and make complete bills of material, than that they should design a Greek god in solid bronze (made of galvanised iron) to adorn the facade of a city front, or that they should be able to construct (on paper) some of those wonderful creations which are intended to be perpetuated for all time in hemlock scantling and shingles."

The subject of public buildings is an especially burning question in a country where millions of dollars a year are appropriated to this purpose, and where one municipality after another is the result. Mr. Richard M. Hunt, the leading New York architect, and the first president of the new Institute, said only the other day in regard to this very subject:—

"The way national buildings and public buildings are generally created is a disgrace to this country. There is an architectural bureau in Washington from which the plans for all the post-office and public buildings of the land are turned out yearly. A single man is in charge of this work. It makes no difference what his capabilities as an architect and an artist are. He has more buildings to plan each year than fifty conscientious architects would undertake. The result is the worst of the public buildings of the land are practically planned by his employes—mere draughtsmen—men who would command no salaries on score of ability from an independent architect of any standing. Besides that, the nation's architect is saddled with the job of keeping all the national buildings the country over in repair. And all this he does for a salary which would not compensate a fairly good architect in private business for his own yearly business. It is outrageous; it is no wonder that the country is filled with public buildings of hideous design and in bad repair."

An architect of our acquaintance, who is of a somewhat statistical turn of mind, so to speak, gave us some figures the other day, for the accuracy of which he vouched. "There are," said he, "in New York and its immediate vicinity over 800 practising architects—so-called. Of these there are not more than thirty-five whose names can be said to be fairly well-known. That is to say, thirty-five out of 800, or less than five per cent., make good incomes, while the remaining 765 starve more or less gracefully." This may be an exaggeration, but there is a modicum of truth in it, for while there is a vast amount of building going on in the city, there is not a great deal of architectural work apparent, and the number of capable draughtsmen out of employment must be very large.

The New Madison-square "Garden" which, when completed, will perhaps be the most elaborate and comprehensive edifice devoted to the purposes of amusement in America, is rapidly rising above the ground. Its position in the very heart of the city is enough to ensure it a constant patronage, even if the ingenious combination under one roof of a circus or amphitheatre, a concert-hall, a banquetting chamber, and a theatre proper should prove insufficient.

We are informed by Mr. R. Clipston Sturgis, the secretary of the Boston Architectural Club, that that body proposes to hold an exhibition of architectural work in the Horticultural Hall, Boston, for three weeks, beginning May 12, 1890, and that contributions are requested from all those who are interested in art and architecture. The exhibits will be grouped into seven sections, including sketches of historical buildings, &c., architectural designs, photographs of executed work, interior work, special exhibits illustrative of the allied arts, including stained glass, decoration, iron work, furniture, &c.

The Enlarged Council Chamber at Spring-gardens.—In our description last week it should have been stated that the scagliola columns were manufactured by Messrs. Bellman & Ivey.

MODERN INDIAN ART.*

THE arts of India in which we are most interested are, like ourselves, aliens to the country; they belong more to the military splendour of the conquering Mongols than to the pastoral simplicity of Aryan Hindu life. The period of Roman and Greek history which left such glorious remains in Europe is scarcely represented in India by existing monuments or works of importance, and, setting architecture aside, it is only by rich arms, metal, glass, and jade vessels, woven and embroidered stuffs, and such-like objects, from the time of Akbar, that we form the standard by which modern Indian art can be judged; and a glance into the history of that period is sufficient to show how very unfair it is to compare the objects produced under such very different circumstances with the ready-made goods offered to travellers by the *bonnivalas* and merchants of the Indian cities.

We do not know how far it was the system of Hindu princes to maintain in their Courts artificers of various trades, but as it is the custom amongst the higher class of Hindus to have many things made in their houses, either by members of their own family or workmen hired for the purpose, it is probable that the princes maintained a staff of workmen always engaged in producing for the Court. But as several of the Hindu princes use the Persian "Karkhaneh," or workshop, for this portion of their establishment, it may be that this custom was only introduced in imitation of the Moghul Court. It was in these royal *karkhanehs* that all the great work was done, and as these artificers were allowed to work for outsiders rich enough to pay them liberally, a very high standard of excellence was set, which the small workers of the bazaars tried to emulate.

Very much of the high quality of the work may be attributed to two great causes. Time was not of the slightest object, as the workmen were in receipt of regular allowances, and even their families were supported. Each of these courts also had what might be called a committee of taste in the leading artificers themselves—such as the master builders, jewellers, calligraphers, illuminators, and seal engravers—who were often professional draughtsmen, thoroughly skilled in the scientific as well as the artistic branches of pattern design.

There is no greater mistake made by many writers on Oriental art than that of asserting that the knowledge of ornament is instinctive with this or other Oriental nations. Speaking with more than twenty years' experience as a teacher and a traveller, I can confidently assert that everywhere there is about the same average of people who can draw and design instinctively. In some countries there are better opportunities, or a condition of affairs more suitable to the development of art; but in the individual the quality we denominate "good taste" and its opposite "vulgarity," are both fairly meted out irrespective of position or race.

There is also not that diversity of design which is so often mentioned in relation to Eastern ornament. On the contrary, although it is difficult to find two objects exactly of a size, yet there is very little variety in their forms or surface decoration.

These Eastern peoples have done in remote antiquity what we attempt from time to time, that is, to lay down rules for the regulation of form and colour in ornamental decoration. These are known to have existed amongst the ancient Egyptians, and a canon of proportion exists in the art of the masters of the Greek and Russian Church. The Silpashastras of India do not only refer to building, but also give rules for the preservation and reproduction of the forms and features of their gods, and use secret means for hurrying these ornamental forms into simple lines of writing, from which every curve and feature can be reproduced by anyone knowing the key.

Mr. James Wild, when studying in Egypt nearly fifty years since, found the Arab workmen producing geometrical designs by empirical means, rules of thumb; and Mr. Crace, some years back, in Damascus, was shown books of similar design which, however, he was not allowed to acquire. A few years later, in Persia, where I was completing the building of the Embassy, my workmen brought me, secretly, curious book rolls of design, both for plans and buildings, and every kind

* From a paper by Mr. C. Purdon Clarke, F.R.I.B.A., read before the Society of Arts on the 15th inst.

of ornamental decoration, floral and geometrical. These were not shown to people outside of their trade, but were learnt by the men, who apparently invented beautiful designs when called upon to show their skill. When at Jaypore, Major (now Colonel) Jacob showed me some patterns with rule-of-thumb methods for producing the curves of the ogee or cusped arches similar to those I had seen in Persia, and in Cashmere I came across certain bundles of paper closely covered with columns of writing in secret character, which a weaver could transform into the curve and colour of floral forms, or inversely; if given a design—no matter how complicated—he could translate it into these columns of written character.

All these belonged to the old system under which the Oriental arts were produced and perpetuated; and the high quality of the work was due to a slight development of the style in cultured hands, working their very best in court and temple for the approval of princes and the blessing of the gods. From this state of things we come to the totally different condition under which modern art exists, and, therefore, we should not wonder if, with causes so different, the results should not be the same.

Analogous changes have been at work all over the world, and if we look at home also it is easy to see that the arts of the past have very little in common with this positive, scientific nineteenth century.

In a few places, such as Jaypore, Ulwar, and Vizianagram, royal *harkhanahs* still exist, but somehow, owing to a mistaken sense of their utility, they could be scarcely said to be producing works of art, except at the Ulwar Court, where much decorative work is going on, and I found there a bookbinder who stated that his family had been in the Palace at Delhi from the time of Shah Jehan, and when driven out, after the Mutiny they had been taken under the protection of the Ruler of Ulwar, a very intelligent and liberal-minded prince.

At Jaypore the *harkhanah* had developed into a School of Art, in charge of a very well-intentioned Bengali gentleman, who, however, seemed to try to make it self-supporting, and consequently its productions were wanting in the true artistic character.

It was only towards the close of the last century that we began to leave our mark on Indian art. This we did by first of all attempting, as far as possible, to stamp it out, as we had succeeded in doing with our national Gothic and Elizabethan styles at home, substituting for it a bald and cold so-called Classical style which, in our houses, was about as far from the actual dwelling-houses of Greeks and Romans as it was from the beautiful exteriors and interiors we were endeavouring to supersede.

Instead of this paper it would require a heavy book to describe our various attempts at raising monuments of shame for ourselves in India. And after running the gamut of the styles in Greek, Strawberry Hill Gothic, and representations of the several periods of Pointed architecture in colleges and churches, we eventually woke up to the fact that India had a style more suited to the country than any of those we had tried to introduce, and, without waiting to consider, at once started people who had little previous experience or education in Oriental design to erect important works, which, though certainly far more appropriate than any of our previous efforts, yet, unfortunately, will remain—as they are generally very well built—for a very long time as records of our want of appreciation of the essential Eastern art.

Not in architecture alone but in other ornamental arts has the same hind course been followed.

For more than twenty-five years Schools of Art have been established in different parts of India, and for a time their influence was most disastrous, although it was impossible to have procured better men as directors than the Government was fortunate enough in selecting. In all cases the directors of these schools were most enthusiastic about native art, but, unfortunately, they were fettered with a two-fold chain. On the one hand, they had in a manner to follow our system of art-education, which, do what we can, turns out more painters than designers; and, secondly, they had the wrong material in their students, and were cut off from the assistance of the master craftsmen of the art-trades, whose system of teaching was radically different from our own academic course.

As in Europe in the Middle Ages, drawing was taught in every workshop in India, and every apprentice soon became skilled in the delineation of the ornamental forms used in his craft. He had no general education in drawing or ornament beyond this; therefore his mind was free from uncertainty and weakness in the treatment of his work. Here and there a clever man would introduce some slight change or improvement; and, if this was really good, it held its own, and was adopted by others, and thus the style slowly developed. Every detail in ornament had its special name, often apparently fanciful, but always with some hidden or symbolical meaning. There were quaint histories attached to many, and an unbroken thread of meaning running through all prevented any great alteration or interference.

As the apprentices learnt to draw,—sometimes with their fingers on the sanded floor, or with charcoal on a tracing-board,—they simultaneously learnt to use tools, whether chasing in metal, carving in wood, or weaving on a loom; and with this knowledge of what the tool could do always in their minds they did not depict upon paper inappropriate forms, or those impossible to be artistically rendered in the material they were treating; and the whole individual mind being concentrated on the one particular class of work, there was the necessary emulation amongst the fellow-craftsmen to perfect it.

But our earlier School of Art system changed all this. Drawing was taught independently of its application to any particular art; a jumble of styles, Greek and Gothic, and pictorial representations of natural objects, launched them on a sea of undigested ideas, without the restrictive rudder of the requirements of any one handicraft to guide them. All the workshop lore, the rule-of-thumb methods, and valuable tradition were absent, and replaced by vague ideas of a possible rivalry with Europeans in European processes, to be rewarded by a European scale of pay.

Against this system the later School of Art masters had to struggle, and Bombay, Lahore, and Madras did so with some success by turning their schools into art workshops, where the pupils learnt and practised ornamental handicrafts, as well as drawing; and there is no doubt that had there been any combined system of working together, or had the Government shown the slightest true consideration for them, a very great success might have been secured, as also with respect to the great jail manufactures of carpets. But all the Government really cared for was to make their art workshops self-supporting, and, therefore, the superintendents were forced to work down to the level of mercantile people, who only want cheap goods. I do not wish in any way to blame the superintendents of these institutions, on the contrary; they have only done their duty, and I believe they have been in constant strife with the authorities in trying to bring about a better state of things, and invariably with the same result, that when, after several years' insistence, they at last succeeded in getting a consideration of their proposals from the Central Government authorities, — who, in India, rule all matters,—the short term of office of the high officials expired, and the superintendents had to start all over again.

The arts of stone and wood working are in India very closely connected, both in Hindu and Moghul architecture. The two very different modes of construction are so mixed, and borrow so much from each other, that it seems almost a principle that the masons treat stone like carpenters, and the carpenters use wood after the fashion of masons, in solid masses, depending upon weight for stability. The modern form of both arts, excepting in Nepal and the extreme south, has become distinctly Saracenic, retaining always certain peculiarities of the Hindu style, which stamp it with a distinct character, and separate the Hindu Saracenic styles from all other varieties of Mohammedan architecture.

For native use, architectural wood-carving is still a very important industry, and I question whether it has in any way deteriorated. It is so important and widespread that I cannot attempt even to give the leading districts of its production, as I should fail to do justice to the subject for want of space. There remains, therefore, only to notice the inlaid furniture of Hoshiapur, in which *shishan*-wood is inlaid with ivory—often with the most graceful and happy effects—in Saracenic style, and the

purely Hindu carving of Mysore and Kanara, which, for finish, is unequalled in any part of India. The decorations of the latter, unfortunately, are merely transcripts of the designs used in the temples, both wood and stone, and although most exquisite in execution, and often in drawing and composition, the reckless use of labour in their production places them above the reach of ordinary commerce, and the faulty construction of the objects makes them unsuitable for any practical purpose.

Stone-carving belongs principally to the North-west Provinces and Rajputana, and here, again, is an art which cannot in any way be said to have lost ground. All travellers in India know the wonders of the past, the temples at Abn, Akbar's dream in stone at Fatehpur Sikri, and the Taj Mahal; but if they doubt that it is possible to emulate these works, it is only necessary to visit the modern cities of Khoria and Balanshar to see that natives, working for themselves, can still design and do all the work they produced in the old time. Then the college buildings at Ajmere, Colonel Jacob's People's Palace at Jaypore, Mant and Chisholm's royal buildings at Baroda, and Chisholm's Government buildings at Madras, show how much can be done where Indian and European work together; and we should be thankful for a movement in the right direction in time to save us from the reproach of having destroyed a school of architecture which, if it could not claim to rank amongst the great styles of the world, yet at least had many beautiful features, and was certainly the most suitable to the country and its mixed races.

In conclusion, I am forced to repeat that a very great responsibility rests upon ourselves for the part we have taken in destroying the ornamental handicrafts of India. Nor is this much lessened by the costly efforts in recent years to save ourselves from this reproach. Whilst handicrafts are perishing before our eyes, which in many instances are all that is left to us of the great arts of antiquity, we are squandering large sums on antiquarian historical research in India of little practical value. We have spent over 30,000, in useless copies of the cave paintings at Ajanta, and yet we are allowing the few craftsmen to die out who possess the secrets of some of the noblest arts of antiquity, such as true fresco paintings; not the half-wrought work of the Middle Ages, but the marble-like, hard, silicious work which we find at Pompeii, and still practised in India.

The reason of all the anarchy and destruction we have introduced into the artistic productions of India is our failure to appreciate the great value of workshop lore and rule-of-thumb trade secrets, which all the colleges and schools in the world can never replace when once lost; and, worst fault of all, our habit of considering art questions as mere matters of individual taste, and not as pertaining to a science as positive as any other, and only more difficult owing to its vastness, and the want of common agreement as to its terms.

It is to the preservation of the old workshop traditions that we should devote our energies if we are in earnest in all our talk about preserving the industrial arts of India. It is this workshop life of master and apprentice, as old as when Jacob served Laban for seven years, that brought these arts into existence, and only these conditions will in any country maintain true art in vigorous life. Great craftsmen like William Morris and Herkomer have realised that this is the only way of salvation in the ornamental arts, and if there is to be any future for our now middleman-crushed arts, it will come from work produced under such happy conditions as exist at Merton and Bushey.

Last of all, the Indian Government cannot clear itself from blame by spending annually a large sum of money on schools of art, museums, and archaeological work, when it neglects every opportunity for giving effect to the repeated statements of its desire to encourage native art. When presents are exchanged with Indian and other Oriental princes, the best craftsmen in the country should be employed to prepare the gifts, and a fashion set to the princes and wealthy, who would gladly follow such a thoroughly Oriental and congenial example.

The newly-built palace of the Viceroy at Simla afforded such an opportunity, but instead of illustrating the art resources of the country, even from the School of Art point of

view, and overlooking the fact that the fastidious Rothschilds of Paris, and Vanderbilts of New York, were obtaining furniture and decorations from Bombay, the Viceroy in Council handed over the decorations, upholstery, and furnishing to an advertising firm in the Tottenham-court-road, London. It is not to be wondered, therefore, that with this example, the Gaikwar of Baroda followed suit, and, flying a little higher, furnished his palace from the Faubourg St. Antoine at Paris.

There is only one remark I wish to add, and that especially for any Indian gentleman who may be present. I most sincerely believe that as the rulers of India we have ever had but one idea, and that the amelioration of Indian peoples; and if, in carrying out this idea, we have neglected or injured native Indian art, it has been from the same mistaken good motives which led us, during the same ill-starred period, to neglect and injure our own indigenous English art. If we introduced a travesty of Classical architecture in the last century at Calcutta, and have since filled the palaces of rajahs with libels on French furniture and decoration, we were doing the same at home; and if, some years back, the museums of Calcutta and Madras contained English art pottery, Italian stone carvings, and pictures, whilst Indian art works were conspicuous by their absence, we in England, to this day, show just as little respect in our national museums for English art, taking no trouble to systematically collect examples to illustrate its history, although we pay the highest price of any of the nations of the world for anything in the shape of a foreign "curio."

THE SURVEYORS' INSTITUTION.

THE following Student Candidates have passed the examination for the Professional Associateship:—

- Aylon, Cecil Hugh, London Colney, St. Alban's, Herts.
 Bancroft, Frederick Herbert, 83, Mosely-street, Manchester.
 Barclay, Thomas, Lonsdale House, Alcester-road, Moseley, Worcestershire.
 Beadell, Maurice Frederick, 97, Gresham-street, E.C.
 Buckland, Herbert Tudor, The Oaklands, Augustus-road, Mosley, Birmingham.
 †Cobham, George William, 3, Edwin-street, Gravesend, Kent.
 Garrard, Arthur Norman, 8, Kensington-court, W. Green, Alexander Ernest, Kingsdown Lodge, The Common, Ealing, W.
 Hampton, George Frederick William, 8, Pall Mall East, S.W.
 †Hayward, Frederick George, 4, Warwick-road, Upper Clapton.
 Lake, Vivian Davoy, 17, Glanville-road, Tavistock, Devon.
 Leaving, Henry John, 60, Holland-road, Brixton, S.W.
 *Merry, Arthur Walker, Southcourt Farm, Leigh-ton Buzzard, Beds.
 Moynaux, Herbert Ernest, 83, Cazenove-road, Stamford Hill, N.
 Nockolds, Alfred George, Castle Hill House, Saffron Walden, Essex.
 Ogden, Michael Guy, Wensleydale, Lingfield-road, Wimbledon.
 Potter, Herbert George, Gardner House, Hampstead, N.W.
 Savill, Edwin, Chigwell, Essex.
 Smith, James, 8, Oxford-street, High Wycombe, Bucks.

 Smith, James Frederick Kemp, Market Harborough, Leicestershire.
 Snaillum, Walter Wadman, 33, St. George's-terrace, Trowbridge, Wilts.
 Townsend, George James, The Nook, Trafalgar-road, Twickenham.
 Wood, Edward Bryan, Langley Green, Chippenham, Wilts.
 Wood, Charles Bruce, 37, Irene-road, Parson's Green, S.W.

The result of the examination for the Fellowship will appear next week.

CRYSTAL PALACE ENGINEERING SCHOOL.

ON Saturday, on the closing of the Easter term, Professor Francis Elgar, LL.D., F.R.S.E., C.E., Admiralty Director of Dockyards, presided at the usual meeting of the students and their friends, and others interested in the school, and presented the certificates awarded by the Examiners, who were, on this occasion, Mr. F. Wentworth-Shields, C.E., and Mr. J. P. Knight, A.M. Inst. C.E. It was mentioned in the course of the proceedings, that thirty-five years ago Mr. Wentworth-Shields had been intimately associated with designing and superintending the construction of the tower in which they were assembled, and that Mr. Knight, his co-examiner, had passed through the school as a student.

Professor Elgar, in his address to the students, referred in complimentary terms to Mr. A. M. Struben, a student from South Africa, by whom the award of the medal of the School had been achieved in his having obtained the necessary nine certificates, an evidence of all-round merit more honourable and difficult of attainment than the highest place in single subjects, and well worthy of emulation. To pass well in examination was, of course, most satisfactory; but the after career of the student as an engineer might not correspond with his place in the examination-list; his success would depend upon the manner in which he applied his knowledge, and power of adapting himself to new conditions and circumstances as they occurred. The students who were comparatively low in the examination might, in the future, attain a higher place and greater success than their rank in the examination-list might indicate. There were accidents that interfered with their success, the state of health, not being in good form, errors of judgment, and other causes. The best students did not always turn out the best engineers. On the other hand, it should be remembered that the examination questions did not reach all the useful knowledge of which a student might be possessed, or disclose the qualities essential to success with which he might be endowed.

The Professor then presented the certificates. The lectures for the term were on "Steam and the Steam-engine." The highest number of marks attainable was 296. Sixty-three students attended the lectures; fifty-eight were eligible for examination, thirty-six passed satisfactorily and obtained certificates. Mr. H. E. Heald was first with 263 marks; Heald was also first in the order of merit for work in the Fitting-Shop.

§ Driver Prize, 1890.

Mr. F. D. Maw was second in lecture examination with 243 marks, and an equal first for work in the drawing-office.

In the Drawing-Office nineteen certificates were awarded; T. Nitta, an equal first, with certificate, 197 marks, for lecture examination. For work in the Pattern-Shop twenty-one certificates were awarded. A. F. Franks and G. H. Laidman equal firsts; the last-named had also a certificate for lecture examination, 205 marks.

For work in the Fitting-Shop, eighteen certificates were awarded.—Heald, already-mentioned, first.

For students of the second year's course,—civil engineering,—F. W. Wheadon was first for students of the first term; E. M. Proes for students of the second term; and A. M. Struben (medallist) for students of the third term.

In the Colonial Section, four certificates in three grades were awarded, O. C. Ormsby being awarded a certificate of the last grade.

In his address at the close of the proceedings, Mr. J. W. Wilson, Principal, stated that 832 students had passed through the school, and that he had trustworthy intelligence concerning 370 of these, who were occupying responsible professional positions.

The usual votes of thanks concluded the proceedings.

THE SANITARY INSTITUTE:

EXAMINATIONS FOR INSPECTORS OF NUISANCES.

AT an examination held for Inspectors of Nuisances, April 17 and 18, 1890, 120 candidates presented themselves. Questions were set to be answered in writing on the 17th, and the candidates were examined *visà voce* on the 18th.

The following candidates were certified to be competent, as regards their sanitary knowledge, to discharge the duties of Inspectors of Nuisances:—

- | | | |
|----------------|------------------|-----------------|
| Abbott, A. R. | Groom, W. E. | Saunders, P. |
| Baron, W. | Halstead, R. | Savory, C. |
| Bond, G. | Harris, F. | Simpson, J. |
| Chambers, M. | Holland, P. | Smith, J. S. |

| Graves, M. D. | Ruscoe, E. H. | Wrack, H. P. |

THE LONDON COUNTY COUNCIL.

THE London County Council held its first meeting in its enlarged Council Chamber at Spring-gardens on Tuesday last, the Chairman, Lord Rosebery, presiding.

Review of the First Year's Work of the Council.

The minutes of the last meeting having been read and confirmed, the Chairman said he had hoped that day to have been able to lay on the table the annual reports of committees, but unfortunately many of them reached him late, and two of them had not yet arrived at all, and therefore it would not be possible for him to do so. In the meantime, he would commence the review of the year that he proposed to lay before them, and he would continue it at their next meeting.

Council Chamber and Office Accommodation.—His (the Chairman's) first pleasant duty was to bid them welcome back to their home. He hoped that the hall in which they were assembled would be found, probably not so magnificent, but more available for work than the Guildhall. He did not think they could ever sufficiently express their gratitude to the Corporation of London for their hospitality in that hall, but at the same time he thought, without looking a loan horse in the mouth, that he might say that utility had been a little sacrificed to magnificence, and he thought that very often false issues were raised and divisions took place under a mistaken apprehension, because of the bad acoustics of that building. If gentlemen seated on one side could not hear arguments advanced on the other it was quite clear that no satisfactory conclusion could come before the Council for decision. Later on in his speech, the Chairman

Mr. R. W. GIBSON, ARCHITECT.

aid on this subject that it would be ungrateful at that meeting not to notice the work of the Council Chamber and Offices Committee. Of them it might be said, "*Si monumentum requiris circumpice.*" Of course, it was too early to pronounce definitely on the merits of that chamber. The only thing that they cared very much about was that it should be well ventilated, and that it should be a good room for hearing in; but at any rate it was not too early to congratulate the Committee and Mr. Blashill, their Architect, on the very handsome apartment that they had furnished them with. But they had even more important work than that. Owing to the constantly developing work of the Council they had had to hire 8 and 17, Spring-gardens, 56, Charing-cross, and 40, Craven-street, Strand; and the Chairman of the Committee thought they would soon have to hire another. [Sir W. de Souza: I believe so.] The Chairman, continuing, said that was five houses that they had already to hire outside their own building. Though they might be able to get along for a certain time with that as a makeshift, they could not permanently hope to conduct their business efficiently in them, and it was under that impression that the Council, some short time ago, by a majority of 9—a small majority under the circumstances—determined that this Committee should have authority to look out for a site for the new offices. He did not understand that it was the intention of the Council that they should get a site or try to find a site regardless of expense or other considerations, but it was placed in their power, if they found such a site, to report that they had found one to the Council, and nothing more than that. He believed that they were still looking out for a site. Of course sites did not commonly occur in London of the magnitude required, but he himself did not anticipate that the selection would fall to the present body.

The Work of the Committees.—Speaking of the work of the various Committees of the Council, the Chairman said that one difficulty that they had had to contend with in regard to the Committees was that some of them at times overlapped each others' functions and work, but was marvellous, considering in how great a state the first references to these Committees were settled, how successfully on the whole they had been enabled to be carried out. The fusing of the Working Classes Committee had overlapped the Sanitary and Corporate Property Committees on several points, but by their ample system of conferences this overlapping did not present any serious complexity, and he did not know why it should in the future.

The Housing of the Working Classes Committee had sent in their report, and they stated their wide resolution, as he thought it, not to take rapid or inconsiderate action that might prejudice their future usefulness, but to view their vast field of operations as a whole. He remembered when the Committee first began a good many members said, "Let us do something at once to show that we are in earnest," but he believed the Committee, as a whole, chose more wisely in determining not to do anything at once without the most ample consideration, because to put their foot forward and draw it back in a matter of such importance could not but affect seriously the character for sober acting of the Council. They subdivided themselves into four geographical sub-committees, and they collected from vestries, District Boards, public boards, and private companies all available information. They had further examined the state of the law, and came to the conclusion that amendment or consolidation was imperatively required. They regarded this view on the Home Secretary, and consolidation had been promised by the Government; and he did not doubt that the further recommendations of the Committee, were also under the favourable consideration of the Home Secretary. The Committee further represented that the amendment of Torrens's Acts was necessary if effective action was to be taken with regard to insanitary areas. That this question was urgent was apparent from the fact that the Committee had had under consideration no fewer than 198 insanitary areas, most of them small. They found great difficulty in working Torrens's Act in regard to these insanitary areas because they had to work them through the district authority, and the district authority preferred working them through Lord Cross's Act, but he hoped they might expect from

the Government some assistance in the matter of the amendment of that Act. The Housing of the Working Classes Committee had not been content with this. They went to Glasgow, if not to other towns in the north, and made a very careful inspection of the municipal lodging-houses in the second city of the Empire. They would see by the very careful and able report which the Committee had laid on the table that they had now come to the conclusion that they would take action as the result of that experience and learning. He should propose to defer the consideration of the report as to municipal lodging-houses for at least one week in order to give fuller time for its consideration.

The Parks Committee illustrated very strongly and strikingly the results of popular as compared with indirect election. The late Metropolitan Board of Works felt an interest in parks, but it was not an interest that came from a direct impulse, and he might illustrate that by saying that, whereas in nine months the Parks Committee of the late Board only held twenty-four meetings, the sub-Committees and Committees of the parks now held no fewer than 129. The fact was the members came from their constituencies, finding those constituencies greatly in earnest about the parks question, and with that impulse they set themselves to work with great vigour to deal with it. They divided themselves into four geographical committees, besides again sub-committees, and they knew from their reports with how much earnestness they set themselves to visit the localities which they superintended.

The Main Drainage and Bridges Committees.—These were the two committees which were united by the interesting link of the Engineer—the Main Drainage Committee and the Bridges Committee. The Main Drainage Committee, as they all knew, was one of their most important committees. It had before it probably the greatest problem of any of their committees, and they had suffered very much from the unfortunate fatality that had beset the post of Chief Engineer of the Council. When they considered that Sir Joseph Bazalgette resigned at the commencement of the Council; that after some time taken up in selecting a successor for the vacant post they were fortunate enough to find Mr. Gordon, but unfortunately enough to lose him at the time he had received their whole confidence; that Mr. Dunscombe was attacked by ill-health as soon as he took office, they could well understand the difficulties under which the Main Drainage Committee had laboured during the past year. They wanted every assistance that the Council could give them, and he was sure that his friend Mr. Arnold, the Chairman, would not deem the assistance of any one superfluous in dealing with the vast problem before him. What was the problem? Grave complaints had arisen from the inefficiency of the pumping machinery, and that at any time in the heat of summer a state of things might arise which might produce a most poisonous condition of the metropolis. They had therefore to consider what was required in the way of the repair and reconstruction of the pumping machinery. They had taken over from the Metropolitan Board of Works contracts for an enormous amount—Barking outfall works, 448,567*l.*; similar works at Crossness, 259,816*l.*; sludge vessel (Barking), 24,785*l.* They had had before them the question of the sludge vessels, which was not merely important as raising a vast string of questions, but also as involving the whole position of the sewage system. The sludge they had to take to the sea, or get rid of in the sea, or somewhere or other, was no less than 70,000 tons a month. The Council had shown a reluctance to lay down a principle, that it would abolish this system of taking their sludge by vessels, and they had endeavoured to get time with regard to the consideration of the problem by telling the Committee to hire sludge-vessels as a makeshift. The Committee reported that it was impossible to do this, and although they were able to carry on for the present, they could not very well long postpone the consideration of the great problem which would force itself upon them before the summer recess. In the meantime it was engaging the attention of the Committee. Their main drainage works were planned for London at a time when the population of London was 2,000,000 less than it was at the present moment, it was daily increasing, and, furthermore, they would have places like Erith apply-

ing to be included in their main drainage system; therefore, he thought they had a problem before them which he did not exaggerate in saying was by far the greatest before the Council at the present time. The Council had authorised Sir Benjamin Baker to confer with their present Chief Engineer (Mr. Binnie) as to the best means of dealing with this problem. He believed that in acting in that way the Council had behaved wisely in not rushing to a decision with this drainage problem hanging like the sword of Damocles over their head. The other committee which was connected with the Engineer specially was the Bridges Committee. They had not a long report to send to them, but they had had the Free Ferry at Woolwich to superintend. Members would remember that up to within a day, he thought, of their coming into office they were called upon to open the Free Ferry at Woolwich. He was ordered by the Council to open it, which he did very silently and very reluctantly, because he felt that in opening that ferry they were opening something with which they had nothing whatever to do, and that the honour of opening it should have fallen upon his predecessor in that chair. However, as the Metropolitan Board of Works would not open it, it fell on the Council to open it, and he thought they might congratulate themselves that their very first entry into office coincided with a very great boon to the people. Two and a half millions of people had crossed by that ferry already. That alone showed the advantage it had been. The Bridges Committee had been very much taken up with the re-building of Battersa-bridge, the completion of which was promised for April, but owing to the difficulty of obtaining iron work it would not be open, he was afraid, till July. That was not the fault of the Committee, who had given it all the attention that had been in their power. But, of course, the real problem before the Bridges Committee was one which he hardly dare mention, he meant the Blackwall Tunnel—means of communication at Blackwall, the "provisional works" at Blackwall; as long as he remained in that chair he would never give way to the word "experiments." There was a feeling about the Blackwall Tunnel, that he was afraid prevailed largely in the Council, that they would just as soon hear its name mentioned as that of the coal and wine duties.

Among other Committees whose work was referred to by the Chairman were the *Asylums Committee* and the *Fire Brigade Committee*. The Chairman, having spoken for three-quarters of an hour, postponed the conclusion of his review of the work of the Council until next week.

On the motion of Mr. Boulnois, M.P., seconded by Mr. Lemon, a vote of thanks was passed to the Council Chamber and Offices Committee; and it was also resolved to print the Chairman's statement *in extenso*.

The Council having transacted a great deal of miscellaneous business, and taken its first division in the new lobbies (which resulted in a tie, 43 to 43, on a proposal of the Parks Committee to take over certain open spaces, the Chairman declining to give a casting vote), adjourned, after a sitting of nearly four hours.

The English Iron Trade.—There has been a further depression in the English iron-market this week, the demand being exceedingly quiet on the part of users, who expect to see lower prices still, while producers are unable to offer anything at ruling rates, considering the cost of production. From all pig-iron centres the reports show a very dull market and lower prices. A large business has been done in Scotch warrants, with quotations going down steadily. Scotch makers' iron is quoted from 6*d.* to 2*s.* 6*d.* per ton less. Cleveland pig has lost 1*s.* 6*d.* per ton during the week. Hematites have declined to a like extent. Spiegeleisen has been depreciated 3*s.* a ton since the beginning of March, and old materials are from 1*s.* to 2*s.* lower in prices. The manufactured-iron market is very quiet, values having receded from 2*s.* 6*d.* to 1*s.* on the week. Although steel works are, as yet, fairly well provided with orders, there is very little new business, and steel is cheaper to the extent of from 2*s.* 6*d.* to 7*s.* 6*d.*, and even 1*s.* Ship-builders are not looking forward with any great confidence, while engineers are taking very little fresh work.—*Iron.*

Illustrations.

UNITED STATES TRUST COMPANY'S
PREMISES, NEW YORK.

THIS building, of which we give a view of a portion of the front, is designed by Mr. R. W. Gibson, an English architect now settled in New York. The illustration, as will be at once seen, is from a photograph taken from the actual building, a fact which explains the presence of the motley group of boys who have introduced a human element in the illustration which we could well have spared. The photograph being a very good one otherwise, and the building a good representation of what may be said now to be the modern American style of architecture, we give it as it stands.

The building was the subject of a competition in which Mr. Gibson's design was successful. We append plans of two floors; and the following quotations from the report sent in by the architect with the design will furnish some further information as to the intention and construction of the building:—

"The style adopted is Romanesque. This may fairly be said to be the National style of the United States, and it is the only one distinctly deserving that title. In its ready adaptability to modern purposes it has assumed new beauties, without losing those more ancient. The unaffected dignity of large buildings is perfectly expressed by it. The severest simplicity is permitted in it, and the most elaborate and fanciful carving. It is eminently practical in its construction and weather resistance. It demands no useless expenditures in cutting and polishing facings and pilasters. These are the reasons why American architects are so rapidly appreciating the Romanesque style.

The front is designed with the stories grouped in tiers of carefully-studied proportions.

The first story and basement are massive and almost severe. The second story is of rich horizontal composition, as a finish or ornament to that below. Then the three succeeding stories are grouped in a central tier, expressive of their purpose, with large, round arches resting upon handsome carved capitals. Upon these is one story absolutely plain, for the sake of repose and apparent weight, giving a due importance to those below. The remaining stories form a cornice group. They are designed with long shafts and high proportions, so that they will be effective even when viewed from the somewhat narrow streets.

The Kibbe sandstone and Millford granite are recommended as the materials, although the design could be equally well rendered in others.

An entrance, enriched more than the other parts, gives access to the principal floor. This is raised a few feet above the street level, so as to obtain command and importance, and it affords the advantage of light to the basement, and lesser depth of foundations. The floor can be made nearer street level if desired.

Whether with or without a roving basement the entrance is designed to occupy the height of principal story.

The insignificant doorways of many modern buildings of great pretension are sufficient arguments in favour of this arrangement.

The windows of the front are of ample size for perfect lighting, and the external effects are obtained without making any of them inconveniently high or low within.

The windows of the banking room, and nearly all others, have straight heads close to the ceiling, admitting the most valuable light.

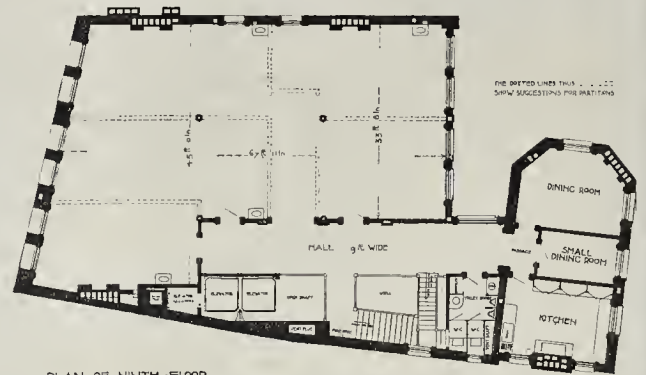

All windows are simple sashes of plate glass. The stonework of the front is all of genuine, massive, truthful character, with no concealed iron supports or imitations. The elaboration by carving can be increased or decreased to any degree required.

The main entrance hall is lighted by the great doorway, and, in addition, by the very large open space only partly occupied by the elevators and stairways. This is 36 ft. long and over 8 ft. wide, built with glazed brickwork and other finishings to reflect the light.

The floor of the public halls and the banking department are to be of Lonsdale marble.

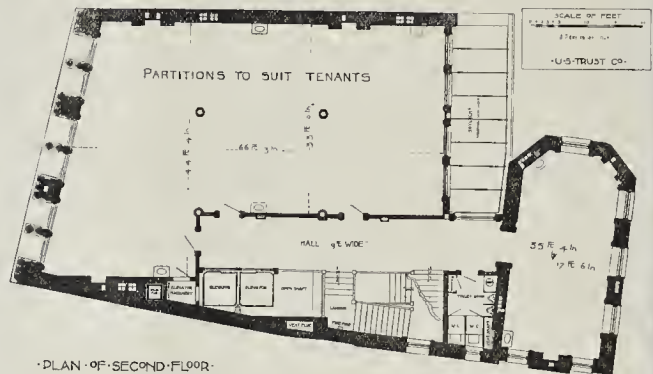

The wainscavings are to be of Champlain marbles, mostly white, with relieving mouldings and bands in colour, mostly yellow. The characteristic of the Champlain marbles is their extreme hardness. They are equal in price with those in general use, and they are among the most beautiful in the world. The white has a soft yellow tinge much warmer than that in general use, and the various colours are equal to the best used in Florentine work. The use of yellows will relieve the monotony of the white without lessening the light and cleanliness. Bronze anchors and bolts will be used to secure the marble work.

Open fireplaces are provided throughout the building, each fitted with which forms an extracting shaft of the best kind. There are also large shafts

PLAN OF NINTH FLOOR

R. W. GIBSON, ARCHITECT, NEW YORK.

PLAN OF SECOND FLOOR

The United States Trust Company's Building, New York.

adjoining the boiler flue, which will be connected to rooms, &c., by pipes horizontally.

Arrangements can be made for cooling certain rooms in summer if desired.

Heating will be accomplished partly by indirect radiation in connexion with the ventilation, and partly by direct radiators.

The strength of the building will be of very high standard; and the stone and granite recommended are both unusually strong. Actual experiment has shown that from 3,000 lb. to 14,000 lb. per square inch are required to crush Kibbe stone, and the granite is of even higher power of resistance. The building has been designed to sustain a load of 200 lb. per square foot upon the floors, and any separate sections will be capable of a greater strain.

The walls are according to the building laws of the City of New York—in some parts are in excess of those provisions.

The cost of the building has been approximately estimated. While it may be influenced, for economy or otherwise, in the detail of finishings, the sum stipulated, viz., 400,000 dol., will give a fair substantial interpretation of this design according to the specifications."

SHEFFIELD MUNICIPAL BUILDINGS
COMPETITION.

WE publish two more of the designs submitted in this competition, that by Mr. J. W. E. Tilley, of Belfast, and that by Mr. W. Henman, of Birmingham.

In regard to the first-named design, Mr. Tilley sends us the following remarks as to some of the points kept in view:—

"The suggestion that the basement floor might be considered a lower ground floor has been acted upon, and there is an entrance to it from Norfolk-street. It contains the health department, and some of the minor rooms of the Water and Borough Surveyors' departments, which were to be on the ground-floor.

It was thought desirable to have a direct entrance to the ground-floor from Surrey-street, in addition to the principal one in Pinstone-street, as by that arrangement the Accountant's general office would be well suited for a general rate office, for which, it is said, it will probably be used at some future time

As the plans show the general arrangement, it need only be said that the positions of the several departments agree with the "Instructions," and the rooms in the majority of cases are larger than the given minimum sizes; also, that all drawing offices have a north light.

The Council chamber has been placed in such a position as would secure quietness and good lighting, as well as a separate entrance for burgesses to the gallery, without their having to otherwise enter the building.

The reception and dining rooms and the Mayor's parlour are arranged en suite, and can be used as one room or divided into three, as desired.

As suggested, the office lavatories are grouped together on the lower, ground, and second floors; while the two public lavatories are on the lower ground floor, at the Cheney-row end of the Pinstone-street front.

The future extension of the building would be an additional story towards Cheney-row.

The building would be fireproof, the floors throughout being of steel decking. The fronts would be faced with some stone that has been proved to weather well in Sheffield, and the roofs slated.

The heating would be by low-pressure steam, fresh air being drawn in at a turret at the corner of Surrey-street and Norfolk-street, and heated by steam-pipes in air-chambers under the different corridors before being discharged into the building, while outlet flues near the ceilings would remove the foul air.

In addition to the above, radiators would be placed at the entrances, and near the windows in offices without fireplaces. The ventilation of the lavatories would be kept entirely distinct from that of the main building.

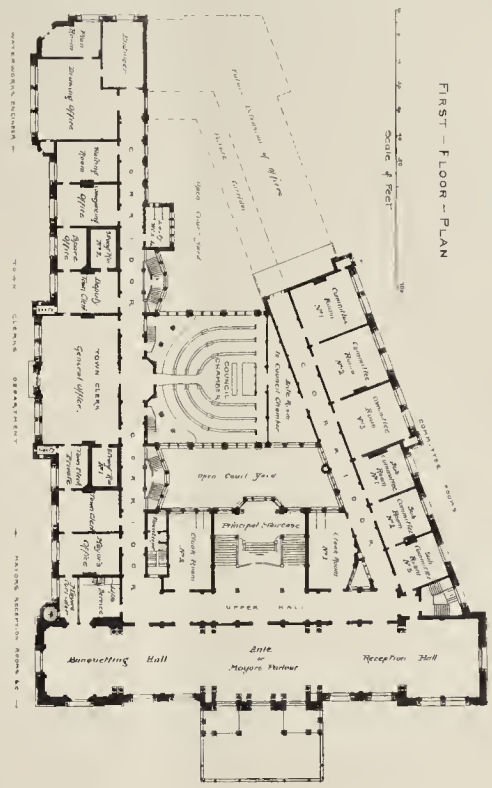

The lighting throughout would be by electricity, the boilers, engines, and dynamos being in an out-basement towards the Norfolk-street end of the building."

In regard to Mr. Henman's design we quote the following passages from his report which accompanied the drawings:—

"In the general arrangement of the plan adopted and the external design I have been influenced by the following, among other, important considerations, viz.,—

1. The convenient grouping of the offices, &c., in the separate departments,

SHEFFIELD MUNICIPAL BUILDINGS COMPETITION
 DESIGN SUBMITTED BY MR. W. HENMAN, A.R.I.B.A.

ELEVATION

Lower Ground Floor Plan.

Convenient access between those departments well-lighted corridors and easy staircases.

To give, as nearly as the requirements of actual construction admit, offices, &c., of the size specified in the 'Instructions,' and to place them on the floors indicated.

To arrange the several rooms of different sizes and the proportions of each without the intrusion of mezzanine floors, which, in public offices, of questionable convenience.

To utilise the fall in the ground so that towards east and the lower floor becomes in reality the ground-floor.

To provide externally an effective predominating feature, which, while not clashing with recent buildings, will mark the edifice as being of important municipal character.

To take the last consideration first, I am of opinion that the near proximity of the Tower of St. Martin's Church, with its dome-like termination, precludes the introduction of a dome as the principal feature of the new building as well as of a central tower, but, inasmuch as Surrey-street, Fargate, Fould-street, and Barker-pool, all converge towards the north-west corner of the site, and that at the principal front towards Pinstone-street (west from the church tower, indicate that there should be the main feature in the design.

On turning up this argument, and in consideration of the minute details of the surrounding streets, it is evident that to give an imposing character to the Municipal Buildings such tower should be of ample dimensions, both in bulk and height.

The smoky atmosphere of Sheffield gives a gloss to buildings severely Classic in design, and the minute details of later Gothic and Baroque styles are quickly marred thereby. I have opted a free treatment, Romanesque in character, in order to secure the boldness of the former, combined with the piquancy of the latter, which, however, can only be faintly indicated by the small-scale elevation.

The front is recessed to secure a play of shadow and variety, as well as good light to the lowest floor.

Lighting.—Particular care has been exercised in order to secure the perfect lighting of all rooms, corridors, staircases, &c.; the windows are numerous and of ample dimensions. It is intended that the light should be abundant, but there is an abundance of space on the lowest floor for the installation of electric-lighting plant.

Heating.—Space for boilers in a central position provided below the lower ground floor, so that all principal rooms, offices, corridors, &c., may be warmed by hot water, open fireplaces being provided for use in the private offices, &c.

Ventilation.—It is proposed that proper ventilation shall be effected by a system of propulsion, fresh air being drawn from a suitable source, warmed in cold weather, and forced by fans of a Blackham fan-wheel through channels along the corridors, with suitable openings into the several rooms, exhaust-shafts being provided for the exit of the air.

Materials.—Externally, all the street-frontages of the building towards the churchyard to be faced with selected stone of good colour, granite bases being supplied for the columns to principal entrance-porches. Around the inner courtyards flags of cream-coloured bricks with stone dressings to be employed. Internally, except to the entrance-hall and grand staircase, which are to be of stone and marble, the walls, ceilings, &c., are to be finished in plaster. The floors to be of fireproof construction, laid with encaustic tiles mosaic to the halls, corridors, &c.; boarded to the rooms, offices, &c.; in oak to the principal apartments, with parquet borders.

SCULPTURE: "TURENNE ENFANT" AND "LULLY ENFANT."

THESE two statues, both of which have been purchased by the Municipality of Paris, are interesting examples of a kind of ideal portrait sculpture to which French sculptors have never taken of late years, viz.: the representation of the boyhood of eminent men.

The statue of Turanne was in the Salon of 1878; the sculptor, M. Hercule, was a pupil of Caffrey, and some years since executed a work titled "Primevère" which attracted much notice and was purchased by the Corporation of Paris, and is now in the Salon at Auteuil. The "Turanne" will probably be either erected in some public site in Paris, or also placed in an Art Museum.

The figure of Lully the musician, who filled a considerable place in the early development of modern instrumental music, is by M. Gaudet. The figure is in bronze, and is to ornament one of the squares or public gardens of Paris.

Appointments.—Mr. C. J. Dawson, F.R.I.B.A., Barking, has been appointed architect to the newly-formed School Board for Barking, Essex.

COMPETITIONS.

Proposed Municipal Buildings, South Shields.

On Monday, the 21st inst., a meeting of a committee of the South Shields Town Council was held at the Marine Board Offices, Mill Dam, to receive the report of Mr. G. G. Hoskins, F.R.I.B.A., the assessor appointed to make a selection from the thirty-three sets of competition drawings sent in for this building. The scheme is estimated to cost 10,000*l.* The three sets selected by Mr. Hoskins in order of merit are those bearing the following mottoes:—(1) "Constable;" (2) "Ad Rem;" (3) "Magistrate." Mr. Hoskins's report having been unanimously adopted, the sealed envelopes were opened, when the names of the successful competitors were found to stand as follows:—(1) Messrs. Perkin & Bulmer, of Leeds; (2) Messrs. Clarke & Moscrop, of Darlington; (3) Mr. J. H. Morton, of South Shields.

Yardley Board Schools.—We are officially informed that, acting on the advice of Mr. William Henman, A.R.I.B.A., of Birmingham, who was appointed the assessor in this (limited) competition for schools at Red Hill, Coventry-road, for 1,000 children, the Board has selected the design of Messrs. Crouch and Butler for execution, and awarded a premium of 15*l.* to Mr. W. N. Gething and one of 10*l.* to Mr. F. J. Yates. Six sets of designs were received.

ARCHITECTURAL SOCIETIES.

Cardiff Architects' Society.—The architects of Cardiff held a meeting on the 16th inst., and adopted rules drafted by a committee appointed for the purpose at a previous meeting held on March 12, when it was resolved to form the Cardiff Architects' Society, for the advancement of the profession of architecture, and the consideration of questions of professional practice. The architects in practice in Cardiff number about thirty, and the Society will, it is believed, include all these as members, in addition to many others in the surrounding district. The Hon. Secretary is Mr. F. Baldwin, of Church-street, Cardiff.

Edinburgh Architectural Association.—On Saturday, the members of this Association, under the leadership of Mr. David Macgibbon, visited that relic of the younger branch of the Douglases, Tantallon Castle. On arriving, attention was drawn to the immense size and strength of the wall of encinte, with its central keep and gateway, and to the method which James V. had adopted to render the walls fit to resist artillery. The remains of the outer ditches and of the earthworks, which had probably been thrown up during some of the sieges of the castle, were also examined. The operations recently executed by Sir Walter Dalrymple were then pointed out. By these a great deal of the rubbish which had accumulated in the ruins has been removed, and safe access has been provided to various portions of the structure formerly inaccessible. Particularly, the stairs leading to the battlements of the great wall of encinte have been restored, and the party were enabled to mount to the top and enjoy the fine prospect obtained from there. The defensive arrangements of the battlements and the central tower were noticed, and also some round shot of iron, 6 in. in diameter, which have probably survived since the siege of Cromwell. The large hall and other buildings remaining of those which formerly surrounded the courtyard were commented on as indicative of the work of a late period. Tantallon was originally a Royal castle. In 1377 Alan de Lauder was constable. Like Doune Castle, it belonged to and was possibly rebuilt by Murdoch, Duke of Albany. In 1475 it passed into the hands of the Earls of Angus, with whom it remained till taken by the Covenanters in 1639, and was afterwards destroyed by Cromwell.—*Scotsman.*

The Albany Club at Kingston-on-Thames. occupying the fine old mansion of the late Sir Charles Freaque, recently known as "Bank Grove," was formally opened on the 12th inst. It is delightfully situated on the banks of the Thames, with a frontage of 420 ft., overlooking one of the most charming parts of the river. The club-house contains commodious dining and drawing-rooms, library, morning, billiard, smoking, and card-rooms, and the whole have been furnished by Messrs. Oetzmann.

"GOTHIC ARCHITECTURE."

SIR,—The notice of my book, "Development and Character of Gothic Architecture," published in your issue of March 15, seems to me somewhat unfair; and I trust you will allow me space to offer to your readers the following remarks in reply to a few of its statements:—

I have not, I believe, as you imply, written from prejudice, or with a desire to detract anything from the true merits of the Pointed Architecture of England—an architecture which few Englishmen, I suppose, appreciate better than I do—and I am not conscious of having had a wish to establish any ill-founded or fanciful theory. On the contrary, certain marked characteristics of French Gothic architecture had, in the course of my study of it, forced themselves upon my attention as fundamentally distinguishing this architecture from all others. Whichever style one may prefer, every intelligent student must, I think, sooner or later reach the conclusion that the French and the English styles are radically different both in structural organisation and in artistic character. And since the distinctive qualities of the French Gothic derived from the logical carrying out of a certain set of architectural principles, and since also this cannot be said of any other Pointed architecture, it seemed to me that confusion might be avoided by confining the term "Gothic" to this developed French work; while, as I say in my preface, the general term *pointed architecture* might be used to designate the various styles of other countries. These latter styles are, as I try to show, essentially but decorative modifications of the Romanesque. The Gothic idea was never fully or consistently carried out in them.

Two important considerations, it is said, I seem to have overlooked, namely: (1) That "it does not always follow that the most complete carrying out of a system to its logical conclusions produces the most satisfactory artistic results;" and it is questioned "whether the system of reducing the piers to the smallest possible area and propping everything with a scaffolding of flying buttresses, which has been carried out so completely in many typical French cathedrals, is really consistent with the aims and the highest expression of architecture;"—it is a questionable credit to French Gothic to have carried out a system . . . at the expense of monumental mass and solidity of expression;" and (2) "the importance of mouldings and ornamental details in characterising style." I believe that I may assert that I have overlooked neither of these considerations. In regard to the first, there was no occasion to speak in the book for typical French cathedrals of the true Gothic period never exhibit any extreme reduction of piers, &c. It appears to have always been recognised by the builders of the best time, that the exigencies of the eye must be regarded as well as other exigencies. A strictly monumental and dignified aspect is pre-eminently characteristic of typical French Gothic. In the declining style we do indeed meet with instances of the extreme carrying out of the principles of the system. And in the Church of St. Urban of Troyes, for example, the monumental aspect of the building is seriously impaired thereby. But it did not fall within the scope of my book to treat of the declining style. As to the importance of mouldings and ornamental details in characterising style, I supposed that I had duly recognised it in giving separate chapters to their consideration—besides including them in my general introductory definition. But I have endeavoured to show that these have but a secondary importance, as, in fact, you admit where you say: "It is true that this consistency of construction and of constructive expression is the most important element in style."

But the chief misrepresentation, which even inadvertence can hardly excuse, is that which occurs where the reviewer says: "It must be observed also that while Mr. Moore is never tired of picking out the logical defects of English architecture, he appears completely blind to defects of logical design in French architecture." He quotes (in illustrations) a bay of the Cathedral of Sens as showing how the ground plan was laid out and the sections of the piers determined by the intended plan of the vaulting, entirely ignoring the fact of the intermediate circular pier having no suggestion on plan of the transverse groins of the expanded vaulting, or the fact of the vaulting shafts for this beginning over again, with a new base of its own, from the abacus of the ground-story cylindrical pier. This system of placing little bases for the vaulting shafts on the abacus of the lower piers, which was more used in early French Gothic than anywhere else, is in fact one of the most illogical and distinctly un-Gothic features in early Gothic architecture; it entirely breaks the connection between the vaulting and the ground-story, and very materially weakens the homogeneous character of the design; yet this the author passes over without reproband, and even in silence, because it is a French defect." It is true that I did not criticise the circular ground-story pier in this place, but a little further on (p. 61), when I come to treat of the development of the typical Gothic pier, I say, referring to similar circular piers of Laon and Paris: "These round columns were soon felt to be

unsatisfactory, as affording no independent supports for the various members of the superstructure. Such columns did not partake of the new principles that now characterized every other constructive member of the building. Attempts to improve them were therefore made, and a new and strictly functional form was soon devised, a very early, perhaps the first, example of which may be studied in the nave of the Cathedral of Paris." It is, therefore, far from correct to say that I pass this matter over in silence because it is a French defect.

The reviewer accuses me of "picking out, in various matters of detail, undoubted weaknesses of English Gothic and representing them as typical." To this I may remark that in no way could I have more effectually weakened my argument, and exposed myself to merited blame, than by having done so. I have, however, a hope that unbiassed readers will see that I have fairly set forth the leading characteristics of pointed buildings in England. If I have not done this, let it, by all means, be shown.

On what you call "the author's blindness to English characteristics," concerning which "it is sufficient to note that he has not a word to say about so graceful and characteristic an invention as fan-vaulting," I need only observe that this invention was posterior to the epoch of which my book treats, and that special reference to it was, therefore, uncalled for. Had the index been consulted, it would have been found, however, that incidental mention of fan-vaulting occurs on p. 144.

CHARLES HERBERT MOORE.

Cambridge, Mass., April 10, 1890.
 * * * Writers who are prejudiced never are aware of the fact, or it would not be "prejudice," but something else. Mr. Moore's reply is quite beside the real point of our criticism. The main defect of his logic lies in taking a particular plan of building, with three aisles and a chevet termination, and defining that as "Gothic." We pointed out that he might just as well take the plan of the Parthenon as representing Greek architecture, and say the Breechtheon was not Greek architecture. As to the question of his "passing over in silence" a certain feature because it was a French defect, our statement was strictly correct in regard to the illustrations we were speaking of. The author gives illustrations (pages 45 and 47) with the intermediate pier-circular on plan and with a vaulting shaft illogically placed on the capital of the pier (or rather column), and says, "it will be seen that the architect not only intended from the first to vault this choir, but that he perfectly understood what the form and construction of the vaulting was to be; that he had in fact settled in advance his scheme for the vaulting in every detail"; while the very illustration employed shows the contrary, and shows an illogical treatment which, as we said before, we are quite certain the author would not have passed over if the illustration had been taken from English Gothic. As to fan-vaulting, the index was searched with that precise object, and what we found was the following sentence: "This peculiarity marks an early step in the direction of the so-called fan-vaulting system which subsequently became so conspicuous a feature of English pointed design." That remark, without any illustrations, is the whole reference to fan-vaulting in the book. As to the general question of Mr. Moore's firmness in his representation of English Gothic we may give the reader an illustration by reproducing the accompanying sketch of an Early English capital which Mr. Moore has the assurance to present to the reader as a typical form of the Early English capital. This kind of thing leaves only one of two conclusions possible: either Mr. Moore is ignorant of the details of the English Gothic at which he scoffs, or he is deliberately misleading his American readers (who may possibly know no better) to subserve his own argument. His book, in spite of a great deal of ability displayed in it, is one-sided, dogmatic, and misleading, and an entirely unsafe guide to the study of Gothic architecture: it is a piece of advocacy to subserve a captious theory. —Ed.

Early English capital as illustrated (1) by Mr. Moore for the information of American students.

His book, in spite of a great deal of ability displayed in it, is one-sided, dogmatic, and misleading, and an entirely unsafe guide to the study of Gothic architecture: it is a piece of advocacy to subserve a captious theory. —Ed.

DAMAGE TO GAS PIPES BY STEAM-ROLLERS.

SIR,—In reply to "A Borough Engineer," whose letter on the above subject appears in the last issue of the *Builder*, I think the case he has in his mind is that of The Gas-light and Coke Company v. Vestry of St. George's, Hanover-square, which came before the Queen's Bench Division of the High Court of Justice in December, 1887, and in which the company were successful in restraining the vestry from using steam-rollers of such weight

as to damage their pipes. I am afraid, however, that this case will not assist him in resisting the claim of the Gas Corporation (or is it a company?) in question, if they have fulfilled the condition precedent to making such claim—namely, laid their mains in a proper manner. As far as my recollection serves me, this was the whole question in the case cited above. The Company's mains were laid so as to resist "legitimate pressure" from the surface, they were submitted to unusual—i.e., illegitimate—pressure by the use of a steam-roller; and the users of the roller were told in plain language not to do it again at their peril. I know of two instances in which local authorities have recognised their liabilities in cases of damaged mains, and have settled with the companies rather than let the matter go into court.

With regard to the question of liability, a learned Judge once said that any one who took into a public thoroughfare an element of danger,—for, instance, a bear,—did so at his own risk, and consequently he was responsible for any damage resulting from his act. Gas companies have the use of the subsoil of the public ways, and they convey beneath it an element of danger,—a "bear," but properly chained and muzzled in service-mains, "well-made and properly laid," to use the words so frequently repeated in the Gas-light and Coke Company's case. The local authorities, as the parties responsible for the proper condition of the roads, also take into the streets an element of danger in the shape of a heavy steam-roller,—a "bear" of another kind. Now, does the passage of this roller over the street subject the pipes beneath to legitimate or illegitimate pressure? That is the whole question, as it seems to me. If in the "Borough Engineers'" case he can show that the pipes were laid too near the surface, or upon improper soil, loosely thrown in so as to allow subsidence with little pressure from above, it would appear that he would be in a position to resist a gas company's claim for damages. If, on the other hand, the pipes were "well made and properly laid" to resist ordinary pressure, I think their claim will be upheld, if the matter is taken into court. X. Q. S.

London, April 19, 1890.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—XVII.

SHUNT-WOUND DYNAMO-MACHINE (continued).

THE characteristic curve for a shunt-wound dynamo may be constructed by methods similar to those employed for the separately excited and series machines.

The diagram (fig. 45) is, however, a little more complicated from the fact that, whereas in the two former cases the whole of the armature-current flows into the external circuit, in the present case a part of it is diverted through the field-magnet coils, and the proportion of the field-current to the armature-current varies as the external circuit is altered.

Let OA be the line for the resistance of the armature; OF that for the field magnet coils. If the armature is producing a current represented by OC, PC is the E.M.F. set up in it. But a part of this electro-motive force, viz., PC, is absorbed in the armature itself, so that Pp is the E.M.F., or difference of potential, between the terminals of the machine, and it is this E.M.F. which drives the exciting current round the field magnets. Draw P'E' parallel to OA, then O'E'=Ip, and if E'M is drawn parallel to OX, E'M represents the current in the field magnet coils; O'C' is the projection

of this line on to OX, and the balance of current, C'C, is that available for use in the external circuit.

If the line OP is drawn, then tan POC, or $\frac{P}{C}$

is the total resistance in circuit, and $\frac{Pp}{CO}$ is the resistance of the circuit external to the armature; it must, however, be pointed out that the circuit consists of the field-magnet coils and an external circuit proper, placed abreast.

Many interesting comparisons may be made between series and shunt-wound machines. A shunt machine, open circuited, becomes simply a series machine, whose field-magnet coils have an abnormally high resistance, short circuited, a series machine open circuited can produce no effect because no current can flow round the field-magnets; similarly, if a shunt machine short circuited it can be seen, from fig. 45 or by looking at the connections in fig. 44, that it can produce no effect for the same reason; hence, a shunt machine short circuited, and a series machine open circuited, are in practically the same condition.

If the line OP turns about O towards OX and ultimately becomes a tangent to the curve at C and the machine ceases to work; in the shunt-wound machine, therefore, there is also a critical resistance, but one below which no current is produced.

When a machine is always required, as frequently happens in the case of small dynamos, to send a certain current through a constant resistance, the type of machine used is of little importance. The point P on the curve never moves, so that the shape of the curve, which reveals the peculiarities of the particular machine, is a matter of no consequence. With large machines, however, the load will generally, under ordinary working conditions, alter from time to time, and the current which flows between its terminals will probably be used for many independent pieces of plant or apparatus, through which current can be made to flow at will.

If, for example, the external circuit consists of a number of large electric lamps, placed in series, a lamp would be turned off by short-circuiting it, that is, by providing a by-path of no resistance for the current to pass on to the remainder of the lamps as before; although the act of turning off a lamp reduces the resistance of the circuit, the value of the current flowing from the machine must not change. The machine must, therefore, give a constant external current, irrespective of the resistance of the circuit, which will vary from its maximum value, when all the lamps are turned on, down to nil when all the lamps are off, in which latter case the machine will be practically short-circuited.

The smaller electric lamps are usually placed abreast; when a lamp is turned off, the current through it is stopped by open-circuiting it, and the current from the machine correspondingly decreased; but this must not alter the difference of potential between the terminals of the machine, or the remaining lamps will be affected. In this case the machine must, therefore, give a constant external electromotive force, irrespective of the resistance of the circuit, and consequently, of the current flowing, which will vary from its maximum value, when all the lamps are turned on, down to nil when all the lamps are off, the machine being then open-circuited.

A glance at the three characteristics already drawn (figs. 39, 43, and 45) will show that none of the machines hitherto described could fulfill the requirements of either of the above cases. The external characteristic of a constant-current machine is a line parallel to OY, of a constant-potential machine a line parallel to OX.

The output from the armature of a machine may be controlled by altering (1) the speed, (2) the position of the brushes, (3) the magnetisation of the field magnets.

If the motive-power is a steam-engine it may be fitted with an electric governor, which can be made to work over almost any range, but a considerable change of speed constantly taking place is open to objection, though, as a supplementary means of obtaining more perfect regulation, it is of great value. Shifting the diameter of commutation is at best but a clumsy device, and, with a machine of no great size, the sparks produced at the commutator are so mischievous that special measures have to be adopted for extinguishing them. The third method possesses distinct advantages over all others, and, in some form or other, has long

n used for regulating electricity supply from dynamo-machines. If a shunt of variable resistance be attached the field magnet coils of a series-wound machine (fig. 40), or if a variable resistance put in series with the field magnet coils a shunt-wound machine (fig. 41), the necessary excitation of the field magnets can be controlled by hand, or by some suitable electro-magnetic device. The same end, however, can be attained without involving the use of a variable resistance, or, indeed, any special apparatus at all, by what is known as compound-winding the field magnets of a machine.

Fig. 46.

Fig. 46 shows the connexions in one method of compounding. The current comes from the machine through the positive brush +B, and is taken a few times round the limbs of the field magnets, emerging from the machine at the shunt terminal +T. From +T a sufficient quantity of finer wire is coiled round the shunt magnets, and the other end attached to the negative terminal -T. If fig. 46 is compared with figs. 40 and 45, it will be seen that the compound-wound machine may be regarded as a combination of an ordinary series and shunt machine.

Continuous current dynamo-machines are not frequently compounded for giving a constant external electro-motive force or difference of potential between +T and -T (fig. 46); but shall therefore consider how this may be accomplished; indeed, it must be shown that a machine such as that shown in fig. 46 is capable of maintaining a constant E.M.F. in the external circuit. It is important to note that if the difference of potential between +T and -T (fig. 46) is constant, the current through the shunt will be constant too, the machine will therefore be, from an electrical point of view, a combination of a separately excited and series dynamo-machine, rather than of a shunt and series machine as the connexions seem to indicate. The constructions will be the reverse of that hitherto adopted, for we shall first draw the shunt characteristic, and then determine what winding of the field-magnets will produce it.

Fig. 47.

At point O E, fig. 47, equal to the external E.M.F. required, then the characteristic will lie in the line E P drawn parallel to O A, the resistance line for the armature and the winding on the shunt in series with it. Draw O F the resistance line for the shunt winding, and as in the case of the simple shunt-machine, find the current C' which flows through them. Take two points, P₁ and P₂, on the characteristic and draw P₁ C and P₂ C₂ parallel to O Y.

On O Y (fig. 48) set off the lengths O S', O S₁, O S₂ proportional to O C', O C₁, O C₂ (fig. 47) respectively, so as to represent on a suitable scale the magnetising effect of the armature

Fig. 48.

currents on field. Along O X set off on the same scale O N', O N₁, O N₂ to represent the resultant field in each case, and proportional to C' E', C₁ P₁, C₂ P₂ respectively; S' N', S₁ N₁, S₂ N₂ are respectively the fields which the field magnets must produce in each case (compare

Fig. 49.

fig. 48 with figs. 38 and 42). If O Q, fig. 49, is the curve for the flux through the field magnets, lay off K' Q', K₁ Q₁, K₂ Q₂ proportional to the lengths N' S', N₁ S₁, N₂ S₂ respectively, fig. 48, then O K', O K₁, O K₂ are the numbers of ampere turns required on the field magnets to produce the necessary field. Unfortunately the figures are too small to show how far the obviously-desired condition K' K₁ : K₁ K₂ = C' C₁ : C₁ C₂ is fulfilled.

But a consideration of the geometry of the various steps will show that if Q' Q₁ Q₂ are approximately in a straight line, the true characteristic of the machine will also be very nearly straight. Now, the earlier part of O Q is very nearly straight, so that the machine can be made to automatically regulate, provided that the current drawn from it is not such as to cause the field magnets to show any signs of approaching saturation. From O K₁ the number of turns in both sets of coils can be calculated, from K' K₁ that of the series coils alone.

The constancy of the external E.M.F., which the compound wound-machines of good makers maintain, is very remarkable.

Books.

A History of Cumberland. By RICHARD S. FERGUSON, M.A., Chancellor of Carlisle. Elliot Stock.

IN this contribution to the useful series of "Popular County Histories," the author takes a very much stricter view of his task than most of his predecessors. In fact, he begins by limiting himself to the somewhat narrow scope which the old-fashioned county historian took in the "General Introduction" prefixed to his ponderous volumes. Mr. Ferguson is probably right in thus interpreting a county history to mean a history of the county and nothing more, but this treatment of his subject has some very decided disadvantages. It precludes him from dealing with individual persons and places, and from varying his narrative with accounts of abbeys and churches, castles and manor-houses, and of the "worthies" who have helped to make their hitherplace illustrious. The result is that his book is not so entertaining to read as it might have been; but, on the other hand, it is extremely instructive, and affords as complete a history of the condition of Cumberland from prehistoric to modern times as one could desire. On the earliest period there is, indeed, little to be said, for up to the present time no implements of the Paleolithic Age have been found,

either in caves or river-drift, in any part of the North of England. Glaciers, in all probability, covered the whole area, and when these disappeared and the land was occupied by the Neolithic races, Cumberland was a tract of un-cleared forest, moor, and mountain, with, perhaps, three great meres filling the valley of the Eden. When the Romans invaded the country, it was little better in most parts than a cold and watery desert; the air was chilly and the sun but seldom seen. But however uninviting a region, the invaders thought it worth retaining, and the evidences they have left of their occupation of the land are among its most remarkable features. These are depicted with considerable skill by Mr. Ferguson, who takes the reader on a circular tour through the district, and endeavours to call up before his eyes what they would there have looked upon in the year 300 A.D.

The tourist and his guide find at Ravenglass,—now an insignificant town, with a harbour choked with sand,—a busy scene, full of craft loading and unloading. Wild-looking men from Hibernia are discharging cargoes of cattle, with a total absence of regard for what the cattle feel; while Spaniards and Italians, with much more care, are unloading from their craft great amphore full of wine, olives, anchovies, sardines, garum, and other luxuries which the Romans love, and have taught the Britons to love, or to pretend to do. In return they are shipping, among other commodities, large sporting dogs and dejected-looking natives, some of whom are recruits for military service, others to be sold as slaves. The beach is strewn with bales and packing-cases. Foreign sailors stroll to and fro, and mix with the soldiers of the garrison who are off duty, and chatter with the women of the town. By special invitation we take up our abode for the night in the Tribune's villa, and from the guests at his table we learn much as to the trade and commerce of the district, while the Tribune's wife shows us with pride a necklace of British pearls, collected from one of the rivers which form the harbour. She also calls our attention to the rose-coloured plaster of the walls, on which mythological and other figures are floating in mid-air, as it might be; while in a niche, in the western wall of one of the rooms, stands a marble bust of the Emperor, presented by himself to the Tribune.

What amount of truth there may be in this fancy picture of Roman Cumberland we will not pretend to say, but the extract will show that Mr. Ferguson is by no means a dry historian, dealing only with hard facts and figures. In truth, he is rather open to the charge of want of dignity in his treatment of history. Such expressions as, "No lapidary inscriptions, bar one, have been found at Ravenglass"; "The Celtic race was, compared with their non-Aryan, predecessors, a set of very ugly customers, &c., are unnecessarily lively, and the author's excursions into that land of freedom from whence derivations are brought back deserve the same epithet. He tells us, for instance, that from the Danish term *by*, corresponding with the Saxon *ton*, we get "hye-laws"—i.e., "town laws," and that the *lug-mark*—a bit cut out of a sheep's ear that it may be recognised by its owner—is really the *lög-mark* or legal mark, from the Icelandic *lög*, i.e., law. We are quite ready to recognise the great influence on the nomenclature of the district exerted by the Scandinavian settlers, but its acceptance will not be promoted by such advocacy as is here involved.

We cannot follow Mr. Ferguson in tracing the gradual growth of the kingdom of Cumbria,—the name seems to have been first applied to the district of Galloway, Strathclyde, and parts around Carlisle at the end of the ninth century,—nor the Norman settlement, with the various baronies into which the territory was carved. The subject is well treated by Mr. Ferguson, who seems to have a very complete knowledge, not of the country only, but of its successive lords. He gives an excellent account of Carlisle, a royal city, enjoying special privileges; and the narrative of Border warfare,—peculiar to no one age, but becoming systematic and for a set purpose in the reign of Henry VIII. and afterwards,—is extremely good. An entire chapter is rightly given to the risings in '15 and '45, and one may say that with the Battle of Culloden the history of Cumberland comes to an end. There was, indeed, a contest of another character between the Pentricks and the Lowthers, which was fought out to the bitter end in the eighteenth century, and of this Mr. Ferguson has given a full account; but of other

incidents the county chronicle is destitute. By slow degrees commerce and agriculture have improved, and with the development of the latter, and the consequent enclosure of common lands, the manly race of "statesmen" (estatesmen) has decayed, and is fast dying out. However inevitable the circumstance, we cannot but regret it. We remember, with gratitude, what all England owes to it.

Factory Accounts, their Principles and Practice.
By E. GARCKE and J. M. FELLIS. London: Crosby Lockwood & Co.

THE accountant of bygone days would find that the modern methods of production had, in many instances, rendered it necessary for him to multiply his books and greatly extend his operations. Indeed, the different branches of work in a large manufactory present many distinct features, each requiring a separate education; and our authors show that the "works" accounts of a factory,—as distinct from the office or commercial accounts of the same concern,—may advantageously be treated on a scientific basis. The sooner the rough-and-ready element is made to give place to systematic and accurate records, the more satisfactory it always proves both to employer and employed. We have recently commented upon the disinclination frequently evinced by the latter, in the case of strikes, to accept corroboration from books of the statements made by their employers. Their view is, probably, that books and figures can be made to prove anything, and that they themselves are powerless to prevent undue advantage being taken of this. Our authors' opinion upon this point is that, under a well-organised system of factory accounts "each employer feels that he is contributing to the attainment of accurate records of costs; and thus, on the occasion of strikes, have less hesitation than they otherwise would in accepting the results shown by the books as correct, and as based upon fair principles." This satisfactory state of things, we apprehend, will hardly be brought about until the workman is also educated up to a more intelligent and correct idea of the real nature of the relations between himself and his work on the one hand, and his employer and his capital on the other,—points which the leaders of some of the recent strikes have persistently misrepresented. This was particularly noticeable during the recent strike at the Spillegate Ironworks, Grantham,—a case, of course, in which the authors' remarks would apply with more force than in those of the miners and dock labourers. The work before us deals exhaustively and clearly with all the multifarious details of the different departments of factories, and is copiously illustrated by specimen rulings and useful diagrams. Among the important matters dealt with in the appendices are the Acts relating to Income-tax, Insurance, and Rating of Machinery. The latter subject is of especial interest at the present time, as it is once more before Parliament. Several cases and authorities are quoted, full reference being given throughout the book for such quotations. It is carefully arranged, and is accompanied by a short glossary of terms, and a very complete index.

VARIORUM.

"FIRE BRIGADE DRILLS, with Hints on Management," and "Rules and Regulations for Volunteer and other Fire Brigades," are two very excellent little handbooks, just re-issued in new and revised editions by Messrs. Shand, Mason, & Co., of Upper Ground-street, Blackfriars. The first-named handbook is supplemented by some useful rules for ambulance work. The second of the two handbooks is prefaced by a hint that the use of the term "volunteer," as applied to fire-brigades, should, as far as possible, be avoided, "as its use has been made the excuse for non-payment of legitimate charges for assistance and appliances by insurance offices, and also owners of property, who have suffered by fire." So mean and paltry an excuse has, we regret to learn, "been admitted in more than one test case before eminent judges." This handbook gives some very useful directions to be observed by inmates of buildings in the event of fire, the precautions to be taken against the occurrence of fires, and hints on the choice and management of petroleum lamps. The two handbooks together will be found very useful in large establishments and public institutions.

—The Year-book of Photography and Pho-

topographic News Almanac for 1890" (London: Piper & Carter) purports to contain "the results of photographic experimenting during the year 1889, and special contributions by leading photographic authorities, professional and amateur." Dry-plates and other improvements have made photography so popular as an aid to the student and the tourist that we can have no doubt as to the utility of the "Year-book" now before us, which contains lists of photographic societies and clubs, standard formulæ and memoranda, and a great mass of information on photographic subjects. It also contains a portrait of the distinguished French savant, M. Alexandre Edmond Becquerel, who has done much for photography.

—"The Handbook of Stations, Junctions, Sidings, Collieries, &c., on the Railways in the United Kingdom," by Henry Oliver and John Airey, of the Railway Clearing-House, London (published there and by McCorquodale & Co.), has now reached its seventh edition. It is alphabetically arranged, and purports to show "the accommodation at each station, maximum crane-power, country, railway on which situated, and exact position." It is clearly arranged and well printed, and cannot but be found useful in every business house.

—"The Garden Oracle" for 1890, by Shirley Hibberd, Editor of the *Gardeners' Magazine* (London: 4, Ave-Maria-lane), has now attained to its thirty-second year of publication—a fact which in itself attests the value and usefulness of this "illustrated floricultural year-book," to give it its subsidiary title.—Index to the First Volume of the Parish Registers of Gainford, in the County of Durham. Part II. Marriages: 1569-1761" (London: Elliot Stock). This is the second instalment of a very useful though unpretending work, the first part of which we noticed last year. The compiler, whose name does not appear on the title-page, is setting an example which might be followed with advantage by people of leisure and means in other parishes. Such work deserves the thanks of antiquaries, genealogists, and historians. The vicar, we understand, is bearing the cost of printing the work.

—New Zealand's material resources and commercial activity are very clearly treated of in "Two Addresses by the Presidents of the Chamber of Commerce, Canterbury, N.Z., in 1886 and 1889, and now republished by Messrs. Wm. Clowes & Son (Limited), Charing-cross. The address for 1886 is by Mr. G. G. Stead, and that for 1889 by Mr. A. Kaye." The *Asclepiad*, No. 25, vol. vii. (London: Longmans, Green, & Co.) is the most recently-issued part of what claims to be "a book of original research and observation in the science, art, and literature of Medicine, preventive and curative." It is entirely written by Dr. B. W. Richardson, F.R.S., and, needless to say, contains a good deal of matter interesting to the sanitarian and even to the "general reader." Dr. Richardson has been known for many years as a "cyclist" and a friend of "cycling;" but in his article on "Cycling and Physique," in the present number of the *Asclepiad*, he strongly deprecates the too ardent pursuit of that means of physical exercise. Without laying down as a hard and fast rule that cycling ought never to be commenced by boys or girls, Dr. Richardson says he is satisfied that "it is always best to delay the commencement of cycling until the body is closely approaching to maturity." There is an interesting monograph, with portrait, of Alexander Monro, M.D., F.R.S., the founder of the Edinburgh Medical School. "Monro Primus," as he is called, to distinguish him from his son Alexander, was born in 1687, and died in 1762. He was mainly instrumental in building the first Edinburgh Royal Infirmary (rebuilt some fifteen or twenty years back), and assisted the architect Adam (not "Adams," as Dr. Richardson, or the printer, puts it) in planning it. The work of erecting the Infirmary was, it appears, taken up by the inhabitants with great spirit and unanimity. "The proprietors of many stone quarries made presents of stone, others of lime; merchants contributed timber; carpenters and masons were not wanting in their contributions; the neighbouring farmers agreed to carry the materials gratis; the journeyman masons contributed their labours for a certain quantity of hewn stones; and, as the undertaking was for the relief of the diseased, maimed, and lame poor, even the day labourers would not be exempted, but agreed to work one day in the month gratis towards the erection of the building." As Dr. Richardson remarks, this

is a very pleasant picture of sympathetic devotion to a great work.—*Science for All* is the title of a new serial work, the issue of which has just been commenced by Messrs. Cassell & Co., Limited (Bell's Sauvage-yard). Part I, which is before us, gives as a frontispiece a diagram printed in colours, showing the order of succession of the various rocks composing the crust of the earth, with an especial reference to those found in England. The work is clearly printed on good paper, and is well illustrated. One of the most interesting articles in Part I. is on "A Piece of Limestone" written by Prof. H. Alleyne Nicholson. The new serial is likely to meet with wide appreciation.—*Cassell's Family Magazine*, which issues from the same press, continues to maintain its reputation for varied and interesting reading. One of the best articles in the April number is on "A Yorkshire Dale," by T. Vickars-Gaskell. It is well illustrated.—*The Leisure Hour* (published at 56, Paternoster-row) for March contains an interesting article on "The Newspaper Printing Press of To-day" with special reference to "cut-work." The various "processes" by which blocks are made, and the methods of printing them, are described in detail. Some useful hints are given for the guidance of draughtsmen who have to prepare drawings by reproduction by "process." The April number of the same periodical gives an interesting "unwritten chapter" about Chat Moss, upon which it appears that Mr. William Roscoe introduced a railway, designed by Mr. Robert Stannard about the year 1816. The railway was designed to assist in the work of cultivating the Moss, and the rails were of wrought iron, like inverted V, thus \wedge , the wheels being V-grooved so as to fit the rail.—*The Sunday at Home* published at the same office, contains, in its April number, a second series of "bell mottoes" collected by Mr. W. J. Gordon. It also gives an illustration, by permission of Messrs. Doulton of Mr. George Tinworth's terra-cotta panel "At the Foot of the Cross."—Among other magazines reaching us from the same office are the *Boys' Own Paper* and the *Girls' Own Paper*, both of them excellent publications for youth. The two last numbers of the *Girls' Own Paper*, for March and April, contain interesting articles by Mrs. Holman Hunt describing Mr. Flinders Petrie's discoveries in "The Fayum," Egypt, copiously (somewhat roughly and "sketchily") illustrated. The same two numbers also contain articles on "Celebrated Monuments of Eminent Women," very ably illustrated by page engravings by Taylor from drawings by Mr. H. W. Brewster. The monument illustrated in the March number is that of Lady Berry, in Stepney Church, whose name is associated with the well-known legend of the ring and the fish. The April number gives an account and illustration of Lady Bankes's monument in Risleip (or, as it is not spelt, Ruislip) Church, near Pinner, Middlesex.—*The Church Monthly* (edited by Frederic Sherlock, and published at 30, Bridge-street, Westminster) is perhaps the best of the cheap magazines available for parochial circulation. It is published for a penny, is varied in its contents, and fairly well illustrated. One article in the March number is on the interesting parish church of Holy Trinity, Dartford, of which two illustrations, specially engraved from photographs, are given. The article is written by Mr. Robert Crane, who refers to the discovery, in 1833, of an ancient fresco, measuring some 20 ft. by 12 ft., illustrating the story of St. George and the Dragon. The writer says that this fresco was formerly fully visible, but that some years back the organ was placed in front of it (almost completely obscuring it) by the vicar, the Rev. J. G. Blomfield, M.A., and his cousin, Mr. (now Sir) Arthur Blomfield, the well-known architect. Can this statement be correct?—"Everybody's Pocket Cyclopaedia of Things Worth Knowing, Things Difficult to Remember, and Tables of Reference" (London: Saxon & Co.) is a useful little book, but we see this without being able to guarantee its accuracy in all respects. Some of the matter under the heads "Architectural" and "Science" is questionable. The book sells for 6d.—Shelle & Co.'s "Complete Press Directory for 1890" (published at 5, Leadenhall-street, E.C.) is a very handy publication for the office. It is a special feature of its own, not the least useful being a summary of the leading newspaper cases for the year 1889, recording important decisions affecting copyright and the law of libel. It is well printed and arranged, and sells for 1

Maps.

FROM Mr. Edward Stanford, of Cockspur-reet, we have received two useful maps of London. One of them shows the areas granted to the electric light companies under the Electric Lighting Acts of 1882 and 1888. The areas granted are mostly at the West End. The East End is not at present interfered with by any of the companies, but a considerable portion of the south-eastern district has been allotted to the London Electric Supply Corporation. The other map shows railway and tramway lines, and other works (including those proposed by the London County Council) for which powers are being sought in the present session of Parliament. Both maps are clearly printed and coloured, and will be found very useful for reference.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

8,019, Ventilation by Sash-windows. W. Macdonald.

This invention consists in placing a continuous sheet of wood or metal to block up the bottom sash. This piece is formed with a rebate and head behind the sash, and is supported by a series of small pieces of wood or metal, which are fixed to the sash. This block is in position when the sash is lowered, and is some distance above the meeting-rail of the upper sash, and the space thus maintained is a continuous source of ventilation all along the length of the sash.

8,129, Parquetry. S. Ingham (and others).

The ordinary method of making and fixing parquetry is to prepare the small pieces or patterns in the workshop, afterwards fixing them upon the floors already laid to receive them. This is laborious and costly, and the present invention is designed to remedy this. The pieces of prepared parquetry are attached at the manufactory to suitable lengths of floor-boards, passed through thickening and smoothing machines, then taken to the floor, and fixed in large or small blocks or sections cut by the workman to fit special positions when necessary.

8,182, Kitchen Fireplaces. J. Burford.

According to this invention, swing and movable grates are used for the bottom and front of the grate, which being actuated admit of the height of the fire being kept uniform relatively to the height of the opening at back, but varying the height of the fire at front. Arrangements are also incorporated in the improvements for increasing and directing the draught.

8,444, Sash-fastener. W. Macdonald.

In order to effectually secure the windows to which the improvements noted in the first paragraph (8,019) have been fitted, the inventor has designed a special fastener, which consists of a piece of metal screwed to and projecting from the inside of the window-frame, and through this works a pin or bolt, secured into a hole on the upper sash. There being only two or a limited number of holes the sash can only be raised a certain height.

8,795, Roofing, &c. A. N. Ford.

In manufacturing an improved material for roofing, wire netting of a suitable mesh is, according to this invention, secured into a fabric such as canvas. This is passed through a series of rollers, and a heated liquid composition is fed on to the material.

8,808, Plasterers' Lathing. B. Westerdahl (Sweden).

This improved lathing consists of a series of wood strips of angular shape, connected together by means of wires, which wires are twisted together between each pair of splints, preferably in different directions on opposite sides of the same splint.

NEW APPLICATIONS FOR PATENTS.

April 1.—5,029, J. Treloning and J. Westaway, Improv'd Curtains for Theatres, &c.—5,082, J. Hinge or Fastener.

April 2.—3,096, O. Wagner and E. Howard, Patentings for Windows.—5,104 and 5,105, H. Ver, Automatic Sash-fastener.—5,112, T. Collen 1 R. Wilson, Opening and Closing Window-frames.—5,118, H. Beeson, Machinery for Beveiling Sashes.—5,129, J. Plumridge and others, Band Sashes.—5,181, J. Gillespie, Water-closets.

April 3.—5,175, G. Shanks and others, Stock and Bindings for Brick Moulds.

April 5.—5,268, S. Jennings, Draw-off Taps for Cans, &c.—5,270, G. Jennings, Removable Stoppers for Manhole Covers, &c., for Drainage Purposes, &c.

April 8.—5,310, Sharp, Roofing with Slates.—5,311, C. Weber and C. Freeman, Artificial Stone Tiles, &c.—5,363, S. Chambaz and L. Schmid, Sash-keepers.

If we read this description aright, something very like it has absolutely identical to what appears to be described, has been in use for many years.

April 9.—5,403, J. Smeaton, Flushing and Water-waste-preventing Apparatus for Closets, &c.—5,415, W. Horn, Brick-machine.

April 10.—5,459, W. Vears and others, Storage Cisterns or Water-waste Preventers.—5,466, W. Thompson, Hiding Doors or Window Sashes in a more or less open position.—5,475, A. Booth, Sawing-machines.

April 11.—5,515, P. Justice, Material for Building Purposes.—5,533, O. McLean, Asphalte Paving.

April 12.—5,544, J. Prida, Cowl or Ventilator.—5,554, G. Salter and H. Trubshaw, Locks and Latches.—5,555, T. Benson, Ventilating Rooms and Buildings.—5,572, W. Millington, Tubular Boiler for Fireplaces or Stoves.—5,581, G. Skalsey, Cement Kilns, &c.—5,588, R. Chantray and W. Peters, Water Waste Preventers.—5,593, H. Newey, Water Waste Preventing Cistern for Flushing Closets, &c.—5,595, W. Ingram, Adjusting Spirit Levels to any required gradient.

PROVISIONAL SPECIFICATIONS ACCEPTED.

2,828, R. Friend, Opening and Closing Skylights, &c.—3,162, J. Merryweather, Paving Material.—3,340, S. Sutcliffe, Hinge.—3,346, F. Barnett, Low-level Composite Bridges.—3,671, B. Mills, Hinges and Door Checks.—3,994, J. Anderson, Morticing Machines.—4,129, G. Sykes, Window Fasteners.—4,316, J. Day, Sash Fasteners.—4,377, J. Marsh, Attaching Door-knobs or Handles to Spindles.—4,497, J. Bradley, Hot Water Apparatus.—4,504, E. Lee, Kiln for Burning Bricks.—4,603, C. Mackey, Roses of Door-knobs, &c.—3,431, J. Naylor and H. Williams, Moulding and Pressing Sandry Bricks.—3,459, J. Thomas and T. Stabb, Raising and Lowering Window Sashes.—3,882, T. Birtwistle, Safety Hinge for Folding Ladders.—3,883, C. Whitfield, Fireplaces.—3,942, G. Smith and B. Cooper, Joining Lead Pipes.—4,147, E. Miller, Wood Working Machinery.—4,155, C. Crosby, Firegrates.—4,289, J. Cullen, Gas Bracket and Pendant.—4,662, J. Bayly, Beveiling Square.—4,705, G. Tweedy and E. Lanrouca, Wood Blocks, &c.—4,735, F. Averil, Flush Bolts.—4,900, R. Roberts, Chimney Tops, &c.

COMPLETE SPECIFICATIONS ACCEPTED.

Open to Opposition for Two Months.

8,511, E. Bussy, Bricks, White Enamel, &c.—8,554, F. Davies, Fastenings for Doors, &c.—14,787, A. Mitchell, Joint for Drain-Pipes, &c.—17,447, E. Christie, Door Chain and Latch.—18,249, J. Wilson, Fireproof Hinges, &c.—19,724, H. Aland, Fans for Producing or Inducing Currents of Air.—205, W. Kneen, Attaching Door Knobs to their Spindles.—2,619, J. Schultz and E. Hopf, Flooring for Roofs, &c.—2,966, G. Bayley, Fastenings for Window-sashes.—9,045, G. Belling, Window-sash Fastener.—10,524, J. Brunton and L. Griffiths, Mixing Materials for making Artificial Stone, &c.—16,214, A. Bout, Metallic Crossbars.

MEETINGS.

SATURDAY, APRIL 26. Association of Municipal and Sanitary Engineers and Surveyors.—Home District Meeting at Acton, Ealing, and Hampton.

Royal Institution.—Captain W. de W. Abney, F.R.S., on "Colour and its Chemical Action." II. 3 p.m.

Junior Engineering Society.—Visit to the Deptford Central Station Works of the London Electric Supply Corporation.

MONDAY, APRIL 28. Surveyors' Institution.—Mr. F. Marshall on "The Principles of the Exemption of Public Undertakings from Rateability." 8 p.m.

Leeds and Yorkshire Architectural Society.—7.30 p.m.

TUESDAY, APRIL 29. Institution of Civil Engineers.—(1) Further discussion on Sir Frederick Bramwell's paper on "The Application of Electricity to Welding, Stamping, and other Cognate Purposes." (2) Mr. J. Robinson on "The Barry Dock Works." 8 p.m.

WEDNESDAY, APRIL 30. Civil and Mechanical Engineers' Society.—Presentation of Report and Election of Council. 7 p.m.

Society of Arts.—Mr. T. R. Dalmeier on "Photographic Lenses." 8 p.m.

THURSDAY, MAY 1. Guild and School of Handicraft.—Mr. E. Prieleau Warren on "Parlour Architecture." 8 p.m.

Society for the Encouragement of the Fine Arts.—

Mr. Phil. R. Morris, A.R.A., on "Impressionism, Realism, and Philistinism."

Institution of Mechanical Engineers.—(1) The President, Mr. J. Tomlinson, will deliver his Inaugural Address. (2) Paper by Professor A. B. W. Kennedy, F.R.S. 7.30 p.m.

Royal Archaeological Institute.—(1) The Worshipful Chancellor Ferguson on "Dunbar Grenadiers from the County Hotel, Carlisle." (2) Mr. J. P. Harrison on "Anglo-Norman Ornament Compared with Designs in Anglo-Saxon MSS." 4 p.m.

Society of Arts.—Mr. Lewis F. Day on "Design Applied to Wood-carving." 8 p.m.

Royal Institution.—Annual meeting, 1.30 p.m.

FRIDAY, MAY 2.

Architectural Association.—Mr. Keith D. Young on "Hospitals." 7.30 p.m.

Institution of Mechanical Engineers.—Ordinary General Meeting (continued). 7.30 p.m.

SATURDAY, MAY 3.

Royal Institution.—Captain W. de W. Abney, F.R.S., on "Colour and its Chemical Action." III. 3 p.m.

Miscellaneous.

Kells Abbey.—Mr. Webb is about to bring under the notice of the Chief Secretary for Ireland a state of things which would have moved Monkbarons to righteous anger, and the story of which Sir John Lubbock, the author of the Ancient Monuments Protection Act, will scarcely hear without a shudder. It is stated that a portion of the Abbey of Kells, County Kilkenny, is being used for building walls elsewhere; that the ruins at Kilmallock, some of the finest in Ireland, urgently need protection; that the great tombs at Rathmore are being carted away to repair the neighbouring roads; and that there are numerous other instances in which, if immediate steps be not taken, ancient Irish monuments of great interest will be seriously injured, and possibly destroyed. Existing statutes, it seems, afford no sufficient protection in such cases, and Mr. Webb asks whether there is any intention of legislating with a view of preserving these interesting relics of the past. Surely there should be no difficulty in getting a short Bill through which should effect this desirable object. — *Daily Chronicle.*

Association of Municipal and Sanitary Engineers and Surveyors.—The ninth voluntary pass examination of candidates for the offices of municipal engineers and surveyors to Local Boards, carried out by this Association, was held at the Institution of Civil Engineers on Friday and Saturday, the 18th and 19th inst. Nine entered for the examination, the written portion of which was taken on the first day. The greater portion of the second day was occupied with the *visu mee* portion of the examination. The examiners were—(1) For Engineering as applied to Municipal Work, Mr. Joseph Lobley, M.Inst.C.E., Borough Engineer, Hanley (Past President); (2) Building Construction, Mr. Jas. Lemon, M.Inst.C.E., F.R.I.B.A., Consulting Engineer, Southampton; (3) Sanitary Science, Mr. C. Jones, A.M.Inst.C.E., Surveyor to the Local Board, Ealing; (4) Public Health Law, Mr. T. De C. Meade, A.M.Inst.C.E., Surveyor to the Hornsey Local Board. The next examination will be held in London in October, 1890.

Vienna.—According to the *Wochenschrift des Nieder-Oestr. Generebe Dereins*, 371 buildings, with 5,739 dwellings, have been officially surveyed and given over for public use during the year 1889. Only sixty-two houses, with 727 lodgements, have been pulled down during the same year, and hence the number of dwellings in the Austrian capital has been increased by 5,012, a number far too high in proportion to the increase of population. If this unreflecting activity in the building trade continues, the time for the prophesied "crash" cannot be far hence.

Bank of Spain, Madrid.—We are informed that this large building is to be heated throughout with hot water, and that Mr. Renton Gibbs, of Liverpool, has secured the contract for this part of the work. It is one of the largest contracts of the kind ever undertaken by any firm of heating engineers, and will occupy about six months to complete. There will be no less than twelve miles of piping and twenty-one of Mr. Gibbs' largest boilers, besides 119 coil-cases.

Royal Academy: Architectural School.—The course of lessons on Architectural Modelling has terminated for the session, and Mr. Stannus will commence a series of demonstrations on "Architectural Ornament: in Panel, Frieze, and Capital" on Monday, May 5, at 6.15 p.m.

Weighing Machinery.—At a meeting of the Society of Engineers, held at the Town-hall, Westminster, on Monday, the 14th inst., Mr. Henry Adams, President, in the chair, a paper was read by Mr. William Henry Brothers on "Weighing Machinery and Automatic Apparatus in connexion therewith." The author commenced by commenting on the interest which was beginning to be felt in weighing machinery. He thought it surprising that so little was popularly known of the scientific principles which underlie the construction of appliances of such general utility. There were extant one or two pamphlet treatises on the balance, and fugitive articles were to be found in the encyclopedias, but there was no standard literature on the subject in the English language. The increased interest in weighing machinery was probably due to recent legislation, rather than to the peculiar mechanical conditions which it exemplified. The author pointed out that the Weights and Measures Act of last Session removed a glaring anachronism in previous enactments, in that it provided for the verification and stamping of weighing instruments, whereas those operations had hitherto been confined to weights. The demand for accurate and reliable weighing instruments was on the increase, the many-sided requirements of trade could not now be content with the simple balance with equal or with unequal arms—the *libra* and *statera* of the Romans—and many important improvements in such apparatus had been devised for the convenience of the public. The statement that the fundamental principles of the balance remained unchanged from the earliest times, preceded a description of the American torsion balance, which aimed at superseding the knife-edge fulcrum. Weighing machinery in this country was shown to be of an exceedingly diversified character, adapted to the various purposes of trade. The author pointed out how obviously unreasonable it was to expect weights and measures inspectors, who were, as a rule, without technical or mechanical training—to adjudicate intelligently upon the complicated weighing machinery in use at the present day; and referred to the new edict requiring all newly-appointed inspectors to pass a technical examination. If to this guarantee of a certain degree of special knowledge in inspectors were added the official recognition of such forms of weighing instruments only as would answer to scientific requirements, and not tend to the commission of fraud, the author confidently anticipated that the weighing apparatus in use in the United Kingdom would eventually come up to a standard of excellence commensurate with the importance of the work it was called upon to perform. The German laws relating to weights and measures were cited as worthy of imitation in many respects; and several notable precision balances of English make were described in proof that the British manufacturer is not behind his competitors of other countries. The author then proceeded to trace the gradual evolution of automatic weighing apparatus, from the simple but ineffective pendulum balance down to the Snelgrove electric self-operating and self-indicating weighing machine, manufactured by Messrs. Avery, of Birmingham. A number of automatic machines were passed in review, most of them being illustrated by diagrams.

New Buildings for the Salvation Army.—At Walthamstow six large shops and "Citadel" buildings, capable of accommodating 1,000 persons, are to be erected in the High-street, for the Salvation Army. The total cost will be about 4,500. Mr. J. Williams Dunford, of London, is the architect.—At Sunderland, the site of the old Lyceum Theatre, which has been vacant for some time past, situate off High-street, has just been acquired by the Salvation Army for 2,000. Mr. Dunford is preparing plans for the erection on the site of a large "Citadel" capable of accommodating 3,000 persons, at an estimated cost of 3,500.

The Turners' Company again offer their Silver Medal, the Freedom of the Company, and (subject to the consent of the Court of Aldermen) will also obtain the Freedom of the City of London for any workman, whether master, journeyman, or apprentice in the trade in the United Kingdom, who may send in the best specimen of turning in pottery, stone, and glass. The specimens must be sent in during the week ending October 25. Further particulars can be obtained from Mr. Edgar Sydney, at 53, Gresham House, Old Broad-street.

The Lighting of Warehouses.—The greatly increased value of land, and the overcrowded state of buildings in the City of London frequently oblige warehousemen and merchants, wishing to extend old premises or to erect new ones, to build them either in whole or in part in positions where day-light cannot be obtained by ordinary windows either in front, back, or sides. A possible means of obviating these difficulties to a very great extent is now to be seen in a large block of buildings situated in such a position that ordinary windows are not possible. We refer to the large extensions which the Fore-street Warehouse Company have recently made to their premises at the back of Fore-street. The architect is Mr. Herbert Ford, of 21, Aldermanbury. The extensions consist of two blocks having an area of about 4,000 ft. and 2,100 ft. respectively, and both blocks are practically roofed with polished plate-glass in large squares (9 ft. by 2 ft.). To accomplish this Mr. Ford has availed himself of the Bessemer steel lead-clothed glass (British Patent) system of glazing. The large plates of glass are held firmly in their places by means of a narrow frame of steel and lead, which automatically allows for expansion and contraction, and also makes a water-tight joint impervious to rain or dust. The light thus admitted at the top is, with little interruption, flooded down and distributed by means of galleries on the different floors over the whole area. Goods, we are assured, can be most perfectly seen and their texture and colour matched in any part of the building, even in the basement. Roofs glazed on the above plan (of which there are a good many now in the City) are exceedingly light, and at the same time very strong. We called attention to this method of lighting four years ago.

The Architectural Association Soiree was held on Friday, the 18th inst., in the Westminster Town-hall. There was, as usual, a large attendance of members. The first part of the programme consisted of a concert, in which Messrs. C. D. Imhof, J. Dixon Butler, A. C. Bulmer Booth, E. A. Lambert, Edgar H. Homan, Arthur Thomas, C. Gordon Killmister and Captain J. Watson took part. The songs of Captain Watson and Mr. Arthur Thomas, and the violin performances of Messrs. Lambert and Homan, received well-merited encores. The second part of the proceedings consisted of what was described on the programme as "Grand Variety Entertainment," entitled "Looking Forward, or a Professional Meeting of the Future."—The very remote future, we may safely say, it was, in fact, a "palger entertainment." The President of this "meeting of the future" wore a full-bottomed wig and a purple robe, and his address dealt with and "afforded an easy solution" of "many of the much vexed topics of the time," including professional education, examination, and registration. There were a few striking "bits" in the dialogue, which was interspersed with songs and dances. Questions of professional practice, such as the of competitions, were humorously dealt with by "the meeting," and jokes were cracked at the expense of "good old 'Gwilt.'" The performers in this amusing travesty were Mr. H. O. Creswell ("President"), Messrs. A. C. Bulmer Booth and C. H. Brodie ("Secretaries"), Messrs. J. Dunn, P. Bowyer, R. Welsford, and T. Rutter (banjoists); Mr. E. Garth (singer); Mr. C. G. Killmister (pianoforte), Mr. S. J. Beale (bones), and Mr. E. A. Lambert (tamboourine). They all acquitted themselves well of their several parts.

Fine Art Exhibition at Cordwainers' Hall.—An interesting exhibition of works of art was opened on Monday last, in the Hall of the Worshipful Company of Cordwainers, 3, Cannon-street, E.C. All the pictures and other works exhibited are the property of members of the Company, there being no outside exhibitors. Though the number of contributors is small, the collection is very interesting one, including as it does pictures by George Morland, F. Sand Teniers, Wouvermans, Wynants, Terburg, C. Greuze, Nicolas Poussin, Old Crone, Constable and other masters. There is also a good sh of engravings by Albert Durer, Bartolozzi, and others. Water-colours, miniatures, porcelain and pottery, bronzes, and rare printed books are also well represented. The only exhibits all associated with the craft over which the Cordwainers' Guild formerly held sway are good ancient and modern specimens of book-binding. The exhibition will remain open every week-day from 11 a.m. to 6 p.m. until May 1.

CONTRACTS AND PUBLIC APPOINTMENTS.

Epitome of Advertisements in this Number.

CONTRACTS.

Table with 5 columns: Nature of Work or Materials, By whom Required, Architect, Surveyor, or Engineer, Tenders to be delivered, Page. Includes entries like Construction of Mixing House, Sewage Works, Erection and Completion of Parcelled Buildings, etc.

PUBLIC APPOINTMENTS.

Table with 5 columns: Nature of Appointment, By whom Advertised, Salary, Applications to be in, Page. Includes entries like Temporary Assistant, County Surveyor's Office, Borough Surveyor, etc.

BISHOP'S STORTFORD.—For the erection of a new police-station, &c., at Bishop's Stortford, for the Standing Joint Committee of the Quarter Sessions and the County Council for Hertfordshire. Mr. Urban Smith, County Surveyor, architect. Quantities by Mr. Alfred Barr.

HEMEL HEMPSTEAD.—For the erection of a new Congregational Church and Sunday-school classrooms. Mr. A. Fisher, architect, Hemel Hempstead. Quantities supplied.— Church. Class-rooms. Total.

BLOEMFONTEIN (Orange Free State, South Africa).—For the erection of a new Raadaal (House of Deputies) in the City of Bloemfontein, for the Orange Free State Government. Mr. Lennox Canning, A.R.I.B.A., and Mr. Fred. G. Good, C.E., joint architects, Bloemfontein and Johannesburg. Quantities by the architects and Mr. W. Leck.

REvised Tenders for Church, less allowance for Old Materials, Boundary Walling, &c. Judge £1,993 0 0. Seal 1,980 0 0. Martin & Co. 1,869 0 0. Miskin 1,960 0 0. Payne 1,932 0 0. Hora (accepted) 1,843 0 0. [Architect's estimate, £1,970.]

BOURNEMOUTH.—For erecting the new Richmond Hill Congregational Church, Bournemouth. Messrs. Lawson & Donkin, architects and surveyors, Bournemouth. Quantities supplied.— Stephens, Bastow & Co, Bristol. £12,999 0 0. W. Hoare, Bournemouth 12,730 11 4. Jenkins & Sons, Bournemouth 12,500 0 0. J. Shillito & Sons, Bury St. Edmund 12,390 0 0. F. Hoare & Sons, Bournemouth 12,178 0 0. J. T. Chappell, London 11,890 0 0. George & Harding, Bournemouth 11,845 0 0. F. Merrick & Son, Glastonbury 11,775 0 0. J. S. Kimberley, Banbury 11,322 0 0. T. H. Kimberley, Oxford 10,649 0 0. * Accepted.

LEIGHTON BUZZARD.—For the erection of a detached private residence at Leighton Buzzard, Beds, for Mr. T. H. Bishop, Mr. St. Pierre Harris, architect, 1, Basinghall-street, E.C. Quantities by Messrs. C. Stanger & Son, 21, Finsbury-pavement:— Holt & Son, Croydon £1,860 0 0. H. Edwards, Leighton 1,860 0 0. Tutt Bros, Leighton 1,690 0 0. Cook & Sons, Leighton 1,680 0 0. Webster & Gannon, Aylesbury 1,656 0 0. G. Garcia, Leighton 1,390 0 0. W. Gilven, Eastington 1,424 0 0. W. & W. Scott, Newcastle 1,389 0 0. J. Tremble, Hetton (accepted) 1,328 12 0. J. Heslop, Pittington 1,258 12 5. * Accepted.

BOURNEMOUTH.—For supplying two sets of three throw pumps for the Bournemouth Commissioners. Mr. T. W. Lacey, Engineer and Surveyor.— S. Owens & Co., London £1,050 0 0. Bible, Hobson & Co., London 818 0 0. Ed. Humphries, Limited, Pershore 608 0 0. Wood & Co., Bournemouth 548 0 0. Warner & Sons, Cripplegate, E.C. 546 0 0. Crossley Bros., Manchester 512 15 3. Conduley, Iron Works Com-pany, Bow, E. 590 0 0. G. Waller & Co., London 498 0 0. Day & Co., Bath (accepted) 385 0 0.

LONDON.—For erecting residence in Beaumont-street, W. Mr. T. Durran, architect, 41, Upper Baker-street, N.W.:— Stevenson £3,600 0 0. White 3,590 0 0. Ward, Clarke & Co. 3,475 0 0. Bovis 3,387 0 0. Atchison 3,390 0 0. Higgs 2,437 0 0. [Architect's estimate, £2,500.]

LONDON.—For pulling down and rebuilding No. 324, Holloway-road, for Mr. Mathews. Mr. Truettit, architect, 5, Bloomsbury-square.— Drey £1,776 0 0. Ward & Langle 1,677 0 0. Gould & Brand 1,630 0 0. Hunt 1,419 0 0.

LONDON.—For new roof and sundry other works at the School of Medicine for Women, No. 7, Hunter-street, and 30, Handel-street, Brunswick-square.— McCormick & Sons, 34, Canonbury-road, N. (accepted) £450 0 0.

LONDON.—For alterations at the "Nightingale" Hotel, Southgate-road, Wood Green, Mr. R. A. Lewcock, architect, 85, Bishopsgate-street Within.— F. Voller (accepted) £398 0 0.

The Metropolitan Water Companies and the Public.—The London County Council have not failed to see that the quinquennial assessment of property in London, which will come into force next year, will largely increase the sum of money which must eventually be paid by the ratepayers when London becomes assessed of the property of the Water Companies. The Council has therefore determined to bring a Bill to suspend the powers of the Water Companies to increase their charges for water consequent upon any increase at may be made in the assessment of property in the country. This resolution will recommend itself to London ratepayers. The stem of charging upon the rateable value of house is not equitable, seeing that rateable value and the amount of water consumed often have no relation to each other, and already rough the existing arrangements many London householders are paying largely in excess of that which would be a proper amount for the water used. The Vestry of St. James, Westminster, has determined to memorialise Parliament in support of the Council's views, and it may be expected that other local authorities will adopt the same course. The resolution of the Council makes more necessary in London the requirement by London of its water-supplies, but the basis of compensation one which is not now casier of settlement in when the subject was under consideration years ago.—The Lancet.

Architecture at the Royal Academy.

WHEN the Royal Academy first decided to devote one room in their extensive galleries to the representation of architecture at the annual exhibitions, they were regarded by the architectural profession as having fulfilled a long-standing duty, and by others as having been beguiled into a quixotic piece of complaisance. The Academy annual exhibition was an exhibition of pictures, with a little sculpture thrown in for those who liked to look at it. Sculpture used to be treated worse than architecture is now, and relegated to a small room without light: it has at length taken something more like its proper place in the annual exhibition. And when first there was talk of a separate room for architecture, it was said that the Academy had at last recognised its duties to that central and oldest art. But ideas about art march quickly now; we are in an age of progress in regard to the critical appreciation of art at all events; and we doubt if the hanging of a collection of small drawings in the smallest room in the Academy suite of galleries will long content those who know what architecture really means and how much it includes; and it may even be doubted whether the public will not before long be conscious of a disproportion between the space allotted to pictures and that allotted to architecture. The mind of the exhibition-going public was a good deal enlightened by the process of devoting the new water-colour gallery (a large room) at a loan exhibition two or three years ago, to works in decorative art. It was found that this was the most popular room that year. An experiment which was tried at a loan exhibition might just as well be tried at one of the May exhibitions. Perhaps the result might be as surprising.

People are never tired of talking now about architecture being the central art, the mother of the arts, and all that. We have heard the sentiment at times even from distinguished painters among the R.A.s, but more in private than in public. Painters as a rule do not in public commit themselves to any such ill-regulated and imprudent expressions. But plenty of critics have said it for them. It is a

curious commentary on this to look at the plan of the Burlington House rooms, and compare the space set apart for architecture with that devoted to pictures. And it is in great measure owing to this confinement within narrow bounds that the architectural exhibition is uninteresting to the public. It consists necessarily of a limited number of mostly small drawings, representations of architecture to a miniature scale. The architects are not to blame for this. If they were minded to send in such large geometrical drawings with every detail fully shown, such models, and such drawings of full-size detail, as French architects are fond of sending to exhibitions, they know very well that it is useless; there is no room to hang or to place such things if they were sent. We are reduced for the most part to sending small pictures of buildings; and these, regarded as pictures, are no doubt of inferior interest to many of the pictures in the other galleries. But the illustration of architecture is not to be carried out solely or in the best manner in mere pictures. It is a matter of plan, of detail, of modelling, and of decoration. And if the Royal Academy gave facilities for its full and adequate treatment at the annual exhibitions, we believe there would be a great deal more public interest manifested in the architectural section than there is or ever can be so long as it is confined to the exhibition of small drawings in a small corner room.

The Royal Academy professes to be an academy "of art," not a school of painting merely. Let them act up to that, and give us the long gallery for architecture, the central and largest gallery for the central art. Let them announce that they have space to hang large and elaborate drawings on the walls. Let them devote the centre area of the rooms to architectural models; both models of whole buildings to a small scale, and models of detail, and specimens of architectural ornament of various types, models of relief work in the round, examples of mosaic and inlay and other architectural decoration. They will soon fill their room, and they will find a new interest added to their annual exhibitions; and the public will not be so ready to think the architectural room dull, or regard it as a department *pro forma* only, and with which visitors are not expected to concern themselves.

To some of the painters (the people who tell us "they never look at the sculpture") we have no doubt this proposition would

seem merely matter for laughter; but we are not at all so sure that it would be so regarded outside the Academy. The more educated section of the public are slowly beginning to find out what architecture means, and would probably give such a proposition a considerable support. What is certain to us is that the present treatment of architecture at the Academy is ridiculous: that the art cannot be represented or illustrated properly in the manner and within the bounds now allotted to it; and that the relegation of an art which is really the centre around which all other arts are grouped, to a small out-of-the-way room at one corner of the establishment, is an anachronism, in the present state of artistic knowledge and perception, which the Academy will have to be made to recognise before long, unless they take the lead in recognising it themselves.

The present year's show, in this inadequate gallery, is on the whole equal to the average; perhaps not equal to that of one or two other recent years; there are not so many designs of the first interest or importance. There are a considerable number of smaller things, however, that are of interest and merit, and, undoubtedly a sufficient variety both in subject, style, and drawing. We will confine ourselves in this article to speaking of a few of the more prominent works; going through the majority of the remainder in order of hanging, in subsequent issues.

The central position at one end of the room is occupied by Professor Aitchison's restoration of the interior of the House of Pansa (1893). We stand in the atrium with the impluvium in the centre, laid with marble flags of various tones, but in no very pronounced design; near the impluvium is a small checker-work of dark and light squares, and larger squares of dark marble accentuate the position of the piers at each side. The walls are coloured red and black in the accepted Pompeian style, the larger masses of red forming a background to the statues on pedestals which are ranged along the wall at equal distances. Between them are curtained openings, the space over which is occupied by a trellis, and over that a black panel with the thin graceful Pompeian festoon ornament painted on it. Through this we see beyond the peristyle open to the sky, with columns of yellow tone (gilt?) in the lower portion, and white above. The blue sky is seen through the roof openings. The general effect is very agreeable, but in order to get at the softness of aerial

effect desired the details are hardly shown with the sharpness and precision which one would wish for in a drawing the essential object of which is the restoration of an elaborate scheme of architectural decoration. The whole however, forms a very suitable and interesting pendant to Professor Aitchison's restoration of the Thermæ of Caracalla which occupied a prominent place in a former year.

At the top of the room, above this, is a large drawing for a frieze decoration, "Hedonon Potamos" (1886), "the river of pleasures," which is very effective where seen, and looks as if it might have claimed a better place in the hanging; it represents a row of nude or semi-nude figures, in various attitudes but forming a continuous chain, painted in delicate cream tones against a dark red background; over the figures is a decorative frieze with triglyphs (is it not time something were invented to take the place of the triglyph on these occasions?), and below is a horizontal string with brackets forming the margin of a decorative river into which the figures seem preparing to plunge. The drawing is hung too high to judge of the separate merit or interest of the figures taken separately, but the effect of the whole in a decorative sense is very good.

Another centre-piece is Mr. Norman Shaw's "New Scotland Yard—part of South Front" (1838), a large and powerful but also highly-finished pen drawing signed with the name of Mr. Gerald C. Horsley. A peculiarity in the design is that the lower portion of the wall, containing (as we see by the size and treatment of the windows) the more prison-like portion of the building, is treated differently from the upper portion as regards the character of the masonry, but without the orthodox string-course to divide the one from the other; an omission highly characteristic in effect. The lower portion is in not quite regular masonry of squared stones; the upper portion is built of brick with flat stone bands at intervals. The whole treatment speaks the purpose of the building very well; the upper portion, with its evenly-spaced large windows with cornice heads, is essentially official and administrative; the lower portion, with smaller windows spaced unevenly and without reference to those above, and some of them grated, is, as observed before, essentially prison-like. The doorway, with its boldly-rusticated pilasters and heavy cornice, is also prison-like, unless we except the iron balcony projected between the two halves of the broken pediment, a feature the object of which is not quite evident: perhaps to read the Riot Act from in the case of an attack on the prison by a mob. The heavy circular corbelled-out turrets at the angles assist the rather stern aspect of the whole, which is quite in keeping with the object of the building. The wrought-iron V.L. and crown bracketed out from the masonry at the angle, so as to stand free, is another characteristic touch in the detail. There is little other ornament about the design; but the whole is a satisfactory and solid-looking piece of building.

We referred to the fact that the drawing was a highly-finished though powerful one, not without intention, inasmuch as we cannot but think that the tendency to "rough but effective" drawing is being carried too far occasionally in these days. The interior of Mr. Sedding's "St. Peter's, Ealing" (1777), for instance, is clever and original enough in design to claim a good place, it may be said, in almost any style of drawing; but it would certainly have been none the worse for a less careless and scrupulously style of execution; and although we have frequently protested against the Academy Architectural room being made a mere draughtsman's exhibition, we are nevertheless of the mind that a certain standard of execution should be kept up in drawings for exhibition in this room, and that the practice of running up a drawing for exhibition at the last moment, and trusting to spirited effect to atone for roughness of execution, though it is not an error on the worst side, is yet not a system that should

be encouraged. There is a curious kind of paradox in the method of dealing with these things at the Academy; there are designs to be seen there often which obviously owe their position entirely to the skill and craft of the draughtsman, and we even see the same hand and style of drawing coupled openly with the names of architects who have connexion with each other, but who have put their work through the same drawing-manufactory. On the other hand, there appear to be favoured persons (we will not name names, but the consciences of one or two may accuse them) who may send in any kind of scrawl and get hung; we have even heard of those who make a boast that they never commence their Academy drawings till the day before sending in. Now as this is, after all, not an exhibition of architecture (for that we can only have out in the streets), but of architectural drawings, it is certain that drawing ought to go for something; and architectural drawing is a beautiful branch of art in itself and worth keeping up as an end and not only as a means. The true principle would be that the architect whose name appears in the catalogue should make his own drawing; there are eminent men in the profession who do, and have done so for many years, thereby setting an example to be much encouraged and followed. The interior of Mr. Sedding's church, the drawing of which suggested these reflections, was illustrated in the *Builder* for November 16, 1889, and therefore we may refer the reader to that number for further knowledge of it, repeating here our appreciation of its bold and picturesque originality of treatment. Mr. Bodley's water-colour drawing of "Interior of St. Mary's, Clumber" (1780), which hangs next to the last-named, and occupies the central position on the west wall, is a curious contrast, as a completely archaeological Gothic church, very correct and very good of course of its kind, but a mere repetition, as far as the main architectural design is concerned, of a Medieval church. There is an elaborate chancel-screen with open-work tracery and the usual coved cornice proper to the period. A heavy roof-beam above carries a central cross and two side statues, and beyond is seen a glitter of decorative work in the chancel, very well expressed in the drawing. Next to this hangs another large church interior, Mr. F. B. Walters' "Church of the Sacred Heart, Wimbledon" (1785), an elaborate pen drawing, with a strong effect of massed shadow behind the rather heavy foliated arch in front of the altar. This also has its roof beam, rather curiously designed, with two egee arches commenced below the line of the beam and interpenetrated through it to form finials above, which are crowned with statues; this is a treatment better suited no doubt to woodwork than to stonework, but not quite pleasing even there, and the heavy bracket depending from the centre of the beam seems to hang too much weight on it; a large crucifix rises above the centre. The style is of the Late Decorated period. Transverse arches are built solid across the aisle at each pier. These three drawings form an effective group in the centre of this wall.

Mr. Garner exhibits a "First Design for the Reredos at St. Paul's Cathedral" (1759) which we wish had been carried out in place of the actual one, and which shows that first thoughts are sometimes the best. This is a reredos placed transversely on the chord of the apse, as it should be, and which evades the difficulty of connexion with Wren's architecture (a difficulty which is clumsily ignored in the existing reredos) by keeping the architectural design to the centre only, and filling up the side spaces with a light but elaborate and graceful wrought-iron grille. The centre portion resembles considerably the centre of the executed reredos, being in fact a kind of baldachino with gilt and twisted columns; the subject of the crucifixion is shown in bas relief under the central arch. The design is more modest and less obtrusive on the building, by far, than that which has been carried

Of Mr. T. G. Jackson's exhibits a very pleasing example is "Northington Church, Haunts, exterior" (1769), in late Gothic style with a square tower with richly-treated pinnacles and open tracered balustrade; the east end is octagonal and diversified with stone inlay decoration on the walls, an arched ornament of this type being carried round this part of the building, under the windows, with very good effect; the tower is partially decorated with the same type of work. The same architect's "Brasenose College; one bay of the new front" (1794) is remarkable for the unusual and rich effect of the sumptuous open-work carved cresting to the projecting bays, a very fine and bold piece of detail which gives great individuality of character to what is in the main a quiet piece of collegiate architecture of domestic Gothic style. Mr. Waterhouse's only contribution to the architectural room (he exhibits a landscape in another department of the exhibition) is a water-colour drawing of the "Offices of the Prudential Assurance Company, West Regent-street, Glasgow" (1828), a solid-looking brick building with a strong bracketed cornice, and two heavy corbelled-out circular turrets on the canted angle of the front, which are sprung in a novel and effective manner from large brackets below their centre, which are turned over each way in two arches or coves ornamented with radiated fluting, after the manner commonly used for the heads of niches in one period of Renaissance work. Among the designs for business buildings a very notable one is the "New Buildings for the Metropolitan Life Assurance Society" (1793) by Mr. Aston Webb and Mr. Ingress Bell. This is something quite unusual in London street architecture of the commercial class, in its richness and originality of treatment. The drawing is a coloured one, and shows a plain granite (?) plinth, over which the ground story is treated very plainly with square-headed

columns separated by plain engaged columns of no special "order" but with a design of their own; on the next floor the windows have partially arched archivolts springing from shafts, divided by a pier plain in the lower part but developing into a flat fluted pilaster above; the bases of these pilasters are carried by a projecting corbel the effect of which we do not quite like, as it gives the feature rather a stuck-on appearance; on the next floor the arch form is more developed in the window heads, and the wall between remains a flat plane but with a sunk carved enrichment in the upper portion, the effect of which is excellent; on the top story the piers and windows are doubled in number and form a continuous range, the exterior angle of the piers between them being treated as a shaft. Each story has a special and original treatment, increasing in richness as it goes up; and the angle of the building, canted off, is also specially enriched by bas relief sculpture between the windows. For originality combined with effectiveness this is one of the best secular buildings illustrated.

In the matter of collegiate architecture we have, besides Mr. Jackson's Brasenose College, just mentioned, two charming little coloured elevations by Mr. Pearson of new chambers at Sidney Sussex College, Cambridge; the "Quad side" (1771) and the "Garden side" (1788). The former shows a cloister of three-centred arches on columns, built in stone; over this the main portion of the building is brick; three gables of Elizabethan type break the roof line, under each of which are single arched windows in the two stories, in a wide expanse of wall; between these points is a special treatment with three stone pilasters finishing in finials above, and the windows, balustrade, and wall decorations forming continuous horizontal lines between them; the contrast of this richer portion with the rest is most picturesque and characteristic. The "garden side" elevation shows somewhat similar characteristics, without the cluster arcade; but why were the pilasters finished with halls and long spikes like decanter stoppers? The one blot in a charming

design. It is a pity to see this sort of commonplace in detail under the shelter of so good a name. Among other collegiate designs Sir Arthur Blomfield exhibits two views of his design for the "Church House" (1,889 and 1,897), pen drawings showing an exceedingly simple, suitable, and unaffected building with the low square centre tower over the entrance which has become a kind of accepted typical feature of buildings of this class. Messrs. Micklethwaite and Somers Clarke also exhibit a geometrical elevation and section of their design for the Church House, a fine and dignified Gothic façade of which one side appears to be intended as a great vaulted hall with large traceried windows and buttresses, with a low ground story under it; the façade is divided in the centre by a rich and effective tower with massive octagonal angle turrets the lower portions of which form abutments to a wide segmental pointed arch spanning the whole space between them. The wall of the tower over this arch is enriched with niches, tracery, and sculpture, stopped above by a battlemented cornice. The portion of the building to the right of the tower is kept lower and treated in a more simple and domestic manner. The whole is a stately design, but is perhaps a little too much so for the proposed purpose, a little too cathedral-like in style.

The recent Sheffield competition contributes its quota to the architectural room in the shape of various monuments of blighted architectural hopes. Among these Mr. Arnold Mitchell's is by far the finest and most striking drawing; he has worked out the design of himself and his partner Mr. Butler into a large brown-tinted perspective drawing in his finest style, making a design for the return end of the front block, not required to be shown in the competition drawings. The façade has a centre tower kept very plain below and treated with great richness at the crowning stage, with balustrades, angle turrets, and a central lantern; the detail is peculiar and original, with a semi-Oriental effect about it, as a whole, though made up of rococo details. The return gable is enriched in the same effective manner. The treatment of the large windows of the principal story, projecting slightly as bays, and stopping under the projection of the cornice, is very effective. The angles are treated with octagonal angle turrets, with open balustraded canopies as finials. A porte-cochère appears in this design, which is also richly and effectively treated, but which does not alter our opinion that a porte-cochère is and always must be architecturally an excess and an injury to the effect of a building. It seems quite a pity that so original and picturesque a design should have missed fire in the competition, but we fear the plan which is appended explains this: for one thing, the Town Clerk's department is arranged, compactly enough in itself, in a block at the farthest end from the principal entrance, and also at the furthest point from the Mayor's territory. Now the Town Clerk is of all officials the one who should be most central in a municipal building: the public constantly want to see him or his functionaries, and he constantly wants to communicate with the Mayor; to put him at the furthest point from both was a fatal error in planning. Mr. H. H. Statham exhibits (1,720) an enlarged drawing of the sketch elevation made for the design submitted by Mr. J. Slater and himself in conjunction, of which for obvious reasons we say nothing here, except to remark that in the first editions of the catalogue ("under revision") this has by some accident been wrongly named, and is called "competition design for Birmingham Law Courts," which should be the title of No. 1,870, another enlarged drawing from a small-scale competition sketch elevation. Messrs. Morris and Hunter send their original sketch-elevation to 16th-inch scale (1,872), a very neat and sensible elevation apparently designed with a laudable desire to keep within the stipulated cost; it is a classic design with a rusticated ground story and

basement, and an Ionic order in the upper story; a campanile rises behind, but has no connexion with the principal façade. There is no balustrade and the roof is frankly shown. There is a semi-circular turret at the right-hand angle with a little cupola over, which however sits rather awkwardly on the roof, the main cornice being carried through. The long level line of roof and cornice seems rather to want something to break it in the centre, but the building would have had a dignified effect in execution, and the drawing is a good specimen of the class of "sketch elevation" on a small scale. Messrs. A. G. Gordon and D. Brown send also their original sketch elevation (1,873), a more ambitious one with a good deal of merit; the Campanile (in the rear) is rather prodigious in proportions but gracefully designed; the centre of the front is well accentuated, and the octagonal turret is a pleasing feature, as also the continuous arcading under the cornice. No plans are appended to these, nor to the design by Mr. Woollard (1,929), who sends a neatly-executed pencil perspective of his idea for the building, a design of the now prevalent type of thin pilasters with large mullioned windows between, square-beaded below and arched above; the centre gable is flanked by two octagon turrets, and a lantern rises from the centre of the roof ridge. The whole is picturesque and in good taste: no plan is given. Nos. 1,720, 1,825, and 1,872 will be published in our illustration pages shortly, with the plans of each.

There is much more to say about the architectural drawings, which include a fair proportion also of good decorative work.

BUILDERS' PRICE-BOOKS FOR 1890.

IN examining the price-books of the year,* the marked improvement which has taken place in their arrangement, accuracy, and comprehensiveness within a few years cannot fail to impress the experienced reader. There is, however, still room for further improvement. In the whole of them the majority of the prices are higher than any current contract rates, and the profit included is certainly not uniform. The importation of a trained measuring surveyor into a suit at law would be apt to modify the confidence of those persons who bold the view set forth in "Laxton's" preface that it is "the acknowledged standard to which, in disputed cases in the various law courts, reference is made."

The most valuable information in "Laxton," "Lockwood," and "Spon" respectively is that on building stones, in which relative labour is compared by a ratio; we believe this originated with the first-named.

These books would do good service if they would supply the constants in all cases; some of considerable importance are omitted. Greater precision, moreover, in the description of some of the stones is desirable; for example, the labour on White Mansfield is given as "about equal to Portland," but there is a difference of probably 25 per cent. in the labour on ordinary White Mansfield and that on a first-rate stone such as Mansfield Woodhouse.

The tabular form adopted by "Spon," which is possibly imitated from the report prepared by the Commission on the stone for the Houses of Parliament, is most convenient for reference.

It has become the custom in price-books published in recent years to preface each trade with directions for measurement and construction. These directions are generally either superficial or obsolete; indeed it is difficult to furnish any good reason for the introduction of such information. In the restricted space available in price-books it is

* "Laxton's Builders' Price-Book." Seventy-third edition. London: Kelly & Co. 1890.
 "Lockwood's Builders', Architects', Contractors', and Engineers' Price-Book." London: Crosby Lockwood & Son. 1890.
 "Spon's Architects' and Builders' Price-Book." London: E. & F. N. Spon, 125, Strand. 1890.

impossible to do justice to the subject, nor does any judicious builder attempt to learn his business from them. The current text-books are plentiful enough, and deal with these studies in a thorough manner. Space must be considered of little importance by the publisher of the following piece of information:—"To find the number of cubic yards contained in an excavation, multiply the length by the width, and that product by the depth, which being divided by 27, gives the number of cubic yards. The superficial area is obtained by multiplying the length by the width and dividing the product by 9 instead of 27; the result will be the area in superficial yards."

We may instance also the recommendation in one of these books to measure labour to openings in brickwork,—an unreasonable suggestion derived from Northern and Midland practice, and inconsistent with the London habit of pricing, which is based upon the Metropolitan system of measuring. Reference to a priced bill of quantities for work in the Northern counties will show a very low price for brickwork compared with London prices, but the extra labours not measured in London go far to bring the price up to the same level.

That the practice of the London measuring surveyor is in the main superior to any provincial system is generally admitted. Some of the worst features of country practice are mere ignorant survivals of methods which the London surveyor has long discarded, and any return to them must be deprecated as tending to retard the assimilation of methods of measurement and consequent valuation. On this score it must be a matter for regret that there has appeared within the last few years a "Northern Builders' Price-book," which may assist in some degree to emphasise the divergence.

The orderly arrangement of advertisements, and the tables of weights, capacity, and area, given in these books are of value to the estimator. The introduction of various Acts of Parliament affecting building operations is also useful enough, and the same may be said for conditions and form of contract: but both these latter require consideration to adapt them to particular cases.

The memorandum in "Laxton's" at the end of a suggested form of contract, "In cases where the quantities are provided, it is recommended that, unless a surveyor may be mutually agreed upon by the architect and builder, two surveyors be employed to take off the quantities, one appointed by the architect and the other by the builder at a meeting convened for the purpose," is a proposal to revert to a condition of things which never had much to recommend it, except in the case of very large works, and is not likely to be revived.

The new colonial woods, we observe, are making their appearance in these books; the prices for American white wood and basswood, however, are not to be found in any of them.

In examining particular prices one finds that the hire of building plant is still higher than is ever allowed by experienced persons, in spite of the increased value consequent on the Employers' Liability Act.

The price for drain-pipes in "Laxton" is the list price without comment; in "Lockwood," list price, and so described; in "Spon," a little over prime cost, described as prime cost of pipes.

Digging in common soils and throwing out, not exceeding 6 ft. in depth, is priced 7d., 8d., and 9d. respectively; all three add for basketing 8d. per yard cube, a price dependent upon the distance (of which no mention is made), and too low.

For concrete, composed of 1 part ground lime to 6 of pit ballast, we have 8s. 6d., 6s. 6d. to 10s., and 10s. 6d. respectively.

In "Laxton," for concrete, 1 of Portland cement to 7 of Thames ballast, 16s. 9d. per yard cube is the price given. In "Spon," for concrete of the same specified quantities, 13s. to 15s. 6d. per yard cube. In "Lockwood," for concrete, 1 of Portland cement to 6 of Thames ballast, we have 14s.

Turning to the Bricklayer's prices, we have in "Lockwood," for brickwork, labour, and mortar, 3*l.* 5*s.* per rod. "Spon," for brickwork, labour, and mortar, 5*l.* per rod.

"Laxton."—Stock brickwork, labour, and materials, 15*l.* 6*s.* per rod.

"Lockwood."—Stock brickwork, labour, and materials, 13*l.* 10*s.* per rod.

"Spon."—Stock brickwork, labour, and materials, 14*l.* 5*s.* 10*d.* per rod.

For paving of common hard stock bricks, laid flat in mortar, per yard superficial, we have:—"Laxton," 4*s.*; "Lockwood," 3*s.* 6*d.*; "Spon," 2*s.* 6*d.* There is a considerable difference in the prices for facing in the various books. Extra for facing of best white glazed bricks appears in two of the books at 2*s.* per foot; it has within the last year been contracted for in several buildings known to us at 1*s.* 9*d.*, including pointing. Pointing is always measured with the extra on facings, and in only one book is it mentioned in that connexion.

"Lockwood" is the only book which deals with terra-cotta in the ordinary way, by the foot cube; it gives moulded terra-cotta and fixing, 7*s.* 3*d.*,—a high price except for small quantities. In the three price-books, the prices per thousand for glazed bricks of "Spon" and "Lockwood" agree; "Laxton" has precisely the same price per thousand "delivered on job." All three use the words "prime cost," which certainly does not in either case mean the price after deduction of trade discount.

The prices of stone display curious differences. Portland stone, averaging 20 ft. cube in a block, which costs 1*s.* 11*d.* at the depot, appears thus:—

	Wharf.	Including hoisting, scaffolding, setting, and cleaning down.	
	s. d.	s. d.	s. d.
"Laxton" ...	2 8	4 9	
"Lockwood" ..	2 10	3 2	
"Spon"	2 5	4 0	

A common contract price per foot cube, including scaffolding, hoisting, setting, and cleaning down, is 3*s.* 3*d.*

"In block at wharf, including hoisting, scaffolding, and setting," is the curious prefix to a price in "Spon" for Portland stone (p. 163).

The Carpenter's measured prices, "Labour only," are somewhat difficult to account for. They are thus headed in "Laxton" and "Lockwood"—"The prices are calculated at the rate of 10*d.* per hour." To the general public such prices are valueless, and they are not available for paying men piecework, as the average carpenter is paid 9*d.* per hour, or less. If intended for valuation of the work of a sub-contractor (a small master of labour), one doubts whether the builder would pay so much as 10*d.* per hour.

"Laxton" also gives the price per square for labour only, 4 in. framed and braced partitions, 6*s.* 2*d.*

This section has an archaic air. "Labour and nails measured per yard superficial" is customary in the northern counties, but the practice is unknown in the south. The valuation by the foot cube is much more reasonable, in addition to being customary.

The price of timber in floors, partitions, &c., is too high in all three books.

The ironmongery prices, when makers' names are not given, may mean anything. Those of the articles for which makers' names are given are trade-list prices.

The price for nails and screws in day-account is, as usual, ridiculous in all three.

The relative value of work in Keene's and Portland cement is not quite in accord with general opinion. Work in Keene's cement is worth 20 per cent. more than in Portland.

For iron welded tubing, both "Laxton" and "Spon," as usual, give a copy of a manufacturer's list without comment. Would the law courts consider this "the acknowledged standard," &c.? "Lockwood" also gives the same list with a heading, "List Prices."

In this trade, as in others, not much light is afforded by such a price as 9*s.* to 12*s.*, and the like; an exact definition, and a price without

alternative, would be better. "Lockwood," in stating the weight of rain-water pipes, makes a step in the right direction. The principle might be extended to other rain-water goods with advantage.

The same book gives for unloading, getting in, hoisting, and fixing rolled iron joists, 3*s.* per cwt., which a builder would only get by great good fortune. In the Plumber, "Spon" and "Lockwood" still adhere to the unmeaning distinction of pipes under the heads "light," "middling," and "strong." On this point, "Laxton" properly says, "the terms 'light,' 'middling,' and 'strong' are but seldom used now, and are practically valueless." The application to pipes of these terms may be useful in a specification, to define their purpose, but only with a table of the weights at the beginning of the trade. The London surveyor usually makes his price for lead pipe, up to 2 in. diameter, include bends, wall-hooks, and fixing, and he includes in his lineal measurement running-joints to all pipes. Joints are all separately stated in these books. Probably the value of a price-book is greater the more closely its descriptions resemble those usually in vogue with measuring surveyors. The distinction as to the amount of labour and consequent precision of measurement of lead-work has increased of late. We see no reference to this either in directions for measurement or prices.

The long lists of apparatus by special makers in "Laxton" and "Lockwood," both for the plumbers' and other trades, indicate great care and pains in their compilation. "Laxton's" price of 3*d.* per superficial foot difference between lead lights in square quarries and lead lights in geometrical patterns is insufficient.

An exhaustive analysis and comparison of prices would obviously be out of place here. The foregoing are a few of the more noticeable features. The prevalent belief that the rates of a price-book, as compared with those of the average estimate, would, taken as a whole, bear a discount of some 15 per cent. or thereabouts, will be modified by an examination of "Lockwood." Many of these are really contract prices. Parallels occur in the other two, but the greater number are to be found in this. All the three books contain some prices at a rate of profit which might be used for current estimating; others with an exorbitant rate of profit; others upon which the profit is inadequate; and a long list of manufactured articles upon which the trade discount varies from 5 per cent. to 50 per cent., without its being clearly indicated to which category a particular item should be referred.

One naturally asks, What are the objects which the author of a price-book has in view? To set forth the rates at which an estimate may be priced with a view to success in competition? To furnish information of first cost? or the value of items with a reasonable profit attached? We rise from the perusal of the three books before us without being able to give a clear answer to these questions.

The attempt to do several things at once is rarely successful. The fable of the old man who tried to please everybody and pleased nobody is a lesson for all time, and may be commended to the makers of price-books. The usefulness of these in many respects valuable books is impaired by the versatility of their intention. They might be more correctly described as handbooks of matters connected with building. The production of the ideal price-book, which shall be orderly in arrangement, consistent in its rates of profit, accurate in the values stated throughout, and easy of reference, requires a combination of qualities rarely found in one person, although one qualified person could do it better than an association of several. Above all, its author should be possessed of long and varied experience of building values, and it is rarely the case that a man so qualified cares to devote time and attention to a pursuit which must of necessity be paid for at a rate far below his possible earnings in other ways. It is, however, too late at the end of this article to enter in detail upon the consideration of

the method at once the most scientific and the most practical of compiling a builders' price-book.

NOTES.

THE Annual Report of the Institute of Architects, which we print in another column, touches on two or three subjects of special interest. The constitution of the Council has become much more cosmopolitan, and for the first time since the establishment of the Institute the presidents of various provincial societies have had, *ex officio*, seats on the Council. The contemplated enlargement of the premises is to include, we are glad to see, the removal of the whole business of the Secretary's department to the ground floor of the building; a much more convenient arrangement for visitors calling on business than the present one. But the report is not satisfactory in regard to one most important department, the Library. In the first place, there seems a most remarkable and uniform falling off in the use of the library, in every branch of its statistics. We place this here in a schedule form:—

	This Year.	Last Year.
Number of readers	3,039	3,906
Tickets for admission to use of loan collection ...	94	103
Volumes issued on loan ...	985	1,255
Attendances of A.A. members as readers ...	296	570

The year means of course the sessional year; now there must be some reason for this remarkable diminution in library attendance. Is the library ill-managed, or what is it? Another point we regret in the report is the statement as to the want of funds to keep the library up to its proper standard. The former by-law requiring every newly-elected member who did not read a paper to make a contribution in money to the library has been abrogated. Its operation brought in a certain fund which nothing else has replaced; nor do we see very well, from the statement of accounts, where a sufficient annual sum is to come from. But this is a serious matter. We regard the library as being really the most valuable concrete fact in connexion with the Institute; as is claimed in the Report, there is no other like it in the United Kingdom; but good as it already is, it is not all it might or should be; there are various important anti-periodicals wanting in it which should be there; and in regard to other works of more permanent value there is a constant necessity for the acquisition of new architectural works of importance which any student ought to count on finding in the Institute Library. There seems to be a half admission in the Report that this is not the case even now, and that the library is not properly up to date; and apparently, unless some decisive action is taken, this state of things is likely to become worse rather than better. This is a very important matter, and ought not to be allowed to drop. If there are not funds to keep the library to the highest standard of a modern architectural library, steps ought to be taken at once to raise a special fund for the purpose. It would be a grievous slur on the Institute that its unique library should be allowed to deteriorate. And the causes of the falling-off in the use of the library recently should also be enquired into.

THE Architectural Association has been considering the question of some further development of its mechanism for Architectural Instruction. A Sub-Committee was appointed on June 21 of last year to consider what alterations, if any, in the methods and working of the Association would improve its usefulness as an educational body, and to report upon the same. The Committee commenced by applying formally to the Institute to enquire if its Council contemplated introducing educational schemes in connexion with their own body, and elicited first a reference to Mr. Waterhouse's recent address, and subsequently a distinct statement that the Institute was not a teaching body. This the Association might

have known; but at the same time they were making a safe course in making the formal inquiry first, and they have some right to complain of the "cold-shoulder" and evasive answer they at first obtained from the Institute, which is constantly putting itself wrong in this kind of way by want of ordinary tact. The main question entered upon then by the Association was whether there should be a salaried staff of teachers engaged, and the report comes to the conclusion that this must be done, and that the "mutual system" cannot be depended on longer. This must have been seen to be inevitable in the long-run; as such societies increase, there always comes a period when the work becomes too great for voluntary effort, and in this respect the Association is only repeating the history of the Institute. Other conclusions embodied in the Subcommittee's report are that the Institute Examination programme should be recognised, but not regarded as the final end or limit of the student's work (though we doubt if many of them will be able to cover more ground than it covers); that a combination of lectures with class teaching was better than either system taken singly; that if possible an architectural studio should be started in connexion with the Association, and that it should be open in the day-time as well as in the evening. The report says on this subject:—

"We have given our attention to the question of the establishment of day classes, recognising that there is, at present, a strong feeling amongst many of especially the leading members of the profession, that architects should allow their pupils additional facilities for study during office hours. We feel that, if such classes were established, attendance at them would soon be accepted by the profession as part of the ordinary work of pupils, and, therefore, strongly recommend that classes of this description should be established as part of the work of the Association."

We hope this programme will be successfully carried out, and especially that architects will recognise the propriety of allowing their pupils to attend day classes, within reasonable limits. For those who wish for the advancement of the standard of professional education in the future there ought to be no foolish hesitation on such a point.

THE "Great Tower" scheme has now reached a further stage. The drawings in competition have been submitted, and we have been exhibited this week at Drapers' Hall, Throgmorton-street. Eighty-six schemes have in all been sent in, out of which eighteen have been disqualified, "sent in as suggestions, but not admissible for competition." Of the remaining sixty-eight designs, it is in many cases hardly possible to speak seriously,—indeed, the competitors themselves seem to have treated the matter as a huge joke, and have submitted to the public gaze as curious a collection of objects as it has been our bad fortune to see for any long day. It was naturally certain that a number would take the idea of the Eiffel Tower as a basis of design, and if in any details of construction they differ from it, they, at least, pretty closely reproduce the general outline. No. 66 is one of these, with pavilions at the base and on the first and second stages. Others, such as 51, are "provided with buildings for residential and other purposes." The base of No. 52 is flanked with a large dome of the "onion" type, to be used as a winter garden; and the author of No. 21, not to be outdone, describes his work as "Light, health, rest, pleasure"; beacon, sanatorium, people's hotel," &c. &c. Full advantage has been also taken in many cases of the "full liberty in the combinations" allowed by the conditions. A steel mast 200 ft. high, with steel ropes as stays; a concrete tower (43); a granite tower on the lines of the Pisa Campanile (29) are some of these. One has submitted a glorified new, 1,900 ft. high; while a second name is a "Vegetarian Tower," for what reason is not apparent, and proposes to make his building, which is in the form of an obelisk, serve

as a vast field for the display of what appears to be transparent advertisements. No. 23 proposes a tower which will stand on a piece of ground of about 64 acres! Of the designs which at all approach architecture in character, little can be said in praise. Two of those before mentioned, Nos. 29 and 43, are the principal ones which have been carried out on anything approaching architectural lines. Several have hotels, pavilions, &c., more or less grotesque in character. What appears to be the best is No. 37, the entrance of which has been designed in the Indian style, and makes a very effective elevation. It was, we suppose, too much to expect that "Gothic" would escape. One or two of the designs are apparently intended to follow the general outline of a church tower and spire of colossal dimensions, and various forms of "tracery" occur, chiefly of geometrical character. If praise cannot be bestowed on the designs, it must be in justice acknowledged that some of the drawings are very fine examples of draughtsmanship and colour—notably Nos. 11, 20, 37, 53, and 54, and it is to be regretted that so much valuable time has been spent in the production of works which are in a large number of cases little short of a farce. The decision of the judges, we are informed, is to be given on Saturday, and we shall be curious to see what opinions are held by the jurors, amongst whom are well-known and honoured names, of a scheme the results of which so far only strengthen the hopes we expressed on a former occasion that the whole would be a failure.

A ROYAL COMMISSION has been issued "to inquire into the present state of the Abbey of Westminster as regards the facilities which it offers for providing for the interment, and otherwise preserving the memory, of the most illustrious of our subjects, in the manner which has been customary for many centuries; and to hear evidence and to consider plans for providing at the Abbey, or elsewhere, an additional place for memorials, should such a provision appear necessary." The Commissioners appointed are:—Mr. D. Plunket, First Commissioner of Works; Sir A. H. Layard, Sir F. Leighton, the Dean of Westminster, Mr. Louis J. Jennings, and Mr. Alfred Waterhouse, R.A. It is with real satisfaction we observe that in this case at all events a Commission to consider an important architectural question has been apparently appointed with some reference to the special knowledge and capabilities of some of the Commissioners for dealing with such a subject. The *Pall Mall Gazette*, with the customary fatuity of our daily papers in regard to all matters of architecture, laments that Mr. Shaw-Lefevre is not on the committee, but accounts for it by the supposition that he preferred to remain as an independent critic. This may be so, but it is just possible also that people are beginning to discover that Mr. Shaw-Lefevre is not the authority on architecture which he has given himself out to be.

SIR WILLIAM HARCOURT is apparently posing as the art-critic of the House. Last week he asked the Chancellor of the Exchequer whether, in view of the prospect of a great issue of new gold coin to replace the present light gold, he would take measures to procure a new design for the future gold coinage. The Chancellor replied that a new design for the head of the Queen was under consideration. As for the reverse side, it appeared to him that nothing could be more handsome than St. George and the Dragon, and he proposed to retain that design. Evidently Mr. Goschen and the honourable members who shouted "hear, hear," are not aware of Mr. Ruskin's keen criticism of that "handsome design," or, being aware of it, do not think it worth consideration; but we are so far with them as to consider the modelling far superior to that of the new effigies of the sovereign on the other side. Sir William next turned from numismatics to architecture, and asked the

Home Secretary "whether the new police buildings on the Thames Embankment represented the æsthetic views of the Secretary of State for the Home Department." When the laughter of the House had subsided, Mr. Matthews made reply: "I will not express any opinion as to the buildings on the Embankment." And again the House laughed, and Sir William gave notice that he would call attention to the subject on the Home Office vote. It may enlighten Sir William Harcourt to learn that a drawing of a portion of this building forms one of the most prominent and central exhibits in the Architectural Room at the Royal Academy at this moment, and our opinion on its architectural merits may be read in our leading article on the Academy Exhibition. The building makes no pretence to being a very picturesque or ornate one, for that would have been unsuitable to its purpose; but it is a thoroughly refined and sensible piece of architectural design, carried out by one of the very first architects of the day, Mr. Norman Shaw, whose merits the Home Secretary appears at all events to have understood. That the architectural design of an artist like Mr. Norman Shaw is to be called in question by such a critic as Sir William Harcourt is very characteristic of the effrontery of English public men in dealing with questions of art; and it is all the more contemptible because the whole thing is palpably only a piece of worry directed against a political opponent, and in which the artistic pretext is a mere stalking-horse.

THE principal point discussed at this week's sittings of the Railway Rates Inquiry has been the demand of the traders to have all hardware goods included under the generic term "hardware." This has evidently long been done in practice, for a railway classification before us, dated several years back, contains a "hardware list," comprising 168 articles; and it is there stated that where special rates exist for "hardware" they apply to all the articles enumerated. The companies object, however, to a hard-and-fast rule being imposed upon them by Act of Parliament, and strongly resist the demand. This point is considered by the Court as being of greater importance than any other yet raised during the inquiry, and Lord Balfour of Burleigh decided that the matter should be fully argued by counsel on each side. The traders' representatives had put on a very bold front, and courageously declared their readiness to argue the point out there and then with the railway representatives present, but they were overruled. A great deal of conflicting evidence is being offered as to the value of different commodities, the variation in the estimates of the railway managers and the traders (given, of course, with differing ends in view) being most remarkable; and unless it should be considered necessary to adduce further evidence to substantiate that already put in, the Court will be compelled to adopt a medium as representing the required figure. But value, after all, is a factor frequently having no weight whatever in the determination of rates,—bulk, liability to damage, and many other considerations being of far greater importance. The evidence on these latter points also, however, is sometimes very contradictory and confusing.

THE case of the Governing Body of Charterhouse School v. Le Marque, Surveyor of Taxes, decided on April 29, raised the question whether Charterhouse School was exempt from payment of inhabited house-duty under 14th & 15th Vict., c. 36, which exempts "any charity-school" from payment of the duty in question. The case is of larger importance than at first sight it would appear to be, because grammar-schools and similar foundations might gradually become large public schools. The Court decided that the duty was payable. This decision is clearly sound, but it certainly raises the question whether the inhabited house-duty is not rather a local than an imperial tax.

AN inquiry has been instituted by the Local Government Board in regard to an outbreak of diphtheria at Berkhamstead, Herts, and the state of sewerage of the town. Dr. Blaxall's Report to the Board (April 1) states that the sewerage of the town is of the most defective character, involving faults in construction, and a method of disposal of sewage fraught with nuisance injurious to health.

"The main sewer which runs along High-street is merely an old brick sewer originally laid down by the highway authorities at a depth of about 2 ft. for the conveyance of surface water, and is utterly unfitted for the purpose of carrying off sewage; it permits leakage, and it favours deposit. I had the sewer opened in two places, when I found some 4 in. of thick black mud at each place. This sewer receives the contents of various branch sewers from the streets on the south, and gives off sewers on the north which pass down certain streets, and ultimately discharge into the stream. The principal of these is the sewer which goes down Castle-street and empties into the stream on the east side of the bridge. Another sewer takes the sewage from the west end of the main sewer, and ultimately enters the stream on the west side of the bridge. This sewer is actually provided with two catchpits for the subsidence of the solids; the larger catchpit being only a few feet removed from cottages, and giving rise to intolerable emanations, especially during the time of removal of the solid contents. I received loud complaints of the nuisance caused by the sewer outlets, which is said to be intensified by the admixture of hot brewery refuse.

The branch sewers are said to be constructed of glazed pipes. But no provision is made for the ventilation or flushing of the sewers. From the foregoing it will be seen that the Berkhamstead Sanitary Authority have failed to fulfil the requirements of the Public Health Act, 1875, sections 15 and 19. That the evidence of this report goes to exculpate the sewerage evils existing in this town from direct concern in the causation and spread of throat illness on this occasion does not constitute the smallest justification for the present state of the sewerage. Not only is its condition a distinct violation of law, and a standing cause of offence and other danger to health, but its condition is such as to ensure the spread of such diseases as cholera and typhoid fever should they by chance be introduced into the town."

MUCH has been written and said of late years, though little has been done, respecting the planting of trees in large towns. Manchester has recently shown a disposition to take up the question seriously, and its "Field Naturalists and Archaeological Society" has prepared a report on the subject. Circulars were sent two or three months ago to a number of gardeners and others, and to these circulars forty replies have been received. It is pleasant to find that the majority of those appealed to consider the successful growth of trees in Manchester a possibility, and as many as sixty kinds of trees and forty kinds of shrubs are recommended for planting in streets. It is also suggested that "when trees are planted in broad thoroughfares they should not be placed near the edge of the pavement, but along the middle at convenient intervals. So placed," the report continues, "they would not impede the traffic, but contribute rather to its assistance. The best methods of planting and subsequent treatment are also stated. It remains to be seen whether this report, like so many others on the same subject, will be without practical results.

AMONG the different works of civil engineering now being carried out on or in close proximity to the coast of the Baltic Sea, those on the German side in the old free town Lübeck may be well worth mentioning. We here find that the harbour lines are being relaid, that the water passage is to have a depth of 6½ metres (about 6 ft. more than formerly), and that this passage will be flanked by embankments of monumental construction, backed by rows of warehouses and sheds. A monster crane will be placed in a convenient position, and a new swing-bridge will form the connecting link for the railway service on either side of the water. Owing to the miserable condition of the ground, the foundation-work of the embankment walls is exceedingly difficult, so that these broad borders of béton (faced with brick) have to rest on piles of some 15 to 16 metres length,

of which 4 or 5 go to the metre. The estimate for the work now in hand shows a figure of 2,000,000 marks, and the authorities hope that this sum will suffice for the present. The design of the harbour plan shows that the engineers expect the approval of the Imperial Ministry of Public Works to the new North German Canal scheme, which latter, when carried out, may in some way recompense the old town for the loss of trade which it will most likely suffer as soon as the new sea-canal connecting North and Baltic waters is completed.

IT is proposed to repair and restore, at an estimated expenditure of 3,000l., the Chapel of King's College, Aberdeen, which was enlarged to a capacity of about 350 persons in 1827. It contains the tomb of the founder of the University, Bishop William Elphinstone, to whom Pope Alexander VI. sent a bull dated February 10, 1494, nearly a year after George Keith, fifth Earl Marischal, had founded Marischal College. Of King's the first principal was Hector Boethius, who came from Paris, at a salary of fifty marks Scots,—about 2l. 8s. 4d. a year. Mr. James C. Watt's prize measured drawings of the interior and exterior of the chapel, showing the stall canopies, door in screen, the lantern, with its crown, and other details, were published in the *Builder* of June 6, 1885. In that same year the home on School-hill of George Jameson, the celebrated portrait painter, was doomed to destruction. We published a cut of it on October 3; it is also illustrated in R. W. Billings' "Baronial and Ecclesiastical Antiquities of Scotland," 1815-52, vol. i., and is therein spoken of as being, traditionally, the manse of St. Nicholas. The adjoining building, shown in our cut, was the school to which Lord Byron used to go. Billings' volume contains an interior view of King's College Library; some of Jameson's paintings were hung in the two college halls, notably the set of female portraits, known as "The Sibyls," at King's College.

THE members of the Manchester Cremation Society met on April 23rd and decided to form a company under the title of "The Manchester Crematorium Limited," for the purpose of acquiring land and erecting thereon a crematorium and chapel. Among the directors of the new company are the Duke of Westminster, Chancellor Christie, Dr. Emrys Jones, and Professor Munro. The capital will be 10,000l., and it is expected that the cost of a crematorium on the smallest scale will be 3,000l. Mr. T. C. Horsfall, a gentleman well-known in Manchester for his advocacy of sanitary reforms, drew attention to the state of Ardwick Cemetery. "For more than half a century hurials had taken place at that cemetery far in excess of the purifying power of the soil, and it was horrible to think of the festering mass of human remains that were lying there virtually in trenches. There was no means of escaping such an evil except the one advocated by that society, and in a few years he believed they would have all the thoughtful men and women in Manchester on their side." Certainly the movement in favour of cremation is spreading, but Mr. Horsfall must not be too sanguine: sentiment dies hard.

IN the last number of the small magazine which circulates among the members of the Architectural Association under the title of "A. A. Notes," a tolerably outspoken opinion is expressed as to the recent appointment to the Professorship of Architecture at King's College.

"Another of our members, Mr. Banister Fletcher, J.P., F.R.I.B.A., D.L., has been appointed Professor of Building Construction and Architecture at King's College, London, in place of Professor Kerr. The appointment has certainly come as a surprise to at least the younger members of the profession. Professor Fletcher has long been known as a successful surveyor, and as the architect of certain buildings; his name, too, appears on the title-page of some well-known hand-books on "Dilapidations," "Quantities," and so on, but these books have nothing to do with architecture,

and not much with building construction. He has never been generally credited with the kind of learning that one looks for in a professor of architecture, and it does not seem as if being a J.P. and past M.P. could be qualifications for the post, so that one may be excused for wondering upon what grounds the appointment was made." We have also "wondered."

THERE seems to have been a little local quarrel about the new Leamington Board schools, concerning the rights of which we know nothing, but a writer signing himself "Parallax" made some deprecatory statements concerning the way the work had been done, in the columns of the *Leamington Courier*. The point that concerns us is that in the next number of that journal the editor published a very well-meant expression of regret at having printed a letter reflecting upon the architect of the schools, which must, be thought, have been an unfair attack, seeing that the architect was a member and a local secretary for the "Society of Architects," so that his professional brethren had confidence in him, and also that the Editor of the *Builder* had "solicited the privilege" of publishing the design. This only shows how things get misrepresented to (and consequently by) well-meaning country journals. We never saw the design, and our solicitation of the "privilege" of publishing it amounted merely to an ordinary routine offer to publish a new building, but which never implied any approval of the design. Occasionally a building gets a factitious celebrity in newspapers which an inspection of the drawings by no means confirms. The more serious point is the absurd and mischievous confusion that is made in country places, and which is promoted we have no doubt as much as possible by those whose interest it is to promote it, between the real representative body of the profession and the recently-constituted sham one. Will country newspapers please take note that the representative body of the profession is the *Institute of Architects*, and they will then be preserved from the unnecessary abasement of doing koodoo to people who have no claim to it.

LETTER FROM PARIS.

THE Municipal Councillors of Paris,—elected for a term of three years, which has just expired,—have separated without having voted the prolongation of the Boulevard Haussmann, leaving it to their successors to settle this matter of considerable interest to the Parisian public. In the same careless fashion, having voted recently for the preservation of the buildings on the Champ de Mars, they have adjourned the question of the Chemin de Fer des Invalides.

It is a year since the Exhibition opened its doors, and the event is to be celebrated by a fête organised by the former Commissioners and the exhibitors who have been "awarded." There was to have been banquet and ball on the first platform of the Eiffel Tower, which, after a closure of some weeks, has again been opened to the public; but the unsettled state of the weather has decided the managers of the fête to take refuge at the Hôtel Continental instead.

The liquidation of accounts in connexion with the Exhibition is proceeding rapidly, and everything will probably be settled by the end of the year. The preparation of commemorative medals is nearly completed, and the Direction des Monnaies has already received more than 3,000 medals for the engraving of the names. The diploma, which was designed by M. Galland and the engraving of which has cost M. Waltner more than seven months' work, is being multiplied in electrotype for quicker printing; and it is hoped that the distribution of medals and diplomas, in the order of classification, will be commenced in August.

While Parliament is putting into legal form the making-over of the Champ de Mars and its buildings to the Municipality of Paris, the arrangement of the Palais des Beaux-Arts for the "Salon Meissonier" is in active preparation. The main public entrance will be opposite the dome and facing the Avenue Bourdonnais. The exterior galleries, formerly occupied by restaurants, will be decorated with plants; and sculpture,—not a great deal, it is said,—will be exhibited in the central hall, which will be

decorated with the tapestries lent by the municipality of Paris. In regard to the paintings, which will occupy the position of the exposition retrospective "of last year, the jury is said to have been very hard to please, and to have admitted only about 250 pictures on outside; the total number of paintings exhibited, including those of Associates and Sociétaires," is expected to be about 1,200. The old Salon, which will have opened by the time this letter is published, will include about 400 pictures (300 less than last year). During the present month, it may be observed, will be placed the sale, for the profit of the Société des Artistes Français, "of the works of Delbuth, which were all left by the artist as a legacy to the Société.

The smaller exhibitions, the delight of amateurs, continue to succeed each other during his lull before the opening of the large ones. The eclectics have succeeded the Water-colourists at the Georges Petit gallery. This is the sixth and certainly the best exhibition of this society; including many works remarkable for purity of colour, perfect taste, and an assemblage of varied and curious talent. We may mention among many others the flower studies of M. Hellen; a remarkable portrait of Madame Adeline Lemaire by M. Bessard; M. Roll's portrait of M. Antonin Proust; five pastels by John Lewis Brown; a whole series of rustic scenes by M. L. Lhermitte; some beautiful sea scenes by M. Duez, a fine portrait of a young girl by Mme. Lemaire, and various works by M. Bissot, Dagnan-Bouveret, Elliot, and Forain. Another interesting exhibition is that of Adelle Abbeville, including portraits, pastels, and decorative panels.

The public has been much interested in an exhibition of the works of M. Chéret, who has received deservedly a nomination as Chevalier of the Legion of Honour, having obtained a gold medal in the Universal Exhibition. This artist has for many years been designing decorative and artistic placards and advertisements which have covered many walls in Paris and in provincial towns, and have done much towards raising advertising pictures to the level of a branch of art. The breadth and simplicity of style natural to him have served him well in his class of work, and he may be regarded as an artist peculiarly representative of the present epoch. Other special exhibitions have been those of M. Nozal, landscape-painter, that of H. Renouard, a clever illustrator of Parisian life, and that of the Russian painter Alvasorski, whose mannered and hard style is a curious contrast to that of contemporary French painting of the "plein air" school.

A few days since there was opened, at the Ecole des Beaux-Arts, an exhibition of Japanese engravings, got up by M. Ph. Burly, the well-known art critic, who has collected some very fine specimens of the work of Japanese artists, ancient and modern, of very curious and unique interest.

We ought not to omit in this list of exhibitions the reopening of the panorama of the battle of Champigny, which had such a success some years ago. For those who participated in the sanguinary actions of November 30 and December 2, 1870, this masterly work by Détaillé and De Neuville has a painfully realistic impression.

The Conseil-Général de la Seine, before separating (the term of office of the present council having expired) has given various commissions to artists. Two of these are for paintings for the Tribunal of Commerce, to replace those of Robert Fleury, now in the museum of Versailles, and which have been removed from their original position from an absurd stretch of political prejudice, because they commemorated scenes of the First and Second Empires. M. Delance is to paint in their place "Les Nauties de Lutèce à l'époque Gallo-Romaine"; and MM. Gilbert and Dupré, working in concert, are to illustrate "Une Gare d'Arrivée de Marchandises à Paris." In addition to these, M. Debon is commissioned to decorate the new Mairie of Charenton-St.-Maurice.

An architectural competition has just been decided at the Hôtel de Ville for the new "Ecole de Meuble," mentioned in our last, to be erected in the Faubourg St. Antoine. From among twenty-six designs sent in, the jury have selected for execution that of M. Léopold Decron, and given premiums to those of MM. Guyon, Blavette, and Durand. A sum of 600,000 fr. has been voted for the work.

The Collège de France, the enlargement of which, often talked about, is not yet taken in

hand, is to receive shortly an important addition in sculptural decoration, on a scheme drawn up by M. Ernest Renan. In the Cour d'Honneur adjoining the Place Cambrai is to be erected a group by M. Guillaume representing Francis I. and his sister Marguerite of Valois founding the Collège de France. In a court adjoining the Rue St. Jacques will be placed two statues by M. Delaplanché, representing "La Science de la Nature" and "La Science de l'Humanité." For the Assembly Hall of the Professors M. Alfred Larion is to execute a work symbolising "Le Génie de la Renaissance;" and on the grand staircase is to be placed a bust of La Boulaye, the learned professor who preceded M. Renan as administrator of the establishment. This last will be executed by M. Chaplain.

At the Madeleine an important piece of decorative work of mosaic on gold ground has been commenced by M. Gilbert Martin, after the cartoons of M. Charles Lameire. This decoration, which will occupy the frieze between the colonnade and the domed ceiling of the apse, will consist of a series of figures, the whole occupying a space 30 mètres long, the figure of Christ triumphant occupying the centre, with figures of Apostles and disciples on either hand. This work will give some encouragement to the school of mosaic founded by M. Gilbert Martin at St. Denis, though it is to be feared it may somewhat disturb the harmony and completeness of effect which at present characterise the interior. It might have been better to take the new Church of Sacré Coeur as a field for this experiment.

The clearing away of the exterior scaffolding from this last-named church has resulted in some disappointment. Considering the admitted and exceptional talent of its designer, the late M. Abadie, and the time and money that have been expended on the work, there is a feeling that the effect of the façade, at all events from a distance, is meagre and deficient in grandeur, suggesting a chapel rather than a great church. The addition of the large flight of steps intended by the architect will do something to give it more breadth of effect, but perhaps even then not all that was expected.

The restoration works at Versailles are still in progress. The "Nymph à la Coquille," by Coysevox, after its restoration by M. Suchetot, is to be transported to a museum, and its place in the park will be taken by a copy to be executed by the same artist.* A statue of Houdon, the sketch-model of which has just been completed by M. Tony Noel, is also to be erected at Versailles.

M. Falguère and M. Mercié have just completed their sketch for the monument to Alfred de Musset for the Place St. Augustin. On a pedestal designed by M. Formigé the poet is represented seated in an attitude of meditation. By him stands a female figure representing Poetry, who holds a lyre.

A new work by M. Ernest Barrias deserves mention; this is a massive silver cup offered by the Jockey Club to the "Société d'Encouragement des Courses des Chevaux," under the title of the "Prix de la Coupe." The cup represents, or rather symbolises, the two principal races of France, Longchamps and Chantilly. On one side the artist has reproduced the ancient abbey of Longchamps in the time of Louis XIV., and on the other the actual chateau of Chantilly. To the right and left are small figures representing the Seine and the Oise; the first leans on her elbow holding a vase from which water issues; the latter bears a shield on which is sculptured the figure of Condé.

At the Ecole des Beaux Arts M. Constant Moyaux, "Grand Prix de Rome" and Inspector-General of "bâtiments civils," has been appointed professor of architecture, in the place of the late M. André.

The final competition for the Prix de Rome has just commenced at the Ecole. There are ten candidates in each of the sections of Architecture, Sculpture, and Painting. The annual examinations have resulted in the conferring of the diploma of "Architecte du Gouvernement" on the following:—M. Malgras, pupil of M. Ginain; M. Guénot, pupil of MM. Vaudremer and Raulin; M. Cousin, pupil of MM. Coquery and Gerhardt; M. Garnier, pupil of MM. Douillard and Thierry; and MM. Destor and Febvre, pupils of M. André. The Duc competition, which has for its object "To determine as far as possible, and under the patronage of the Académie, the style and form of the element of our modern architecture," has only attracted

* Most English readers will consider this a very doubtful mode of carrying out restoration.

four candidates. The prize has been awarded to M. Yasson, for a design for a Salle de Concert at Nancy.

A landscape painter who received last year a commission for a large decorative panel for the Hôtel de Ville, has died before having executed his task. This is Mr. Hector Hanoteau, who has died at the age of sixty-seven, after a long and painful illness. A pupil of M. Jean Gigoux, he received medals in the Salons of 1861, 1868, and 1869. He devoted himself especially to pictures of scenes in the neighbourhood of Nivernais, in the midst of which he lived. The Luxembourg possesses two of his principal works, "Les Némuphars" and "Mare du Village." The death of M. Émile de Lansac is also announced, who gained a repute as a portrait-painter. Among his best works are his portraits of Olivier de Clisson and Marché de la Palisse, both now in the Museum of Versailles. He was a pupil of Ary Scheffer, and obtained medals in the Salons of 1836 and 1838. He was eighty-six years old at the time of his death.

Engène Ciceri, the painter, who also died during the past month, was the son of the decorator Charles Ciceri, who was well known for his designs for scenery and decorations for "Guillaume Tell" and "Robert le Diable." Engène Ciceri was pupil of his father, and designed the decoration for the Salle de Spectacle at Mans, but he devoted himself mainly to landscape painting in water colour. He obtained a troisième médaille at the Salon of 1852.

We have also to record the death, at the age of eighty, of M. Brisset, an old pupil of Picot, who assisted his master in the execution of the frescoes in the Church of St. Vincent de Paul, and subsequently executed decorative paintings in a good many churches in Paris, a class of work for which he gained a certain reputation, though his work cannot be said to have risen higher than mediocrity.

In the premature death of the young sculptor, M. Sul-Abadie, pupil of Jouffroy, we have lost one who would probably have attained a high position in his art.

Although collecting is not art, the collector has an important influence in bringing together and preserving art treasures which might otherwise be lost or remain unnoticed, and on this ground we should include in our obituary notes some mention of M. Spitzer, the well-known collector, who, in his splendid house in the Rue Villejust, had accumulated an immense quantity of artistic objects of various kinds, among them a reliquary of the Renaissance period which was valued at 500,000 francs. He was the contributor of the most remarkable objects in the loan exhibition of ancient French art collected in the Trocadéro Gallery last year, of which a detailed account was given in the *Builder* at the time.

The annual congress of French architects will be held this year, to meet the wishes and convenience of some of the departmental societies, in the third week in June, from the 16th to the 21st.

The Académie des Beaux Arts has classed in the following order the candidates for succession to the place vacated by the death of M. André: "première ligne," M. Ancelet; deuxième, M. Pascal; troisième, MM. Guadet, Guillaume, and Harly. But to these five candidates nominated by the Section of Architecture the Académie has added the names of MM. Dutert, Sédille, and Corroyer. The election of the new Academicians will take place shortly.

THE NEW GALLERY EXHIBITION.

The Exhibitions at the New Gallery are less mixed than those of the Academy, where there are levels of commonplace which we do not find at the New Gallery, at which latter, however, it must be remembered the number of works is much smaller: 436 this year, as against 2,119 at the Academy. Consequently the first impression on entering the New Gallery is that of being in a rather select and specially high-class exhibition; an impression which on closer inspection is rather weakened. There is a choice of poetic subjects prevalent, but not always a poetic treatment of them; and a good deal which looks at first sight original seems on further acquaintance rather more correctly classed as eccentric.

There are two very ambitious paintings in the exhibition which peculiarly illustrate the shortcomings of the artists of this following in regard to poetic subjects. Mr. Richmond's large paint-

ing illustrating a quotation from Shelley's "Eppisychion" (72) is merely a reduction of the wild fancy of Shelley to a decorative picture, with a hardly painted and uninteresting damsel walking through a landscape where flowers sprout in a decorative manner, with equal spaces between them. The picture is an absolute failure as far as it professes to be an illustration of Shelley's poem. Equally a failure is Mr. Kennedy's "Persons" (162); worse than a failure, a vulgarising of the legend. The Andromeda is odious; a smirking young woman making vulgar love to Persus. The treatment of the sea-monster is good; but as a whole the thing is nothing but a bad stage scene.

Mr. Watts's "Ariadne" (31) is another sort of thing. A fine picture at all events, though she is too placid for Ariadne, this large and rosy nymph in her ample drapery; there is a richness of colour, in the drapery, in the face, and in the bands of heavy foliage and dark clouds which cross the background. There is at all events nothing commonplace here in the conception; and there is that harmony and unity in the whole, rather to be felt than described, which goes to make what can really be termed in the full sense a picture.

Mr. Alma Tadema's "Eloquent Silence" (51) is another masterpiece of colour. A Greek man and woman are seated on a marble bench, with a mass of purple clematis on the wall behind them, whose colour is repeated in the purple jar which forms a background to the woman's head. There is a little more of interest and expression in the figures, in the man at all events, than this painter generally gives us; but the interest of the painting does not lie in that, we care nothing for them; it is an incident of composition and colour presented with consummate skill. The small and exquisitely-painted portrait of "Miss McWhirter" (52) by the same hand, is very interesting, for it shows Mr. Tadema for once dealing with a different type of female face from that which he had been for so long continually repeating; there is a great deal of character about it; and as a painting, in the matter of execution, it is a perfect gem. Below these, and lower than it should be hung, is placed a beautiful little nude study by Mr. Poyner, "High Noon" (55), a young girl seated on rocks by the sea and shading her face from the sun with a palmetto fan. This is a curious contrast to Mr. Tadema's method in flesh painting; less realistic, warmer and richer in colour, and broader in execution, and as far as the figures taken alone are concerned it is a finer work. Mr. Tadema's strength lies in his brilliant combinations of figures and accessories.

It may be doubted whether Sir John Millais has achieved what he intended in his remarkable attempt to represent "Dew-drenched furze" (119) under the light of the morning sun. The scene is in a wood facing the full glare of the morning sun, and the furze-brake is glistening with myriads of dewdrops. The dazzling effect of the sun is conveyed by the loss of form and detail among the trees, which vanish in the light in the centre of the picture. The attempt to represent in painting an effect which depends on an infinite number of scintillations or reflections of light seems almost hopeless; we can see what is intended, but the effect is not realised, though the experiment is a most interesting one.

Landscape takes for the most part, at the New Gallery, the form of studies of special effect or special sentiment expressed in a more or less impressionist treatment. Thus we find as a typical example immediately on entering, Mr. Padgett's "As the red moon rose o'er a Sussex down" (2), a ghostly effect of moon over an expanse of down, the whole worked up into a kind of dreamy effect of demi-tint. This is not Nature; it is very pretty art, but an art of which one is apt to tire, and of a kind which it is not very difficult to manufacture. There are some fine landscapes to be seen however. Mr. Alfred Hunt sends a large painting of "Windsor Castle, Twilight" (92), which is the larger edition of that which is seen on a small scale in the gallery of the Water-Colour Society; an effect of atmosphere expressed with even more delicacy and beauty in the oil painting than in the water-colour. Mr. Adrian Stokes's "Breaking Wave" (97) is a fine painting in regard to the form and movement of the water, but there is a want of light and "glisten" on the inner surface of the turn of the wave which gives it a dead and un-waterly look; the dark bulk of the following wave, behind the foam of the first one, is finely given;

but the whole picture is not one of Mr. Stokes's great successes.

Mr. Parsons even has become sentimental in the atmosphere of the New Gallery; his "When Daylight Dies" (149) has the usual arrangement of trees but with a sunset sky and a figure—actually a figure, of a melancholy lady leaning against a tree trunk to gaze on the sunset, but we cannot say the figure adds to the sentiment of the scene. Mr. East's "Pershire Pastoral" (133) is a fine work, the method of Corot with a different and warmer scale of colour. Mr. R. W. Allan has made a fine landscape under the title "Homewards" (96); we say "made" advisedly, for it is a contrived picture with a kind of "old master" style about it, and not a transcript from nature; but it is a powerful and poetic work. Mr. Wetherbee's "O Lovely Spring" (105) is a joyous effect of sunlight. Mr. Lemon's fine and poetic work, "The Horse Pond" (125), is made out of the same materials as his picture in last year's Academy; well-studied but dimly-discerned horses in the foreground and successive stretches of dull moorland in the background; it is an admirable picture, but we hope the author is not going to fall into the mere repetition of a receipt: he is worth something better than that.

Among the figure pictures that are prominent is Mr. La Thanguc's "Leaving Home" (132), a painting which pretends to be pathetic while the real and evident object is to display the artist's cleverness in painting a horse and cart "end on." This is a false cleverness which always defeats itself in regard to any effect of the picture on the sentiment of the spectator.

Mrs. Alma Tadema's "Battledore and Shuttlecock" (138) is one of the best works we have ever seen of hers; it is a study in light tones, a girl in a white dress in the middle of a mostly white room; her figure is very pretty and her action as she prepares to hit the shuttlecock very well conveyed; the lookers on fill up the incident of the picture well. Mr. Nettleship sends one of his large and interesting animal paintings, "The Adversary" (8), a huge serpent (which we think we know at Regent's Park) stalked by two tigers: the colour of the serpent seems rather heightened beyond that of Nature. Mr. Edgar Barclay's "Shelter" (34) is a pretty combination of figures and landscape, a group of girls in the foreground sheltering under a tree. Mr. Watts sends one of the little jokes which he has taken to lately, "Little Red Riding Hood" (47), charming in colour but rather stiff and artificial as a child picture.

Among the portraits are some really fine ones, of which we prefer Mr. Shannon's portrait of "Sir Alfred Lyall" (64) to all the rest; it is a full-length portrait in which the artist has contrived to give both ease and dignity of attitude; a combination not often achieved in portrait painting. His "Mrs. Whitelaw" (98) is not happy in colour; but a half-length portrait in the South Room, "Miss Cooper" (227), is beautiful. Mr. Herkomer's portraits of Mr. Cawkwell, Mr. Grierson, and Sir James Pender, (28, 33, 43) are masterpieces of straightforward realistic portraiture. Among smaller portraits Mr. Julian Story's "Mrs. Humphrey Ward" (123), and Mrs. Swynnerton's portrait of two little boys (192) should be looked at; as also Mr. Clifford's large and fine portrait group of the Earl and Countess of Radnor and Viscount Folkestone (237). Mr. Sargent has out-Sargented himself in his portrait of poor Mrs. Comyns Carr (82), nor is his rather bald picture of "Ightham Moat" (188) a compensation, though topographically interesting.

Among various pictures we noted but have not space to comment on further are Mr. Waterlow's "Night before Shearing" (6), an effect of light well conveyed; Mr. Buxton Knight's "All on a Summer Day" (19), noticeable because it is out of the painter's usual style and looks like a leaf taken out of Mr. Mark Fisher's book; Mr. Alfred Parsons's "Beafield" (46); Mr. Wylie's "Fallow" (61); Mr. Leslie Thomson's "Summer" (78), a clever example of the artificial landscape effect, "with bathers," a new tune on an old instrument; Miss Tennant's "Street Arabs at Play" (170), a more ambitious work than she has generally attempted; Mr. Thorne Waite's "The Shepherds Meet" (232), a beautiful chalk coast landscape; and Mr. Harper's "The Singers; Byzantine Interior" (217), in which the figures are perfectly stiff and uninteresting, but which may appropriately be recognised in an architectural journal as a remarkably finished study of mosaic and glass decorative effect in an interior.

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS: THE ANNUAL REPORT.

The annual general meeting of this Institute will be held on Monday next, May 5. The Annual Report of the Council, to be formally submitted for consideration, has been already issued to the members. As usual, we make some extracts from it:—

"The thirty-four members of the present Council are the first who have been elected by voting-papers issued to every subscribing member of the Royal Institute in the United Kingdom; and they include representatives from Bristol, Cambridge, Glasgow, Leeds, Leicester, Liverpool, Manchester, Newcastle, Nottingham, and Sheffield, with a representative of the Architectural Association (London). For the first time since the foundation of the Institute, the Presidents of allied societies at Bristol, Leicester, Liverpool, Manchester, Newcastle, Nottingham, and Sheffield have been elected to seats on the Council; as also two Associates, in accordance with the provision of the by-law. The Council, since their election on June 3, 1889, have held twenty-five meetings, and, since the issue of the last annual report, Committees of Council have held in all fifteen meetings, for the consideration respectively of questions relating to Professional Practice, the Certificate of Membership and the new sea alliance of non-metropolitan Societies, the acquisition of additional premises, the qualifications of technical officers appointed under Acts of Parliament, and the Architects' Registration Bill.

The Birmingham Architectural Association, whose rules had been previously approved by the Council, and whose list of members had been duly submitted, were admitted to alliance with the Institute by a resolution passed at a special general meeting held on March 1, 1890.

During the official year now terminating forty-two Fellows (of whom twenty-four were previously Associates) and seventy-eight Associates have been elected. The number of Fellows is now 519 as against 497, and the number of Associates 768 as against 727, at the corresponding period last year. The number of Hon. Associates is now eighty.

In accordance with the provisions of By-law 13, three Fellows have been transferred to the new non-subscribing class of Retired Fellows—viz., Messrs. H. Clutton and James Murray of London, and Mr. Milford Teulon of Leamington. Professor E. A. Freeman, D.C.L., and the Right Hon. Sir Henry Layard, G.C.B., who have been members for many years, have been elected Hon. Fellows. One Hon. Cor. Member has been elected—viz., M. J. Van Ysenyck, architect, of Brussels.

The losses by death since the last annual meeting have been eight Fellows,—viz., E. C. Aytton-Lee, Joseph Jennings, Charles Lockhart-Lock, W. Millican (Leicester), Samuel Musgrave, H. R. Newton, Sir J. A. Pictou, F.S.A. (Liverpool), and E. W. Stephens (Maidstone) (three Associates,—viz., J. Mechelen Bogers, Ralph Nicholson, and E. P. Willis (Norwich)) and three Hon. Associates,—viz., J. F. Latrobe Bateman, F.R.S., Gerard Ford, and George J. J. Mair, F.S.A. Among the non-subscribing members the Institute has lost by death John Turtle Wood, F.S.A., Hon. Fellow, Firminger Epellet, Hon. Cor. Member (Arras, France), and Louis Jules André, architect-academician in the Institut de France, Hon. Cor. Member.

The need of further accommodation for the purposes of the Library and the Office of the Institute, and the opportunity offered by the removal of Messrs. Hutchings and Romer, the music-sellers, who have long occupied the shop on the ground-floor of No. 9, Conduit-street, led the Council to consider the possibility of taking the vacant premises. They have consequently arranged with the Architectural Union Company for a lease of the shop and the basement under it, at a rental of 220*l.* per annum; and as the seven years' lease held by the Institute of the Arbitration-room would expire at Christmas, it was thought desirable to enter into a lease of both the shop and the Arbitration-room for the same period, and on the same lines as that of the other portions of the building rented by the Institute, viz., until the year 1958. The Council, therefore, having made a recommendation to this effect, have been empowered, by a resolution passed at a special general meeting held on March 31, to execute a lease of the premises in

question at a combined rental of 350l. per annum. Possession of the shop, it is understood, can be obtained at Midsummer Day, when it will be necessary to make certain alterations therein, in order to fit it for future use as a Council-room and Secretary's room. The proposal is to remove the whole of the secretarial work to the ground-floor, the present Arbitration-room to be fitted as a general office, and the basement divided into a strong-room, store-room, lavatory, &c., thus leaving the whole of the first-floor free for the library and reading-room, and for committee purposes. The probable cost of the necessary alterations and fittings will be about 1,000l.

An enlarged edition of the 'Kalendar,' issued to members in September, 1889, contained, besides most of the matter in former editions, lists of the names and addresses of professional members of nine allied societies, particulars of the Progressive Examinations, a list of the principal contributions to the original series of the 'Transactions,' with the new By-laws and revised appendices incidental thereto.

The Certificates of Membership, authorised under the provisions of the Charter of 1887, are being issued to Fellows and Associates, at home and abroad; and, in accordance with its requirements, a new seal has been prepared, from drawings made by Mr. J. H. Metcalf, the gift of the President.

A Preliminary Examination of candidates for registration as Probationers of the Institute,—the first under the newly-established system of Progressive Examinations,—was held in November last, and the Council desire to acknowledge the cordial assistance they received in its inauguration from the nine allied societies. Of the 107 candidates admitted, 41 were declared exempt; and of the remainder, 36 were examined in London, 3 in Dublin, 8 in Bristol, and 16 in Manchester. Forty-three passed. At a second Preliminary Examination held in March, 1890, in London, Bristol, and Manchester, 18 out of the 70 candidates admitted were declared exempt; and of the remainder, 34 passed. The names of 139 gentlemen have consequently been entered on the Register of Probationers. The Council have decided to hold the first Intermediate Examination next November, on condition that a minimum of six Probationers offer such testimonies of study, and have so advanced in their studies, that by special exemption they can be admitted to it in less time than the prescribed two years.

At the Qualifying Examination for candidature as Associate, held last November, 28 out of 40 gentlemen who presented themselves passed; and at the Examination held in March, 26, out of 53 who presented themselves, passed. Thus, during the official year 1889-90 (from May, 1889, to May, 1890), 54 gentlemen have qualified for candidature as Associate. During the Kalendar year 1889 the number who passed at the three Examinations held in London and Liverpool amounted to 79. Of these, Mr. Herbert Baker was declared by the Board of Examiners to have most highly distinguished himself, and the Council awarded him the Aspietial Examination Prize.

At the Statutory Examinations held in October, 1889, when six candidates presented themselves, a certificate of competency to act as District Surveyor in London was granted to Mr. George Lay Crickmay, Fellow; and certificates of competency to act as Building Surveyor under Local Authorities were granted to Mr. Henry Heugh Tasker and Mr. Robert Williams, Associate. The second half-yearly Examinations are to be held on the 24th and 25th inst.

The Royal Gold Medal for the promotion of architecture was presented in June, 1889, to Sir Charles T. Newton, K.C.B., Antiquary to the Royal Academy of Arts, and late Keeper of Greek and Roman Antiquities in the British Museum, for his works as a man of science and letters. That for the current year has been awarded to Mr. John Gibson, for his works as an architect; and, the royal sanction having been received, the medal will be presented at the closing meeting of the present Session.

The public presentation of the Studentships and Prizes for 1889-90, the award of which, in accordance with the provisions of By-law 66, was made by the Council in writing under the common seal, and announced at the business general meeting held Monday, January 13 last, took place on the subsequent Monday, when the President delivered an interesting address to students. The exhibition of drawings consequently remained open until after the presenta-

tion of the prizes, an advantage to all concerned.

The Council regret to be obliged to record that no Essays were submitted for the Silver Medal and twenty-five guineas offered last year, the subject of which was 'Fenestration: its treatment in secular buildings of various styles.' A similar subject has been set for the current year, under the title of 'The treatment and disposition of windows in Civil and Domestic Buildings in the United Kingdom.' The Silver Medal and ten guineas for Measured Drawings were presented to Mr. Alex. Mackintosh for illustrations of Pluscardyn Priory. In the same competition, Mr. J. E. Mowlem, of Swanage, obtained a Medal of Merit for illustrations of Cranborne Manor House.

None of the designs submitted for the Soane Medallion appeared of sufficient merit to justify the award of the Medallion or of a sum of money for foreign travel; but Medals of Merit were presented to Mr. Francis W. Bedford, who sent in the best plan, and to Mr. Charles S. Spooner and Mr. Ernest W. Gimson, who sent in the best architectural designs for the exterior.

Mr. John Begg, of Edinburgh, was elected the Pugin Student; and Mr. Detmar J. Blow received a Medal of Merit for the drawings he submitted for the Studentship.

The Godwin Bursary was awarded to Mr. A. Arthur Cox, who has undertaken to make a tour in the United States.

The Lite Prize for Design in the Italian Style was presented to Mr. James C. Watt, of Aberdeen; and the Grissell Medal for Construction to Mr. Walter Percival, of Longton, Staffordshire. In the latter competition Medals of Merit were presented to Mr. J. A. Pywell and Mr. Thomas F. Pennington, Associate.

In the Scientific Masonry Competition, the first prize of ten guineas was gained by Mr. Harold A. Woodington, and the second prize of five guineas by Mr. A. Whitford Anderson, Associate. These prizes were the gift of three members of the Council. Three similar prizes, offered during the current year from a sum of twenty guineas subscribed by members of the Institute, are open to all British architects and students of architecture.

During the twelve months elapsed from April 1, 1889, to March 31 of the present year, the additions to the library amounted to 208 volumes and 222 pamphlets, and to the Loan Collection six volumes and five pamphlets, exclusive of Parliamentary Papers, periodicals, reports and transactions of societies, parts of works issued in a serial form not yet completed, and trade-lists.

The number of volumes presented to the Library was 190, and to the Loan Collection three. Of pamphlets, 164 were presented to the Library, and five to the Loan Collection. The foregoing enumeration includes 123 volumes and 58 pamphlets forming the Pink Bequest.

Of drawings, engravings, and photographs, 103 sheets were presented, and seven volumes of drawings and sketches of Indian scenery and antiquities by T. and W. Daniell were presented by Mr. J. D. Crace, Hon. Associate.

The works purchased comprise eighteen volumes and fifty-nine pamphlets for the Library, and three volumes for the Loan Collection, together with several Parliamentary Papers.

The want of shelf-accommodation, a subject that has frequently been mentioned in the annual reports, has again begun to make itself felt; but the Committee trust this may be met by increased accommodation when the changes in the Institute premises, now under consideration, are carried out.

The Report then gives statistics as to the attendances of readers in the Library, which during the year numbered 3,039, as against 3,906 last year. The number of tickets (exclusive of renewals) issued for admission to the use of the library and loan collection was 94 (last year 108). The number of volumes issued on loan was 985 (last year 1,255). The attendance of members of the Architectural Association as readers in the library were 296 (last year 570), and the number of issues on loan (both these items being included in the gross returns above given) was 91 (last year 185).

The bookcases opened last year for general access to certain books of reference have

* See some remarks on this subject, and the state of the Library generally, in a "Note" on page 316.—Ed.

fairly answered their intended purpose, and many of the books are in frequent use.

"The Committee have called special attention to the fact that, since the abrogation of the by-law referring to the special donation" which every newly-elected metropolitan member was expected to make to the library, the amount of money the committee have at their disposal for the purchase of books is extremely small. In the absence of adequate funds it is quite impossible to maintain the Institute Library (the most valuable architectural reference library in the United Kingdom) at the standard of usefulness desired for it. There is every year a very large number of books published which ought to be at once purchased: delay in waiting until they can be bought second-hand, or by chance be presented, tends to foster in the minds of members a belief that the Institute library is of value only for the consulting of books long since published.

The *Literature Standing Committee* report that at the first meeting, held on July 9, 1889, the following officers were elected under By-law 48:—As Chairman, Professor T. Hayter Lewis, F.S.A., Past Vice-President; as Vice-Chairman, Mr. Alex. Graham, F.S.A., Member of Council; and as Hon. Secretary, Mr. Paul Waterhouse, M.A., Associate. The committee have held eight meetings, and the average of attendance of members therat has been between eleven and twelve.

The *Standing Committee for Art* have held seven meetings, and have had under consideration and inquiry subjects that have been referred to them by the Council, or have been brought to their notice.

Their attention having been drawn to the proposed demolition of well-known old houses in the Butter Market at Dartmouth, a resolution was passed expressing their sense of the interest and value of the buildings, and their wish that the efforts of the Mayor of Dartmouth for their preservation might be successful. Upon this resolution the Council forwarded a letter to the Mayor of Dartmouth, and it is understood that the threatened demolition has been averted.

In view of the public discussion upon the preservation of the existing buildings of Emanuel Hospital, Westminster, a resolution was adopted expressing the interest felt by the committee in the ancient hospital, and their hope that any scheme for reconstructing the charity would not involve the destruction of the building. This resolution was communicated to the Governors by the Council.

A communication on the subject of the sculptured panels at St. George's Hall was considered, and the committee stated that, while not prepared to express an opinion on the details, they would welcome the completion of the sculpture of the building.

London street improvements have been constantly under consideration by the committee, and they observe with satisfaction that the plan proposed by the London County Council in their scheme for the Strand improvement provides for the preservation of the Church of St. Mary-le-Strand. The improvement of Piccadilly-circus and the erection of a memorial fountain there have been considered, and Mr. Gilbert, A.R.A., the sculptor of the fountain, has been consulted in order that the committee may be in a position to make recommendations to the Council at an opportune time. The advisability of removing houses at the corner of Tottenham-court-road and Oxford-street has been considered, and a plan submitted and discussed for the improvement proposed. The committee drew attention to the fact that, at the junction of Shaftesbury-avenue with Oxford-street, a frontage designed for a permanent advertising station had been erected, as they considered that a protest should be made against such a use of a commanding site by public bodies.

The *Practising Standing Committee* have held eleven meetings, and the following is a summary of work done by them:—

Revised Conditions of Building Contracts have been completed, and, with the authority of the Council, have been submitted to the Institute of Builders, and are now under consideration by that body.

The committee have approved a modification

* The old by-law was thus worded:—"All metropolitan Fellows and Associates are expected within twelve months after their election to deliver an original paper to the Council, on some subject connected with architecture or kindred subjects, or to make a donation to the library or collection."

of the forms of Articles of Clerkship which they had prepared.

The committee have considered and reported to the Council upon the following Bills dealing with building and sanitation in London:—London County Council (General Powers) Bill; and Public Health (London) Consolidation Bill.

The committee have given great attention to a question raised as to a clause inserted in some advertisements for tenders throwing the onus of checking upon the contractors. They have obtained much information upon the subject from all parts of the kingdom, but have not yet been able to report.

There are numerous other subjects, some having been referred to the committee by the Council, which have engaged their attention, among which may be mentioned the amendment of the Acts relating to buildings in the metropolis, the question of ownership of drawings, &c. The committee are making a careful study of the various points suggested for consideration in regard to amending the Metropolitan Building Acts.

The Science Committee have held six meetings, and the principal subjects discussed have been the amendment of the law with regard to light and air, and the draft Bill proposed to be introduced by the Government for the consolidation of existing enactments affecting Public Health in London. The subject of light and air has been the occasion of much consideration and discussion, and the committee are now engaged upon the consideration of certain proposals dealing with the question of existing prescriptive rights.

Before the present Council came into office, arrangements had been made, with the assistance of the Art Standing Committee, to obtain a select number of architectural drawings and of photographs of executed buildings for the International Exhibition held in Paris last year; and the Institute was accredited by the Fine Arts Department of the British Section as the channel through which such drawings and photographs were to be selected. The exhibition of drawings and photographs was duly held, and Mr. E. J. Tarver, F.S.A., then hon. secretary of the Art Standing Committee, went to Paris for the purpose of superintending their hanging. The President of the Institute, Mr. Waterhouse, R.A., and the Secretary, Mr. William H. White, were appointed to represent the United Kingdom on the International Jury for Architecture, and were received in Paris with great cordiality by M. Bailly, Hon. Corr. Member, and the other members of the jury.

An International Congress of Architects was also held in Paris last June, which was attended by the President and other members of the Institute, and to which the Secretary was accredited by the Council as the representative of the Institute.

Early in the official year, the Council agreed to the appointment of a joint committee, composed of members of the Institute and of gentlemen nominated by the College of Organists, to consider the subject of musical requirements in church planning—a subject brought before the Institute by Mr. John Belcher last session. The following gentlemen consented to serve thereon,—viz., Messrs. Belcher, Carpenter, Sedding, Stannus, and Statham, on the part of the Institute; and on the part of the College of Organists, Dr. Martin, of St. Paul's Cathedral; Mr. Walter Parrott, of St. George's Chapel, Windsor; Mr. James Higg, of the Royal College of Music; and Mr. Turpin, Hon. Sec. of the College. The committee have held meetings, and have the whole matter now under discussion.

The Council have also had under consideration the qualifications necessary and adequate to technical officers intrusted with duties under the provisions of the Public Health Act, and of Acts bearing on the same; and, an opportunity having presented itself, they addressed a letter on the subject to the President of the Local Government Board. In this communication the Council strongly advocated the desirability of further legislation by the Government to improve the qualifications of such officers and afford a real test of their efficiency; to which end the Secretaries were directed to inform the Local Government Board that the Council would gladly assist in any way that might be deemed necessary or desirable.

At a special general meeting held on January 13, 1890, a Form and an alternative Form of Articles of Pupilage were approved,

and a copy of each will in due course be issued to every member.

On the same evening a discussion was opened by Mr. William Woodward, Associate, on the 'Sundry Powers and Provisions' portions of the London County Council (General Powers) Bill. A full report of the discussion was placed before the Practice Standing Committee, then engaged at the request of the Council in considering the subject. This Bill is entitled: 'A Bill to provide for the improvement and alteration of a Bridge over Bow Creek at Barking, and the acquisition and management of Brockswell Park, and to confer various further powers on the London County Council'; and the Council, in their letter to the County Council, expressed regret that important amendments of Building Regulations should have been introduced into a 'General Powers' Bill. They urged that such a system could be only of temporary expediency, and that in their opinion the time was approaching when the County Council might advantageously introduce a new Bill for consolidating and amending the laws relating to building within the county of London. The Council then submitted for the consideration of the London County Council some suggestions relating to certain sections of the Bill, and printed copies of their letter were forwarded to the members of the County Council, the metropolitan members of Parliament, the City Corporation and the twelve principal Companies, and other owners of landed property in London. The letter was published in 'The Journal of Proceedings' of March 20, 1890.

Prior to this, a communication was received from the Building Act Committee of the London County Council, asking for an opinion on questions relating to the appointment of District Surveyors, to which the Council gave full consideration, and their reply was forwarded in November last.

The President of the Local Government Board having been good enough to furnish the Council with two copies of a draft Bill to consolidate the Acts relating to Public Health in the Administrative County of London, the same was referred for consideration and report to the Practice and Science Standing Committees; and the Council, having received from the two committees their respective reports, ordered a communication to be made on the subject to the President of the Local Government Board, and submitted suggestions in regard to certain sections of the Bill, expressing at the same time satisfaction that the consolidation of the laws affecting public health in London had engaged Mr. Ritchie's attention, and adding a hope that the Bill would soon be brought before the Legislature.

A Bill for the registration of architects was read a first time in the House of Commons on February 13, 1890, and now stands for a second reading on May 14, 1890. The Bill is precisely the same, with the exception of its heading, as that introduced into Parliament last year. A Statement of Objections to it, prepared by the Council, was extensively circulated, and a petition under the common seal of the Institute, affixed by the authority of the Council, was presented to the House of Commons by Mr. Dixon-Hartland, M.P., praying that the Bill might not pass into a law, and that if it were read a second time the same might be referred to a Select Committee of the House, and the Institute heard by counsel against the Bill. The action of the Council in this matter was strengthened by the support of most of the allied societies and of the Architectural Association, petitions to the House of Commons having been presented against the Registration Bill from the Royal Institute of the Architects of Ireland, the Bristol Society, the Glasgow Institute, the Leicester and Leicestershire Society, the Manchester Society, and the Nottingham Society.

A requisition* made in accordance with the provisions of By-law 60 having been received from fifteen Fellows and six Associates for a special general meeting to consider the subject of a compulsory Examination (by statute) of all architects hereafter seeking to practise, whether members of the Institute or not [see the R.I.B.A. Journal, p. 232], the Council convened the meeting on March 31, 1890. At this meeting† the following resolution was carried:—

'That, while not opposed to the principle of compulsory examination as applied to those about to practise architecture, the Royal Institute of British Architects

* See Builder, p. 208, ante.

† See the R.I.B.A. Journal, pp. 261-274; and the Builder, p. 244, ante.

is of opinion that the difficulty of restricting by statutory powers the practice of architecture to those who have passed an examination is at present so insuperable that it is undesirable to make an immediate application for such powers.'

On the demand, however, of six Fellows, made at the meeting in accordance with the provisions of By-law 62, the resolution was suspended in order that a poll might be taken thereon by voting-papers. Scrutineers were appointed, and 1,182 voting-papers were sent out to the professional members resident in the United Kingdom. The report of the scrutineers was presented on April 21, 1890,* when it was found that 702 votes had been received within the prescribed limit of time, and that the result was 520 For, and 164 Against the resolution, which was therefore carried by a majority of 356 votes. In the scrutiny 18 votes were rejected as informal.

The revenue accounts and balance-sheets of ordinary and trust funds for the year ended December 31, 1889, are submitted, with the Report, duly audited and signed by Mr. Henry S. Legg, Fellow, and Mr. Bernard Dicksee, Associate, the auditors appointed at the general meeting held June 3, 1889.

An estimate of receipts and disbursements of ordinary funds for the year ending December 31, 1890, to which are attached statements of the amounts actually received and spent in 1889, is also submitted with the Report. The subscriptions for the current year are estimated at £4,150L, as against 3,837L last year, and the total receipts at 5,250L, as against 5,061L. The estimated disbursements for the current year are 4,790L, against 4,534L last year. The Council have invested the balance of 506L 11s. 3d., which remained at the close of 1889, and a sum of 276L 5s. 9d. taken from the current year's ordinary revenue, making altogether 783L. This amount has been devoted to the purchase of fifty-eight shares, at the rate of 13L 10s. per share, in the Architectural Union Company (Limited).

Illustrations.

SOME CHURCHES UPON THE LOWER RHINE.—III.

WE have previously illustrated and described the exterior of the magnificent minster church of St. Victor, at Xanten.† The general effect of the interior is even more striking than that of the exterior. It consists of a nave with four aisles, ending in five apses to the east, arranged in a singularly picturesque manner. To the west of the nave is a kind of transept which formed a portion of an earlier church, and is made up of the lower parts of the towers and a square bay of the old Romanesque nave between them. The arches which separate the nave from its aisles are supported upon very richly-clustered columns, which have deep foliated capitals and elaborate tabernacle niches attached to them. These niches contain one of the finest series of Mediaeval statues in all Germany. There is no triforium, but a pierced parapet, supported upon an elaborately-foliated cornice, runs round the whole church. The clearstory is very lofty, and the vaulting very elegant. There is no architectural division between the nave and the choir, except the stone roof-screen, an interesting work of the latter part of the fourteenth century. Two doorways in this screen give access to the choir, which, by the way, occupies half the length of the church. The effect upon entering this choir is surprisingly beautiful. Not only is the architecture of this portion of the building singularly graceful, but it retains the whole of its very sumptuous Mediaeval furniture.

The high altar is surmounted by a vast triptych reredos, with double doors or valves. When the inner series of these is thrown open it displays a number of elaborately carved niches filled with Mediaeval reliquaries, that in the centre being the splendid thirteenth century shrine containing the body of St. Victor; below these niches are three panels,—the centre, painted by Jean Mabuse, and the sides by Bart de Bruyn. The wings, or valves, are also works of the same painter. Above the whole is a large semicircular lunette, adorned with a beautiful painting of the Crucifixion, possibly by John of Calcar. The architectural portion of this

nautilus' record is in the Earliest Renaissance style, and dates from about the year 1520. Immediately in front of the high altar is a magnificent brass screen supported upon two columns bearing statues, and sockets for thirty-six great candles. It appears to be Flemish work, rather than German, and is, we believe, a perfectly unique feature; though quite Gothic in character, it is probably of the same date as the altar itself. Of course it will be seen at once that this elegant candle-screen is neither a roof-screen nor a sanctuary-screen, and is executed in a totally different manner to such structures; perhaps it must be considered as an adjunct to the altar, rather than as a separate work. The sedilia are of stone, richly canopied, the *sakramentshuischen* or tabernacle is Renaissance, of a somewhat later date than the altar, the side-screens of the sanctuary are of stone, lorned with canopy work and statues, and over them are curious wooden reliquaries, an arrangement, by the way, which we see at Winchester Cathedral. The stalls are early fourteenth century work, and at their back are some interesting tapestries dated 1520. Near the west end of the choir is a great triple indelstick of brass. The windows of the choir contain a great deal of ancient stained glass, though very much mixed up and disarranged, that in two of the lower windows of the apse must certainly have belonged to an earlier church, as it is thirteenth-century work; most of the glass, however, is not earlier than the sixteenth century.

ESIDENCE, INGLEWOOD, CALIFORNIA.

This residence, situate a few miles from Los Angeles, Southern California, is a prominent feature in the extensive and rapidly-growing township of Inglewood, founded and developed by Colonel Freeman, who has the reputation of being one of the wealthiest and most public-spirited citizens of the State. The residence is built in the form of a hollow-ware, the front being occupied by an immense alcove hall, the right by reception-rooms *a suite*, the left by culinary offices, &c., and the rear by a verandah and octagonal tea-room, the whole surrounding a large arcaded courtyard.

The premises have a brick and rock-faced one basement, and brick and stone piers supporting the external verandahs, and the whole of the superstructure is built of Oregon pine and California red wood, the ground-floor walls being covered with rusticated boarding, and the first-floor and gables partly half-timbered and plastered, and partly covered with ornamental tiles; and the roof is also covered with tiles.

The interior is most elaborately fitted up, principally in red wood of various finishings. The principal stairs are of oak, very massive, with richly and quaintly-designed screens, swells, and balustrades, &c. The ceilings of the hall and reception-rooms are panelled with moulded-wood ribs, the floors are of parquetry, and the fire-places have specially-designed chimney-pieces, with over-mantels and tile-panels, &c. A considerable amount of stained glass has been inserted in the windows.

The extensive stables in the rear of the residence have a deep well and water tower in connexion, with windmill for pumping the water to the tank in the upper part of tower, from which is obtained a fine view reaching to Los Angeles on the one hand, and to the Pacific Ocean on the other.

The building has been designed and carried out for the owner by Messrs. Curlett, Eisen, & Hetherington, architects, of Los Angeles and San Francisco.

HOUGHTON-LE-DALE CHAPEL, NORFOLK.

The Pilgrims' Chapel of Houghton-le-Dale is the way-side of the main road from Fakenham to Walsingham, in Norfolk, about a mile and a-half from the latter town. The building is seen better days, for it is now used as a barn or general farm-house store. The work is late Decorated, and very rich in appearance, the material for the general walling being squared at; the date is about the year 1350.

ARNOLD MITCHELL.

ST. JOHN'S FREE AND OPEN CHURCH, MACCLESFIELD.

This church, the ground for which was given to the late Sir Edmund Buckley, was completed and opened in October, 1887. The

building is thirteenth century in style, and consists of an apsidal chancel, 31 ft. by 20 ft., with organ chambers on the north and clergy and choir vestries on south sides. The nave consists of four bays and a half, and measures from chancel arch over 70 ft. The north and south aisles extend the same length as the nave, and the entire width across the two aisles and nave is some 50 ft.

The building seats 600. The chief entrance is by the south porch, the view of which is shown in the illustration. There is also a large entrance at the west end. The roof is covered with reddish-brown tiles, and internally is panelled and moulded in pitch pine. The internal lining of the walls is of dark-red brick, relieved by Hollington stone around windows and in arches. The external walls are faced with local teggsone parapoint stone, which is of a delicate mauve colour relieved with Hollington stone around the windows and in the string-courses, pilthns, &c. The entire cost has been about 5,600. There is still the tower to be finished, the cost of which will be some 700l. more. Mr. Moores, of Macclesfield, was the contractor for the first portion, and Mr. B. Haywood, of Alderley Edge, has carried out the last contract. Mr. C. Gordon Killmister and Mr. R. A. Briggs, of London, are the joint architects.

CARVED ORNAMENT, BLACKHEATH, FRISTON.

The brick panels shown in the illustrations are taken from the west front of the mansion.* They are illustrative of the heronry, the river, and the birds found thereon, such as wild geese and swans, and those which are to be found in the surrounding woods and heaths, such as hawks and owls. Wild boars were originally, no doubt, to be found in the neighbourhood.

The stone frieze from the dining-room chimney-piece illustrates "Sport," the house having been erected for shooting purposes.

The whole of the above are from my designs, and have been admirably executed by Messrs. John Groom & Son, of Ipswich, from my full-size details.

E. F. BISHOPP.

ADDITIONS TO GREYFRIARS, DUNWICH.

The accompanying illustration shows the exterior of the additions now being made to Greyfriars, Dunwich, the seat of Colonel St. John and Lady Constance Barne.

To the south is the drawing-room (an interior illustration of which appeared in the *Builder* for April 19), to the east the boudoir and smoking-room, whilst the north is occupied by the gun-room, sportsman's entrance, and offices. Suites of bedrooms occupy the first and second floors.

The works are being executed in red brick, made on Colonel Barne's estate, with the moulded and ornamental work from Messrs. Gunton's yards. The roofs are covered with dark Broseley tiles. The plastering in best rooms is in *Parian*.

The heating is by hot-water pipes and open fire-places, and the house will be lighted throughout by the electric light, whilst a ram is the chief power used for the water-supply.

Mr. Alfred Brown, of Baintree, is the contractor, and the whole of the works are being executed from my designs and under my supervision.

E. F. BISHOPP, Diocesan Surveyor.

THE SURVEYORS' INSTITUTION:

EXAMINATION FOR THE FELLOWSHIP.

The following Professional Associates have passed the Examination for the Fellowship:—

Adkin, Beniah Whitley, 33, Walbrook, E.C.
Darch, John, 74, Sarsfield-road, Balham, S.W.
Denny, William Cooper, 49, Fordwych-road, Bronesbury, N.W.

THE ARCHITECTURAL ASSOCIATION VISITS:

THE ALBERT MANSIONS, KNIGHTSBRIDGE.

THESE mansions, which are being erected by Messrs. J. W. Hobbs & Co., Limited, from the designs of Messrs. Archer & Green, were visited on Saturday afternoon by a party of members of the Architectural Association. Messrs. Archer & Hooper, under whose superintendence the work is now being completed, met the party, and gave an interesting description of this novel pile of buildings.

The buildings comprise a collection of flats for families on the lower floors, with bachelor suites on the upper floors.

The right-hand portion of the lower floors forms a separate building, and has been designed to accommodate a separate club, having a private entrance at the east end of the Knightsbridge frontage.

The portion of the ground-floor on the left of the central entrance contains dining, reading, and other club rooms for the exclusive use of the tenants.

The site is an exceptional one, with frontages to both Knightsbridge and the Park.

The plan of the building is H-shaped, one block facing the Park, the other fronting Knightsbridge. The two blocks are centrally joined by a block, containing the staircases and passenger and service lifts. This latter divides the area for light and air between the blocks.

The principal entrance to the building is in the centre of the Knightsbridge front, and opposite it, in the centre of the Park-front, an open loggia is provided on each floor, so that the tenants may enjoy a view which is hardly surpassed anywhere in the metropolis. A circular iron staircase in the centre of the loggia, from the top to the bottom of the building, makes escape in the event of fire an easy matter.

The space between the front entrance and the loggia, as already mentioned, contains the principal staircase and lifts, as well as chambers for pipes of all kinds. From this central position on each floor access to all parts of each block is readily obtained.

The usual combination of concrete and rolled iron renders the construction of all floors fire-proof.

The great height of the buildings, upon which so much comment was recently made, has rendered it necessary to provide machinery in the basement for pumping water to the large storage tanks in the roof of the central tower.

The state of the works at present hardly allows the formation of an opinion as to its ultimate decoration and finishings, and the elevations are more or less obscured by scaffolding; but as regards the plan, every care appears to have been taken to utilise the exceptional advantages and peculiarities of the site, and there is little doubt that these latest additions to the residential accommodation of the West-end will be much sought after.

BAYNARD'S CASTLE.

BAYNARD'S CASTLE, says Peter Cunningham, stood on the banks of the Thames, immediately below St. Paul's, and was so called by Baynard, a nobleman that came in with William the Conqueror. This fortress was fortified by him, or one of his descendants, in the year 1111, and granted to Robert Fitzgerald, son of Gilbert, Earl of Clare, in whose family it remained for three centuries. The Castle, however, is of Roman foundation, as can now be proved from two large stone corbels and other Roman relics recently discovered there in the erection of Messrs. Pilkington's new warehouse now in course of completion.

These relics were exhibited and described by Mr. J. H. Macmichael at the recent meeting of the British Archaeological Association. Mr. Macmichael said that in the course of the late excavations of this warehouse for Messrs. Pilkington, glass-factors, of St. Helen's, Lancashire (Messrs. Chambers, architects), many interesting relics had been unearthed, which, one may trust, will never be dispersed, but may eventually find their way to the Guildhall Museum. "If you thrive well, bring them to Baynard's Castle," says Gloucester to Buckingham, in allusion to that wily nobleman's efforts to engage the sympathy of the citizens. Other monarchs were entertained here down to Charles II., who is described by Pepps in his

"Diary" as going, accompanied by "my Lord Sandwich to supper at Baynard's Castle," June 19, 1660. The Earls of Shrewsbury resided here till the Great Fire, which six years afterwards (1666) left only the blackened walls, never to be rebuilt. It had been twice burnt and twice rebuilt. In 1128 it was almost entirely destroyed by fire, and rebuilt by the good Duke Humphrey of Gloucester. Henry VII. again repaired or rebuilt it, and changed its form, says Pennant, "into that of a palace for quiet times." It is to the structure as rebuilt by Henry VII. that the few architectural remains, such as the transom of a double or two-light window, and the two stone corbels, to be shortly hereafter referred to, appertain. The Roman wall along the whole south side of London proper terminated in Roman times, both east and west, with a fortress, which was called *Arx Palatina*, or the *Imperial (Palatine) fortress*: upon the site of these fortresses the Tower and Baynards Castle were built, the limits of the City having been in 1274 extended to Blackfriars. In the course of erecting the new warehouses for Messrs. Pilkington, some oaken piles were encountered by pick and shovel. These are probably identical in age with the "strong oaken piles" which Mr. Roach Smith tells us were used for the foundations of the Roman wall. Besides the transom of a window and the two stone corbels, one of the objects which have been lately dug up is an old steel-yard. There is only one perfect example of the Anglo-Roman steel-yard in the British Museum, and that is but 6 in. in length. Mr. Sutton, the Clerk of the Works, who is himself a Devonshire man, and to whom is owing the preservation of this and the other relics, at the happy instigation of Messrs. Pilkington, says there is a steel-yard of similar construction in use at the present day in his county. He does not, however, remember having seen anything like the incised ornamentation. The stone transom contradicts all the old engravings in which the windows are represented as single lights, this transom being that of a double or two-light window, as described by Pennant. But the two carved stone corbels are probably the most important discoveries yet made. They are both in low relief: one represents a pair of wrestlers, and the other a ram. The ram is not heraldic; it can, therefore, only represent the prize which the *Medieval* or Roman wrestler received—either a *ram* or a *cock*—as a reward for his dexterity when victor. But the circumstance of the conjunction of two corbels measuring 1 ft. 6 in. in height, each, both carved in low relief, one representing two nude wrestlers and the other a ram, and both found built into a wall 16 ft. below Upper Thames-street, is surely worthy of adequate attention. Not the least interesting feature of the excavations was the meeting with a black, manure-like stratum of substance about 2 ft. in thickness, and 17 ft. below the surface. What could this have been but the green rushes which were strewn upon the floor in the Middle Ages? Hence our straw from sterno, stratum, to stretch out, word being used in winter, as well as rushes in summer, to spread upon the floor—when they were said to have engendered a delightful sensation of coolness, as well as presenting a very pleasing appearance, recalling as it did the "simple manners of other times." There has been no necessity to strew the church-floors, said Mr. Macmichael, with rushes in summer or straw in winter, since they were paved or flagged, as was generally the case after the Tudor period, and unusually so since the Reformation. "Is there a village church," he asked, "in the United Kingdom and Ireland where the bare floor still exists?" Grassmere Church is said to have had a bare floor in 1828. One at least of the numerous tiles or fragments which have been preserved dates from the original building of the Castle by "one Baynard,"—that with two birds back to back. There is a similar one in the Geological Museum. Two fragments of skulls were also found 6 ft. below the foundations, and 24 ft. beneath the level of Thames-street, and *mirabile dictu!* beneath an oak tree which was found *in situ!* A marbled tile (like scagliola of to-day), an ornamental metal hoop, and boat-hook were all found together, also four spurs, a Roman nail, bone stilus, a primitive pegtop, a fragment of a short pendant, ear-pick, and a shoe, Norman or Plantagenet, with pointed toe; the peak was stuffed with tow or hay. Mr. Macmichael also exhibited some other objects of interest which had been found elsewhere, and which he described.

THE LONDON COUNTY COUNCIL.

The London County Council held its second meeting in the enlarged Council Chamber at Spring-gardens on Tuesday afternoon. Lord Rosebery presided, and after a few preliminary items of business, resumed his review of the work of the various Committees of the Council. He said that at the previous meeting he had reviewed the work of seven Committees. That left thirteen or fourteen Committees still to be reviewed. We give extracts from Lord Rosebery's speech:—

"The Sanitary Committee, from the multiplicity of its functions and their domestic character, might almost be called the nurse of London. If he read out to them the heads of the report of the Sanitary Committee he thought they would feel that that name was justified:—Public Health (London) Consolidation Bill, By-laws, Medical Officers of Health, public baths and laundries, chalet accommodation, fogs, water supply, Railway and Canal Traffic Act, coroners, notification of infectious diseases, ambulances, gas supply, testing of gas meters, weights and measures, licensing cow-houses and slaughter-houses, supervision of offensive trades, Explosive Acts, Petroleum Acts, Infant Life Protection, and Prevention of Cruelty to Children. He was sure they would feel that it was not possible for him to go through these heads in detail, but a cursory review was necessary on one or two of them. In the first place, the Committee thought that its powers were very inadequate; it had found them to be very inadequate; they said that the sanitary administration of the metropolis was in a completely and entirely unsatisfactory state, and they wished strongly to emphasise their opinion that the London County Council should be empowered to frame By-laws for the proper sanitary government of London; that the new District Councils or the existing local bodies should put them in force, and that the County Council should be the supervisory body to see that they were properly carried out. He believed that to be a sound recommendation. They had in view also the dealing with a subject which occupied much of their time at the last meeting, which was called chalet accommodation. They had endeavoured to urge on Vestries and District Boards their duties in that respect, and they had received from no less than twenty of these authorities their promise to take action. As regarded fogs, which was a subject on which they had built some hopes, they found that it was impossible to make any practical suggestion. As a matter of fact, the only existing legislation on the subject was in the Smoke Abatement Acts, which provided that engines and furnaces and buildings used for trade should consume their own smoke, but there was no enactment in regard to the smoke of private houses, and in any case the police were entrusted with the enforcement of these Acts, and they had no control over the police for that or for any other purpose. As regarded the gas supply, which was one of their most important functions, they had the whole gas-testing for London, except at the City stations, and they had endeavoured to make considerable improvements in this examination. To make it more real and more thorough, they had endeavoured to persuade the Board of Trade to introduce a Bill to legalise portable photometers, so that gas might be tested at other places than the regular testing-places. He had no doubt whatever that no testing of gas could be efficient unless it was extended much beyond its present scope. The duties of the Committee in regard to licensed cow-houses and slaughter-houses were very considerable. There were 728 licensed slaughter-houses on April 1, 1889, when they came into office, and they renewed the licences in 691. The number of licensed cow-houses in London was 745, and they renewed the licences in 673 cases. They had, further, a large control of the explosives and inflammable materials of London. As regarded inflammable materials, their duties were not very considerable, because they had only the power to sample petroleum on dealers' premises so as to ascertain whether it was petroleum of the flashing point to which the Act applied. But when they considered that the import of petroleum into London annually was not less than 2,000,000 barrels of 40 gallons each, and that the number of fires proceeding from mineral oil lamps was very considerable, there being no less than 259 last year, he thought they must see that the committee had some reason for urging that they

should be given extended powers in the respect.

The Highways Committee was mainly concerned with business under three heads,—main roads, electric lighting, and tramways. With regard to main roads, they received from the Government the duty of contributing to the maintenance of certain disturnpiked roads, there were eleven miles of them, he thought. That was one of the new duties and new expenses which had been imposed upon the ratepayers by the new Act, and which contribute in some degree to what was supposed to be the increase of the rates. The Committee, however, wisely, as he thought, decided to contribute the same sum to these disturnpiked roads that had been previously contributed by the Government—that was 3,558*l.* From the district authorities who were charged with these roads there was much grumbling that the Committee did not recommend a larger contribution, but he confessed that he thought the Committee were perfectly right in taking the action they did, knowing of no reason whatever why they should give more than Parliament or the Government did for these roads, and he thought the Committee was right in leaving an authorities that were aggrieved to take the own action in the matter. They had a large and more complex business in connexion with roads. The 41st section of the Local Government Act extended to London the provisions of the Highways and Locomotives Acts Amendment Act of 1875 relative to main roads. If the Common Council or any Vestry or District Board might apply for an order asking that a road might be made a main road, and it kept up by the Council. Every district authority in London, except the Common Council on the Strand, had made this application, and the total amount of that application was 412 miles of main road. The Committee had come to the conclusion that it could not have been the intention of Government to east on the central authority the charge of these 412 miles of road, over the maintenance of which they could not possibly exercise any supervision. They had decided that the enactment was practically unworkable, having regard to the peculiar conditions under which the roads were managed and the number of authorities concerned in their management. He confessed he thought that that was one of the cases where in order to make the Local Government Act uniform, the legs of London had been cut to fit into a Procrustean bed which was meant to adapt itself to every small community in the country. Another great power of theirs was in regard to electric lighting. The favourable terms of the Act of 1888, as regarded length of tenure and conditions of purchase at the termination of tenure, as well as the advance of science, had led to a great development last year which also coincided with the coming into existence of the Council. The Council had been entrusted with great powers of supervision and control, and they had, he thought, last year fifty-five notices to apply for these powers from different companies, and in every case he thought the affixed special conditions, which had been applied with. This year they had had twenty-three provisional orders and three Bills, all of which they had considered and which they brought into line, as far as they could, with those that they gave last year. They had other work with regard to tramways. There were five schemes in 1889. In all those that they had passed, clauses had been inserted to satisfy the requirements of the Council. There were seven in 1890, of which two had been withdrawn, and he had no doubt that the Committee would be equally successful in dealing with the balance of five. With regard to the Overhead Wire Bill for the regulation and control of overhead wires, which was a matter of so much importance, they had withdrawn their clauses with regard to subways, at any rate for the present. Then there was the question of bars and gates which came before this Committee. If he were asked to take an intelligent foreigner or Londoner and to show him the most remarkable thing in London he should not take him to Westminster Abbey, or St. Paul's, or the House of Parliament, or even the County Council, he should take him to the mysterious region of London which was shut up from the contagion of the outer world at eleven or twelve o'clock at night by these bars and gates. There was no such thing in any other city of the world. He did not believe they could persuade a foreigner who had not seen these bars and gates that they were in actual existence in London.

the last decade of the nineteenth century. He believed there was an arrangement analogous to it in the time of the Pharaohs in Egypt, when the children of Israel were relegated to a part of that country which was shut off, he had no doubt, by bars and gates at a fixed hour of the night from any communication with the outer world; but that was really the only precedent that he knew for it, except the precedent of walled and fortified cities. [Captain James: "The Ghetto."] Well, the Ghetto; but the Ghetto had long ceased to exist in its secluded form. The committee had endeavoured to deal with this through the medium of the Parliamentary Committee, and they thought that for a condition of things like this compensation was hardly required. But they had endeavoured to compromise on the question of compensation, he believed, by offering to provide a silent pavement in that neighbourhood at the expense of the Council to some extent, which would soften to some degree the rude change from the sacred slumbers which at present prevailed in that quarter of London to the sleep enjoyed by other less privileged inhabitants of the metropolis. In addition to this, they had had the charge of their embankments and the closing of streets. Last year they had closed, wholly or partially, 166 streets, and they had had 59 applications for closing. They had the control of railway bridges over streets, and all the plans for such bridges had to be submitted to them for approval. They had had four bridging schemes and two for widening bridges, with all of which they had dealt. He thought everybody would feel that this was a very creditable record of work.

The *Corporate Property Committee*, as they knew, managed their property and their ground rents. The value of the property was very considerable. The capital value was not less than £2,300,000. He could not notice the work of the Committee in detail, because it was a work of detail, and it could not more be described in a hasty review of this kind than they could describe a land agent's work on a large estate in this country. But it had been, as he believed, very efficiently managed, and the result of the first auction that had been carried on under their Valuer, last week, he thought was a most decided success.

The *Building Act Committee* was also a committee very much of detail, and they would forgive him if he could not enter into their yearly report any more than the Council entered into the details of its weekly report. The greatest compliment to that Committee, and it was a deserved compliment, was that their recommendations or reports were swallowed whole. He would only give one or two figures to point out what manner of work it was they had to do. For instance, they had sanctioned the opening of no less than eight miles of new streets in the past year. They had considered and reported upon 2,979 cases of dangerous structures, taken out 853 summonses against recalcitrant house-owners, abolished 316 subsidiary and other names of streets, and re-arranged the numbers of 7,896 houses, approved 65 names of new streets, and ordered the re-naming and re-numbering of 241 streets. He could continue these statistics *ad infinitum* to show the enormous amount of detailed work which was thrown on this Committee. In each of those cases that he had mentioned they went carefully into the matter; very often, he believed, the Chairman of the Committee went into the whole of the report before it came before the Committee, and therefore they might form some idea of the work which was occupying that Committee in dealing with the management of London. They had also had one great question of principle to settle—the question of District Surveyors. They had not yet fully reported to the Council what their recommendations were in that respect, but they seemed to favour the idea of District Surveyors being paid by salary instead of by fees, and being divorced from private practice. He did not know what view the Council might take of that, but it was very clearly a point of very great importance in their administration, and they left it with great confidence to the Building Acts Committee. They also stated that it was extremely unsatisfactory that so many separate Acts of Parliament were enforced in the metropolis with reference to building matters. Yet no opposition to a really useful and comprehensive Bill introduced into Parliament by the Board, which to an extent would have

obviated the difficulty, was so determined as to defeat the Bill. Hon. members might know that it was not only the Council that found opposition to its measures in Parliament. The Committee was of opinion that the building law, both constructional and sanitary, should be strengthened and then consolidated.

The *Special Committee on Water-Supply* had submitted a report which was a very interesting record of the history of the question drawn up by their colleague, Mr. Beal, but, as a matter of fact, when they came to inquire into their subject they found that they had no power to incur expenses in connexion with the inquiry as to the matter referred to them, and they had to put a special clause into the County Council Bill for obtaining money for that purpose. That clause was not favourably received by Parliament, and they were only able to renew it this year. That matter was a very urgent one. It was not so much that they should obtain control of the water companies that the question was so urgent, but it was in view of the quinquennial valuation that took place next year. Now, the annual increase in rateable value of property in London, as the Committee pointed out, averaged about 1½ million at each quinquennial valuation. Taking the average authorised charge of the several companies for domestic supply to be five per cent. on rateable value, the increase of income to the companies at each quinquennial valuation would amount to 75,000*l.* a year, solely in respect of the increased rateable value of existing property, and without reference to any increase of supply. The consequent increase in value of the water companies' stock would probably exceed two millions, and that at each quinquennial valuation would probably be the very lowest increase which could be added to the value of these water companies. They would see from that that it would become after ten or fifteen years impossible for London to face the enormous expense of controlling its own water supply. He thought that the Committee were right to urge that a Bill be brought into Parliament to deal with this question in the interest of the ratepayers and in the interest of the metropolis at large.

Suggested amendments in the Laws relating to the Government of London.—The only point to which he should call their attention further was this—the number of committees that found their powers inadequate under present Acts of Parliament. Of course, it might be said to that that bad workmen quarrelled with their tools, and that it was the fault of the workmen, and not of the tools, that this discovery should be made. But he did not think that that view of the case would hold water for a moment. Why was the Local Government Bill made to apply to London at all? Simply to remedy the chaotic condition of things which existed in the metropolis, which consisted of a city and fragments of three counties. Well, it was quite clear that when they tried to reduce that chaos under a system, more especially by a Bill of universal application, both to rural and urban counties, they could not help finding that a great deal of their machinery required renovation. That was the case on this occasion, and they were also well aware of the fact that their predecessors in part of their functions, the Metropolitan Board of Works, repeatedly had to seek the assistance of Parliament, and very often in vain, to enable them to perfect their machinery. He thought that on a calm survey of the whole situation they would find that, with the machinery at their disposal, these committees had done the best that could be done, and that Parliament would not long consider it unreasonable if the Council should apply for some assistance in re-modelling and re-sharpening the machinery with which they had to work.

The greater part of the remainder of the sitting was devoted to the consideration of the report of the Housing of the Working Classes Committee. As this debate was adjourned, we will revert to the subject next week. The Council adjourned shortly after 7 o'clock.

Appointment.—We are informed that the Lord Lieutenant has, in accordance with the wish of the Grand Jury at the recent Spring Assizes, appointed Mr. P. O. Cowan, B.Sc., A.M.I.C.E., County Surveyor for South Down, to be County Surveyor for the entire county, in which the annual expenditure on Grand Jury works is about 45,000*l.*, and there are eleven Assistant Surveyors.

COMPETITIONS.

Baths, Salford.—[The Baths Committee] of the Salford Town Council met on the 23rd ult. and selected the plans submitted by Messrs. Mangnall & Littlewood for the new baths, Regent-road, Salford, which were submitted in competition under the *nom de plume*, "The Regent."

Breslau.—In the competition for a design of an equestrian statue of the deceased Emperor William, the first prize has been obtained by Messrs. Behrens & Licht, the former a sculptor of Breslau, the latter the well-known City Architect of Leipzig.

WORKS OF THE LATE J. T. WOOD.

SIR,—Professor Aitchison is in error in assigning to Mr. J. T. Wood, of Ephesian fame, the office at the north-east corner of King-street, Cheapside (with one front in Gresham-street), as it was designed and carried out by the late Mr. Sancton Wood, and he was well known in connexion with other works.

T. BOS. CHATFIELD CLARKE.

GOLDEN CHANCES FOR SURVEYORS.

SIR,—I notice by the list you publish [p. 302, ante] that fifty-seven young men have passed the Surveyors' Institution Examination, some of whom may be now shortly seeking a start in life. Perhaps you will allow me space to point out a few splendid openings in Local Board Surveyorships now offered, so that those gentlemen may be on the *qui vivit*. Who shall say the profession is overcrowded, and that when you have spent hundreds upon education and pupillage and become "P. A. S. I.," the difficulty of earning bread and cheese then begins?

There is Google Surveyorship, "salary 100*l.*, which is to include travelling expenses." To the careful man (who cycles) here is a prospect of saving up for old age! Then Rugeley, salary 50*l.*, travelling not mentioned.

Then South Molton, salary 100*l.*, which includes rate-collecting. But the greatest prize is at Worksop, 120*l.*, and *nothing much to do*, although the

"Surveyor must give the whole of his time to the duties, no extras nor private practice allowed. He will have to make surveys, prepare and approve plans, estimates, and tenders, schedules of prices, supervise and carry out the construction of works, keep accounts, pay wages and bills, superintend and manage the sewage-pumping station and drainage systems, fire-bridges, engines and hydrants, lighting of the public lamps and streets, and forty-eight miles of highways."

Now, in a sincere like this any active young fellow believing in the dignity of labour could very well fill up his leisure by sweeping up the roads, putting in an odd house-draught or two until tea-time; and then run round to the lamps, and after a bit of supper clean up the fire-engine, and in case of a call run it out and extinguish the fire, by which time he would be ready for bed.

This is so good a chance that I expect it will not go out of the town; or at least only be given to some clever M. I. C. E.

April 30.

VENTILATION BY SASH-WINDOWS.

SIR,—In your issue of April 25, among the "Recent Patents," I notice one, No. 8,019, "Ventilation by Sash-Windows." If I understand it rightly, I have used this method of ventilation for years, with a piece of wood alone. My method is to remove the sash-band, and nail a piece of wood on the window-sill about 1½ in. deep, cut in tight between the inside lining, shorten the sash-bands 1½ in., and replace the sash-band, which will simply be the depth of the new piece higher than it was before. It can be applied to any sash-window at a very trifling cost, and answers admirably.

Of course the piece could be more than 1½ in. if desired, but I find that size the most convenient to allow of the sash-lifts being fixed on bottom rail of sash.

HULL, April 26.

. This method of obtaining ventilation from sash-windows without draught,—the fresh air entering at the meeting-rail and passing upwards some distance and gradually becoming diffused with the air of a room, has been in use for many years by many people who are aware of its advantages. We ourselves have used it for many years. As far as we know, this simple method was first suggested by Dr. Hinecks Bird, who thirty or forty years ago described and illustrated it in the *Builder*. Dr. Hinecks Bird did not patent the idea, but published it for the benefit of the public. As indicated by us in our foot-note last week, we were rather surprised to see that a patent has now been granted for what appears to be practically the same idea.

Glaucus Club.—The *Sportsmen* announces that Mr. Arthur Green, architect, will be engaged to make designs for this new club-house. The premises will comprise a large theatre.

CHURCH BUILDING NEWS.

Glyn Farrell.—A correspondent says:—"A new Mission Church is about to be erected at Glyn Farrell, in the parish of Llanyddid, Breconshire. The old parish church is well known for its unusually large churchyard, its exceeding picturesque position, its grand yew trees, the retention of so many of its interesting old features, such as the fine old font, the sounding board over the pulpit, which was doubtless made out of part of the rood screen, and the old doorway; the remains of the fine old oak porch, and some old windows and a number of monuments. It was carefully repaired and re-fitted with seats about fifteen years ago by Mr. Kempson, then of Hereford, and now Diocesan Surveyor for Llandaff. The new Mission Church, which will be commenced at once, will accommodate about 120 adults. It will be situated about two miles from the mother church, close to a good road, and in a part of the parish where its want has been long felt. It will be built of fine hard native stone, with local and other hard stone dressings, the walls will be thick, the roofs very strong, the seats of substantial character. The font will be of stone, the pulpit of oak, the chancel floor of tiles. There will be a reredos of quiet design, a western bell-cote, and the roofs will be covered with green slates. The designs, which are of simple thirteenth century character, with details full of careful treatment of true old Welsh type, are by Messrs. Kempson & Fowler, of Llandaff."

Kington (Herefordshire).—A new mission chapel is about to be erected in this interesting little town. The new chapel will accommodate 165 adults. It will be built of local stone, with bard stone dressings of fine colour; the roof-timbers are all of large size, and the covering will be the best North of England heavy green slates; the floors of the nave will be of wood blocks, those in the chancel of tiles. The screen will be of oak, as will also the chancel fittings. The contract has been entrusted to Mr. Wislade, builder, Kington. The designs are by Messrs. Kempson & Fowler.

Linkinhorne.—The restoration of St. Mellor Church, at Linkinhorne, near to Liskeard, Cornwall, has been taken in hand. The church consists of a nave with five bays, aisles, chancel, and transept; the embattled tower has turrets with pinnacles. The parish is renowned for its granite quarries, the property of the Duchy, and for its monolithic remains, including the Cheesewring on Stoves-common, the two stone-circles known as the "Hurlers," the "Lingstone," and the elevated sharp Point Tor. Here, in a habitation which he had made for himself in the rocks, lived the eccentric philosopher and mathematician, Daniel Gwyn.

Stockland (near Honiton).—A new pulpit has lately been fixed in the old fifteenth-century parish church here, designed by Mr. B. Edmund Ferrey, F.S.A., to harmonise with the surroundings. It is octagonal in plan, the superstructure being of English oak with three pierced traceried panels to each side, trefoil-headed, and with a cornice having carved roses conventionally treated. The pedestal is of Bishop's Lydeard stone, with Keinton steps. The work was executed by Mr. W. T. Berry, builder, Honiton.

DISSENTING CHURCH BUILDING NEWS.

Birkenhead.—A few days since the new Congregational Church, Prenton-road West, was opened. The church is the first section of a comprehensive scheme, which will include a church to accommodate about 600 people, having tower and spire, and schoolroom for 250 children, having five class-rooms for senior scholars. The present building is so arranged that it may be used for Sunday-school in addition to congregational purposes. The contract has been carried out by Mr. John Shaw, of Birkenhead, from the designs and under the supervision of the architect, Mr. Thomas W. Cubbon, of Birkenhead, whose plans were selected in competition.

Leek (Staffordshire).—Brunswick Chapel is at present closed for alterations and decoration, the congregation meeting meanwhile in the Balbhay-street schools. The improvements are somewhat extensive, and are being carried out by Messrs. Matthews, builders, to the designs and under the superintendence of Messrs. W. Sugden & Son, architects. The whole of the galleries are being considerably

lowered, so as to group the audience more closely together, and improve sight and hearing from the gallery. Moreover, they are being lowered bodily, and without being taken to pieces.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—XVIII.

ALTERNATING-CURRENT DYNAMO-MACHINE.

A SKELETON alternating-current dynamo-machine was shown in fig. 28, representing a single turn of a coil, on a drum armature, revolving between the poles of a magnet. Very small machines are, indeed, sometimes constructed on this principle, but the type most commonly adopted for machines

Fig. 50.

of larger size is that shown in fig. 50. The armature coils A_1, A_2, A_3 are fixed in the plane and around the circumference of a disc, being made to revolve between an equal number of pairs of faces of field magnets, which are separately excited by a little continuous-current machine; the alternating current produced is then connected with the external circuit through collector rings. The coils may be connected in series, as in the figure, or when a large current and low electromotive force is required they may be put abreast.

Fig. 51.

Fig. 51 is a plan of a section of the part of the machine shown in fig. 50, the field being represented by a few dotted lines of force. The centre of the bobbin A is exactly on the axis of the first pair of the field magnets, the full circles being the sections of the wire on the bobbin. In this position no E.M.F. is being set up, as the bobbin is cutting practically no lines of force, or whatever E.M.F. is set up in one side of the bobbin, by the few lines it may cut, an exactly equal and opposite E.M.F., round the coil, is set up (see fig. 26) on the other side, so that, as a net result, the bobbin contributes no E.M.F. to the circuit. As the coil moves onward an increasing E.M.F. is produced, until its centre is half-way between pairs 1 and 2 of the field magnets, when both sides of the coil are in the strongest parts of their respective fields, and both contributing E.M.F. in the same direction; hence, in this position, the available E.M.F. in the coil has risen to its maximum value. It falls to zero when A has reached the axis of the second pair of field-magnets, after passing which, E.M.F. is again

set up, but in the opposite direction. In the lower part, II., of the figure the positions of the centre of the bobbin are marked off along $O X$, and the E.M.F., in any position, measured parallel to $O Y$. The direction of the E.M.F. is indicated by setting off electromotive forces in opposite directions on opposite sides of $O X$. The curve drawn is a simple curve of sines.* The curve which shows the current flowing from the machine will have the same form, though modified by the conditions of the circuit.

TRANSFORMER.

In a dynamo-machine the coils of the armature revolve and cut the lines of force produced by the stationary field-magnets; in some cases the armature is stationary while the field-magnets revolve, carrying their lines of force with them so as to cut the armature coils. A transformer may be regarded as a dynamo-machine in which both armature and field-magnets are stationary, but in which the lines of force, proceeding from the field-magnets, are made to move by varying the current in the field-magnet coils, thus cutting the conductors in the armature. Faraday, in 1831, described certain types of transformers for the "Evolution of Electricity from Magnetism," but the name "transformer" is of later date, and modern transformers differ considerably in detail from those used by Faraday.

In fig. 53 two coils, P and S , are shown wound round an iron ring, which must be divided, like the core of the armature of a dynamo-machine, at right angles to the direction of winding of the coils, so as to prevent, as far as possible, the induction of currents in the core itself. Such an arrangement represents, in principle, the most common type of transformer, though in practice the magnetic circuit is made as short as possible, and its shape, therefore, differs considerably from that shown in the figure; we are not, however, concerned with the design of transformers, but with their action. If a varying current is sent through P , E.M.F. is set up in S . Owing to the similarity between a transformer and an ordinary induction coil, P and S are usually called respectively the primary and secondary coils; though, regarding the transformer as a peculiar form of dynamo-machine, P and S might be respectively called the field magnet and armature coils.

Fig. 52.

The reason for the production of E. M. F. in S , when a varying current flows in P , can be seen from fig. 52. Let P represent the section of one inside turn of the primary wire, carrying a current, and let l_1 be one of the circular lines of force surrounding it in air. If the current in a wire is rising, the closed lines of force surrounding it at any point are being propagated outwards, very much in the way that rings spread over the surface of water from a point at which a stone has been dropped into it. Suppose, then, the current in P to be increasing, the line l_1 will expand until part of it enters the iron and assumes a shape somewhat like l_2 , finally expanding so as to lie wholly within the ring like l_3 ; in expanding this line has cut through the single turn drawn of the secondary coil, and hence produced an E. M. F. in it.

If the line extends still further so as to cut S on the outside of the ring as it quits the iron the effect of such cutting would be to neutralise the E.M.F. set up by the line following it which happened at the same instant to be cutting S on the inside of the core, for clearly the two electromotive forces set up in the two portions of S would act in opposite directions round it. The net effect then of any lines of force which pass out of the core again is nil, but until the core shows signs of saturation they may be neglected, as practically all the lines remain within the iron ring.

If the current in P could go on increasing indefinitely, E.M.F. in one direction would be

* Any periodic curve has, for its components, a greater or less number of simple curves of sines, the true curves, obtained experimentally from machines actually in use, differ but slightly from that drawn above, the simple curve will always be used.

produced in S, and a transformer might then replace a continuous current dynamo-machine; as, however, this is impossible, the current in P is varied by connecting it with an alternating current dynamo-machine, an alternating E.M.F. is then set up in S, the E.M.F. reversing when the number of lines included in S begins to diminish. The considerations which apply to single turns of wire in fig. 52 will obviously apply to the number of turns in fig. 53.

Fig. 53.

Let N = number of turns of wire in P (Fig. 53); C = maximum value of current; a = area of cross section of iron core; μ = permeability of the iron; l = average length of line of force in core; F = maximum flux. Then,

$$F = \frac{4\pi N C + 10}{\mu a}$$

Again, if n = number of times the current has its maximum value in the same direction per second; n = number of turns in S; then F n is the number of lines which cut into and out of S per second; if E = average E. M. F. set up in S.

$$E = 4\pi F n \times 10^{-8}$$

4π F n being the number of cuttings by lines of force per second which S experiences.

The advantage of the transformer lies in the fact that the magnitude of E can be made any thing we please by giving the proper value to n, so that if a certain amount of power is being wanted, obtain as high an E.M.F. in S, by sacrificing current, or as large a current as we please by sacrificing electro-motive force. Transformers are usually employed for producing a larger current than that in the primary circuit at a reduced E.M.F.

If the current in P is one ampere the number of lines of force enclosed by S is 4π N a (100)⁻¹, and these lines in getting into the coil cut out the wire 4π N n μ a (100)⁻¹ times (1); similarly if an ampere flows in S the number of lines enclosed by P will be 4π N a (100)⁻¹ and these lines have cut out the wire of P 4π N n μ a (100)⁻¹ times ... (11), but these expressions (1) and (11) are identical, and this identity is called The Co-efficient of Mutual Induction of the two coils, a quantity that clearly varies with the relative positions of the coils and the medium between them. It must also be noticed that when P embraces 4π N n μ a (100)⁻¹ lines produced by its current of one ampere, each line has cut through each turn, and the number of cuttings is 4π N n μ a (100)⁻¹; this quantity is called The Co-efficient of Self Induction of the coil, varying both with the shape of the coil and the medium surrounding it.

Self induction, therefore, causes a varying local E.M.F. in the coil itself, opposing the current as it rises, assisting it as it falls in value.

In a system consisting of (1) an alternating current dynamo-machine delivering current to the primary coils of a transformer; (2) the secondary coils of a transformer delivering current to an external circuit; we have to consider (1) the E.M.F. produced by the machine; (2) the local E.M.F. in the primary coils; (3) the current in the primary circuit; (4) the E.M.F. produced in the secondary coils; (5) the local E.M.F. in the external circuit, due to self induction; (6) the current in the secondary circuit.

St. Peter's (R.C.) College, Glasgow.—Bishop Eyre on the 22nd ult. laid the corner stone of St. Peter's College, at Bardsen, a few miles from Glasgow. It is a large building, designed by Messrs. Pugin & Pugin, London. It gave an illustration of the College in the Builder for September 21st last.

The Swan United Electric Light Company (Limited).—We are informed that the directors have decided to pay an *ad interim* dividend at the rate of 6 per cent. per annum for the six months ending March 31, 1890.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

5,775, Bricks, Tiles, Building Blocks, &c. J. D. Denny.

This invention principally relates to improvements in the method of manufacture of bricks, &c., by machinery, and consists in arranging a plate on which a device is carved in the mould, and in dressing the plastic surface with ground dust.

6,949, Flushing Apparatus for Water-closets. J. Middlehurst.

According to this invention, a movable flushing-tank is used, and this is pivoted on a water-inlet pipe and suitably balanced. By its form it allows the water to come in through the inlet passage, and then directly after discharge it returns to a normal position, closing the supply-valve. The balancing power of the water is the chief feature, as this influences the discharge and supply, opening or cutting-off the inlets or outlets as required.

7,089, Gully-Trap, Cover, &c., for Drains. C. W. Miller.

This invention consists of an air-tight man-hole cover provided with a central opening protected by a grating, under which is a gully-trap of ordinary construction, but having on one side a fresh-air inlet with valve formed of mica, or some such substance. This valve is acted upon by the pressure of the fresh air being drawn through the grating by the friction of the ventilating shaft of the drain, but immediately the current ceases the valve falls. The presence of foul air or gases causes the valve to close and remain closed, preventing the escape of noxious smells or dangerous odours.

8,051, Paperhangings. W. Scott.

It is claimed that by this invention improved and cheaper materials are used. Sponge, fluely-out or ground, is applied to plain paper by means of adhesive substance. This gives a rich, velvety appearance, which may be increased by successive printings or embossing if desired, and is cheaper than "flock" papers.

19,634, Ventilators. W. and W. Gray.

The improvement which is the subject of this patent consists mainly in the uptake pipe or shaft of the ventilating head being fitted with a double casing lined with hair, felt, or woollen fabric or non-conducting material, sufficient to keep the external air from cooling down the internal air, and so reducing the induced up-draught.

NEW APPLICATIONS FOR PATENTS.

April 14.—5,666, H. Marsden, Nails.—5,627, J. Rome, Metallic Trough Flooring for Bridges, &c.

MEETINGS.

SATURDAY, MAY 3.

Royal Institution.—Captain W. de W. Abney, F.R.S., on "Colour and its Chemical Action." II. 3 p.m.
Association of Public Sanitary Inspectors.—Mr. T. Lowther on "The Drainage of Buildings, Public and Private, and its Relation to Health." 6 p.m.
Edinburgh Architectural Association.—Visit to Edinburgh Castle, Parliament Hall, Argyle Tower, and St. Margaret's Chapel.

MONDAY, MAY 5.

Royal Institute of British Architects.—Annual General Meeting of Members only. 8 p.m.
Society of Engineers.—Mr. F. H. Cheeswright on "Breakwater Construction." 7.30 p.m.
Guild and School of Handicraft.—Mr. C. R. Ashbee on "The Architectural Story of England." 8 p.m.
Liverpool Architectural Society.—Annual General Meeting. Closing Address by the President, Mr. T. Mellard Reade. 7 p.m.

TUESDAY, MAY 6.

Royal Institution.—Mr. Louis Pagan on "The Art of Engraving." I. 3 p.m.
Institution of Civil Engineers.—Mr. S. W. Barnaby on "The Screw-Propeller." 8 p.m.
Society of Biblical Archaeology.—Two papers will be read. 8 p.m.
Glasgow Architectural Association.—Paper by Mr. A. N. Prentice.

WEDNESDAY, MAY 7.

Institution of Civil Engineers of Ireland.—Society of Arts.—Dr. P. K. Franklin on "The Aim and Scope of Higher Technical Teaching." 8 p.m.
Liverpool Engineering Society.—(1) Election of Council and Officers for ensuing Session. (2) Adjourned Discussion upon Mr. T. L. Miller's paper on "The Efficiency of Gas-Engines." 8 p.m.

THURSDAY, MAY 8.

Society of Arts.—Mr. Lewis F. Day on "Design Applied to Wood-carving." II. 8 p.m.
Royal Institution.—Professor Dewar, M.A., F.R.S., on "Flame and Explosives." I. 3 p.m.

FRIDAY, MAY 9.

Royal Institution.—Mr. E. Brudenell Carter, F.R.C.S., on "Colour-Vision and Colour Blindness." 8 p.m.

SATURDAY, MAY 10.

Royal Institution.—Dr. Charles Waldstein on "Recent Excavations in Greece." I. 3 p.m.

Miscellaneous.

Liverpool Engineering Society.—The thirtieth ordinary meeting of the present session was held in the Royal Institution, Colquitt-street, on Wednesday evening, the 23rd ult., Mr. Henry H. West, M.Inst.C.E., President, in the chair. After the election of new members, the nomination of council and officers for the ensuing session took place. The adjourned discussion upon Mr. Thomas L. Miller's paper, entitled, "The Efficiency of Gas Engines," which was read before the Society at the meeting on March 26 last, was then opened by Mr. Joseph Price, jun., who was followed by Messrs. J. Hargreaves, C. G. Beechey, Ernest R. Royston, and others. The discussion, which was well sustained, was further adjourned to the meeting to be held on the 7th inst.

The Salvation Army in Brussels.—We are informed that a large block of buildings recently burnt out, and having a fine frontage to one of the main boulevards in Brussels, has just been purchased by the Salvation Army. Plans have been prepared by Mr. J. Williams Dunford, architect, of Queen Victoria-street, E.C., for adapting them to army uses. Arrangements have been made with a Brussels architect to carry the plans into effect.

National Registration of Plumbers.

A public meeting in connexion with the District Council for Bristol, Gloucester, Somerset, and Wilts was held at the Guildhall, Small-street, Bristol, on the 22nd ult. The High Sheriff of Bristol (Mr. Lockley), who is Chairman of the Bristol Sanitary Authority, presided, and there was a large attendance.—The Chairman said no one could estimate the value of that institution, and to it the Medical Officer owed a great deal. The mortality of a city was raised or lowered according to the efficiency of the plumbers engaged upon plumbing work in their residences. Jerry plumbing was an offspring of jerry building, and the object of the society was to get rid of the evil, and thus to reduce the rate of mortality.—The High Sheriff then distributed the certificates of registration, and Mr. W. H. Perry explained the conditions under which they were granted. The applications had been carefully inquired into, so that none but those who had had experience in the trade should be placed on the list.—The Chairman remarked that with such a body of master plumbers and of journeymen, they had a right to look forward to a better state of things in plumbing work than in the past.—Mr. G. H. Pope congratulated those associated with it on the success of the movement which was so recently started. They were to be congratulated also, though he ought not to say so, in having ready to hand technical instruction in plumbing at the Merchant Venturers' School. He had to move the following resolution:—"That after October 31 next the candidates for registration will be required to prove their qualifications by examination in the theory and practice of plumbing." In a new movement like that it was manifestly impossible to require all who had been in the trade for years to prove their fitness by examination, but it was thought there should be a limit to this, and those who did not apply before October 31 should be required to pass an examination.—Mr. Thos. Dyke seconded the resolution, and remarked that there was a certain amount of opinion about plumbers not altogether complimentary, and that opinion was partly founded on ignorance and prejudice. The work of that organisation would do a good deal to remove the idea of which he had referred. The resolution was carried, as was also the following one, moved by Mr. W. Brock and seconded by Mr. Tuckey:—"That in view of the public importance of a recognised qualification of plumbers we desire respectfully to call upon all public bodies, local authorities, architects, and the public generally in Bristol and throughout the counties of Gloucester, Somerset, and Wilts, to support the movement by giving preference to registered plumbers."

A Pavilion for the Finsbury-square Inclosure.—We understand that the committee of the inhabitants of Finsbury-square have accepted a design by Messrs. Crompton & Fawkes, horticultural builders, of Chesham, for a pavilion for the centre of the square. The building will be 24 ft. by 18 ft., and about 40 ft. high, cruciform in plan, with ornamental gables facing four ways, surmounted by an octagonal lantern, in which a four-dial clock will probably be placed at a future time. The base will be of red rubbed brickwork, and the sides will be glazed for the remainder of the height. The roof will be covered by red tiles. It is contemplated that the building will be opened the first week in June. All the details have been designed by Mr. Fawkes.

Potsdam.—Great alterations have been made in the interior of the so-called "New Palace" at Potsdam, owing to the Emperor having made known his intention of making this beautifully-situated home of Frederick the Great his regular summer residence. Not only have the halls and rooms been re-decorated and the valuable old furniture put into a state of repair, but also the arrangements in the kitchen and offices of the household have seen a great change. In accordance to the special wish of his Majesty the heating of the building has undergone a thorough reformation, a system of hot-water coils being substituted for the former ordinary fireplaces.

Messrs. Pontifex & Wood (Limited).—The business premises of this long-established firm of brassfounders, copper-smiths, and engineers will be put up for sale at auction on May 30. The property, which covers a total area of nearly 24,000 feet superficial, whereof the greater portion is freehold, is situated at the northern end of Farringdon Market, and has frontages to Shoe-lane and Plumtree-court.

Edinburgh and Leith Master Builders' Association and the Caledonian Railway Edinburgh Extension Bill.

At a general meeting of the Edinburgh and Leith Master Builders' Association, held at 5, St. Andrew's-square, on the 25th ult., it was unanimously resolved:—

I. As it is the interest of the public to promote intercommunication, the proposed extension of the Caledonian Railway to Leith, in competition with the North British Railway system, is regarded by the master builders, as a portion of the community, with favour, and as eminently desirable, being calculated to greatly increase and develop trade, and the means of transit from the west to the east of the City of Edinburgh.

II. As the future prosperity and extension of the city largely depends upon its amenity, it is incumbent upon the master builders to carefully criticise and, if need be, to strenuously oppose any scheme calculated to injure or destroy said amenity. Having, as practised men, considered the proposals of the Caledonian Railway Company, the master builders are of opinion that the construction of the proposed line of railway will not injuriously affect the amenity of the city; that a thoroughly practical scheme for the construction of the line has been submitted; and that it can be safely carried out without special risk to either property or life.

III. That the master builders and those of the public interested in the extension of the city in the Easter-road and neighbouring districts have a special interest in desiring and promoting an extension of the Caledonian Railway to the east, as the conveyance of building materials without undue cartage will materially lessen the cost of erection of new property in the districts referred to.

IV. That a copy hereof be forwarded to the Edinburgh Town Council, with the expression of the opinion of the master builders that in their determined and uncompromising opposition to the Bill they do not have the public interest in the construction of a railway whose interests would be better served,—1, by securing as large a sum as possible for wayleave through or under the property of the City; 2, by endeavouring to arrange for the public interest in the construction of a subway between the platform of the North British Waverley Station and the platform of the adjoining station on the proposed line; 3, by seeing that the proposed railway should be elevated and viaducts or viaducts of an architectural character as to enhance in place of injuring the amenity of the city; 4, by securing access wherever necessary to the property on both sides of the proposed line, so as not to repeat the objectionable by which the City has allowed both the Caledonian and the North British Railway to prevent all direct communication between the Fountainbridge and Dalry with the Roschire or Gorbals district; 5, by arranging economic through-rates both for passenger and mineral traffic in the public interest.

V. That a copy hereof be also forwarded to the secretary of the Caledonian Railway Company, with the assurance of the hearty co-operation of the master builders, and their best wishes for the success of their Edinburgh Extension Bill.—Scottman.

The Keepership of the Monument.

Mr. Thomas Peto Ward, of 10, Campsbourne-villas, Pembroke-road, Hornsey, well known to many of our readers as the founder of the Builders' Clerks' Benevolent Institution, is a candidate for this appointment, and has our best wishes. In his address to the Lord Mayor and Corporation, he says:—"As a nephew of the late William Ward, who died in 1881, of the Ward Bequests to the Poor of London, and of James Ward, of the Court of Common Council for Aldersgate, also related to the Wards, several contractors for upwards of 100 years, within your City, and who carried out several of the important contracts, permit me, in consequence of a severe reverse of circumstances, to solicit at your hands such employment as you are enabled to bestow. My family were supporters of many of the charitable institutions of London and suburbs, members of the Tylers' and Bricklayers' and Lorryes' Companies, of which last, by patrimony, servitude, and purchase, I am a freeman, and I have the great gratification of seeing much good resulting from my foundation in 1866 of one successful benevolent trade institution, the Builders' Clerks' Benevolent, the success of which was assured by the support rendered me then for the benefit of others by Sir William Lawrence, one of your respected Aldermen and former Lord Mayor, and the late George Godwin, Esq. For fourteen years I held important positions in the offices of four leading London contractors, Messrs. George Mansfield & Son, James Macey, Newnan & Mann, and Browne & Robinson, the latter building your Markets, the interior of Newgate Prison, and Sessions House alterations. For fourteen years I was a master builder; such position was ruined by the results of a five years' litigation (Ward v. Pillely). I have since held two appointments as Clerk of Works, receiving sealed testimonials, thanks, and testimonials from Engineer and Architect."

Royal Victoria Hall, Waterloo Bridge-road.—The following are the arrangements for the Science Lectures to be held here during May.—May 6, "Birth and Death of Mountains," by W. W. Watts. May 13, "London Water Supply," by Prof. Bonney. May 20, "How a Photograph is taken," Dr. J. A. Fleming.

The Central London Railway Bill.—During last week and this week evidence has been given before the Select Committee of the House of Commons for and against the proposals made by the promoters of this Bill. It proposes to make an underground railway (on the plan adopted in the Southwark City Subway) from Bayswater, along Bedford-street, Holborn, and Cheapside to the Bank. Last week evidence was given to the effect that the project was likely to endanger the safety of such buildings as St. Mary's Cathedral and the Church of St. Mary Bow, Cheapside, but on the 25th ult. Sir Benjamin Baker was called, and said he quite agreed with Mr. Hutton Greathead, the responsible engineer, that iron stations would prevent any such damage to property as may have occurred on the Southwark Subway route, where the stations were built with bricks. The underground Railway went within a short distance of Westminster Abbey, and no damage was done to that structure, and he did not anticipate any to the buildings on the route of the proposed line. Near St. Paul's Station the Metropolitan Railway passed under a very heavy bridge belonging to the Chatham and Dover Railway Company without injury to the structure. The witness produced some photographs showing the manner in which a similar railway on the proposed line was constructed, and explained the system to the Committee. While the line was in course of construction there would, said Sir Benjamin, be no obstruction whatever. Anything that would take traffic off the road, or prevent further traffic, was for the benefit of the public. Their system of generating the electricity would cause no annoyance whatever. They did not intend to alter the level of a single sewer on the Metropolitan line. In the construction of the Metropolitan Railways sewers had to be altered every yard, which was accomplished without any difficulty. The present scheme was mere child's play compared with what had to be done in the construction of the Metropolitan Railway. He had very carefully considered the question of the possibility of injury to the Holborn Viaduct, and he was content that none would be done. St. Paul's Cathedral was so far away that it need not be taken into consideration at all. Sir John Fowler gave evidence in support of the Bill. He stated that electricity had passed the experimental stage, and he expressed the opinion that the Metropolitan Railway would be worked by electricity in a few years. This closed the promoters' case, and the inquiry was adjourned till Friday last, when the proceedings were resumed on behalf of the opponents of the scheme.

The A.A. Lyric Club.—The seventh and smoking concert of the season in connexion with the A.A. Lyric Club took place on Thursday, the 24th ult., at the "Mona" Hotel, Piccadilly Garden, Mr. G. Richards Julian, President, in the chair. A very good programme was got through very creditably to all the artists and performers, including Messrs. C. D. of, C. W. Davies, Thomas Roberts, F. T. Stanley, F. J. Dyer, E. W. Arthur Thomas, F. H. Collins, and H. Weeks. Special mention must be made of the services rendered by four sopranos, Messrs. S. Wright, A. E. Williams, A. Cr., and M. Holdsworth, whose performances as a string quartette were deservedly applauded. Mr. Richards Julian distinguished his abilities as a reciter, and Mr. Arthur Julian his versatility as a vocalist. During the evening Mr. W. Burrell was elected President of the Club for next session, and Messrs. Henry White and Theo. Moore, secretaries, are asked to mention that on Monday, the 22nd (not the 15th, as previously announced), there will be "a ladies' night," when a concert exhibition of drawings will be held at 9, St. James-street.

Berlin.—Looking through the official estimates of the expenses of the City of Berlin for the financial year 1890-1891, we find that the Public Works Division of the Board of Public Works requests a grant of some 70,000, for a new lunatic asylum, 30,000, for a new obstetric hospital, some 49,000, for new high schools, and 79,000, for the erection of new schools. The Civil Engineering Division of the same Board request a grant of about 600,000, for the cutting through and laying out of new streets, and nearly 68,000, for the construction of new bridges. The total of the estimates of the two divisions shows a figure nearly 1,000,000.

Architecture at the Paris Salon.

Go from the architectural room at the Royal Academy to those of the Salon furnishes a striking contrast. At the Academy room everything is on a small scale, and perspective views, architectural pictures, are in the majority. At the Salon they are so rare as to be a subject of remark when one encounters them. Large geometrical drawings, often of the most highly-finished character, and got up with a power of effect to which we are almost strangers in England, are the rule here. Gilt frames are not demanded, and the most important drawings are merely mounted on strainers laid with toned paper on the margins, as competition drawings are usually mounted in England. The principal architectural drawings occupy two large rooms, each much larger than the one Royal Academy room, and extend along the end and well up the two side walls of the gallery surrounding the great central court of the Palais d'Industrie. Another feature in the collection, which we do not approve of so much, is that nearly all the drawings which are not illustrative of ancient monuments are ideal designs, which have not been and probably never will be executed. Many of these are of much interest and evince remarkable talent and acquirements; and no doubt it is a seductive thing to evolve on paper architectural ideas that need not be limited by considerations of cost and expediency. But after all, one object of an annual exhibition of architectural designs should be to illustrate the state of the current architectural work of the year; and in this department the Salon collection is even more deficient than usual; in fact, the drawings illustrating buildings executed or commissioned might we believe in literal truth be counted on the fingers.

In the centre of one room is M. Jean Bréasson's model, one-tenth actual size, for a monument "to the Glory of the Republic." This is a composition with a large circular base in four stages, of which the two middle ones are fountain basins, the water flowing from masks in the band of floral ornament which surrounds the upper stage. On the latter rises a great quadrangular stele terminated with a cantilever cornice, which is sur-

mounted by a draped figure of "La République," holding a statuette of Victory (?) in her upraised right hand. The lower portions of the four faces of the stele are decorated, on one face with has-relief figures of Liberty, Equality, and Fraternity, on the reverse of this with a profile figure of a lion, and on the other two sides with has-relief trophies of arms &c. Opposite the four angles of the stele, on the oblique angles of the plan, four pedestals project into the upper fountain basin, bearing groups of sculpture. "Égalité devant la loi" is represented by a seated female figure pointing out to a European and a negro boy the tables of impartial law; "Instruction pour tous" by another seated woman teaching two children ("instruction for two" we heard it translated); "Liberté de Conscience" is a seated female with a torch and a book; and "Suffrage Universel" is a seated figure of a working man with a hammer dropping his vote into the ballot-box. The design compares well architecturally; the basement groups would be better with a perfectly plain plinth behind them, leaving the elaboration of mouldings to commence above; the architecture and sculpture here seem rather to interfere with each other, but there is a great deal that is striking in the design, and it has the merit of having a meaning in every part.

Large restoration drawings of course occupy some space on the walls, but rather less than is usually the case at the Salon. Nearly the whole wall of one room, however, is occupied by the huge strainers containing M. Redon's drawings of the ruins of Baalbek and a restoration. Four frames are devoted to the "actual state," which is shown in splendidly-executed colour elevations such as we see nowhere but in France, no incitement being given to English architects to produce work of this kind. The colour and texture of the walls are shown to perfection, both in the actual and the restored drawings, which are masterpieces in the art of coloured elevation. The restored elevation would convey a more true effect however, if the two pediments of the temples, which are far back from the frontplane of the elevation, were kept more flat and distant by a more subdued tinting. An actual and a restored plan are also added. The author treats the hexagon court in the rear of the entrance façade as a colonnaded court with tiers of niches and statues in the walls at the back of the colonnade, and places a colossal bronze statue in the centre of the court, for which however his plan of

"état actuel" does not pretend to show any authority. But as a whole, the set of drawings is a great credit to French illustrative architecture. We are bound to add that this splendid workmanship does not seem to attract any general notice among visitors, and that the architectural rooms at the Salon are almost as empty as that at Burlington House, though there is much more to look at.

M. Fournereau's drawings of the temple at Angkor-Thôm in Cambodia are the only set of restoration drawings equalling the last-named in scale and importance. These splendid drawings are part of the result of the architectural "mission" to Cambodia organised by the Ministry of Fine Arts, and the magnificent drawing of the restored elevation, a drawing covering the space of a small room and full of the most elaborate detail, is an effective example of what may be done in the way of archaeological illustration of architecture under a Government that will spend public funds in encouraging such studies. No doubt the architecture itself is *bizarre* in the extreme, from a European point of view; but it represents the ideas of people who were once a great and powerful race, as their architectural remains amply show, and who had moreover, after their own manner, that kind of enthusiasm which pushed them to do the greatest and most elaborate things in art that they were capable of. We referred last year, in speaking of the contents of the Trocadéro Gallery, to the extraordinary boldness of scale and style of some of the casts from Cambodian sculpture exhibited there; and this restored drawing of the temple gives the same kind of impression of extraordinary though barbaric power; especially in the effect of the immense mass of wall, with its portentous mouldings, which forms the base to the whole fantastic composition. M. Fournereau's drawings include plans and sections as existing and as restored, and also (which is unusual in French sets of drawings of this kind) an effective coloured perspective of the existing remains, with their extraordinary and multitudinous carved detail.

Another of the largest drawings exhibited is M. Boileau's design for a monument of 1789, shown as occupying a space to the west of the Place de Carrousel and facing the Tuileries gardens. This is an immense coloured elevation showing a built-up piece of monumental architecture, consisting of a gallery with a triumphal arch and dome in the centre of the long side parallel to the Rue des Tuileries, and a return wing at each end

connecting it with the road, where there is at each side an arched entrance with a cupola over, kept however very much below the line of the central dome, which stands high above the rest of the composition. It does not appear what use is to be made of the interior of the gallery, which is not a colonnade but confined within solid walls and covered with a glass roof; the exterior is divided into three bays at each side by wide pilaster-like piers with vertical panels containing inscriptions in gold on a dark marble ground; the lower half of the spaces between is occupied by an engaged order with wide spaces between the flanking columns filled with sculpture representing scenes in the history of the revolution,—the taking of the Bastille, the voluntary enrolment, banquet of the Girondins &c. The piers terminate in coloured marble obelisks with big gilt stars as finials. Above the bas-reliefs are panels with portrait heads in wreathed medallions. The treatment of the curtain walls is much the best part of the design; the centre dome, on an open circular colonnade of Corinthian columns, looks insecure and gimerack, and the treatment of the eud cupolas is commonplace and showy.

Let us turn to some of the smaller drawings. M. Lafillée exhibits seven frames of most interesting coloured studies of "peinture murale au moyen âge en France," dated approximately and with their place given. Any English architectural student visiting the Salon should look at these, which we hope the author intends to produce in a chromolithograph volume. M. Cordonnier exhibits an elevation of his design for the new façade for Milan; an elaborate Late Gothic façade of which however the details strike one as rather thin and cast-iron in appearance, and in which the author has adopted the principle of flanking the façade with two immense towers far over-topping the central lantern, a treatment which we long ago condemned as a mistake, in speaking of the selected competition designs for Milan.

M. Lambert's "Crouis et relevés des Monuments Français" consist of a large frame of beautifully-executed small pen drawings, chiefly from various châteaux in France, in which artistic touch and effect in pen drawing are combined with accuracy in the indication of detail.

M. Moynéau's series of drawings for the restoration of the château of Nemours, a very prettily-got-up set of water-colour elevations, have for their main object the renewal of the courtyard walls and towers, which are ruined, and the replacing of a timber gallery of communication, of which only the traces now exist, between the angle towers of the principal mass of the building, round the outside of the walls. This restoration of Middle Age castles to their original state is a kind of mania apparently in France at present; it is very pretty work on paper; whether it is worth while carrying into execution all this pretence at the renewal of feudal architecture is another question. This we presume is a private commission, as it bears no official indication of any kind. The imprimatur of the "Monuments Historiques" appears on M. Petitgrand's charming set of drawings of the Romanesque Church of St. Paul at Issore, one of those buildings in which the development of the buttress is so curiously illustrated by the employment of engaged columns and buttresses in two apses of the same chevet. We presume some part of this drawing is restoration, or at least that the building has been finished-up into an appearance or completeness greater than it actually has, in order to give a complete record of its design. The drawings consist entirely of tinted elevations.

M. Deverin's fine set of drawings of the Abbey Church of St. Jouin-des-Marnes include drawings, in the same style, both of the actual state and of the proposed restoration. The north side elevation showing the actual state presents a most strange jumble of an apsidal chevet without its proper cornice terminations, with red tile roofs hanging over the curves like a blanket; a Romanesque tower with

half-effaced details; square "churchwarden" windows built into the wall of the nave, and the remains of a Late Gothic traceried cloister below them. The west front, which requires but little in the way of restoration, is a singular piece of architecture, with flanking turrets formed by a combination of three great shafts on each face, having with their capitals more the look of very elongated Classic columns than of anything Gothic; this columnar collection being crowned with two arched stages and a conical turret. The restoration of the eastern end which is contemplated, or at any rate shown, is very complete, but we fear is likely to confuse history very much. A number of interesting drawings of capitals and other details are added. M. Esquié's project for the restoration of the extraordinary castellated-looking brick church of Venesque (Haute-Garonne) hangs next to this; the drawings do not show very clearly what is intended, but it seems to include a rebuilding of the west front in a characteristic brick style, and with a grey stone or granite base on which the brick is built direct without the intervention of any moulding, as we noted the other day it was done in Mr. Norman Shaw's new building on the Embankment; so he is after all not alone in this piece of architectural immorality. Behind the front is seen the top of the low broad battlemented tower, with bells of unequal sizes hanging in open arches. Altogether this is one of the most curious and interesting bits of work among the drawings connected with restoration work.

M. Marcel's restoration of the Château of Tonquedec is illustrated by some fine water-colour drawings of the existing remains and a set of equally fine tinted elevations of the restoration, together with a bird's-eye view perspective in monochrome. This, which includes no less than twelve large frames, is one of the finest sets of drawings in the collection. The studies for a restoration of the Château of Mesnières, by M. Conin, include a fine water-colour perspective of the building occupying three sides of a courtyard, with a Francis I. façade towards the court, and two immense circular machicolated towers, with conical roofs, at the outer angles of the building. M. Lafargue's restoration of the Château of Lestang is another admirable set of drawings of the same class. Next to this are M. Ridet's drawings and restorations of the Abbey of Fontevrault. The architect has restored the central tower with a short bulbous-shaped spire or pointed dome in masonry, which has rather too modern an appearance, though it is certainly an improvement on the existing ugly timber and slated termination. The most remarkable incident in the plan is the "cuisine," a separate eight-sided building with a lofty conical roof in masonry, and an apse on each side of the octagon, giving it the appearance of a chevet continued all round the centre. This extraordinary structure stands apart opposite the west end of the refectory, which runs parallel with the church on the south side of the cloister. The church itself has a one-aisled nave, with pious piers dividing it into four bays, from which spring transverse round arches with flat soffits, carrying the domes which internally form the roof to each bay. These domes are a restoration, but no doubt a correct one as to the general scheme of the architectural design. As it now stands the nave is covered by a continuous timber roof. A full plan of the church and the contiguous buildings is given. This is a remarkable set of drawings, got up with great completeness. A set of water-colour perspective sketches of existing portions is added. The cloister is partly Renaissance work, with circular arches divided by coupled columns of a small Ionic order.

M. Libaudière shows a beautiful coloured elevation of the Romanesque Church of Le Caillère; and M. Lemoine exhibits drawings of the existing Château de Veul and restoration, with its circular towers curiously divided up into panels by a series of

what may be called wall-mullions. M. Albert Gayet exhibits a fine set of coloured drawings of a restoration of the pavilion of Rameses II. at Medinet-Abou; the colouring is rather harsh and crude, but so probably was the original. Among the drawings illustrating ancient work there is perhaps none finer, as a specimen of illustrative architectural drawing, than M. Bressillon's coloured elevation of the portal of the Church of Sainte-Pierre at Avignon. The sculptured details are worked up with remarkable force and reality of effect, producing almost the appearance of actual relief.

As observed, designs for modern buildings form the minority of the collection; there seem to be rather more of these than usual, at first sight, but on examination it turns out that a large proportion of these, including the largest and most striking drawings, are only "projets"; castles in the air, and the number of illustrations actually executed or commissioned is very small indeed; a practical deficiency in French architectural exhibitions which we have often commented on. M. Laborey shows a good interior view of the "Chapelle de Notre-Dame-de-Sion," at Paris, a Renaissance building with the domed ceiling decorated in a pretty but rather timid manner with powderings and medallions on a gold ground. M. Jasson's drawings of the Victor-Poirer Salle-de-Concerts at Nancy show a well-detailed design of the modern French Renaissance type. Among the "projets" a very pretty one, shown only by a single lightly-tinted elevation, is M. Monpauze's "Façade d'une Eglise Paroissiale," a Renaissance façade with an octagonal dome seen in the rear and a bell-turret at each side of the façade. M. Destors' "Un Cercle Artistique" is a student's competition design of great pretension and shown in a set of very large and well-executed geometrical drawings, but spoiled by utter lack of repose and refinement in the details. M. Le Ray's "Un Hôtel de Journal, avec imprimerie" is a fine and grandiose design, fully illustrated with plans, elevations, and sections, the hotel forming a separate block to the street, the printing rooms a great iron-roofed building in the rear; the façade has the fault of being too showy and occasionally a little vulgar in the details, but its general effect is dignified and suitable; the best part of the design is the treatment of the back of the building towards the courtyard which intervenes between the front block and the printing house. The plan is well laid out, and all the practical details of the building completely shown. "A theatre for a provincial town," by M. Dupuis, is another Students' Competition design; there is nothing of the provincial town about it, for it is nearly as costly and decorative as the Paris Opera House; there is a very rich effect in the treatment of the centre part of the principal façade with its Corinthian order and open arcade between the coupled columns, the lower parts of which are enriched or rather encrusted with ornament in the shape of masques and scrolls; the large detail elevation is a capital piece of work of its kind. In strong contrast to these showy designs is M. Moreau's "Etude d'Hôpital," a plan for an immense pavilion hospital treated with uncompromising simplicity in the architecture. Then we have a "Hôtel pour un architecte décorateur" by M. Gaston Cousin, the slightly tinted elevation of which is a really refined bit of work; there is no order, and the designer has known how to hold his hand and be reticent with his ornament, which is well-placed and well designed; there is a plain masonry wall with a rusticated basement, and windows with decorative "encadrements" equally spaced in the wall, the main wall space being terminated by a cornice with a broad band of carved ornament beneath it as a frieze. M. Le Grand's design for a Mairie for the Xth Arrondissement shows on the plan a clever treatment of an irregular and awkwardly shaped site, but the design is commonplace.

M. Emmanuel Garnier's "Hôtel de M.

G.—at Nismes," we may take to be one of the very few real modern buildings of which any drawings are exhibited. It is shown in a very large and elaborate set of drawings, but does not please us much. It is a Classic building without an order, and to which a certain special effect is given by the treatment of all the window architraves with continuous carved ornament all round, on a basis of perfectly plain masonry; the effect is meant to be rich but is somewhat monotonous, and considering the great size of the elevations the detail really ought to have been better shown; it is not worth while making drawings on so large a scale except with the object of showing detail thoroughly. M. Mougenot's drawings showing a design for baths for Epinal are also only a "projet," but are very interesting. This is one of a class of buildings in which French architects excel; buildings for a practical purpose in which a simple and economical architectural treatment only is admissible. We have here a long red-roofed stone building flanking the sea, with a rusticated basement-story immediately above the pier, with small windows only; and above this two stories with the windows connected vertically and enlivened with a little inlaid tile ornament between. The entrance is on the end elevation at right angles to the sea, with a low wing pavilion at each end of it with heavily rusticated angles, and three large arched entrance-doors in the centre of the connecting wall. The treatment is perfectly unaffected and simple, the building looks like what it is, and the firm and distinct manner in which the elevations are drawn and tinted deserves special praise.

M. Delort de Gléon's "Hôtel Particulier" at Cairo is a strong contrast to the last-named exhibit, being a Cairene treatment by a European architect; a mass of white and yellowish plaster wall with a characteristic cresting, and coloured tile ornament liberally inserted in connexion with the fenestration; the delicately-tinted elevation has a charming effect. Next to this is an admirable coloured elevation of a very different type, M. Baril's competition design for the Mairie of the Xth Arrondissement: a very pleasing design with a slightly-projected centre block with pyramidal roof, a Corinthian order in the upper story with mullioned windows between, and plain wall below with three arched entrances; the slightly-receding wings are kept very plain, throwing out the centre portion; the design is delicately and very artistically tinted, an excellent example of geometrical architectural drawing. The plan is treated with a centre court and a colonnaded loggia round, with a handsome external staircase from the courtyard level to the loggia.

M. Cabanis's coloured drawing of the church of Clermont-Ferrand, a kind of elevation with the effect of a perspective (the ground-line is actually drawn in perspective though the cornice lines of the apse are straight) deserves mention as a very effective drawing, tinted in a light reddish tone which, with the blue sky above, gives a powerful effect of sunlight. It is difficult to determine whether M. Gontier's Château de Villefargeau represents a new house, or is a drawing of an old one: it is a very quiet unassuming house, with a long stretch of low red-roofed buildings, partly offices, behind; if it is a new building, it is a rather agreeable variety among modern French house designs for its exceedingly simple, unpretending, and home-like character.

Of decorative design there is not very much: and what there is will not appeal much to English taste, which in the present day may at least boast of evincing a far more delicate perception and taste as to colour and decorative style than is exhibited in French work of this class. M. Marnze exhibits two designs for tombs, apparently in red granite, and which realise nothing better than the old sarcophagus pattern with sham rings at the sides, and mounted on a lofty and solid mass of plinth. M. Lorain exhibits a drawing of his façade for the portal of the gallery of "Classe 24" at the

1889 Exhibition, a gewgaw arrangement in blue columns and gilding, which might do as a temporary exhibition design, but was certainly not worth exhibiting here for more mature and considerate criticism. M. Onillon exhibits some sketches for decorative tapestry, with the Renaissance *motifs* on a yellow ground which seem to be the prevailing modern idea for tapestry design in France; in the middle of one of them is a nude figure in an architectural alcove, and relieved upon a ground of bright red. The colour effect is what the French themselves, in moments of more sober consideration, would perhaps call *criarde*, and it is needless to remark that of all things in the world classical architectural detail is the kind of thing least suited for treatment in tapestry; it demands clean lines and clear-cut outline, which is exactly what tapestry cannot furnish. M. Guillaumot, a provincial architect at Marly-le-Roi, and pupil of Viollet-le-Duc, sends three coloured interiors illustrative of rooms and furniture in the Château of Marly, which are well executed and interesting as illustrations.

The drawings by M. Robert-de-Massy, representing coloured design for the walls of three rooms, a "cabinet de toilette," a "cabinet de travail," and a "salle de bains," are the same class of design which is exhibited on the Royal Academy walls by Professor Aitchison: they are more precise in execution and more brilliant in colour—much more brilliant; but what colour! The "salle de travail" shows a green self-coloured wall with red doors and a white mantelpiece with strongly coloured blue tiles; in the "salle de bains" the whole wall is enclosed in a bright red frame, within which are tiles, and within this a similar bright red frame enclosing paintings of marine creatures. The "cabinet de toilette" has a very pronounced wall tile pattern as a dado, above which is painted an imitation trellis with flowers trained over it! There are some things, at all events, that we do better in England. M. Hourlier exhibits a design for a ceiling intended to illustrate the twelve months of the Republican calendar, which is enough to knock one down; the general design forms a great red cross from angle to angle of the ceiling, with panels between the arms in which are allegorical figures with representative reptiles and flying things scattered about them in profusion; the thing is not only not decorative in effect or treatment, but it would be enough to lower any room to which it was applied to about half its real height; the large figures in the angles, at the extremities of the cross, are however well designed in a large and grandiose manner. Beneath this is a clever piece of archaeological decorative study by M. Mayeux, the colour statue of Artemis of Ephesus, the nude portion of the figure (down to the waist) painted a strong red, with a pair of wings seen behind somewhat on the model of the decorative wing familiar in Egyptian work. This semi-barbaric figure stands relieved against an alcove of strong and dark blue, and bases her feet on a marble pedestal somewhat resembling an egg with the small end upwards. The figure and niche are framed in a polychrome architecture looking rather of the proportions of wood than stone. The whole effect is distinctly Asiatic rather than Greek, and may so far be in keeping with the probabilities of Ephesian decoration, it is at all events a powerfully executed drawing to which some thought has gone. M. Massy exhibits a small and very delicate water-colour elevation for the Uruguay Pavilion of the 1889 exhibition, this is a very pretty little building; a portion of the "decoration of classe xv." shown in the same frame, is, like nearly all the coloured decoration design, somewhat hard in effect and inharmonious in colour, though it does not do such violence to the eye as some we have mentioned. The best piece of decoration by far that is to be found in the collection is the study by M. Espouy for a scheme for the decoration of the ceiling of a room in the Villa Medici. This is in a not very pure style it is true, the

details consisting of scrolls and festoons and figures dancing about among them after the Renaissance fashion, but it is really refined in design and execution, and pleasing and delicate in colour, and the little figures are very well drawn. A design in another school of Renaissance is that by M. Paquet, for a decorative ceiling in Louis XVI. style; a large circular moulding gives an opening in the centre into the sky and clouds and pink cupids flying about, the sprandrils are loaded with bundles of multifarious objects on a gold ground: a clever drawing reproducing a most vicious style of decoration. A design for a decorative ceiling by M. Pedroni, consisting of very heavy mouldings dividing the ceiling into panels of various shapes, with Renaissance scroll-work on a gold ground in the panels, is inoffensive in taste though not in any way remarkable. If we have a good deal to learn from the French about architectural drawing properly so called, and a good deal to envy them for, we have at all events no cause to be jealous of them in regard to decorative design, in which, if we may accept the Salon as a test, their best things are only tolerable and their worst rather intolerable.

NOTES.

THE advocates of the registration of architects in this country (or those who pose as such) have, we believe, been referring in support of their views to the demonstration which has been got up on the subject in France and America. The French architectural papers have lately been full of excitable and piquant letters from individual architects discussing the subject from various points, most of which however, showed so little pretence of seriousness, and were so obviously prompted mainly by the desire, so common among Frenchmen, to evolve smart and humorous epigrams, that they hardly called for serious consideration. But the decision came to by the official Commission appointed to consider the question of an architectural diploma in France, is insignificant enough. It should be borne in mind that France is the country in which architectural education is more systematically and elaborately carried out than in any other country in the world; that there is probably no country where architecture and architects are held in more respect; and that the Commission consisted almost entirely of men specially qualified to consider the subject in its bearing on the highest interests of architecture as an intellectual art. The decision of this Commission is that the theory of a compulsory or obligatory examination is rejected by a majority of 15 to 3, and that of a "diplôme facultatif," or a diploma given as a distinction to those who claim and can show that they are worthy of it, was rejected by a majority of 12 against 6. This, as is remarked in the *Semaine des Constructeurs*, from which we take the facts, "amounts to the rejection en bloc of all diploma." In regard to the subject of provincial instruction in architecture a resolution was passed that "the Commission is of opinion that the provincial architectural societies should be invited to study in concert with the state or official authorities ('pouvoirs publics') the means of developing or creating schools of architecture."

THE speeches at the Royal Academy dinner of last Saturday were quite up to the usual mark of an occasion when some of the best of the after-dinner speeches of the year are usually made. The Marquis of Salisbury's sketch of the manner in which artists would in future times be taken care of under a "grandmotherly" Government of advanced progress was very happily hit off. "But the time may come when there will be a committee that will examine you and a commission that will reconstruct you. And, worse than that, you will receive the assistance of the Treasury, and you will be exposed in Committee of Supply to the microscope of Parliamentary taste. You yourself, Sir, or at least your successor, will be appointed by

competitive examination, and you will be forbidden by Act of Parliament to work for more than eight hours a day. Then an inspector will come down to you here as everywhere else, and I fancy that it will be an inspector from the County Council. His duty will be to examine beforehand the subjects to which your artists are to devote themselves, and to see that the models whom you employ are properly draped." This prophecy must have been a satisfactory one to Mr. Horsley, at all events. The chief interest of the evening lay in the appearance of Mr. John Morley as the respondent to the toast of literature, who took the opportunity of pointing out the sense in which literature also was an art—"the happiest of all callings, and the most imperishable of all arts," and who made a plea for the protection of the English tongue against such barbarous inventions of words as have already been coined, and are still further threatened, in connexion with the practical application of electricity.

THE London County Council is still on its trial, but it has had its case very succinctly put before the public by Lord Rosebery in his review of the first year's work of the various Committees of the Council. These committees are upwards of twenty in number, and it is therefore not surprising that Lord Rosebery's review, divided into three instalments, occupied nearly an hour in delivery at each of the three last meetings of the Council. There is no doubt that the Local Government Act of 1888, which authorised the election of County Councils all over the country, does not meet all the requirements of London government, and it was confessedly only made applicable to London by reason of the state of things which was revealed by the Royal Commission of Inquiry into the proceedings of the Metropolitan Board of Works. Modified as some of the general provisions of that Act were to meet the special needs of London, and containing as the Act does special clauses applicable to London alone, the working of the measure in London has entailed a great deal of friction and delay in many mere matters of detail. Amendments of the law (some of which are now before Parliament) will no doubt make the administrative machine work more smoothly. In the meantime, the Council will do well to profit by Lord Rosebery's excellent advice, and to bear in mind that they are an administrative and not a legislative body. By the intelligent and diligent discharge of the important work committed to them they will gradually gain the public confidence, and may ultimately have the satisfaction of developing into an ideal municipal body.

WE have good authority for saying that Professor Raschdorff's new design (dated March 9) for the new Cathedral at Berlin has been approved of by the Emperor.

SIR WILLIAM HARCOURT attacked the Chancellor of the Exchequer in the debate on the Budget provision on Monday for not abolishing the Inhabited House Duty. This produced from Mr. Goschen the confession that the entire abolition of this tax had been in his mind, but that he did not like to abolish a tax entirely, on account of the difficulty of introducing it again. But this reasoning seems to be one against abolishing any tax or any part of a tax; because, if necessity requires it, it can be no valid argument against the re-imposition of a tax that at a time when it was not needed it was abolished. The Inhabited House Duty is no doubt a tax easily and inexpensively levied, which is a reason for its continuance, but in the case of many persons it is a tax on a necessity of life. It certainly ought, if possible, not to fall on houses below £250 in annual value—a house above that value falls into the category of luxuries. The fairest way to levy it would be to exempt houses under that value, and to exempt also that amount in the case of houses above that value. Thus a house valued at 200*l.* a year would pay on 75*l.* The present amount is too low.

THE case of "Proudfoot v. Hart," which was decided the end of last week by the Court of Appeal, is one of considerable interest and importance, but whether it really throws light on the relations of landlord and tenant seems rather doubtful. The action was brought by a landlord against the tenant for not delivering up his house at the end of the term in "good tenable repair." The reports of the case which have been published are rather too meagre to be satisfactory, and it may be that when this decision is reported in full in the Law Reports, it will be of greater value than it appears to be at present. In the course of the judgment the Court gave the following definition of "good tenable repair":—"Good tenable repair" is such repair as, taking into account the age, the character, and the locality of the house, would make it reasonably fit for the occupation of a reasonable-minded tenant of the class who would be likely to want the house." It is obvious that this definition requires each case to be judged by its particular facts, and also leaves a good deal to the inclination and personal views of the man who has to decide between landlord and tenant. In the case in question the official referee gave the landlord the costs of painting and papering with new paper (similar to the old paper), some of the rooms; but the Divisional Court and the Court of Appeal reversed this decision, and held that such work was decorative repair, and was not required to be done by the words of the contract. But we might ask whether a house is in tenable repair if it is not papered? And the exclusion of decorative repair in the case in question does not seem to follow from the definition which was laid down by the Court.

ACCORDING to the *Illustrirte Zeitung* of the 3rd inst., the sculptor Reinhold Begas (who is at present favourite of the Emperor), has completed a new model for the much spoken of "National Monument to William I.," which is to have a site found for it in Berlin, and this model is supposed to have been designed in accordance with the ideas of his patron. The same journal brings the news that a new, a second, competition for this monument is being arranged, to which, however, besides Begas, only sculptors, *i.e.*, the four winners of the second prizes at the grand competition of October last, Messrs. Hilger, Otto, Schaper, and Seibling, will be invited. By whom these latter arrangements are being made the journal does not notify; but it distinctly mentions that in this competition, that site against which the assessors of last year's competition distinctly voted, but which seems to have taken the fancy of the young Emperor, *i.e.*, the "Schlosspeihheit," is to be chosen. If this plan really be followed, it will cause great complaint in German artistic circles, and especially among architects, as it will be remembered that the two first prizes in the grand competition were awarded to members of the profession, in whose designs architecture and not sculpture was the prominent feature.

THE great suspension bridge at Buda Pest, which was erected 1842-1849 by Messrs. William & Adam Clark,—famous not only for its construction, but also for its extremely fine outline from the artist's point of view,—is in danger of breaking down, this danger being caused by the rusting and giving way of the worms of the screws on which the main strain tells. The Dutch engineer, Haentjens, who has been consulted as to the quickest and surest way of saving the bridge, is preparing plans for this purpose with the utmost speed.

IT may be worth note that the managers of the Exhibition of Gardening and Horticulture, opened at Berlin on the 25th ult., took special care that the floral arrangements should be brought into connection with architecture, and that the visitors should have not only plants and flowers to

study at their show, but also the different modes of arranging these on, or in combination with, buildings and parts of buildings, both exteriors and interiors.

A VERITABLE Elizabethan house, known as the Shelleys, in St. Anne's, Lewes, will shortly be offered for sale at the Mart, by order of the executors of the late F. W. Cosens, F.S.A. Built of stone, and surrounded by a garden, it retains many of its earlier fittings and decorations. The house derives its name from the removal thither, *circa* 1630, of the Shelley family, descended from the Henry Shelley, of Patcham, Sussex, who towards the close of the sixteenth century migrated from Patcham to the house in Southover, Lewes, which is illustrated in Horsfield's "History and Antiquities of Lewes" (1827). That work states that the male heritable line of the Shelleys of Lewes, one of the three families of this name in Sussex, failed with the death, in 1811, of Henry Shelley, M.P. for the borough. Mr. Cosens's collection of pictures, &c., will be put up for sale at Christie's on Saturday next, May 17, and the following Monday and Tuesday. It includes many cabinet works of the modern Spanish and French Schools; a set of topographical drawings to illustrate the works of Johnson, Goldsmith, Dickens, and other authors, by E. Hull; together with T. Faed's "From Dawn to Sunset" and "Lady of Shalott," Sir F. Leighton's "Dante in Exile," L. Alma Tadema's "Confidences," Clarkson Stanfield's "Dort" and "Naples," D. Roberts's "Edinburgh" and "Interior of St. Peter's," Holman Hunt's "Rienzi," Sir J. E. Millais's "Trust Me," E. W. Cooke's "Millwall," W. P. Frith's "Railway Station" and "Coming of Age in the Olden Time," J. C. Hook's "Valley on the Moor," and John Phillip's "Fair at Seville" and "La Alameda."

IT is stated in the *Standard* that Mr. James Jardine, lately High Sheriff of Cheshire, has contributed 2,500*l.* towards the restoration of the south porch, Manchester Cathedral. The north porch was recently rebuilt, at a cost of 5,600*l.*, by the munificence of Mrs. Worthington and Messrs. Jonas and Thomas Craven. The present cathedral was originally the parish church of St. Mary-the-Virgin, St. Denis, and St. George, famous for the beauty of the stall-work. In 1422 a royal charter was addressed to Thomas, fifth Baron de la Warr, for making the church collegiate. The college having been valued, in the suppression, at 236*l.* 12*s.* 5*d.* yearly, was dissolved in 1547, and in 1578 was refounded as the College of Christ. Dr. Dee was warden during the period 1597-1607. Reinstated at the restoration of King Charles II., the collegiate foundation survived until 1847, when, in terms of the Act 10 & 11 Vict., c. 108, a see was set up, and Dr. James Prince Lee was elected first bishop. The collegiate buildings were latterly occupied by the Blue-coat School. Having been repaired and refitted in 1815, the fabric was restored, and the western tower rebuilt, in 1862-8, by Mr. J. P. Holden, Chapter Architect. Of the two organs, one is by "Father" Smith, the other has an oakencase designed by the late Sir G. G. Scott. Dr. Dee died at Mortlake in December, 1608. His magical black stone (said to be a bit of canal coal) was sold at Christie's on July 14, 1888, in Lord Lonsborough's collection. It had belonged to Lord Peterborough, Lady Betty Germaine, and to Walpole, and is "the Devil's looking-glass, a stone" mentioned in "Hudibras" as used by Kelly, who had been Dee's associate.

CAERPHILLY is known as the site of a great Medieval castle, but it gains another kind of notoriety in Mr. Spear's Report to the Local Government Board upon the prevalence of diphtheria and croup in the Registration Sub-district of Pontypridd, and upon the sanitary condition and administration of the sanitary areas therein contained. One of the first places mentioned in the report, however, is Cilfynydd, a new mining village, with a

population that has grown within the last four years from a couple of hundred, at most, to over 2,000. Here the houses are built in rows and terraces half way up a steep hill-side. "There is no regular sewer system. Most of the 370 houses (or thereabouts), have top-water drains which ultimately discharge into a highway drain and thence into the canal; or, where this method is not available, the sewage runs over adjacent unoccupied land, or into the streets or back lanes; occasionally into the privy cesspools. The back lanes have the appearance of quagmires, and the yard space about dwellings is often sewage ladden. Cess-pit privies, and cesspools receiving the discharge of closets, are in general few. When full, they overflow into the back lanes; and, in times of storm, water from the hill side causes them to overflow, and the contents have been known at such times to be washed into the very houses." In the village of Caerphilly "the sewer is inadequately ventilated by a few small pipe ventilators, and by a few untrapped roadside gullies. The private drains, even in the case of new houses (and in their case in contravention of by-laws) are unprovided with special means of ventilation; and, occasionally, rough untrapped gullies are situated close by the doors and windows of houses, a considerable amount of sewage still finds its way into the rivulet crossing the centre of the village and causes there nuisance. Some of the houses of the village have no privy accommodation of any sort, others have the old-fashioned privy-pit, which is often neglected and the source of much nuisance; others again, and these perhaps the majority, have closets connected with the public sewer, but, as no flushing apparatus is provided, their condition is often very unsatisfactory." "In one of the divisions," we are told, "is a properly organised method of administering sanitary affairs, or of ensuring that the many and varied conditions injurious to health be brought in detail to the knowledge of the Sanitary Authority. The Medical Officers of health never attend the meetings of the Sanitary Authority, and their representation is confined to their annual reports. . . ."

What is wanted in this rural district is one Medical Officer of Health, whose salary should pay the expenditure of time and labour in sanitary organisation and supervision, and who should have under his direction an efficient staff of Inspectors of Nuisances. At present the single Inspector of Nuisances is engaged as a surveyor, engineer, superintendent of scavenging contractors, and collector of rates in districts where the Sanitary Authority have the water supply under their own control."

In spite of the split in the artistic camp in Paris, the exhibition of pictures at the Salon does not seem very materially affected in regard to the general level of work displayed. We are conscious, of course, of missing some eminent and well-known names, and much has been really lost to the Salon last year when the new Salon opens on the fifteenth. But the general appearance of the galleries of the old Salon, considering their extent and the number of works hung, is a remarkable testimony to the extraordinary vitality of French painting at the present time. We shall give a more detailed account of the exhibition when the new Salon is also opened and the two can be compared.

WHILE referring to the subject of French exhibitions, let us once more enter a protest against the insane and exasperating system of cataloguing art exhibitions to which the French adhere. As every English visitor pays to his cost, more especially every one who attempts to make notes or write an account of the exhibition, the catalogue of the pictures is arranged with the names of the artists in alphabetical order, and the numbers in numerical order, but the numbers on the wall follow no order at all: the picture you are looking at may be No. 217, and the next 1,128 and so on. To any one

making a regular progress through the rooms this necessitates a continual and most irritating exercise of constantly turning the leaves of the catalogue backwards and forwards. But this is the smallest annoyance; the serious one is that it is impossible to know where to find any picture you wish to see. You may read in the catalogue the name of a painter and the subject of a work which you know is likely to be one of the best things in the collection, but there is not the slightest guide as to where you may be able to find it over a space of literally several acres of galleries. If it is a small picture, the search for it may cost the best part of an hour, and be unsuccessful after all: it is a mere chance whether you find it or not. At the Royal Academy the arrangement of the catalogue, with the galleries numbered and the picture numbers running consecutively, tells us exactly where to find any picture we wish to see, with the least possible loss of time. Why will the French keep up this absurd and illogical system? If they think that they have not much to learn in art from us, they may at least take a hint from us in the humble but not unimportant practical matter of the convenient arrangement of catalogues.

THE ROYAL ACADEMY EXHIBITION.

THE remark which is heard regularly every year from loungers at the private view, that "it is not a good Academy this year," happens on this occasion to be more true than it sometimes is. The proportion of pictures that are of interest, as against those that are of none, is perhaps pretty much the same every year; but there are years when the best men are not at their best, and when there is no one picture that makes a marked impression; and this is the case with the Academy of 1890.

As far as mere charm of form and colour are concerned, the President has perhaps never done better than in the "Bath of Psyche" (243), which shows a beautifully-painted nude figure standing sideways to the spectator, and with the delicate tints of her body relieved against white drapery hanging on the further side of the figure, which is partially reflected in the water of the bath; the back of the scene is formed by marble Ionic columns with gilded volutes, and a reddish purple curtain hung between them, over which the blue sky is seen. The face of the figure, too, is lovely in its way, though it may be rather *spiritual* than spiritual; and though it must be admitted that the intellectual interest of the work is of the slightest, it at all events succeeds at every point in realising its aim, viz, sensuous charm of a delicate and refined order. The picture has been purchased for the nation from the Chantrey bequest fund, and it is no doubt worth purchasing, but did Chantrey intend that the Royal Academy should act as trustees of a fund for purchasing their own pictures? The "Tragic Poetess" (310), by the same artist, is a picture with more meaning in it: the figure, in dark robes, is seated facing the spectator, and the face is a very fine one, full of intellectual expression; the drawback to the picture is the theatrical effect of the brassy sky behind, which is like nothing in Nature. Mr. Tadmema's contribution, in its usual place in Gallery III, is as good as usual, without more human interest than usual. It is entitled "The Frigidarium" (324); in the foreground is a kind of vestibule to which a lady comes from the bath which is seen beyond, some drapery loosely held round her, while an attendant pulls back a curtain for her admission, showing the open-air bath beyond and the bathers, and bits of architectural detail in the distance, and over the bath enclosure a bright bit of hill, and the open sky: the picture is a variation upon an old theme, but each variation has a charm of its own, though the continued repetition of the same rather expressionless type of face is an element of monotony. Of the same class of work is Mr. Poynter's charming "On the Temple Steps" (866), where a girl is seated on a balustrade beside a profusion of fruit; in this, however, while Mr. Poynter's treatment of architectural and other accessories cannot be said to equal Mr. Tadmema's, the interest of the figure is much greater; she is no cold abstraction of a typical Roman life, but a blooming girl full of warmth and life and expression, and is the centre of attraction of

the picture, instead of being a mere figure to hang draperies on; and though Mr. Tadmema has never been equalled in his technical treatment of marble and Classical architectural detail, and in the clear effect of sunlight which floods his scenes, one cannot but feel that the production of a beautiful and attractive figure counts for more than the best marble-painting.

One of the most important pictures of the year is unquestionably Sir John Millais's landscape (25), bearing for title Byron's hackneyed line,—

"The moon is up and yet it is not night."

Painters really might go a little further out of the beaten track than they do for quotations; one would suppose, to look at the Academy catalogue in this light, that artists never read at all. The landscape in question, being, like all Sir John Millais's landscapes, not "composed" at all (to all appearance), but simply a transcript from Nature, and representing a scene in a half light, is not striking at first sight, but it grows upon one very much as it is studied (it is one of the pictures that will bear study), and we feel how true it is in effect both in foreground and distance; poetical too it is in its result, but it is the poetry of the scene itself, not of the picture, which seems totally free from any attempt to produce an effect, or to do anything but copy Nature as faithfully as possible, within the limit of the powers of painting. This last qualification is important, because there are painters who wreck themselves by attempting a closer imitation than can really be achieved, thereby losing all breadth and tone; Sir John Millais never, in these days at least, carries realism to the verge of hardness. The scene, we should observe, appears to be on the outskirts of a deer-forest. The work will be a valuable addition to the small but remarkable series of landscapes by this gifted painter. Of his large portrait of Mr. Gladstone this year (361) we cannot say much, and we fear it has generally been felt not to be a success; its reputation being perhaps killed in advance by its far more brilliant predecessor a good many years ago, the standing portrait of Mr. Gladstone, one of the most remarkable portraits ever executed by ancient or modern artist.

Mr. Orchardson's work is one of the first things one looks for each year, because he is one of the few painters who not only has a style of his own but who paints pictures which have an intellectual significance and form a "criticism of life." In the latter sense he has disappointed us this year, his principal picture being only a collection of people seated in a room and forming "Portraits" (235). In regard to pictorial effect and harmony of colour the picture is in his best manner, but of course one cannot feel the same interest in a collection of portrait figures who tell no story that one does in such imaginative scenes of history or society as Mr. Orchardson has been wont to give us. Mr. Seymour Lucas, on the other hand, is unusually successful and interesting in his historical scene representing "Louis XI." (291) acting the gracious monarch in a morning call in the house of an artisan. The naturally shrewd and cynical cast of features in the countenance of the old fox, with which the desire to appear the benevolent monarch evidently struggles, is represented admirably, and this is something like a real personification of a character in history, not a mere stage figure labelled with the name. The woman and child are very reverential to their guest; the face of the husband, turned towards his wife but unseen by the King, does not convey by any means the same serious view of the situation. Altogether, this is a very clever and dramatically expressive work. Another historical painting in the same gallery, Mr. Crofts's "Whitehall, January 30th, 1649" (216) has also the merit of reality, save and except as regards the building itself, which is certainly not well painted. The spectator is among the crowd of horsemen in the road, Puritan soldiers on guard, and looking up at the scaffold, on which are conspicuous the figures of Charles and Bishop Juxon at the moment when the King gives something into his keeping, and the Bishop holds out both his hands, in an attitude in which eager attention and reverence for the King are touchingly combined. The figure of Charles is dignified and characteristic; as even a Puritan poet said,—

"He nothing common did or mean
Upon that memorable scene."

These two figures stand out as very real and

life-like in conception; they are the principal figures in the scene, though on a small scale. The painter had a difficult task in dealing with the foreground figures, in representing a number of mounted men all turned away from the spectator and looking towards the scaffold; he has partially broken the monotony of this treatment by showing one of the Puritans turning round to repress the zeal of a belated cavalier who mourns with clasped and uplifted hands. The painter is to be credited with a serious and powerful rendering of one of the most remarkable scenes in English history; a picture which has the rare merit of giving us a more real and vivid conception of the scene, without which quality a historical painting (so-called) is a mere fraud and pretence.

Can the same be said of Mr. Gow's "After Waterloo: 'Sauve qui peut!'" (123) It is a variation, at all events, from the conventional treatment of such a scene. The artist shows us not a wide field of battle, with clouds of smoke, but a small portion of the road to Gemappes, which we are told in the accepted accounts was choked with the stream of fugitives and with wounded and dying men. Napoleon and some of his staff ride down the road in the middle of a medley of men and horses, a camp waggon driven by a woman in front of the group. This does not seem true: Napoleon was probably far ahead of most of the fugitives; he and his staff being well mounted would most likely have made a quick cut across country and struck the high road in advance of the throng. The look of Napoleon in the picture, somewhat dazed in aspect and forgetting to guide his horse, is dramatically effective, but we think out of keeping with the character of the man, who was always cool-headed. It does not therefore impress us as real, but it is a very clever painting, with much to study in the various figures.

Mr. Dicksee's large picture of the "Redemption of Fannhauser" holds a very conspicuous position in the rooms, its claim to which, except in regard to size and number of figures we confess we cannot see. Mr. Watts's contribution, a study of an old white horse (137) his coat stained with the rust, of his constant chains, is pathetic in intention; it is an appeal on behalf of the suffering and patient brute creation, and as such to be regarded with respect; it is what may be called a moral picture, and its intention in this sense is not perceived, we imagine, by many who see it; but we fear that pious moral intentions do not make a picture, and the work is from an artistic point of view a mistake. Another animal painting, without a moral, we confess, but much more successful as a painting, is Mr. Swan's powerful picture of "a lioness defending her cubs" (614); the little animals are half-hiding behind their mother, yet spitting and snarling at the same time; the lioness crouches with an expression of determined ferocity against an unseen foe whose presence is indicated by an arrow in the ground. Mr. Collier's "Death of Cleopatra" (55), a very large picture which hangs opposite the entry from the octagon, is essentially a very brilliant picture of an Egyptian architectural interior, painted with great power; but the stout recumbent figure of Cleopatra extended on a couch and lightly swathed in its semi-transparent coverings, is a most prosaic conception; one of the attendant maidens has fallen on the pavement in a swoon, the other sits at the head of the couch in a somewhat *nonchalant* attitude. Remembering the wonderfully tragic and pathetic character of the scene as presented by Shakespeare (to which the picture evidently refers), one can only regard this as another of the numerous instances in which English painters have reduced a great poetic scene to mere prose. Mr. Chevallier Taylor, on the other hand, in "The Last Blessing" (758) a scene at the death of a peasant boy, has treated a scene in ordinary life with real pathos. The priest, a short and rather coarse-looking personage, stands at the foot of the bed in the act of benediction; the dying invalid's countenance is fixed on him, the mother bows her head at his side; the father, a rough working-man, kneels with reverence of posture but almost expressionless countenance. There is a truthfulness in the whole scene which raises it above the ordinary level of pictures of this class. Mr. Walter Urwick's "A Worcestershire Hop-garden" (895) is fine in colour and original in style, but unreal; the figures are specimens of the ideal or sentimental peasant who exists chiefly in the works of a certain idyllic school of painters.

A strong contrast to this is Mr. Stanhope Forbes's frankly realistic picture "By Order of the Court" (1,146), a sale by auction of effects which, from the heterogeneous mass of objects on the table, painted with the greatest care and truth, does not seem likely to realise very much. The picture is perhaps hardly so interesting as the artist's last year's picture, "The Health of the Bride," but it has the same quality in the careful study of character in the personages, each of whom has his or her specially-marked character and physiognomy; they are not so many "figures" but so many real people, whom we should know again, and whose idiosyncrasies of character we can estimate from their personality and behaviour. The nature of the scene has allowed the artist to give more force to his representation of the humbler class of persons represented by contrasting them with the lady and gentleman who have come to the sale to see what they can pick up; on the opposite side of the group of buyers a sad-looking elderly woman holds out her hand in a timid and helpless kind of way to make a bid. The scene is mainly lighted from a window at the back, through which one sees the heads of curious spectators looking in. This arrangement throws a good deal of the interior group more or less into shadow and gives a rather heavy and dulled effect to the whole; but there is something to study in every figure.

Mr. Logsdail's "Ninth of November" (1,028) is another realistic picture far inferior in delicacy of characterisation to the last-named, but a success, as it deals with a subject in which, in every sense, the colours can be laid on thick. It represents the Lord Mayor's coach on Show-day, preceded by three liveried functionaries who are depicted with contemptuous fidelity; the crowd contains some good and interesting figures, and the whole scene, with its well-known architectural surroundings, is treated with a great deal of effect. It is exactly the kind of subject to bring out the special powers of the artist, who is a very clever painter of ordinary life and of commonplace crowds in all the height (or depth) of their commonplaceness. Mr. Dendy Sadler's "Hunting Morn" (1,034) is a very clever realisation of what must have been the style and personality of the well-fed John Bull type of country gentleman, when the human machine was entirely given over to the work of hunting and feeding, and no brain exercise interfered with its expression of rucund jollity. Mr. Eyre Crowe's "Rifle Match at Dunnotar, N.B." (794) may be classed with these in regard to the type of subject, a realistic picture of actual life, but it is far superior to them in delicacy of taste and handling. The rifle match takes place near a headland projecting into the sea, at the extremity of which the target is situated; a man lies prone in the foreground taking aim, and other figures stand round in different attitudes of interest, conspicuous among whom a tall big man with his Tam o' Shanter on the back of his head, planted in a sturdy attitude behind the marksman, is a capital figure, evidently a faithful study from life. The distant sea is hardly a success, but the general open-air feeling of the scene is well conveyed, and the painter has entered thoroughly into the spirit of it. Is the marksman aiming straight for the target, is a query that may occur; his rifle appears to point rather to the right of it. Mr. Eugène de Blaas has a very clever picture, "Scandal" (1,062), which however is only of the same young women and the modest and conscious man who looks in an embarrassed manner at his round hat, with whom we are familiar in other pictures by the same artist.

Mr. G. Hitchcock's "Tulip Culture" is one of the specialties of the year (750), a bright and effective transcription of the appearance of the successive heads of the flowers, each bed of one prevailing hue; one or two figures are introduced, but the object of the picture is the succession of tulip beds with their bright colours. It is not a subject out of which a picture in the proper sense can really be made; but it is a pretty incident worth reproducing in painting, and makes a point in the exhibition. Another very clever piece of painting which cannot be passed over is Mr. Chadwick's "A Greek Girl" (790) in which however the figure is very poor, but the painting of the white polished marble architecture, the strip of sand and the dark blue of the sea beyond, forms a leaf taken out of Mr. Tadema's book with remarkable success.

Among landscapes the largest are not the best, and Mr. Goodall's "Thames from Windsor

Castle" (366), and Mr. Vicat Cole's "Thames at Greenwich" (390) belong to that painful, respectable order of large landscapes about which it is almost equally impossible to say either good or evil. "Summer Time in the Channel Islands," by Mr. Henry Moore (257) is one of those paintings of dark fresh breezes the equal of which cannot be found at the present day among the works of any other nation, though one or two French paintings appear to have been "trying it on," so to speak, with doubtful success. Mr. Shaw's two seas, "A November Day" and "Off Bolt Head" (20) are good examples of his rendering of the sea, a Mr. Peter Graham's "Low Tide" (215) presents another aspect of it as it appears to him. A these pictures contain remarkable truth in the way, each representing one aspect of the sea as it appeared to one artist. Mr. Mackworth's "Cloud Chariot" (156) is a fine and unusual painting of the grandeur of cumulus clouds which however seem a little too thick and heavy in substance and too yellow in tone. Mr. Herkomer's "Our Village" (143), a view of the open space in the centre of a village with groups of people and children scattered about irregularly, has the defect that it is in no sense a picture. Mr. H. W. B. Davis's two pictures on the Wye (68 and 780) are only variations of the same theme, a sunlit landscape, rippling shallows, and peaceful white cattle loitering in the foreground; they are painted with great brilliancy and wonderful truth of texture and local colour—are almost deceptive in the effect on the eye, in fact; but they are not more than that.

Among Mr. J. C. Hook's works the most prominent in his usual style is "Last Night's Disaster" (75), a morning sea after a gale, and some men employed in clearing out an unfortunate wrecked boat from the sand which had been piled round her; but the painter also sends an example of what may be called his "brimming Holland" style of picture, "Dutch Pedlar" (305), one of those paintings of a calm and full river waterways which he paints with such sympathy. Mr. F. Brangwyn's "Stand by" (248) and one or two other works of the same type, is treating shipping craft with spirit, knowledge, and originality, but why veil them all in such monotonous greyness? This is not truth; the deck of the steamer in "All Hands Shorten Sail" (76) for instance, is not the colour that the deck of a steamer really is; it is merely conventionalised grey tone to produce a certain effect of coldness and desolation in the whole work. One of the finest sea-pictures of the year is Mr. Fraser's of a deserted ship on a reef (1,107); this is a powerful work both in regard to execution and sentiment. Of landscape and portrait, and miscellaneous works of various types, we may have some further notes to make.

Dispersal of the Wells Collection.—The sale will be begun on Saturday, May 10, by Messrs. Christie, Manson, & Woods, of the late Mr. William Wells's fine collection of porcelain water-colours, and ancient and modern pictures. In the latter are included examples of A. Van de Velde and W. Van de Velde, Hobbema, Rembrandt, and Murillo (the Magdalene), together with several paintings rendered popular by engravings, such as Wilkie's "Dissemination for Rent" and "Jew's Harp"; Creswick's "Killarney"; T. Webster's "Smile and Frown"; E. W. Cooke's "Rembrandt's Mill"; W. Collins's "Hop-Pickers"; and Sir Edwin Landseer's "None but the Brave Deserve the Fair," "Shepherd's Grave," and other works by him, all painted especially for Mr. Wells.

Royal Military Exhibition, 1890.—An exhibition of soldiers' industrial work, military equipments and manufactures, a loan collection of pictures, and other objects of interest in connexion with the military service, past and present, was opened on Wednesday by the Prince of Wales. The exhibition is being held by the kind permission of the Commissioners on a portion of the grounds of the Royal Hospital, Chelsea, in aid of the establishment and maintenance of Church of England Soldiers' Institutes. These institutes are club-houses, are open and free to every man wearing the Queen's uniform, and are described as absolutely unsectarian. Those which have been established at Aldershot and Colchester show how much such institutes are appreciated and made use of by soldiers of all denominations.

ARCHITECTURE AT THE ROYAL ACADEMY.—II.

1,710. "A Theatre Façade": Mr. W. T. Horton. This is a pretty pen perspective drawing, a kind of practical protest in favour of a less pretentious and more simple and sober style of architecture than is at present considered "generally necessary" for theatres. The basement story, in which the entrances are located, is rusticated, there are plain walls above and an open loggia of rather Eastern character in the upper stage. The two side portions are advanced slightly as wings. It is not very easy to see how this should express the internal character of the entrance portion of a theatre; a plan should have been given. This quiet sort of architecture is no doubt preferable to the vulgarities of average theatre design in this country, but we do not know that it would suggest a theatre, which after all is a class of building to which show and a kind of *bravura* architectural design, if it be carried out with refinement, seem naturally to belong.

1,711. "Design for Premises, Market-square, Dover": Mr. Kingsley Oliphant. A street front with a shop on ground story, treated with elliptical arches with dark and light courses and voussours, thus separating the shop portion from the rest. The upper portion, in light stone (a water-colour elevation), is very rococo in detail, rather by comparison with the plain pillioned windows in the centre portion: but it has a certain special character as shop architecture.

1,713. "Notting-hill Free Library": Messrs. P. Figgis and R. H. Wilson. This is something really original, at all events. It is a brick building with stone dressings, the angle and entrance marked by square turrets with vertical strips of stone run up them and terminated by niches with foliage ornament: the salient point of the design is the treatment of the upper part of the front over the main windows, which is treated as an expanse of flowing foliate carving with three statues in front of and partially involved in it. As far as can be judged from the drawing, which is rather rough in execution, we should say the detail of the carving was much too large and coarse for its situation and for the scale of the building, and that the general design had better be considered in detailing it; the execution (we believe the building is not finished); but the architects are nevertheless entitled to the credit of a bold and new treatment of a district library front, which will give the building a special and picturesque interest.

1,716. "Bed-room in a Country House": Professor Aitchison, A.R.A. We may as well consider this along with No. 1,744, which bears the same title, and of which a reproduction in monochrome will be found among the illustrations to the present number. Both are rooms unscotched to a considerable height, with a pattern paper over. In 1,716 the panelled wainscot is left plain, apparently stained oak, with a mantelpiece in the centre, which we prefer of polished walnut or some such wood. There is a main shelf and an upper one with colonnettes of Renaissance type: the grate is surrounded by a tile border of prevalent green and blue with a warm-toned pattern; the paper above leans to yellowish greens and yellow ochres. In 1,744, as will be seen, the panels of the wainscot are treated with inlay, and the mantel is more important and of more dignified design than the other; the grate tiles in this case are light blue in ground tone, and the wallpaper is a prevalent green powdered with light flowers. In the matter of harmonious colour-effect we rather prefer the simpler scheme of 1,716; the inlay ornament in the one illustrated seems a little too busy, and leaves no rest to the eye; the mantel is very rich and effective; whether it is not a little too important in style for a bed-room might be a question.

1,717. "New Font and Canopy, Bentham Church, Lancashire": Mr. W. B. Lethaby. This is a piece of really original work. The font is solid circular marble oak, with a bold moulding at the base and a curved enrichment round the upper edge, it stands on a plain octagonal base of less diameter than the bowl; the canopy supported on eight broad flat wooden supports radiating (on plan) from the centre of the font, and curved into a pierced foliate design of very rich character: these supports carry a cornice and terminate in pinnacles above, the centre of the canopy is crowned by an armillary sphere as a terminal: we do not know whether this has any special significance; if not, it is not a good deco-

orative form for the position; but Mr. Lethaby may be congratulated on having produced a font design which is effective in itself and quite original.

1,718. "Design for Church of St. Thomas, Keusal-road": Mr. John T. Lee. A good coloured perspective view hung high, showing a red brick and red-tiled church with stone dressings, with windows in a very simple style of tracery; there is a bell-cot over the east gable of the nave. There is little attempt at architectural effectiveness, but the building is solid and unaffected in style, and a satisfactory example of modern Gothic of the simpler variety.

1,721. "Design for a Corner of a Boudoir": Mr. T. Armstrong Stenhouse. A white-wainscotted room, with a frieze of white rococo ornament on a gold ground; the "corner" is seen through a wide arch below the capping of the wainscot, a window on one side and a bookcase on the other; the carpet and upholstery are in harmony with the general scheme, which has a bright and attractive effect.

1,722. "Catholic Church, Calcar, Germany": Mr. H. W. Brewer. A pencil edition of the drawing published in the *Builder* of March 8, 1890.

1,724. "Staircase in St. Maclou, Rouen": Mr. Arthur E. Bartlett. A good specimen of rather slight and free pencil sketching.

1,725. "Melrose Abbey: South Transept": Mr. John Begg. This is an admirable drawing of a bit of ancient Gothic architecture; executed as a monochrome on tinted paper, the whole exceedingly carefully and correctly drawn.

1,729. "Corpus Christi Priory, Manchester: sketch design": Mr. Leonard Stokes. This is a remarkable and unusual design; it appears to be architecturally a kind of Christian Pantheon, the plan showing a circular church with an arcade round, a projecting porch or entrance, and an apse opposite. The main drawing is a view of the interior. Round the lower portion runs a low and solidly-built arcade in handed courses of red and white stone; above a tier of lofty pointed arches with deep splays and each containing a narrow window; above this is what might be called a triforium arcade of round arches on shafts, placed in the position of a frieze. Above the arcade is a cornice and a hemispherical dome, the surface of which appears to be covered with decoration rather too faintly indicated to be made out in the sketch. A flat pilaster strip, but without a capital termination, runs right through from the floor to the dome cornice, between each bay of the arcades. We hope this work is going to be carried out; the sketch promises something very fine and original in the way of interior church design.

1,730. "St. Saviour's, Southwark: New Nave." Sir Arthur Blomfield, A.R.A. We give an illustration of this drawing in the present number; it is a pencil drawing very slightly and delicately tinted, and which consequently does not reproduce in a manner to do justice to the original, but it serves to show the design and renders description here unnecessary. The question of building a modern nave in a pure reproduction of Medieval architecture, instead of giving it frankly the aspect of a modern addition, is one on which, as we have before suggested, there is a good deal to be said; but if it is to be done, it could not be done with better taste and feeling, or in a manner more in harmony with the ancient portions of the church, than in the design here shown.

1,731. "Sculpture Gallery, Avery-hill": Mr. Thomas W. Cutler. This is a very good water-colour drawing showing a gallery built of very sumptuous materials but of rather ordinary design. It is a long room with an order of dark red marble pilasters, dividing the wall into bays, between which the wall is treated as a large panel of grey marble with a darker border. There is a plinth of dark red marble. Small rectangular windows in the upper part of the walls between the pilasters are filled with stained glass, with good effect. The Gallery is suited for its purpose of exhibiting sculpture, but this device of planting pilasters at wide distances along the walls of a picture gallery or sculpture gallery, however sanctioned by fashion, is a very poor and commonplace architectural treatment, in however costly materials it may be carried out.

1,734. "6, Carlton House-terrace": Messrs. Ernest George and Peto. A drawing of an interior of hall and staircase, in a very sketchy style in brown ink line drawing, and which gives no information as to what is new and what is old. We presume the coffered ceiling

is part of the new treatment. If the pilasters and cornices to the doors are part of the new treatment, they are ill-proportioned and too wide for their height. Not a bit of detail is really discernible throughout the drawing; nothing but a kind of scribble which produces a generally picturesque effect, and leaves all detail to the imagination. That is not the way to draw architecture.

1,735. "Beauvais Cathedral: sketch of Apse": Mr. H. Wilson. A slight but very spirited water-colour sketch of the exterior of the apse, with its scaffolding and buttresses, the only fault of which is that it does not seem to give the scale of the building, especially by comparison with the roughly-sketched figures in the foreground.

1,733. "Church of St. Luke, Richmond; interior." and 1,736. "St. Mary's Chapel, Mill Hill; interior": Messrs. Goldie, Child, and Goldie. These claim mention as excellently-executed pen drawings of very solid and correct modern Gothic interiors, of which however there is really nothing to be said except that they are solid and correct. No. 1,736 was illustrated in the *Builder* for April 27, 1889.

1,738. "New organ case, St. John's College Chapel Cambridge": Mr. J. Oldrid Scott. A carefully executed pen drawing. The organ is divided into two equal portions, symmetrically treated, and appearing side by side beneath two contiguous arches. The lower part of the case is covered over as a bracket, and the pipes arranged in turrets, square or lozenge shape on plan, with wooden cresting and perforated ornament over the upper part. The general effect is pretty, but a little angular in line. It does not suggest any new ideas for organ cases, of which we are a good deal in need.

ON THE PLANNING AND CONSTRUCTION OF HOSPITALS.*

THE subject for our consideration this evening is one which beyond all others demands from the architect the utmost knowledge and attention to the laws of health. For while in any building devoted to the reception of large numbers of people in normal health careful precautions are necessary in order that nothing in the structure itself or its surroundings shall prevent or hamper the maintenance of a proper standard of health, in a hospital the very fact of bringing together a large number of sick and wounded people is of itself an element of special danger, and calls for special means of defence.

A hospital is primarily a building devoted to the care and treatment of the sick and injured poor; in its secondary and scarcely less important function, it is a training-school for the teaching of the science and art of Medicine and Surgery.

Now, in order that both these functions may be performed to the best advantage, it is necessary that large numbers of patients should be brought together in one hospital, for it will easily be seen that the task of administering one hospital for 300 beds will be far easier and less costly than that of administering ten hospitals for thirty beds each; and for teaching purposes the larger the amount of material the better both for teachers and students.

The risks, therefore, inherent on the aggregation of large numbers of sick people, are, and must be, encountered, because it would be impossible to furnish the necessary medical and surgical aid to the sick poor in any other way.

Let us consider briefly of what these risks consist, and how the experience of the past helps us to overcome them.

In the first place, it must be remembered that a hospital ward is filled either with people whose condition is that of disease, the exhalations of whose bodies are laden with infection; or with those with open wounds, to the exposed surfaces of which the contact of impure air means the production of a special class of traumatic or wound diseases. In either case it is the contamination of the air of the ward which retards or prevents the recovery of the patients. This contamination of air may be accomplished in several ways: it may either be by the overcrowding of patients in the wards; by imperfect ventilation; by improper arrangement of buildings; by defective drainage, or by defective keeping or maladministration.

As an example of all these defects, the old

* A paper by Mr. Keith D. Young, F.R.I.B.A., read on the 2nd inst. before the Architectural Association, as elsewhere mentioned.

Hôtel Dieu at Paris was full of instructive lessons. This remarkable institution, whose origin as a hospital for the sick dates certainly from the twelfth century, possibly from earlier times still, had become, at the time Tenon wrote his notable "Mémoires sur les Hôpitaux de Paris," an enormous mass of buildings built partly on one bank, partly on the other bank of the river, the one part connected to the other by two bridges, one of which was actually occupied by wards. Into this vast network of buildings, where ward opened into ward, so that each was, as it were, but the ante-chamber to the next, and consequently the air in each was freely in communication with that of all the others, between three and four thousand patients were crowded. Every imaginable case of disease, including even lunacy and infectious fevers, was received, and a large proportion of the patients had to lie two, four, and even six in a bed. With remarkable prescience Tenon points out one by one the insanitary conditions of this hospital; the want of ventilation to the wards caused by the crowding of offices of all kinds, blocking up the free air-space on all sides, and by the placing of wards side by side; the crowded condition of the wards; the abominable and "unspeakable" state of the latrines; and the infected state of the whole atmosphere of the hospital consequent upon these and other defects. The result of all this was that operations which were performed with comparative safety in other hospitals were almost uniformly fatal in the old Hôtel Dieu.*

The example of the Hôtel Dieu has been often quoted, but the lesson which it teaches cannot be too strongly enforced, as it lies at the root of all hospital hygiene.

Coming now to more recent times, the experience, dearly bought indeed during the Crimean War, showed how terribly the injuries wrought by human weapons can be multiplied and intensified by foul air. In the hospital at Scutari,—which at one time, according to Miss Nightingale, had 2,500 sick and wounded under its roof,—two patients out of every five died; while in the huts on the heights above Balaklava the mortality did not reach three per cent. The lessons thus taught have not been without their value, for the great wars that have followed, notably the Civil War in America and the Franco-Prussian War, have been comparatively free from wound diseases. Instances could be multiplied almost indefinitely showing how in this hospital persistent attacks of pyæmia or erysipelas were traced to the contamination of the ward air by emanations from the foul linen in the closely-adjacent laundry; in another, similar evils were traceable to the close proximity of the out-patient department or *post-mortem* room to the wards; and in a third, how foul, leaky, and unventilated drains and cesspools produced a chronic condition of unhealthiness both in patients and staff.

Time will not permit me to enlarge more on

* We published a view and plan of the new Hôtel-Dieu at Paris (M. Diet, architect) in the *Builder* for January 3, 1880. —Ed.

this part of my subject, but the vital importance of it cannot be too strongly insisted upon. Cleanliness supreme and all-pervading, cleanliness of air, of soil, of building, is the key-note of every point of good hospital construction and administration.

In considering the principles which should guide us in the planning of a hospital, the first question to be determined, assuming that the number of patients and staff and the necessary classification has been settled, is the position of the various buildings in relation one to another.

There must be in every general hospital,—and it is with this class of hospital only that I am now concerned,—at least five separate departments:—1. The administration, which comprises all the purely official and domestic parts; 2, the nurses' quarters; 3, the wards; 4, the out-patient department; and 5, the mortuary. In many important hospitals of recent date these have been again subdivided, and separate buildings provided for kitchen, offices, and the operation-room. The main fact, however, which I wish to impress is that all these five buildings should be as separate and distinct as it is possible to make them.

In most hospitals erected during the last century you will find that every department, including also frequently a laundry, is housed in one building, and that every part of that building is in more or less direct atmospheric communication with every other part. The evils of this arrangement have over and over again been demonstrated, and many such hospitals have been within recent years either demolished or very materially altered, much to the gain of the patients.

As an example of what is thought necessary by eminent medical authorities in our day, I have here the plans of two recent hospitals,—the University Hospital at Halle, and the Johns Hopkins Hospital at Baltimore.

The University Hospital at Halle consists of sixteen detached buildings, of which thirteen belong to the hospital proper, the remaining three being devoted to teaching purposes only. The large central block (see block plan above) with four wings is the surgical department, and forms in itself a complete hospital in all but the kitchen offices. The E-shaped block in the south-east corner is the Gynaecological department, with the Director's residence adjoining; and the two blocks between this and the surgical house are respectively the kitchen offices and the engine-house. Behind these is another E-shaped block, with two detached buildings, one on either side. These together form the Medical Department. The long building at the extreme west contains isolation wards, and the two smaller blocks between this and the surgical house are for additional isolation, the small building between them being the chapel. The E-shaped block to the north of the surgical house is devoted to diseases of the eye, the throat, and ear.

The Johns Hopkins Hospital at Baltimore, the munificent gift of the citizen whose name it bears, occupies a site rectangular in form and

thirteen acres in extent. The buildings are twenty-two in number, and are all connected together by corridors. The corridors, however, which connect the ward blocks communicate only with the basements under the wards. The communication between the wards themselves being by way of the flat roof over the corridors. Thus the wards themselves are practically detached buildings. In the block plan (see next page) the large block marked A is the administration building, B B are blocks for paying patients; C C, bath-houses; D, dispensary and drug-store; E, kitchen and domestic apartments; F, nurses' house; H H pavilions with octagonal wards; K K, isolation blocks; L, lecture theatre and students' building; M, out-patient's department; O, mortuary and *post-mortem* room; P, laundry and wash-house; S, greenhouse. The principle of absolute detachment of wards is here carried out, but not quite to the same extent as at Halle, while the plan of restricting the height of the wards to one story only is strictly observed. The progress of this hospital will be observed with especial interest from the fact that it is the outcome of the matured experience and observation of one of the most experienced surgeons in the United States, and that no time, pains, or money have been spared to carry into effect what have been thought the essentials of perfect hospital hygiene.

In these two hospitals the principle of absolute severance between the several parts is carried to an extent that has not, so far as I know, been attempted in this country, and certainly could not be carried out except at enormous cost in London or in any great town. There is, too, in this country a strong opposition to the system of detached buildings, and it would probably be very difficult, if not impossible, to get any Committee to approve of a plan in which no covered communication between the wards and the administration department existed.

Assuming, then, that the wards and the administration building are to be connected by means of a corridor, it is essential to provide that any interchange of air between the two shall be, as far as possible, abolished.

In the Great Northern Central Hospital we have endeavoured to accomplish this upon a very limited site.* The wards are attached to the back portion of the administration building by a short piece of corridor, which is ventilated on both sides, and the lifts and staircase, which necessarily form shafts of communication between the different floors, are kept entirely outside the ward pavilion.

The necessity for keeping the mortuary building absolutely detached is sufficiently obvious. Nothing could be more fatal to the health of the living than any communication between the wards and air tainted with the emanations from the dead.

* A view, plan, and description of this hospital were published in the *Builder* for December 25, 1886; and further descriptive particulars on the occasion of the partial opening of the hospital (see *Builder* for July 28, 1888). —Ed.

SAINTE SAVIOURS CHURCH
SOUTHWARK
NAVE RESTORED
ARTHUR W. BLOOMFIELD A.R.A. 1867

"INK PHOTO. SERAQUE & CO. 40, MARTIN LANE. ARCHT. ST. LONDON, E.C.

The Johns Hopkins Hospital, Baltimore—Block Plan.

The out-patient department should be kept separate, because the air of the waiting-rooms, and in a lesser degree of the consulting-rooms, becomes much vitiated from various causes, and also because it is practically impossible to foretell what cases of an infectious disease may at any moment present themselves.

The nurses' home may or may not, be in direct communication with the hospital proper. For the sake of the nurses themselves, probably the more complete the severance is the better.

Let us now consider these various departments more in detail.

First, then, the administration department. Under this head are comprised the official quarters, including the Board-room, Secretary's Office, and Matron's Office,—the residential quarters comprising the rooms for the resident medical staff, the Secretary or Superintendent, the Matron, the Steward, and the servants,—and the domestic department including the stores, kitchen offices, and linen-room.

The detailed planning of the administration building will necessarily vary according to the size of the hospital, and no very minute rules can be laid down respecting it. I may, however, point out that unless the kitchen offices are placed in a one-story separate building they should certainly be put at the top of the house. There is no practical difficulty attending this arrangement, examples of which may be seen at the Hospital for Consumption, Brompton,* the Great Northern Central Hospital, and the Hastings Hospital.†

The provision of ample store accommodation is also an important point. It is far better to provide too much store room than not enough, for the difficulty of increasing store room in an existing building is very great indeed.

We may now pass on to the wards, which, together with their offices, form the most important part of the building.

Formerly a ward was regarded merely as a room into which a certain number of beds were

* View, plans, and descriptions were published in the *Builder* for November 22, 1879.—Ed.

† A view and plans, with description of the design first prepared for the East Sussex, Hastings, and St. Leonards Infirmary, were published in the *Builder* for December, 1884. These plans were subsequently considerably modified, and circular wards added. For view and plans of the hospital as erected see the *Builder* for January 29, 1887.—Ed.

to be put without much thought being taken of how the well-being of the patients would be affected by the conditions under which they were to be housed. The old Hôtel Dieu, at Paris, was, of course, a typical instance of how wards should not be arranged. At La Clinique, another large Paris hospital, the wards were long and narrow, and the windows were placed in the two ends; between these windows no less than eight beds were placed. Again, in many old hospitals the wards formed a series of rooms arranged on each side of a corridor, which formed a channel of communication connecting all the wards together. Yet another form of ward is what is called the "double ward," which consists of two long wards placed side by side with the windows in the sides, and with openings out through at intervals in the dividing wall. This arrangement gives four beds between the opposite windows. The fault of all these forms is in a greater or less degree the want of efficient ventilation, and it was the recognition of the evils consequent upon a defective air-supply that resulted in the pavilion system of wards.

The essential feature of the pavilion system is that the wards are long rectangular buildings, projecting out usually at right-angles to a main corridor. The space between the pavilions should be equal to at least twice the height of the buildings, and the long axis of the wards should be nearly due north and south, so that the maximum amount of sunshine available should be admitted to the wards.

The question of the number of stories admissible in a ward pavilion is one upon which authorities differ materially. In many of the most recent hospitals in France and Germany, and notably in the magnificent hospital at Baltimore, the wards are restricted to one story only. Such a system is obviously a most costly one in the matter of site; and it seems to me that it is to be justified only on the score of really important benefit to be gained. Personally, I am unable to see any sufficient gain to be obtained at all commensurate to the enormous cost involved.

But,—and this lies at the root of the matter,—if two or three stories of wards are to be superimposed, each must be absolutely independent atmospherically of the other; there must be no shafts, whether for staircases or

lifts, to communicate the air of one floor with that above.

In nearly all the earlier pavilion hospitals you will find that the staircase and one or more lifts, and sometimes that abomination called a dust-shoot, are all closely adjacent to the ward. It is so at the Herbert Hospital, Woolwich,* one of the earliest pavilion hospitals, at Leeds, at the Norfolk and Norwich, and at St. Thomas's.†

At the Great Northern we have placed the staircase and the lifts in such a position that they cannot form shafts from one ward to the other. It would appear from the plan of the Johns Hopkins Hospital that the staircase and the lifts are so placed that they must form channels of communication between the different pavilions by way of the basement; but the system of artificial ventilation is intended to act in so perfect a manner that all chance of such an occurrence is obviated.

In considering the internal arrangement of the wards, the first point to be settled is the space to be allotted to each patient. Space in a ward is very commonly referred to as cubic space only; but it is equally important to consider floor-space, and the distance to be allowed between each bed and its neighbour. Upon this question of space authorities differ widely. In the table given in Mr. Snell's work, the floor-space varies from 69 ft. per bed to 149 ft., and the cubic space from 864 ft. to 2,544 ft. The last figures are those of the Hospital of St. Andrew at Genoa, whose wards are considerably over 20 ft. high. Now it was the opinion of so eminent an authority on ventilation as the late Professor de Chaumont that nothing is gained by making the height of a ward exceed 12 ft., and in making calculations in actual practice he was accustomed to exclude all space in excess of this amount. You will see, therefore, how important it is to arrange your cubic space in relation to your floor-space, and not to increase the one at the expense of the other. In the first place, then, the wall space or distance from centre to centre of each bed should be determined. In a large ward, say for twenty beds, the space should not be less than 8 ft.,—8 ft. 6 in. or 9 ft. by preference. For the width of the ward, 25 ft. is a good dimension. It allows plenty of free floor-space in the centre of the ward, which is a point that must always be remembered, especially where clinical teaching is carried on. These figures give a floor-space of 112 ft. as a minimum. Taking 12 ft. as the standard height, you get a cubic space per bed of 1,344 ft. A height of 12 ft. will, however, be found, for appearance sake, too low for a ward upwards of 80 ft. long, and I think something must be conceded to one's sense of proportion.‡

Building Materials in Hungary.—We have been officially informed by the Commercial Department of the Imperial and Royal Austro-Hungarian Embassy, 11, Queen Victoria-street, E.C., that, acting on the initiative of the Minister of Commerce, who wishes to develop as far as he can all industrial enterprise in Hungary, a law has been passed granting for many years exemption from rates and taxes, and allowing certain reductions of rates, for the carriage of building material on the Hungarian State Railways, in order to encourage the establishment of new factories of every description and the working of mining undertakings.

National Physical Recreation Society, for the promotion of Physical Recreation among the Working Classes.—At a meeting of the executive committee of this Society, held at the offices of this Society last week, it was reported that the Royal Agricultural Hall, Islington, had been secured for the purpose of the annual display, which has been fixed for the week commencing Monday, May 26, and will include mass gymnastics, physical exercises by girls, quarter-staff play, pole-jumping, reeling, boxing, musical drill, football matches, and a house on fire, with the rescue of the inmates by the Metropolitan Fire Brigade.

* A birds' eye view and ground plan of this hospital were published in the *Builder* for April 14, 1890.—Ed.

† We gave a view and ground plan of the new St. Thomas's Hospital in the *Builder* for August 5, 1865. A view of the Albert and Victoria wards, and of the Chapel, as seen from the river, and a plan of the same, were given in the *Builder* for June 24, 1871.—Ed.

‡ The remainder, with some notes of the discussion, in our next.

Illustrations.

SAINT SAVIOUR'S, SOUTHWARK.

SINCE the publication in 1881 of Mr. F. T. Dollman's valuable and profusely illustrated work on the Priory of Saint Mary Overie, Southwark, the history of the church (now known as "Saint Saviour's") has been familiar to all students of ecclesiastical architecture, who owe the author a deep debt of gratitude.

The present nave was begun in 1839, and finished in the following year.

Without any reference to the architectural character of the work, its condemnation is carried in the fact that it is so constructed as to render its use in connexion with the transepts and choir impossible—the floor being raised 7 ft. 6 in. above the old level.

The work shortly to be begun consists in the first instance of taking down this modern building and erecting a new nave and aisles on the lines of the old structure, which was finally demolished in 1838.

It is believed that the whole of the old foundations remain intact, though how far this is the case, and of what value they may be if it is so, can only be determined after the removal of the existing superstructure.

Some small portions of the old work which still exist in the modern nave will be carefully preserved.

After anxious thought and consultation with those most interested in the work, and best qualified to form a correct judgment in the matter, it was decided that the proposed new building, while not professing to be an exact reproduction of what formerly existed, should be carried out on the old lines, and made to harmonise as far as possible with the beautiful work of the choir.

Until this portion of the work is completed the remainder of the church will not be touched, except so far as may be necessary for the safety of the fabric.

The architect for the new nave is Sir Arthur Blomfield.

COMPETITION DESIGN FOR SHEFFIELD MUNICIPAL BUILDINGS.

We give the elevation and the three principal floor plans of the design submitted in the Sheffield Municipal Buildings Competition by Mr. John Slater and Mr. H. H. Statham.

The elevation is not of course, the one originally submitted; it is taken from an enlarged drawing made to $\frac{1}{4}$ inch scale, the original of which is hung in the Architectural Room at the Royal Academy. The drawing shows the detail a little more fully, but the design is exactly as sent in, with the exception of a slight modification in the treatment of the balustrade over the main cornice.

The following quotations from the report sent in with the drawings will explain the intention of the design:—

"The system adopted in this plan is to arrange those departments in which the rooms are comparatively small on a mezzanine between the ground-floor and first-floor, the general Water Office and the main entrance hall going up through both stories, thus giving more height and dignity to the entrance hall.

For a building in which state receptions are given, a state staircase is essential for dignity of effect; a staircase which is in everyday use for the traffic of the building cannot be kept in a fitting condition for receptions. This staircase is intended to be used by the councillors on ordinary occasions, but not by the public or the general staff of officials. The business stairs are each arranged in single flights from floor to floor, and in connexion with the eastern staircase is a public lift for use if required. The introduction of the ante-room between the reception-room and the dining-room is not a necessity of the plan, but it is offered as a great improvement to the effect of the rooms. Large double folding-doors could be arranged to divide off the rooms when required, and otherwise to fold back against the blank portion of the walls on either side of the ante-room.

A private entry and staircase for the Mayor is provided, with a special entrance to the Council Chamber. The ante-room to the Council Chamber can be used *en suite* with the other state rooms if required.

The site towards the churchyard is obviously the quiet quarter for Council Chamber and committee-rooms, and the small committee-rooms are arranged in this quarter on the mezzanine, councillors having direct communication with this floor by doors from the landing of main staircase. The Council Chamber,

Plans of Competition Design for Sheffield Municipal Buildings. By Mr. J. Slater, F.R.I.B.A., and Mr. H. H. Statham, F.R.I.B.A.

BEDROOM IN A COUNTRY H

THE PHOTOGRAPH BY MR. MARTIN LANE, KNIGHT, LONDON, E.C.

BY ARCHITECT, A.R.A., ARCHITECT.

THE BUILDER, MAY 10, 1890.

PHOTO LITHO. SIMMONS & CO. 22, MARK LANE CANON, ST. LONDON, E.C.

CHURCH OF THE SACRED HEART, WIMBLEDON.—MR. F. A. WALTERS, A.R.I.B.A., ARCHITECT.

in committee-rooms, and Town Clerk's department are all on the first floor.

The ladies' and gentlemen's cloak-rooms for the latter are available at other times for staff, are placed on the ground-floor; it would be a complete mistake to place them (as required) on the first-floor, as it would destroy the whole action and meaning of a state staircase to have a motley company in overcoats and wrappers jiggling up it; in such a case it would be absurd to have a state staircase at all. A special lavatory floor-arrangement for councillors is provided on the 1st-floor.

The public lavatories are at the east end, sunk very below the ground, with prism lights from pavement. In case of extension of the building, provision for lighting these otherwise, from an arcade, is made and indicated by dotted lines on sub-basement plan.

Future extension is provided for at the east end by the addition of a semi-circular block, as shown by dotted lines, with the existing main corridors carried round it and meeting. In this way, the new addition, instead of being an excrescence, would form a new and effective architectural feature to the building, without in any way interfering with the original design.

The design of the Finstone-street front speaks for itself; it need only be remarked that the idea is to have an enriched story of "plano nobilis" on a lofty very solidly-treated basement. A large screen made, with niches for statues, gives dignity to the arcade, and forms the exterior expression of the entrance-hall. Great importance is now attached to the combination of sculpture with architecture, and these niches might be filled with historic portraits of eminent citizens of Sheffield in past times.

The upper portion of the tower is designed for a bell with forty-eight bells, hung visibly in open bays, and struck by hammers from within; rivaling in effect the celebrated carillon of Louvain.

As to porte-cochère is shown: a porte-cochère is always more or less an architectural excrescence, and experience in similar cases has shown that there is no facility in providing for the comfort of drivers at receptions by a large temporary awning.

As the Corporation have decided to adopt stone, we are convinced that the only stone which it would be right to use for a building of this importance is a close-grained sandstone containing as little foreign matter as possible. We believe that the best stone in the United Kingdom for use in Sheffield would be the Craigleith stone obtained in the neighbourhood of Edinburgh. We are of the opinion that the cost of this stone is more than that of any of the Yorkshire sandstones, but it would be worth the while of the Corporation to decide in advance of any other. If this stone should be considered too costly, we should advise the selection of one of the best stones of what is known as the Lower Keuper formation, such as Hollingdale. The hacking of the walls would be of hard red bricks, and all the open areas in the interior of the building would be faced with white glazed tiles. The roofs would be covered with blue and slate interspersed.

All the strong-rooms would be lined with salt-glazed fire-bricks. The floors would be all proof, and we should recommend what is known as Lindsey's steel decking for the purpose. The internal columns of the entrance-hall, vestibule, and staircase would be of various kinds of marble, &c. We should use alabaster for the staircase balustrade, and also as panels in the arcade at top stairs. The internal finishings of the suite of committee-rooms would be of American walnut.

Although in the United States steam-heating is easily adopted, yet there are many drawbacks and is so attendant on it, and we are of opinion that on the whole the best plan to adopt would be hot-water-heating. In the sub-basement would be a boiler and furnace sufficient to heat the water for the whole of the building, and from it would be a series of flow and return pipes which would in some cases be merely covered by an iron grating, and connected with coils of pipes, as might be most expedient. We should have separate flow and return pipes for the hot water which would be required for the various lavatories. In all cases fresh air should be introduced into the rooms by Tobin tubes. In those rooms which are of excessive size the air would be exhausted by flues 9 in. square cut on the walls and ascending to the roof. In large rooms, such as the Rates Office, the Water Office, the Town Clerk's general office, the Council Chamber and the suite of reception-rooms, this is not sufficient, and we should propose a series of flues from these rooms to a small chamber in the roof, which would be placed an exhaust fan worked by a small electric motor. By means of a small electric motor would be effectively eliminated.

We should certainly recommend that the whole lighting be lit by electricity. We calculate that about 1,100 incandescent lamps of sixteen-candle power would be required for the whole building, though probably not more than 750 would ever

be in use at the same time. These would necessitate two gas-engines of forty-horse power indicated, and to guard against contingencies it would be desirable to have three dynamo machines, which would all be placed in the sub-basement, as shown on plan. We should not, however, depend upon dynamo alone, as we should advise that storage cells forming an accumulator-battery sufficient to supply the whole building for one day be fixed in the store-room appropriated to them, and that the whole of the current from the dynamo be conducted through the accumulator. This would prevent any fluctuations in the beat of the gas-engine being perceived in the lamps. We should place two glow-lamps in each strong-room, arranged so that the opening of the door turns the light on and closing it again turns it off. This will be found practically of the greatest possible convenience. The small electric motor previously mentioned would be driven from the accumulator."

DECORATION OF BEDROOM FOR A COUNTRY HOUSE.

THIS is a reproduction of a design by Professor Aitchison, which is exhibited at the Royal Academy, and is referred to in our notes on Royal Academy architecture in another column.

The room is panelled in sequoia wood, which is beautiful in its colour and markings, but difficult to carve, as it requires very sharp tools, and rapidly takes the edge off them. In consequence of this, the chimney-piece was executed in pale mahogany. The whole is in a low tone, but a bit of brilliant colour has been got with Mr. De Morgan's tiles. The carving was done by the School of Wood-Carving, at the Guilds Institute, Princes-gate.

CHURCH OF THE SACRED HEART, WIMBLEDON.

THIS church will, when completed, consist of apsidal chancel, with ambulatory round same, side chapels (with organ-chamber over that on south side), nave, aisles, western tower, and south porch. The total internal length will be 160 ft., and the width 65 ft., the height of the nave being 60 ft. from floor to top of over-side of

panelled ceiling. The style is of the "Flowing Decorated" period of English architecture, and externally the walls are faced with knapped flint, with dressings of Ancaster stone, Deer stone being used internally. The nave is divided into eight bays, separated internally by clustered columns and moulded arches, with a richly-sculptured and canopied niche projecting from the wall at every alternate bay. The clearstory is filled with a series of lofty three-light windows of varied design, between which are wall-shafts with foliated caps supporting the arched principals of the roof, over which is a panelled ceiling with carved and decorated wood bosses at intersection of ribs. The wall-shafts are supported between the arches by angels bearing instruments of the Passion. The roof and beam filling the upper part of the chancel arch are richly sculptured and decorated in gold and colour, the chief figures being studded from those in the Collegiate Church at Louvain, while the banking chernikon on wheels are similar to those formerly in Westminster Abbey, and as described in the "Kites of Durham". The lower arch across the chancel stopping the vaulting of apse is surmounted by canopied niches containing figures of Our Lord in Glory, SS. Peter and Paul, and attendant angels. The high altar will stand on the chord of the apse under a baldachin supported by clustered columns, and crowned by a rich and lofty canopy. Mr. Fredk. A. Walters, F.S.A., is the architect of the church, and the contractors for the nave and other portions built were Messrs. Goddard & Sons, of Farnham, the carving being all by the late Mr. James McCulloch.

THE INSTITUTE OF BUILDERS.

THE annual dinner of this Institute was held at the Savoy Hotel on Thursday, the 1st inst., Mr. T. F. Rider, F.R.G.S., President, in the chair. Among those present were the Deputy-Chairman of the London County Council, the Master of the Carpenters' Company, Col. Bird, Dr. F. Elgar, Messrs. Eddle, Franklin, E. S. Henshaw, Maton, Preston, and Rickman.

After the toast of "The Queen," and that of "The Prince and Princess of Wales and the other members of the Royal Family," the President proposed "The Navy, Army, and Auxiliary Forces," to which Col. Bird responded.

Mr. H. T. Ashby proposed "The London County Council" to which Mr. A. H. Haggis, Deputy-Chairman of the Council, replied.

The toast of the "Architects and Surveyors" having been proposed by Mr. H. H. Bartlett, was responded to by Mr. Banister Fletcher and Mr. Franklin.

In proposing "The Institute of Builders," the President said that although only incorporated in 1854, the Institute had been in existence as the "Builders' Society" for fifty-six years, and was greatly extending its usefulness.

Mr. J. Howard Colls proposed "The President," to which Mr. Rider responded.

The toast of "The Visitors," proposed by the President and replied to by Mr. Stanton Wm. Preston, was the concluding item on the list.

THE ART-UNION OF LONDON:

ANNUAL MEETING AND PRIZE DISTRIBUTION.

THE annual meeting of the Art-Union of London was held on Tuesday last in the Adelphi Theatre, the President, the Earl of Derby, in the chair.

The Annual Report of the Council, read by Mr. J. A. Hallett, contained the following paragraphs:-

"For the year now closing, the Council have to report the amount of subscription to be £5,192 18s 6d."

The following is a brief summary of the receipts and expenditure: a detailed account will, as usual, be printed in the Report.

Table with financial data: Amount of subscriptions £5,192 18 6; Allocated for prizes £1,198 0 0; Set apart towards providing works of art for accumulated payments 361 10 0; For print of the year exhibition, report, and reserve 1,781 7 8; Agents' commission and charges, advertisements, printing, postage, rent, &c. 2,578 12 9; Total £5,192 18 0.

To the local honorary secretaries and agents in all parts of the world we have, as usual, to express the thanks of the Art Union.

The amount to be expended on prizes will be thus allotted:—One work at 100l., one at 50l., four works at 30l. each, four at 25l. each, six at 20l. each, ten at 15l. each, twelve at 10l. each, making a total of 300l. In addition to ten Bellerophon repoussé bronze vases and thirty silver "Stothard" medals, making with the prizes given to unsuccessful members, 270 prizes.

In October last the Council was deprived by death of the valuable services of Mr. Troughton, who had been Honorary Secretary since the death of Mr. Pocock. Mr. Troughton was one of the founders of the Art Union in 1836, and was a most diligent attendant at the meetings of Council. His practical knowledge of art, and excellent taste, rendered his opinion highly valuable in the selection of works for prizesholders requiring assistance, and in the arrangement of the exhibitions the want of his presence will be keenly felt. His genial and urbane character justly endeared him to his colleagues. Mr. Troughton was a writer of no mean order, his tragedy of 'Sina Sforza' was produced at the Haymarket Theatre during Mr. Macready's management.

In February last died Mr. H. R. Haines, who had been for several years a diligent and useful member of the Council. Mr. Haines was possessed of great taste and much knowledge of art, and his colleagues will deeply feel the loss of his judicious and practical suggestions.

At Kensington, on the 16th March, 1889, passed away Mr. Samuel Carter Hall, who for many years occupied a very prominent position in art literature. He was born in 1800. A casual remark of Charles Landseer at a public dinner, that there was no periodical publication to represent art led to the foundation of the Art Journal, or, as was first called, the Art Union, from the initiative of this society. It is the lot of but few periodicals to prolong their existence into a second half century, and it is an almost unique circumstance for the conduct of a magazine to have had but a single change during that period. It was on February 13, 1839, that the first number of this journal appeared, and for more than half a century the veteran originator had the pleasure of seeing his offspring grow, mature, and prosper in its career of usefulness. The number printed of the first edition was 350—since then as much as 70,000 has been received from its sale in a single year. At the time when the journal first appeared there was no patronage for British art—collectors would look only at old masters, which were consequently manufactured and imported for them, at a rate which was certified by the customs at 10,000 a year. To Mr. Hall was due the bursting of this bubble, and he had to assert the truth of his strong language concerning this traffic in the law

courts. In 1843 Mr. Hall visited every important manufacturing centre in Great Britain, and found that nowhere was there any persistent or consistent effort being made to weld together arts and manufactures. Everywhere there was an entire dependence for patterns and designs on borrowings, purchases, or thefts, from France and other countries, and a regular trade in foreign patterns brought much gain to those concerned in it. Mr. Hall retired from the editorship of the *Art Journal* in 1858.

After chronicling the death of Mr. T. O. Barlow, R.A., Mr. Fred. Taylor, and Mr. J. R. Herbert, R.A., the Report went on to give a summary of the proceedings of the Edinburgh Congress of the National Association for the Advancement of Art. One paragraph which occurred in the summary or review referred to was as follows:—

"It is remarkable that no one was found at the meeting to say a word for the efforts which the Art-Union has been making for fifty years and more to excite in the minds of the people not only of the United Kingdom, but wherever the English language is to be found, an interest and an appreciation of the refining and ennobling effects of fine-art works by the dissemination of thousands of reproductions by choice engraving, of the finest works of British artists, as well as copies, both antique and modern specimens of sculpture. There is abundant evidence to prove that these exertions have not been put forward in vain. The mere fact of the continued improvement in the quality of works selected by prizeholders, year after year, proves that the influence of the Art-Union's teaching has been very considerable."

Following this came a review of the Paris Exhibition, and the Council then make the following remarks as to their programme for the ensuing year:—

"For the ensuing year the Council have secured the services of four well-known Fellows of the Royal Society of Painter-Etchers to produce etchings of the following works in the National Gallery:—

"Landscape" by Thos. Barker, No. 1,033, etched by E. Barclay.

"Entrance to Pisa from Leghorn" by Sir A. Colcott, No. 346 etched by C. O. Murray.

"A House at Hampstead" by John Constable, No. 1,245, etched by H. R. Robertson.

"The Windmill" by John Crome, No. 926, etched by Pery Thomas.

The choice of these four artists has been carefully considered. They represent one of the most remarkable movements in the history of English art.

The landscape painting of Europe had been so completely conventional that reference to nature was not only seldom made by the painter, but was resented as an impertinence by the art critic. Hence the neglect under which Wilson, Gainsborough (as a landscape painter), Crome, Constable, and Müller all suffered. They lived before their age.

Constable said of his work:—"My art flatters nobody by imitation, it courts nobody by smoothness, it tickles nobody by pettiness, it is without fal-lal or fiddle-dee—how then can I hope to be popular?" Nevertheless no English painter has had a more wide-reaching power as a teacher, and his picture of "The Haywain," sent in 1824 to Paris, for which he received the Gold Medal, is acknowledged by the French critics themselves to have had a vast influence on French art.

There is no doubt that the school of Troyon was initiated by the admiration of these fine works. He brought about the frank acceptance and induced an admiration for nature as taking the place of the ordinary conventional "composition" which prevailed so exclusively before his time and the time of his contemporaries.

The group of Englishmen (whose work we shall put before our subscribers next year) had the gift to see nature again after centuries of blindness.

So with Gainsborough and so with John Crome, who with Constable were all natives of Norfolk and Suffolk, a district which at the end of the last century was little visited, and retained a rural wildness of aspect that has since been improved off the land,—wide wandering roads, wayside pools, large oaks and other timber. These characters sank into the minds of the gifted men who were so numerous in the last century, and stimulated Gainsborough to a most artless recording of the country he lived in. The same may be said for John Crome, who by his faithful rendering of the canals, oaks, and heaths of his native county will live as a great painter as long as his canvas lasts.

In all, the truly English impression of nature is seen, large, without meretricious effect, with a due respect for what has been called the "passion of nature" in her stormy, showery, and breezy moods, without excess of minute detail, yet all that is essential is there.

Sir A. Colcott took the middle phase and was a successful and even fashionable painter. His Italian sketches, made after he was fifty years of age, show a masculine directness that is very valuable, and characteristic of his age and its way of regarding nature.

Of Thomas Barker, of Bath, too, we may say he worked like a man; his contrasts of colour as of form and human expression are full of force, and all in the truly simple English taste, strong without theatrical exaggeration. These men were the masters and fathers of our English Landscape art, and deserve our truest and frankest acknowledgments for their work.

Aprons of English art a very interesting address was given by Mr. Orrock at the Society of Arts on March 11 last, on the claims of the British school of painting to a thorough representation in the National Gallery. . . .

When the attention of the officials of the National Gallery is called to the desirability of securing at a sale some fine rare examples of one of our own masters, the reply always is, "There are no funds." Out of available funds amounting to some 45,000*l.*, about 3,000*l.* was spent on English pictures. We want fine specimens of English art for the benefit of painters, students, and all lovers of national art.

It is believed that several large sums and a number of choice works in water-colour have been already promised towards the formation of a real Gallery of English Art; but it is not likely that such an arrangement will be carried out if the works presented are to

be hidden away in badly-lighted underground rooms. Let there be a properly-lighted and proportioned gallery provided, open to the calm, clear silver light which is required to allow their infinite beauty and delicate treatment to be studied and felt, and thus we shall encourage others to add to the collection, and convince the nation that we indeed have a school."

Lord Derby, in moving the adoption of the report, said it was not his wish or his duty to follow the various points raised in it, but he was compelled to admit his appreciation of its spirit. He thought he could venture to say, as one of the Trustees of the National Portrait Gallery, that the Trustees would be glad to receive portraits of eminent artists, though he did not think it would be advisable to hang them in a distinct group or class. He was sorry to say that there had been a very considerable falling off in the list of subscribers to the Art Union, who in 1880 numbered 15,000, but to-day only 6,000. It could not be said that this was owing to a decline in the artistic taste, for the demand for artistic work was greater now than it had ever been before. Probably the cause would be found to rest partly with the commercial depression which existed of late years. If they had suffered in bad times, it was only reasonable to hope that with the revival of trade they would benefit. Another and perhaps permanent cause arose from the Art Union's own success, which had brought imitators into the field. He did not despair of the Art Union's prospects, and urged the executive not to lose heart, but to energetically face the increased competition. The report was unanimously adopted.

Several votes of thanks having been passed, the drawing for prizes took place, with the result that the principal prize of 100*l.* was drawn by Mr. H. R. Ferry, of Granville Park, Blackheath.

THE LONDON COUNTY COUNCIL.

The usual weekly meeting of the London County Council was held in the Council Chamber at the "County Hall,"* Spring-gardens, on Tuesday last, Lord Rosebery in the chair.

The Chairman resumed and concluded his review of the committee-work of the Council for the past year, dealing with the work of the Standing Committee, the Standing Joint Committee, the Theatres Committee, the Parliamentary Committee, the Finance Committee, and the Contracts Committee. With regard to

The Finance Committee, which by its statutory obligations had, he said, exercised the most invidious functions of any of their committees. The Finance Committee had had the difficulty of imposing the rate—that much-abused, much-explained rate. After the two letters of Sir Thomas Farrer in the *Times*, he should have thought that all misconception was impossible, but none were so blind as those who would not see, and it might be worth while for one moment to touch upon that subject. Their critics said: "The Metropolitan Board rate was 10*l.* 10*d.*, and your precept is 13*l.* 2*d.*, therefore your rate is 3*d.* more than the Metropolitan Board rate." That was perfectly true, and if the work of the School Board were added to the work of the County Council their rate would be 15*d.* more than the rate of the Metropolitan Board of Works, and if the care of the British Museum were added to their charges their rates would be again considerably enhanced; and if they had to pay for the Brigade of Guards and their maintenance their rates again would be considerably enhanced. That was the whole question. The rate they were raising was not the rate of the Metropolitan Board; it was a great many other rates; and of course those who desired to discredit the London County Council deliberately ignored that fact and made capital out of their supposed ignorance. They had a good many other rates the collection of which was not voluntary, but was imposed upon them by Parliament. As it happened, their rate for Metropolitan Board purposes last year was smaller than that of the Metropolitan Board itself. It was 10*l.* 6*d.*, as against 10*l.* 10*d.*. But they were a totally different body to the Metropolitan Board of Works; they were a municipality, not a Commission of Works and Sewers. The Government wished to create a great municipality for London, and, having created that municipality, it had handed over to it the powers of the

Metropolitan Board of Works and a great many other powers besides. It handed also a certain income over to them with which to discharge those new duties. That income was totally inadequate, and it was in respect to that inadequacy that the rate was raised in the present year. He read out a list of the new duties imposed upon them by Act of Parliament in addition to those imposed on the Metropolitan Board of Works, each which involved expenditure to the County Council—payments to Guardians towards remuneration of teachers in Poor Law schools, to public vaccinators, to local authorities for Medical Officers of Health, to Poor Law Guardians for registrars of births and deaths, to Guardians for Poor Law medical expenses, to Guardians and others for pauper lunatics, to Guardians of 4*d.* a head a day,—that alone was an item of 4326,000*l.* a year,—and to Croydon for union officers. Besides these payments there were old county liabilities,—the interest on the debt, pensions of officers of prisons, lunatic asylums, and Feltham School, and the proportion of the liability of 2,400*l.* a year contributed by the old counties of Surrey and Middlesex towards the cost of metropolitan Thames bridges. Then under the head of judicial work—criminal prosecutions, Central Criminal Court expenses, judicial salaries, and Sessions Houses maintenance. Then provision of new lunatic asylums, coroners' salaries and disbursements, industrial schools, weights and measures, main roads maintenance, county bridges (other than Thames) maintenance, registration of voters and revising barristers, Medical Officers of Health, expenses of burial of human bodies cast on shore (that was a small item), licensing for music and dancing, licensing slaughterhouses and cow-houses, county rate—preparation of basis for rate in Penge, and compiling the valuation lists for rest of county, rabies—that was now 4,200*l.*—a new item of expense, and electric lighting. Those items cost the Council altogether 1,206,742*l.*, towards which the Government gave 823,384*l.*, and there were small receipts amounting to 29,771*l.*, so that it set off against their 1,206,742*l.* of additional expenditure they had 853,155*l.* of additional income, which left 354,000*l.* a year to be met out of the rates,—that was, a rate of nearly 2*d.* In the Report of the Finance Committee issued that day there was a very instructive tabular showing how in each parish or union of London the rate was diminished by the contribution which the Council made. This question of rate impaired their popularity, it crippled their usefulness, and it put a stop to metropolitan improvement. Their credit was in no respect diminished. One great feature of the work of the Finance Committee of this year had been the raising of its first loan. The Metropolitan Board created first a 3*d.* per cent. stock in 1869. This continued till 1887. Then one at 3 per cent., which continued till 1887. The average price of issue in that year was over par. A body creating stock does not get the full value of the security when the rate of interest commands more than the price at which the security will be ultimately redeemed. The choice lay between 2*d.* and 2½ per cent. The present Government chose 2½ per cent. The average price produced to the Council on its 2½ per cent. stock was 99*l.* 12*s.*; its net produce 91*l.* 0*s.* 10*d.* The rate of interest on the sterling is 2*l.* 14*s.* 11*d.*, and, adding bank management and Government duty, 2*l.* 17*s.* 5*d.*, exclusive of cost of redemption in par. The average rate of interest on 1*l.* sterling of the three issues of stock (3 per cent.) previously to that of 1889 was—1889, 3*l.* 4*s.* 1*d.*, 1886, 3*l.* 2*s.* 9*d.*; 1887, 3*l.* 2*s.* 10*d.* as compared with 1889, 2*l.* 17*s.* 5*d.*. Their grade was greatly due to Lord Lingard.

The Contracts Committee.—The Chairman referred to the work of the Contracts Committee. They had to examine the allegations that sub-contracting was going on in the works, and sub-contracting meant sweating an inferior work. They had not reported, but the Council had done a good deal in the direction of what the Contracts Committee was appointed to promote.

General Work of the Council.—In conclusion the Chairman made some remarks on questions of policy or principle affecting the work of the Council. The present Council, he said, had lived fourteen months, and they had only eighteen months more to live. In that time seemed to him that they ought to complete

* So the premises in Spring-gardens are designated on the engravings convening the meeting.

their organisation, as far as it was possible, and they ought to lay down a definite scheme of policy to guide them. They could not fully complete their organisation, because that was a matter of growth and development, but he thought from their experience they could evolve a rational and elastic plan which would be of use to themselves and a guide to their successors. Their present position was in some degree anomalous. They were an administrative body without any executive. They worked through some eighteen committees. It was quite clear that under these circumstances their work must always be liable to be faulty and inconsistent. Suppose the House of Commons were to administer in the same way. Suppose that instead of having sixteen or seventeen ministers at the head of departments they had sixteen or seventeen committees administering the War Office, the Admiralty, and so forth, and each of them made a weekly report to the House of Commons and received the House of Commons' directions as to the work it was to pursue, he ventured to say that such a scene of administrative chaos could not have been witnessed in the course of human history. He could perceive the evil, but he did not perceive the remedy. It was quite clear that 137 was too large a number for an executive body, while, on the other hand, he did not quite see what was to assist that body in performing its executive functions. He ventured to think that the Council would not do hadly if it applied itself through some Committee or otherwise to see if they could not find a remedy for that state of things. With regard to the

Relations of the Council with the Corporation of London.—He said that this was a matter of some complexity, and he would beseech them, in what he was going to say, to believe that he spoke, not as member for the City, but as Chairman of the Council. The position of the City was peculiar; it was not natural, it had no elements of durability—in its present shape it had no elements of durability. It was something like the scheme that was planned for Pagan Rome at the Second Empire—that the Pope was to occupy what was called the Leonine City and live in perfect harmony with the rest of the metropolis, which was to be given up to the kingdom of Italy; and so close was the parallel, strangely enough, that when the Emperor Napoleon III. was planning something of this sort, he sent over to London to try and find out if he could not obtain some information about the exceptional privileges of the City of London, in relation to the rest of the Metropolis, which would give him some guidance as to the relations which he might hope to establish between the Leonine City and the rest of Rome; and the result that he obtained was summed up comprehensively by his own Minister in the words that it was not possible for St. Peter to follow St. Paul in this matter. As they were aware, in some respects the Metropolis was one already; but the Corporation and the privileges of the City of London were maintained intact. Their duty, it seemed to him, was to respect that arrangement in all courtesy and good faith. The condition of things, as he had said, must in its nature be provisional. In time, in the fulness of time, the Metropolis would be one,—one in all respects. It would not be easy to reconcile and to blend all the various elements which would be required in order to solve that great problem of mingling the pomp and the splendour of the City with the simple democracy of that body—to sew the purple of the City and that of the County Council together; but that was not their work. It might be it was the work of statesmen and of Parliament, and no action of the Council, as far as he knew, would either further or facilitate that work. He hoped it would be accomplished, when it was accomplished, with the least possible friction and the least possible irritation; but in the meantime he believed that their duty in the matter was perfectly clear, that their relations with the City should be marked by dignity and friendliness and fair dealing; not encroaching on the privileges of the City nor allowing the City to encroach on theirs; not allowing the interests of the community of London at large to suffer by any neglect on their part either in action or in representation, but not unnecessarily interfering with that ancient body where they had no direct interest of the community to serve. Now he ended the record that he had to lay before them. It was a review of hard and

honest work. They had had to learn their business and to do it. Of the quality of that work the results must be the test, but of the quantity he could testify himself. He had watched them doing it through the short days of winter and the long summer afternoons, sometimes baffled and depressed owing to the internal inconsistency of the evils to be overcome and the difficulty of overcoming them. What had sustained them, he believed, in this work had been neither fees, nor fame, nor praise; it had been the pure impulse of a clear duty and a high hope and a generous ideal. He hoped that they would always cherish that spirit among them, for without it their work would degenerate into a revolting round of oppressive detail; without it they might easily dwindle into mean corruption and to petty intrigue; and without it the Council itself could never realise that high destiny which, as the greatest municipality in the world, worked by the greatest race in the world in the greatest city of the world, if wisely guided and well served, in the fulness of time it could not fail to obtain.

The Vice-Chairman (Sir John Lubbock) moved that the Council should request the Chairman to allow his address to be printed and circulated.

The Deputy-Chairman (Mr. Haggis) seconded the motion, which was unanimously adopted.

A Model Lodging-House to be built in Drury-lane.—The Council then resumed the adjourned debate on the report of the Housing of the Working Classes Committee, which recommended that the Council, subject to an estimate to be approved by the Finance Committee, should undertake the erection of a model lodging-house on the model of those erected and controlled by the Corporation of Glasgow, to accommodate from 300 to 350 persons, on a plot of vacant land, now in possession of the Council, in Shelton-street, Drury-lane. To this an amendment had been moved by Mr. Alderman Debenham:—

“That whilst agreeing with the general tenor of the report, the Council disavows the recommendations which pledge the Council to undertake the building of a common lodging-house.”

After a long discussion, the amendment was negatived on a division by 87 to 24 votes, and the recommendation of the Committee was approved.

After the transaction of a great deal of other business, the Council adjourned.

ARCHITECTURAL SOCIETIES.

The Architectural Association.—The ordinary fortnightly meeting of this Association was held on the 2nd inst., at 9, Conduit-street, Mr. Leonard Stokes, President, in the chair. The “House List” of officers and committee for the ensuing session was read, and two additional nominations were taken. After a long discussion, it was resolved by a large majority, on the motion of Mr. Collard, that the votes for officers be counted the evening preceding the next meeting, and that the scrutineers be instructed to report the number of votes given to each candidate. Mr. F. R. Farrow, the senior honorary secretary, announced that the first meeting of the Sketching and Measuring Class would take place on May 17, when Rainham in Essex would be visited. Mr. Farrow also announced that a special business meeting would be held on Friday, May 9* to consider the report of the Committee on Education. Mr. E. S. Gale, honorary secretary, proposed a vote of thanks to Mr. J. M. Brydon, the architect of the new hospital, Euston-road, for kindly showing them over that building on the occasion of their visit. Mr. Keith D. Young then read a paper on “Hospitals.” (See p. 337, ante).

Liverpool Architectural Society.—The closing address of the President of this society, Mr. T. Mellard Reade, F.R.I.B.A., &c., was delivered on Monday last. Referring to the question of the Registration of Architects, Mr. Reade said:—“The Institute at present represents, and I hope will continue to represent, the views of the majority of architects, and so long as this representative body opposes the Bill, it is unlikely to pass into law.”

Royal Institute of the Architects of Ireland.—The regular monthly Council meeting of this Institute was held at 37, Dawson-street, on Monday, May 5. Present: T. Drew, in the chair; J. R. Carroll, R. Millar, S. Symes, J. H.

*According to the advertisement which appears on another page, this special meeting will be held on May 16 instead of the 9th, as was announced.

Peutland, W. M. Mitchell, C. Geoghegan, Albert E. Murray, hon. sec. and treas. The minutes of last meeting were read and signed. A vote of thanks was passed to Mr. A. Oliver, of London, for his kind gift to the Institute of the Design for Royal Exchange, Dublin, dated 1768, by the late Mr. H. Newton, architect. The matter of the Dublin Corporation Improvement Bill was again under discussion, and the correspondence having been read, in which the Corporation declined to accept the amendment proposed by this Institute, the following resolution was unanimously passed:—“Having read the correspondence between the President of this Institute and the Town Clerk relative to amendment (dated February 3, 1890) proposed in clauses 40 and 61 of the Dublin Improvement Bill by this Institute, the Council has to express its disappointment and dissatisfaction that the Corporation Committee having charge of the Bill has determined to maintain those injudicious clauses as drafted. The Council can do no more than enter its protest against the rejection of its advice, founded on thorough experience of the working and wants of building legislation in Dublin, and record its opinion that the arbitrary powers sought under these clauses are unwise in the interest of future Committees of the Corporation as well as in those of the citizens.”

OBITUARY.

Mr. John Carrick.—It is with much regret that we see announced in the Glasgow papers the death of Mr. John Carrick, the City Architect of Glasgow, which occurred on the 2nd inst. According to the *Glasgow Herald*, he was a native of Denny, in Stirlingshire. After completing his education he served an apprenticeship with the late Mr. John Bryce, architect, brother of the better-known David Bryce, of Edinburgh. Afterwards he was assistant to the late Mr. Herbertson, and he also spent a short time in England and in foreign travel acquiring further experience in his profession. Returning to Glasgow, he began business in partnership with a Mr. Brown, under the firm of Brown & Carrick, but the co-partnership lasted only a few years, Mr. Brown retiring on falling heir to the estate of Currie, near Edinburgh. Soon afterwards Mr. Carrick entered the service of the Corporation, succeeding the late Mr. Hume in the office then known as Superintendent of Streets. This was in the beginning of the year 1844.

Mr. James Nasmyth, the famous engineer, whose invention of the steam hammer will have made his name familiar wherever the English language is spoken, died on Wednesday morning last. According to the *Times*, for some six months he had been in failing health, but this arose merely from his great age, and he was accustomed to say till up to a few months ago that he had never known what it was to be ill. About a month ago he left his place at Penhurst, near Tunbridge, and came to town, where he stayed at Bailey's Hotel, Gloucester-road, Queen's-gate, and there he died. He was born in Edinburgh, on August 19, 1808, and he was consequently in his eighty-second year at the time of his death. A very interesting autobiography by Mr. Nasmyth, edited by Dr. Smiles, was published in 1883.

STAINED GLASS.

Brecon.—The officers, non-commissioned officers, and men of the 24th Regiment being desirous of erecting a memorial to their comrades who fell in the Burmese War, have commissioned Mr. Taylor, of Berners-street, to execute a stained-glass window and memorial brass bearing the name of every man who fell in action or died during the campaign, to be placed in the Priory Church, Brecon, where the memorial to their comrades who fell in the South African campaign is erected.

Durton-on-Trent.—Sir Francis Burdett, Bart., has recently presented the church of Foremark with painted glass. In the altar screen angels in adoration are introduced, with a representation of the Holy Spirit, descending in the form of a dove, above. The whole, treated in monochrome, is from the studio of Messrs. Charles Evans & Co., London.

Ingelton.—The parish church of Ingelton, Yorkshire, has lately received a stained-glass window in memory of the late Rev. Richard Denny, B.A., for twenty-nine years the faithful pastor of this parish, and the founder of its school. The window consists of two lights,

and the subject selected for illustration is "The Good Shepherd." The work has been executed by Messrs. Mayer & Co.

SEWERAGE AND DRAINAGE WORKS.

Draycott.—The sewerage works and sewage farm at Draycott, near Derby, are now completed, and the sewage was turned on the farm last week. We are informed that members of local authorities, or others interested in sanitary work, may see the farm at any time. The population whose sewage is dealt with number 1,200. The land is six acres in extent, and it has been drained, levelled, steam scuffled, and laid out with carriers. The sewers are flushed automatically every twelve hours with brook water. The engineer for the works is Mr. W. H. Radford, of Nottingham, and the contractors are Messrs. Holmes Bros., of Nottingham.

St. Helen's.—The first contract of the new intercepting sewer has been commenced, and the contractor, Mr. John Riddell, of St. Helen's, has now made good progress with the work. The sewer is over one mile and a half long, in three sizes, viz., 6 ft. circular at outfall, 6 ft. by 4 ft., and 4 ft. by 2 ft. 8 in. egg-shaped, the greatest depth of cutting being about 30 ft., and the average depth 20 ft. The whole of the work is being carried out by Mr. Geo. J. C. Broom, Assoc. M.Inst.C.E., the Borough Surveyor, engineer for the works. The estimated cost of the whole scheme is over 30,000.

A PARTY-WALL CASE.

FOOT v. HODGSON.

This case came before the Queen's Bench Division of the High Court of Justice on Monday (Mr. Justice Mathew and Mr. Justice Grantham on the Bench). It raised a question of some general importance under the Metropolitan Building Act, 1855 (18 & 19 Vict., c. 122), as to the rights of adjoining owners of houses as to pulling down and rebuilding "party walls" between their houses, and it turned upon what is a "story" of a house. In the schedule of the Act a scale is given for the thickness of party-walls, and the wall of the "two most stories" is to be of a certain thickness, and the rules provide that the height of every topmost story shall be measured from the level of its floor up to half the vertical height of the rafters when the roof has no "tie" or to the "tie" when it has one. The 33rd section of the Act, subsection 7, gives a right to the building-owner to pull down any party structure that is of insufficient strength for any building intended to be built and to rebuild it of sufficient strength for the purpose upon condition of "making good all damage." The house in question, of which Hodgson was the building-owner, was in Little Trinity-lane, in the City, and had been burnt, except the party-wall between it and the adjoining house, of which Foot was building-owner. Hodgson's house, which was burnt, had at the top a floor with a slanting or shelving roof, which is now very common, and he desired to rebuild it with such a top floor as before. But the District Surveyor found that, treating this floor as a "story," and as the topmost story, it required the party-wall to be of greater strength and thickness, and Hodgson accordingly proposed to pull down the party-wall and re-erect it of the required strength. To this Foot, the building-owner of the adjoining house, objected, contending that the top floor was not a "story," and that the greater thickness of the wall was not required, whereas Hodgson insisted that it was. The contention of Foot was that, as the roof was shelving over the top room, and that as a matter of law it could not be "the topmost story," whereas Hodgson contended that it was a "topmost story," and so required the extra strength of the wall, and on a reference under the Act to a surveyor or arbitrator he so decided. But the Act gives a right of appeal to the County Court, and the adjoining building-owner so appealed, and Mr. Kerr, the Judge of the City Court, took the contrary view, and decided against the defendant,* who appealed.

Mr. Spokes appeared on his behalf in support of his appeal. Mr. Finlay, Q.C. (with Mr. Fullerton), appeared for the plaintiff, the adjoining owner, in support of the judgment of the City Court Judge.

The Court came to the conclusion, however, that that the judge was wrong, and that the defendant was right, in his contention as to the mode of measurement to be adopted, which showed the room in question to be the "topmost story," so as to require the wall to be of the greater strength and thickness; and that thus the building-owner was justified in rebuilding it of the strength required.

Judgment was given for the defendant; consequently the award of the arbitrator (Prof. T. Roger Smith) was sustained, and the appeal was allowed.

* As reported in the *Builder* for March 23 last, p. 235.

RUDE CHURCHES.

Sir,—In the notice of "Baynard's Castle" in last week's *Builder*, Mr. Macmichael is quoted as having lately asked, "Is there a village church in the United Kingdom and Ireland (sic) where the bare floor still exists?" I am sure there are many Catholic churches in Ireland that have clay floors. I have been in scores of them, and in many with thatched roofs; but they are fast disappearing. A few years ago I got a tile floor laid in a church near the city of Limerick, and beside a railway station, to replace a clay floor. About thirty years ago I was in walls partly built for a church, but never roofed or floored, in the mountains not far from the town of Donegal. A rude thatched open shed was formed against the inside of the east end, and a rough stone bench, which served as an altar, under it, upon which Mass was said every Sunday, the space enclosed by the walls being first cleaned and swept, as cattle and sheep had free access to it during the remainder of the week. The more careful of the large congregation knelt and sat upon stones.

In the north of the same county, and at about the same time, I saw on the natural grassy terraces sloping down to the sea in Sheephaven, near the village of Milford, what was called a "schabul," being a wall of rough masonry about 10 ft. long and 6 ft. thick for 3 ft. high, and 2½ ft. to 3 ft. thick for a further height of 6 ft. or 8 ft., leaving an offset at one side over which a thatched penthouse roof projected, and under its meagre shelter Mass was said every Sunday, the people kneeling on the fine short grass of the gentle slope to the strand and some on opposite side of the bay half a mile off. I have also been in a quarry-like hollow on the banks of the Black Water, in the county Cork, near Lisamore, where the ground had subsided in a horse-shoe form into one of the oarves of the locality, leaving a recess with a ledge of rock upon which Mass was said whenever it was safe, and the yeomen were away, for whom my father-in-law, when a boy, not being a suspect, watched on a neighbouring hill to give a signal to the Papists to disperse if the "yoes" were coming. M. M. May 6, 1890.

METHOD OF TAKING ANGLES.

Sir,—I should be much obliged if you would insert this question in your next issue, or answer me otherwise:

In taking angles with the theodolite round any figure, is it more correct to clamp the reading of an angle, say, at A, and bring this reading to bear on A from the next point B, so measure the angle at B, than to adjust the vernier at O° each time an angle is measured? If so, why?

ONE IN DOUBT.

** "One in Doubt" is referred to The Student's Column," Article XV., April 9, 1887, and Articles V. and VI., July 30 and August 6, 1887, where the operation of multiplying the angle mechanically is shown to lead to numerical inaccuracies, as the process of dividing the total angle read by the number of repetitions obtains an average, calculated to obviate any slight mechanical inaccuracies of subdivision in the instrument, but of course this does not overcome errors resulting from want of adjustment.

VENTILATION BY SASH WINDOWS.

Sir,—I can back up what you have said on pages 309 and 325. I have used various ways of carrying out Dr. Hinkes Bird's principle of admitting fresh air between the sashes. One plan I used for years was placing a movable piece of wood, about 2 in. thick, below the bottom sash, which, of course, raised it up 2 in., and so allowed the fresh air to come in between the sashes; when the wood was removed the lower sash could be pushed down. Another plan, which I like better, is to put a thin strip of wood, ¼ in. thick, close along the top of the upper sash, either outside or inside. It is about 3 in. deep, so that when the top sash is pulled down the fresh air comes in between the sashes. This has been in use for several years at my present house, and wood slip being fixed inside for all the front windows, and outside for the back ones.

I published a drawing of the plan in 1883, and stated it was Dr. Bird's. It will be found in fig. 297 F, page 275, of "Buchart's Plumbing," in Weale's Series. W. P. BUCHAN.

New Stores in High Holborn.—The Great Central Hall, High Holborn, recently erected as a fire-proof structure, after the designs of Mr. R. Emerie Yorke, architect, is about to be opened as the Central Co-Operative Stores. The property extends over 21,794 feet superficial, and has three entrances in High Holborn, and three in Eagle-street. Partly freehold, and partly leased for 5701 annual rent, it has been valued *ad hoc* at 60,900.

The Student's Column.

ELECTRICITY, MAGNETISM, AND ELECTRICITY SUPPLY.—XIX.

ALTERNATING CURRENT CIRCUIT.

THE application of Ohm's law to an alternating current is not so simple as in the case of the continuous current, owing to the difficulty of assigning the right value to the electro-motive force producing the current at any particular instant.

Fig. 54.

Fig. 54 represents two alternating current machines, M_1 and M_2 , of which M_1 is the larger, coupled up in series through an external circuit. The resistance, through which current flows, is R , but self-induction is supposed to be entirely absent. If the machines have the same number of armature bobbins, and run at the same speed, the curves representing the E.M.F. in each will have the same period, though that for M_1 will be the taller of the two. Again, if the armatures are not at the same time in the same position, relatively to their field magnets, the phases of the curves will be different; in other words, they will not have their maximum and minimum values at the same instant.

Fig. 55.

Draw (fig. 55) the curve S to represent the E.M.F. of M_1 at any instant, and B that of M_2 ,* then the curve C , representing the resultant E.M.F. acting at any instant, can be obtained by taking for its ordinates the algebraic sum of the ordinates of S and B , giving the positive sign to ordinates measured above, the negative sign to those measured below OX . We do, in fact, precisely what we should do in any other case in which we desire to use Ohm's law, viz., consider electro-motive forces acting in one direction round the circuit \rightarrow , in the opposite direction \leftarrow , find their algebraic sum and take this sum to be the value of E in the expression $C = \frac{E}{R}$.

To draw a curve representing the current flowing at any instant, the ordinates of E_2 must be divided by R ; to avoid confusing the figure, R is assumed to be 1 ohm, so that the curve C_2 for the current is coincident with E_2 .

The curve B can be made to assume any position, relatively to S , by shifting the armature of one of the machines backwards or forwards; in the figure, B is drawn for the special case in which it cuts OX when C_2 has its maximum or minimum value, and *vice versa*. Now substitute for M_2 a bobbin, *b*, fig. 56, having a high co-efficient of self-induction. The actual number of lines of force within *b* at any instant depends upon the value of C_2 , but the E. M. F. set up in the coil depends upon the rate at which the lines are passing into or out of the coil, that is, upon the rate at which the value of C_2 is varying. When C_2 is on the point of reversing, it and the lines of force it is producing are, for the instant, steady, and the E. M. F. due to self-induction is therefore zero, so that B cuts OX when C_2 or E_2 has its highest and lowest values. Again, the current is changing in value most rapidly where C_2 crosses OX , hence when C_2 is zero, B has its maximum or minimum value.

It has been shown that self-induction opposes an increasing current and helps a diminishing current.

* A similar curve was shown, fig. 51, in the previous article.

one; it follows, therefore, that the curve B is exactly a quarter phase behind C_1 and E_1 .

If we suppose the machine M, to be replaced by the secondary coil, *s*, fig. 56, of a transformer, the curves in figure 55 will now serve for the secondary circuit of the transformer system shown in figure 56.

Fig. 56.

Since the resistance of the secondary circuit has been assumed to be 1 ohm, if there were no self induction in *b* the curve S would represent the current flowing at any instant, as well as the E.M.F. of the secondary coil. The current could, however, be reduced to its former value by throwing extra resistance into the circuit; but although the curve for the current would still be shaped like C_2 in the figure, its position would be shifted, as it would then cut O X in the same points as S does. When the current is diminished by the introduction of resistance, heat is generated in that resistance and power absorbed; we have seen that the current can also be diminished to the same extent, not by increasing the resistance of the circuit, but by shunting it so as to introduce the necessary amount of self induction; it is, therefore, sometimes erroneously supposed that the "self-induction" will absorb the same amount of power as the "resistance" that would have to be employed to achieve the same object.

The power at any instant is measured by the product of the number of volts into the number of amperes, or, in fig. 55, by the product of the corresponding ordinates of C_1 and B. Between O and x_1 , these products are negative, the cutting into the coil of the lines of force sets up an E.M.F. opposing the current, and the coil absorbs work, but between x_1 and x_2 these products are positive, though of the same numerical value for the same value of C_1 , hence from x_1 to x_2 the lines of force in cutting out of the coil put back into the circuit exactly as much work as it absorbed between the points O and x_1 . The difference between the action of resistance and self-induction may otherwise be resisted in this way—Resistance absorbs electrical energy, both while the current is increasing and while it is diminishing; the energy thus absorbed is returned as heat energy to the atmosphere and surrounding bodies. Self-induction absorbs electrical energy while the current is increasing; the energy thus absorbed is returned as electrical energy to the circuit while the current is diminishing, and as a net result no electrical energy is taken from the circuit. From these causes, "choking coils," that is, coils with a large co-efficient of self-induction, are used for reducing alternating currents, instead of wasteful resistances.

Passing on now to the consideration of the primary circuit, identically the same lines of force which set up E.M.F. in the secondary coil, *s*, fig. 56, also produce a corresponding E.M.F. in *p*, the primary coil; indeed, these lines are the connecting link between the two circuits. If N and n are the number of turns of wire in

constant $\frac{N}{n}$. A new diagram is used for the primary circuit, to avoid confusion.

The curve P now shows the E.M.F. in the primary coil at any instant; it must be noted P indicates not the flux of lines through the core of the transformer, but the rate at which they are changing, and a curve showing the actual value of the flux will be one which is a quarter phase in advance of P. Calculate the value of the flux from the expressions given in the last article,* and draw the flux curve F on a scale such that the flux produced by one ampere in the primary coil is represented on the same scale as one ampere. Now, the magnetisation of the core is due to the algebraic sum of the ampere turns in both *p* and *s*. Imagine, for the purposes of construction, the ampere turns in *s* transferred into *p*; this we can do by multiplying the ordinates of C_2 , fig. 55, by $\frac{n}{N}$ and tracing the dotted curve C_2' , fig. 57, to represent the equivalent current in the primary coil. But F may be regarded as being produced by the sum of the real current in the primary circuit, and this fictitious current C_2' ; subtract, therefore, C_2' from F, and we obtain C_1 , the actual current flowing in the primary circuit.

Again, to avoid drawing a separate curve, assume the resistance of the primary circuit, like that of the secondary, to be 1 ohm, then E_1 , the curve for the resultant E.M.F. producing current, is coincident with C_1 . But E_1 is the sum of P and M, representing the E.M.F. of the machine. Hence M is obtained by subtracting P from E_1 .

Starting from the machine; it produces an electromotive force, M, the current from it experiences an electromotive force, P, lagging considerably behind it, in the primary coils of the transformer, the two combined, E_1 , being the actual electromotive force which determines the primary current, C_1 . The varying lines of force in the case of the transformer produce the electromotive force, S, in the secondary coils, and the secondary current, C_2 , together with C_1 , determine both P and S. The current in the secondary circuit sets up an electromotive force, B, due to self induction in the external circuit, and this, together with S, determines E_2 , the actual electromotive force which causes the current, C_2 , to flow.

Owing to the size of the figures, 57 and 55, it has been impossible to draw them to scale; M is, as a rule, more than 100 times higher than S, and the other curves assume corresponding proportions. The object, however, of these figures is to show the general positions of the curves relatively to one another, and the methods of drawing them.

RECENT PATENTS.

ABSTRACTS OF SPECIFICATIONS.

8,852, Wood Mosaic or Parquetry. F. F. Faulkner.

This invention provides an improved method for covering floors, walls, &c., with wood mosaic or parquetry work, or imitations thereof, without the trouble and expense due to the special preparation of the floor or situation of the doors or other parts of the rooms because of the extra thickness of the parquetry work. The work is made in thin layers like veneer, and backed with canvas, and then laid on and cemented down in much the same manner as veneer is laid.

8,914, Flush Bolts. A. G. Tonks and F. R. Baker.

This patent relates chiefly to improvements in the manufacture. The cases or bodies in which the bolts slide are made of a trough or channel form, the trough receiving the thumb-pieces of the bolts. The cases may be stamped out of one piece of metal, and afterwards shaped for use.

13,196, Sanitary Pipes. J. P. Baylis.

The pipes which are the subject of this patent are made with an invert shoulder at the socket-end of the pipe, and the spigot end of the adjoining pipe is bedded therein. This causes the pipes to be laid with a true gradient. It is said that pipes as at present made and laid never have a true gradient, the spigot of the pipe always resting on the flange and causing a difference of level of pipes at every joint, and the joints at inverts can never be properly clayed or cemented, thereby leaving an open space at inverts, allowing the draining of water out of the land to get into the pipes.

18,003, Fastening for Doors and Windows. W. Batley.

According to this invention, a circular plate or segment of metal is let into the floor, or let into the

frame of the door or window. A pin or bolt at the end of a rod, controlled by the latch or lock, slips into holes in this segment, and allows the door to be held securely fast in any position.

18,323, Sen-walls, &c. D. Nicoll.

This specification relates to an improvement in the form of slabs or blocks of concrete previously patented. The blocks are moulded while in a plastic condition, and perforated by an iron column or columns when they are required to be extra strong. This also prevents the blocks from shifting from the tenon and mortise formation provided for the completion of the structure.

1,960, Door-plates. F. Boffa.

By this invention, zinc door-plates are cast with the number plainly shown in the centre, and around the border inside is formed in raised letters the name of the street or square, to facilitate reference.

Miscellanea.

Breakwater Construction.—At a meeting of the Society of Engineers, held at the Town-hall, Westminster, on Monday evening, May 5, Mr. Henry Adams, President, in the chair, a paper was read by Mr. F. H. Chesewright, Assoc. M. Inst. C.E., on "Breakwater Construction." The author touched upon the origin of breakwaters, showing that the earliest system employed in their construction is virtually the system in use at the present day. He then described some of the modifications that have taken place, and briefly demonstrated the inefficiency of this system by pointing out some of its most salient defects. This was followed by a short descriptive account of some of the typical breakwaters of the world, both at home and abroad, with a view to proving that even the best-constructed leave a great deal to be desired. Some expert evidence before Select Committees of the House of Commons was quoted as a further proof that up to the present day no perfect breakwater has been constructed, and that improvements in the direction of obtaining a vertical wall structure would lead to the best form of breakwater. The author then went on to show that all the suggestions of these eminent experts are embodied in the Lewthwaite System, which he fully described. It is claimed for this system that it produces a perfect vertical wall on any bottom; that it possesses perfect continuity, that most desirable of qualities in a breakwater; and that in cost it is cheaper by three-fourths than any other known system. In conclusion, the author pointed out the possibilities that lie in the adoption of this new system, not only in the construction of breakwaters, but also for the erection of deep-sea semaphores, probably the complete suppression of lightships, certainly the protection of our coast lines from the encroachments of the sea, and the erection of sea walls and docks. He believed that its utility for national purposes was very great in the construction of works which have hitherto been impossible, as, for instance, fortifying such places as Bombay, and constructing a harbour of refuge at Dover, the latter being a work which has defied the ingenuity of the greatest experts in breakwater construction.
